The latter is exceptionally good this year; the plants had a top-dressing of some good cow manure when the Roses were mulched, the buds to which they shoots were headed back were plump and strong and the heads of flowers very fine. The *Montbretias* commenced flowering early in July and have been very gay ever since. A very pleasing contrast has followed the carpeting of the bed already partially filled with *Paj Gontier Rose* with a good dark *Heliotrope*. This *Rose* has a deservedly high reputation as an autumn bloomer; also well earns the name of *perpetua* for the bushes are very seldom without flowers. In the bud stage it is very charming alike in shape and colour and shows to great advantage again: the *Heliotrope* carpet. *Scarlet* and nearly white *Pentstemons* have made two very effective beds on carpets respectively of *William Niel* and *Mr. Bellamy Pansies*. Reverting for moment to *Heliotropes*, beds of scented flowers that are always appreciated, in which they take a part, were filled this year in a somewhat haphazard style with (besides the *Heliotrope*) *Eucalyptus citriodora*, *Aloysias*, scented *Pelargoniums* in variety, both plain and variegated, with occasional plants of *Princess Alice Stock*, *Mignonette*, and *Harrison Musk*. I am partial to these beds; there is an attraction about them that is very pleasing, and it is interesting to stay by them occasionally and try all the different perfumes. Having referred lately to the different forms of *Phloxes*, it is only necessary to add that special beds devoted to this family have been for some time as bright and attractive as any in the flower garden, and that the idea of grouping together the early and late-flowering sections has tended both to prolong the season and to do away with a certain formality inseparable with planting in quantity.

things of similar height and season. Marguerites held their own bravely this year. It seemed possible to keep the maggot in check, so far as pot culture was concerned, and to preserve healthy clean-looking plants, but all those planted have developed into nice clean bushes and are flowering splendidly. Both the white and yellow varieties associate well with different forms of Cus and pompon Dahlias, and they also do admirably as occasional tall plants for things of darker habit, such as pink and scarlet Pelargoniums, purple Petunias, and the like. Small pots are gradually being filled with suitable perennials, of which tufted Pansies, Pinks, Carnations, the dwarf Veronicas, Campanulas, &c. may be cited as examples, and others not so old are furnished with Phlox Drummondii and Noesia Suttoni. For other small beds I find the semperflorens (fibrous) type of Begonias among the best things. They resemble the best kinds of herbaceous Lobelias in that they combine deeply coloured foliage with bright flowers, and they may be used, either in a mass or as occasional plants, on a carpet of variegated Mesembryanthum or Cannell's dwarf Ageratum. Tuberous Begonias are not a success; our soil is too light and dry, despite either a natural carpet or a heavy mulching of cocoa fibre or spent mushroom manure. Constant watering might give the colour required, but our facilities in that direction are very limited. The old strains of annual Lobelias were too short lived to be serviceable, but Carter's Perpetual seems likely to prove a decided acquisition. E. BURRELL.

PERENNIAL PHLOXES.

It is to me inexplicable that in scarcely any flower show schedules can we find a class, or classes, for either plants in pots or single trusses of herbaceous Phloxes. Surely there are few highly florists' flowers that will make a more beautiful class than these would. How much I should like to see some hardy plantsman, instead of setting up one of these eternal collections of perennial flowers, which includes so many things everybody has got and is already getting tired of, putting up instead on the Drill Hall like a group of Phloxes in pots, single trusses, raised from spring cuttings, mixed with Ferns, or else on a table a collection of spikes also set up thickly in Ferns. If the collection included the best of the beautiful varieties we have so many of in commerce, I will undertake to say that such a group would create a distinct sensation. What is our average experience of the Phlox and its culture, or rather lacking it, in gardens? We see the hardy plant borders big clumps that have been there several years, and now are soon withered up by heat and drought, of few varietical and those of the poorest. They are also usually tall. The plants seem rather to be tolerated as necessary evils than cultivated for their beauty. No plant should be allowed to stand untouched more than two years from the cutting, and the should be a free propagation of the best every spring, the collection occasionally getting some additions, whilst inferior ones are destroyed. I am assured that if gardeners would but grow the plants more intelligently they would furnish to their employers objects of beauty they have in these hardy Phloxes no conception of; and if, still further, flower show committees would but offer prizes at late summer shows for twelve trusses set up in Ferns or Asparagus, and for twelve plants in pots, single stems, they would help greatly to the popularisation of one of the hardiest, yet most beautiful, of hardy plants in cultivation. Some two years ago I made a similar suggestion at one of the meetings of the Royal Horticultural Society, and Mr. Douglas, who presided, made a note of it. I have looked interestedly through the class at one of the meetings, but have not yet found it. But that knowledge of the best varieties is general is, I am certain, not the case. I could but realise this much when looking over the extensive collection just now blooming at Long Ditton; indeed, many of these

forms came as a revelation to me, and I was very thankful to be enabled thus to become acquainted with them. Not all the plants were from spring-struck cuttings; some had been divided last winter and replanted. Apart, too, from the rich and varied colours, what huge trusses and what splendid round, flat pips many had. Then as to height. There were many varieties blooming profusely, the plants carrying eight or ten fine trusses at only 15 inches in height; others were 20 inches, and others ran up to 30 inches. Thus in planting them it is well to know heights, so that the varieties may be suitably arranged. Growth elongates each year if plants are allowed to stand in the same place, and the shoots become thicker, while the elongation results from the fight after light and air caused by denser growth. It is so easy to obtain shoots from the roots 2 inches or so in length, even in March, to set them as cuttings into pots filled with sandy soil, stood in a very gentle warmth, and to root them well in a few weeks. Some may then be grown on singly into 6-inch pots, in which, being moderately fed with liquid manure, they will bloom finely, or may be planted outdoors in good soil to carry fine trusses. It is with such treatment the finest properties of the herbaceous Phlox are fully seen. Of the best varieties I noted among so many good ones were Sylphide, pure white; Flocon de Neige, bluish-white; Leonidas, bright reddish rose; and Aurore, rich carmine. These four are very dwarf, blooming at 15 inches in height. Rather taller, ranging from 20 inches to 30 inches, were Sesostris, rich rosy lake, very fine; Eclairer, rosy puce with pale centre, a huge pip and beautiful form; Okera, rich salmon-carmine; Coccinea, fiery red, pips not large, but of perfect form; Mme. Antoine Denis, an oculated form, having deep red eyes. On a white ground, singularly attractive: La Sicile, rich deep pink, flushed blue; Wm. Robinson, rosy salmon, a superb variety; Aurore Boreale, almost rich scarlet, wonderfully effective; and Regulus, carmine, shaded mauve, also a lovely variety. Many others might be selected, but these are all first-class. The novelties now range more largely amongst carmines and reds, as these are the favourite hues amongst Phloxes. The old purplish reds have largely disappeared from good collections, and striped or flaked forms find little favour. It seems only needful for gardeners or amateurs to see these good varieties to lead them to become enthusiastic growers. A. D.

**Herbaceous Lobelias.**—I read with interest the note on these showy subjects (p. 124). They are certainly effective during the autumn months, their brilliant scarlet colour being noticeable from a long distance. At Bickling they are freely used in the flower garden, Mr. Odele having them rising from varied and suitable ground, works such as blue Violets. The spikes of bloom stand a wet season fairly well, but they must be securely fastened to neat sticks, or wind soon plays havoc with them. Formerly propagation was effected only by division of the old plants, these being either lifted in autumn and protected from frost in a cold pit or greenhouse, or in light warm soils mulched with leaf-mould. Many people now, however, and Mr. Odele amongst them, raise annually from seed, and find as good, or even better results from so doing, as the fine strain at Bickling amply testifies.—GROWER.

**Zauschneria californica.**—For some days past the rock garden has been brightened by a well-maintained profusion of the flowers of this brilliant plant. It is somewhat strange how partial the plant is to some gardens and soils, growing almost as a weed in some instances and in others almost refusing to grow at all. Usually in a light sandy, loamy soil the plant grows freely, and where it does this it is one of the most acceptable of plants for the rock garden at the present season. Indeed, I know of nothing to compare with it for brilliancy of colour, and for this reason alone it is worthy of special culture. In some few instances the plant increases too freely, and in its ardour encroaches on other important subjects.

Such, however, are rare, and I do not call to mind any instance where the growth was such as to become troublesome, though I am aware of several instances where attempts to grow the plant have proved futile. A deep and fairly rich sandy loam and a warm, well-drained position in the rock garden or border is, perhaps, the best place for it, and if these prove favourable, a tuft will carry quantities of its vermilion-scarlet flowers for some time. In gardens where clay soil exists it will be found a good plant to provide it with special soil and good drainage. A tuft 2 feet across is a very striking object when in flower and not more than a foot or so high in most cases. In very severe winters a shovelful of cocoanut fibre over it will keep the plant secure from frost.—E. J.

**Tropæolum speciosum.**—A most welcome hardy climber if, indeed, as it must be confessed, it is somewhat fastidious as to soil, position or locality. In some gardens, where the old-established plantations are a feature, it is indeed a lovely plant, difficult to adequately prize at its full worth. In other gardens the fleshy roots have been planted again and again, only to fail badly, as they were not seen after. One of the surprises in this connection is the way in which the plant flourishes in some Scotch nurseries. Quite small pots will be crowded with its roots, that appear to possess enough vigour to threaten to become a most troublesome weed. In the south, however, its growth is rarely vigorous, and never sufficiently rampant for the majority of those interested in gardens. In the rock garden at Kew an attempt has been made to establish this beautiful plant, which around London, at least, requires a good deal of coaxing. Perhaps if, instead of planting the dormant roots, as is usually the case, the planting be deferred till spring when growth begins, giving a good bed of prepared soil of light material and planting freely, better results may be obtained. Frequently, when the pots containing it are plunged in ashes and cocoanut fibre, the roots over-run the sides of the pot and grow quite freely in the plunging material. At the same time, one of the best displays we have seen was in a midland garden where the soil is quite heavy, a fact which makes the soil question somewhat puzzling.—E. J.

FANCY PANSIES.

It is unfortunate that the fancy Pansy does not succeed better in the south than seems to be generally acknowledged, as its flowers are so handsome. There are few gardens in the south of England where anything like a representative collection may be seen growing, and at the same time giving evidence of their well-being in robust growth. Unfortunately, the constitution of these plants is not so good as it might be, or we might enjoy the display these flowers make in districts where the climatic conditions are more favourable, and where the more popular tufted Pansies repay us for our trouble with their wealth of bloom. It may be possible in the course of time to raise a race of plants capable of withstanding the trying climatic conditions which usually prevail in the south of the United Kingdom, and it is also probable that we may be nearer the realisation of our hopes than may seem possible to many. Flowers of the fancy Pansy of exceptional beauty and size distinguish the newer sorts sent out from the Tamworth collection of Mr. W. Sydenham, this raiser taking a very prominent position in the introduction of new sorts. A visit to the Pansy gardens in the height of the season is the best proof one can have that these plants succeed remarkably well in the midlands, the many thousands of plants, new and old, looking the picture of health, and each carrying a number of blooms typical of what a fancy Pansy should be. This Pansy is essentially an exhibition flower, and although it is difficult to approve of the flowers set up in the orthodox

fashion, one would appreciate them much better arranged in some less formal manner, and in such a way that a little artistic taste might be brought into use. Some trade growers exhibit the blossoms in sprays of six, and this is certainly to be preferred to arranging them individually on a flat tray. We want plants of free and fairly compact growth, and, combined with this, a tendency to flower more profusely. The sorts which call for special notice are

**MRS. WM. LOCKWOOD.**—This is a large flower with a deep velvety purple blotch, edged ruby and white, with top petals of rich purple and a white lacing.

**MRS. R. G. MOIR.**—Large circular bloom with velvety black blotch, laced pure white and tinted crimson, upper petals white with a broad band of reddish purple, and a thin margin of white. This is a standard variety, and should be in all collections.

**COL. M. R. G. BUCHANAN** is a very fine flower, with a dense, rich dark brown blotch with amber margins, and upper petals violet and amber. This is a very popular sort.

**MRS. BUTLER BARTON.**—This is a seedling. It has a large flower, with deep rich blackish purple blotches, edged rosy plum on a white ground, top petals a beautiful plum colour.

**MISS ISABELLE HIBBARD** is a beautiful flower, with a neatly defined purple blotch, edged garnet on a cream ground, upper petals similar to edging. A capital seedling from Tamworth Herald is

**MYOSOTIS.**—This has a rich dense blotch of violet, laced rosy white, lavender top petals, shaded rose and white. Another exquisite flower is

**STEPHANIE**, with purple blotch, edged creamy yellow.

**GLEAD** is being sent out for the first time this season. It is a very large flower, with deep rich purple-plum blotch on a yellow ground, with a very neat narrow margin all round. A very fine seedling was seen in

**MANDOLIN**, this flower having a splendid blotch of deep reddish brown colour, edged bronzy red and yellow, upper petals purple, paling off to a plum colour. This is a very lovely flower of perfect form.

**GEORGE HOSKISON** struck us particularly with its dense well-defined blotch of purple, edged a reddish plum colour, and may be considered a very fine flower. A large bloom is

**MRS. W. L. FRASER**, of good form, with dark blotches, laced pale yellow, upper petals pale yellow, streaked with bright rosy purple. One of the best fancy Pansies we have is

**MYRIE PAUL**, with large, round indigo blotches, edged pure white, top petals white, suffused with indigo. A very fine flower is

**AGNES MABEL**, possessing large circular purple blotch, with white lacing, tinted rose, the upper petals being shaded dark purple and rose. A large showy flower is

**MRS. JAMES INGLIS**, having rich deep violet blotches, edged pure white, upper petals white, veined violet. This is a very constant sort and of standard quality.

**MRS. D. P. RITCHIE** is a big flower and very fine too. The bloom has rich violet blotches, edged primrose, upper petals primrose, flaked with violet.

**JAMES C. ERSKINE** is a pretty flower, with a dark circular blotch, edged cream and shaded crimson, upper petals cream, prettily reticulated with crimson.

**MRS. W. STEELE** is considered a champion flower, being one of large size, grand circular bluish purple blotches, with cream edging, upper petals cream, heavily suffused with light purple. A fine flower named

**TOM WATTERS** is the best thing raised by Mr. J. D. Stuart. It has dense glossy blotches of purple on a red ground, the red colour forming a unique margin round the blotch and edged with rich yellow, upper petals having a band of deep maroon, shot with red.

These are just a few of the special things in the Tamworth collection, and show a most dis-

tinued advance. A few acres of these plants when in full flower are very rich in appearance, and the time is not far distant when they will be far more popular than they are even now.

D. B. CRANE.

**Incarvillea Delavayi** from seed.—This beautiful species of *Incarvillea* has with me produced a couple of seed-pods, which ripened a fortnight ago, the pods then splitting to such an extent that many seeds were visible. They were sown at once, and several of them have already germinated, and others will probably follow. The plant that produced these seeds was flowered in a sunny greenhouse and allowed to remain there till the seeds were ripe. As this *Incarvillea* can be increased so readily from seeds, we shall doubtless before long meet with it far more often than we do now.—H. P.

**Carnation Burn Pink** (syns., *The Burn and Duchess of Fife*).—It is to be regretted that this most useful of all border Carnations should have so much confusion in its nomenclature. The heading of this note is an extract from a trade list now before me, and your correspondent "J. C.," on page 146 of *THE GARDEN*, uses two out of the three names. Surely one name is sufficient, and I think I am correct in saying that *Duchess of Fife* is the name it is usually known by. The colour is a lovely pink, and it is of very robust constitution, very free blooming, and delightfully fragrant. In association with *Carnation Miss Audrey Campbell* (yellow) it is most effective.—A. J. R.

**Bedding Calceolarias.**—I was lately surprised to see in the suburbs of Norwich the yellow forms of bedding *Calceolarias* doing so well. The beds and borders in villa and cottage gardens were perfect, no trace of the *Calceolaria* disease being noticeable. I think locality has a deal to do with the success or otherwise of bedding *Calceolarias*, as in many places where the disease was troublesome the original soil of the beds was entirely removed and fresh substituted, while some gardeners refrained from the use of manure in the soil, but these measures were unavailing, and the culture of the plants was at length abandoned. Although there are several substitutes for the *Calceolarias* in flower gardens none, so far as I have seen, can equal them in brilliancy and good effect.—GROWER.

**Helenium grandicephalum var. striatum.**—Is not this plant current in nurseries under the name *H. nudiflorum* of Nuttall (see Asa Gray's "Flora of N. America," vol. i., part 2, p. 349). I have not had an opportunity of comparing specimens in the herbarium of Kew with the garden plants which I have grown for many years; but it seems to me, as far as I can judge without going into botanical technicalities, to correspond with the description of that species, the only one described by Asa Gray as having rays striped with orange. He also says that it hybridises with *H. autumnale*, and even if botanists should consider it to be one of these hybrids the name, at least in nurseries, had better be changed. The height of *Heleniums* varies so in cultivation that it is an uncertain botanical character.—C. WOLLEY-DOD, *Edge Hall, Malpas*.

**Violets.**—The present season has so far been most trying for the double section of Violets, which are being prepared for supplying bloom during winter and spring, as the drought has encouraged the spread of their greatest enemy, red spider. Where they are grown in the full glare of the sun, which is a bad practice, and not mulched or syringed regularly, the chances are that the foliage will become yellow and undersized and the crowns poor. The plants need just as much, and very similar, treatment during summer as a pot Strawberry, as if they are not fully grown, and the crowns large and prominent by September, no amount of trouble in winter will make up for it. Mulching is a great help in hot weather, yet how few gardeners trouble to give it to Violets. I always use old Mushroom

manure, which answers admirably, yet does promote a rank growth.—J. C.

**Tufted Pansies.**—Mr. Crane sends us an interesting collection of the new tufted Pansies. The flowers are beautiful in colour and form. The varieties comprise *Lavinia*, in the way of *Violet* colour of *Border Witch*; *Pembroke*, rich orange-yellow in centre, gradated to white on edge, shape and crimped edges; *Princess Louise*, the above, but more lemon in colour and not so deep in centre; *Sir Robt. Peel*, also similar, paler still (the last three mentioned are charr kinds of shades of yellow); *Celeste*, pale lavender blue; *Ethel Hancock*, a splendid white variety of excellent habit; *Jestyn*, creamy white, streaked or mottled with porcelain-blue, very free; *Lavinia*, good violet-blue; *Symphony*, violet-lavender, with bluish eye.

**Statice latifolia.**—This hardy *Statice* is gaining popularity, especially amongst those who require graceful subjects for mixing in their decoration. A cool, semi-shady position suits *Statice* well, the roots revelling in abundant moisture. A north border is a capital position although the flowers may be a little later in coming than when grown in a more sunny position. The bloom lasts well either on the plants or cut state and has a very elegant appearance, the colour being a lavender-blue. The plants increased by division at the roots, which may be done in October or November, or indeed any time during winter in open, frost-free weather. When done at the latter date it is best to put a mat of leaf-mould over the surface of the ground.—C. C. H.

**Mignonette on north borders.**—In hot summers *Mignonette* often does indifferently, owing to an insufficiency of root moisture, and difficulty often being experienced where the soil is shallow. It is a mistake, unless in deep, retentive soils, to sow *Mignonette* on south borders on any position fully exposed to the sun, as even if it comes to maturity it lasts but a short time, full beauty compared with that grown in shaded situations. I find a north border just the place for sowing on in May for a supply of blooms in August and September. If the old trusses are cut off, the plants will continue to grow and yield until frost cuts them down. Where the soil is too strong and close, a little finer material in the shape of potting-shed mixture and a little leaf-mould worked in will make matters right. I find the taller, stronger growers, such as *Queen*, better for outdoor work than *Spiral*.—C. C. H.

**Two good bedding Geraniums.**—It would be difficult to name two more attractive or more flowering bedding *Geraniums* than *Henry James* and *John Gibbons*. The former is perhaps the most extensively grown of the two; indeed, one seldom sees a flower garden of any importance without a few beds of it. The truss is very large, and the colour, which is intense dark scarlet, is telling. It has a good constitution and a branching habit, the bloom trusses being produced in great numbers. *John Gibbons*, a fine scarlet, is equally good as a bedder, so far as its form in growth and flower is concerned, though not so telling at a distance. Both these varieties should be grown where first-class bedding *Geraniums* are in demand. It is wonderful what a length of time *Vesuvius* has remained popular. There are few places in which it is not in flower, and as a dwarf free-flowering all round scarlet it is hard to beat.—C. C. H.

**Bedding Begonias.**—The present summer has not proved the best for bedding *Begonias*, having been too dry and arid; as autumn approaches, however, they will no doubt improve considerably. A cool, moist summer seems to suit *Begonias* best, their wants being quite the reverse to that of the *Geranium*, which revels in hot sunshine so long as sufficient root moisture is supplied. Much may be done to induce *Begonias* to grow and flower well even in adverse summer by incorporating with the soil of the beds a quantity of well-decayed manure; and if a pot

holding loamy compost can be spared to work in well so much the better, especially where the plants occupy the same beds two years running. Moreover, a good mulch of some short material applied early in the summer, as soon in fact as planting is completed, well repays for the labour, the roots being thereby kept in an equable condition and labour in watering saved. The pink shades are very telling associated with scarlet Carnations and Calceolarias.—J. C.

**Carnations.**—In THE GARDEN of August 7 "C. B." (under the heading of Carnation Salisbury) makes some very sensible remarks about the development of a strain of Carnations with stout stems needing no support, but it is doubtful whether it would be possible to do without the stick altogether in Carnations, for the majority must be liable to sway about at the year. What is wanted is Carnations that when cut to a short stick will hold their blooms erect. Among those that have this useful characteristic, added to its other many charms, is a fine new yellow self which was shown at the R.H.S. exhibition of, I think, July 27. It is named Mr. Moore Binns, and as I have had the good fortune to grow several plants of it on trial for a few years, I can strongly recommend it as a perfect border or pot Carnation. The flower is of good size and good substance, of a pure yellow colour, and of a strength and robustness not to be equalled by any flower of its delightful family.—S. TAYLOR, *The Gardens, Diglis House, Worcester.*

## NOTES OF THE WEEK.

**Antibretia Tigridia.**—A very beautiful hybrid form of this pretty and useful class, with compact spikes and flowers of a clear orange-yellow, with scarlet eye. It is a beautiful and pleasing variety in the border and equally so in a pot.

**Carnation Lady Hindlip.**—This variety is destined to occupy a front place in the future, the clear scarlet blossoms being of a very intense shade and of excellent form. The flowers are not remarkable for size, yet sufficiently large for ordinary purposes.

**Abelia Night.**—This is a flower of very dark colour, in fact, a deep crimson-maroon of a very heavy or intense shade. But it is also a capital specimen of the Cactus-flowered section, and as such recently obtained the award of merit from the Royal Horticultural Society.—E. J.

**Rose Empress Alexandra of Russia.**—The Roses of recent introduction are more beautiful than this, which is of a salmony bronze tone, though these words do not adequately describe the lovely shade that predominates in this beautiful flower, and which catches the eye again and again.

**Phlox banaticus** is one of the best of the globe Thistles, and now in its best form. A large clump of this kind with many of its globular heads of blue is very attractive in the rougher portions of the rock garden. In the border or shrubbery, too, it is a good and showy plant in summer.

**Tufted Pansy Norah Creina** has the appearance of being a capital sort for bedding. Its growth is compact and free, and the constitution seems to be all that is required. The flowers are of good size, lavender-blue in colour, something midway between Blue Gown and Sweet Lavender, with an orange centre and free rays.—D. B. C.

**Lymphæa odorata rubra** is a very charming and beautiful Water Lily, that should be found more frequently in lake and pond alike, and being easily accommodated in rather shallow water may be reared with ease from the margin of the lake. The brilliant colour of the flowers renders it one of the gems of the older sorts, and it may be obtained at reasonable rates.

**Rhus radicans variegata.**—This very pretty marked plant obtained a first-class certi-

ficate at the recent meeting of the Royal Horticultural Society, when it was shown by Mr. W. Bull, of Chelsea. The plant is likely to prove of considerable use to decorators, and should have some value in the greenhouse or conservatory, where such plants may be put to divers uses.

**Statice latifolia** is now very fine, more especially a few clumps that were replanted a year ago and now again fully established. In the border or the rock garden the plant is always striking when in flower—a rather extended period, as the longevity of the blossoms and the colour also are remarkable. A plant of the easiest culture that should not be overlooked in any collection of hardy plants.

**Tufted Pansy Walter B. Child.**—This is a most exquisite little flower, neat and pretty, and everyone interested in Tufted Pansies should possess a batch of plants. The lower petals are white, with a pretty margin of azure-blue, and the upper petals are azure-blue also. The blossoms are rayless and develop most profusely. It has a nice spreading habit and is a free-growing sort.—D. B. C.

**Kniphofia Lachesis.**—This is one of the most beautiful of the now somewhat numerous hybrid section of the family, the blossoms of a very pleasing and delicate shade of apricot and light orange. Among many of the newer shades this is quite conspicuous by its colour, and being free-flowering should prove a useful kind. This handsome form is among the best in Mr. Perry's collection at Winchmore Hill.

**Colchicum autumnale.**—These pretty flowers are now occurring quite freely in the shrubbery, the hardy fernery, and little nooks in the rock garden, everywhere giving pleasing results. Best of all, perhaps, where they appear in grassy spots or banks, for here the naked blossoms are clothed, as it were, as soon as they emerge from the earth. In this way they are pretty indeed, and give so little trouble.—E. J.

**Erica vulgaris Hammondi.**—Among the hardy Heaths this variety, with its pure white blossoms so freely produced on spikes 6 inches or 8 inches long, is very charming, the flowers being conspicuous for their snowy whiteness among the rather predominant blue and purple that obtains among these dwarf free-flowering shrubs. In a collection of these from Messrs. Veitch at the Drill Hall recently this white kind was indeed beautiful.

**Echinacea purpurea.**—This handsome perennial still continues to produce a fine succession of welcome flowers, welcome because of their colour in the hardy plant garden now. Planted in bold groups, we have no more useful plant at the present time. One large bed of it with the well-known Hyacinthus candicans interspersed among the Coneflower is very satisfactory, the pure white drooping blossoms of the latter displaying the Coneflower to advantage.

**Lobelia cardinalis.**—For weeks past no hardy plant has maintained such a succession of brilliant flowers as this old-fashioned garden plant. Brilliant beyond compare, though only luxuriant where moisture or a very rich soil is at hand, it is a plant to be prized for its colour at this season. Where moist places exist this is one of the best of plants, for here the stems will attain 6 feet or 7 feet high, always giving flowers in proportion. A few clumps well disposed give a very fine result.

**Tufted Pansy Mrs. Chas. Turner.**—In the trial of Tufted Pansies at the Royal Botanic Gardens, Regent's Park, this old sort looks remarkably well. Its colour, a rich and bright bluish purple, stands out so distinct from everything else, that it stamps the flower as being a very useful sort where this colour is required. The blossoms are large and the colour is a good fixed one. The habit of growth is nice and compact, and the constitution most robust.—D. B. C.

**Gladiolus Saundersi.**—Few members of this genus, even among the large number of hybrid forms that now exist, could possibly make a more effective display than this when freely grouped in

the garden. The brilliantly-coloured flowers, so freely spotted with white, are not only effective from a colour point of view, but there is a distinctness of form also that materially adds to the beauty of the freely-flowered spikes of the plant. In the Winchmore Hill district the plant grows quite freely, and as seen in the nursery beds closely planted an almost dazzling effect is produced.

**Hibiscus Mrs. Mackintosh.**—This very beautiful and showy kind was exhibited at the last meeting of the Royal Horticultural Society, when it attracted considerable attention. The specimen was some 5 feet high and carried a number of large and handsome, clear yellow blossoms of the size and colour of the large yellow Evening Primrose. It is evidently a free-flowering kind, judging by the clusters of terminal and auxiliary buds on the rather free-branching habit of the plant, and with the deeply cut digitate foliage makes up a distinct and striking plant.—E. J.

**Helenium autumnale striatum.**—This very showy perennial is now a striking feature in many gardens, and especially when the blossoms are of a crimson hue. In Mr. Perry's hardy plant nursery at Winchmore Hill some handsome clumps of it, bearing a large proportion of crimson flowers, make a most effective display. A crimson-flowered variety of this plant, which appears of a sportive nature, would prove welcome among the many composites now in flower, and an attempt should be made to fix the sport if possible. A large spray of it has all the flowers of a rich crimson shade.

**Euphorbia corollata** is one of the most elegant of flowers at the present moment, and produces a large branching panicle of small, pure white blossoms, the latter of the size of the Forget-me-not. For vase decoration it is simply charming, as is also the disposal of the much-forked branches, that carry from two to four of its blossoms on each tiny branchlet. The neat and elegant foliage is quite as attractive as the flowering, and, altogether, a plant that would prove of great service generally where such things are needed. Some good tufts of this pretty plant are now flowering freely at Winchmore Hill.—E. J.

**Tufted Pansy Molly Pope.**—This handsome flower is evidently at its best late in the season, at least so far as regards its growth in the south of England. Just now it is one of the most striking clumps in the garden, with rich and deep yellow flowers of the most beautiful description. Early in the season the centre is slightly rayed, but as the summer advances and cooler weather is experienced, the blossoms are absolutely rayless, and the plant is a good one for all purposes. It has a nice compact habit, yet possesses a freestyle of growth. This is the second season of its distribution, and there is little doubt it has come to stay.—D. B. C.

**Senecio pulcher.**—This handsome composite promises to do good service this year, a fact, however, mainly due to the replenishing of the stock. This is most readily done by means of root cuttings in winter, and when these break into growth to be treated as cuttings or tender seedlings for a while, eventually transferring them to their permanent positions. When this latter is done in the June of the preceding year good strong plants are formed that give excellent results when in blossom. A deeply-dug soil of good quality will grow this handsome plant to perfection. Where the best results are required frequent renewal of the plants is the simplest way.—E. J.

**Michauxia campanuloides.**—I saw this very interesting hardy plant growing and blooming well just recently on Messrs. Dobbie and Sons' seed farm, Orpington. Seed was sown last summer and the plants wintered well in the open. The foliage is elongated and of Acanthus-like nature. The flower-stems reach 6 feet in height, and carry a great profusion of white star-like flowers with narrow petals that slightly reflex. The seed-pods much resemble those of the Canterbury Bell. The second flowers come from the

axils of the first, just as do the blue flowers of the Chicory, but those of the *Micbauxia* are three times the size. Because so easily raised and so hardy the plants merit wide cultivation.—A. D.

**Chrysanthemum Flora.**—This old bright yellow pompon seems as much in demand as ever for market work, as well as for the embellishment of the hardy flower garden. In this neighbourhood the cottagers' front gardens are made quite bright and cheerful now that the summer flowers are on the decline, and in the parks and large gardens it is proving itself invaluable by the free display its pretty little blossoms make. The growth of this old sort rarely exceeds 2 feet in height, while its free growing character and dense, rich green foliage render the plant highly valuable for massing in large beds and borders. Unlike many others, this variety is a most continuously blooming one.—D. B. C.

**Chrysanthemum Mme. Marie Masse.**—For two or three weeks past the first blooms of this sort have been perfecting on the earliest batch of plants. In the hardy border, however, the plants are looking particularly well, and the colour of the later flowers, which are developing quite fast now, are very pretty indeed. The earliest blossoms were lilac-mauve in colour, but those from later buds are heavily suffused with bright magenta, this colour being very useful under artificial light. A free manner of growth, and without disbudding, suits this variety best, its fine branching habit ensuring a long-continued display. The flower belongs to the Japanese section and is a decided acquisition.—D. B. C.

**Clematis Davidiana.**—A singular-looking species with Hyacinth-like blossoms that alone are scarcely distinguishable from *C. heracleifolia*, though in foliage the two kinds are widely dissimilar. The flowers are quite unlike those of the ordinary forms, somewhat inclined to be tubular in shape with the tips heavily recurved; in colour a deep azure-blue. These flowers, though comparatively small, are produced in considerable numbers, and have a distinct effect when established in the garden. Both kinds herein named are of non-climbing type, and would probably give some interesting progeny if used in conjunction with some of the best flowering types, or even by crossing such as *C. erecta* or *C. integrifolia*.

**Mixed plants in a long, narrow border,** which skirts the greensward in one part of the gardens at Regent's Park, have been very interesting and pretty all through the spring and summer months. At the present time the *Zinnia* is well represented in many different shades of colour and in individual blossoms of good form and large size. *Celosia pyramidalis* is very showy and of great use now that the summer season is ending. By its free use a bright array of colour is ensured in blossoms of a kind rarely seen by the ordinary visitor anywhere else. *Phlox Drummondii* is also used, and *Begonia semperflorens*. Stocks, as well as other popular flowers, all seem to succeed remarkably well in this garden in the heart of London.—C. A. H.

**Cockscombs as bedding plants.**—An exceedingly pretty circular bed of handsome heads of the crimson Cockscomb is one of the best features in the bedding at Regent's Park just now. Each plant has a fine bold head of bloom, and these are pleasingly dotted all over the bed, with the free use of a pretty form of the *Artemisia* as a contrast. A few plants of the graceful *Acacia lophantha* give an elegant finish to a very pleasing association of plants. An edging of one of the Saxifrages, with its rich green carpet of growth, and devoid of blossoms, completes a unique bed. Another striking bed of Cockscombs was seen with yellow and crimson flowers, each toned down beautifully by the wise association of other plants.—C. A. H.

**Gypsophila paniculata.**—That is undoubtedly an interesting point that is raised by "R. D." in relation to the use of flowers of this plant with Carnations, &c., at exhibitions. Fern is employed as freely with cut flowers as Parsley

is with vegetable collections. But, of course, if *Gypsophila* be utilised as Fern is, why not other flowers? and if so, where is the practice to stop? All will admit that the introduction of the *Gypsophila* as commonly utilised is an exhibition gain. Why not then in schedules make its use as a decorative element with Carnations, or other cut flowers, permissive? Of course, its presence makes no difference to the quality of the Carnations, &c. Even Sweet Peas look all the prettier when set up in vases with *Gypsophila*.—D.

**Lilium longiflorum.**—The typical form of this Lily has flowered well this year in the open, and in the case of some freshly-planted bulbs has given every satisfaction, the long pure white fragrant trumpets on sturdy vigorous stems being handsome in the extreme. Fortunately, these escaped the very severe storms of hail that caused so much destruction in some parts, and which would have quite spoiled the Lily blooms had it touched them. When seen in all its purity this Lily is indeed difficult to surpass, and if planted in the open garden, it is a good plan to secure them in a measure by giving them a position near to shrubs of 5 feet high or thereabouts. In this way the Lilies receive a good deal of protection from driving storms that often do irreparable mischief.

**Tuberous-rooted Begonias** are used with good effect where other plants may be utilised to relieve their somewhat cumbersome appearance. A bed of rose, rose-pink and light salmon shades of colour is a very lovely combination, and with blossoms of these kinds the display in Regent's Park has been further enriched by the free use of the variegated *Chlorophytum*, just now showing its flower-spikes, and as a carpet to the bed there is the handsome foliage of *Lysimachia aurea*. Saxifrage as an edging forms a contrast to the richly-coloured foliage of the other plants, and gives a neat finish to the whole. Another bed of rich crimson tuberous-rooted Begonias, with a similar association of plants to that first mentioned, is a welcome change where variety is of importance.—C. A. H.

**Lilium tigrinum fl.-pl.**—Less beautiful perhaps than the purely single forms of this group, this variety certainly is quite distinct, and in the double flowers there is less confusion than in many flowers that possess abnormal quantities of petaloid segments. This variety, too, is fully as useful as the single kinds in the garden, and, for grouping among shrubs, all these Tiger Lilies have a value of their own by reason of their hardiness and easy culture. They may be increased to any extent almost, by the many axillary bulbils that are to be found on the stems of the plants. Sown in light sandy soil in boxes and left for a year, many will have attained to a good size, at which time, and when dormant, they may receive a more liberal treatment for another year, and then be planted permanently into their places in the garden.

**Azolla filiculoides.**—Wherever there are shallow pools of muddy or half stagnant water this exquisite little aquatic cryptogam is easily grown, and in such situations it spreads rapidly and even drives out, or crowds out, the native *Lemna minor*, a plant pretty well able to survive and take care of itself. The *Azolla*, after a shower or early in the morning, is covered with pearly globules of water or dew that glisten in the sun like so many diamonds. It is impossible to wet the upper surface of its tiny fronds, which soon right themselves if placed upside down on the surface of water. Early in the year it is suffused with a soft pale salmon-rose colour, but is now green in its fruiting stage. A supply is available to any gardener or botanist who would like fertile specimens on their sending stamped and addressed label.—F. W. BURIDGE, *College Botanic Gardens, Dublin*.

**Acæna microphylla.**—There is perhaps no more beautiful carpet plant in the rock garden at the present moment than this, though its pleasing effects are not seen at a glance. If closely re-

garded, however, the richly coloured heads of crimson spines that shield as it were the inconspicuous blossoms are very attractive, possessing indeed a beauty that is at once curious and rare. On warm, sunny rockwork the plant spreads quite freely into large creeping patches of deep cut pinnate leaves, and above these the new globular tufts of crimson spines appear quite freely in late summer and autumn. The whole plant is scarcely more than 2 inches high, and may be used as a carpet for spring flower bulbous plants, such as *Glory of the Snow*, *Snowdrop*, with good results, and in no wise detracting from its usefulness later on.—E. J.

**Carnations from Kelso.**—Messrs. Laing & Mather, of Kelso, have sent us a fine selection of Carnation blooms, which show how well the flowers do in the open air in Scotland. Among the varieties received were *Lady Nina Balfour*, *Mrs. Cochrane*, *Duchess of Fife*, *Kelso Abbey*, *Gift*, *Scarlet Seedling*, *Viscountess Melville*, *Dey*, *Dundas Scarlet*, and *Hayes' Scarlet*.

**Royal Horticultural Society.**—The fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, September 15th, in the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 p.m. A lecture on "Pitcairnia" will be given by Mr. H. J. Veitch, F.R.S., at 3 o'clock.

**Gardeners' Royal Benevolent Institution.**—The committee, treasurer and trustees, acting on behalf of the members and subscribers of the above institution, with the concurrence of the president, the Duke of Westminster, recently awarded through the Home Secretary a loyal address to the Queen, for forty-six years the gracious patroness of the charity, congratulating Her Majesty on the completion of the sixtieth year of her beneficent reign; and a reply was received from the Home Secretary, stating that Her Majesty was pleased to receive the same graciously, and that with reference to the application for permission to make use of the words "Victorian Era" in connection with the title fund now being raised by the institution, he would inform them that Her Majesty approved of desired permission being granted.

**Holidays for gardeners (G. H. C.).**—Answer to inquiry re holidays for "A Working Gardener," we should consider that ten days would be fair. A deal would depend upon time worked and if all overtime is paid for. If overtime is paid for, a fortnight would not be too much holiday to allow.—H.

**The weather in West Herts.**—The temperatures during the past fortnight have been very uniform and rather cooler than is seasonable. On several occasions the rain has again fallen very heavily. August proved a wet summer month, especially the early part of it. Rain fell on seventeen days to the aggregate depth of 3½ inches, which is more than half an inch in excess of the August average. Of the amount nearly the whole was deposited during the last fortnight. Indeed, until the 20th, rain-water at all had passed through either petalation gauge, but since then 1½ inches has come through the heavy soil gauge, and nearly the same quantity through the light soil gauge. A record of sunshine was in excess of the average for August. There was, however, a marked contrast between the weather of the first and second half of the month, the former being very warm, clear and sunny, while during the latter half the temperature was only about seasonable, the rain heavy and persistent, and there was comparatively little sunshine.—E. M., *Berkhamsted*.

**Names of plants.**—*Anxious.*—*Dæmonorops* probably *D. palembanicus*; will keep in health some time in a cool conservatory, but needs more light to grow it successfully.—*D. Thomson.*—*Tacta mollissima*.

## ORCHARD AND FRUIT GARDEN.

### PLUMS AS CORDONS.

A recent note contributed to these pages I mentioned the fact of cordon Plums being a useful form of tree for quickly clothing walls, and also for planting in odd corners and awkward positions where ordinary trained trees would be unserviceable. My object in referring to the subject is to give a list of the kinds which I have found to succeed best grown in this way, and at the same time to state the various aspects the trees occupy against the walls. The list will be found to comprise cooking and dessert kinds, and among the latter a few of the best Gage Plums are included. The trees are all grown against walls, the latter varying in aspect, some being due east, due west, and others north-west and due north. In all these aspects the trees succeed well, and produce plentiful crops of fruit in any but very severe seasons. They are all trained as single upright cordons, and the majority stand from 2 to 14 feet apart, the space between being occupied either by Plums, Cherries, or Peaches and Nectarines, according to the aspect of the wall, and they afford the latter a certain amount of shelter, inasmuch as they act as wind-breaks. The culture accorded them is simple enough, and consists merely in stopping young side growths to four leaves about the middle of June, and after this all shoots produced are regularly pinched—generally about twice, the last time at the end of August—with the result that the spurs bristle with fruit buds by the end of autumn, there being little or no winter pruning to do beyond shortening back any pieces of wood found to be of undue length. In the course of time the spurs protrude some distance from the wall, but unless they become unduly long this is rather an advantage, as they then bear larger crops of fruit, while the fact of their standing out a foot or 15 inches serves to form a fine break to the wind when the

latter is blowing from certain directions, to the benefit of the trees growing between them. However, when they grow too far away from the wall, a judicious spur-pruning soon puts matters right again, and the Plum being so accommodating in this respect, the stems can be clothed afresh with new spurs in the course of two seasons. It is sometimes found necessary to partially lift some kinds and lay the roots out afresh until the trees come into full bearing; after this it is unnecessary, unless any are found to be making rampant growth, as a result of failing to carry crops of fruit, such as is the case with a few this season. Young cordon trees will reach the top of the wall in from two to three seasons, generally the second, and invariably commence bearing the second year from planting. I prefer maidens for this purpose, planted as early as the trees can be sent out from the nursery, and cut down to within 1 foot of the ground about midwinter. A barrow-load of fresh soil is placed about the roots to give them a start, and, as a rule, they break away strongly, and the stems by autumn are generally well clothed with prominent fruit buds. The following spring the stems are shortened back somewhat according to their strength, and unless anything should go wrong with them, they break again and reach to the top of the wall, and require to be stopped before autumn arrives. The next year the wood buds on the stem will break freely, and by the end of the third season the trees become clothed throughout their entire length with spurs, and will then be firmly established. Should no fruit buds be formed by the end of the second year, the trees should then be lifted, partly or wholly so, according to the condition of the wood, and this will give the necessary check to induce fruitfulness. If a too rich soil should be the cause of failure, a little lime rubble mixed with it acts as a capital corrective.

### VARIETIES.

The first variety to head the list is Rivers' Early Prolific, which is so well known that a

further description is unnecessary. This succeeds admirably as a cordon, and I have it on all the aspects mentioned, with the result that the fruits may be had as late as the second week in September. The wood produced by this kind is of a most fruitful character, and it is but seldom that winter pruning of any description is required. The next is The Czar, and this is almost equal to Prolific in productiveness. This I have on an eastern aspect, where it does exceedingly well, and the fruit keeps in good condition until the end of August. Cox's Emperor on the same and a north-east aspect crops well, and bears fine handsome fruits. This is rather a strong grower until it commences to bear, but a check at the roots soon remedies this, and afterwards it behaves satisfactorily. Autumn Compôte and Belle de Septembre, two excellent Plums somewhat similar in appearance, bear heavy crops grown as cordons, and if protected the fruits last in good condition for a long time, or until Coe's Late Red is ready for use. The last as a cordon is a marvel of fertility, and should always be included when forming a collection on account of being so productive and valuable as a late cooking kind. This and the two foregoing I have on an east wall, the trees being about twenty years old. Angelina Burdett on a western and also on an eastern aspect is a great success, as it bears regular crops of its medium-sized, but richly-flavoured fruits, which are alike useful either for cooking or dessert. As is well known, this Plum has very distinct foliage, and it makes but medium growth, but is very fertile. Reine Claude Violette is a good companion to the last, and is a delicious Plum for the dessert. This I have growing on the same aspects as the last mentioned, and if not quite such a heavy cropper as that variety, it is very certain and seldom misses. The fruits of both Angelina Burdett and Reine Claude Violette will hang a long time, but must be protected from flies and wasps, which will otherwise soon make short work of them, so deliciously flavoured are they.

Webster's Gage is a good cropper and comes into use about the middle of September on a west wall. Unlike the last mentioned, this is a golden-yellow Gage; it attains a much larger size than Webster's, while in point of flavour they are about equal. The tree is rather a strong grower and perhaps not quite so prolific as some, but it is, nevertheless, deserving of culture as a cordon, as its handsome golden fruits when properly ripened amply compensate for all deficiencies. Guthrie's Late Green is somewhat similar in appearance to Webster's Gage, with the exception of the colour, which is a greenish-yellow. It is, however, a deliciously flavoured Plum and a good cropper, and coming into use, as it does, towards the end of September, it is then invaluable either for cooking or eating. The next is the old Green Gage, which invariably bears well on an eastern aspect, the individual fruits being finer than those gathered from either fan-trained or standard trees. This sort is the worst of the whole lot for growing away from the wall, and, no matter how closely the wood may be pinched, the older wood has a habit of thrusting itself, as it were, out from the stem year by year until it forms an obstruction when passing up and down the alley. One good thing, spur-pruning soon rectifies this matter, and if part is pruned away one season and the remainder the next, there is then only a partial loss of crop. In spite of this objection, if it can be termed an objection, several trees of this kind should be included by anyone feeling tempted or disposed to adopt this system of growing Plums on account of its intrinsic value both as a cooking and dessert variety. After all said and done, no variety of Plum that we possess can surpass the old Green Gage for flavour, and no apology is therefore needed in recommending it to be grown in quantity. The last on my list is Coe's Golden Drop. This I have both on eastern and western aspects. It is a grand Plum for general purposes, and is a constant and heavy cropper, and several trees should be grown if a long supply is needed. It is a sort that will hang well until the first and second weeks of November if pains are taken to protect the fruits from insects, and when shrivelled the fruit is delicious. The trees are moderate growers, and always set a profusion of bloom-buds once they commence to bear, and if kept clean and the roots fed when the trees are heavily cropped, they will continue in a fruitful condition for many years. Victoria I have grown in this way, but it is not satisfactory, and I intend removing the trees this autumn. I have some of the newer varieties planted on a northern aspect, and, according to appearance, many will fruit another season, but until this takes place I am not in a position to give an opinion either of their merits or demerits.

No doubt there are other varieties which are eminently suitable for growing in cordon form, but those named I have found to succeed here, and if from three to six trees of each kind were planted they would furnish a long succession of fruits, particularly if the aspects could be varied. Even if this could not be done and the trees were all planted against a wall having, for instance, an eastern aspect, the supply would last a long time, and as they may be as near together as 18 inches they will not take up a great deal of room, and this where wall space is limited is a consideration. A. W.

Stoke Edith, Hereford.

**The Mirabelle Plum not the Cherry Plum.**—A much needed correction is made by "A. F. B." in the *Gardeners' Chronicle* last week. Those who

describe the Mirabelle [and the Myrobalan as one and the same thing are in error, and this we see done in the lists of good houses. "A. F. B." says: "Some confusion seems to exist as to what is meant when the Mirabelle or the Myrobalan is named, the lecturer seeming to consider them one and the same, whereas they are as distinct as two Plums can well be. The former—the Mirabelle—is a small, round, early yellow Plum. It is not much grown in this country; why, I do not know. In France it is much esteemed. As a stock for the Plum this Mirabelle is, in fact, not used, and does not appear suitable."

**Nectarine Early Rivers.**—I saw the other day at Coldham Hall, Bury St. Edmunds, a grand young tree of the above-named Nectarine carrying several dozen ripe fruits. That it is an advance on Lord Napier in point of earliness is undoubted, and the fruits are very fine in size, colour and quality: but what struck me most of all was the splendid growth the tree was making in spite of its heavy crop. In this respect it also is well ahead of Lord Napier, which is only a moderate, not to say puny, grower at the best, and seldom lives long, though it has the knack of finishing up a heavy crop of grand fruit on very meagre growth, and always performs better than it promises. If the constitution of Early Rivers is anything like as good as it promises to be at Coldham, it is indeed an acquisition.—J. C. T.

**Apricots and Nectarines.**—At this season Apricots need copious supplies of moisture at the roots, and though there has been some rain, I find it has failed to reach the roots, especially where the borders are cropped. Much mischief is caused by dryness at this season. The trees in many cases bore a thin crop and are making a free growth, needing ample supplies of moisture. I find the more robust the trees the less danger there is of branches dying. Should this occur, it will be less felt if there is some good wood made to fill in the blank spaces. Few fruits love moisture at certain seasons more than Apricots, and by giving free supplies the wood is better able to stand our variable spring weather, which tries the trees so much. The Apricot does best when its roots are near the surface, hence the need of moisture in dry seasons. A mulch at this season is of great value in such soils, as it retains the moisture given and promotes root-action. I do not advise a thick mulch.—S. H.

#### THE EVILS OF GRAFTING AS REGARDS THE APRICOT.

THE *Gardeners' Chronicle*, which has hitherto made somewhat light of our efforts to call the attention of the public who suffer by it to the dire results of grafting, now itself begins to get some evidence together about the evil:—

In its native country and in Central Asia the natives propagate the Apricot by seed. True reproduction of a variety is, however, only obtained by means of the graft, and to this end, in more northern latitudes and in Central Europe, in ground with a good subsoil, the stock generally adopted is that of certain varieties of the Plum tree, such as Myrobalan, St. Julien or Damascus.

At the pomological congress which, not long ago, was held at St. Petersburg, M. Simireuko drew attention to the value of the wild Apricot for grafting cultivated varieties of the Apricot itself, as well as those of the Plum and Peach trees. He gave it as his opinion, based on the results of many years' experience, that the wild Apricot is the most valuable stock.

The President of the French Pomological Society, who has recently referred to this subject in the *Pomologie Française*, states that the average duration of Apricots grafted on the Plum in the Ain department, for instance, does not exceed four years. Nor does the cause appear to have been hitherto explained. The Apricot, almost invariably grafted on the Plum in France, grows at first very vigorously, the scion dies, though the subject (stock) continues to thrive.

If anyone who reads the above extracts has ever looked at the gumming and dying Apricot trees growing under the most favourable conditions in English and Irish gardens, he may begin

to see cause for the misery, without looking any further for all or other vain subtleties which have characterised seed writings devoted to the cure of a trouble which has now gone on for generations. It almost entirely deprives us of the fruit of a good fruit.

What is to be done? First, for the fair understanding of the question, we have to consider what is done now. The nurseryman has a stock of one of the wild Plums noted for vigour and belonging to the same genus of plum as the Apricot, so that the alliance is close enough to allow the stock or base of the future tree to push up a vigorous growth for the first year or two, or the time when the tree is in the nursery. The unnatural alliance goes on very well until the tree is of a saleable size and happily disposed into some good garden, but the vigour of the stock does not go very much further, except trying to escape from its burden, and it is very long before the Plum begins to creep up and injure the Apricot upon it. By pulling away suckers continually—which is part of the unfortunate gardener's duty—we may escape some of the evils of the forced union for a time, but we come on the gumming, and loss and death in other ways, and the poor state of health of the tree. Now it might be remedied, we think several ways, or at least a trial made to solve the question. If M. Simireuko is right, we take the wild Apricot, but why not also, following the example of the people in the native country of the Apricot, *i.e.*, sow some seeds of the finest fruit we can get and raise it naturally? We might get a poor variety, but also we might get a precious sort. As these things vary indefinitely, we might get quite distinct varieties of seed, and perhaps find—at least in warm soil on the sheltered warm walls that abound in British gardens—healthy and fruitful trees. By adopting the cordon system of training, the seedlings could be planted rather close, so that the poor ones could be weeded out and the seedling varieties take their place. Lastly, we are layers and cuttings, as we cannot say that this tree is less amenable to the propagation than many other trees of its family.—*The F*

**Pear Marie Louise d'Uccle.**—This, though not equal to its parent, Marie Louise, in point of flavour and general excellence, surpasses it in vigour of constitution and productive power, and being, as it is, a pretty certain cropper, a capital kind to grow for market. For production it is much valued in many places, particularly where Marie Louise itself is but indifferent success, and the fruits when thoroughly well ripened are certainly not to be despised. In cold soils the flesh is coarse grained and is half melting at the best, but on a warm, rich soil it becomes buttery and melting and the flavour fairly good. Cultivated in pyramidal form on a Pear stock, it will form a handsome specimen in a short time and prove very prolific. When grown as a bush or cordon on the Quince stock, it is equally as satisfactory and never fails to produce heavy crops of very fine fruit. I would recommend its being grown in private gardens where Marie Louise succeeds well, as it can be used for stewing, a purpose for which it is eminently suited.—A. W.

I was lately somewhat amused when visiting round a small garden at being shown a well-loaded Pear tree on a south wall which the gardener called Improved Marie Louise. The variety was Marie Louise d'Uccle, which, so far as being an improvement on the old variety is not to be compared with it. It is true that when once established the tree is a good cropper, a fact making it so popular amongst market growers, but as to flavour the less said the better. I think it keeps longer sound, but in nine cases out of ten it eats gritty and has very little juice. It is a good Pear for stewing or for growing in cold localities where the better class of varieties seldom succeeds; but certainly the title of "Improved" is quite out of place, as all who know well

good Pear is and have tasted the two sorts will testify.—C. C. II.

**Grafting old trees.**—Whatever may be the benefits resulting from the grafting of old trees, notably Apples and Pears, with diverse varieties, my experience has always been that it is better to do such grafting by using strong grafts on large stems than to employ small grafts on many stems. However, not everyone coincides. I saw the other day in an old orchard at Ruxley Lodge, near Hereford, admirable examples of the plan I favour. Some Pear trees that were several years ago beheaded and regrafted, and now have splendid raminal heads of the best possible character. The gardener, Mr. Miller, having formerly resided in Worcestershire, where grafting old trees is a common practice, and where, as he said, even the large shoemakers are in the slack season expert grafters, saw such admirable results from the practice, that having a number of large trees at Ruxley Lodge that required the operation performed on them, had one of the Worcestershire operators up to carry out the work. The present robust heads show how well it was done. The trees were cut back to three or four large branch stems, into which were inserted in each case two or three large grafts fixed in wedge position and driven hard home. Mr. Miller mentioned that he once saw an operator who, having given a stout graft of this nature home, before hanging the whole weight of his body on to it, showed how firmly it was fixed to the tree. It is such grafting as this which eventually produces not only stout growths, but results in far earlier fruiting than is the case when many grafts of varying wood are put on to small numerous branches. Not only is the result better, but such grafting is more quickly done. As to beheading the old trees, that may be partially done early in the winter, such as during frosty weather if desirable, but at the time of grafting a fresh cut should be made to the point at which the scions are inserted.—A. D.

## ROSE GARDEN.

### HYBRID PERPETUAL AND HYBRID TEA ROSES.

I THINK that simplicity of classification ought in all cases to be aimed at with regard to cultivated flowers, and hence I have always protested against the recent "fad" of making a separate class for what are called Hybrid Teas. I was certain it would lead to confusion, and, at more, moreover, there was no necessity for it, as all the Roses so called might very well be regarded as Hybrid Perpetuals, and that the additional Roses added to this class might as well once have been put into that class. I think we all know that the so-called Hybrid Perpetuals are of a very mixed origin, some showing more affinity to Bourbons and Damask roses, others more inclining to Teas and Chinas, but all of a very mongrel character. The committee of the National Rose Society ought otherwise, and ventured upon forming a distinct and separate class and issuing a list of those Roses which were to be regarded as belonging to it. The idea seemed to please the French Rose growers (I think simply from a commercial point of view); they have poured in upon us of late years such a quantity of useless Roses of the H.P. class, that, seeing signs of the popularity of the new class on this side of the Channel, they announced from time to time several additions to it, but their first step was a very curious one. La France and the sports from it, Augustine Guinoisseau and Danark, and Capt. Christy were transferred from the H.P.'s—amongst which they had been always classed—to the new class of Hybrid Teas, while on this side Lady Mary Fitzwilliam

and Viscountess Folkestone were similarly treated, and were no longer to be regarded as H.P.'s. Another notable example was Kaiserin Augusta Victoria, a very beautiful Rose of Hungarian origin, but in no way—according to the opinion of some experienced growers of Teas—distinguishable from a pure Tea; and this last season we have seen it carrying off the medal for the best H.P. or H.T., thus excluding many of those which we have hitherto regarded as deserving of an award in this class. What are we to say of Gloire Lyonnaise? Guillot sent it out as a yellow Hybrid Perpetual, which, of course, it never was, for the faintest suspicion of primrose colour at the bottom of the petals did not warrant it being so called; but now we are told to regard it as a Hybrid Tea, and that the raiser was all wrong in calling it a H.P. Assuredly some of the Roses which have been of late put into the class, such as Clara Watson, Mrs. W. J. Grant and Caroline Testout, might very readily have taken their place among H.P.'s instead of, as at present, Hybrid Teas. One is continually asked by correspondents, even so far off as Cairo, how to define a Hybrid Tea and distinguish it from a H.P., and one's answer must always be that there is no way in which a satisfactory reply to these questions could be given. Thus, while agreeing with a paper which appeared in THE GARDEN, August 21, in many of its statements I see the same confusion upon this subject; thus all through La France and Viscountess Folkestone are regarded as H.P.'s, but if the writer were to compete for a prize offered for Hybrid Perpetuals he would find himself disqualified if either of these were found in the exhibit.

I entirely agree in the strictures passed upon scentless Roses. I do not think that we ought to have any of them, even although it would lead us to discard such as Baroness Rothschild. We have now so many Roses of all colours which are perfumed, that I do not think any encouragement ought to be given to a new Rose which lacks this essential. Unquestionably the dark Roses seem to have the true Rose scent more distinctly than the lighter varieties. There are some people who do not care for the scent of the Tea Roses. I do not go so far as this, but I unquestionably prefer the scent of such Roses as Charles Lefebvre, Prince Camille de Rohan, Earl of Dufferin, Jean Souppert, and Horace Vernet, as they have the true attar of rose perfume. There is one sentence in the article in question which completely puzzles me: "Almost without exception the dark red Hybrid Perpetual Roses are sweet scented, the want thereof being principally confined to some of the pink varieties, as Merveille de Lyon, Susanne Marie Rodocanachi, and Duke of Edinburgh," for Merveille de Lyon is a white and not a pink Rose, and generally takes the prize as a white Rose in the classes arranged for flowers of that colour, while Duke of Edinburgh is a most brilliant scarlet-crimson and is so described in the Rose Society's catalogue, and is very sweet-scented. Merveille de Lyon is not so, and is generally supposed to be a sport of Baroness Rothschild. It is somewhat curious that so few Roses of recent years either in England or France belong to this highly coloured section of the H.P.'s. Sir Rowland Hill, sent out nearly ten years ago, is a sport from Charles Lefebvre. Captain Haywood, the last Rose raised by the late Mr. H. Bennett, is very brilliant in colour and unsurpassed as a dark Rose for forcing, and in the supplement of the National Rose Society Captain Haywood is the only dark Rose mentioned. The Duke of Fife is certainly a dark sport from

Etienne Levet, and Duc d'Orleans is said to be a brighter Marie Baumann, but neither of them has the colour we especially now want. Two of the very best dark red Roses, Reynolds-Hole, raised by Paul and Son, and Louis van Houtte, one of Lacharme's, raised some twenty-eight years ago, have, unfortunately, not very good constitutions and do not answer as cut-backs. There is therefore plenty of room for hybridists to see if they cannot give us something more decided in colour and at the same time sweet scented. Probably, by going back to the old Gloire des Rosomanes, which is only semi-double, we might, after two or three generations of careful cross-fertilisation, obtain what we want. In these matters, however, I write entirely as an outsider. I have never hybridised and never raised seedlings, and therefore my suggestion may be worth nothing; but at any rate it is worth trying, and I hope some of our more experienced hybridisers may attempt it. DELTA.

## NOTES OF THE WEEK.

**Phlox Regulus** is a very showy and beautiful variety of the herbaceous Phlox, the flower large and of a bright rose-crisse shade, that is very effective in a mass. The habit also is good.

**Caiphora aurantiaca** is a very charming annual of climbing habit, and bears a profusion of rich orange-coloured blossoms that are very striking. In many positions where there is no room for the more rampant growing climbers this plant should be found of service.

**Andromeda arborea** is a very distinct species, with large terminal heads of creamy white blossoms that are produced in great numbers. The foliage is quite distinct from that of the other species and much larger and broader. Flowering too at this season, it should be useful in the garden.

**Chelone Ottigna.**—This at first sight bears some resemblance to *C. obliqua* vars. The flowers are, however, richer in colour and the habit much more refined. The flowers are of a warm rose-purple hue and very attractive. Mr. Ware had some bunches of it at the Drill Hall this week.

**Hibiscus totus albus.**—The pure snow-white blossoms of this plant are very chaste, and seen in the mass are effective in the extreme. At the Drill Hall this week Messrs. Veitch had some compact, well-flowered examples that could not fail to attract attention. Small plants, not more than 2 feet high, were laden with flowers.

**Lilium Batemani.**—For the late summer this has no equal in the open ground, where with a little care it may be easily cultivated if planted in a deep bed of loam and peat. Even at this late date there are a few blossoms, as was exemplified at the Drill Hall this week, when Messrs. Barr exhibited flowers in their mixed group of hardy plants.

**Hibiscus Manihot** is a yellow-flowered form which gained an award of merit at the Royal Horticultural show this week, though to our thinking inferior to the variety called Mrs. Macintosh, which only gained a vote of thanks on the 24th ult. Both are yellow-flowered, the latter having the larger blossoms and also a well coloured base.

**Kniphofia Leichtlini distachya** is one of the most curious and beautiful of the large family of perennials. Individually the blossoms are of an orange tone, and much shorter than in the majority of the varieties of this group; so much so, that the stamens which protrude very considerably predominate by their exceeding brilliancy, and provide a most distinct result.

**Acidanthera bicolor.**—Cut spikes of this very distinct plant were shown by the Messrs.

Veitch on Tuesday at the Drill Hall, and attracted attention by reason of the distinct form of the flower and its quaint colouring at the base. This latter is a sort of violet-purple shade, not wholly uniform, but embracing different hues of heavy and light shades of the same colour.

**Cornus florida.**—In your issue of last Saturday (p. 177) you ask if *Cornus florida* is known to flower well in England. I have two plants here which flower more or less every year, and some years very plentifully, and they are then a very pretty sight.—B. E. C. CHAMBERS, *Grayswood Hill, Haslemere.*

**Chrysanthemum Barbara Forbes** and *C. Queen of the Earlies* are both pure white kinds of distinct form. Flowers of each came before the floral committee of the Royal Horticultural Society without receiving any award. Both are Japanese in form, the former with incurving petals, and the latter, which is somewhat flat in form, incurving slightly at the tips; the flowers are of medium size.

**Rosa rugosa.**—Though we have scarcely realised that this handsome plant has finished its flowering for the year, we are reminded of the near approach of autumn by the masses of richly coloured berries the plants produce. These in their way are also effective, and give the plant a value of its own during the early autumn months. The handsome foliage of this species is also an attraction both before and after flowering.

**Helianthus Queen Victoria.**—This rather distinct form, exhibited by Mr. T. S. Ware at the Royal Horticultural show on Tuesday, is said to be a sport from *H. multiflorus* var. It differs from the *H. multiflorus* pl. in the almost tubular form of the central tuft of florets, in the same way as may be noted in the Anemone-flowered *Chrysanthemum*. The outer or guard petals are the same as in the old form, while the tubular florets impart a certain neatness and compactness to the flower.

**Aster Mrs. W. Peters** is a seedling variety of the Michaelmas Daisy with small white flowers. Though rather pretty in the case of the pot plants as shown, the two-year-old plant from the open ground possessed no merit whatever to entitle it to an award of merit. Indeed, it is not too much to say that the Drill Hall could easily be half filled with seedlings possessing as much merit as this one. If we remember aright, much better varieties were passed over by the conference committee a year or two ago.

**Eucomis punctata.**—Judging by several well-flowered examples at the Drill Hall this week, this distinct plant is receiving attention for pot culture, for which purpose it is well suited. This species is perhaps the largest of the genus and the leaves reach quite 3 feet in length when well grown. The flower-spike, rising from the bulb to fully 2 feet high, is for some half its length densely clothed with wax-like starchy blossoms of a creamy white and freely spotted with rose. The blooms are also sweet-scented.

**Verbena venosa.**—Since the recent abundant rainfall this old garden plant appears to have assumed a fresh vigour that has also given effect to the fine mass of flowers so characteristic of the plant. As though approving of the lessened sunlight and sun-heat, the flowers are of much deeper hue and the stems more elongated than was the case during the great summer heat of this season. For these reasons it is now a most welcome mass of colour, and being of good habit and very profuse flowering it is a valuable autumn plant.

**Senecio pulcher.**—While some plants deteriorate with constant rain, particularly when accompanied with wind and cold, others again improve, and this is so of this *Senecio*. During the great heat of the present year the young plants put out in spring made little progress, but as noted recently in the collection at Long Ditton they have improved considerably. Some of the best formed flowers of the plant we have seen were in Messrs. Barr's group at the Royal

Horticultural show this week, each bloom being nearly 4 inches across.

**Erodium macradenium.**—This pretty flowering plant appears to be hardly ever without many of its blossoms expanded when the tufts are large and well grown. In the herbaceous borders at Kew a very handsome tuft spreads out over nearly 18 inches, and the very pleasing foliage and dainty blossoms combine to make it both a choice border plant as well as a most desirable and beautiful object for the rock garden. The plant may be easily raised from seeds, that should be gathered at intervals throughout the year, in consequence of the profuse flowering of the species.

**Bougainvillea glabra.**—Among the more uncommon plants that are employed for furnishing the flower beds in Hyde Park are several specimens of this *Bougainvillea*, which, being thickly studded with their bright-coloured bracts, are not only very showy, but quite distinct from any of their associates. Many beautiful subjects are to be seen along Park Lane in the shape of large plants all flowering freely. Beside the *Heliotropes* and *Fuchsias*, which are always a special feature, may be particularly mentioned, beside this *Bougainvillea*, *Plumbago capensis*, *Streptosolen* or *Browallia Jamesoni*, and *Erythrina Crista-galli*.

**A pretty combination.**—A pleasing effect is sometimes accidentally produced from very simple materials, as in the case of a plant of the wild Teasel (*Dipsacus sylvestris*) here, about 5 feet high, round the base of which some shoots of the wild *Convolvulus* (*C. sepium*) sprang up, and have now clothed the lower half of the stem with a conical mass of dense foliage, the combination suggesting the idea of a huge candelabrum with a richly embossed base. This chance arrangement of two simple wild plants is quite as effective and pretty as many things which I have seen that required some thought and taste in designing them.—W. M., *Wexford.*

**Lilium speciosum Krætzleri.**—This very handsome pure white Lily is without doubt one of the best things among the hardy plants now in flower. Indeed, all the forms of the *speciosum* group are valuable because of the season of their flowering, while their perfect hardiness and free growing characteristics render them invaluable. A single bulb when well planted will make a fine specimen in a year or two, and where three or six can be grouped so much the better for immediate effect. Against the frequently over-abundant sombre hue of many shrubs in the borders the warm rose or crimson shades of these Lilies appear with surprising results; so much so that it is a wonder they are not more often seen.

**Colchicums.**—The Meadow Saffrons have again come into flower with almost wondrous rapidity. The first to come into bloom was *Colchicum Bertoloni*, which has now many companions. Among these the pleasing *C. byzantinum* is a general favourite, although cast in the shade in some respects by the more massive flowers of *C. Bornmulleri*, *C. speciosum*, *C. speciosum rubrum* or the fine chequered blooms of *C. Sibthorpi*. The common *C. autumnale* and some of the less plentiful Meadow Saffrons look magnificent in size beside them. None of the double varieties had opened in the first week of September, and the constant rains have deprived the single forms of much of their usual brightness.—S. ARNOTT, *Carsethorn, N. B.*

**Anemone japonica Brilliant.**—At Winchmore Hill Mr. Perry has a variety of this well-known plant bearing the above distinctive title. The coloured forms of this fine autumn flower are open to much improvement, and the name above given is certainly suggestive of improved coloration. An acquaintance with the growing plant, however, in such a case is the only real way of deciding as to its merits or otherwise. Many years ago a red form that was distinct from the type bore the varietal name of *A. j. rubra*, but whether it remained constant we are not aware. Different soils and localities are at times respon-

sible for certain colour changes in garden flowers these latter often reverting to their original state at no distant period.

**Campanula nobilis.**—This is an excellent plant for a cool spot even where a rather heavy soil obtains, as by its vigorous nature the species is at home, both growing and flowering freely. The flowers, too, which are of a reddish-lilac hue in the type, are both large and handsome, a very striking when seen in a cool and moist spot. In such a place the plant spreads quite freely means of underground stems, though it may not be accepted as being of a weedy or even troublesome nature. Indeed, in these respects the plant is readily kept in hand, as is also the creamy-white form known as *C. nobilis alba*. The plant will grow from 18 inches to 2 feet high, the large drooping blossoms each upwards of 3 inches long. It is a native of China and a good border plant when once it becomes established.

**Campanula barbata.**—This very beautiful species is certainly not largely grown, and it only occasionally met with even in some botanical gardens. Its scarcity in collections of hardy plants may be due to the fact of its not being a good perennial and frequently perishing after flowering. For these reasons it is best to register it rather in the light of a biennial, and as seeds are produced somewhat freely, it is quite easy to raise sufficient plants to form a very pretty collection in the rock garden, which is the best place for the plant. Grown in a deep and rather sandy loam the plants will reach 1 foot high or rather more. The pale blue of its drooping corolla is of a very charming shade, the plant being of a neat and attractive habit withal. The white variety is especially beautiful, and worthy of the best position that can be given it, viz., a warm and sunny aspect. A very pretty group may be formed the two in mixture in the rock garden, where will at least equal the best of its genus.

**Lilium speciosum album novum.**—Among several good forms of this beautiful section of autumn Lilies the above holds a prominent position, the reason being not far to seek. Pure and spotless in the chasteness of its fair white flower that are even of greater substance of petal than is usual in the other white kinds, the blooms present an almost massive appearance, while the orange-yellow anthers at once distinguish them from other white kinds. In other minor details it is also quite distinct, and flowering a day or two in advance renders it useful on this account. When grown in a deep bed (say at least 3 feet) loam and rough peat, with a little manure added and plenty of sand, this lovely Lily, the second or third year, will reach 8 feet in height. To achieve this, however, the beds should be slightly sunken at the surface and the position a partially shady one. In the growing season and until the flower buds are fully grown the plants should not lack moisture. Thus grown this is one of the grandest of the hardy Lilies during September, and as such should be in every garden.

**Crococsmia imperialis.**—This is undoubtedly one of the finest hardy plants extant, and therefore we can only hope for the time when such a really handsome autumn-flowering plant shall become plentiful in our gardens. At present, however, it is anything but common, though we are reminded of its value by meeting it in flower lately. The really handsome flowers are often 4 inches across—some, indeed, we have seen must be even larger than this—while the clear orange-scarlet of the flowers, produced on stems about 4 feet high, give a very striking effect in the garden. It is a plant to take care of and increase freely both by seeds when these are procurable, or by division, which is more easily accomplished after flowering is complete. Though regarded as a perfectly hardy perennial, care should be taken to secure it from severe frost, firstly, by planting in position naturally sheltered and having perfect drainage; and secondly, either by deep planting or subsequent mulching overhead. It is altogether too valuable a plant to be risked without some winter protection.

STOVE AND GREENHOUSE.

FOURCROYA BEDINGHAUSI.

The Fourcroyas or Furecroas belong to the same tribe, to which both in leafage and flower-spike they bear a marked resemblance. They are mostly natives of Mexico and Tropical America, and are thus generally unfitted to withstand the climatic conditions inseparable from open-air culture in England. In the Isles of Scilly, however, *Fourcroya longeva* flourishes to perfection in the genial atmosphere that pervades those favoured shores, encompassed by the warm tides of the Gulf stream, and in the gardens of Tresco Abbey it may be seen in quantity, rearing its tall bloom-spike in some cases to a height of 25 feet. *Fourcroya Bedinghausi*, at one time confounded with *F. Roezli*, is said under favourable circumstances to attain and even exceed this stature. When in flower this *Fourcroya* is far more ornamental than *F. longeva*, its inflorescence being pendulous and forming almost a curtain around the central flower-stem. S. W. F.

ACHIMENES.

It is gratifying to find these old-fashioned showy greenhouse flowers gaining favour again. Years ago I used to like to inspect the fine specimen pans of Achimenes which found their way to the South Kensington exhibition, these being from 2 feet to 3 feet across. Two collections that recently came under my notice had been well grown. One of them was in pots, the other in hanging baskets. They do best in rather shallow receptacles, or if grown in ordinary flower-pots the drainage should reach nearly half way up, as they only like as rich soil as they can permeate with roots during the limited season of growth. Although fairly easily managed when once established and growing freely, Achimenes are sometimes difficult to coax into active growth, unless a fairly warm moist atmosphere is given them. Indeed, although classed generally as greenhouse plants, I always find them to enjoy an intermediate house. They are often spoilt when quite in a young state by allowing the morning sun to strike on them when in a wet state from the syringe. When the plants get older and the foliage more hardened they stand it better. Afraid of scorching, growers sometimes give too heavy shade or keep the pots too far from the roof glass, hence a lanky, weakly growth and ill-furnished pots or pans with little bloom in the end. A compost of light fibrous loam, rubbed down by hand in preference to being sifted, with the addition of a small part leaf-mould and sufficient sand of a coarse nature to keep the whole porous, will grow Achimenes well. Care is necessary at the outset in watering, as any excess in this matter is injurious to a fair quantity of roots being made so that the young plants yellow and stop growth. When about 3 inches high the tips may be pinched out to induce side breaks and a stocky foundation. As soon as the blooms are freely produced syringing must be abandoned and atmospheric moisture supplied by frequent damping down. Harry Williams, Dazzle, Longiflora mor. Doctor Andry, Ambroise Verschaffelt, Ave Queen, and Sir Treherne Thomas are all excellent varieties. J. C.

summer, when growing freely, these *Celosias* are liberal feeders, particularly if confined in pots, but in autumn and winter care must be taken not to overwater them, as, being of a somewhat succulent nature, an excess of moisture will often cause them to decay. This *Celosia* is by no means a new plant, having been introduced from India in 1820, but it is only within the last few years that it has been grown to the extent that it is at the present time. By continued selection we have now several well-marked forms, which in a general way can be depended upon to come pretty true from seed. An ally of this *Celosia*—viz., the Cockscomb—may also be seen bedded out occa-

*Fourcroya Bedinghausi*. From a photograph sent by Mr. W. Sangwin, Trelissick.

mistake often made in its culture is growing it too well, or rather too strongly, rich soil causing grossness of foliage. To get nice shapely little plants, cuttings of half-ripened wood should be struck under bell-glasses in firm sandy soil, potted on and grown rather pinched for pot room in a light, warm house. For compost use a third of good loam, one-third of peat, the remainder made up of broken bricks, charcoal, or some similar material, and a good sprinkling of sharp silver sand. In the earlier stages care is necessary to prevent the plant damping, especially if the cuttings were placed rather deeply in the first place. Afterwards a free supply of water is advisable, and when the pots are quite full of roots a little weak soot water is helpful. The plants may be cut down and will break freely in spring, or, if late ones are required for grouping, they may be taken up in single stems and hardened a little before being taken to the house or conservatory. *P. pallidifolius* is also known as *Reidia glaucescens* and is a native of Java.

STREPTOCARPI.

THE recent illustration of these useful flowering plants, together with the cultural remarks by Mr. Tallack, would, I am sure, be welcome to readers of THE GARDEN. Some gardeners succeed well with them, while others find a difficulty in growing them well, their soil not seeming to suit them. I am glad Mr. Tallack gets the paler and more delicately coloured varieties to grow vigorously and flower satisfactorily, as I must confess that the latter with me have up to the present made indifferent headway. The older, darker strains seem to possess a far more vigorous constitution and soon grow into large plants. I have some in 8-inch pots that in one season have borne 100 spikes of bloom, while the foliage is very long and of a dark glossy hue. The paler varieties start well enough when repotted and subjected to a gentle warmth, but gradually lose their vigour when placed in a greenhouse temperature. Several of my neighbours have experienced the same difficulty. I think the paler coloured, less vigorous varieties require to be potted in a lighter compost, of which leaf-mould forms a good part, the pots to be no larger than is absolutely necessary, and to be thoroughly well drained. Some gardeners have condemned the use of any heat whatever for *Streptocarpus*, but my experience is that an intermediate temperature, charged with a fair amount of atmospheric moisture, suits them well, a slight shading being given, and if those who do not succeed with them in a cool greenhouse were to give this treatment, better results would follow. During the winter months the foliage takes on a rusty appearance, and care is needed not to give too much root moisture, or the plants are apt to die right out; in fact, no more should be given than will keep the foliage from flagging. C. H.

HERBACEOUS CALCEOLARIAS.

THE earliest sown batches of these will now be ready for transferring to 6-inch pots, but before doing so it will be advisable to subject them to another gentle fumigation, as when newly potted they do not care for the ordeal. Some growers condemn the use of tobacco fumes for *Calceolarias*, but I have always found that mild doses administered say once a fortnight or three weeks will keep the plants quite clean and not injure the foliage in the least. It is when the pest is allowed to get a strong hold and heavy fumigations are given that injury follows. A north aspect is the most suitable for the plants at present, but to leave the lights entirely off the frames and the plants quite exposed, as some do, is only to court failure. They should be tilted sideways, so that a free current of air can pass over and around each plant. If the pots were well drained and the plants vigorous, the roots will, when working freely in the new soil, take water freely, but anything approaching excess must be guarded against, or

sionally, generally with satisfactory results.—H. P.

**Phyllanthus pallidifolius.**—The pretty little red and yellow blossoms of this plant depending from the finely-cut leaves have an elegant yet striking appearance, and one wonders why it is not more grown. As a warm greenhouse shrub it is very fine, the glaucous foliage showing thus to great advantage, while single-stemmed plants are light and pretty for table decoration. A

*Celosia pyramidalis*.—This, as represented by numerous forms, is frequently used for bedding, the vivid-coloured blossoms being associated with the sober-hued subjects in forming some of the most bedded that are now so popular. The season of blooming may be varied to almost any extent by sowing the seed at different times, and during autumn and winter months the brilliantly-tinted blooms impart a colour totally wanting in *Chrysanthemum*, which forms the bulk of the flowers at that time met with. During the

yellowness of the foliage will quickly follow. Care is also necessary to prevent the water from settling round the collar of the plants, or rot will set in. For this reason it is always advisable when potting to keep the neck or collar of each plant slightly elevated. A good yellow fibrous loam five parts and one part well-decomposed cow manure free from worms, leaf-mould and coarse sand or road grit form a good rooting medium. Slugs must be watched for, as they are very partial to the young sappy foliage, a dusting of soot and lime over the ashes on which the pots stand being a good safeguard. When well established, *Calceolarias* like an occasional watering, say once or twice weekly, with weak diluted farmyard liquid. Old *Calceolaria* growers like to see the water beads hanging from the edge of the leaves at daybreak; this they consider a sign of good health. J. C.

#### GLORIOSA SUPERBA.

This beautiful plant appears to be getting more popular; at all events it is seen much more frequently than formerly. I noticed it in several gardens last week in the west of England, a very strong plant of a good form of it being in full beauty at King's Weston, the seat of Mr. P. N. Miles. It was growing on a wire trellis close under the roof of one of the plant houses, and the stems were apparently about 20 feet in length, closely covered with the bright showy blossoms. These are a deep orange, with tips of scarlet when fully developed, the segments standing erect owing to their recurving form. *G. superba* is not a difficult plant to grow, provided a few simple details are observed. It is a native of some of the hottest parts of the world, consequently it must have plenty of warmth while growing, and even when at rest must not be kept in a cold place. The bulbs are offered as imported, but established ones are possibly preferable, especially for inexperienced cultivators. They should not be disturbed unduly when shifting on, as the roots are easily damaged, being so brittle. Equal parts of good loam and peat, with a little dried and pounded cow manure and some rough, sharp sand, will grow it well. Bulbs that do not start freely may be placed in a brisk bottom-heat, such as afforded in a stove propagating pit, and kept there until the shoots are a few inches in length. They may then be slightly hardened, but will grow and flower best in a stove temperature. Direct sunlight is injurious to the foliage, but the plants, I think, are often kept in too dense a shade. While there are no flowers open the syringe may be somewhat freely plied about the stems. The roots must be kept moist until the foliage and stems begin to die down, when it must be discontinued by degrees. During winter the pots containing the bulbs may be laid on their side in any dry, warm shed or house, but they are not safe where the temperature falls below about 50°. When potting up the bulbs in spring, offsets may be taken off and set going on their own account, but if a large specimen is required, these are better left to increase its bulk. H.

#### TABERNÆMONTANA CORONARIA.

White scented flowers are always in demand, especially when they may be cut with their own foliage, as in the case of this pretty plant. When it is healthy the leaves take on a deep shining green that goes far to counteract their somewhat stiff appearance, while the style and carriage of the little panicles of flower are perfect. Few things look nicer under artificial light, so that it is useful for table decoration, while the flowers are produced over a long season. To grow the plant well it must have liberal treatment from the first. The best way to propagate it is by cuttings of the young wood, these striking very freely in a warm house, under a bell-glass or in a propagating frame. As soon as these are well rooted they may be potted into small pots and grown on as rapidly as possible in a brisk, moist

heat, stopping them frequently to produce a bushy plant. It is not so bushy in habit as a *Gardenia*, but will make a nice shapely plant with care. Large plants may be kept for years in pots, using a compost of peat, loam, and sand, with a little manure, but much the best results are obtained by planting them out in a bed of good soil. The growth they make under these conditions is remarkable, and they produce an immense quantity of flower. A suitable place for it, too, is planted in a warm conservatory, and one of the prettiest things I have lately seen was a fine specimen loosely trained over a trellis on a conservatory wall. Plenty of light and warmth and a moist atmosphere while growing are essential, and I have known excellent results follow the use of highly diluted soot-water for syringing the foliage and damping the house wherein it is grown. During winter growth is less active of course, and if the wood has been well ripened by exposure to sun and air in autumn, a cool, restful temperature suits it best. A very dry atmosphere is even now harmful, though naturally less moisture is needed than in summer. Insects, mealy bug especially, are fond of the foliage, and it is difficult to thoroughly clean the plants if ever this pest gets a firm hold on them. But this they will not do if the syringe is kept well at work and the plants are not starved at the root. Old specimens in pots need a lot of feeding, and there is nothing more suitable for the purpose than clear soot water varied occasionally with weak applications of guano. H. R.

#### FUCHSIAS.

SINCE the advent of the tuberous *Begonias* these have not found so much favour as formerly, yet even the great strides that have been made in improving the *Begonias* cannot eclipse the older favourites entirely. We still find some who go on raising and obtaining improved varieties of the *Fuchsia*. I lately saw some remarkably distinct varieties in Mr. W. Bull's nursery, particularly Alfred Raimbaud, with flowers of immense size, crimson tube and sepals, corolla of a rich purple and very full double. Tribute is a single variety with crimson tube and sepals and a fine purple corolla, the plant being of good habit. Mme. Carnot is a striking variety, the large double white corolla being veined and suffused with pink. In Duc d'Anmale the tube and sepals are of a bright red, corolla very full, double, of a clear white. A great number of other varieties were flowering in the same house, all of which were comparatively new, and showed improvement or some distinct characteristics from older sorts. Like many other subjects which will grow and flower freely under almost any kind of treatment, *Fuchsias* will well repay a little extra care and attention. The same plants will flower year after year, but where plants of medium size are required, young stock is decidedly preferable. Cuttings put in in the spring will make fine plants for flowering the same season.

The first thing is to have clean, healthy cuttings, which can only be done by starting the old plants where they are not likely to get infested with green fly or other insects. The stock plants can be thoroughly cleansed by fumigating or dipping, either of which can be done more effectually than after they have started into growth. There is a great advantage in getting strong cuttings. They require to be kept close until rooted, but should be gradually exposed before they have started into growth and potted off singly as early as possible. There are some varieties which cannot be grown into shapely plants without stopping, but some will make symmetrical pyramids without any stopping, and I much prefer plants grown this way; they must be grown on without receiving any check from the time they are started. If a good rich loamy compost is used for potting, large pots are not necessary. Some of the examples seen in Covent Garden Market well illustrate what may be had in a 5-inch pot, though for keeping up a succes-

sion of bloom in a conservatory it is certainly advisable to use larger pots. After the plant commences flowering, liquid or artificial manure may be used regularly, and with fair treatment there are few plants that will keep up a bright display of bloom for a longer period than *Fuchsias*. H.

#### ZONAL PELARGONIUMS FOR WINTER FLOWERING.

So much improvement has been made both the colour and habit of this section, that it is now possible to keep up a display throughout winter. Varieties are too numerous to enumerate I may, however, refer to the improved variety *F. V. Raspail* and the semi-double form of *W. Brighton Gem* as two of the most popular among those grown for market. One of the best double whites is *Mme. Rozain*. Those who would have greater variety should make their selections according to their own individual taste. It is difficult to judge which will prove good in winter, even if seen in summer. Those of coarse growth, with long joints, should be avoided. Generally those with a short branching habit of medium-sized trusses prove the best. Of course treatment makes a great difference in the habit but when a collection is seen, all being under same conditions, it is easy to select the best. Good summer treatment will go a long way towards ensuring successful winter flowering. Like to pot the plants early in June, select short-jointed, sturdy plants either from those propagated the previous autumn, or early spring struck cuttings will answer as well. A compost consisting mainly of good fibrous loam, with little manure and sand added, may be recommended, and I like to pot fairly firm. This to some extent prevents too vigorous growth being made. After potting, the plants may be set out in the open where they are fully exposed to the sun. Care should be taken that no water penetrates the pots. It is better to err on the side of keeping them too dry than over-water, and no manure should be used until they are in flower. All bloom-buds should be taken off as soon as they appear, and so sorts require stopping from time to time, while others will branch out freely without being stopped. The time of taking the bloom-buds will depend upon when the plants are required to be in flower. Those required to be in flower in October should now be gone over for the time, taking off the forwardmost trusses only. It takes about six weeks from the time the trusses first show until they are well in flower. The plants should be taken under glass early in autumn, or before we get heavy rains. When first housed, air should be left on night and plenty of room should be given. More bloom will be got from a dozen plants standing wide apart than from two dozen crowded together. Light and air, with just enough fire-heat to keep damp, will ensure success early in the season, later on more heat must be given. For winter work I prefer a house with a southern aspect though a light span house running north and south may answer fairly well; the direct rays of the sun, which are so beneficial, can better be obtained from a southern aspect. Although during the early part of the autumn it is best to keep the plants as cool as possible, later on more warmth may be given. One of the finest batches of zonal *Geraniums* I ever saw at Christmas-tide was grown in a lean-to house, facing the south, the plants being arranged on a stage near the glass, and the temperature was kept far higher than is usually given for such plants. H.

#### SHORT NOTES.—STOVE & GREENHOUSE.

**Variegated Pelargonium Mrs. Parker.** This is a vigorous-growing, yet compact-habited variegated zonal which makes a delightful pot plant, with flower pink in colour. I am not sure if it is in commerce, but I saw it recently at Messrs. W. Balcin's.

ns' nursery at Hassocks, where it seems to be grown gely. Whether for the flower garden or pots it is most desirable variety. The variegation is white, leaves being somewhat deeply edged.—R. D.

PARK AND WOODLAND.

GERMAN FORESTRY.

REGENERATION AND ROTATION.

ANY of the German forests are produced by natural regeneration. In hard woods, the Beech, sometimes mixed with Hornbeam and other species, affords the best example of natural generation and illustrates the effects of crowding well, because, as is well known, the Beech naturally branchy and wide-spreading in the open, like others of our British forest trees which also conform to plantation culture, developing trunk instead of lateral branches of little or no value. In these German forests of Beech what strikes the English forester is the density of the young trees and the great height they are allowed to reach before thinning is attempted. The regeneration process with the Beech begins with the first opening of the overhead canopy, when the light is admitted to the ground. The crop will then be approaching 10 years of age, and the regeneration process occupies about twenty-five years, by which time the new crop has been established from the naturally shed seed of the previous crop in its first stage. At this young stage a Beech forest looked at casually has the appearance of a thin English wood with underwood, and has been mistaken for such by English foresters. But they are not like our woods, for the mass of underwood seen consists not of Yews, Hollies, Hazel, and such things, but exclusively of young timber trees, the same as the preceding crop. There is no attempt at thinning till the trees are nearly forty years of age, in ordinary rotations. The overhead canopy is carefully preserved, and the woods are dark and found almost destitute of undergrowth, but as soon as the light is admitted the young trees come up in millions, looking at a distance like masses of wild Raspberries. At this stage I tried to form some idea, by counting, how thick the plants were when about 18 inches high, and calculated that there were from 80 to 100 to the square yard in most places. The struggle for existence now sets in, and by the time the trees are above one's head they have decreased in number to about ten or less to the square yard, standing just like seedlings in a hotbed. The struggle continues until "height growth" is attained, and at this advanced stage the trees are so dense that the sides of the paths are trimmed like hedges to keep the road clear. One seems to be walking between two Beech hedges, only the other side of the hedge is forest. By the time the trees have reached the height of 40 feet, or perhaps more, according to soil and condition, they have thinned themselves proportionally, but are still rank and the canopy broken. Many trees in process of being "othered"—the "dominated trees"—are ready to be removed, and are thinned out for firewood. In thinning, the operator looks up at the tops and not at the ground, and if the removal of any tree is going to make a hole in the overhead canopy it is left. The consequence of this is that the trees, especially in Fir woods, are not so regularly distributed over the ground as we try to have them in England. I counted, where I happened to stand, as many as four Scots Firs, each 50 feet high or so, in the space of one square yard, and close by these three others standing in a line about

20 inches apart—groups, as it were, here and there, perhaps 5 feet or 6 feet apart, but above the canopy was complete. It is at about this middle stage that the condition of the hard woods like the Beech strikes one at first unfavourably, who has been accustomed to Scotch thinning practices and theory. The trees up to from 30 feet to 60 feet in height or thereabout, though tall and straight, are of all girths, from rails no thicker than one's arm up to good poles of useful measureable dimensions. In this country the smallest trees would be classed as rails in a fall of timber, and sold for next to nothing as corkwood or "cratewood," and a wood crowded with such examples just answers to Brown's description, in the "Forester," of a wood ruined from want of thinning. Such long slender rails have reached a stage after which, in Britain, it is thought impossible they can ever become useful timber trees. Our idea is to carry trunk bulk on along with height growth from the beginning, but the German idea, put into English, is to get height growth first and girth afterwards. The wand-like poles look as if they would never do this, but they do. I walked through these Beech forests from the first to the last stage, where the rotation period was about to end. Here I measured an average example of Beech which squared by the tape

In a German forest. High forest gloom.

about 17 inches near the ground, and 13 inches about 90 feet up, with a considerable tuft of branches above that, but none below, the trunk being clean and wonderfully round and cylindrical up to the above height. I said to the oberforster, "Now, has this tree, and all those like it standing here, grown up to its present dimensions under the crowded conditions, from youth to age, that we have seen where we have come through to-day?" and the answer was, "Yes, you have seen it all." I could have selected bigger trees, elsewhere in the valleys, where they reached 150 feet, but the above examples were about 1000 feet above the sea, or perhaps a little more. The Firs are produced under exactly the same conditions. One passes through compartment after compartment till the end of the rotation is reached in the mature crop. So much for the results. The German theory is as follows: The crowding produces clean, straight trunks, and as the dominant or tallest trees are left, and keep pace with each other, they are bound, while their tops keep alive and in health, to deposit a layer of wood in their trunks annually, and, given the required number of years, the girth desired is simply a question of time. The increase to the girth may be small, where the top of foliage is restricted, but it is constant while the tree

lives. The trees have remarkably small heads for their length, according to our ideas, but large enough to produce good stems. When thick trunks are wanted, the heads of the dominant trees are allowed greater development, and the annual rings become broader, and *vice versa*, but timber of the best quality is produced by those trees in which the annual increase has been most regular and the rings are of moderate breadth. The average production to the acre as regards quantity is not so much affected, because the thicker the trunks the fewer the trees, and so on. The Germans do not go in for very big timber. Plenty of it of useful size is what they want, and a vast proportion never passes pole size. I saw nothing that we could not do equally well at home in the same way, and occasional examples are to be seen here and there on almost every estate. There cannot be the least doubt but that the German system of forest management could be easily adopted in this country, and that, too, without interfering with game preservation in the least. Good crops of timber and pheasants, &c., could go on perfectly well together by a right method of procedure. One could see in these German forests that, if game were an object, dense coppice shelter could easily be provided by simply leaving a space here and there for it to grow, and under such conditions, what we call underwood cover would grow better than under the trees. Without this, however, the Spruce, Scotch Fir, and hard wood forests of Germany produce ideal coverts for pheasants, wild pigeons, and other game, both fur and feathers. The Spruce and Beech form dense covert up to a late stage of their existence, and as by the compartment system a regular succession of plantations is always coming on of all ages, covert is abundant. In Scotland no better covert tree for pheasants and hares is found than the Spruce, affording as it does both shelter or shade and an incomparable roosting tree for the birds. Moreover, for shelter in winter these dense German woods quite beat a thin English wood, even though the undergrowth may consist of bare poles only. In winter the canopy overhead prevents excessive radiation, and the stems of the trees filter the gales, so that neither severe cold nor keen winds are felt. I was in a dense high forest one day when a gale was blowing outside, and yet so still was the air inside the forest that the gale would hardly have deflected the flame of a candle. In short, with regard to the production of timber, as Professor Schlich states in his third volume, "the principles of forest management hold good all over the world," and there is not a wood, however small, in this country that might not have been made a miniature counterpart of a well-managed German forest. The allotments in Holland, planted with a crop of trees instead of corn, show this conclusively. As to game preservation, gentlemen who are sportsmen should judge for themselves what is most practicable and best to be done, to have good crops of timber and plenty of game also.

REGENERATION BY PLANTING.

The purely natural Pine forests of Germany are not so common as one might think. Many of them have disappeared by the axe and are being replaced by planted forests. Some are raised from seed sown on the spot, but wherever I went in the Hartz, and in Thuringia,

planting was the rule. The worst and highest situations are give up to the Spruce, but Spruce and Beech do well together. What Dr. König called an ideal compartment consisted of Beech and Spruce, the latter planted ten years later than the Beech, but now 20 feet higher. This, which may be called a handicapping process in forestry, is practised by German foresters in mixed woods to prevent strong-growing species dominating the weaker ones. In England any sort of mixture goes in pell-mell at the same time, and the smothering process goes on from the very first, necessitating far more attention than German plantations receive. The Germans also pay much attention to the shade-bearing power of different species and plant accordingly. The Spruce bears shade well, and Oak woods crowded beneath with Spruce are to be seen, but Beech is the shade-bearer *par excellence*. In the photo of a "clear cut" in my first chapter the spray seen in the gloom of the forest is from Beech trees 50 feet or 60 feet high, growing as straight as the Spruce between their legs, as it were. In planting Spruce and Scots Fir the hack is used instead of the spade, and the plants are about 6 inches high and home raised. Regeneration begins in the home nursery, a very homely affair, but well adapted to the purpose. These nurseries are little enclosures here and there in the woods, railed round with small Firs cut near. The ground is dug and cleaned and the seed sown, and while an English nurseryman would be sowing and transplanting and adding to the price of his forest trees every time they were handled, the German forester has his plants out and in the wood at a tithe of the labour. Of course the work is all planned, and stock does not accumulate in the nursery from want of time to get it out, and it is not wasted, as happens in both public and private nurseries here. In the German forests there is no rank undergrowth to contend with, and the trees can be planted out very young and small without fear. In the Hartz Mountains 4 feet apart appears to be the usual distance between the plants, but in the Thuringia Waldt 3 feet is common. This distance is allowed in the more favourable localities and soils, but at high elevation "bush" planting is adopted, three trees being put into each hole sometimes less than 3 feet asunder. This is to ensure an early covering of the ground. In plantations thirty years old the three trees in each hole are in many cases all still alive, but as a rule one takes the lead and the weaker ones die off. I asked the forest officer how he reconciled the 4-feet-wide system with the opinions of German authorities, that complete cover of the ground (canopy) should be established if possible within five years in order that the lower branch growth might be arrested, and his reply was that thicker planting was desirable, but the initial expense was greater. The Spruce and Scotch Fir forests, I must say, do not look well inside in the earlier stages, when the lower branches are all dead, but have not yet fallen off. Later, however, when this has taken place a long way up the trunks of the trees, a Pine forest is a beautiful sight, and the long, straight, narrow forest paths, with the tall clean trunks ranked densely in a straight line on each side, look more like a cathedral aisle than anything else one can think of. Indeed, when looking at the tall columns inside of Cologne Cathedral, it occurred to me that I could have easily picked out trees of different sizes in the Hartz forests which, when packed together in proper order, would have made a pillar almost exactly the same as the massed columns that supported the nave, so tall and cylindrical are the trees. After plant-

ing, little attention is bestowed on the compartment for perhaps as long as twenty-five years, and in some cases more. Then a thinning out of the dead and dominated trees takes place. These are not thicker than one's arm or thereabout and are long and even. The best go for deer fencing, bean sticks and firewood. Towards the end of the rotation period (100 years), at perhaps the age of seventy-five years, the timber crop begins to be reaped, ending when the last fall is cleared off. British foresters are loth to believe that such crowded woods can ever grow into fine massive timber, but there are the trees in all the stages, miles upon miles of them. The photo of "A clear cut" in last chapter shows a crop of Spruce, in which every tree is just as perfect a timber tree as once could imagine.

As regards the weight and value of the timber crop per acre, from 6000 cubic feet to 8000 cubic feet in the last fall at about 6d. per foot seems a common thing from what I was told, and what I saw and calculated myself. That would pay even in Britain, and pay well on land, like the German hills, worth so little agriculturally. That is Fir timber, but our Ash, Sycamore, Larch, Elm, &c., would be worth much more. The German forests are mostly "pure," and Scotch Fir, Spruce, Beech and Oak form the staple crops. Ash is beginning to be appreciated, but, as a rule, the Germans are behind us in the variety of species cultivated. They have just taken up their natural woods as they found them, and the whole art of German forestry consists in adhering to Nature as closely as possible. They have studied the principles on which Nature proceeds in the manufacture of timber, and they have explained these principles and reduced them to practice in a systematic way. "It is an art, but the art itself is Nature." Our British forestry is an empirical invention only, having no foundation in either Nature or art. It is just the exact opposite of both Nature and of German practice, so far as the production of timber is concerned, and produces the exactly opposite results.

The above quantities to the acre are ordinary. In experiments conducted in the dukedom of Saxe-Weimar they have been much exceeded. Herr Kallenbach showed me the complete record of results from a crop of timber grown on one hectare. The quantity amounted to 112 cubic metres, which is equivalent to close upon 20,000 cubic feet per English acre. This was sold by auction at the rate of £475 per English acre or thereabouts, 27 per cent. being sold for firewood. The timber consisted mainly of Fir ninety years of age.

#### ROADS, TRANSPORT, AND CONVERSION OF THE TIMBER.

Much forethought is exhibited in the laying out of the forest roads for the removal of the timber in the mountain regions. They are all laid out at a certain gentle gradient, winding through the woods in a continuous ascent to the highest elevations; consequently the timber is all hauled down hill principally by cattle. I took the contents of one load of timber—an average example—and estimated it about 2½ tons, or 100 cubic feet, loaded upon a timber waggon not nearly so heavy or expensive as the timber waggons used in England, and drawn by three horses, the load seldom reaching the above weight. Our wood roads at home run anyhow, and the haulage is much more expensive. Six milch cows hauled two waggons like the above, and would be milked when they got home. Everywhere the work is done with marked economy, and, judging from the rate of wages

and other charges, I should say that German forestry is conducted at about one half the expense incurred here. Another point in favor of German management is the speedy conveyance of the timber on the spot. Factories are brought to the forest, and not the timber to the factory, as with us, involving expense that has to come off the price paid for the timber in the wood. Of course the German forests have created permanent industries that employ a large portion of the population. In some parts builders are carpenters more than masons, and many of the wooden dwellings of the better classes are models of comfort and seem to endure. The entire framework of many houses is of Spruce or Scotch Fir beams, many of them apparent of great age. After the wooden framework completed the filling in of the walls with plaster or brick does not seem to be a difficult affair. Some of the most famous castles in Germany—the Wartburg, for example, a palace inside, appears outside to be built principally of timber and red tiles. This is a beautiful place, but without any pretensions to fine law or gardening—no ornamental trees, no Hollie Rhododendrons, Yews, Laurels or other shrubs worth mentioning, only good approaches, rough park and dense forest up to the very windows of the mansion, but no remarkable trees. So far as I had time to look, my travels being almost confined to the forests, I thought German flower gardening poor, neither bedding-out nor hardy plants being remarkable. The woods are the gardens of Germany. For perfect order and good management they look more like ornamental woods than timber forests, and there are few or no fences, and the roads through the forests are also the highways, the public have full access to them and enjoy them greatly. Everybody, even the humblest, seems to understand the importance of maintaining the forest at a high standard and of undiminished extent. Forestry is quite a recognised institution of the first importance, and more than once apprehensions as to the state of the forests have nearly caused a panic amongst the public in the wooded regions of Germany. J. SIMONS.

*The Gardens, Wortley Hall.*

## FRUIT AND VEGETABLE CROP

### EASTERN.

**Opped Hall, Epping.**—The fruit crop the whole in this neighbourhood is very poor. Strawberries being an exception, also Peaches and Nectarines in this garden, but it is somewhat remarkable, with regard to them, that on an inner south wall all the trees are bearing very good crops, while on the outer (south) wall there are several trees with no fruit at all on them, a many of the sorts are the same on both walls; instance, Noblesse Peach, outside wall no fruit inside wall a good crop; Elruge Nectarine, outside no fruit, inside a good crop. All the trees were covered up the same in the spring. Apples are hardly half a crop, the best being Lady Early and Moorpark. Morello Cherries are a fair crop, but of other sorts the trees are too young to bear, and I have no other standard trees but Cherries here. I attribute the failure with Raspberries to the fearful ravages of the sparrow amongst the buds. Of Black Currants I had but half a crop. I have gathered a nice lot of Figs from outside trees, and still have a good show, the Brown Turkey being a little late. Plums are quite a failure on standard, bush wall trees, with one exception, and that is a small trained tree of Pershore Yellow planted last year against a north wall, the only tree here, but

all plant more, for it is a good cooking Plum, have never known it to fail either as a standard trained tree since first it came under my notice no twelve years ago. I have seen some good crops of Pears about here on standard, pyramid and wall trees, but mine are very poor, taking them as a whole. Raspberries showed well, but failed from the want of rain. Gooseberries were a fair crop, and would have been a heavy one if not for the blight taking the buds. I was very much troubled with mice eating the Strawberries this season, spoiling what would have been a very heavy crop, the late frosts doing very little harm. I think Apples must be looked upon as a failure about this part, for I have scarcely any, and other people are the same. There is now and then a tree with some on, but the fruit is very poor. Medlars, Mulberries andinces are not very good this season.—JAMES HIGBROCK.

**Coldham Hall, Bury St. Edmunds.**—The fruit crops in this neighbourhood cannot be described as good, Apples and Plums especially being very much below the average. Here cooking Apples are fairly good, but the choice dessert kinds are almost a total failure; the old Keswick Codlin and Dr. Harvey alone are bearing full crops. Plums on young standard trees are only about half a crop; on the walls none. Orleans and The Czar are the best. Strawberries have been good, the season longer than last year; but Raspberries, on the other hand, were quickly over. Gooseberries have been abundant and good, but the late varieties are ripe before the usual time. Young trees on espaliers have borne good crops and are making capital progress. Red Currants very short, Black a full crop of the fruit, and White about an average. We have very few Pears on espalier or standard trees, Jagonelle and other early varieties being quite few. In the earlier stages Peach and Nectarines outside were in a bad plight from blister, but they have outgrown it now and are carrying a heavy crop. Inside the trees have done remarkably well, the fruit fine and of good quality, the appearance of the trees being all that could be desired. Walnuts are very uneven, some trees being very heavily laden, while the crop on others is very thin. Cob Nuts and Filberts are carrying good crops.

Vegetables of all kinds have been, and are, abundant and good, but each season shows more and more plainly that stocks of seeds of all kinds are getting mixed and not saved with proper care. Onions raised under glass and planted out are a very good indeed. Early Peas were good, the season fair, and since the welcome rains the rows are looking well. Again Autocrat is exceptionally good and Chelsea Gem is very useful sown late in May. Lettuces have been a failure through the summer, one of the very best to stand drought being Sutton's Favourite. Turnips and root crops generally were very good early in the season, but felt the drought severely. Potatoes came in later than usual, but have been a capital crop in every case so far. The later quarter will need lifting to prevent second growth, but the rain came just in time for the latest field crops. Broccoli and other winter crops were suffering badly in July, but are now growing freely.—H. R. RICHARDS.

**The Abbey Gardens, Ramsey, Huntingdon.**—Here in North Hunts the fruit crops are far below average. Plums with a few exceptions are a failure; Apples half a crop; Pears the same. Strawberries are a heavy crop of good fruit. Fish fruits, such as Currants, Gooseberries, &c., are only half a crop. Walnuts are a failure. Vegetables have done extremely well with few exceptions, the following varieties of Peas being remarkable for their productiveness and high qualities: Veitch's Earliest Marrow, Prodigy, King, Gradus, Autocrat and Masterpiece. Potatoes are below average owing to late frosts.—F. W. SEABROOK.

**Donnington Castle, Peterborough.**—The fruit crops in this neighbourhood are far below

the average. We had an excellent show of bloom here, and in some cases a good set of fruit, but the continual cold winds in spring, with an occasional frost, proved too much for it. The only Apples that are carrying a fair crop are Kentish Fillbasket, Lord Suffield, and Alfriston, while among the Pears Glou Moreceau and Louise Bonne of Jersey are cropping fairly. Plums are quite out of the question, hardly any of the trees carrying a dozen fruits, excepting the Orleans. One tree of Morello Cherry on an east wall bore an excellent crop of fruit, while those on the north and west aspects are barren. Raspberries also have been almost a failure, while Strawberries have been above the average.

Vegetable crops generally are good. Early Peas did remarkably well, particularly a new one sent out by Dicksons, of Chester, called Dicksons' Harbinger.—ARTHUR G. GATLAND.

MIDLAND.

**Gopsall, Warwick.**—The outlook during the spring had every appearance of a fine crop of fruit, the blooms on everything being most prolific, especially Apples and Pears, but owing to the cold, cutting winds and severe frosts during April and May many kinds suffered badly. This is especially noticeable here with Apples, for, with the exception of the Codlin tribe, they are very thin, although in some of the neighbouring gardens and orchards I notice a full crop of most of the popular varieties, whereas in others almost adjoining there are but few. In our own case the orchard, which is situated a short distance from the fruit garden, is this year quite barren of fruit. Pears in the walled-in garden are plentiful with such varieties as Marie Louise, Louise Bonne of Jersey, Trout Pear, Easter Beurré, Glou Moreceau, and Beurré Bosc. Plums are a very thin crop, as are also Cherries and Apricots. Peaches and Nectarines are a fair crop, but much subject to parasites, and have taken a deal of labour to keep going. Of small fruits Black Currants are a light crop, also Raspberries. Gooseberries and Red Currants are average crops.

Vegetables, although very backward and slow in making a good start in the spring, have done well, the early crops being good, especially Dicksons' Harbinger Pea and Sutton's Excelsior Potatoes, small, but of good quality. The later kind of vegetables are showing the want of rain, such as Peas, Cauliflower, and Lettuce, ripening up and running to seed very quickly, and they can only be kept going by mulching and watering copiously.—J. LEE.

**Broomfield Hall Gardens, Derby.**—Some of the Apples are good this year; in fact, far better than last year. I have a crop of Mr. Gladstone, a good bearer with me on pyramid trees. Worcester Pearmain comes next, bearing good crops (does well here), and the following sorts are all bearing good crops: Pike's Pearmain, Domino, a good old sort for cooking, and in my own opinion hardier in bloom than any other sort; Russian, Lord Suffield, Potts' Seedling, Warner's King, New Northern Greening, nearly perfection in growth, bearing and quality; New Candwell, good bearer, tree a large grower, but I would like the fruit a little larger, and Blenheim Orange. I still like the old Eve Apple, which is a good bearer and full this year. New Bess Pool is a grand Apple, but rather poor bearer, the bloom easily killed by frost. Many of the Pears this year are fruitless. Doyenné d'Été on pyramids is good, but the standards are a failure. The following sorts are good this year on the pyramid: Louise Bonne of Jersey, Marie Louise d'Uccle (it is twenty-four years since I planted this sort and I have never known it to fail after it got established), Beurré d'Amanlis, Beurré d'Arenberg. Plums on standards are a failure, also on walls except Victoria. Gooseberries only moderate crop. Raspberries a failure. Black Currants none. Apricots a few. Red and White Currants good.

Spring Peas, that we have some years gathered at the end of May, this year were gathered in the second week in June, but on the whole they have cropped well. Early Potatoes were caught with frost and have turned out under average. Late Potatoes are suffering from the long dry weather and crops will be light. Onions good crops. Lettuce failed to heart from want of rain. Early Cauliflowers are moderate, late Cauliflowers looking well. Dwarf French Beans here are only moderate. Scarlet Runners are now doing better and will be good crops. Other vegetables looking well.—F. OLDHAM.

**Burghley Gardens, Stamford.**—In the early part of the season there was every sign of an average fruit crop, but owing to the easterly winds and late frosts it seems to have suffered more or less. Out of a great number of Apple trees here, Keswick Codlin, Lord Suffield, Grenadier, Schoolmaster, Golden Noble, Warner's King, Barnack Beauty, and several Pippins are carrying very good crops; whereas other kinds are totally bare. Pears on walls are fairly good, of which late kinds predominate. The most prolific are Beurré de Jonghe, Bergamote d'Espèren, Van Mons Leon Leclere, Winter Nelis, Easter Beurré, Uvedale's St. Germain, and Catillac. Morello Cherries are an average crop, very fine, and free from insect pests. Red Currants good both on walls and bushes. Black Currants scarcely any, and Gooseberries none at all. Outdoor Peach trees, although every effort was made to protect them, were blistered very much by the cold east winds so prevalent in May and June, which not only caused the blossom and the set fruits to fall off, but have very badly crippled the fruiting wood of the coming season; yet I may say that only a few varieties have suffered in this manner, the worst being Barrington, Late Admirable, Crimson Galande, and Princess of Wales; whereas there are several varieties in the same aspect which have entirely escaped being blistered; still these have lost the majority of their fruit.—A. METCALFE.

**Enville Gardens, Stourbridge.**—This is the worst year we have had here for about six years. Peaches outside fairly good. Nectarines fair. Apricots bad. Plums poor; some varieties are bearing nice crops. Rivers' Early average crop. Victoria very good, scarcely ever fails. Orleans very good. Kirke's very good. Jefferson's very good. Denniston's Superb good. Angelina Burdett good. Coe's Golden Drop under average. Apples are a bad lot generally, the following doing best: Lord Grosvenor, Golden Noble, Lord Suffield, King of the Pippins, Stirling Castle, Warner's King, Cellini, Ribston Pippin, Mère de Ménage. None of these are bearing an average crop, however. Pears are the best fruit crop here, the following being best: Williams' Bon Chrétien, Gratioli, Doyenné Grey, Louise Bonne of Jersey, Ne Plus Ultra, Glou Moreceau, Marie Louise, Hesse, Doyenné d'Été. Gooseberries very good. Currants (Red and Black) good. Raspberries good. Nuts (Cob and Filbert) heavy crops. No Walnuts grown. Hazel Nuts in woods and hedgerows immense crop.

All kinds of vegetables have done well here, Cauliflowers especially, but Peas have suffered a little from drought and midew. Potatoes (early kinds) fairly good crop and of very good quality, especially Puritan, which has been best of the early kinds. Second earlies are looking very well, but none lifted. All kinds of late ones are looking well, and promise a good yield.—G. H. GREEN.

**Eastwood Grange, Ashover, Chesterfield.**—In this district Apples and Pears are much below the average, and in many places a complete failure. Plums and Cherries are also very poor. There was an excellent show of bloom in the spring, but the late frosts and heavy wind proved very destructive. Gooseberries in these gardens are an enormous crop and of good quality. Currants a good crop, but small. Raspberries are a good crop, but deficient in flavour.

Vegetable crops of all kinds are good. Peas up to date have been exceptionally good and the late

varieties promise well. I find Criterion for the main crop one of the very best, both for quality and quantity combined, and it seems to withstand the hot weather better than many of the main-crop varieties. Cauliflowers have been good and promise well, the variety Veitch's Extra Early Forcing being particularly good from plants sown in February. I cut Cauliflowers of medium size the first week in June. Winter Brassicas promise well. Potatoes are a good crop, but small.—F. HARBROW.

**Barkby Hall, Leicester.**—Apples are variable, being good crops in places, but not quite an average crop on the whole. Pears the same. Plums are scarce in the open and on the wall trees, Victoria bearing the best. Peaches and Nectarines are not quite an average crop. Apricots good average crop. Cherries decidedly under the average. Gooseberries good full crop. Currants, Black, very scarce; Red, good crops. Strawberries good heavy crops. Nuts good full crops. Walnuts average. Raspberries fair average crop, but scarce in places.

Peas have been good, considering the dry weather, especially in trenched ground, also on heavy land. Dwarf Beans have been fair, but runners have dropped their blooms. Cauliflowers fairly good. Spring Cabbages were very late; I had some sown in May, 1896, that gave the best heads as spring Cabbage. Celery has run to seed far more than usual this year. Onions not quite a good average crop in this neighbourhood, rather small. Early Potatoes good crops, but rather under size; no disease at present.—J. LANSDALL.

**Castle Gardens, Warwick.**—Fruit on the whole is decidedly under average; the only varieties of Apples giving full crops with me are Ecklinville, Warner's King, and Stirling Castle. Cox's Pomona, which rarely fails in this district, was a very scanty crop. Speaking generally, Pears may be termed a failure; the exceptions are Beurré d'Amanhis (heavy crop), Glou Morceau (average), and Jargonelle (light, but clean and good). Plums very thin. Royal Hative, Pond's Seedling, and Goliath are the only varieties I have met with carrying full crops. Peaches, Nectarines, and Apricots much below average. Figs on walls good crops, ripening well. Morello Cherries average, good. Raspberries and Black Currants average, good. Red Currants and Gooseberries under. The latter, where grown as single cordons, are in many instances a heavy crop. This is a fact which cultivators should note and act upon. Strawberries a heavy crop of good quality. The season was, however, a short one, owing to the absence of rain. Filberts are a wonderfully heavy crop.

Vegetable crops are generally good where high culture is given, but in poor soil, where deep digging and liberal manuring are not practised the produce is, as a matter of course, inferior in quality and small in bulk. With me Carrots, Parsnips, and Beet never looked better. Onions are not quite so large as usual, but still a fine and even crop. Early Peas turned out well. Mid-season varieties were not so good, owing to the presence of drought just at the critical time. A continuous supply of Lettuce has been difficult to maintain. The copious rains received during the last few days came just in the nick of time to save large breadths of the Brassica family, and the prospect of a good supply during the coming winter is good. Potatoes are a good average crop, and but for the fact that the tubers are somewhat smaller than usual, the crop would have been a heavy one. A few days ago I noticed some diseased tubers among a crop of Early Puritan which was being lifted.—H. DENKIN.

**Hopton Hall, Wirksworth, Derbyshire.**—Apples, the principal fruit grown, are good crops, with fine fruit. Nonsuch, Irish Peach, Keswick, Lord Suffield, and Old Northern Greening are heavy crops, as are also Bramley's Seedling, Stirling Castle, Newton Wonder, Warner's King, Ecklinville, Cellini, Fearn's Pippin, Gascoigne's Scarlet Seedling, New Hawthornden, King of Pippins, Lord Grosvenor, Margil, New

Northern Greening, Potts' Seedling, and Worcester Pearmain; other varieties moderate crops. Plums very few; Victoria and Rivers' Early poor crop. Damsons are a failure in this district; one large tree in my garden at home on the west side has looked like a tree scorched all the summer—from the effects of frost. Cherries, May Duke good crop; Morellos half crop of last year. Gooseberries fine crops (though I hear of many failures higher up the Peak of Derbyshire); these are mostly on standard trees. Black Currants a failure; Red good; White excellent, still hanging. Raspberries very good, still gathering (August 17).

Vegetables are excellent this year. Potatoes are clear and good eating; not over large, but full crops. French and Scarlet Runner Beans are early and good. Peas excellent, just in full bearing now (August 17).—GEO. BOLAS.

**Enderby Hall, Leicester.**—Apples under average with the exception of Keswick Codlin, of which variety there is a good crop. Pears fair crop both of early and late kinds. Plums very bad. Apricots under the average. Gooseberries good. Red and Black Currants good. Raspberries fair crop. Strawberries very good. Walnuts and Filberts fair crops. The fruit crops suffered from the severe frost during April and May.—J. W. SIGEE.

**Henbury Park, Macclesfield.**—The Apple crops here and in this district are very thin; the only kinds carrying good crops are Mère de Ménage and Lord Grosvenor. Pears are a very light crop. Plums much under average. Damsons none. Cherries average crop and very fine fruit. Strawberries very good. Raspberries, Gooseberries, and Red Currants average crop. Black Currants none.

Vegetables are very good all round. I never saw them look better.—W. CHEESBROUGH.

#### WESTERN.

**Batsford Park, Moreton-in-Marsh.**—Fruit in this garden and neighbourhood, with very few exceptions, has not been so scarce for the past ten years, and in many instances the crop is a total failure. This may be the result of a combination of causes. Last autumn was very wet and sunless, after a hot, dry summer, and the wood had scarcely a chance of ripening properly; there was a prevalence of cold north-easterly winds in the spring, and several frosts occurred about the middle of May. Apples had a scarcity of blossoms, especially on orchard standards, and the crop is far below average, many large trees being without a fruit, including Blenheim Orange, which is extensively cultivated and does well when established. A few cooking varieties are better, including Keswick Codlin, Stirling Castle, Tower of Glamis, Warner's King and Cockpit, the first-named as a standard and the others garden pyramids. The best dessert Apples are very scarce. Very few Pears on trees in the open; on a south-west wall, Marie Louise, Josephine de Malines and Doyenné du Comice are bearing better. Peaches and Nectarines were badly blistered and the crop is very light, the best of the first-named being Dymond and Royal George, and of Nectarines, Elruge and Hardwicke Seedling. Nearly all of the trees lost their foliage, at least it had to be picked off, and some have not recovered sufficiently to be worth keeping. Apricots were under average for this garden, as they succeed well as a rule; but the quality was pronounced excellent, and the trees have made fine growth. Dessert Cherries were very good, and the trees kept fairly clean, while Morellos flowered splendidly, but nearly all the fruit dropped. We attributed it to frost when in flower, as these trees are generally to be relied upon for a good crop. All the best Plums, Gages of all sorts, &c., are very scarce; Victoria and Pond's Seedling are bearing much better and are most valuable this season. Strawberries were a heavy crop, though the quality on the whole was not considered so good as last year, and

the fruits were not so bright in colour as usual. They suffered a little from droug towards the end of the season, which was near the middle of July. Raspberries were plentiful though rather small, the weather being very hot and dry at the time of ripening. Gooseberries and Currants were much injured by birds taking the buds (even Black Currants do not escape) and there seems nothing to save them except netting all winter and spring, and this is not always a certainty. Dusting with lime and so is a preventive to a certain extent, but with heavy rains it soon washes off. In the cottage gardens bush fruits have been plentiful. The destruction of buds is not so serious here as in larger gardens, where there is comparatively less disturbance. Nuts of all kinds are plentiful.

Vegetables taken altogether have done very many things better than usual. Spring Cabbages were rather late, as the plants did not get away well in the autumn, although started at the usual time. Broccoli was plentiful and good. Early and successional sowings of Peas bore heavy crops, which matured rather too quick for all to be used, and the later ones have come on earlier than was intended. Asparagus was plentiful, but not so fine as in some years. Early Potatoes gave an excellent yield, and very good in quality; some planted for succession of the same varieties are partly diseased. Late ones have been looking very promising, but at the time of writing it is too early to judge of the crop. Magnum Bonum is still one of the most reliable for this locality. Beans have been doing well. Cauliflowers also, considering the hot season, roots are much better than at this time last year, and green winter vegetables have grown perhaps more than is desirable, especially Broccoli, which rarely stands the winter so well without being too sappy. Seakale growing on a slope in a field with late Potatoes for forcing seems to have been suited with hot sunshine, as it has rarely looked so strong. Lettuces have been good, and means of sowings made during the hot weather on a north border an unbroken supply has been maintained.—JOHN GARRETT.

## GARDEN FLORA.

### PLATE 1135.

#### OXALIS ENNEAPHYLLA.

(WITH A COLOURED PLATE.\*)

This is one of the most distinct and attractive of the many species of Oxalis known, but it has never attained to the position of a garden plant because until lately it has been practically beyond reach. It is a native of Fuegia and the Falkland Islands, being abundant in the latter where, according to Sir Joseph Hooker, it grows on banks overhanging the sea, covering them with a snow-like mantle of white flowers in the spring. It was introduced to Kew along with other plants brought in a Wardian case from the Falkland Islands in 1876 by H.M. Challenger, but, although kept alive ever since it has remained a *rara avis* until recently, as failed to ripen seeds or to afford any other means of multiplication. In 1895, however, Kew supplied a gardener, Mr. A. Linney, of Government House at the Falkland Islands, and he has since sent to Kew quantities of the and other plants of interest peculiar to the region, among the latter being the remarkable Senecio Smithii, a peculiar form of Lomara alpina, Sisyrinchium filifolium, and others. The Oxalis has done well in the rock garden at Kew being planted in a somewhat shaded and moist position against a stone; here it flowered free

WHITE CROWN GARDEN

June. Some 9-inch pans were also filled with it, and these were kept in a cool frame to be brought into the alpine house in spring; these were at their best in May.

The root-stock is ovate, tubercled, bulb-like, the largest 2 inches long; the leaves have short reddish petioles and a wheel-like whorl of from one to twenty leaflets, which are glaucous and rather fleshy; the flowers are borne singly on short stalks and are about 1½ inches in diameter, the sepals ciliate, the petals overlapping, pure white or tinged with lilac along the veins. The leaves all wither in the autumn and the plants rest to rest for the winter. If grown out of doors it would be advisable to cover it with a flannel or pane of glass to ward off excessive moisture and severe frost during the winter. Some notes on the best species of *Oxalis* for the garden will be found in *THE GARDEN* for May, 1890, plate 755, along with a picture of *O. Bowieana*. W. W.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**INTER TOMATOES.**—The plants should be well established in their fruiting pots by now, but move them to a light, airy house directly wet, hilly weather sets in. To leave them in the open after this there is a danger of the roots receiving too much water, growth being long-jointed and sappy, and what flowers do form will fail to set properly. A more sturdy growth will be secured if the plants can be placed where they receive plenty of light and air during the day with little artificial heat at night. Keep them to a single stem if possible, as there is a better chance of the fruit setting, and more plants can be arranged in a small house. Young, vigorous plants which are in full bearing should have all fruit that is larger than a marble removed if they are expected to keep bearing through the winter. This will relieve them for a time and cause fresh flower-trusses to form. Give a surface dressing of rich loam and bone-meal if the plants require assistance and thin out old leaves. As most of the winter fruiters will be destroyed in the spring, a batch of young plants should be in readiness to succeed them. These are obtained by sowing seed at the present time. It being desirable to keep such plants as sturdy as possible, sow the seed very thinly in pans filled with rather stiff loam, and only subject them to gentle warmth. When sown thickly in rich, loose soil and forced quickly, they seldom prove serviceable. They should be potted up when large enough and kept at the glass.

**TURNIPS.**—Winter crops should be thinned early, or there is a danger, when they are left in a crowded state, of the roots bulbing on the surface of the ground instead of being well covered with soil, which forms a great protection during the winter. Free thinning and frequent hoeing while the ground is in a dry state will help this crop very much. Hoeing should follow directly after the crop has been thinned, as this fills up the crevices in the soil and keeps the permanent roots firm.

**WINTER SPINACH.**—This crop should be treated in a similar way to allow each plant to stand just clear of its neighbour, so that the leaves may become strong and of good colour. When the plants remain in a crowded state the lower leaves turn yellow and they soon decay, especially after a fall of snow. It is not uncommon for this crop to become patchy, but the gaps may be filled up by transplanting, so long as the plants are lifted carefully while young and a nice portion of soil retained round the roots. A dull, showery day should be selected for doing the work, as the plants not only lift better, but there is less danger of them flagging. Young plantations should have one or two dressings of lime, soot, or fine ashes toward of the attacks of slugs, which are very fatal to the young foliage.

**CAULIFLOWERS.**—With the new early varieties which are now raised in heat in February autumn-raised plants are in many gardens dispensed with, but they still prove very acceptable as forming a succession. Walcheren is still about the best, and a sowing made now should furnish a nice batch of plants, which should be wintered under handlights or in cold frames. In cold, wet districts sow the seed in boxes, or it may fail to germinate and much time would be lost. Seed that is sown in the open should be coated with red lead, as it preserves it in wet soil, and also protects it from birds and slugs. Mould up late batches of Savoys, Broccoli, &c., as this is a protection against wind and frost. In very exposed positions it is a good plan to heel the plants over, covering most of the stem with soil, and by doing the work at once they become established again before hard weather sets in.

**CABBAGE.**—The planting of these will now be general, and the desired number should be got in with all speed. I have recently seen large breadths in a cold northern district, and I noticed such kinds as Ellam's Early were planted 1 foot apart each way. The planter found that by putting them close together they suffered less from the searching winds experienced in that district, and it is also a great saving of space.

**RADISHES.**—Make a sowing of these in shallow frames, as sowings made outside seldom prove successful after this unless it be in very favoured and warm gardens. Remove the lights on all favourable occasions, but replace them at night when heavy rains are expected. A sowing should also be made in a frame of Early Nantes or French Short Horn Carrots, the small tender roots being preferred to the longer ones for many purposes. Keep the seed bed well up to the glass and use rich sandy soil. Thin the seedlings out early, affording a good watering afterwards with tepid water. RICHARD PARKER.

### FRUIT HOUSES.

**MELONS.**—Plants set out during the past few weeks have had bad weather to contend with, but they have made good progress and will soon be ready for stopping. The plants being robust, will then produce plenty of fruit-bearing laterals, but as no one thinks of waiting to secure a heavy crop of fruit at this late season, it is always advisable to set the first pair of female blossoms which open together and swell them off quickly. As soon as this is discernible, rub out all the other shows and reduce lateral growth to safe limits, so that the whole energies of the plants will be confined to maintaining a fair amount of foliage in good health, and in the production of two fruits only. The plants should be urged forward by the application of a continuous and steady bottom heat of 85°, and fire-heat must also be requisitioned during the day, also when the weather is dull and cool; in fact, after this time of the year it can but seldom be dispensed with. Give every attention to watering, and although water in a cold state should never be applied to the roots of Melons, the fact that it should always be of the same temperature as that of the house cannot be too strongly emphasised now. Be careful not to wet the stems and the soil just immediately surrounding them, and syringe but once a day, and that only when bright and directly after closing for the day. Keep the roots active by giving them a little fresh compost to root into once a week, and warm it before laying it over the roots. As the autumn advances and nights get colder, it is a good plan to cover the roofs if there is any difficulty in maintaining a proper degree of heat, and this may be done at dusk. Plants on which the crops of fruit are in a more forward condition will need every attention if they have to be ready for cutting early in October. The utmost use should be made of sun-heat to advance the temperature during the forenoon, and early closing should be practised, varying the time according to locality. This, with the aid of fire-heat during the afternoon and night, will induce the fruits to swell rapidly, provided judicious applications of water and

mild stimulants are given whenever the condition of the soil about the roots demands it. Water, it need hardly be mentioned, is not required so often or in such large quantities as during the summer months, when moisture is evaporated so much more rapidly, and it is better to err in the direction of giving too little than too much when autumn sets in. Keeping the soil in a condition approaching saturation at this time of year is a fruitful source of canker, while it also causes full-grown fruits to split. The same care should be exercised with regard to syringing as mentioned above, and as the fruits approach maturity, dispense with it altogether. Should canker show itself either on the stems or any other part of the plants, immediately apply quicklime or powdered charcoal, and follow up these remedies until the moisture exuding from the diseased parts is dried up. Houses in which fruits are now ripening or are about to do so must have a free circulation of warm, dry air to ensure good finish and high flavour. Therefore as soon as colouring commences cease damping and syringing, and gradually withhold water at the roots. Maintain a dry atmosphere with the aid of fire-heat, keep up the bottom-heat until the last fruit is cut, while a little air at the top will materially assist in improving the flavour, and this may be kept on both day and night.

**FRAME MELONS.**—With a few exceptions these will be over for this season, and in those few instances the greatest care will be necessary to ripen up the fruits where linings alone are depended on for supplying warmth. No more water should be given at the roots than is absolutely necessary to keep the plants growing and the fruits swelling, and entirely dispense with syringing and damping. Little or no ventilation will be required except to change and sweeten the internal atmosphere until the fruits change colour, when a little will be needed during the day. If the temperature falls to a low point, mat the frames over nightly.

**CUCUMBERS.**—The young plants for winter work should at once be planted, if not already done, so that they may become established before autumn gets too far advanced. Like Melons, these will require plenty of heat to keep them in active growth, and damping and syringing must be made use of in a judicious manner. As canker is not to be feared, and no modification of treatment is necessary as regards the fruit when ready for use, a moister atmosphere may be maintained, but it should be varied according to climatic conditions. For instance, on dull days a damping of the floors and perhaps the surface of the beds will be ample, while on bright mornings damping may be freely done, and at closing time the foliage and beds may be thoroughly syringed with tepid water. The vapour troughs should be kept constantly filled and a steady bottom-heat maintained. Attend to stopping and training and get the trellis well covered with growth before allowing the plants to bear. Give the roots a little fresh compost every week, which will keep them in an active condition, and lead to young growths being freely produced. This compost should consist of fibrous loam torn into pieces about 2 inches square, a little charcoal broken up to the size of Walnuts, and a little bone-meal. Always apply it in a warm state. When stimulants are required nothing can equal real Peruvian guano for the winter-time, and enough may be used when necessary to just colour the water. Summer fruiting plants showing signs of exhaustion may be brought back into health again if a part of them is entirely relieved of fruits and rested for a few weeks, or if there are two houses of such plants, the one may be rested for a time, while the other is made to do extra duty by keeping up the supply, and rested in turn afterwards. In addition to cutting off the fruits, remove all the oldest leaves and thin out the most exhausted portions of the bine. Keep the house and the roots moderately dry for a few days, and where the plants show signs of breaking afresh, syringe them and water the roots with tepid water. Then remove any loose soil there may be over the roots,

and give a top-dressing of the above-mentioned compost with a little soot added. If the roots are healthy this will speedily have the effect of inducing the plants to make an abundance of new growths, with which the trellis should be covered before being allowed to bear again, and it will set them up for the winter. If these plants have been badly infested with red spider or thrips, syringe them once or twice with an insecticide after trimming them up. Autumn fruiting plants must have attention in the way of training in the young growths and stopping the same at two leaves beyond the fruits, but avoid both overcrowding and overcropping.

FRAME CUCUMBERS will soon be drawing to a close in the case of unheated frames and pits, and even where heated they are a source of trouble during such weather as that lately experienced, as they cannot be properly attended to. However, where it is necessary to keep them going as long as possible, in the absence of a Cucumber house proper, the linings should be frequently renovated to prevent the heat from declining in the first case, and the precaution taken to mat the frames over at night. In both cases give proper attention to stopping and keeping the bine thin and evenly distributed over the beds, and remove all fruits as soon as they are large enough for use. Discontinue damping and syringing and use but little water at the roots, though at the same time do not allow the soil to become so dry as to cause the leaves to flag. Air the frames and pits daily if possible to liberate moisture, otherwise mildew will attack the foliage, and the fruits, instead of growing to a useful size, will mould at the points and become useless.

A. W.

### THE GREAT DROUGHT OF 1896.\*

If the great frost of 1895 was the most notable feature of the year, certainly the great drought was the most notable feature of 1896, yet neither the frost of the one, nor the drought of the other, stood alone in the two years; they were preceded and followed by other conditions equally noteworthy, and it is the story of these conditions which will be the subject of my paper.

The twelve months that have past between December 1, 1895, and December 1, 1896, divide themselves into three well-marked periods; a very mild winter, a very dry spring and summer, and a very wet and cold autumn. It may be convenient to say something of each of these separately. The

#### MILD WINTER

comes first, and how very mild it was can be seen at once by this short record. Leaving out the previous Decembers, because they were almost alike, with seven days of slight frost in the one year, against six days of slight frost in the other, and confining ourselves to the three months of January, February and March, we find that there were in those three months of this year, twenty days in which the thermometer fell below 32°; in the same months of 1895 there were fifty-five such days; and this was not all; the frosts of 1895 were unusually severe, the frosts of 1896 were very slight. The thermometer in 1896 was seldom below 30°, and the lowest reading was 26° on February 3. The thermometer in 1895 was often below 20°, and was as low as 10° on February 8; and to put the matter shortly, the winter of 1895 was one of the coldest, and the winter of 1896 one of the mildest on record. Now, what were the results of this mild winter? They were very marked, and in some respects very unexpected. The most obvious result was that plants which had

been weakened by the cold weather of 1895, but not killed, and which had made a struggle for life during the summer and autumn of the year were largely helped in the struggle by the mild winter, and were able in spring to come on with their usual vigour. That was a real gain; and another gain was that many plants which were apparently quite killed by the winter, and put in no appearance at all during 1895, came up well in 1896, and so taught us a lesson of the extreme vitality of all vegetable life, and a lesson not to despair or be in too great a hurry to root up all that have been injured, but to be hopeful and patient. Among the plants that so reappeared in 1896, after having disappeared in 1895, I may mention these: the sweet-scented Verbena (Aloysia), Vitis striata, Allium giganteum, Bulbine annua, Hypericum coris, Behmeria nivea (the Himalayan Nettle), the Japanese Yam (Dioscorea Batatas), the Indigo (Indigofera Dosa), Azara microphylla and others. The mild winter also brought a very early flowering, especially of flowering shrubs, which was partly the cause of many shrubs flowering twice; this is a doubtful benefit, but a more certain one was that the plants were able to make good and healthy growth, which have had full time to mature, and so are better fitted to face the winter. On the other hand there was one result of the winter which was rather unexpected, and that was that some plants which were uninjured during the severe weather of 1895, were much injured, and in some cases killed during the mild winter of 1896. At first this was a surprise, but a very little thought soon gave the reason: the plants were not killed or injured by the mild winter, but by the severe weather of the previous October and November. You may remember that we had a great wave of heat in the latter part of September and the beginning of October, followed by an unusual wave of cold in the end of October and beginning of November; and it was these two combined that brought injury to many plants. The warm wave had unduly stimulated the plants in many cases into new growth, and in many more by arresting the natural decay or change that plants go through in the late autumn. Herbaceous plants prepare themselves for winter by gradually dying down, and preserving their life by underground life only; if the frost comes too soon, much of the nourishment which would have been carried down to support the underground life during the winter is lost, and the plant is so much the weaker, and so much the less able to resist cold. With shrubs the case is of course different, but the result is the same. In the normal state the leaves fall, leaving the buds for next year fairly protected by their own well-ripened coverings, "the plant has time to become a chrysalis slowly, in preparation for the winter" (Kerner), and the sap, or what botanists call "the water of imbibition," is gradually withdrawn to the roots, to remain there till it is wanted for the new life in the spring, and so the branches are said to be "ripened;" but if there comes an early frost, while the plant is still growing and full of life, the buds are injured, and, if not killed, they fail to produce flowers, and the sappy branches are easily frozen, and either die altogether, or are rendered quite useless for the next year's growth. I entirely put it down to the early frost of last October and November that my Japanese Persimmon (Diospyros Kaki), which had been quite uninjured by many previous winters, was cut to the ground last winter. Fatsia japonica also was more injured than I ever knew it before; my Palm had no flowers, the first time for six years past; Halesia hispida, though a very healthy tree and always

a free flowerer, had no flowers this year; and so with other plants. Before leaving the subject of the mildness of the winter, I should like to call your attention to one thing connected with it. You may remember that two years ago I quoted to you an observation of Sir Robert Christison, that when frost occurred on the last week of October or the first ten days of November, it was always followed by a mild open winter; this was certainly the case this last winter to a very remarkable degree, and I mention it again because I have been looking into the forecasts of other observers to see how far the same thing had been noted by others. Sir R. Christison was a thoroughly scientific man, a man who was content to make accurate observations and to record them; but not man to say that because A followed B, therefore A was caused by B. This was, and is still, the error of most weather prophets. They note in some years that a warm January has followed a cold October, and they prophesy for all time that a cold October is sure to bring a warm January; they argue from the particular to the universal, which is absurd. The error shows itself in the common belief that abundance of Holly berries is a sign of a hard winter to come. They are a proof that the previous seasons have been favourable to the formation of Holly flowers and berries, but they can tell us nothing of the weather to come. Yet though a mild winter is not a consequence of a previous cold October and November, it is a coincidence which may be well worth noting, and it is curious how universal has been the forecast of a mild winter from a cold beginning. The turning point in the weather of November has been from time immemorial fixed to St. Andrew's Day and St. Martin's Day, November 3rd and 11th; and no doubt that has arisen from the observation that fine warm weather so often comes, though for a very short time, at that time, making the "All Halloween" summer and the "St. Martin's summer, halcyon days," that Shakespeare notes. There are several of proverbs grounded upon this common observation, but I need only mention one or two.

"If there is ice in November that will be a duck, there'll be nothing after but sludge and muck."

"If it's fair, dry, and cold at Martinmas, th cold in winter will not last long."

"If the geese on St. Martin's Day stand on ice, they will walk in mud at Christmas."

There are many such proverbs used in many European countries; and without attaching much importance to them as universal rules, they are worth attending to and testing because they are the result of many years observations both of scientific and unscientific men; and looking again at Sir R. Christison's remark, limiting the time to be noted to the last week in October and the first of November, it is curious to notice how almost all weather prophets profess to attach great importance to such weeks. I have spoken at some length about the autumnal cold, followed by a mild winter, not only because last winter was such a marked example of it, but also because we have been passing through a cold Halloween and Martinmas of more than usual length, and it may be interesting to note whether the same result will follow this year, but I am afraid we must at present content ourselves with hoping only. But before I quite leave that part of my subject I must ask you not to suppose for a moment that I consider the mild winter of 1896 as the result of, or in any way caused by, the severe cold of November, 1895. The weather of any month we may be passing through is not caused by the weather of any preceding month

\* Paper read by Rev. Canon Ellacombe, M.A., before the members of the Bath Natural History and Antiquarian Field Club, December 9, 1896.

can it have any effect on the weather of any month to follow. The weather of each month is used by atmospheric and climatic conditions which may have existed hundreds of miles away. And, perhaps, many weeks or months that may have long passed; and it is only when the conditions draw near our globe, and our portion of the globe, that we are able to make a poor rather forecast of four and twenty hours, a forecast which, as we all know, is often far from the reality.

I have said quite enough about the mild winter, and it is time to come to the other marked feature of the year,

#### THE GREAT DROUGHT.

During January and February the rainfall was above the average, but during March it was below the average; and then from the first of April to the end of July the total rainfall was only 3½ inches, of which more than half fell on few days in June. Since that time we have had enough rain, especially in September and the first half of October, to bring the total rainfall of the year almost up to the average. We may say that for four months there was no rain; and what was the result in our gardens? We may put out of the question all the newly-planted shrubs and other plants; of course they would suffer more or less in such a drought and they needed for a good deal of labour and watering. At the point that most forcibly struck me was at with well-established plants the injury was very small indeed. My own garden has a rich deep soil, and so is able to contend against a long drought better, perhaps, than some others; and during the summer I visited many other gardens, and everywhere I met with the same surprise at the little amount of suffering that the plants had to bear, and I had not much difficulty in finding the explanation of this, which is so interesting that I must speak of it in some little length. The first factor in the inquiry is, I think, the good rainfall of March, by which the ground, which was by no means dry before March, got an ample supply; and owing to the mild weather the plants were sufficiently forward at once to take advantage of the supply. Now, you are probably all aware that water is of no use whatever to plants except at the roots, and plant life is full of all sorts of devices to gather in a good supply of water to the roots and to keep it there. Almost all the water that comes to the leaves of plants finds its way down to the roots by gravitation chiefly, but in no case through the leaves or the stems. The skin of the leaves of plants, and the rind or bark of their stems, are almost like the human skin, able to exude moisture, but in very few instances—some botanists say in none—can they imbibe water. Their function is to give out water, and there are many instances in which the water that has been drawn up from the roots is given out so largely by the leaves that it flows down again from the leaves to the roots, not, of course, the same way it came, but through the air, almost like rain. Familiar instances of this are found in our common Peazle and in the Alchemillas; but as the subject is not perhaps familiar to you all, and is very closely connected with the provisions made in Nature to provide against drought, I will venture to give you two or three well-marked examples. One of the best examples of the extreme provisions made to prevent access of water to the leaves or stems of plants it is to be found in the Bamboos; and any of you who know the common hardy Bamboos can test it. Not only is there a general provision of rings or hairs on the stems, which effectually prevent any lodgment of water that may come

from rain by throwing it off, but the leaves are so made that every provision is made to prevent the entrance of water and to facilitate its fall from the leaves to the roots. If you will take a leaf from the Bamboo and plunge it into water and hold it there, you will find on drawing it out, that the underside of the leaf is absolutely dry. Now Bamboos are great pumps; they consume much water, but instances are found where they absolutely weep and keep the ground beneath them quite moist. M. Carrière has noted this in Algiers, and in Gregory's account of the Great Rift Valley in Tropical Africa he tells of some thickets of gigantic Bamboos, whose "upper foliage interlocks into an impenetrable thatch, which is always sodden with moisture," and amongst them would grow nothing, "except Mosses, but in places the soil was covered with Iceland Moss (*Selaginella*) and the Maiden-hair Fern," and "a mist hung over the Bamboos and kept the vegetation sodden with moisture, and made the soil as saturated as a sponge."—"Great Rift Valley"—1—290. That is one way in which "the wilderness is made into a standing water and water-springs in a dry ground," and is an instance of the way in which thirsty plants can supply themselves with water in a dry, tropical country. I will give you another example from a very different climate. In the Death Valley of California the rainfall does not exceed 5 inches in the year, yet the district has really an abundant vegetation, chiefly, however, of low trees and shrubs, with Cacti and Yuccas. The problem is how this 5 inches can be made to answer for the support of the vegetation, and the problem is thus solved by Nature. The trees and shrubs are low and far spreading, and so the evaporation from the earth is reduced as much as possible; the roots spread to enormous distances, and so are able to suck up every particle of moisture; and the transpiration is reduced to a minimum partly by some leaves not transpiring at all, partly by the leaves being clothed with a thick, and in many cases a woolly epidermis, and partly by the leaves falling very early, and so stopping at once the leaf transpiration. This is a most curious example of the way in which difficulties are met in plant life; but really, we have in our own gardens many instances as curious, which were especially notable this year. There are many plants which we may fairly call Resurrection plants; plants which apparently die during a drought, but which come to life again at the first approach of rain. A very familiar instance is found in the pretty Fern that is so abundant in many parts of this district, though very rare in many parts of England—the *Ceterach officinarum*. As soon as the dry weather comes, and sometimes almost before it comes, the leaves shrivel up, showing only the under part of the fronds, and looking like so many shreds of brown paper; but on the first approach of rain the fronds go back into their proper position, they regain their full colour, and carry on their life as if they had had no check. To those of you who grow alpines, the pretty *Ramondia pyrenaica* will be almost as familiar, and in that, too, you will see the same power of resisting a long drought. After a week's drought the leaves will be shrivelled and brown and almost reduced to nothing; it will remain in that state for weeks, and then when the rain comes the leaves regain their colour and the plant is as happy as ever. In these two plants there is a mystery which I cannot explain. I can understand a plant losing its leaves by drought and then getting new leaves, but I cannot understand how leaves can lose all their colour and then regain it, as these two plants and many others are able to do, and

it seems as if plants had the power on the approach of danger to part with their chlorophyll not entirely, but to store it in a safe place, their roots, from whence they could draw it again when the circumstances were favourable. But there is another still more common instance, which I do not mention with these two, because I am not sure whether or not the result is produced in the same way. Many of you must have been distressed at the state of your lawns this year. My own having a deep soil stood the drought well for a few weeks, but the battle was too long, and at last it was almost the same colour as my gravel walks; yet before we had a week of rain it was a brilliant green, as green as the freshest growth of spring. I do not class this with the other Resurrection plants, because I think it likely that the fresh green arose from young leaves freshly grown, and not from the old leaves recovering their colour. But it was really marvellous how soon everything responded to the rain; the lawn was perhaps the most conspicuous example, but it extended in a very pleasant way to our fruits. I had a good crop of Peaches on the wall and a good crop of Apples, but both Peaches and Apples were very small, and the Peaches at first were dry and flavourless; but as soon as the rain came both Peaches and Apples became visibly and very rapidly plumper, and I had no cause to complain of their size or flavour. And, indeed, smallness, either of fruit or leaves, is one of the many provisions that Nature uses to prevent the bad effects of drought; and you will have noticed many such cases this year. With me the Willow-leaved Gentian (*G. asclepiadea*) grows very well, and is often more than a yard high; this year it was about half that size, and that meant about half the usual quantity of leaves, and that, again, meant that the plant had only to part with one-half the amount of moisture that it does part with when in full leaf. That shows why in a wet summer there is always an abundance of foliage; a greater quantity of leaves is required to carry off the moisture that the plant sucks up by its roots, and leaves are provided accordingly. The conclusion, then, at which I have arrived is very shortly this: that there was never a complete failure of moisture at the roots during the long drought, and that, in one way and another, Nature economised the store, and so the plants were saved. I might say more on the drought, but I must leave myself room to say something on

#### SOME OTHER ASPECTS OF THE YEAR.

I think the drought has confirmed what I said last year as to the value of rich suitable soil to enable plants to stand against frost. That statement was objected to by some of my friends, though I gave it on the high authority of Humboldt; but I am sure it is right, and this year's experience has taught me that plants cannot stand against either drought or frost unless they are strong and healthy, and that a good rich soil is the best way to make them so. I think my own garden is to some extent a proof of this; with its deep alluvial soil it gives many plants all that they ask for, but I saw it more fully proved in another, and far grander garden. I went in October with your vice-president to Abbotsbury, in Dorsetshire. Though I had often heard of the beauty of the garden, I had never seen it, and when I did see it I could scarcely believe my eyes. There were trees and shrubs, and other plants from Australia, New Zealand, the Cape, Mexico, Brazil, and other parts, not merely living, but flourishing as if they were in their native countries. Then came the puzzling question,

how do these plants grow at Abbotsbury with a luxuriance that is almost unknown north of the Riviera? The garden is near the sea, facing the south, with the low hills of the Chalk Downs behind sheltering it from the north, and is well sheltered by walls, fences, and other artificial protections; but this will not explain it. There are hundreds of places round our coasts as well situated for aspect and protection, but with no such gardens; and I have been driven to the conclusion that the secret must lie to some, perhaps to a great, extent, in the soil. As we walked to the garden from the village we passed a small roadside cutting, showing a section, which at once attracted the attention of my geological companion. It was a ferruginous oolitic brash, and I should have considered it as bad a material for a garden as could be found; yet the Abbotsbury garden is almost entirely on this. There is no doubt that iron in the soil is a great help to many plants; gardeners like it for their Hydrangeas, and in my own neighbourhood I have a good example of its value. I have never succeeded in growing the beautiful *Tropaeolum speciosum*, which in many parts, especially in the north, grows like a weed. I know of one place where it is even a troublesome weed; but I do not know of it growing well anywhere in this district, except at Iron Acton, where the soil is strongly charged with iron. Yet, I do not say that good soil by itself will enable plants to resist drought; it can only be a great help, and on whatever soil plants are growing, a long drought will test the skill of the gardener. Perhaps the skill, or no-skill of a gardener is shown in nothing more than in his way of watering his plants. Plants soon show when they are thirsty, and a good gardener will at once quench their thirst by a plentiful supply of water at the roots; the unskillful gardener loves to water the drooping foliage; it looks pretty and is of no use; and if he has a plant drooping by the side of a gravel path, he is rather surprised to be told that he had better soak the gravel path well than wet the foliage only. There is an advantage in watering leaves when they are choked with impurities, and in some places, as at Kew, where they have to contend with an atmosphere charged with blacks, constant and copious syringing is useful; but this is cleansing, and not watering, and is the same use to the plant that a good washing is to a dirty man, opening the pores by cleansing them of their choking impurities. Very shortly I will mention two other features of the garden this year. I attach a high value to the autumnal tints as one of the chief ornaments of the garden, and this year I had none. We are now told that it is wrong to speak of equinoctial gales, but this year we had very strong gales at the time of the autumnal equinox, with the unpleasant result that the trees were stripped bare long before their time, and so there were no leaves to be tinted. The only compensation that can be had for this loss is in the old weather forecast that if the leaves fall before Martinmas the winter will be mild. I hope this forecast may come true.

The year was not so remarkable for abundance of unusual fruits and seeds as I should have expected. The Catalpa, some Magnolias, and the *Koelerteria* fruited well, and I had fruit on *Enothera macrocarpa*\* and berries on *Solanum crispum* which I never saw before, but I did not notice many others out of the

\* The fruit of *Enothera macrocarpa* is most curious. From a central line spring four wings each about an inch wide, each wing being the pod containing the seeds. The length of the fruit is from 3 inches to 5 inches.

common; but the Hollies and the Hawthorns are beautifully set with berries, and the berries on the Privets were, this year, quite remarkable from their number and the intense depth of the black colour. I think, however, that the mild winter, dry summer, and wet autumn of this year will have a marked influence on the vegetation of next year. Fruit trees of all sorts are well set with fruit-buds; the spring-flowering shrubs, such as the Magnolias and *Calycanthus*, are full of promising flower-buds, and though all November was cold and had an unusual amount of frost, plants, even tender plants, seem to have been very little affected by it, which shows that they have made strong and healthy growth, and are well prepared for the cold when, and if, it comes. The animal life of the year requires a short notice. I do not know whether the mild winter was in any way the cause, but I think that the number of

time, and I believe it was a good honey year but there was a sad lack of moths and butterfly flies. I always consider that one of the most beautiful things in the garden in autumn is the swarm of peacock butterflies on the Michaelmas Daisies; this year there were scarcely any.

In my last paper, and in this, I have tried to show you what I feel myself that frost and drought are not the dreadful visitations that heartless gardeners make them out to be. More than that, I am sure, that though unpleasant while they last, they have their use and are as necessary as mild winters and plentiful fruitful rain in its season. We may, in fact feel quite sure that they are absolutely necessary; and though we may not understand how it should be so, they do fill their proper allotted parts in the grand scheme under which we live the scheme that has for its great object the well-being of all organic life.

A group of white Phloxes.

our immigrant birds was much below the average. I noticed this especially with the swallows and redstarts. Of redstarts we had very few, though we generally have them in abundance; we had a great many swifts, but the swallows are certainly few in number and arrived very late. I did not see one in my garden till the last week in April. But this may have been a purely local occurrence, for the number of swallows in the autumn was as large as usual. Of course, there are always more in autumn from the accession of young birds, but the great addition must have been from the southward rush, which always swells the numbers in our southern counties, and the full number that we had in the autumn probably shows that in other parts the number was not below the average. Wasps were rather plentiful for a short time, but it was a very short

is also directed, they are scarcely so well suited as when packed after being cut many of the flowers fall. For home decoration these Phloxes are invaluable, either in beds or for furnishing bold spikes of flowers as occasion require. Years ago, however, these Phloxes were exhibited each summer by the late Mr. Robert Parker, and cut with long stems, *i.e.*, about 2 feet long, and about three trusses of each variety; the display was very imposing. In Mr. Parker's case, however, little packing was needed, and the large handsome panicles of bloom suffered but little. The system adopted was very simple, though effectual, and was as follows: Some 6-inch or 7-inch pots were rendered watertight and afterwards nearly filled with quite wet silver sand. Three large spikes with all the lateral branches intact were thrust into the sand, the latter gently watered

## FLOWERS OF THE GARDEN.

### HERBACEOUS PHLOXES

THERE is a great deal of truth in the remarks of "A. D." at p. 1 concerning the neglect attending Phloxes. In the majority of instances even where the highly decorative border flowers are found at all, they are to be seen very much in the background, scrambling for an existence with a forest of young sucker growth from such things as Lilacs and other things that have for years run wild. Another place equally unfitted to the well-being of these showy subjects is the neighbourhood of trees that both by root and branch tend to rob the ground of the very moisture the Phlox need when in the season of growth. I have repeatedly seen them in both positions in several of the London parks and gardens. Even supposing it were impossible to set aside a few beds on the grass for these plants where they may receive special treatment, it would still be an easy matter to arrange a series of large groups in the border at intervals, either in a mixture of the best kinds or these latter employed separately. In either case they would surely prove interesting and attractive. To show flowers, to which attention

and all was ready for placing in a light spring run. In this way the exhibits were conveyed to their destination, where they invariably arrived little or no worse. In much the same way did Mr. Parker exhibit a large number of early things flowering in the autumn, and generally most successful. Flower-pots, too, of the sizes named are infinitely superior to the small, narrow-necked bottles so much in vogue to-day and so ill-suited to a good representative bunch of many good hardy flowers. Such pots are easily made watertight with a plug of cement in the hole at bottom. It was in this simple manner, by the utter exclusion of wooden boxes for packing everything for exhibition, that Mr. Parker reserved so much freshness in his exhibits of autumn flowers. Seen in this way there is no need for either Fern or Asparagus to assist the display, for the foliage of the Phlox, when properly grown, is abundant for all purposes. Such exhibits of Phloxes were made each year and attracted a good deal of attention, and, moreover, by the general system of culture as then obtained good trusses were always forthcoming. I cannot agree with "A. D." that "No plant could be allowed to stand untouched more than two years from the cutting"; for to pull up a plant to pieces at this time of the year is virtually to destroy the plant at the very time it has become established and capable of creating a show. Furthermore, I have cut some of the best heads of these Phloxes from plants twice the age, and the advice to frequently pull such plants to pieces is often attended with very poor results. Possibly "A. D." will explain the need for such frequent renewal. Provided a start made now with a fresh young plant, preferably from the open ground with single stem, that next year hence will produce three or four moderate heads of bloom. A year later the same plant will easily carry twelve much better heads, and in the third flowering the same plant will produce fully double the number, and very large and handsome into the bargain. This is not an imaginary ideal, for it may be accomplished by any good gardener who will take a little ordinary care in preparing and enriching the soil, early discarding the growths not required, providing an open position, and so arranging that the beds containing them may be deluged once a week at least with liquid manure and once with water. It was no unusual occurrence with Mr. Parker to exhibit fine heads of Phloxes from stools that must have been five or six years old; but then the Tooting Phloxes were in close proximity to some huge tanks of water, and of this they had their fill. On the other hand, there may be those who cannot command such a supply as the above, or even the quality. These must compensate as much as possible with rich as well as deep soil, mulchings equally rich, and occasional soakings with moisture. In all these respects it is possible to err, and when the gardener will advise these facts, and act up to them, the herculean Phlox may be made one of the finest ornaments of the garden.

The heights given at page 189, if accepted as they stand, will prove misleading, because no Phlox, whether a spring cutting of this year or a divided plant of the previous autumn, can possibly attain maturity in a single season. I have here a bed of a splendid white kind, planted six years ago, and this season scores of inches have been taken from it, and, in spite of age and heat and drought, the plants have reached about 4 feet high and carried beautiful foliage to the soil. Cuttings of the same kind in their first year are rarely more than 20 inches or 2 feet high; the year following the same plants will be 3 feet, and just so those men-

tioned at page 189. All will increase in height with age. The variety which in a season reaches 20 inches to 30 inches will attain fully 5 feet in its third or fourth year, and, if "intelligently grown," produce very handsome heads of flowers, that would put to shame many of the scraps shown at the Drill Hall. It is want of culture and the non-attendance to small details of annual mulching and early thinning of shoots that cause these plants to look unsightly. If some hardy-plant specialist during the present month were to plant two or three dozen in as many oak tubs (paraffin casks cut in two are best), and make a feature of the same, these plants could be exhibited in the year 1899, with an average of a dozen trusses each, that may cause a sensation to be remembered; and while this can be accomplished in such a time, why need the hardy-plant nurseryman be content with bringing poor, often very wretched examples of such a beautiful class of hardy flowers? Such examples would require neither Asparagus nor Fern to show them off, and I only regret my limited space prevents me taking the thing earnestly in hand. There is no better time than September for planting Phloxes, a fact that renders the subject quite opportune at the moment. E. JENKINS.

Hampton Hill.

**Lilium Henryi.**—This is often referred to as an orange-coloured *L. speciosum*, but, apart from any other consideration, the bulbs are very widely removed therefrom, as those of *L. Henryi* are far more like those of the Burmese *L. nepalense* and *L. sulphureum* than they are those of *L. speciosum*. Again, while the individual blooms are quite of the *speciosum* stamp, the general aspect of the plant reminds one of *L. tigrinum*.—H. P.

**Montbretias.**—These charming flowers are gradually working their way into public favour and being estimated at their true value, so I think it is worth noting that they are capital "shade" plants, and although the growth under such circumstances is not quite so strong, the flowers are produced with equal freedom, and, as they are later, the season is naturally prolonged. I planted a batch early last autumn in a portion of a hardy Azalea bed, over which there is a dense growth of Deodar Cedar, and have been very pleased to note the satisfactory results. Are the newer varieties of *crocosmiiflora* as vigorous as the type? Spikes of the latter from strong corms replanted last autumn are now 3½ feet in height.—E. BURRELL.

**Lilium speciosum.**—The different varieties of this fine species are among the best late-flowering Lilies for planting outside in exposed gardens and other places, where they have to take care of themselves to a certain extent. Two years ago I planted some scores of bulbs of it in variety with no special preparation of the soil, just a little light compost being placed around the bulbs, as the soil is heavy and at this time of year very retentive of moisture. In every case these are now fine clumps, many of them sending up four and five spikes, while the bulbs of *L. auratum* have almost vanished. No doubt the latter fine Lily requires special and careful preparation of the soil. As a really hardy plant to take its chance with the other occupants of the herbaceous border it is a failure. Among varieties, the pure white *Kratzeri* is one of the best, and there are one or two other fine white forms more or less distinct. *Melpomene* is one of the very best dark forms and a distinct advance on the better-known *L. speciosum roseum*.—H. R.

**Begonias outdoors.**—After a careful inspection of the splendid show of outdoor Begonias at Cowdray, I came to the conclusion that where the same amount of skill and attention can be bestowed they rank unmistakably among the best of summer flowers, and the result is obtained in this case mainly from seedling plants and home-

saved seed. Although Mr. Geeson has long been known as the raiser of doubles of all shades, some remarkable for their size and others for their perfect shape, it is only very recently that he has been able to unite to the perfection in shape a strong flower stem and a stiff neck, that keep the flower erect. Naturally, size of flower has to be sacrificed to a certain extent, but this is certainly no loss, for, given a fair-sized flower, holding itself well erect, quite first-class in shape and of pleasing colour, one has, I fancy, the *beau idéal* of an outdoor Begonia. I came upon a batch of some 2000 seedlings just after a heavy storm, and the flowers looked none the worse for the deluge they had experienced. They were in all shades, from white, primrose, yellow, through pink and scarlet, to deep crimson, and the habit was nearly as varied, some making large bushes and others having a smooth leaf and a close, compact habit that reminded one of some of the Saxifrages. In the flower garden many beds were filled with types that had been selected from previous years' seedlings, planted thinly on carpets of *Mesembryanthemum* or *Veronica incana*, or mixed with *Dactylis glomerata*. The fact that all this grand show of doubles was the result of home-saved seed made the display all the more worthy of notice, as any gardener can testify who has made the saving of seed from these flowers a speciality. I noticed a strain of double white that was both very free and vigorous, just the sort of plant to be put out thinly on a carpet of dwarf *Ageratum*.—E. BURRELL.

#### BORDER CARNATIONS.

In Mr. Woodall's very interesting paper on this subject in your issue of September 4 there is little to which exception can be taken from his point of view, gained by the experience of his lovely garden at Scarborough. Here, however, matters are somewhat different; all my Carnations have been out of bloom for three weeks at least, but though they do not continue so late in bloom, they begin earlier. Your correspondent says "that no flower has been so killed by kindness." This, I hope, I may be permitted to dispute. Does he mean to say that the list of beautiful varieties, the names of which he gives, is not a great improvement on those grown a dozen years ago? The efforts of Mr. Martin R. Smith have, I maintain, greatly improved the standard of these lovely flowers, and buying, as I always do, most of the new varieties as they come out, I have never as yet found any of them "dearly bought novelties"—those at least that have emanated from that quarter. I do not propose to argue the advisability or otherwise of having a proper standard or what a good Carnation should be. I presume there is some good reason for the fact that a smooth flat petal is considered desirable, that a clear white or yellow ground should be a *sine qua non* in the matter of Picotees, and that the stem should as far as practicable be strong enough to support the bloom and not flop about all over the place. From the purchaser's point of view, it may be a good plan to leave his plants for three years in the same place, but I maintain that he will not have such good blooms on his two or three-year-old plants as he would on those that are layered annually.

Now as to varieties. Mrs. Gifford is the only one that I do not know and have not grown in large quantities. The statement that Mrs. Sydenham (Mrs. Robt. Sydenham) "is quite worthless as a border plant" is, according to my experience, quite incorrect. I have had this plant growing in my garden from the first, when Mr. Sydenham purchased the original stock from Mr. Douglas (the raiser), and of all the Picotees or Carnations I have grown, I never found any variety grow so strongly or flower more freely in the open border. It is annually greatly admired by visitors who come to see my Carnations when in bloom. Your correspondent says neither *Corunna* nor Miss Audrey Campbell are "improvements in any way." As far as *Corunna* is concerned, I admit I am somewhat of his opinion,

but Miss Audrey Campbell is a totally distinct variety, a splendid border Carnation, and one that will please amateurs. That it pleases professionals as well is proved by the great use that was made of it both at the National Carnation and Picotee Society's show at the Botanic Gardens in July last and at the Midland show in August at Birmingham. As to fanciers, I should take up too much of your space if I were to go into this question; but there is one which I am rather surprised your correspondent did not mention, and that is President Carnot (Douglas). Of this flower I am particularly fond; if he has not got it I should advise him to get it.

H. W. WEGUELIN.

*St. Mary Church, Torquay.*

#### THE CULTURE OF CALOCHORTI.

I SHOULD like to add a few remarks to Mr. Purdy's very interesting letter in a recent issue on the above subject, especially in reference to the disease or mildew which he mentions as attacking certain species. It generally makes its appearance with me in *C. Nuttalli* just when this species is about to open its flowers, and speedily wrecks the plant, so that I only save about 10 per cent. of the flowers.

It has been confined with me entirely to the desert species, *C. Nuttalli*, *C. Palmeri*, *C. flexuosus*, *C. macrocarpus*, and *C. Kennedyi*. This last, planted by itself 100 yards away from the others, was affected just in the same way. *C. Gunisoni*, though classed by Mr. Purdy as subject to disease, has been quite free from it with me the last two years, but I fancy my bulbs have come from a different locality of late. He also includes *C. splendens* and *C. splendens atroviolaceus* as partially subject to the attack, but I have never noticed it on either of them in any year, nor on *C. Lyoni*, which is particularly vigorous and free.

There is, however, one point of congratulation about this disease, that the kinds that are attacked by it, though beautiful, are not the most so by a long way. The lovely *venustus* and *Eldorado* groups are quite free, also the *Cyclobothras* and *Star Tulips*. One would like to know more about the disease. I have tried several remedies, but they apparently make no difference, and it is very strange that it confines itself to the desert species and never spreads to the others, though planted side by side. I have not found so far that it affects the bulbs, as they always turn up larger than when planted. I have lifted immense bulbs of *C. Kennedyi* of which the flower-spikes have gone off just before opening. All the *Calochorti* make good bulbs and larger than when planted. This is due, I believe, to cutting the flowers and not letting them seed. It cannot be too often repeated that to grow *Calochorti* successfully you must give them the necessary soil and situation, and the principal factor of all, thorough drainage. Even this is easily obtained on a clay soil by means of a raised bed and a mixture of a light porous material. I do not think there is any garden where a small spot could not be made to suit their requirements, which have so often been mentioned in these columns. R. W. WALLACE.

*Co'chester.*

**Erodium chrysanthum and Stachys chrysantha.**—Two exceptionally charming alpine plants are in flower here now, viz., *Erodium chrysanthum* and *Stachys chrysantha*. I raised them this spring from seeds collected last year in the high mountains of the Southern Peloponnese, so their complete hardiness has yet to be tested. In each the colour is a delicate lemon-yellow, and in the *Erodium* it is set off by most attractive foliage. The sight I once had of a plant of the *Erodium* in Herr Froebel's nursery at Zurich loaded with flowers is a thing I shall not readily forget.—A. K. BILLEY, *West Kirby.*

**Acers in flower garden.**—Silver-leaved Acers are now much used in flower gardens, and with very good effect too. In large beds three or four nice-sized dwarf bushes break the monotony and blend well with such things as scarlet Geraniums,

yellow *Calceolarias*, *Petunias*, and the like. They may either be planted permanently, being kept judiciously trimmed in each season, or grown in large-sized pots, and each year plunged in the beds in June. One *Acer* in the centre of smaller round beds suits well, and in corner beds the plants trained in standard form and planted beneath with *Lobelia cardinalis* on a groundwork of blue Tufted Pansies produces a very good effect. Flower gardens frequently are far too flat and formal, and anything of the above character used sparingly helps to give grace and beauty.—C. C. H.

**Clematis Vitalba.**—Few plants are more beautiful during the late summer and autumn

wall. For many years this plant must have held possession, for it was yards away from the wall in places, and the long pendent shoots in every direction were full of the characteristic corymb of flower, which scented the whole garden. Such a plant is extremely beautiful, and would be much more often seen but for the shearing, clipping and clearing-up propensities of many who take charge of such gardens.—R.

## TREES AND SHRUBS.

### MYRTLES IN TUBS.

THE accompanying illustration represents one of five specimen Myrtles which we have here in tubs. They are the finest plant of the kind I ever saw. I have therefore sent you their dimensions, which are as follows: Height, 10 feet from the bottom of the tubs diameter, 4 feet, and each specimen is the exact counterpart of the one represented in the illustration. The plants are placed outdoors for the embellishment of the grounds during the summer months. I consider them far better for the purpose than such things as *Bays*, *Laurustinus*, *Portuguese Laurel*, &c. They require to be housed during winter but Myrtles are worth the attention more than many subjects which find shelter during the winter months in cold greenhouses. A few degrees of frost, however, will not harm them. You should be interested to know where finer plants in tubs or pots can be seen.

J. EASTER.

*Nostell Priory Gardens,  
Wakefield.*

*Myrtle in a tub. From a photograph sent by Mr. J. Easter, Nostell Priory, Wakefield.*

months than our indigenous *Clematis* or *White Vine*. In moist places in almost every county it follows the beautiful wild *Spiraeas* in hedgerows and banks, rambling through and over the thickest hedges, and making a feature for months after the flowers have faded by the feathery seed-vessels. It should be more freely planted in connection with semi-wild gardening, and even in the garden proper it does not look out of place. In a fine old garden in Gloucestershire, well known for the grand old specimens of herbaceous and other plants therein contained, I noted it a week or two since growing quite loosely and naturally over a wide arch in the kitchen garden

little additional warmth. The flowers are arranged in a totally different manner from those of the well-known *E. Crista-galli*, forming as they do a dense cluster on the upper portion of a tall raceme, which stands quite clear of the foliage. Probably the reason that it is so seldom seen is that it cannot be grown as a bush however it may be stopped and tied about; but its natural habit is to form a tall rugged stem, branching out at a height of 6 feet or so, and the lower portion is altogether bare of foliage, the leaves being confined to the points of the shoots. Any appearance of nakedness may, however, be readily prevented by associating this *Erythrina* with other subjects.

clusters of leaves on the points of the shoots are admirably adapted to a setting to the brilliantly coloured blossoms.—T.

**The Venetian Sumach** (*Rhus Cotinus*).—This shrub, also known as the Smoke Plant, is at present very beautiful, the rosy purple feathered clusters with which its shoots are smothered being most effective. The great recommendation is the lasting qualities of its display, which continues attractive for nearly two months.

**SOCIETIES AND EXHIBITIONS.**

**NATIONAL DAHLIA SOCIETY.**

CRYSTAL PALACE, SEPTEMBER 3 AND 4.

It is not too much to say that the introduction of the Cactus Dahlia saved the large show and fancy exhibition from extinction as exhibition flowers. The Dahlia had been a prominent exhibition flower for many years, but these who take an interest in it are tired somewhat of it. The Dahlia Society had declined, and the demand for varieties was restricted. Then came the Cactus type in the form of Juarez, and with it the single scarlet Cecinea. The advent of these brought something which at once hit the popular taste, and from that moment a revival of interest in the Dahlia commenced. One or two old species or varieties of the single Dahlia also appeared. These were seeded from. Many new varieties were raised, and for a time this type had an unusual run of popularity. But their fleeting character told against them, and they are now but little grown as compared with their popularity ten years ago. Meanwhile, the pretty, small, symmetrical pompon varieties—one of the most useful sections grown, either for cutting or garden decoration—were being recognised, and since then a great many new varieties have been raised. The habit of growth has been reduced and rendered more compact. The improved varieties are wonderfully free flowering, and better suited than any other section of Dahlias for garden decoration. But the Cactus type has advanced by leaps and bounds. The decorative varieties, so called, are rapidly disappearing, and the new forms of Cactus taking their places, and though at the outset some attempts at crossing with the decorative varieties were necessary, in order to obtain new tints of colour, the peculiar form of Juarez has not only been retained, but rendered more refined. Quite unexpected tints of colour and peculiarities of form, as seen in the new spire-like varieties Fantasy and Arachne, have appeared. A wealth of new Cactus varieties has appeared this season, many of exceeding beauty and symmetry. An improvement in the habit of growth is now necessary; it needs to be reduced, to be rendered more compact; greater free flowering is indispensable, and the flowers thrown on erect stems well above the foliage. In some of the newer varieties these desirable characteristics are being developed, and they will be further extended in the next few years.

This was one of the most extensive exhibitions, perhaps, yet held by the National Dahlia Society, and on some respects one of the best, especially in the class for Cactus varieties. There were five collections of eighteen bunches, each bunch having six blooms, and there were four collections of two varieties, also with six blooms in a bunch. This made a most imposing bank of rich blossoms and attracted considerable attention. Despite the stormy weather, the blooms were generally fresh and unstained. The same may be said of the pompon varieties, which were shown in bunches of ten and six blooms, and highly delightful in many of them were—small, symmetrical, and gay in tint.

**SHOW AND FANCY DAHLIAS.**

The objections made to the present method of exhibiting the show and fancy Dahlias are always heard at exhibitions, but nothing yet attempted has answered in the way of change. If the lines of flowers are formal, yet the whole of the bloom can be seen, and it is possible to make the stands

quite attractive by an intermingling of contrasting colours. The largest collection was for sixty varieties, show and fancy distinct, and the admission of the fancy varieties helps the attractiveness of a large number of blooms. Messrs. Keynes, Williams and Co., nurserymen, Salisbury, took the first prize with a fine, bright, even lot of flowers, among them the following dark and crimson selfs: William Rawlings, Nubian, Willie Keith, Arthur Rawlings, Thomas Hobbs, and Duke of Fife. Of tipped flowers there were Miss Barker, J. T. West, Mrs. Saunders (a charming fancy yellow, each petal distinctly tipped with white), Mrs. P. Wyndham, and Henry Walton. Of pretty light varieties there were Virginal, Mrs. Gladstone, and Mrs. Slack. Of yellow selfs, William Powell, R. T. Rawlings, John Hickling, and J. N. Keynes. Mr. Charles Turner, Royal Nursery, Slough, was a good second, some of the blooms showing the effects of the weather; and Mr. John Walker, Thame, third. Mr. Walker came in first with forty-eight blooms; he had well-finished examples of John Standish, Willie Garratt, Victor, Shirley Hibberd, Duke of Fife, Mrs. Langtry, Harry Turner, Miss Cannell, R. T. Rawlings, Glowworm and J. T. West. Mr. C. Turner was second, having a few specially good blooms in Mrs. Saunders, George Gerdon, Rosamond, Prince Bismarck, Mrs. Langtry, Matthew Campbell and Shottesham Hero. Mr. S. Mortimer, Farnham, was third. Then came thirty-six varieties, and here Mr. G. Humphries, nurseryman, Chippenham, was first. His finest flowers were Duke of Fife, Harry Turner, Miss Cannell, J. T. West, Mrs. G. Rawlings, William Rawlings and William Powell. Mr. J. T. West, Cornwallis, Brentwood, was second, and Mr. J. Stredwick, St. Leonards, third. Mr. Humphries was also first with twenty-four varieties, and Mr. West second. The best twelve blooms came from Mr. J. R. Tranter, Henley-on-Thames; Mr. A. Rawlings, Romford, was second.

The amateur growers also had certain classes for show and fancy Dahlias. There were ten competitors with twenty-four varieties. Mr. T. Hobbs, Lower Easton, Bristol, was first, and as his flowers were particularly good we name a few of them, viz., Duchess of York, Vice-President, John Hickling, Matthew Campbell, Imperial, Mrs. Gladstone, Mrs. W. Slack, Thomas Hobbs, Muriel Hobbs (new), and Prince of Denmark. Mr. A. Starling, Havering, Romford, was second, and Mr. T. Anstiss, Brill, third. Mr. S. Cooper, Chippenham, had the best twelve; Mr. W. Mist, Ightham, Sevenoaks, was second. Mr. C. F. Keep, Streatham, had the best six, Mr. G. Wyatt, Twickenham, being second.

Then came two classes for fancy Dahlias only, Mr. S. Cooper having the best twelve varieties, his leading blooms being Frank Pearce, Mrs. John Downie, Mr. Saunders, Matthew Campbell and Lottie Eckford; Mr. R. Burgin was second. Mr. A. Starling had the best six blooms of fancies, very good indeed; they were Rev. J. B. M. Camm, S. Mortimer, Peacock, Duchess of Albany, S. Cooper and Dazzler. Mr. E. Jefferies, Langley Burrell, was second.

There were also classes for Dahlias in colours. The best dark Dahlias were Prince of Denmark, Shirley Hibberd, and W. Rawlings; the best light, Mrs. Gladstone, each of the three prize-winners having this variety. The best yellow selfs were John Hickling, J. N. Keynes, and R. T. Rawlings; the best reds, Mrs. J. Downie in a self form, John Standish, and Arthur Rawlings. The best white self was John Walker. The best tipped Dahlia was Mrs. Saunders; the best striped, Mrs. J. Downie; the best edged, Miss Cannell and J. T. West.

**CACTUS DAHLIAS.**

The best eighteen blooms of Cactus Dahlias, six in a bunch, came from Messrs. J. Burrell and Co., Cambridge, very bright, fresh, and even, and a good representative collection. They were Palka (new), Mrs. A. Beck, Mrs. W. Noble, Lady Penzance, Gloriosa, Delicata, Fantasy, Fusilier, Matchless, Mrs. K. Foster, Starfish, Cinderella, and Regulus (new). Messrs. Keynes and Co.

were second, having some very fine varieties, such as Keynes' White, which promises to be a serviceable sort; Starfish, one of the very best; Lady Penzance, Cycle, Delicata, and the following fine new varieties: Ruby, Arachne, Alfred Vasey, and May Service. Messrs. J. Cheal and Sons were third. Mr. J. T. West had the best twelve bunches, among them a beautiful pale mauve seedling named Island Queen. Mr. G. Humphries was second, also with an excellent stand. The best twelve decorative varieties came from Mr. M. V. Seale, Sevenoaks. Messrs. J. Cheal and Sons were second.

In the amateurs' division, Mr. W. Mist had the twelve best Cactus, showing in fine character Starfish, Mrs. Wilson Noble, Mrs. A. Beck, Miss A. Nightingale, Matchless, and Gloriosa. Mr. E. Brown, Harley, was second. Mr. E. Mawley, Berkhamsted, had the best six varieties, and Mr. C. E. Wilkins, Swanley Junction, was second. The best nine Cactus competing for the special prizes offered by Messrs. J. Cheal and Sons came from Mr. C. E. Wilkins, the leading varieties being Mrs. Wilson Noble, Lady Penzance, Fusilier, and Charles Woodbridge. Mr. H. A. Needs, Horsell, was second.

**POMPON DAHLIAS.**

The best twenty-four varieties, ten blooms in a bunch, were staged by Messrs. Keynes and Co., and comprised many of the leading varieties; Messrs. J. Cheal and Sons were second, and Mr. C. Turner third. Messrs. J. Burrell and Co. had the best twelve bunches, all very good. The leading sorts were Emily Hopkins, Eurydice, Distinction, Bacchus, Nerissa, E. F. Jungker, Douglas, and Geo. Brinckman, a good white, but rather large. Mr. J. T. West was second, and he had, differing from the foregoing, Captain Beyton, Donovan, Little Dorrit, and Tommy Keith. In the amateurs' division for six varieties, Mr. W. C. Pagram, Weybridge, was first, and Mr. J. Hudson, Gunnersbury House, Acton, second. Mr. J. Jefferies had the best six varieties, six blooms of each.

**SINGLE DAHLIAS.**

Only two collections of twenty-four bunches were staged, ten blooms in a bunch. Messrs. J. Cheal and Sons were placed first with some charming varieties such as Phyllis, Aurora, Alba perfecta, Beauty's Eye, Amos Perry, Donna Casilda, orange and rosy-purple, very effective; Jack Sheppard, Marion Hood, pink; Naomi Tighe, Demon, Polly Eccles, and Miss Glascock. Mr. Seale was second. Mr. John Walker was the only exhibitor of twelve bunches, the flowers a little large, the best varieties Victoria, Mrs. Harris, Miss Roberts, Maude and W. C. Harvey. Mr. T. W. Girdlestone had the best six varieties, ten blooms of each, consisting of Cadet, Naomi Tighe, Jeannette, Polly Eccles, F. Leslie, and Phyllis. Mr. C. Osman, Sutton, Surrey, was second. Mr. E. Mawley had the best six bunches; Mr. J. Hudson was second. Fancy single Dahlias were represented by some very pretty varieties. Mr. M. V. Seale was first, having an excellent selection, viz., Fanny Harker, Miss Parrot, May Sharpe, Emmie, Miss Glascock, Duchess of Albany, Mrs. Wythes, and Alice Seale, with four others. Messrs. J. Cheal and Sons were second. They had, differing from the foregoing, Duchess of Marlborough, Harry Brater, Jack Sheppard, Jeannette and Gulielma.

For an epergne of Dahlias, the first prize was won by Miss L. Hudson, of Gunnersbury House, who used small blooms of Cactus varieties in shades of yellow and mauve, and light-coloured blooms of singles and single Cactus varieties. Mr. W. C. Pagram, of Weybridge, was second, with a large and imposing arrangement. For a vase of twelve Dahlia blooms, Mr. R. Edwards, of Beechy Lees, Sevenoaks, was first, with a well-arranged exhibit consisting of enormous flowers of Mrs. F. Fell and Fusilier. Miss L. Hudson was second, using flowers of Beatrice, Earl of Pembroke and Mrs. Peart. In the great commemorative class for an extensive decorative exhibit, the first prize was won by Mr. Seale, of Sevenoaks, whose arrange-

ment was highly effective. It consisted of a groundwork of the orthodox exhibition bunches, from which rose bouquets and epergnes, the whole being softened with Ferns and ornamental foliage. Graceful arches were used at the back and shorter ones in front. On the front of cloth which surrounded the table were the dates 1837-1897, very skilfully worked in two shades of red pompons. The second prize went to Messrs. Cheal and Sons, Crawley, for a less ambitious, but very tasteful exhibit, in which all the flowers used were of the highest quality. A pyramid of Cactus varieties formed the centre piece, with smaller banks of pompons on each side. Two epergnes filled with single Cactus varieties were very pretty. The table was effectively lightened by the use of graceful Palms and Ferns.

Certificates of merit were awarded to the following new varieties: *Show Dahlias*: Muriel Hobbs (T. Hobbs), a clear, soft yellow self of fine shape; Mrs. W. Fellowes (W. Fellowes), yellow ground, heavily suffused with orange-red, excellent outline and centre; Harbinger (G. St. P. Harris), soft pinkish rose, a very pleasing shade of colour, fine shape; and J. R. Tranter (J. R. Tranter), pale orange-red, good petal and outline. *Cactus* varieties: Night, rich maroon, brighter towards the edges of the petals; Daftodil, soft primrose, a lovely variety of exquisite shape, and Tillie, salmon, suffused with pale rose, the petals tinged with soft mauve; all of the best Cactus shape. From Mr. J. Stredwick, St. Leonards. *Regulus*, deep shaded crimson, came from Messrs. J. Burrell and Co., Cambridge. Alfred Vasey, brilliant orange-salmon, flushed with rose; Mary Service, golden salmon ground, flushed at the points of the petals with delicate rosy mauve, very distinct; Capstan, salmon, suffused with red, and Arachne, one of the curious spider-like forms, the curling, white, tubular forets margined at the sides with bright crimson, came from Messrs. Keynes, Williams and Co., Salisbury. E. J. Deal, a bright scarlet, came from Mr. S. Mortimer, Farnham. Annie Turner, orange-red, with pale cerise shading, and Island Queen, soft lilac-mauve, a lovely variety, came from Mr. G. Humphries, Chippenham. *Pompons*: Hypatia, deep terra-cotta, with yellow centre, from Mr. C. Turner; and Nellie Broomhead, soft lilac, of fine shape, from Mr. J. T. West, Brentwood. *Singles*: Colton Beauty, white, with edging of pale yellow, an exquisite variety; from Mr. T. Bonny.

#### MISCELLANEOUS.

A large, handsome group of tuberous Begonias and ornamental-foliaged plants was staged by Messrs. J. Laing and Sons, Forest Hill. The blooms were remarkably good in form and colour. The most striking of the foliage plants were the very beautiful Caladiums. A miscellaneous group of cut flowers and hardy herbaceous plants came from Messrs. J. Peed and Sons, Roupell Park Nurseries. An extensive collection of Cactus, decorative and pompon Dahlias was shown by Messrs. Cannell and Sons, Swanley. Mr. T. Charlton, Tunbridge Wells, staged a collection of hardy herbaceous flowers, including some good varieties of Helianthus. A large exhibit of Cactus, decorative, and pompon Dahlias came from Mr. T. S. Ware, Hale Farm Nurseries, Tottenham. The pompons were not generally very fresh, but the Cactus bunches were very good. A group of exceedingly good Cactus Dahlias, with a few pompons, was shown by Messrs. Carter, Page and Co., London Wall, E.C. The blooms were arranged in vertical rows on very narrow staging, each flower in a tiny jar, which was practically invisible when the exhibit was finished. Excellent Cactus Dahlias were also shown by Mr. John Green, Norfolk Nurseries, Dereham, who also had some perfect blooms of the lovely pompon Ganymede. A large exhibit of cut Roses came from Messrs. Wm. Paul and Son, Waltham Cross. Some of the most pleasing varieties were Queen Mab, a lovely apricot-tinted China; the common pink China Rose, Marie van Houtte, Kaiserin Augusta Victoria, Viscountess Folkestone, Georges Nabonnand, Gloire des Polyanthas, and Mme. Pierre Cochet.

### ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 7.

THE show on this occasion was again a comparatively small one, though it was by no means devoid of interest. The majority of the exhibits were submitted to the floral committee, and in this section the most striking were a large group of Nepenthes from Chelsea, Eucharis amazonica from the Fulwell Nursery, Twickenham, and a very fine collection of Dahlias from the Lowfield Nurseries, Crawley. Before the fruit committee, one of the principal exhibits was an imposing collection of fifty dishes of fruit from Syon House Gardens, containing varieties of Peaches, Nectarines, Apples, Pears, Plums, &c. There were also two dozen good Melons from Barnes, and a very beautiful collection of outdoor Peaches and Nectarines from the Royal Gardens, Windsor. The fruit was throughout well coloured. Not many Orchids were shown, the largest exhibit being a collection from the Royal Exotic Nurseries.

#### Orchid Committee.

A first-class certificate was awarded to

CATTLEYA EUPHRASIA, a cross between *C. superba* and *C. Warscewiczii*. The sepals and petals are deep rose-purple, of fine form and substance. The front lobe of the labellum is the most intense in colour we ever remember to have seen, being of a rich velvety crimson-purple margined with a lighter shade of colour, the side lobes rich purple, shading to white and yellow at the base, where it is lined with the purple of the front lobe. The plant carried a raceme of two flowers. From Messrs. Veitch and Sons.

An award of merit was given to

RHYNCHOSTYLIS CELESTIS (Cambridge Lodge variety).—The sepals and petals are nearly white, shaded with blue. It is the finest form of this well known Orchid we have seen. The plant carried two spikes of flower. From Mr. R. J. Measures.

Botanical certificates were awarded to the following: *Acineta Barkeri*, the sepals deep yellow, the petals yellow spotted with deep brown, lip yellow, heavily spotted with deep brown. The plant bore two racemes of thirty flowers each. From Major Joicey, Sunningdale Park. *Oncidium panduratum*, a small-flowered pretty species with brown and yellow flowers, from Mr. W. Ellis, Dorking; and *Brassia Lawrenceana*, the sepals and petals pale yellow spotted with brown, the lip pale greenish-white spotted with brown at the base, from Messrs. J. Veitch and Sons.

Messrs. J. Veitch and Sons were awarded a silver Flora medal for a large and interesting group, amongst which were finely-flowered plants of *Oncidium incurvum* and *O. varicosum*. Amongst *Cypripediums* there were large pans of *C. oenanthum superbum*, *C. Charlesworthii*, a dark form of *C. Carnusianum*, *C. Morganae langleyense*, and *C. Leucetia*, a new variety of the *Selenipedium* group, the result of a cross between *C. calurum* and *C. Boissierianum*. The most prominent amongst the hybrid *Cattleyas* was a grand form of *Laelio-Cattleya Clonia*, the sepals and petals delicate rose, of fine form and substance. The lip was deep velvety crimson, the side lobes being of the same colour and lined and mottled with yellow and purple through the throat. *L.-C. Nysa*, another distinct variety, is the result of crossing *L. crispa* and *C. Warscewiczii*. The sepals and petals are pale rose, lip deep crimson, heavily tinged and margined with rose, the side lobes pale rose, shading to deep yellow and rich purple-brown at the base. *L.-C. callistoglossa* bore two fine flowers. *L.-C. Eunomia*, a grand form of the dwarf-growing section, is the result of a cross between *C. Gaskelliana* and *L. pumila*, having the characters intermediate between both parents. *L.-C. Epicasta* (*C. Warscewiczii* × *L. pumila*) and *L.-C. Parysatis* (*C. Bowringiana* × *L. pumila*), also belonging to the same section, were most interesting. *Cattleya Melpomene* (*C. Forbesi* × *C. Mendeli*) is a new hybrid with very pale rose-veined

sepals and petals, the lip rose in front, veined with a darker shade of rose, the base deep yellow shaded and lined with deep brown. *Cyrenocyclorhizon* with two flowers, *Angraecum Eichlanum*, a good form of *Aerides Lawrenceana*, *Odontoglossum grande*, a spotted form of *O. P. catorei* and *Miltonias* in variety were also shown. Messrs. F. Sander and Co. sent *Cypripedium callo-Rothschildianum*, another very similar variety between *C. barbatum* and *C. Rothschildianum*, a fine form of *Miltonia Morrelliana*. M. Peters (a small-flowered variety with colouring of *Miltonia Morrelliana*), and a grand plant of *Odontoglossum Kramerii* with fifty spikes of bloom. Messrs. Hugh Low and C. Clapton, sent *Cypripedium Alfred Hollington* dark form of *Laelia elegans*, *Cattleya Minucia* with four flowers, and *Cypripedium Memoria Men*. Mr. F. Hardy, Tyntesfield, Ashton-on-Mers was awarded a silver Flora medal for a collection of rare and interesting Orchids, amongst which was a fine-grown plant with four flowers *Cattleya Hardyana*. *Cattleya Ashtoni* is a small-flowered variety with pale rose sepals and petals, lip purple, shading to yellow at the base. *C. phytophlebica* has delicate rose sepals and petals, lip rose, suffused with purple in front, shading white, and lined with purple at the base. A *Laelio-Cattleya elegans* and *Cypripediums* in variety were also included. Mr. A. Warburton, Vine House, Haslingden, sent *Cypripedium signe* Laura Kimbell with two flowers. R. J. Measures sent a dark form of *Cattleya Schofieldiana*, the sepals and petals beautifully spotted with deep brown. Mr. C. J. Ingram sent *Laelio-Cattleya Gazelle* (*C. bicolor* × *L. elegans*) similar to *L.-C. Andreana*, and *Laelia splendens* (*L. crispa* × *L. purpurata*). This is a lovely, profuse flowering hybrid, the sepals and petals deep rose, much fringed at the edges; the lip is crimson-purple, heavily fringed at the margin with rose, the side lobes pale rose, shading white, and heavily lined with purple at the base. This is a most interesting hybrid, as it clearly shows the parentage of *C. exoniensis*, proving that *crispa* was not the seed-bearing parent. M. Harris, Lambhurst, sent *Cattleya Miss Harris* hybrid resembling both in growth and general characteristics of the flower a dark form of *Schilleriana*. It is the result of crossing *Mossia* and *C. Schilleriana*. Mr. T. Stat Stand Hall, Manchester, sent *Cypripedium Derby*, a lovely hybrid, previously certified and described in these columns. It certainly proves under cultivation. *C. Lady Isabelle* (*Rothschildianum* × *C. Stonei*), a pretty form of the foliage showing considerable tessellate which is remarkable, seeing that both parents have plain green foliage, and *C. triumphans* (*Sallierii Hyanum* × *enanthum superbum*) was also included here.

#### Floral Committee.

A first-class certificate was given to—

NEPENTHES TIVEYI.—This is a handsome variety of excellent growth, the pitchers very sharp dull green in colour, marked with reddish ochraceous late. The parents are *N. Veitchii* and *N. Cucullaria*. From Messrs. Veitch and Sons.

Awards of merit were given to—

MICHAELMAS DAISY MRS. W. PETERS.—A plant of dwarf and bushy habit, the flowers pure white each about an inch across, and borne in great profusion. The plants were from cuttings struck in April of this year. From Mr. W. Peck, Leatherhead.

HIBISCUS MANHOT.—This is of strong, shrubby growth, the flowers delicate lemon-yellow with shade of maroon on the backs of the petals, rich deep maroon in the throat. It is a charming variety, and appears to be a free bloomer. From Mr. Fulford, Moor Hall Gardens, Cookham.

CACTUS DAHLIA F. C. PAWLE is a bloom good form with fluted and pointed petals. It has a good centre, and in colour resembles *Bertram*, but is somewhat richer, and does not burn in the sun like the variety just mentioned. From Messrs. Cheal and Sons, Crawley.

An excellent collection of *Nepenthes*, containing many very fine varieties, was staged by Messrs. Hitch and Sons, Chelsea. Some of the most striking were *N. mixta* × *N. Curtisi*, with various little green pitchers each about 1 inch long; *N. ampullaria vittata*, with beautifully spotted and delicately-tinted little pitchers; *N. mastersoniana*, *N. Hookeriana*, *N. Morgana*, *N. urkei excellens*, with very beautiful and brightly-coloured pitchers, and *N. albo-marginata* (silver-gilt Flora medal). Another exhibit of exceptional interest was a collection of *Sarracenia*s and *Phalotia*, from Mr. R. J. Measures, Flodden Road, Cumberwell (gardener, Mr. H. J. Chapman). A few of the many good things were *S. planorrhoda*, *S. Chelsoni*, *S. Courti*, *S. Stevensi*, *Wrightleyana*, most exquisitely marked; *Darlingtonia californica*, and some beautiful plants of *Phalotia follicularis* (silver-gilt Flora medal). A very handsome effect was produced by a large and representative group of *Crotens* from Mr. Pears, Isleworth (gardener, Mr. Farr). The plants were very clean and admirably grown, and the colouring very good (silver Flora medal). A group of fine plants of *Eucharis amazonica* came from Mr. F. Knight Eames, Fulwell Nursery, Twickenham; all clean, healthy plants, and flowering freely (silver Flora medal). Messrs. Hitch and Sons were represented by a group of *Erine Fothergilli*, finely-grown plants, bearing freely masses of brilliant scarlet flowers. Mr. Robert Owen, of Maidenhead, sent a small collection of cut *Cannas*, the best being *Comte de Douchaud*, *Camille Bernardin*, *Louis Van Houtte*, *Général de Miribel*, *Monsieur Celembet*, and *President Chandon*. Messrs. J. Cheal and Sons, Lawley, staged a splendid collection of *Dahlias*, containing good examples of show, *Caetus*, *Single*, and *pompon* varieties. The shows were remarkably good both in form and colour. Particularly striking were *Major Barttelot*, Mrs. Morgan, *Goldfinder*, *Crimson King*, *Duchess of York*, and *Thomas Hobbs*. The singles were clean and bright. The best bunches were *Polly Peles*, *Cadet*, *Donna Casilda*, *Northern Star*, *Limon*, *Harry Brown*, and *Miss Morland*. The *Cactus* varieties were fresh and of splendid form. Some of the finest kinds were *Lady Penzance*, *Gas*, *Woodbridge*, *Beatrice*, *Starfish*, Mrs. Leonard Seymour, Mrs. Kingsley Foster, and F. C. Cole. The pompons included some good bunches of *Phoebe*, *Clarissa*, *Eurydice*, *Jessica*, *Donovan*, *Arion*, and *Gaiymede* (silver Flora medal). Mr. J. F. Such, Royal Berkshire Nurseries, Maidenhead, also had a collection of *Caetus Dahlias*, in which were good blooms of *Gloriosa*, *Kynerith*, *Allicata*, and Mrs. Peart. Mr. John Walker, Tame, Oxon, exhibited *Caetus* and show *Dahlias* in good form. Of the former, *Beatrice*, Mrs. W. Noble, and *Harmony* were good (bronze Banksian medal). Baskets of cut shrubs, &c., came from Messrs. Veitch and Sons, the varieties being *Episcus totus albus*, *Hibiscus Lady Stanley*, *H. Single Painted Lady*, *H. celestis*, *Andromeda aurea*, *Hymenanthera crassifolia*, *Acer palmatum sanguineum*, and *Robinia hispida*. A small but interesting group of cut flowers came from Mr. Trevor Lawrence, Burford, Dorset (gardener, Mr. Bain). Notable things were *Clematis Davidiana*, *Lobelia Gerardi*, *Mina lobata*, and a collection of very fine *Pentstemons*. A group of hardy flowers, containing *Verbena venosa*, *Clematis flammula*, *Alstroemeria psittacina*, and *Lobelia Meri*, came from Messrs. Barr and Sons, Covent Garden (bronze Banksian medal). Mr. T. S. Wre, Tottenham, also showed hardy flowers (bronze Banksian medal). A group of very handsome French *Marigolds* was shown by Mrs. Dobbie and Co., Rothesay.

**Fruit Committee.**

There were some excellent collections of hardy fruit, notably those from the Royal Gardens and Syn House. Melons were shown in quantity, with some good Grapes, Peaches and Tomatoes.

Awards of merit were given to the following:—**ELON MRS. HERRIN.**—The result of crossing Favorite with an unnamed seedling. It is a

fruit above medium size, flesh white, of good depth, and of excellent flavour, skin bright golden, nicely netted. From Mr. Herrin, The Gardens, Droppmore, Bucks.

**BLACKBERRY MITCHELL'S SEEDLING.**—A very fine fruit with a brisk acid flavour. It is a very free bearer. From Mr. Mitchell, Fir Cottage, Farnham Royal.

Mr. O. Thomas, the Royal Gardens, Frogmore, sent nearly forty dishes of Peaches and Neectarines, and a couple of baskets of Tomato Golden Jubilee. There were a few duplicate dishes, but all were good and well deserved the award given. Mention must be made of Pine-apple, Lord Napier, Elruge, Humboldt, Victoria, Hardwick Seedling and Spenser Neectarines. The best Peaches were *Grosse Mignonne*, Stirling Castle, Noblesse, Bellegarde, Princess of Wales, *Crimson Galande*, Dymond, *Violette Hâtive*, Prince of Wales, Barrington and Dr. Hogg (silver-gilt Knightian medal). Mr. Wythes, Syn House Gardens, Brentford, sent a collection of early Apples and Pears, with a dozen varieties of Peaches and a few Neectarines. They were nicely arranged in small groups on coloured foliage, and not on plates, as is usually the case. We like this mode of arrangement for hardy fruits. The best Pears were *Williams' Bon Chrétien*, *Souvenir du Congrès*, *Margaret Marillat*, *Durendean*, *Emile de Heyst*, *Fondante d'Automne*, *Gratioli of Jersey*, *Pitmaston Duchess*, *Dr. Jules Guyot* and *Louise Bonne of Jersey*. Of the Apples, *Gravenstein*, *Duchess of Gloucester*, *Worcester Pearmain*, *Irish Peach*, *Yellow Ingestre*, *Lord Suffield*, *Grenadier*, *Wealthy* and *Cellini* were the best. Peaches in variety, Plums and Mulberries were also included (silver Knightian medal). A collection of Melons in variety came from Mr. W. Kemp, Barnes, the best fruits being *Hero of Lockinge*, *Golden Ball*, *Earl's Favourite* and *Blenheim Orange*, with several seedlings (silver Banksian medal). Mr. Miller, Ruxley Gardens, Esher, sent some very fine Princess of Wales Peaches, with a good dish of Yorkshire Beauty Apple (bronze Knightian medal). A cultural award was given to Mr. W. W. Taylor, Forest Hill, for three excellent bunches of Grape Madresfield Court, good berries and well coloured. Similar awards were given to an excellent dish of Stirling Castle Peaches, well grown and nicely coloured, from Mr. Howe, Streatham Common, and very fine Peaches (Exquisite) from Mr. J. Coles, Heger-Balcombe, Sussex. A new seedling Nut was sent by Mr. Mitchell, Farnham Royal, and thought well of by the committee. Melons were plentiful. Mr. Herrin staged several seedlings, also Mr. Scott, Lydney Park, Gloucester, Mr. Marsh, Clarence House, East Cowes, and others, but most of them lacked flavour. Mr. Farr, Spring Grove Gardens, Isleworth, sent a plant of All the Year Round Tomato laden with fruit and bearing enormous clusters. Mr. Russell, The Nurseries, Richmond, Surrey, sent fruiting plants of a Tomato named Campbell's Prolific. This the committee asked to be sent to Chiswick for trial. The plants had been lifted from the open ground and were fruiting very freely. Tomatoes were sent by Messrs. Francis, Frew and Son, Lyminster, but of no special merit.

The Veitch prizes for flavour brought forth nine dishes of Pears and eight of Apples. The first prize was given to Mr. Herrin, Droppmore, for *Williams' Bon Chrétien*, the second going to Mr. Wythes, Syn, for larger fruit, but less ripe. The other varieties staged were *Dr. Jules Guyot*, *Jargonelle*, *Jersey Gratioli*, and *Early Roussellet*. Apples were good, Mr. Mayne, Bicton Gardens, Budleigh Salterton, being first with a nice dish of *Kerry Pippin*; Mr. Wythes second with a good sample of *Gravenstein*. The other varieties staged were *Worcester Pearmain*, *Oslin*, and *Devonshire Quarrenden*.

The lecture on *Nepenthes* given by Mr. H. J. Veitch was well attended, the lecture being illustrated by diagrams and specimens. Mr. Veitch stated he would avoid as much as possible the botanical part, dealing chiefly with the plants from a horticultural standpoint. No wonder

travellers expressed great surprise when they first met with these plants. The first record we have of the *Nepenthes* was in 1661. It was then lost sight of for a time. In the eighteenth century, Linnaeus, to whom we owe the name *Nepenthes*, gave us interesting facts and named new varieties, but as regards the latter they were not plentiful at the date named. Many plants were lost owing to our houses at that period being unsuitable for cultivation. To Messrs. P. Veitch and F. W. Burbidge we are indebted for four splendid species from Borneo. Dried specimens from their native habitat, also some very fine ones from Dublin (Trinity College), showed to what size the pitchers grew and their colours. Sir H. Low nearly fifty years ago found some splendid varieties, but at that time, unfortunately, failed to get them alive to this country. Others also a little later sent plants, but our stoves of that day, owing to the dry, hot fires, were no doubt answerable for many losses. In 1858 Sir H. Low made another attempt to send the splendid *N. Rajah*, a noble species, but met with little success, and of seeds sent but few survived. Since 1872 many hybrid varieties have been raised, and at that period, through the aid of Miss North's drawings at Kew, we got the beautiful *Northiana*. Mr. Burbidge, after much labour, secured this fine Pitcher, which is such a great ornament to our stoves. The lecturer noted the value of *N. Mastersoniana*, one of the best of the hybrids. This, the result of crossing *N. Khasiana* with *N. sanguinea*, is one of our best and most easily-grown Pitchers. Plants of this variety were shown, some following one parent, some the other. The hybrids raised in this country in most cases made a much freer growth than the older imported plants. Seedlings in their various stages were handed round, and the newer *N. Tiveyi* certificated that day was much admired. This is one of the latest crosses. The *Nepenthes* occupied a wide range of country and were much scattered, but most of them were close to the sea. The larger species had been found from 5000 feet to 8000 feet above the sea, but there was a great uniformity of temperature—rarely more than 5° difference during the day, with abundance of moisture. Many other interesting points were referred to, including their mode of growth, shape of leaves, &c. Mr. Burbidge said they owed their best thanks to Mr. Veitch for his most interesting paper and for the specimens sent. He described the various formations of the plant, how built up, and the best means to get fine Pitchers in this country. He also made some interesting remarks on collecting and the difficulty in obtaining new species.

**NATIONAL CHRYSANTHEMUM SOCIETY.**

SEPTEMBER 7, 8, and 9.

THE display made by the combined efforts of the *Dahlia*, *Chrysanthemum* and *Gladioli* growers at the Royal Aquarium, Westminster, may be considered quite a success. In most cases the classes were each well filled, and the exhibits were also of a high order of merit. *Chrysanthemums*, as usual at this first exhibition, were only shown in a very limited quantity, and this year's display being more of an experimental one, supporters of the early flowering sorts may rest satisfied. On this occasion exhibitors were confined to the varieties included under the heading of "Early-flowering" in the society's Jubilee Catalogue, 1896. There were several interesting exhibits, and to make the show of these flowers more popular it will be necessary to add proved sorts to the list each year. Already it has been noticed several very excellent varieties have been omitted from the catalogue. That the early-flowering *Chrysanthemum* is essentially a plant for the hardy flower garden the class of exhibits staged seemed to distinctly prove, the bunches of small and medium-sized flowers having evidently been grown in the open with little or no disbudbing. *Dahlias* were the chief feature, these being exhibited in fine form and in large numbers. In the leading classes the blooms of the show and fancy sorts were very fine.

The chief interest was without doubt centred in the beautiful flowers of the Cactus type, their rich colour and pleasing form appearing to interest the majority. The winning stand of singles in the class for twenty-four bunches was a very fine lot, and well merited the distinction it gained. Pompons were largely shown. The trade display of Dahlias was not so fine as on some former occasions, but this was amply compensated for by the numerous entries in the competitive classes. Gladioli were shown in fine form by Messrs. Burrell and Co.

#### CHRYSANTHEMUMS.

In the class for twenty-four bunches there was only one competitor. Mr. Eric F. Such, the Royal Berks Nursery, Maidenhead, was awarded first prize. This was a fine exhibit, and contained large bunches of good coloured flowers in fresh condition. The most notable among them were Harvest Home, a pretty crimson and gold flower; Mme. Marie Masse, M. Gustave Grunerwald, M. G. de Dubor, Le Poete des Chrysanthème, and Mme. Eulalie Morel, pretty cerise and gold colour, of the Japanese sorts; while the best of the pompons, and these were good, were Mr. Selly, Piercy's Seedling, grand colour; Mr. W. Piercy, Longfellow, Blushing Bride and its bronze sport, Bronze Bride, Strathmeath, and Mme. Edouard Lefort, a pretty crimson and gold flower. There were three entries for twelve blooms of Mme. C. Desgrange. Mr. B. Calvert, gardener to Col. A. Houblon, Hallingbury Place, Bishop's Stortford, was an easy first with an even lot of flowers. Mr. Chas. Crook, gardener to Dowager Lady Hindlip, Hodson House, Droitwich, who had very fine blooms too, was placed second. The class for twelve blooms, any large-flowering variety or varieties except Mme. C. Desgrange, brought only one competitor, Mr. Calvert again showing handsome flowers of G. Wermig. These were good, full, and deep, and of a rich colour and fresh. Mr. Such was placed first for twelve bunches of pompons. His best sorts were Bronze Bride, Piercy's Seedling, Mme. E. Lefort, J. B. Duvoir, and Longfellow. This was a nice lot of flowers, large, fresh, and clean, but arranged on Moss, which was anything but attractive. Miss R. Debenham, St. Peters, St. Albans, secured second honours with smaller flowers, not well set up. Mr. Calvert was first with a vase containing six blooms (Japanese) of Mme. C. Desgrange, but the effect was lost by bad arrangement and the want of a little foliage. Miss Debenham was second, showing Edwin Rowbottom, a pretty little yellow flower, and arranged with Fern fronds. The class for six bunches of any of the yellow sports of Mme. C. Desgrange resulted in the first prize being awarded to Mr. Calvert, who staged four bunches of G. Wermig and two bunches of Mrs. Hawkins. This was a very handsome exhibit, and would have been better had more space been taken in arranging the flowers. In this class, as well as in one or two others, there was evidence that blooms of the late sorts had been hurried forward, but these were excluded, not coming within the list of those described as early flowering. Extra prizes were, however, given to these exhibits. In the amateurs' classes Miss Debenham was accorded premier honours for twelve bunches of Chrysanthemums (pompons allowed). Her best flowers were Vicomtesse d'Avene (splendid colour), G. Wermig, Edith Syrratt (rich purple-magenta), Edwin Rowbottom, Mme. Carmaux (pretty new white flower), Longfellow and Mrs. Cullingford. Mr. D. B. Crane, Highgate, N., was a good second, his best bunches being Mme. Marie Masse, Harvest Home and M. Dupuis. This exhibitor was also first for a vase of six blooms, showing Mme. C. Desgrange and Lady Fitzwygram, arranged with sprays of richly-toned Oak foliage and grasses. The class for an epergne was well contested, resulting in Mr. T. S. Williams, 4A, Oxford Road, Ealing, W., being placed first with a somewhat cumbrous arrangement. The form of the stand resembled a small umbrella in shape, with a neat base. The second prize was awarded

to Mr. D. B. Crane, who had a light arrangement, flowers, foliage and grasses being pleasingly associated together.

#### GLADIOLI.

The class for a collection of Gladioli spikes always brings a very large and handsome display, Messrs. J. Burrell and Co., Howe House Nursery, Cambridge, being invincible. This exhibit covered one side of a table arranged across the building, and included many dozens of very beautiful flowers. The most striking varieties among them were Oriental, Rosalind, Atlas, Ella, Flambeau, Eunice, Grande Ronge (many very fine spikes), Archduchesse Marie, Ruth, and Baroness Burdett-Coutts. The trusses were very large and the individual blossoms very fine. Messrs. Harkness and Sons, Bedale, Yorkshire, were placed second.

#### DAHLIAS.

The principal class was one for forty-eight blooms of the show and fancy type of the flower, and in this there were five competitors. Mr. J. Walker, nurseryman, Thame, Oxon, was deservedly first with a very fine lot of flowers. These were large, well finished, of good colour, and set up in a neat and even manner. His best flowers were T. W. Girdlestone, Joseph Ashby, Maud Fellowes, James Cocker, Queen of Autumn, Shirley Hibberd, Victor (very fine), Chieftain (good colour), J. T. West (excellent), Mrs. David Saunders, Mrs. C. Noyes, S. Mortimer, Hercules, Buffalo Bill, and W. Powell. Mr. S. Mortimer, Farnham, was second, his flowers lacking the evenness which distinguished the premier display. In the class for thirty-six blooms, distinct, there were six entries. Mr. S. Mortimer was first with an even lot of flowers. Second honours fell to Mr. J. Walker, who followed the first prize lot very closely with large even flowers of good colour. For twenty-four blooms, distinct, there were three competitors. Mr. G. Humphries, nurseryman, Chippenham, was first with even, though smaller flowers. The best in his stand were Rev. J. Godday, Shirley Hibberd (very fine), Senator, James Stephens (fine colour), Earl of Ravensworth, and Mrs. J. Downie. Mr. J. T. West, Brentwood, was placed second with a neat lot of flowers. In a class for twelve blooms, distinct, Mr. G. Humphries was again first with a well-balanced lot of flowers. Buffalo Bill (very fine buff, striped vermillion), William Rawlings (fine form), Mrs. J. Downie, James Stephens, Arthur Rawlings, and R. T. Rawlings were among the best. A good second was found in Mr. J. R. Tranter, Henley-on-Thames. In the amateurs' and gardeners' classes the premier one was for twenty-four blooms (show and fancy), distinct. In this Mr. Thomas Hobbs, Easton House, St. Mark's Road, Easton, Bristol, was first out of four competitors with rather small flowers. Mr. R. Burgin, St. Neots, Hunts, was placed second with larger, but an uneven lot of blooms. There were only two competitors in the class for twelve blooms, distinct, the leading position being taken by Mr. E. Jefferies, Langley Burrell, Chippenham. The second place was taken by Mr. W. Wheeler, 53, Bill Street, Henley-on-Thames. In a small class for amateurs who grow their plants without professional aid there were eight competitors with six blooms. Mr. Thos. Hobbs was first with neat and beautifully finished flowers. The pompons were a very pleasing feature of the show, the charming little flowers when well set up making a delightful change to the heavier blooms arranged on boards. The principal class was one for twenty-four bunches, distinct, and arranged in triangular form, with ten blooms in each bunch. There were four competitors, the premier position being secured by Messrs. Keynes, Williams and Co., nurserymen, Salisbury, with a very charming selection. Mr. Chas. Turner, Slough, was second with smaller, yet lovely blooms, but not so well arranged. For twelve bunches, Messrs. J. Burrell and Co. were first with neatly-arranged and high-class flowers. Mr. J. T. West was second with smaller flowers, having Nellie Broomhead, Mary Kirk (a good yellow), and Bacchus. For six bunches, Mr. G. Wyatt was first with a fine lot, having Capt. Boyton and E. F. Jungker in

splendid condition, while Mr. J. Hudson was second with a pretty exhibit, having Mars i splendid colour. The single varieties were seen in exceptionally fine form in the first prize exhibit of twenty-four bunches. This came from Mr. T. W. Girdlestone, Sunningdale, Berks, and was a very beautiful, bright, even, and well-arranged lot of flowers. The second prize went to Mr. F. W. Seale, Vine Nurseries, Sevenoaks, with less even flowers and also less beauty in their setting up. Eclipse, Formosa, Miss Jefferies, W. C. Harvey, and Beauty's Eye were his best bunches. For twelve bunches, Mr. E. F. Such was first. Mr. J. Hudson, Gunnersbury House, Acton, W. was second with smaller, but pretty flowers.

The decorative, including Cactus, varieties were in themselves the most distinct feature of the show, and were an object of interest to most of the visitors. Great improvement seems to be seen each season. The true Cactus form seems to be the essential, and on this account several strongly grown flowers having lost some of the chief characteristics regarding form had to give place to those of truer form. The chief class for this type of the flower was for eighteen bunches, distinct, six blooms in a bunch. Messrs. J. Burrell and Co. were first with a grand lot of flowers of medium size and good form; Starfish, Lady Penzance, Mrs. A. Beck, Falka, Mrs. Francis Fel Cinderella, Casilda, Mrs. Wilson, Noble, Fantasy Harmony and Cycle were the best. Messrs. Keynes, Williams and Co. were second. There were six competitors in the class for twelve bunches, and these made a most striking array of colour. Mr. J. T. West was first with flowers of exquisite form and a pleasing assortment of colour. The second prize was awarded to Mr. Stredwick, Silverhill, St. Leonards-on-Sea, for heavier lot of blooms. Quite a strong competition was seen in the amateurs' and gardeners' class, for six bunches, the premier award going to Mr. G. Wyatt, with small flowers and, with one exception, good form. To several exhibitors this was a great surprise, as the disappointed ones had flowers showing high culture at the expense of form.

#### MISCELLANEOUS EXHIBITS.

These were large and varied, and assisted materially to make a fine show. Mr. H. J. Jones, Rycroft Nursery, Lewisham, S.E., well merited the silver-gilt medal for a charming group. The centre were early Chrysanthemums and Liliu speciosum album artistically arranged, and each end of the group and finished off to a point were fine tuberous-rooted Begonias, both double and single forms. The whole was pleasingly finished off with Palms and edged with Ferns, & Mr. T. S. Ware had a large group of cut Dahlia of all types arranged on the floor, a central cone of large size being composed of the Cactus flower with smaller cones at each of the four corners made up of the pretty pompon flowers. This also received a silver-gilt medal. Mr. Norman Davy, The Vineries, Framfield, Sussex, had a large table of Chrysanthemums, interspersed with flowers of the perennial Aster. A vase of Chrysanthemum Queen of the Earlies and one of Barba Forbes, each excellent early white sorts, were much admired (silver medal). Mr. W. Webb, Earlswood Nursery, Redhill, had a small table of early Chrysanthemums (silver medal). A grand group of Chrysanthemums associated with fine-foliaged plants came from Mr. J. H. Witt, Nunhead Cemetery, and this was awarded silver-gilt medal. Messrs. H. Cannell and Son, Swanley, for cut Chrysanthemums and a nice lot of Saintpaulia ionantha in 5-inch pots; Mr. E. F. Such for a collection of hardy flowers at Dahlias; Mr. J. R. Clard for a large table of decorative exhibits, including some of his most recent designs, and Mr. Seale for a large table of Dahlias in vases and on boards; each received silver medal. Messrs. S. Spooner and Son, nurserymen, Hounslow, had a large table of Apples and Pears set up in baskets and on dishes, for which a silver-gilt medal was awarded. From Reid's Nursery, Sydenham, came Cannas, which a bronze medal was given.

## ORCHIDS.

### DENDROBIUM DEAREI.

These and pretty blossoms of this *Dendrobium* are produced at this season with great abundance, and doubtless this has in a measure increased its popularity. Few species are more suited for cutting, even among the spring-flowering deciduous kinds, and the fact that orchids are now at their best is an additional recommendation. I have been in places where this species grows like a weed, though no particular attention seemed to have been paid to it, while in others it is more or less a failure. As a rule it is most satisfactory in places where a large batch is cultivated, as here it can be given just the right position and treatment, and here a few plants only are mixed with other orchids it is more difficult to do. It comes from the Philippine Islands, consequently plenty of heat must be allowed, and I have always found it do best in a house laden with atmospheric moisture the greater part of the year. The growth, it will be noted, is short, and all such plants take longer to make than those with longer internodes and fewer leaves. Get them into growth then as early as possible in the season, and see that from the time the buds start till the terminal ones are finished no check of any kind is given to the plants. They may be checked in various ways—by neglecting the ventilation or by syringing in spring when cold winds are often blowing at the time the sun is bright, by the presence of insects about the young tender plants, or by sudden fluctuations either of heat or moisture. All this should be carefully guarded against, and after the growth is fully ripened it must be well ripened by exposure to an all air. It is quite a mistake to think that the blossoms are over, the growth therefore should not be ripened. Each pseudo-bulb has to play in the economy of the plant, and its work is only half done when the flowers are over. A well consolidated plant rests during

the winter and starts strongly in spring, but one with green, half-ripened bulbs is never satisfactory. *D. Dearei* should never be unduly dried while at rest; the roots and compost may get quite dry before giving a fresh supply of water, but they must not be allowed to remain long in this condition. If properly potted, it takes water almost daily when both root and top-growth is active. The young shoots begin to emit roots when about 3 inches in length, and if the compost is in need of renewal, this is the safest time to set about it. Nothing is gained by using large pots or baskets, for the roots, though rather freely produced and fairly vigorous, do not seem ambitious in leaving the centre of growth, like those of *D. nobile* and similar kinds. Nice specimens may be grown in pans about 5 inches or 6 inches across; in fact, if the receptacle used allows of a margin of compost about 1½ inches wide all round the plant, it is ample. For potting *D. Dearei* I use about three parts of Sphagnum Moss to one of the best fibrous peat rid of all sand and earth, adding plenty of rough crocks and charcoal, and draining the pans well. Should any of the plants be badly rooted, and consequently difficult to fix in position, a thin copper wire may be run over the convex surface of the compost, catching the rhizome between two of the older pseudo-bulbs, this serving to hold it steady until new roots are emitted, when it may be removed. If sufficient moisture can be otherwise maintained in the atmosphere, syringing overhead is unnecessary, but it will do no harm if judiciously managed, and is sometimes helpful during very hot, bright weather in summer. The most risky time is when the shoots are small and tender, but it is not then needed. The plant is named in compliment to its discoverer, Colonel Deare, who found it in Dinagat about the year 1882.

**Peristeria elata.**—Of this I noted a large plant last week carrying a spike considerably over a yard in length, the upper portion for more than a foot bearing the pure white, sweetly-

scented blossoms. The column and lip bear a strong resemblance to a white dove; hence its popular name of Dove Orchid. *P. elata* is a strong-growing, semi-terrestrial plant, thriving well in large well-drained pots, the compost consisting of equal parts of peat, loam fibre, and Sphagnum Moss. Plenty of crocks and charcoal must be added, the plants grown strongly till they flower and afterwards rested.—H.R.

**Stanhopea guttulata.**—This belongs to the same set as *Stanhopea oculata* and *S. Wardii*, and is a variable and beautiful plant. The flowers are large, the sepals and petals pale yellow, closely covered with large, light purple spots, the lip nearly pure white, with smaller dots of purple. *S. guttulata* does well in any warm, moist house if grown in fairly large baskets suspended from the roof, kept moist at the roots, and regularly syringed overhead twice daily in hot weather. The best compost is equal parts of thereabout of Moss and charcoal, with a little loam fibre over good drainage.

**Trichopilia tortilis.**—This pretty species is still in good condition, the well-known blossoms with their singular twisted segments being very attractive and fragrant. It does well in a shady, moist position in the Cattleya house, and though liking abundant moisture while growing freely, may easily be over-watered during winter. The roots are not very strong or any too freely produced, so care is needed to keep the compost clean and open, so as to ensure ample aëration right through the ball. Where duly shaded, the closer they are to the glass the better, but they cannot stand direct sunlight. *T. tortilis* is a native of Mexico, whence it was introduced in 1835.

**Oncidium leucochilum.**—This is an old species, but a very beautiful one, the long arching spikes of flower having a fine appearance just now. Each bloom is about 2 inches across, pale yellow on the sepals and petals, which are blotched with chestnut-brown. The lip is similar, or lighter in colour, with a reddish centre. It is an easily-grown, vigorous plant, thriving well in quite a cool house during the summer months, and in winter a minimum temperature of 50° is ample. The roots are strong, thriving well in a compost of medium thickness consisting of equal

parts of peat and Moss. It likes plenty of water while growing, and must never, in fact, be dried off. It is a native of Mexico and was introduced in 1835.

**Dendrobium canaliculatum.**—This Dendrobe is not so frequently seen as it deserves, for it is a distinct and pretty plant. The stems are much more thickened than most others of the Australian section of the genus. These bear a few pairs of leaves towards the top whence spring the stout erect spikes of bloom. These are about a foot high as a rule, the flowers occurring chiefly towards the top in a loose raceme. The outer segments are rather narrow, white at the base, becoming yellow at the tips, the lip being white with a very deep purple blotch in the centre. The plants require plenty of heat and atmospheric moisture while growing, but the roots are easily damaged by either a too free supply or too much material about them. The pots or pans used should allow a margin of 2 inches round the plant, and the compost must be made very firm. The most suitable time to repot is when young growths are starting before they begin to root. *D. canaliculatum* comes from almost the extreme point of North-east Australia, and was discovered by Mr. J. Gould Veitch in 1865.

**Cattleya Loddigesi.**—Flowers of the typical form of this plant come from a correspondent for a name. It is a pretty plant that is worthy of more care than present-day Orchid growers give to it. The flowers occur several together on an erect scape at the apex of the newly-formed pseudo-bulbs; they are about 4 inches across, the sepals and petals a delicate rosy-lilac, the lip deeper in colour with an orange blotch in the centre. Its culture is not difficult, being practically the same as for most of the upright growing, autumn-flowering *Cattleyas*. A position not too far from the roof glass suits it best. The plant may be repotted in March or April, using a compost of rough peat and Sphagnum with plenty of charcoal and crocks. Old specimens are apt to become bare in the centre, and when this occurs they ought to be broken up and the young plants either re-massed or set growing separately. In any case let the leads be kept as near the centre of the pot as possible and use the latter of medium size in accordance with that of the plant. Keep the growth dormant during winter if possible and only give sufficient water to prevent shrivelling of the pseudo-bulbs. It is an old plant in collections and a native of Brazil.

#### PHALÆNOPSIS VIOLACEA.

THERE are a great many varieties of this pretty Moth Orchid, differing more or less in the intensity and distribution of the colouring, but every one is a handsome and beautiful plant. In the typical form the blossoms are about 3 inches across, white, prettily marked at the base of the segments and lip with violet-purple. They occur on stoutish scapes, about four or five on each, and these are not as a rule open together. The habit of the plant is dwarf, the leaves deep shining green, about 6 inches in length. It is not more difficult to grow than others in the genus, and may be cultivated in pots, small pans, or wooden baskets suspended from the roof. The growing season is usually from February or March till September, and during this time a hot, moist, and carefully shaded house suits it best. Shading is an important point in its culture, for though it cannot be denied that growing naturally the plants are exposed to almost direct sunlight, this will not do under cultivation. On the other hand, for obvious reasons, too heavy and long-continued shade is not advisable. Enough light to properly consolidate the leafy system of the plant must be allowed or the foliage gets weak and thin, falling off wholesale in spring when the plant begins to get active. Air in abundance the plant likes, provided it can reach it at a proper temperature, but to open the ventilators when cold winds are blowing is simply ruinous. Better by far keep close then and allow more air when the weather is more propitious. Keep the temperature as

regular as possible, and avoid a dry atmosphere at all times. The foliage dislikes heavy syringing overhead; it is unnecessary if the atmosphere is right. The treatment of the roots is simple. The more they can be induced to break up and ramify in broken crocks or similar material the easier they are to transplant, and this has led me in many cases to remove Phalænopsids of various kinds from the cylinder-shaped receptacles often used for them and place them in pots of ordinary make. The roots are exceptionally impatient of anything close or sour about them, cleanliness being one of the important points in its culture. Pots or pans should be clean and dry when used, and the sphagnum about the roots should have all foreign matter removed before using. A winter temperature of 60° by night is high enough, and the day temperature at this time must not be too exciting. A proper annual routine of growth and rest is thus kept up, the plants blooming freely every season. *P. violacea* is a native of Sumatra, and was first discovered in 1859. It has, however, only been in general cultivation since 1878, when it flowered in a Cornish collection. R.

**Masdevallia ephippium.**—This is a singular and interesting species, but not so showy as some other kinds. The flowers are very freely produced, one or two on a scape. The upper sepal is the smaller, being narrow, yellow, stained with brown, the lower ones forming together a cup-shaped process enfolding the column and petals, chestnut or reddish brown at the base, becoming yellow at the end of the tails. Few species are better off for names than this, but the above is the one generally recognised. It is a native of New Grenada, whence it was sent home in 1874, and it has been collected in various localities by different people since. Reichenbach took the specific name from a Greek word, meaning a saddle, but where the likeness to this comes in, it would be difficult to say. *M. ephippium* does not always thrive under cultivation, but, as a rule, it will be satisfactory if kept slightly warmer than the *Harryana* set during winter, potted up in clean Sphagnum and peat, and never dried at the root. The safest time to repot the plant is in autumn, when it has a chance of getting re-established before the winter. Remove all old and sour material from about the roots when repotting, and finish the line of compost a little above the pot. Yellow thrips are its worst insect enemy, and must be kept down by fumigating if needful.

**Promenæa stapelioides.**—This is a quaint, yet striking little Orchid, and I have noted it in flower in several collections recently. In habit it is similar to the other species in the genus, but usually rather smaller, the pseudo-bulbs only about 1 inch high and growing in close tufts. The flowers, usually produced singly on the spikes that spring from the base of the bulb, are each 1½ inches across, pale yellow, with bands of deep purple-brown. The lip is darker than the rest of the flower. Although this species comes from Brazil, its habitat is so high up on the Organ Mountains, that it likes much less heat than Brazilian Orchids generally. It may, in fact, be kept quite as cool as *Sophronitis*, and will be all the better for it. In a shady, cool house of any kind it will thrive if carefully attended to. Perhaps its roots are the most impatient of any respecting closeness in the compost, and for this reason the plants need frequent renewals of the latter. They must not be top-dressed time after time without repotting, as this tends to thicken the bulk of the compost, and thus defeat the end in view. A thin layer of good peat Moss and fibrous loam suits this plant well, and from the time growth starts until the bulbs are made up the roots must not suffer from want of water. Insects are fond of the tender foliage, and these must be kept in check by sponging.—H.

**Phaius Humbloti.**—There is something very singular about the constitution of this beautiful Phaius; in some places it grows very freely, in others even skilled cultivators fail to do much

with it. I am of opinion that not only this many other Orchids vary in robustness and in the individual plants even when apparent as strong and healthy as each other. All events it is not unusual to see plants under exactly the same cultural conditions varying greatly in the progress they are making. Cleanliness very important factor in its well-being, while the term is applied to the plant itself or the post and receptacle in which it is grown. A step in fact in bringing unhealthy plants to root would be a thorough washing of every part root and bulb, repotting into fresh compost. Being a native of Madagascar, it natural quires warmth, but possibly it has been kept hot by many growers in the past. I know least one case where a lowering of the temperature has led to better results, while a nice lot of plants I noted during the week was in the airiest part of a large *Cattleya* and blooming freely. It is very attractive in flower, much more so than the majority of species. The spikes rise to about 18 inches high bear seven or eight flowers each. These individually, are 2 inches across; the sepals petals white, with a rosy-purple suffusion, the a pretty shade of brownish-crimson. The commemorates its discoverer, M. Leon Hur who sent it home with other species in 1879. L.

#### NOTES ON ORCHIDS.

THE weather of the past few weeks has been unsuitable for Orchids, and it has been necessary to use much more fire-heat than usual in the houses. The grower's first care now, of course will be the consolidation of the growth made during the past summer. Most of the deciduous *Dendrobiums* have by now finished growing and are hanging in the full light with the above in view. *D. Macarthiae* has made good growth with me this season and the terminal leaf just appearing, *D. superbum* and one or two being in a similar condition. These will ripen in the warmest house for some time longer is a great mistake to turn them out before they are really finished. This treatment tends to produce and badly-formed flowers, also subsequent growths. The evergreen kinds have been irregular this year, but as the growths of one are made up in a much shorter time than noted above, it does not so much matter if they are a little later. *D. chrysotoxum* and the very snavissimum are now just starting. Newly imported plants of *D. formosum* are grown freely, so are others of *D. Phalænopsis*, *D. F. anum*, *D. bigibbum* and *D. Dearei*—a mixed lot of plants this, but just now they grow wonderfully well together. *Calanthes* are green, and I give these liberal moisture to the root, with now and then a weak application of manure. *Thunias* that have ripened up should by now be under cover, as the night much too cold for them, and as soon as a foliage is off they may be shaken clear of the post and hung up in a warm house for the winter. Late plants and stems that have not bloomed care, or they keep growing too late in the season ripen properly, and such stems never produce good flowering shoots in the spring. In the houses are apt to become covered with dirt or other deposits, owing to the proximity of the stovehole, these must be kept washed off and it is imperative that all the light at command be given to the plants now. Especially is this the case with *Phalænopsids* are grown, for though it is necessary even now to lower the blinds for a while on bright days, they want all the light before this and afterwards. It is too early to reduce the moisture much to these beautiful plants, but a slight difference may be made in the atmosphere. The leaves, especially those of the *Schilleriana* group, show by their appearance when the season's growth is drawing to a close. In the *Cattleya* house *C. Gaskelliana* is flowering, some late plants even yet just showing the buds through the sheath. *C. halimifolia* will soon be the attraction, and

beautiful Dowiana varieties are also forward. *C. uttata* Leopoldi with its olive and crimson tints is just opening, and *C. bicolor*, a quaint and pretty species, will follow it closely. Keep *Laelia purpurata*, *L. grandis tenebrosa*, and *Cattleya Illinoensis* at rest now if possible, also the summer-blooming kinds that flower upon the young plants. *Cattleya Mossiae* is pulling up, but needs warmer, or at all events brighter, weather in time, while *C. Trianae* and *C. Percivaliana* resting in sheath. These fine kinds have the end of the season to grow in, but in the neighborhood of large towns where fogs are injurious throughout seasons for flowering. *Oncidium lanceanum* is an erratic subject, but if the growth can be arrested now that the new fleshy leaves have formed and grown to full size, there is no doubt they start away better for a rest, if only for a few months' duration. Other kinds, as *Orchidanthus* and *roseum*, *O. Cavendishianum*, *O. luridum*, may be treated similarly. None of them like severe drying, but neither are they satisfactory if kept sluggishly growing throughout the year. The cooler section of the genus, such as *O. macranthum* and its varieties, and the dwarf kinds, as *O. concolor* and *oculatum*, are in many cases pushing new roots from the forming pseudo-bulbs, and if the compost is in need of renewal this may be safely carried out now. Many of the *Odontoglossums*, *Masdevallias*, *Phorolithals*, and *Restrepias* may also be looked to. None of these like a thick spongy mass of compost. They delight in one that quickly runs and drains, and has plenty of capacity for retention. The first-named delight in deep pots in rough open material, where the large fleshy roots thrive and ramify freely, but all the dwarf kinds are best with less. The *Schlieperianum* and similar types of *Odontoglossum* are coming really forward, and great care is necessary that the spikes are not eaten by slugs. These pests are more troublesome in the cool house than anywhere else, and this section of the popular genus seems especially to their taste. Disas, too, may not be repotted, the root-stocks being carefully halved or the tiny shoots will be broken off. They will soon again be in growth, and when this occurs a very liberal supply of moisture both in the atmosphere and at the roots must be given. Cool species in pits and frames must be well covered at night, and after the end of the month should be, if convenient, placed in their winter quarters. No drop in the temperature in any of the houses is advisable as yet. R.

BOOKS.

OPEN-AIR STUDIES IN BOTANY.\*

"Come forth into the light of things,  
Let Nature be your teacher."—Wordsworth.

A neat, well-printed, and most interesting little book of 266 pages, with glossary and index, sixty or seventy original illustrations, and seven photographic reproductions of wild plants as naturally growing in their homes. As the author tells us in his preface, this work is

an attempt to exhibit, by means of familiar scenes in our own islands, glimpses of plant life; interpreted not by the examining of microscopic slides in the laboratory, nor yet by the "conning of plant-mummies" in the herbarium, but by the study of actual scenes from Nature. We stand, in fancy, out in the open country, with the wild flowers at our feet, the hum of insects and the rustling of the wind in the pines, and the blue sky overhead, and we use those powers of observation that have been given to us. This is only what we hope to comprehend the life of a plant or of a plant-community, and appreciate the conditions under which each species lives, and the adaptations by which each is able to maintain its

"Open-Air Studies in Botany: Sketches of British Wild Flowers in their Homes." By R. Lloyd Praeger, B.Sc., M.R.I.A. Illustrated by drawings from Nature by S. Rosamond Praeger, and photographs from Nature by R. Welsh. London: Chas. Griffin and Co., Exeter Street, Strand, W.C. 1897.

position in the plant world and fulfil its proper functions.

And we must honestly say that this simple little programme has been well carried out, and it is just the book to interest and encourage those who are fond of our native wildings and do not know much about them.

There are eleven chapters, or "scenes" as the author prefers to call them, representing so many of the peculiar habits generally resorted to by the special plants included under each head. Thus we have A Daisy Starred Meadow—Under the Hawthorns—By the River—Along the Shingle—A Fragrant Hedgerow—A Connemara Bog—Where the Samphire Grows—A Flowery Meadow—Among the Corn—A Study in Weeds—In the Home of the Alpines, and finally a city rubbish heap with its vagrant population is described. The book is by no means a complete flora, but aims at the illustration of our most popular native flowers in a gossiping or familiar manner. In treating of the flowers themselves opportunity is taken to "point a moral and adorn a tale" by pleasant glimpses at the underlying principles of classification, distribution, and movements of plants, as also to those now familiar biological questions of "the struggle for existence" and "the survival of the fittest," &c.

The book is rendered much easier for reference by the particular generic and specific names and other important words being printed in a larger and darker type, though the ordinary body type is also bold and clear. Thus, under colours of flowers the work of Grant Allen is mentioned, and under Orchids there are references to the works of Darwin on cross-fertilisation, and elsewhere the works of Kerner, Müller, Johns, Bentham, Hooker, More and Moore, Babbington, &c., are named, so as to facilitate the studies of those who care for further information.

The book is mainly written from an Irish flora point of view, but will on that very account be more acceptable to many other British readers. The rare and peculiar Irish Orchid, *Spiranthes Romanzoviana*, is figured on the title-page as growing in grass, but, as it seems to me, *minus* its own leaves, and mention is made of the peculiar fact that this delicious almond-scented little flower is found nowhere else in Europe except in three or four Irish localities, but crops up in New York State, and is found at intervals between that place and San Francisco. It is a little disappointing to find the dainty little Fairy Hyacinth (or *Scilla verna*) ignored, though the Wood Hyacinth, or *Bluebell*, is alluded to as *Scilla vestalis* several times; but no doubt Mr. Lloyd Praeger thought it would not be likely to intrude itself upon the majority of those who read his book. Again, very little, except a bare mention, is made of that queen among all British wild flowers, the Lily of the Valley, which makes the woods near Coniston and elsewhere in the English Lake district so fragrant and delightful during May and June every year. We quote *Convallaria majalis* here, as being one of our most exquisite wild flowers, and one to which the botanist has rarely, if ever, done justice. Will it be believed that there is no portrait of it in the *Botanical Magazine*? At the hands of the gardeners and of the general public, however, it has met with due culture and appreciative admiration, and thousands of pounds are paid annually for its roots or "crowns" for forcing, as grown near Berlin, Hamburg, and other German towns. It is also largely grown in France and Belgium, and there are florists, like Jannoeh and Rochford in England, who can now supply its exquisite leafage and pearly bells for at least ten months out of the twelve. This is done by a very clever application of chemistry and physics, a steam engine working a refrigerating apparatus in a cold chamber, where the "crowns" are preserved dormant until required. This is merely one instance out of many in which our native flowers are now attaining to a profitable importance, but little, if anything, less than that of many exotic ones. We have no means of knowing the total sum derived

from the sale of Lily of the Valley flowers in England, but it must be something enormous.

To return to the charming book before us, we may say that it relates to wild flowers only—as its title indicates—nothing being said of the Ferns, Mosses, or fungi, nor do we find any reference to the enormous quantity of Blackberry fruits now gathered in Ireland and shipped to England every year, but as another edition is sure to be soon called for, we would suggest that it should contain a short chapter on the economic and medicinal uses of wild flowers and plants, in the efficacy of which the Irish peasantry to this day so thoroughly believe. Twenty years ago only a very few "hot-house" flowers were seen in a very few of the best shops in Dublin, but to-day flowers are met with everywhere, and there is, moreover, quite a profitable trade established in wild flowers throughout the Dublin streets every spring, when the flower girls and basket women hawk about Primroses, May Blobs or Kingcups, Buttercups, Oxeye Daisies, &c. Later in the year the Blackheads, or Banshee Rods (Typha), and great clusters of golden Corn Marigold and fresh masses of purple Heather appear, while "Holly and Ivy" brings the season to a close on Christmas Eve.

Both author and publisher are to be congratulated on the production of a work as fresh in many ways as the flowers themselves of which it treats, and the reader may feel quite satisfied that the rich store of information the book contains is quite up to date and reliable.

F. W. BURBIDGE.

ROSE GARDEN.

ROSES FROM CUTTINGS.

By the time these lines are in print the preparations for obtaining a quantity of own-root Roses should be commenced. Before explaining the *modus operandi* it will perhaps be as well to consider the advantages of own-root Roses over those that are budded or grafted. These advantages consist of (1) immunity from destruction by frost, (2) absence of suckers, (3) continuity of flowering, (4) greater longevity, (5) economy. Considering these five points in the order given, doubtless the first one is of great moment to most individuals. It is very disappointing, not to say disheartening, to see our favourites totally killed by frost, which during recent years has been so severe. Although we can be tolerably safe with budded dwarf plants if moulding up with earth is resorted to, yet there are times when we are caught napping, the ground being too hard to carry out our intentions, and, consequently, our plants are almost, if not quite, crippled beyond recovery. The Manetti stock is very tender. I have seen it killed outright at the root whilst the plant budded upon this stock was scarcely touched. Of course, one remedy for this would be to use the seedling Brier as a stock, but this is not obtainable everywhere, and unless we can be certain of having plants on the Brier, then I say most decidedly own-root plants are the best. If the cuttings are properly made there will be a continuous throwing up of suckers, but we have the satisfaction of knowing that these suckers are also part of the Rose plant. Then again, we have no suckers to cut away. I was surprised to see quite recently in a first-class private garden huge bushes of the Manetti stock growing amongst the Roses. I think had they been mine I would have budded on to them some good popular kinds or cleared them out. Three or four years ago I was looking over some beds of Roses, and could have cut away almost a barrow-load of wild suckers of the *De la Grifferaie* stock upon which had been budded many of the Teas. Now this is not a satisfactory state of things. Perhaps it will be said that no good gardener would allow suckers to remain on the bushes, but it is not always convenient to search for them, and Roses are often planted in positions where to a certain extent they are not always

under our eye. In the third place we have by planting these own-root Roses a better succession of blossoms. This applies chiefly to the Hybrid Perpetuals, because we all know how perpetual the Tea-scented and allied classes are. But with the Hybrids on the Manetti stock, when the first flush of flowers is over there is a great dearth of blossom for several weeks; but with own-root plants this is not the case. Even before a shoot has developed its blossoms another sucker-like growth is making its way upward, to be finally crowned with a grand head of flowers.

Seldom do we find in gardening perfect union of bud or graft and stock. To show that such is the case, even the production of fruit trees upon own roots is freely spoken of amongst professionals, and there is no doubt in the case of Apricots, Peaches, &c., a more healthy class of plant would be the result if the plan could be successfully adopted. As regards Roses budded on the Manetti, let anyone dig up a plant after being planted three or four years, and he will generally find a mass of roots springing from the Rose plant at the junction of bud and stock. This proves that Roses have a natural inclination to make roots, and it certainly is more in accordance with Nature's methods. Were it not for this rooting from the bud, Roses on the Manetti would be very short-lived. On the contrary, own-root plants practically never wear out. We see this in some of the grand specimens of climbers in old gardens. For these climbers, pillar Roses, hedge Roses, shrubby Roses, cemetery Roses, and indeed everywhere where one wishes to treat them as shrubs, own-root plants are decidedly preferable. Then on account of the greater economy of own-root plants I recommend them. If well-rooted plants are carefully put out in good fibrous soil, they quickly overtake their budded brethren, although at first they have poor puny tops compared to theirs. In grouping Roses one does not want to be constantly filling up vacancies, and this we are bound to do if budded plants are employed. There is a saving both in the plants required and in the time occupied in attending to their requirements, also in their production. Good own-root plants may be obtained in twelve months, whereas twenty-four months from the planting of the stocks are necessary to produce budded plants.

Having said this much in favour of own-root Roses, perhaps a few hints as to

#### STRIKING CUTTINGS

will be helpful at this season of the year. I do not advise trying to strike the Tea Roses in autumn. This is best done in July under hand-lights in a very sandy soil. What I recommend putting in now are the Hybrid Perpetuals, some of the Hybrid Teas, Bourbons, Chinas, Hybrid Chinese, Ayrshire and Evergreen, &c. The Gallicas, Mosses, Damasks, Albas and other summer Roses are best rooted from layers put down in July.

The plot selected should be out in the open in full sunlight. Trench the ground at once and work in some good decayed manure and road scrapings. The advantages of trenching are very manifest in a season like we have had this year. Let the land lie for two or three weeks, then it will be ready to receive the cuttings. If a heel can be taken with the cutting, it is a very good practice. These cuttings should be about 6 inches long. The most suitable wood is that which flowered first this season, cut off level at an eye with a sharp knife. Leave the top leaves on and lay the cuttings in the shade in some old fibre until the ground is ready for them. They must not lie about long, because as soon as calused they emit roots, which break off quickly if rubbed ever so slightly. When planting take out a small trench and cut down the soil with a spade, so as to form, as it were, a wall of soil. Place a small quantity of a mixture of old cocoa-nut fibre, sand, wood ashes and pot-mould in the row, and stand the cuttings about 4 inches apart on to this compost, and slightly lean them against this wall of earth. Only just the point of the cutting should appear above ground. Then dig up some soil and give a fair treading to firm the

cutting; then another row about 12 inches from the first one may be prepared in a like manner. Nothing further will be necessary until sharp frosts threaten; then, if possible, cover over all the surface with a layer of leaves or light litter. If the frost draws up the cutting, it must be pushed down again when a thaw takes place, and a favourable opportunity must be seized when the soil is dry to tread the cuttings up firmly. If kept thoroughly clean, the following summer some fine plants will be produced. These should be removed early in October to their permanent quarters. Lift them very carefully, and when re-planting put a half peck of good soil around the fine fibrous roots. I would not recommend putting in cuttings of delicate miffy growers such as Louis van Houtte, Horace Vernet, Xavier Olibo and such like, but varieties of the style of Charles Lefebvre, La France, Baroness Rothschild, John Hopper, Mrs. John Laing, Captain Hayward, &c., strike most freely. To ensure success, put cuttings in early. W. E.

**Rose Duke of Albany.**—The flowers of this are of a rich scarlet-crimson-rose. It is exceptionally valuable as an autumn flowering variety, the colour at this time of the year being very brilliant. The flowers when fully expanded are richly shaded with blackish maroon. It would surely be very valuable to exhibitors, because it is not one of those "catch" varieties that only give one good flower in a season. It is a good grower, not extra vigorous, but quite strong enough. Perhaps it is most suitable as a bush, although it makes a fairly good head on standards. It is a fragrant variety, having very spiny wood and bright pea-green foliage.

**Rose G. Nabonnand.**—It is at this season of the year that the loose, informal Roses are seen in greatest perfection. Although we admire the stately beauty of Maman Cochet, Souvenir d'Elise Vardon, and such like varieties, we are compelled to admit that it is such kinds as G. Nabonnand that best beautify our gardens and houses. This Rose is beautiful in bud; it is doubly so when expanded; then its immense shell-like petals of a soft rosy apricot colour are lovely. It is a splendid grower, making each season a quantity of strong growths of a deep purplish colour—an admirable contrast to the blossoms.

**Rose Mme. Fanny de Forest.**—This Noisette Perpetual is a grand white Rose for pot work. When its numerous blossoms are fully expanded it makes one of the most attractive plants in a collection. Under glass the flowers remain upon the plant a considerable time, and before any of them show signs of decay the whole corymb of buds has expanded, producing a most striking effect resembling that of a huge snow-ball. The flowers are large for this class of Rose, quite as large again as in Boule de Neige, and they are of a very pure white indoors, but outside there is seen a faint tinge of pink. It is a good grower, making solid, rather stiff shoots, but not of the rampant nature of Boule de Neige. As a standard or a bush it is equally useful.

**Rose Kronprinzessin Victoria.**—It seems a pity that raisers of new Roses elect to bestow such outrageous names as the above upon their novelties. If our German and French friends desire to honour their Roses by giving them the names of members of their Royal houses, surely they would not object if our countrymen anglicised them, and thus rendered them more euphonious to our ears. Although this lovely Rose sported from the old Souvenir de la Malmaison some few years ago, it still remains almost unknown, and I believe the name given to it has hindered it gaining popularity. The flowers are very clear and beautiful, of a milky-white colour suffused with sulphur-yellow, flat in form, but very pretty. In all other respects it resembles its parent.

**Mildew on Roses.**—Will you or some of your readers tell me how best to get rid of mildew on my Roses? I read in Dean Hole's book about Roses that "Mr. Rivers recommends soot as a

remedy," and he gives the following quota from Mr. Rivers' letter: "Have you mildew try soot. . . . Perry" (his foreman) "tried sulphur without end, and at last in desperation smothered them with soot in the dew of the morning. This rested on them for four or five days, and was then washed off. The effect was marvellous; the mildew disappeared, the leaves turned to dark green, the buds opened freely, and the flowers were brilliant." So in the "evening of the morning" I tried soot, and the effect was certainly "marvellous," for although rain came the following night and washed off the soot, it killed all the foliage, which was blighted.—AMATEUR.

**Rose Mme. Alfred de Rougemont** is an excellent variety that should be in every garden where good decorative kinds are prized. The whole of these Noisette and Bourbon Perpetuals are well worth growing. They are so useful for cutting, and although they lack the refinement of their rivals, the Teas and Hybrid Teas, they nevertheless have the merit of being quite hard and most of them make capital town Roses. What conduces to the particular attractiveness of the Rose under notice is the exquisite carmine tinted buds, contrasting so prettily with the pinkish white expanded flowers. The blossoms are produced in real Noisette style. The beauty of this Rose, and, indeed, of all the trilled most revealed when trained in pyramidal form and very sparingly pruned. By isolating them in sunny positions in good soil they are very cones of blossom the best part of the summer in autumn.

**Rose Rosette de la Legion d'Honneur (H.T.)**—This pretty climbing Rose must be very popular, albeit encumbered with a few names. Its very tiny buds are each about 1/2 inches deep and of exquisite shape, every one evenly arranged, bending outward at the point forming, as it were, a miniature trumpet. The colour of these buds is brilliant vermilion. They are of them backed up with their own foliage none of the prettiest button-holes possible. The expanded flowers are only semi-double, but are quite unique in their way, for the petals have a broad line of creamy yellow colour extending from the tip of each right down to base. The ground colour of these expanded flowers is a soft carmine, the base being suffused with yellow. The fine sprays of flowers are borne upon good vigorous shoots. It is one of those climbing Roses, such as Longwa Rambler, Gustave Regis, and others, that flower freely when grown as bushes. It will most certainly be in demand by florists when better known.

**Single Tea Roses.**—I was particularly pressed when at Kew last week with the beauty of a bed of Rosa indica var. diversifolia lovely, rich carmine-red single variety. The idea at once occurred to me, "Why not have a collection of autumnal single Roses?" In the autumn of the year, with its cool nights and days, is distinctly favourable to single flowered Raisers of Roses know full well that they obtain a very large percentage of single varieties, and I maintain that if some of the more beautiful single Teas were retained instead of being ruthlessly destroyed, as they are at present, a delightful feature would be added to the garden. The weakly that the opponents of June-flowering single varieties have been enabled to say of them is that they are too evanescent, but I think even this failing would diminish in autumn-flowering single Tea-scented varieties, if not entirely, at least to a very considerable extent. Some of these single Teas possess the most exquisitely formed buds, long and pointed, and it seems a pity that such lovely gems, so rich and pure in colour and so firm in growth and flowering, are not perpetuated in the adornment of our gardens in late summer and autumn. Hard by the variety noticed above would be seen in all its autumn glory the almost single cream-coloured Isabella Sprunt, and a better illustration could be found of the utility of a decorative point of view that a collection of single Tea Roses would produce.

STOVE AND GREENHOUSE.

LILIUM LONGIFLORUM HARRISI.

Proof were wanted of the beauty of the above Lily it is at once supplied in the accompanying illustration. This lovely form is not only the most useful and handsome of its race, but is also ree-flowering and easily grown. It is a Lily to one can mistake, for no other of the long-flowered or trumpet section is exactly like it or comparable with it. This one may be selected readily by experts in Lily culture from the bulbs alone. Indeed, many years ago, before the present final definition was attached to this kind, it was easy to select it from among the best, which were mostly of the typical kind in the original importations from Japan. The same characteristics are only now more fully developed

sometimes thrice the size of those sent from Japan, the best side of this Lily is brought out, and it is no surprise that a variety characterised by freedom of flowering wherever it is known should by culture that suits it to a nicety possess this in a still greater degree. It is no uncommon occurrence for the largest bulbs of this Lily, producing only five or six flowers from ordinary bulbs, to produce quite double that number from much larger bulbs. But to ensure retaining all its powers intact in this direction there should be no time lost in getting the bulbs into the soil the moment they arrive in this country. Indeed, it should be remembered always in this connection that a Lily grown in Bermuda and shipped to England has already had a much longer season out of the earth than is at all needful for any Lily; and of the long-flowered section this is

may be planted in pots from 5 inches to 7 inches across, that is to say, giving them the pot in which it is intended they should flower. In my experience, this is to be preferred to any subsequent repotting after growth is well advanced. With these importations the roots and stem growth are produced with singular rapidity, and in a few weeks the latter has made its appearance through some 6 inches of coal ashes, while the pots are also filled with roots. Usually these Lilies are in a sound, plump condition on arrival, and all that is needed is to free them from the rough sawdust or other material forming the packing prior to potting. Having no root fibres, a soil fairly moist without being in the least adhesive is best for potting, and to this no water need be given. Plant the bulbs quite firmly in a good sandy loam with which some bone meal has been

*Lilium longiflorum Harrisii.* From a photograph by Mr. F. Mason Good, Winchfield.

Since the culture of this Lily has been so much a feature in the Bermudas. In the typical *L. longiflorum* the base of the bulb is small, widening to the top, which is distinctly flat, while the scales of the scales are arranged in a slight depression. In the Lily now under notice, which is known generally as *L. longiflorum eximium*, the scales are of more uniform size throughout, while the bulb as a whole is so distinctly conical in shape that a glance will decide. The growth of the leaves is also distinct, and so also the arrangement of the flowers on the stem, as well as the aspect of the blossoms. The Bermuda-grown bulbs of *Harrisii*, however, are more vigorous than those of the same variety from Japan. But this does not alter or change the well-defined characteristics. By a system of culture that often produces bulbs twice and

especially true, seeing that in a greater or less degree these are closely akin to evergreen when left alone. It is this fact, indeed, and the readiness to start into fresh growth as soon as flowering is well past that cause the loss of this secondary growth, and often some injury to the bulbs. It was also this fact that gave rise to the theory, long since exploded, that this Lily flowered twice and sometimes thrice in a season. That it is a grand Lily for either pot work or the open ground there is no doubt whatever, but any bulbs intended for the latter if of Bermuda growth should not be planted out in the open till severe frosts are past.

The annual importations from Bermuda usually reach this country in September, and if possible should be potted without a moment's delay. According to the size of the bulbs, they

mixed, and plunge overhead 6 inches deep in a bed of coal ashes. Here they will be safe without water for at least three or four weeks, by which time the stems will be piercing through the plunging material. In the event of wet weather following the potting, the bed containing them should be covered with lights or sheets of corrugated iron to throw off the rain, examining from time to time so that the points do not come into contact with the iron. As soon as up a frame should be placed over them, or remove the pots to a rather deep pit where ample light and ventilation can be given. To leave the pots too long in the plunging bed is to tempt the roots to the surface, and sometimes the formation of stem-roots also, and these perishing by subsequent exposure cannot influence for good, to say the least. Do not place

them in the greenhouse too hurriedly, and when there endeavour to keep them scrupulously clean. Better anticipate green fly, and fumigate in advance, for once it gains a footing in the points of these Lilies it is most difficult, as well as expensive, to eradicate. E. J.

#### SOLANUM CAPSICASTRUM.

THIS useful plant is extensively grown for market, some growers keeping their plants under glass the whole season, while others stand them out in the open quite early. They are usually propagated from cuttings, though some growers depend on seedlings, which, if selected from a good stock, make good plants, but they do not always set their berries so freely as those from cuttings. Cuttings should be put in in January, or even earlier. They may be obtained by putting some plants into heat. All the berries should be taken off and the plants will soon start into growth. Short cuttings from the new growths root freely in a close pit where there is a good bottom-heat. To succeed with Solanums it is essential that they should be potted off as soon as sufficiently rooted, and they must not be checked in any way. During the earlier stages they may be grown on in heat, and later on they will do well in pits, or, as I have previously said, they may be placed out in the open, but should have a sheltered position. Plants grown from cuttings begin to flower early, but if kept well syringed it will prevent them setting berries, or if they do set their berries before the plants have made sufficient growth they must be taken off.

Solanums may be potted in good loam, with a liberal addition of well-rotted manure, and after the pots are well filled with roots, liquid manure may be used freely until the time for setting the berries. At this period the syringe must be withheld and a good circulation of air kept up. After the plants are well set with berries, manure may be used again, and the syringe must also be used freely, otherwise red spider and other insects will be troublesome. An early hatch which has been kept under glass throughout the season is now well covered with ripe berries. Although it is rather early, they come in very useful, and with careful attention the berries will hold on well up to Christmas, but if allowed to get too dry or given a great change in temperature, the berries may drop much sooner. H.

**Winter-blooming Carnations after flowering.**—How to treat these after blooming is a question frequently put by amateurs, and I have occasionally to reply to it, for the desire to have a few Carnations bloom during the winter appears to be keenly felt by a good number of amateur cultivators; yet I find that the "Carnation Manual," which is supposed to deal with the details of culture of every type of the Carnation, is absolutely silent on this point. There are full details as to the striking of cuttings and growing them on into size to flower, but details of treatment after flowering are wanting. Even the yearly calendar of operations is silent as to the treatment of plants after they have flowered for the first time. If the National Carnation Society at any time should bring out an edition of the work, a further chapter dealing with this particular point may be added with great advantage. Many amateurs who have no convenience for propagating by means of cuttings desire to grow on a plant for two or three seasons.—R. D.

**Summer treatment of Cyclamens.**—Cyclamens are a special feature at Carrow House. The old system of growing Cyclamens through the summer in frames behind north walls is fast dying out. In such a position good plants have been and still are grown, but in dull, rainy seasons the plants often go wrong, the leaves suddenly turning soft and the footstalks falling down. The plants do not dry often enough and many of the roots perish. When the frames stand in an open position, as at Carrow, shading of a light nature

can be given just when the plants need it, it being withheld in dull, sunless weather. Plenty of light then reaches the plants. I was rather surprised at the size of Mr. Jones's plants, as the seed was not sown till October, a rather late date, and the plants now occupy 6-inch pots and are from 9 inches to 1 foot in diameter, the foliage of many being beautifully marbled. Mr. Jones is opposed to the use of cow manure, though it is frequently recommended for Cyclamens, as he once had an extra good batch suddenly collapse, the leaves one by one withering. On examination he found a colony of small grubs had attacked the bulbs, these, in his opinion, being introduced with the cow manure. The latter he now excludes from the potting compost, and that its use is not imperative is proved by the fact that many gardeners grow splendid Cyclamens in loam, leaf-mould and grit alone, feeding cautiously when the pots are well filled with roots. In airing the plants when standing in frames through the summer months, care should be taken to avoid draught, as this soon causes the leaves to flag and often wither. As autumn approaches great judgment is needed in watering. Far better err on the dry side, although the happy medium is what should be aimed at. Weak farmyard liquid given about twice weekly is the best and safest stimulant for Cyclamens.—J. CRAWFORD.

#### HOUSING TREE CARNATIONS.

No time should now be lost in placing these under cover. The very heavy and continuous rainfall of late has done much to sodden the plants, and where these are grown in very large numbers and in large pots for market, it is well-nigh impossible to provide frame room accommodation for them all, or even to place lights temporarily over them. Indeed, there is a good deal of risk even in the latter, particularly when the weather is rough and boisterous, as it has been of late. In such a case it is not possible to provide any temporary structure, and the next best thing, or perhaps the best thing under all the circumstances, is to house the plants without further delay. Late-rooted batches have not made so much progress as usual under the great summer heat, but with moister weather and cooler nights considerable progress has been made, and the plants generally are therefore promising. Should the heavy rains continue and for various reasons the plants cannot be taken in-doors, it will be well to lay all the pots on their sides and so prevent the soil becoming unduly soddened. Few plants, taken all in all, are really more delicate in their rooting than these Carnations, and for this reason they are more likely to succumb to over-much water at the root, especially when a low temperature prevails. When the plants are again placed in the greenhouse, all the air possible should be given, and an endeavour made to get the plants thoroughly dry at the root. Indeed, no plant in my keeping will receive water at the root for at least a week, even though the weather be very hot, in which case a very fine spray from the syringe overhead will be given to ward off red spider. It will also be well, when removing any small weeds, to lightly prick over the surface soil so as not to disturb surface roots too much. This will also assist in drying up the soil, which for the time is the most important matter. It is a good plan always to cleanse every house before bringing in the plants. This in my case is done by fumigating with sulphur and a few hot cinders, well filling the house with a blue cloud, and so dispersing much that cannot be detected with the naked eye. The walls and bare places are also well washed with lime in which has been thoroughly incorporated a 4-inch potful of sul-

phur, first mixed to the consistency of thick mustard. Thoroughly working this into the brickwork serves as a deterrent in the future against all insect life. When the plants have become dry enough to permit of it, a good all round syringing of clear soot water will be found of service, as it is equally while the plants are in the open. Some growers at the time of housing give artificial manure as a top dressing, but I strongly advise keeping clear of all of them. A very small application may be tolerated in January or February, but certainly not before for plants that have been propagated within the present year. Clear rain water, or with a little soot occasionally added is all the plants will require to the end of the present year. After housing a very careful supervision must be maintained over the watering, for no plant will more quickly resent care less or indifference in these details. Where a good collection of Tree Carnations is grown, the most careful workman only should have to do with them, or, better still, the principal himself should personally attend to their wants in this respect at least. E. J.

#### FERNS.

##### PTERIS TREMULA.

THE ease with which this species may be grown and its hardiness, fine appearance, and lacin qualities render it one of the most useful Ferns in cultivation. It is one of the best for indoor decoration, and if slightly hardened before being used will last several weeks in good condition. *P. tremula* is perhaps the freest seedling Fern in existence, the back of the fronds on large plants being nearly covered with spores. The ripe fronds should be cut and shaken over a piece of white paper to collect the spores, which should be kept in a dry cool place until they are required, and the sooner they are sown the better. If a dam wall or stage in a fernery or stove is at command they may be sown on this, as they will germinate almost anywhere, or pans of crock and a little rough peat and loam may be prepared and placed in a shady, warm house. They must be kept regularly and constantly moist without sprinkling them heavily with water, as this is apt to swill many of the spores away. A green film over the surface is the first indication that germination has taken place. Soon after the tiny young leaves appear, when they may be pricked off in very small patches into pans or small pots. No amount of care will ensure all the plants coming true, and often Ferns of entirely different species will come up. *P. tremula* shows its distinctive characteristics very early, and as soon as the young crowns can be distinctly seen they may again be divided, this time pricking them off singly around the edge of small pots in a light and open description of compost. Though strictly a greenhouse species, they may be given more warmth now if it is desired to hurry them on, but keep in mind that the more air and less heat they get the longer the frond will last either in a cut state or on the plant. In any case growth is rapid, and they must never become pinched for root room until they have reached the size intended for use. Small plants in 3-inch pots are very useful for standing singly on the table or for grouping with flowering plants, and it is one of the advantages of this kind that a nicely furnished plant with a head a foot or more across may be grown in the size of pot mentioned. There is hardly any arrangement of plants that this Fern may not be used with, the light graceful stems standing

all up, lightening the effect of other plants, which lose nothing by contrast with them. The large flat epergnes in which flowers and fruit combined used to be arranged are not much used as formerly, but where they are used the cut fronds of this Fern set off the fruit admirably. There are also many cut-flower arrangements that are improved by its use in place of the popular Maiden-hair, which it surpasses in lasting qualities. It is also a capital kind for a planted-out fernery where there is plenty of room for its full development, but it is a mistake to plant it among dwarf kinds, as it soon overgrows its station

a widely distributed plant in Australasia, and was introduced in 1820. R.

ASPLENIUMS.

Those of the bulbiferum group are so readily increased from the bulbils, or young plants produced on the surface of the fronds, that there is little need to trouble about raising stock from spores; hence we get very few garden varieties from these. It is remarkable that nearly all the Aspleniums are more difficult to raise from spores than many other Ferns, but as many can only be propagated by this means, it is necessary to persevere. In the first place, they do not germi-

I have seen some distinct forms, and many intermediate between the two above named. In many instances it would be difficult to say to which they belong. *A. pteridooides* has also shown some variations, among which may be mentioned *A. Mayi*, a very distinct and beautiful variety with rather long, arching, pinnate fronds of a rich deep green. Among seedlings of this some prove true, while others vary, some showing some affinity to *A. Baptisti*. *A. Herbsti* is another distinct variety, the parentage being doubtful, though it shows some characteristics of *A. lucidum*; the broad pinnate fronds grow nearly erect, the pinnae are irregular in shape, some being deeply cut and others entire. It makes a most effective plant, and if it should come true from spores it will undoubtedly become a favourite Fern. There are few more useful Ferns than *A. lucidum*, but being difficult to raise and very slow in a young state, it is not likely to ever be over-plentiful.

There are very few crested Aspleniums, except those of our British Lady Fern. *A. Drumii* is an exception; this belongs to the *Baptisti* section. It has rather broad pinnae, each terminating with a flat, almost circular crest. Seedlings vary somewhat, but in its best form it is a very distinct variety. One great advantage of the Aspleniums is that when once established they keep in good character for a considerable time. H.

PARK AND WOODLAND.

THE CORSICAN PINE AT HOME.

The prospect held out to us of a visit to the Corsican Pine forests was a tempting one. We remembered a reply made by a *garde général* in Corsica to the directors of the exhibition of 1867: "Impossible to send you, as you ask, sections of the trunks of our tallest *Laricios*; our longest saws are shorter than the diameters of our great trees." Then there were the more recent impressions got from the accounts of travellers in Corsica, and eloquent descriptions, concluding with the inevitable advice to "make haste if we wished to see really ancient trees and forests in their natural state." An excursion to Corsica was planned in the spring of 1897, but for various reasons the original band was reduced to four. These found their way to Ajaccio under the guidance of a Corsican, by adoption if not by birth, M. Doumet-Adanson, who was so suddenly stricken by death after our return to France. In Ajaccio we were cordially welcomed by the Conservator of Forests, who gave us some valuable information on the present condition of the Pine forests. M. Mabaret also insisted upon planning out an itinerary for us, which enabled us to see the best examples of *Laricio* in the limited time allowed to us.

The majority of the Corsican Pine forests are very easily approached to-day, the department of Bridges and Highways having constructed some marvellous roads, but there are other forests situated in remote valleys which are still only to be reached by way of mule paths and goat tracks. In these the largest trees, even when decayed, are still left standing, as their removal cannot be economically effected; also isolated trees situated in the rockiest and least accessible places remain intact for the same reason. Our party, which included one person already advanced in age and in delicate health, was not equipped for journeying over mule paths and scaling goat tracks: the finest forests within our reach were, therefore, those of Aitone, Valdoniello, Vezzano, Marmano, and Bonifato, the four first being situated in the department of Corte, and the last in that of Calvi, and all being intersected by good roads.

The Corsican Pine at home. From a photograph by Mons. Maurice Vilmorin.

and smothers perhaps choicer and more rare kinds. In a large house a single large plant of in a prominent position has a noble appearance. As to compost, it is by no means fastidious, especially when it gets beyond the first stage. Light fibrous loam mixed with half its bulk of peat-mould and a plentiful addition of sharp river sand suits it admirably. It is safe in winter in a moist house kept at a minimum temperature of 40°. There is a crested form of *P. nemula* in cultivation which by some is thought to be an acquisition, but it is certainly less beautiful and not so easily grown as the type. This is

nate so quickly as many, and are liable to be smothered by *Pterises*, *Gymnogrammas*, and others, but this may be obviated to a great extent by isolating the plants from which spores are to be taken, and taking care that no other spores exist in the soil used for sowing on. In the case of *A. Nidus*, occasionally quite a good crop may be obtained, yet I have known many failures, especially when the spores have been taken from young plants. One great point of interest in raising seedlings is that some variety is sure to be found.

*A. Baptisti* and *A. Neo-Caledonic* belong to a very distinct group, and from seedlings of these

Those which offer most readily to the eyes of the tourist the finest trees set in the most picturesque surroundings are the forests of Valdomiello and Marmano. The vale of Asco is almost alone at the present day in being still able to show some ancient trees as yet untouched by the hand of the exploiter, but we were forced to abandon this part of our excursion, which, however, has a place in our plans for the future.

The finest specimens of *Pinus Laricio* we saw did not exceed 19 feet 6 inches in circumference. Trees of 14½ feet to 15½ feet in girth were frequent enough; some of these were more than 130 feet high, but the mean height of fine old trees is about 120 feet. In the forest of Marmano, near to the pass of Verde, the highest and also the best shaped trees were to be found, the dimensions of these being 11½ feet to 14½ feet round by 130 feet high. They grow in clumps by themselves or pretty thickly mixed with Beech and a few Firs. The *Laricio* in Corsica is found on the slopes of mountains with a marked preference for a northern exposure. Commencing at about 2950 feet, the limit of the Maritime Pine, it reaches an altitude of about 3400 feet. At this point it becomes rare, not because it does not thrive at such an altitude, since fine specimens are also to be found at the extreme limit of the forests, but because these highlands are pasturage in summer for flocks of sheep and goats. Outside this high zone replanting from seed is very easy; the great danger to the young forest arises from the risk of fire during the hot, dry summer months. In the older parts of the forest the risk of destruction by fire is less, the trunks of the trees being stripped of their lower branches and the underwood being generally choked off by Pine. The groups of trees are as close and as regular as in our continental forests of Picea and Silver Fir. This is especially so in certain parts of the Aitone forest, which is one of the most regular as regards growth. But the full picturesqueness of *P. Laricio* is best seen in the higher limits of the forests. Here the growth is sparser, because the conditions of existence are harder, but chiefly because the majority of the plants have been cut down by the sheep and goats. In its struggles with wind and snow the tree is not so high; the trunk thickens and throws out some powerful branches, the leader is destroyed, and the crest becomes flat and spreading. Looking at certain *Laricios* in the vicinity of the pass of Saint Pierre, between the limits of the Aitone and Valdomiello forests, it is difficult not to believe that they are Atlas Cedars, as these grow on the highest of the Algerian mountains. —MAURICE DE VILMOREN, in *Revue Horticole*.

**Caryopteris mastacanthus.**—The bright purplish blue blossoms of this Chinese shrub are quite unlike anything else in bloom at the present time, and being very showy withal, it is a plant well worth consideration where a suitable position can be found for it. This *Caryopteris* forms a bushy-growing plant that reaches a height of from 3 feet to 4 feet, and is clothed with deeply-toothed, oblong-shaped leaves, which are particularly hairy. The flowers, which are borne in axillary clusters on the upper part of the stem, are so numerous, that the greater portion of the plant is quite a mass of blue. It cannot be regarded as thoroughly hardy in this country, but is just one of those subjects well adapted for planting at the foot of a low wall along the front of a greenhouse, or even warmer structure, as in such a position the wood is thoroughly ripened, thus ensuring a good display of bloom. If cut back by the frost during the winter it quickly recovers, and flowers again the following autumn. In many places on the Continent it is more popular

than it is in this country. This *Caryopteris* was one of the great number of beautiful plants introduced by Robert Fortune, but it would appear to have soon been lost. For its re-introduction we are, I believe, indebted to Messrs. Veitch, through their collector, Mr. Maries, who visited China and Japan about the year 1880.—T.

**Desmodium penduliflorum.**—This is a very beautiful autumn-flowering plant usually classed with the shrubs, though at most it is only of a half-shrubby character, as after flowering it dies nearly to the ground, and pushes up the next season's shoots from a few large buds near the base of the plant. These shoots are long and wand-like, the most vigorous reaching a height of 6 feet or more. They are rather thinly clothed, especially towards the base, with trifoliate leaves, while the upper part is occupied by crowded racemes of bright rosy purple, Pea-shaped blossoms. These flowers are borne in such profusion as to quite weigh down the shoots unless some support is given. All stiffness and formality in this respect are avoided if two or three of the principal shoots are tied to sticks and a few of the others looped thereto some little time before the flowers expand, as by then the shoots will dispose themselves in a very graceful manner, and display the wealth of flowers to the best advantage. This *Desmodium* usually commences to bloom about the middle of September, and continues for some time. Early autumn frosts, however, occasionally injure the blossoms. The plant itself is perfectly hardy. This *Desmodium* used to be frequently met with as *Lepedeza bicolor*, a totally different plant, and it is now at Kew known as *Lepedeza Sieboldi*.—T.

## DESTROYERS.

### A LILY BULB DISEASE.

DURING the past year a destructive wave of fungoid disease almost completely ruined the crop of Lily bulbs raised in Japan for exportation to Europe. The first indication of this disease received at Kew was through Messrs. Tozer Bros. and Co., of Gracechurch Street, who sent a large number of diseased bulbs for examination. These bulbs formed part of a consignment received from Japan in November last, consisting of 848 cases, containing 73,050 bulbs of *Lilium speciosum* (Thun.), album, and rubrum. Out of this number only 250 bulbs arrived in a saleable condition, the whole of the remainder being more or less rotten and worthless. At a later date the same firm received a second consignment of 37,590 very large bulbs of *Lilium auratum*, and out of this quantity only 4000 were saleable. Similarly diseased bulbs received from Japan were afterwards sent to Kew for examination from other sources. Finally, a quantity of bulbs obtained through an agent from Japan, for planting at Kew, contained a large percentage suffering from the same type of disease. The bulbs received for investigation showed every stage of disease; in the earliest condition, the base of the bulb is alone discoloured and somewhat soft; this discoloration and softening of the tissues gradually spread from the base, until finally, in the most advanced stage, every part of the bulb is of a brownish colour, and sufficiently soft to admit of being readily crushed into a pulpy mass between the fingers. Microscopic examination revealed the presence of slender, continuous, hyaline, branched hyphae traversing the tissues in every direction; the cell-walls are never pierced, but gradually dissolved, and it is only at the last stage of the disease that the starch grains become irregularly corroded and gradually dissolved. So long as the epidermis of the bulb-scales remains intact there is no trace of mycelium or fructification on the surface, but when the tissue is reduced to a soft pulp, or when a diseased bulb is cut open, the broken surface is within twenty-four hours covered with a dense snow-white mycelium,

which within three days becomes studded with numerous clusters of fruit, resembling to the naked eye miniature pins with round black heads. The occurrence of this particular form of fungus on every bulb examined suggested that it might possibly be in some way associated with the disease, and subsequent cultures and inoculation proved this surmise to be correct. The fungus grows readily as a saprophyte, the spores germinating and forming the characteristic superficial white floccose mycelium, which within a week bears an abundance of fruit, on such variegated culture media as prune juice, sterilised potato decoction of bulb scales, &c. In one experiment four spores were sown in a 5 per cent. solution of cane-sugar in water in a Petri dish, and at the end of six days the entire surface of the liquid was covered with the fungus in a fruiting condition. When spores were sown in a hanging-drop along with a very thin section of Lily bulb-scale, it was observed that the germ-tubes could not enter the tissue through the epidermis, but that they entered readily at those points where the cells were not protected by the epidermis.

A set of experiments was also carried out using healthy Lily bulbs, some of which were furnished by Messrs. Tozer, for inoculation. For the purpose of destroying stray fungus spores the bulbs were immersed for a quarter of an hour in a 1 per cent. solution of corrosive sublimate. The bulbs were afterwards placed in wide-mouthed flasks filled with sterilised tap-water containing 5 per cent. solution of cane-sugar, the base of the bulb being immersed in the liquid; finally, the entire bulb was covered with a sheet of cotton wool soaked in a 1 per cent. solution of corrosive sublimate, the cotton wool being tied round the neck of the flask. When the roots were about an inch long an attempt at inoculation was made as follows: The numerous cultures of the fungus furnished a large supply of spores, which were tested and found to germinate readily. These spores were collected with a wet camel's-hair brush and washed off into a small amount of sterilised water in a flask until it became discoloured by the quantity of spores present; this was the inoculating material. A quantity of this spore-carrying water was added to the water in which two of the bulbs were growing, care being taken not to injure the roots; the inoculating liquid was also deposited freely between the scales of the two bulbs, which were then covered with sterilised cotton wool as before. The water in which two other bulbs were growing was inoculated as above, but the roots of the bulbs were broken off. Finally, 1 per cent. of salicylic acid was added to the water in which two more bulbs were growing a copious supply of the inoculating water added to the roots of the bulbs broken off, the bulbs replaced, and, as in the other instances, protected with cotton wool. At the end of six weeks the two bulbs whose roots were not destroyed appeared to be quite healthy; they were the plants in soil, and are still growing and show no indication of disease. The two bulbs with broken roots showed signs of disease at the end of three weeks after inoculation, and at the six week period the disease had extended nearly half way up the bulb from the base. After being cut open the same kind of fungus showed itself on the surface that has been described as occurring on the bulbs received from Japan. The companion bulb was also diseased, and in about three months was soft and rotten, and covered with the fungus in a fruiting condition. The two bulbs with broken roots that were growing in water containing 1 per cent. of salicylic acid remained quite healthy, made fresh roots, and are still living.

Numerous experiments were made with other kinds of bulbs, and it was found that the fungus refused to grow on Onions, however much mutilated. On the other hand, Daffodil bulbs are very susceptible to the disease; if the roots are broken, or a wound made in the bulb and afterwards powdered with the spores, the disease showed itself within a few days, and was in due course followed by the characteristic fruit of the

fungus. It was invariably found that, however much bulbs were mutilated and then inoculated with fungus spores, submergence for a few minutes in a 1 per cent. solution of salicylic acid or corrosive sublimate prevented the disease; in other words, all fungus spores coming into contact with the above-named solutions are destroyed, whereas the vitality of the bulbs thus treated is not at all affected. Dr. Halstead has described\* a somewhat similar disease, called "soft rot," attacking the sweet Potato in the United States. The fungus causing this disease (*Rhizopus nigricans*, Ehrh.) is closely allied to the species under notice causing the Lily bulb disease. In addition to the kind of fungus fruit already described, a second form, of sexual origin, called zygospore, is present in the genus *Rhizopus*; several large, spiny zygospores were found in the matted mycelium present on bulbs in the last stage of decay, and presumably belong to our fungus. Zygospores differ from the minute spores already described in requiring a somewhat lengthened period of rest before they germinate, and this means tiding the fungus over that period of the year not suitable for its growth, and germinating when favourable conditions, climatic and otherwise, return. During this period of rest the zygospores remain in the soil, or attached to the substance on which they were produced. The minute spores previously described possess the capacity of germination the moment they are mature, and enable the plant to extend its area of distribution; and these spores are produced very quickly and in immense numbers, it can readily be understood how rapidly the disease spreads when once introduced into a given locality. The fungus causing the Lily bulb disease, although allied to *Rhizopus nigricans*, is quite distinct from this and every other known species.

SUMMARY.

The Lily bulb disease is caused by a parasitic fungus called *Rhizopus necans*. The fungus cannot penetrate the unbroken tissues of the bulb, but gains an entrance through wounds, more especially rotten roots. The amount of evidence forthcoming indicates that the bulbs are not diseased until after they are removed from the ground. The pores of *Rhizopus necans* are killed by a short immersion in a 1 per cent. solution of corrosive sublimate or of salicylic acid. Neither of these substances has any injurious effect on living bulbs, provided they do not remain in the liquid for more than fifteen minutes.

PREVENTIVE MEASURES.

The fungus is by no means confined to Lily bulbs for its food, but, as experiments have proved, can live on a great variety of dead or decomposed substances; it may also occur as a parasite on other plants than Lilies in Japan, as it readily attacks and destroys Daffodil bulbs. Judging from the enormous amount of injury caused, it would appear that the fields where the Lilies are grown must be saturated with the fungus, growing indiscriminately on various substances, and attacking the Lily bulbs, along with other things, as a matter of course. If practicable, entirely new localities should be selected for the work. Even if this were done, great care would have to be exercised, so as not to introduce the fungus. The spores are readily conveyed from one locality to another in the soil, in tools, cart wheels, shoes, clothing, &c., in addition to being carried by wind or animals. An important point to remember is not to allow vegetable rubbish of any kind to accumulate, and all diseased bulbs should be burned and not allowed to remain on the ground, otherwise the zygospores that form on such old decaying bulbs would start the disease the following season. As little injury as possible should be done to the roots of the bulbs when they are removed from the ground, and the bulbs should be allowed to sweat\* before they are packed for exportation.

\* New Jersey Agricultural College Experimental Station, Bulletin No. 76.

If the fungus is known to be present when the bulbs are being prepared for packing, they might be placed in a solution of salicylic acid as advised. The sterilised earth in which the bulbs are packed appears very suitable for the work, and cannot be in any way considered as a cause of the disease.—G. MASSEE, in *New Bulletin*.

KITCHEN GARDEN.

POTATOES.

On the whole this cannot be considered one of the most favourable seasons for this crop, for those who planted early had them cut down by the late spring frosts, while those who deferred planting till later in the season had to contend with the dry weather which visited us in July before the tubers had made their full growth, this causing a serious check. In this district the soil is very heavy; therefore, not suitable to the growth of fine tubers. Still, where the ground is properly tilled some very good crops and fine roots are obtained, and even this season there is little to complain of. The early kinds were quite up to the average, while those which are considered midseason varied very much, some being a full crop and others not so good. There is, however, one great advantage, as no disease has presented itself. Amongst the new varieties grown the palm must certainly be given to Carter's Snowball. The tubers in appearance much resemble those of Satisfaction, but they are much rounder than in that variety, have a rough skin and shallow eyes. This is a white Potato of great promise, being a good cropper and free from disease. The haulm is, however, too strong for small gardens, for with me it grew about 4 feet in height. Veitch's Main-crop is a nice variety, having even tubers of medium size; with me there was no disease. English Wonder was fair, but not so good as either of the previous named. Reliance was very fine indeed, the tubers being of fair size and even in shape; this promises to become a favourite. The finest crop of any was produced from tubers sent from New Zealand. These were dug up in February in the antipodes and sent by post. It was early in May when they reached me, and after being exposed for a short time were planted, the yield from one pound being sixty-three. The tubers are even in shape, of fair size, with shallow eyes. The account I had with them was they were the best in the colony. Of the older kinds, Syon House Prolific was very good, so were Supreme, Triumph, Windsor Castle and Flourball. The dry weather in July caused a serious check to the last variety, many of which, having set the skins prematurely, super-tuberated owing to so much wet during the latter part of August. Over 3½ inches of rain fell here during that month, which saturated our heavy land to its fullest extent, particularly in low-lying places. To grow fine tubers on such ground is no easy task. Disease, however, seldom follows rain, unless there is a close, hot atmosphere, and as August, on the whole, cannot by any means be said to be close and hot, there is every hope of the disease passing by. Crops, as a rule, will not be so heavy this season as they are sometimes, unless in districts that were more favoured with showers than this, and where the soil is in a better state of cultivation. I never use any fresh manure for Potatoes, and this I have no doubt is the reason there is so little disease, superphosphate of lime being the only artificial dressing the ground has, and this is given at the time of planting.

Busted Park, Uckfield.

CABBAGE SPROUTS.

I do not agree with the views expressed by "S. M." (p. 155) as to the superiority of young first crop Cabbages during autumn over the sprouts or second crop of hearts made by the main spring crop. On the contrary, given good treatment I fail to see any falling off in the quality of the latter, for autumn rains and cooler nights tend to produce hearts which may be somewhat smaller than those of the first cutting, but which are quite tender and good eating. I consider that a Cabbage bed once cut over has not done half its work, and that the rooting up of the stumps at that period is altogether wasteful, as there are but few things, with the exception of Celery, for which the ground thus cleared is suitable, as one would not expect good results from an immediate re-cropping with any of the Brassicas. As regards the plea of exhaustion of the soil, nearly all the Brassicas do this more or less, but Cabbages at least will come off in good time to allow of manuring and digging taking place during winter, when the ground may be put in good heart for almost any of next year's crops. We do not destroy our Brussels Sprouts and the like until they have finished up the whole of their sprouts, although allowing them to do this drives digging operations well into the spring months, and I fail to see why we should not get full value out of our Cabbage beds in the same way. I grant that a young Cabbage bed looks better than a sprouting old one, but this appears to be the only advantage, and, on the other hand, economic reasons for leaving the latter might be given in plenty. First we have the question of labour; the old bed gives two crops as a result of one preparation; again, there is no hesitation in commencing to cut in spring as soon as hearts are at all fit, for there is the knowledge that a second crop will come as the result of this cutting. Then, too, in a closely-cropped garden it is sometimes a little difficult to find room for all the green stuff that it is necessary to plant during summer, and having to plant, perhaps, a large plot of Cabbages especially for autumn use would only add to this difficulty and leave less room for the hardier Coleworts, Savoys, and Kales that do duty in winter and spring. Given the right varieties, for all Cabbages do not form good-hearted sprouts, I think that old Cabbage beds justify their existence until winter frosts put an end to them.

J. C. T.

**Beets.**—In a garden where there were growing very fine rows of Beets, Dell's Crimson and Nutting's Dwarf Red being singularly good and true, even to colour and texture of roots, which I tested, a stock that is termed selected was sadly marred by having prominent in it numerous coarse red Mangold Wurtzels. This mixture could not have been due to bad selecting, as such things would never have been found in any good Beet stock, and the inference is that some Mangold Wurtzel seed was either negligently mixed with the Beet seed, or else some was left in the cleaning machine. The fact serves to show how very careful seed growers and seedsmen should be, as a little lack of care may thus be productive of grave trouble to the gardener, who, as a rule, has enough burdens to bear that may seem to be unavoidable.—A. D.

**Potato Syon House Prolific.**—Having just finished lifting late Potatoes, I am much struck with the heavy crop of handsome tubers produced by the above new variety, and if the quality, which I have not yet tested, is right, there is no doubt it is the finest introduction of late years. From twenty-four cut sets planted with no extra advantage of room or manure over the other main crop varieties, there were lifted two bushels of magnificent tubers, this being far and away the best crop in the garden, and especially good for such a dry season. I am pleased to note, too, that it sustains its character as a disease resister, for the haulm remained green and growing later than did that of those old and tried varieties Magnum Bonum, The Bruce, and The Gentleman. The tubers are above medium size, pebble-shaped,

rough in the skin, characteristics that all tend towards popularity. I should imagine that Syon House Prolific will make a first-class main crop field Potato, as the haulm is robust enough to withstand ordinary field culture, and the tubers will bear some toning down in size.—J. C. TALLACK.

**Potato Ashleaf Kidney.**—How wonderfully well this fine old Potato, literally the oldest in commerce, holds its own against all comers. I have in the past used pollen from it to intercross with Puritan, Beauty of Hebron and others to endeavour to obtain the fine Ashleaf earliness and flavour with the American crop, but I never have quite succeeded: neither, so far as I know, has anyone else. The Ashleaf has in tuber form, in colour of flesh, and in undoubted flavour, as well as earliness, characters all its own. It serves to show amongst Potatoes how closely yellowness in flesh is identified with flavour. Mr. Crook has a beautiful stock of the old Ashleaf at Forde Abbey. He obtained it originally from Norfolk, where it has been grown for many years. The Chard soil seems to suit it admirably. I could not sympathise with a gardener in a large place who the other day showed me a long border of Magnum Bonum which he had purchased and planted last spring as Ashleaf Kidney.—A. D.

**Large Peas.**—At page 155 "S. M." refers to a note of mine on large Peas, and sees no reason to find fault with them. I myself did not condemn them, but my employer did, and I have known several instances in which employers have done the same thing, apparently considering very large Peas vulgar in the same way that they would a large head of Cauliflower, large Broad Beans and the like. For my own part, a Pea cannot be too large, provided it is tender and of good flavour and colour, but gardeners have to study the fancies of their employers, and I have more than once read and heard of the latter objecting to the very large types of Marrows. Where this is the case the medium varieties named in my notes will be found to give general satisfaction, a thing all second-sized sorts will not do in hot, dry summer weather, as the haulm is generally less vigorous than that of larger podded sorts.—J. C.

**Cauliflower Eclipse.**—I was pleased to read Mr. Tallack's note (page 115) on this Cauliflower. I will remember it first being distributed by a Manchester firm, and it being found, as Mr. Tallack says, most useful for affording a supply in late summer, or to fill the gap between secondary batches of Walcheren and the earliest lots of Autumn Giant, a most trying season for Cauliflowers. I was employed in a garden where some seed of Eclipse was sent for trial previous to its being sold to the public, and the vigorous habit of the plant in a dry season, and the compactness and whiteness of the heads were noteworthy. It was much grown in Essex, being sown in the open in March and April in preference to Walcheren. Good as the latter variety is in fairly moist seasons and on good deep soil, it soon suffers in time of drought on poorer soils, much sooner in fact than Eclipse.—C. C. H.

**Parsley for winter.**—A common reason of gardeners having an insufficiency of good Parsley for use in winter is either depending on spring sowings to carry them through the summer and to afford fronds for the winter months as well, or sowing too late in summer for the winter supply, matters in the latter case being sometimes made worse by hot, parching weather. In cool, deep soils the difficulty is not so great. A friend of mine who needs a good supply of Parsley all through the winter recently informed me that he makes but one sowing, say in April, and afterwards transplants, say, in June, when the young plants are large enough for moving. The undisturbed portion of the seed-bed affords gatherings through the ordinary summer months, while that transplanted is in good trim by August, and remains vigorous and profitable right on to sowing time in April again. It is transplanted into beds to suit frames, which are

placed over it when frost arrives. I saw the beds in September and nothing could be more satisfactory. My friend assured me the system never failed him.—GROWER.

**Soil for Onions.**—It is surprising what fine Onions are sometimes grown in gardens where the soil is sandy and not what is considered a good Onion soil, this being done by altering its character by the addition of various ingredients. Some of the very finest specimens of Ailsa Craig, The Wroxton, and other exhibition varieties I have seen have been produced by Mr. Atkinson in the gardens at Wroxham Hall, Norwich. The soil naturally is sandy and somewhat shallow, and in dry summers soon loses the moisture necessary to support the thirsty roots of Onions. In Norfolk is found a white marl which is much used in road-making. This, with a liberal supply of well decomposed farmyard manure, Mr. Atkinson had wheeled on to a couple of plots and well worked in with the staple. Since then he has had no difficulty in growing fine bulbs and plenty of them. Two plots so treated allow of one being cropped with Onions every alternate year.—J. C.

**Onion Allan's Reliance.**—This is a wonderfully fine type of white Spanish Onion, having been selected and saved for many years by Mr. Allan, of Gunton. I have been a grower and exhibitor of Onions for many years, and am acquainted with most of the best strains in cultivation. Allan's Reliance surpasses them all for shape, colour, and mildness of flavour. Under good cultivation it can be grown as large as any variety. It has an exceptionally thin neck, much resembling Nuneham Park in this respect. Reliance was selected for twenty-six years by Mr. Allan before being sent out, and in looking through a large quarter of bulbs recently I could not detect the least difference between any of them, so true were they. When better known it will be universally grown. It will keep as long and as well as James' Keeping.—J. C.

#### POTATO NOTES.

THE remarks on page 156 in connection with Spinach are applicable to nearly all vegetables. Varieties, or rather names, are multiplied by a constant and endless regularity, and "so-called" new things are purchased at an increased rate, to prove on trial often only old friends under a new name. This is certainly true of Potatoes, a vegetable above all others, when a large supply is expected, of which one likes to have the very best varieties to suit different conditions of soil, and of which it may be said that when once well suited one should be very chary shelving for other names. One of the best finds of late years for first early work has been Star of Reading, decidedly the heaviest cropper with me of the first earlies, and doing its work as quickly as any. This was the name received with it, but I have met with precisely the same Potato at three shows under as many different names. Well grown it is a flat kidney, very even, and considerably larger than the average first early. Given carefully selected seed and the same conditions of soil and general treatment, there is hardly a bit of difference between Duke of Albany, White Beauty and Early Puritan, and mixed up together, it would be difficult to separate them. Of the last-named, a friend who grows it on a rather heavy soil tells me it is apt to run coarse and watery, but this would probably apply to all three; at least, I remember that Duke of Albany, on which I have relied for many years as the main first early, was not so satisfactory from a piece of ground that was somewhat stiff, but was all right the next year after working in a heavy surface dressing, some 4 inches in thickness, of half-decayed leaves. I do not want a better Potato to follow the Duke than Windsor Castle. It is of excellent quality, and invariably yields a heavy crop of even-sized, shapely tubers. King of Russets is a great favourite, especially for baking or to be served when boiled in the skin;

it is a great cropper, with a very small percentage of seed size. A portion of the crop just lifted has given me 32 bushels from 10 rods of ground. The Bruce is the only Potato I grow that degenerates from successive home-saved seed. Others have been continually in stock for years, and the produce is just as good as when first acquired: but after some three or four years' saving The Bruce turns out like a rough Magnum, the yield quite as bad as that of the last-named from heavy soil. Writing above of synonyms reminds me of a question. Suppose good seed respectively of Magnum and Bruce purchased from a first-class firm and planted in thoroughly good Potato soil, would any ordinary grower guarantee to separate the two if they were mixed after lifting? I think very highly of The Saxon as a late variety; it is practically a disease-resister, a very heavy cropper, and of good quality. E. BURRELL.

**Onion Golden Rocca.**—This Onion is much grown in the eastern counties and is frequently exhibited in grand form, sometimes reaching two pounds in weight. It is of specially fine globular form, the skin a beautiful golden colour, which adds to its value as an exhibition Onion. It has a particularly mild flavour and keeps well. It does better when sown in the spring than most of the Rocca class. Those who grow this class of Onion for exhibition should give Golden Rocca a trial. They will, I am sure, be pleased with it.—GROWER.

**The Carter Spinach.**—At page 156 "A. D." asks in what way the Carter Spinach differs from the Flanders, large-leaved Virolay or Victoria, and Longstander. My reply is, in its having much larger and more succulent leaves, borne on long foot-stalks. There is no variety that can touch it in vigour of growth and general excellence. A gardener of my acquaintance, who is expected to supply plenty of Spinach all the year round, has now given up all other summer sorts growing only The Carter. It requires to be freely thinned out, and when grown on fairly good ground it is surprising how it will stand a hot dry time.—MIDLAND GROWER.

— For the information of "A. D.," on p. 156 this fine Spinach was sent for trial to the gardens of the Royal Horticultural Society, and granted an award of merit at the committee meeting of June 11, 1895.—JAMES CARTER & Co.

## GARDEN FLORA.

### PLATE 1136.

#### IRIS LEICHTLINI.

(WITH A COLOURED PLATE.\*)

AMONG the many lovely and beautiful Irises from the Holy Land, Turkestan, &c., the remarkable species appearing in the coloured plate to-day must ever occupy a conspicuous place by reason of the rare beauty of its flowers. This is not so much due to the size of the blooms individually as to the colour, or rather the combination of beautiful colours, so well depicted in the accompanying plate. Visitors to the Temple show in May last will doubtless call to mind the many lovely and rare species that were exhibited, notably by Messrs. Barr and Sons, and likewise by Messrs. Wallace, of Colchester. The former, in addition to the beautiful species in the plate, had cut flowers of such striking forms as *I. violacea*, *I. Korolkowi*, *I. vaga*, *I. lupina*, &c., that made quite a unique little group of these inimitable species. In the Messrs. Wallace's lot were some equally choice gems of this race, *I. iberica*, *I. Hartwegi*, *I. lupina* and *I. Gatesi* being especially note-

IRIS PELOPONNESICA

THE WEEK'S WORK.

KITCHEN GARDEN.

thy. It is noteworthy in a double sense, because showing that these usually difficult and sometimes unmanageable species are now far better understood than was formerly the case. The Chester exhibit, because grown in pots, went a little further, and showed that those who can for many and various reasons cultivate these things in the open ground may even yet attempt their culture in pots, for at least by the proper means extremes of cultural details—e.g., moisture at one time and great heat and drought at another—may be indulged in at will. This latter may be done by removing the pots bodily to a dry, airy shelf in the greenhouse, without the necessity of unnaturally exposing the naked rhizome to external influences consequent upon a fog. On such a shelf the drying and the cooling would be absolute, and with the return of autumn the pots may be put out of doors again. It is quite possible, too, that some varieties may submit to potting and flower all the year, provided the plants are rammed in close, firmly and the pots plunged to the rim on a very sunny border. The amount of soil required by these plants is so very small, that three pots may be well planted in an 8-inch pot, making the soil as hard as possible about them.

The whole group of Cushion Irises, with its near allies, is so greatly varied and remarkable in respect, and so unlike any other plant flowering in the garden, that they are worth any trouble to bloom them, and if this can be accomplished more generally by some such simple method as here described, a much larger number will be capable of enjoying to the full these wondrously beautiful flowers. Some of the chief points in the culture of these Irises are a dry and warm border, a good loamy soil, which is not deep or over-rich, and very firm setting; indeed this latter is most important, and with the pot system suggested above can be indulged in to any extent. The best season for planting is early in September, at which time the good roots start into growth readily and require root moisture in plenty. The majority of the kinds, though quite hardy, are best for some light protection in very severe weather, straw or bracken being one of the best things for the purpose. Things to avoid when giving winter protection to such things are such as straw, hay, straw, or even bracken, all of which once drenched with wet remain so, and, decaying about the plants to be protected, do harm rather than the good that was intended. The example from which the drawing was made appeared in the hardy plant department at Kew this year. The flowering specimen was about 15 inches high, and, so far, is regarded as a more vigorous kind than some of its near allies. The lovely Iris is scarcely a novelty, as it was first flowered by Dr. Foster in the spring of 1881. Notwithstanding, it is still among the most of this beautiful race of hardy plants.—E.

With reference to this Iris the following notes regarding it have been kindly sent us by Herr Dr. Leichtlin, Baden-Baden:—

Dr. Leichtlin was discovered by Albert von Pell in the mountainous districts of Turkestan, where it is found in company with *I. Korolkowi*, *I. v. I. stolonifera*, &c., and is described in *Act Hort. Petrop.*, 1884. It was introduced to cultivation in 1879 from a collection of unknown Irises sent to Baden-Baden by His Excellency Lieutenant-General N. de Korolkow. It is a striking plant by the rainbow-like unusual coloration of its flowers, showing blue, white, rose, and a peculiar brown. It is perfectly hardy, wants a loamy soil and a dry situation, and is best left alone for several years.

HEAVY rains and rough winds, together with a low night temperature, which have been prevalent during the past fortnight, have been unfavourable to most crops, and the wet state of the ground at the present time will for the time being prevent such work as moulding up Celery, harvesting spring-sown Onions, and the clearance of exhausted crops. In some soils wireworms, grubs, and even the common worm prove destructive to the Celery crop, as they not only destroy the outer leaves, but also eat into the centre of the plants, causing them to become quite unfit for table use. The present wet weather is also favourable to the small black slugs so common in some gardens, and which do so much damage to this and other crops. A good dusting of lime about the plants just previous to moulding them up will greatly assist in preserving them from these pests. The lime should be in a powdered state, so that it can be worked well round each plant after the outer foliage has been drawn together and tied loosely with a piece of matting. The ridges of soil, too, which will be used for moulding up the crop, should also have a dressing so as to make it repulsive to the vermin. Some go to the trouble of placing strips of brown paper round each plant to prevent the soil touching the outer leaves. This greatly assists in the work of blanching, and when ready for use each stick is beautifully clean, and there is much less work in preparing it for use. There are properly prepared collars, which may be obtained from all seedsmen for this purpose, but strong paper may be used and kept in position with a strip of matting tied loosely round the top. The crop so far is, fortunately, free from disease, but a close watch should be kept and hand-picking resorted to immediately any of the leaves appear to be affected.

ONIONS.—Spring-sown crops have mostly been harvested in the south, but in cooler districts the tops are still green, and unless we have a few weeks of dry weather, some difficulty will be experienced in ripening them properly, without which they will not keep in good condition for any length of time. Advantage should be taken of the first fine day to get them off the ground when the tops show signs of ripening, and it would be better to remove them at once to a light, dry place under cover to assist in maturing the bulbs, than allow them to remain on the wet soil, as though there may be no rain for a few days after they are pulled up, the heavy dews will prevent the tops drying up as quickly as would be desired. It is not always convenient to spread them out on the stage in a vinery from which the crop has been cleared, but this is one of the best positions to finish them off properly. Failing this, they may be placed thinly in a dry frame or pit, covering them with the lights when rain is expected.

JERUSALEM ARTICHOKE.—These will have reached a great height by now, and it will be necessary to give them some protection against wind, or they will probably get blown over and many of the tubers will be turned out of the soil. In this garden the tops are quite 8 feet in height, and being planted 1 yard apart, they have branched out freely. A few stout stakes have been driven into the soil round the plantation and close to the outer rows, and from these strong cord is fixed to prevent the plants swaying over. Seeing that growth is about terminated now, the central shoot will be shortened back to about half its length, and by retaining the lower side shoots there is less risk of any damage being done by gales and heavy rains, and the size and quality of the tubers will in no way be impaired.

ASPARAGUS.—This is likely to suffer just now from the same cause, and though the season is rapidly approaching when the tops will be sufficiently ripened to be cut down, they should be prevented from being twisted about, or the buds at the base will be damaged, and next season's produce

will suffer in consequence. A few of the most forward seed-bearing shoots will have turned yellow, and these should be carefully removed before the berries fall to the ground, otherwise a number of seedlings will spring up next spring, which if not pulled up at once will become established in the bed, and tend to rob the permanent roots of moisture and nourishment. It is not too late to sprinkle the beds with salt where the soil is light and poor, as the roots are practically active until the ground becomes frost-bound, and feeding in the autumn assists to plump up the buds or crowns which are to furnish next season's supply. Now that the ground is full of moisture, farmyard liquid may also be applied freely. This will enrich the soil to a good depth and benefit the growth next summer.

SEAKALE.—The time will soon arrive when it will be necessary to resort to forcing this useful winter vegetable, but the crowns must have become thoroughly matured and all the foliage ripened naturally before any attempt is made to lift the roots or they will not prove satisfactory when placed in heat towards the end of October. In the meantime the ground between the plants should be kept free of weeds and rubbish, and all decayed foliage removed, so that what sun we may have will reach the centre of the plants and promote early ripening.

FRENCH BEANS.—In the forcing department, French Beans and Cucumbers will require careful treatment, so that growth will be clean and strong. A high temperature by artificial means will prove harmful to French Beans, but closing the house or pit early in the afternoon, so as to run up the temperature by sun-heat, will both strengthen the plants and encourage growth. A successional batch should be sown as soon as the last lot has formed the first few rough leaves, as it is not to be expected that they will continue to bear for any length of time during the short and foggy days of autumn. It is only by making frequent sowings and giving plenty of house room that anything like a regular supply can be kept up after this. RICHARD PARKER.

FRUIT HOUSES.

LATE GRAPES.—Lady Downe's and other late varieties, if well coloured, may be freely ventilated during the day when the weather is fine and bright. With these late Grapes colour is no indication of maturity, and it is not safe to assume that the berries are filled with sufficient saccharine matter to ensure their keeping well into the spring, until the foliage itself begins to give signs of ripening. Therefore, although the colour may be perfect, it is just as well to continue subjecting them to a little mild fire-heat some short time longer, combined with ample ventilation, until the leaves assume their autumnal tints, when it may be dispensed with. After this it will only be occasionally required to keep the house dry during foggy and wet weather, or to prevent the temperature falling too low when frosty. As Alwick Seedling is rather impatient of too much fire-heat after finishing as far as colour is concerned, the pipes in the immediate neighbourhood of the Vine should be covered with boards or mats, and if possible a little more air may be admitted just at that portion of the house. This variety should always be planted at the coolest end of the house, and as it is a Grape that colours grandly and without special treatment, the further it is kept away from the hot-water pipes the better. The new white Grape Lady Hutt has done well this season, and it succeeds in the same house with Lady Downe's, the temperature and treatment accorded the latter seeming to suit it admirably. As outside borders have had a thorough moistening, down to the drainage, they should now be covered with corrugated zinc sheets, old lights, or anything that will carry off water. In cases where the berries of these late Grapes are not properly coloured, regular fire-heat is absolutely necessary, especially if the weather should continue chilly and showery. The pipes should be kept sufficiently warm to allow of air

being admitted both at the front and apex of the house. The internal atmosphere must also be kept dry, and whatever watering is required should be done early in the morning and on bright days only. Again, in case the Grapes are in a very backward condition, no effort should be spared in forwarding them as much as possible by the application of plenty of fire-heat, also by making the utmost use of solar heat to raise the temperature up to 85° or thereabouts. On dull days make use of enough artificial warmth so that the mercury reaches to 75°, but 65° will be ample for the night, and continue this treatment until the berries are well coloured. Attend to the watering of inside borders, using stimulants until colouring becomes general; after this discontinue their use and give pure water only, keeping the surface well mulched, both to check loss by evaporation and to prevent frequent waterings. If the roots are in outside borders the Vines will yet continue to make growth; this must, however, be kept pinched, so that the trellis may not become crowded with foliage, as it is necessary at this late season that the Grapes experience a certain amount of sunlight as an aid towards attaining good colour.

**LATE MUSCATS.**—If these are well coloured and thoroughly ripe the temperature may gradually be lowered, but a dry atmosphere being indispensable for their good keeping, a little artificial warmth will be needed now and again to dry up any moisture that may arise in the house and to keep the air in circulation. The temperature should never be allowed to fall below 50° for Muscats when ripe. At this they will take no harm, but a lower temperature with attendant condensation of moisture will bring about spot on the berries more quickly than any other cause, and this soon leads to their speedy decay. If the foliage on the Vines is thin, it may be necessary to afford a slight shade for a few hours during the morning when the sun shines brightly, and advantage should be taken of such weather to thoroughly ventilate the house, which will be sufficient to dispel all damp arising from ordinary causes. In cases where the Grapes have not yet finished colouring the treatment recommended in a former calendar should be adhered to until the berries are perfectly finished both as regards colour and ripeness.

**LATE HAMBURGHIS.**—These having finished and being perfectly ripe, the house should be kept cool and dry, and to this end well ventilated whenever the state of the weather will allow. Close the ventilators on wet days, and if drip is troublesome through the roof being faulty, throw the ventilators wide open the first opportunity, turn on a little fire-heat, and get all dried up again as quickly as possible. The skins of the berries being very thin, they are very susceptible to injury from changes of temperature, and on no account should they be subjected to a less warmth than 45°. Look the bunches over at least once a week, and remove any berries found to be decaying. In some places spiders are apt to prove troublesome by taking up their abode in the centre of the bunches, not only of Hamburgs, but all other varieties, and they spin their webs around and amongst the berries and footstalks. When once they take possession it is a difficult matter to dislodge them, and the best means of keeping them under is to pass a hair broom into all corners and crevices in the house at least once a week, and if this is continued from the time colouring commences, when a drier state of things obtains, which is more congenial to their tastes, this will keep them under, they not liking the constant disturbance.

**OTHER VINERIES.**—As the Vines are cleared of fruit, partially prune back the laterals, and, if found necessary, take steps to cleanse the foliage if red spider and thrips have been rife. After this proceed to do any lifting that may be required, also make additions to borders, and top-dress if neither is necessary, and for the present leave the surface unprotected, that the Vines may receive the benefit of autumn rains. Advantage should be taken of the spell of rest the Vines will

enjoy to get all necessary repairs and painting done before the winter sets in. The hot-water apparatus should also be overhauled, defects made good, or, if alterations are contemplated, get them done before there is a possibility of the house being required for use.

**YOUNG VINES.**—Those planted last April or May should be encouraged with artificial warmth to ripen their wood at as early a date as possible, but this must not be carried to the extreme, or the object in view will be defeated. If the canes have turned brown, the laterals may be pruned away, and this will benefit the buds, particularly those on the lowermost portion of the canes, provided always that the premier leaves are intact. If any of these have been lost, the laterals emanating from those portions of the canes should be cut back to one leaf, so that the latter will continue to draw sap for the benefit of the main buds until they are thoroughly mature. A little fire-heat and ample ventilation will assist the ripening of the wood in cases where the Vines are in an immature condition. See that they get all the water they require at the roots, and keep the foliage clean and healthy until they have performed their proper functions.

**POT VINES.**—The canes should now be perfectly ripe, and those intended for early forcing will either have done so or will be shedding their leaves. If all lateral growths were pruned away when they were turned outdoors, nothing remains to be done now but to remove them under cover, as the continuous rains we are now experiencing will keep the roots on the move. If placed in a perfectly cool house or shed and water withheld until the soil becomes dry, the Vines will experience the needful season of rest they require before starting. The soil should not be kept dust-dry or too wet, a look round about once a week being sufficient, and the shortening back of the canes to the required length may be deferred until they are quite at rest.

A. W.

## FRUIT AND VEGETABLE CROPS.

### WESTERN.

**Hagley Hall, Stourbridge.**—Apples are a good crop, in some instances a heavy one. Pears, Jargonelle, Bergamote d'Espere, Uvedale's St. Germain, Doyenné du Comice and one or two others are a good crop. Early Prolific Plum is a good crop, most other kinds a failure. Apricots a very light crop. Damsons are a failure. Nuts are a very heavy crop.

Vegetables have been good and plentiful. Runner Beans did not set well until the rain came, but the dwarf Canadian Wonder kept us supplied until the others were ready. The later crop of Broad Beans did not set well owing to the black fly. Globe Artichokes have thrown up very freely; I find they do better if removed to fresh ground occasionally. Peas have done remarkably well this year about this neighbourhood.—D. R. DIXON.

**Badminton Gardens, Gloucester.**—The fruit crops in this garden and neighbourhood are, generally speaking, very much below the average. The Apple crop is partial, and early kinds of the Lord Suffield and Stirling Castle types are plentiful, but mid-season and late varieties are very scarce, except in a few sheltered and favoured spots. Pears are very thin, and Plums almost a total failure. The same may be said of Apricots. Peaches and Nectarines outside are fairly abundant and good, although somewhat late. Strawberries were extremely plentiful and very fine; I do not remember a better Strawberry season. Raspberries were not so prolific here as usual, owing, no doubt, to the poor canes grown during the summer of 1896. Currants of all kinds, also Gooseberries, were abundant and excellent. Nuts (excepting Walnuts) are very plentiful.

The vegetable crops are quite the reverse of the fruit, being extremely fine and good. Peas are suffering from mildew, I think more than

usual, and late kinds do not promise well; but early and mid-season varieties were very good. Beans of all kinds are most abundant. The Potato crop will not, I think, be above the average but if the disease does not set in too virulently fancy there will not be much to complain of, all kinds seem doing well and the haulm ripening gradually. All the Brassica tribe looks well. Brussels Sprouts particularly so.—WILLIAM NAYLOR.

**Cloverley and Shavington, Salop.**—Apples are very partial, especially the better dessert varieties, though others, chiefly cooking kinds, have a fair average crop. Pears on walls and espaliers are an average crop; fruit small, owing to drought, very scarce on pyramids. Plums on walls protected only with fish netting carry a crop of fine fruit; away from walls a failure. Damsons very scarce. Cherries are poor, especially Morello. Apricots are an average crop of good fruit. Currants, Raspberries and Gooseberries are an average crop. Nuts good. Strawberries an average crop.—T. G. CUCKNEY.

**Killerton, Exeter.**—Apples are below average. Among the best are Blenheim Orange, Hawthornden, Manks Codlin, Domino, Stirling Castle, King of the Pippins, Mère de Ménil, Schoolmaster and Tower of Glamis. Pears are under average; Beurré Clairgeau, Beurré Bosc, Comte de Lamy, Victoria, Pitmas, Duchess, Durondeau and Passe Colmar are good crops. Peaches and Nectarines are partial. Hants Early, Royal George, Dymond and Grosse Monne have good crops. Many of the trees were very much blistered in the spring, but have recovered. Apricots were very scarce throughout. Cherries have been a moderate crop. Morello are exceptionally fine; early sorts were below average. Plums are very scarce on the walls, the standard trees in the orchard have fair crops, the sorts being Green Gage, Victoria and Prolific Englebert. Figs are plentiful and fine, the best being Brunswick, White Marseilles and Black Turkey. Cobs and Filberts are fine crops.

Vegetables have been throughout the year good and abundant. Potatoes in the field are very promising; Beauty of Hebron is dying away and the haulm spotted with disease, while Schoolmaster, which I find the best for the general crop and late kinds are looking very promising. The grown many other sorts side by side in the same field for twenty years, but none equals Schoolmaster for cooking and keeping.—JOHN GARLAND.

**Stoke Edith Park, Hereford.**—The fruit crop in this neighbourhood as far as Apples, Plums and Damsons are concerned is a disappointing one notwithstanding the fact that the trees in three instances were covered with blossoms. The cause of this almost total failure in the case of standard Plums and Damsons, both in orchards and gardens, may be traced to bitter cold easterly winds which blew with great persistency near the whole of the time the trees were in bloom. This, as might be expected, had a disastrous effect on the flowers, so that the delicate organs of fructification became seared and shrivelled, and they eventually dropped off the trees. In the walled-in garden the trees fared better, and a good crop set on bushes and pyramids, only, however, to be badly hit by frost later on, when they all dropped. On the walls many of the trees are carrying fairly good crops, these escaped owing to the protection afforded by the broad, over-hanging copings. Among Plums Victoria stands out conspicuously as being the heaviest cropper not only here, but in many other places in the district, while Herefordshire Prolific is the best cropped variety of Damson here. It is satisfactory to note that the trees generally are clean and have made good growth, a good augur for another year. Turning to Apples, the reason for the partial failure in this case is distinctly traceable to two causes, the first of which was the caterpillar and weevil maggot deprivations, and the second the disastrous effects of the morning frosts on May 9, 11, and 12, which alone did great damage. The majority of the trees in the orchard hereabout blossomed well, although traces of last year's insect attack were plainly visible by the

debilitated appearance of the trees in many instances. Unfortunately, through neglecting to take preventive measures, the trees were again fully attacked by insect pests this spring, and this alone would account for the loss of quite half the crop on every tree. Then occurred the frosts mentioned above, and these destroyed numbers of the blooms which had escaped the insect foes, with the result that the aggregate crop for the district can hardly be termed one-half of what it should be. In these gardens, where washing of the trees both in the winter and spring receives the greatest attention, insects put in an appearance, but not in sufficient numbers to do any great amount of harm, and they were quickly subdued by spraying. We can never hope to entirely get rid of these pests so long as matters are allowed to take their course in surrounding orchards, and shall always have to combat them in greater or lesser degree every spring. Our best trees suffered from frost, but in spite of this we have many trees heavily laden with fruit, foremost amongst which are Lord Grosvenor at Lord Suffield, Cellini, Worcester Pearmain, Boston, King of Pippins, The Queen, Ecklinville, Stirling Castle, Cox's Pomona, Annie Elizabeth, Rich, Lord Derby, Beauty of Kent, Kentish Filibasket, Stirling Castle, Tyler's Kernel, Warner's King, Washington, and Pott's Seedling. It is satisfactory to see that many of the late-flowering large Apples are well cropped, and their immunity from frost and caterpillar attacks lies in the fact of their being so late before starting into growth. Pears, through their having flowered in advance of Apples, were set and out of harm's way when the frosts previously noted occurred, and thus both in orchards and gardens are bearing good crops, cordon trees especially. A few sorts calling for special mention are Hacon's Incomparable, Marie Louise, Marie Louise d'Uccle, Birkhouse's Beurré, Chaumontel, Gratioli of Jersey, Beurré Hardy, Glou Moreau, Bergamote d'Espere, Prince Consort, Beurré d'Arenberg at Althorpe Crassane. Dessert Cherries on bushes and wall trees has been abundant and good, while Morellos have been and still are plentiful and the trees in all cases have kept much better than usual. The fine old standard Cherries, of which many are to be seen in the vicinity of cottage gardens in the adjoining parish, have borne so well as usual, they having doubtless suffered from the effects of frost, as the fruit, though apparently well set, dropped in shoals. Taking Apricots next, it is pleasant to be able to relate that, although the trees are not so heavily laden as last year, they have carried excellent crops of fine fruit, which ripened to perfection. The trees have the protection of coping boards and frigid domes, and this seems to be the surest method of ensuring a crop of this delicious fruit each year. In consequence of the hot, dry weather watering has been rather a heavy item, but the rains secured more than compensate for all the labour and trouble involved. The trees are clean and have made good growth, the wood being of a fruitful character. Peaches and Nectarines taken collectively are a good crop, the exceptions being a few trees which made rather strong growth last year, and these will be lifted this autumn. Filbert, which seems to have been prevalent in some parts of the country, has been absent, and this has given but little trouble. Red spider put its appearance on a few trees, the attack being kept in check through some Strawberry plants on the border becoming infested with them, but "Kilmorie" and applications of cold water afterwards soon stopped their depredations. That fine variety Alexander has become an established favourite here, and although not ripe quite so early as in former seasons, the last of the fruits were gathered during the last week in July. Royal George, Crimson Galande, Dymond, Magdalen and Alexandra Noblesse are varieties well cropped among Peaches, and Elruge is the best among Nectarines. Currants of sorts and Gooseberries in variety have been very abundant and good, and the sawfly caterpillar has been entirely

absent. Raspberries were a splendid crop, and stools of Superlative, fed with superphosphate of lime and potash, yielded exceeding heavy crops of extra fine fruit. This is a magnificent Raspberry, and intending planters who wish for crop combined with size and quality should plant Superlative. In all cases the stools are well furnished with stout canes for next year's fruiting, and these are ripening fast. Strawberries have produced heavy crops of fruit which were of fine size and excellent as regards flavour. Royal Sovereign with me has established its superiority over all others as a first early variety. As Strawberries have to be treated on in a separate note, I will say nothing further about them here, and will conclude by remarking that, taken altogether, the fruit crops, with the exception of the falling off in Apples and Plums and a slight deficiency in Peaches, are, when compared with reports to hand from authentic sources, very satisfactory, when the disadvantages laboured under in the shape of insect foes and frost effects are taken into consideration.

The vegetable crops have been infinitely superior in every way to those of last year, and give occasion for congratulation when the heat and dry weather are taken into account. By supplying plenty of water to all crops that needed it, and with the help of the warm rains which have fallen at intervals through the summer, they have been kept going, and the produce has in consequence been good. Early Peas were ready for gathering a little later than last year, but the crop lasted much longer and was of much better quality. A new early wrinkled Pea named Dickson's Harbinger created a favourable impression, it being ready for gathering with the first early round-seeded kinds, and as regards flavour, it is far and away beyond the latter. Successional crops have been excellent. Early Cauliflowers turned in with the early Peas, and have been plentiful since then, the variety being Waleheren. French Beans have borne good crops, although the earliest were soon over, and the pods have been, and are, tender. The first gathering was made from Earliest of All. Scarlet Runners are plentiful and good, while Broad Beans of both sections have been excellent. Celery is looking very healthy and growing fast, the earliest having had its first moulding up. Onions. Carrots, Parsnips, Beetroot, and Turnips leave little to be desired. Seakale, under the influence of heat and good treatment, has done remarkably well and promises fine crowns for forcing by-and-by. Vegetable Marrows present a different appearance from that of last year, and both these and Ridge Cucumbers have cropped well. With regard to green crops such as Broccoli, Cabbages, and the various kinds of winter vegetables, they are, with a few exceptions, making good growth and are in a satisfactory condition. Lettuces, through being planted in shady positions, have given little trouble all through the season. Continuity has proved a first-class Cabbage variety for a dry season. Sharpe's Victor Potato was again the earliest kind ready for use on a warm border, but I think that English Beauty, which has been on trial here, will run it close for earliness, if it does not beat it, another season. Early Potatoes lost their tops prematurely in many cases through the extreme heat and drought, but the varieties mentioned, also Myatt's Prolific, Early Hammersmith, and Early Regent have, under the circumstances, yielded very good crops indeed. Second earlies are ready for lifting and promise a good yield, and the rains of the past few days will do much towards ensuring a good crop of mid-season and late varieties. The ground is now in fine condition for the sowing of the winter crops of Onions, Lettuces and Spinach, and in a short time the first lot of Cabbages for early spring cutting will be planted.—A. WARD.

**Trelissiek, Truro.**—The fruit crops in this neighbourhood are the worst we have had for many years. Plums, Pears, and Cherries are a total failure; Apples not more than a quarter of a crop, and Peaches about the same. I never saw trees of the latter so badly blistered: some trees

were completely killed by it. This, I think, may be accounted for by the cold, blighting storms of the spring. Gooseberries and Currants were a fair average crop, but Raspberries a failure, from replanting after the severe drought of the previous season.

Vegetables have been pretty good. The Peas suffered somewhat from the extremely hot weather in June and July. Potatoes are a fair average crop.—W. SANGWIN.

**Compton Basset, Wilts.**—The crops here in this district generally are under average with one or two exceptions. Of Gooseberries and Currants we have enormous crops. Raspberries were bad. Cherries are an average crop. Peaches and Nectarines are fine and an average crop. Waterloo Peach was very fine, as was Amsden June. There are good crops of Dymond and Goshawk. Pears are under average; I have had to thin in a few cases. Apples are very poor, only a few in the middle of the trees and under branches where they escaped frost. Plums are very much under average. Apricots were an average crop. Cobs and Filberts are much above average. Strawberries were an average crop, but frost destroyed much of the early blossom.—W. A. COOK.

**Glewston Gardens, Ross.**—Apples here are a very heavy crop. Ecklinville Seedling, Stirling Castle, Golden Spire, Keswick Codlin, and Tower of Glamis are carrying the heaviest crops, and of the dessert kinds Worcester Pearmain, King of the Pippins, and Ribston Pippin are the best. Pears and Plums are a failure. The trees were a sheet of bloom, but the cold wind and frost, of which we had 7° and 9°, killed most of it. Apricots are under average. Cherries a failure. Gooseberries, Currants, and Raspberries were an average crop and good. Strawberries average and good. Nuts over average. Walnuts average.—C. A. BAYFORD.

**Membland.**—The fruit crop in this part is variable. Small fruits were abundant and good. Apples are doing much better than was to be expected. There are fine crops of many of the best sorts. Irish Peach, Lord Suffield, Lord Grosvenor, Gloria Mundi, Cox's Pippin, Stirling Castle, Bramley's, Melon Apple and a few others are good. There are very few Pears, but we have had heavy crops for three years, hence we looked for a light crop. Peaches suffered from blister, but are now clean and making good growth. Plums and Cherries are scarce. Filberts and Cob Nuts are good. There is a shorter supply of Raspberries than usual. This and many other places suffered from the dry season last year, and the growth was short.

Vegetables did well up to July: since that Peas have become more or less mildewed, although a good supply of water has been given to them. Carrots and Parsnips are very fine; Onions also good. I fear the Potato crop will be disappointing. The disease showed itself in the last week of June, the weather being damp and warm at the present time (August 14). The late planted and late sorts are very small; on the other hand, early planted and early sorts are excellent. The Ashleaf, Puritan, Sharpe's Victor, Snowdrop, Windsor and Laxton's Victoria are amongst the best. Britannia is new to me; it is a heavy cropper, of good flavour, very short in the haulm, and not diseased. It should be a good sort for forcing.—GEO. BAKER.

**Oldown House Gardens, Almondsbury.**—The fruit crops in this district are rather under the average, although of some kinds unusually heavy ones can be reported. Apples are an average crop and the trees looking well. Blenheim Orange, Tom Patt, Bess Pool, London Pippin, Winter Nonsuch, and Waltham Abbey Seedling, among orchard trees, are heavily laden, and among trained trees, Cox's Orange Pippin, Annie Elizabeth, Ribston Pippin, and Claygate Pearmain are carrying good average crops. Pears on walls are under average, but the quality appears good and the fruit clean. Beurré Bose, Jargonelle, Easter Beurré, Beurré d'Amanlis, Josephine de Malines, Marie Louise, and Beurré Diel are the

best. Among cordon trees, Beurré d'Anjou, Princess, and Marie Louise d'Ucle are good. Pyramid trees a failure. Of Apricots and Plums the crop is almost an entire failure. Cherries of the sweet varieties are a very scanty crop. Morellos good, the fruit large and trees clean. All kinds of bush fruits have done well, especially Red Currants and Gooseberries, fruit large and bushes free from caterpillars this season. Raspberries very scarce. Strawberries have been remarkably good and abundant. Vicomtesse H. de Thury, Sir Joseph Paxton, President, and Wizard of the North have been the best. Nuts, both Filberts and Cobs, are very plentiful; Walnuts average, some trees heavily laden.

Vegetable crops of all kinds have been good. Early Potatoes, Ringleader, Sharpe's Victor, and Myatt's Ashleaf are good, both as regards quantity and quality. Of the later sorts, Magnum Bonum, Schoolmaster, Windsor Castle, and Snowdrop are good and no disease has yet been seen. Early Peas did well, especially Sutton's Excelsior, Chelsea Gem, May Queen, and Exonian; and for midseason, Duke of Albany, Duchess of Edinburgh, Veitch's Mainerop, and Prodigy have done splendidly. Late sorts are almost a failure, the flowers being infested with yellow thrips and the foliage with mildew. French and Scarlet Beans are abundant. Carrots, Parsnips, and Beet are good. Turnips are poor. Onions are an immense crop, especially Veitch's Mainerop and Sutton's Longkeeping. All the Brassica tribe are doing well.—A. G. HOOKINGS.

**Eastnor Gardens, Ledbury.**—Small fruits generally have been fairly good, considering the late spring frosts. Strawberries extra good. Gooseberries very good. Currants and Raspberries both good. Plums are almost a failure, also Cherries, as we had 14 of frost while the trees were in flower. Peaches are a fair average crop, but were heavily protected. Apricots fair. Pears good average. Apples a very disappointing crop, for the trees generally were in splendid order before the flowers opened, but on opening the flowers had a starved, stunted look, which resulted in a very bad set. Some few trees have a nice crop, but even on those the fruit is undersized and deformed.—FRANK HARRIS.

**Abberley Hall, Stourport.**—The fruit crops in this district this year are very bad. In the spring there was a great show of bloom on all the fruit trees, especially the stone fruit, but owing, I think, to the very bad weather, sharp frosts and snow late in the spring, things went back very much. Apples and Pears are very poor. All the stone fruits are a complete failure, with the exception of Peaches, Nectarines and Morello Cherries on walls, and these seem to have suffered very much from the severe weather we experienced in the spring. Strawberries have been a very good crop, also Gooseberries, Raspberries and Currants.

Vegetables seemed to do fairly well at the beginning of the season, and there have been some fine crops of Peas in this district. Potatoes, I think, will be a good crop.—W. CONWAY.

**The Gardens, Longford Castle, Salisbury.**—Fruit is rather varied, an Apple tree occasionally being well cropped, but on the whole the Apple crop is a light one, the late severe frosts in May doing much harm. Pears are light, and what fruit there is is of poor quality. Plums and Apricots are light crops; Peaches and Nectarines a good medium crop. The Nut crop is a very heavy one. Bush fruit is very good; the earliest Strawberry blooms were damaged, but succeeding ones produced a good crop of fruit.

Vegetable crops vary. The disease in Potatoes seems rather prevalent, doubtless owing to heavy night dews. Peas have suffered much from drought and excessive heat. Root crops, except Turnips, seem to be doing well. The Brassica

tribe all through the entire district seems to have buttoned in very badly, at least 75 per cent. being blind. Onions suffered much from mildew and have gone off badly.—E. F. HAZELTON.

**Wilton House.**—Apples under average, bad in quality. Pears under average. Plums a total failure, except on walls and protected. Cherries under average. Peaches and Nectarines over average, where protected by glass coping quality good. Apricots average where protected, quality excellent. Small fruits under average. Black Currants very scarce. Strawberries average crop, quickly over in consequence of dry weather. Nuts over average and of good quality. Walnuts moderate crop.

Early varieties of Potatoes are a light crop; late varieties strong and healthy and there is

*Lilium giganteum.* From a photograph sent by Mr. C. J. Backhouse, St. John's, Wolsingham, Darlington.

every prospect of a good crop. All vegetable crops are looking well except Cauliflowers and Peas, the former having suffered from the dry, hot weather, and the Pea crop has been much infested with mildew.—T. CHALLIS.

**The Gardens, Garnons, Hereford.**—Apples and Pears are only half a crop in this neighbourhood. Apricots and Plums are a complete failure; also Cherries, except in a few cases. I have a fair crop of Morellos on walls. Gooseberries bore the trees to the ground in this garden. Red Currants and Raspberries good, and Black Currants also good, but not generally in the neighbourhood. In addition to the bleak winds we

had in May, I consider the plague of thrips which has appeared in this neighbourhood for the last two or three seasons is greatly responsible for the light crops of Apples and Pears. They attack the bloom-buds before opening and destroy the stamens of the flower, and on that account it is hard to get rid of, as it is impossible to reach them by spraying.—E. FOX.

## FLOWER GARDEN.

### LILIUM GIGANTEUM.

I SEND you photo of this beautiful Lily which has just flowered in my garden at an elevation of 940 feet above sea-level, in a meadow bed of peat and loam. It grew to the height of 7 feet 8 inches; the flowers were each 5¼ inch across and 7¾ inches long—thirty blooms in on two spikes, white, with purple stripes on side. The stems were each 8¾ inches in circumference. It has been increasing in size several years, making young offshoots, but not flowered till this year. *Incarvillea Davayi* also grows remarkably well here in open, and has had three large spikes of flow this year, seeding freely.

C. J. BACKHOUSE

St. John's, Wolsingham, Darlington.

**Lobelia Gerardi.**—This is an exceedingly free-flowering plant, lasting in full beauty many months. It commenced flowering early in summer, and the main spikes still carry crowns of flower, while lateral spikes are numerous. The colour has been described as azure-blue and also as lavender-blue, but here flowers are not self-coloured, and the general tone seen at a distance is purplish violet. The upper portion of the tube and the two stamens are rosy purple, the lower part of the tube striped rosy purple and white, while the lower petals are pale violet, similar in shade to the common Dog Violet. Judging from its healthy appearance, I should say that it proves the hardiest of all the herbaceous Lobelias and not so susceptible to injury from drought as most of them are. The leaves are large for Lobelia and of a deep green colour, which gives the plant a fresh and attractive appearance when not in bloom. It will undoubtedly prove a good plant for massing.—J. C. TALLACK.

**Rudbeckia laciniata Golden Glow.**—It is disappointing but not surprising to read the notice on this *Rudbeckia* on page 172. Last year I sent from Ireland and elsewhere did not favourably impress me. The glowing terms with which the plant was placed before the public led me to expect prettier flowers than those which came under my notice. They were "lumpy" and heavy-looking, and did not augur well for the popularity of the plant on which they grew. It takes a minute and pretty flower to make itself welcome among the crowd of yellow Sunflower-like plants now available for gardens, and in view of the promising character of the blooms I did not think it worth while to trouble with this double *Rudbeckia*. A day or two ago I had, however, the pleasure of seeing it doing very well in the garden of Mrs. Maxwell-Witham, of Kirkeconnell, Dumfries. The plant was not a large one, but apparently in the best of health, and producing several well-formed and attractive flowers. The colour was good, the blooms more elegant than those of the double Sunflowers. Should it do as well in my garden I shall consider it an acquisition indeed. Possibly the climate may have something to do with its success at Kirkeconnell, and it had the advantage of a well-prepared border and good soil. Possibly the wet autumn we have had in the district may have been acceptable to

it, and have helped to make it do so well. When Glow is distinct from anything else we see in its way, and one can heartily join in the expression of a hope that it may yet prove a success in most gardens.—S. ARNOTT, *Carsethorn, Dumfriesshire, N.B.*

**Primula obovata var. fimbriata.**—At the present time in No. 4 house at Kew a strain of Primula bearing this name is flowering, and at once catches the eye by reason of its distinctive characteristics. Not only is the fimbriated character of the petals very pronounced—which itself is a decided break in this plant—and the flowers usually larger than in original *P. obovata*, but the tube of the blossoms in many instances is of a yellow hue, almost amounting in a few instances to a mealy nature, so much so that at first I was inclined to regard it as indicating a hybrid agency, possibly *P. sinensis* var. This, however, so far as Kew has knowledge of the subject, was negatived a little later in consultation with the curator, the seed having been obtained from the Continent with the above name. That the above strain is highly interesting there is no doubt, and doubly so if, while all attempts to hybridise *P. obovata* with pollen of other species of the genus have proved futile in the hands of leading experts, such a break as this to which I now refer has resulted naturally. There are now several distinct varieties of this Primula in cultivation, particularly *P. o. rosea* is the subject of this note. These in the hands of a careful hybridist should now provide a most useful and welcome variety of this almost perpetual flowering race of Primulas.—E. J.

**Phthalodes Luciliae** is still one of the best as it is also the rarest of beautiful alpine plants recently at Kew in the hardy plant department. I saw this really delightful plant still showing its delicate pale blue flowers. It is, unfortunately, rather difficult to grow as well as in greenhouses, and not unfrequently becomes a victim to slug damage during the winter months. Indeed, in some gardens, even in the summer when supplies for these pests are abundant everywhere, the plant is often attacked, and, alas, once attacked it is rarely left alone while a green remains upon it. Slow in growth, the plant can only be increased by division in early spring, and unless the specimen is at least three years old, it will not avail much to attempt to propagate it. A reference to the plant now may be of service if only to direct attention to the seeds which ripen at this time. These should be watched and secured as soon as fully ripe, and when all are gathered for the year they are best sown in pots. In this way, if the seedlings are raised in a few years in succession, quite a nice stock may be secured, as may be seen when it is stated that upwards of 100 seeds have been secured from a single-sized tuft in one year. It is true, however, that all the seedlings do not possess the clear glaucous tint on the leaves, some are quite green, although varying little in the colour of the flowers. A little peat mixed with loam and finely sifted brick rubbish is the best material to grow the plants in, and also for raising the seedlings.—

**Tufted Pansies in the rock garden in Regent's Park** have been very beautiful during the summer, and quite a new idea in their arrangement is well illustrated. For months past this particular spot has been regarded by many as an ideal illustration of the great value of the Tufted Pansies for work of this kind. Mr. Jordan has discovered the right idea in massing the different varieties by themselves, and in this way has secured some most striking effects. The rock garden here is somewhat serpentine in form, and at the end is massed the pretty little sweet-williams and Violetta, with its chaste white blossoms, next to which is a mass of Bridegroom, a very attractive pale lavender flower with a capital upright habit. Toward the centre, raised higher than the other sorts, is the old variety Countess of Kilmore, with its somewhat tall-growing habit, but eminently suited to the position given to it. Behind, the old yellow sort, has been very

fine, especially early in the season. Blue Gown and Rosca pallida, the latter a very pale rosy blush, are two grand sorts for massing together in large numbers, their dense compact style of growth suiting them admirably for the purpose. There is a beautiful assortment of carpeting plants to cover the rockwork and also to form a contrast to the flowering plants. *Lysimachia aurea*, *Sedums* and *Saxifrages* in variety render this corner of the garden a welcome contrast to the glaring colours seen in many of the recognised bedding plants.—D. B. C.

FLOWER GARDEN NOTES.

**TUFTED PANSIES.**—In response to a complaint made as to non-success last year with Tufted Pansies from cuttings—as a matter of fact nearly 90 per cent. failed—a correspondent, I think Mr. Crane, suggested that a better result might possibly be obtained if the insertion of cuttings were held over for several weeks, and the operation performed in the early part of September instead of the end of July. I am extremely obliged for the suggestion, because having followed it out the result is a capital strike, every cutting coming away at once without the least check. It is not easy to understand why after a successful July strike for many years the failure in 1896 should have been so complete, especially as it was by no means the worst growing season I had experienced. With, however, the knowledge of the conditions most favourable to the free growth of the flowers in question it seems only reasonable to infer that, so far as the outside insertion of cuttings is concerned, the best results would be obtained when the sun is beginning to lose its power, when the ground is naturally moist, and nights are long and cool. Having made it a rule to plant out in autumn, I have resorted to early propagation with the view to obtain early well-rooted plants, but have no doubt the later struck cuttings will produce equally good results. Plants from cuttings are by far the most satisfactory here. They come earlier into flower, individual blooms are finer, and there is a longer season than from old plants either left intact or split up into pieces. So far indeed as the latter process is concerned, it is emphatically the case when growing on a light soil that there are many varieties still classed as Tufted Pansies that are not amenable to this treatment. In any preparations for autumn planting on the above soils I should recommend the incorporation of a goodly dressing of cow manure; given this and a heavy surface mulching to follow planting, there is little doubt but that a satisfactory display will be obtained. Perhaps readers who have tried some of the newer varieties will say which are the best selfs among them—that is, from a flower-garden standpoint.

**SOME USEFUL ANNUALS.**—The present season has again shown the value of some of the best types of annuals, and proved that by their aid, allied with perennials, a splendid summer display can be maintained. Although the many different types and varieties of Pentstemons advertised can if necessary be treated as annuals, that known as *Gloxinioides* is about the best for growing in this way, from the fact that it comes into flower so quickly and makes a grand display quite early in the summer if the seed is sown in a little warmth towards the end of February, and the young plants are grown on without a check under shelter until they can be transferred to the open. *Gaillardia Lorenziana* may not be quite so bright or attractive as the single types, but it is a very serviceable annual and of a most enduring character. The flowers are produced in great profusion on fairly long stalks, and stand up better than the majority of the singles. There is also great variation in the shades, although the brilliant colouring is somewhat lacking. Plenty of flowers is available until the advent of frost and they stand very well in water. To ensure an early display, seed should be sown under cover about the middle of March and the young plants pricked out in frames or boxes. *Calendula Orange King* is one of the best substitutes as a fairly tall

plant that can be found for *Calceolarias* where the latter are not satisfactory. Complaints are sometimes made as to the non-enduring powers of this very handsome Marigold, but the short season is generally attributable either to growing in a poor dry soil, to the non-removal of dying flowers, or to both causes combined. I am aware that this and other flowers are sometimes recommended for poor soils, but there is a medium in all things; and although willing to admit that it does not require a rich compost, I have had the best results from a fairly holding soil, and for that reason generally fork in a heavy surface dressing of rather stiff road-sidings to beds that are to be tenanted with this *Calendula*. The plants luxuriate in this when the roots once find it out. So far as the prompt removal of dying flowers is concerned, it is as much a necessity in this case as with Tufted Pansies and Sweet Peas if a long-sustained season is desired. The seed may be scattered broadcast over the bed and the plants thinned to 1 foot apart. If a mulch of spent Mushroom manure or something of the kind can be put on while they are yet in a young stage it will be decidedly beneficial. Among the newer introductions to summer gardening, at any rate on an extensive scale, may be mentioned *Celosias*. A splendid display is to be found this year at Regent's Park, where Mr. Jordan has used them largely and in excellent taste. Now that individual colours are fairly well defined, it is advisable to purchase them separately, and arrangements can then be made for planting on a carpet that will best harmonise with each colour. Ranking among the most tender things that are utilised for summer work, it is obvious that early sowing, quick growth up to a certain stage, and a long hardening off are absolutely essential.

**CARNATIONS.**—We have had showery weather, or, at any rate, occasional showers, right away from starting Carnation layering, and artificial watering has been unnecessary. The plants—as is generally the case under such conditions—have come away at once and are looking remarkably well. Is there something in soil and in atmospheric influence, or in both combined, that is responsible in a great measure for splitting tendencies. I ask because the late flowers of Mrs. Reynolds-Hole have been remarkably good, the calyx holding intact to the end. This seems to indicate that the cool, showery weather has something to do with the improvement. What, however, makes me think that a difference of soil is also responsible is the remark made by a grower from a south-midland county. I had directed his attention to The Pasha and Carolus Duran, and he immediately said that he did not want a better in that shade than Mrs. Reynolds-Hole, and to my inquiry as to whether that variety did not split badly, added, not five per cent. It would be interesting to know if others have had the same experience, and, if so, to what they attribute their success. Of a few sorts comparatively new to me I like Lady Nina Balfour, Miss Audrey Campbell, Sadek and King Arthur, as in addition to flowering freely they make strong grass, and the layers have a robust, healthy look about them. It remains to be seen if these and a few more new sorts will come through the winter as well as the old favourites. Where a considerable number are required for indoor work, the sorts named above, together with Uriah Pike and a good form of White Clove, will be found useful for the purpose, and a sufficient number should be potted as soon as the layers are well rooted. If any particular shade in the named varieties is not looking well it is advisable to layer some of the seedlings if the desired colours can be obtained in them. I am this year trying three that proved very free and vigorous, and that were respectively in their several shades almost the counterparts of Miss Jolliffe, Ketton Rose and The Pasha. Where good seedlings exist and the ground is not required for other purposes they will make a grand show another season if allowed to remain. The ground between the plants can be gently eased up with a fork and a bit of fresh soil, say about 2 inches in thickness, spread over the surface. All

thin weakly growth can then be removed and sufficient of the strongest shoots from each plant pegged down into the fresh soil to cover the bed well. A splendid lot of flowers will be obtained from such beds another season.

**MICHAELMAS DAISIES.**—Among good kinds now in flower are *Aster acris*, *Amellus major*, *cordifolius*, *lævis*, *arcturus*, *Novi-Belgii*, *Purity*, and *Shorti*. The two first named being comparatively

instead of relieving it. The other four *Starworts* are capital border plants and also very useful in a cut state.

E. BURRELL.

*Claremont.*

**Montbretias.**—The note of "E. J." (p. 191) on *Montbretia Tigridia* reminds me of a fine group of this showy flower I saw growing at Carrow

## ORCHARD AND FRUIT GARDEN.

### PEACHES AND NECTARINES AT EXETER.

THE wall on which the Peaches and Nectarines are growing is our boundary wall, and belongs to the gaol authorities. It is 24 feet high, and at

*Peaches and Nectarines on a high west wall at Exeter. From a photograph sent by Messrs. Veitch, Exeter.*

dwarf and compact, and throwing dense heads of flower, are suitable for massing in large beds only. As they are somewhat stiff and formal, it is advisable to relieve them with other things. Perhaps there would be nothing better than *Dahlia Flambeau*, a variety that throws its flowers well above the foliage, and is unapproachable as a free bloomer. *Desgrange Chrysanthemum* is sometimes used and is satisfactory so far as contrast of colour is concerned, only it intensifies the formality

House. At a time when good flowers suitable for vase decoration are becoming scarce the above will be found invaluable, one good point in its character being the long time it lasts when cut. It looks exceedingly well arranged with *Gypsophila paniculata*. The best way to secure a good annual supply of flowers is to keep working up a young stock of plants and to plant in good soil. To prolong the supply of spikes for cutting, plant a batch of roots on a north border.—GROWER.

special spot is built of limestone; at other places it is built of brick. The aspect is due west, and owing to large buttresses and recesses the sun falls on the wall until between 11 and 1 o'clock at this time of the year. The Nectarine tree photographed is Lord Napier, and is about 12 feet high by 8 feet to 10 feet wide. It has borne heavy crops of fruit without intermission for the past ten years.

standard Peach tree shown is Dr. Hogg, and is 16 feet high by 16 feet wide, and has been growing there for more than twenty years. The dwarf Peach is Dymond. It is 12 feet by 12 feet, and is of the same age as the Dr. Hogg. These two trees have been exhibited by us full of fruit regularly for many years to our friends who attend the horticultural show at Exeter, which is usually held on or about August 20. Other trees on the wall are Bellegarde Peach, Pineapple Nectarine, Walburton Admirable Peach, which is bearing a fair crop this season, and Late Venonian Peach, of which there are several trees, one bearing heavily. With reference to treatment, we give the trees plenty of clean water and liquid manure at the usual times, but we give them special treatment in the spring from the time the buds begin to swell to the time they are in bloom by giving them copious waterings with clean water and now and then a drop of liquid. We root-prune them every third or fourth year, laying out the fibres near the surface in good loam and lime rubble. The result has been that we only occasionally get a crop in the leaf, none at all this year, and almost invariably get a good crop. From our examination of the soil under our walls for many years past, we are satisfied that it is often drier than one would expect, and that many trees suffer from dryness at the root, especially during dry weather in March and April, such as was experienced last year and this year.

ROBERT VEITCH & SON.

**Nectarine Cardinal.**—The exceeding earliness of this new Nectarine, coupled with its extraordinary colour and pleasant flavour, is sure to make it a favourite with those who require Nectarines early in the year. As grown in a pot this season at Carrow House it was very prolific, and earlier than the Early Rivers. It is a significant fact that all the early Nectarines are much freer setting than the early American Peaches, Amsden June, and Cardinal is no exception to the rule.—GROWER.

**Japanese Wine Berry.**—It is surprising that this fruit is not more generally grown, as it makes a most delicious preserve and is easily cultivated. At Carrow House Mr. Jones has it in a very fruitful collection, the clusters of Mulberry-like fruit hanging in great profusion. It enjoys deeply-worked, rich ground, and new beds should be made every few years. The general treatment it requires is very similar to that of the Raspberry. The fruit is Mulberry-shaped and produced in clusters. It is necessary to net the fruit over to protect it from birds, which are as partial to it as to raspberries.—GROWER.

**Apple White Juneating.**—One looks in vain in fruit catalogues for the above old-fashioned early Apple. Thirty years ago there were a good many orchard standards of the White Juneating in Sussex, but most of them were very old, and as they have disappeared, young trees have not been planted in their place. A Norfolk gardener markets his surplus fruit recently asked me if I could inform him where he could obtain trees or grafts of it. He had never seen it since he lived in Suffolk many years ago. I could not help him although I have a good espalier tree which never fails to bear a good crop of fruit, this ripening at the end of July. The flavour is brisk, juicy, and refreshing, though it is not one of the sweetest. It must be eaten within ten days or a fortnight after gathering, otherwise it becomes mealy and tasteless.—J. CRAWFORD.

**Black Currant Lee's Prolific.**—Without doubt the finest of all Black Currants, all points considered, is Lee's Prolific. The old Black Naples is excellent, but the former, while being equally as prolific, is much larger in the berry and the quality unsurpassed. There are several other varieties in existence having larger berries even than Lee's—Dunnet's Champion, for instance—

but they are such poor bearers that where profit is aimed at they do not pay to grow. For exhibition a few trees may well be grown, as fruit of Dunnet's Champion is often as large as small Cherries. I find Lee's Prolific is being largely planted in East Anglia, and market gardeners seem to be working up a stock. The fact of the latter class of cultivators taking to any fruit or vegetable is sufficient proof of its value. Many gardeners still prune Black Currants, so as to encourage dense, stumpy bushes, instead of opening out the trees to let in air and sunshine and encourage plenty of young wood.—GROWER.

#### OUTDOOR PEACHES.

This is unmistakably a Peach and Nectarine year, and the fruit is all the more appreciated because of the scarcity of dessert Plums and early Apples and Pears. I do not know how it comes that we are apt to regard Peach blossom as exceptionally tender and make its covering the first consideration, unless it is that the choice nature of the fruit prompts attention. As a matter of fact, it is not so tender and will bear with impunity frost that would be fatal to Plums, Cherries, and Pears, and the small-flowered varieties are a trifle hardier than the large. Waterloo and Hale's Early are the two best early Peaches if one looks to the combined properties of size and flavour. Others may be as good or better on other soils, but these are my best and most reliable sorts, and by planting one or two trees of the latter on a west aspect, a succession of fruit is secured until Early Grosse Mignonne and Alexandra Noblesse come in. Both these are first rate. Alexandra Noblesse has the reputation of not cropping over-well on some soils, but I have no fault to find with it in this respect. Early Alfred is a capital indoor Peach, but is not a success outside with me; both fruit and foliage mildew badly. Royal George is the most unsatisfactory of all, and, bearing in mind that Peaches, as a rule, do well, and that this particular variety in some places is exceptionally fine, I have come to the conclusion that there is a Peach in cultivation sold under this name very different from the true form. This particular tree is just about in the centre of a mixed Peach and Plum wall about 100 yards long, and whilst all other trees are clean and healthy, this for the last three seasons has been simply covered with mildew, both foliage and fruit, the latter, it is almost needless to add, under such circumstances being only third-rate alike in size and quality. I have endeavoured to alter this both in helping the tree at the root with winter dressings and early applications of sulphur, but all to no purpose. My patience is at last exhausted, and the tree will have to come out. One of the finest outdoor trees of Royal George I have seen is on the Peach wall at Cowdray Park, and Mr. Geeson speaks of this and Dymond as about his most reliable mid-season Peaches. It covers 400 square feet of wall, and there must have been at the time of my visit nearly the same number of large, highly-coloured fruits. I failed to detect the slightest sign of mildew. A Peach that every grower has a good word for cannot but be one of the best, and this may be said of Dymond. It has a splendid constitution, is a certain cropper, and the fruit is large and of excellent quality. Where it does well one wants no better Peach in its season than Noblesse, and I find Violette Hative and Bellegarde very reliable sorts. The three best varieties with me are Barrington, Princess of Wales, and Walburton Admirable. As in the majority of cases where Peach culture is practised on a light sandy soil, red spider is one of our worst enemies, and requires constant attention to keep it in check. A great point is to grapple early with the pest. A close watch must be kept, and copious washings of clear water with an occasional dose of quassia extract given as soon as it makes its appearance. An equally dangerous enemy is the earwig, and the remark in connection with spider, *i.e.*, waging an early warfare, is applicable. It is no use waiting until the fruit is approaching the ripening stage: the colonies must

be dislodged while it is yet hard. In looking along the Peach wall at Cowdray, I found that Mr. Geeson had discarded the familiar bean stalks in favour of 6-inch lengths cut from the smaller canes of *Arundo donax*; these answered the purpose admirably. The inner surface is quite smooth and the lengths being perfectly straight, the insects can be blown out much more easily. Where there are facilities for planting a few clumps of this stately plant in outlying parts of the pleasure ground, the stems that are annually cut can be utilised for the above purpose.

E. BURRELL.

**Open-air Figs.**—The severe winter of 1894 crippled and in some instances killed to the ground open-air Fig trees. Some, however, in sheltered situations, were not so badly punished, and it is pleasing to find these old specimens again bearing good fruit. East Anglia has always been noted for its outdoor Figs, the Brunswick being met with even more frequently than Brown Turkey. Near Cromer I saw some remarkably fine Brunswick Figs the last week in August, these reminding me of the luscious examples one used to see about Arundel, in Sussex. Some gardeners seem to be opposed to covering Fig trees in winter, but, after seeing so many damaged and ruined trees caused by the extreme frost of the above winter, I have no doubt as to the wisdom of giving protection. Allowing a thicket of wood to form during summer is a great evil, as this prevents perfect maturity of the wood and gives frost a chance of injuring the trees in winter.—J. CRAWFORD.

**Apple Kentish Fillbasket.**—This is an exceedingly free-cropping cooking variety, which grows to a large size and keeps in good condition until the end of the year. It is somewhat like Beauty of Kent in appearance at first glance, but there is a slight difference in shape, Fillbasket being the rounder fruit of the two, and it generally becomes more highly coloured. In texture of flesh and flavour there is not much to choose between them, and if I were confined to growing but one of the two kinds, I should give Fillbasket the preference, as it is not so apt to spot as Beauty of Kent. The tree is a good grower and succeeds either as a standard or bush. Grown as a low bush and kept summer-pinned, it would prove suitable for growing in suburban and cottage gardens where space is restricted. As a standard it should not be planted near the outskirts of the orchard, on account of the loss of fruit likely to result from autumnal gales of wind, through its large size and weight.—A. W.

**Peach growing at Carrow House.**—A few years since a Peach house was erected at Carrow House, the form being a rather lofty lean-to with high front lights. A trellis tolerably close to the glass was fixed from the top a certain distance down the roof, standard trained Peaches and Nectarines being planted to furnish these, while from near the front lights to where the above-named trellis terminated were fixed, crossways of the house, espalier-like trainers some 5 feet or 6 feet apart; in the centre of each a Peach or Nectarine was planted. Thus a great variety of both Peaches and Nectarines was secured in the one house, and the plan of training has answered admirably. I remember seeing a good-sized house planted on the crossways system near Birmingham, and those who have only one house and wish for variety would do well to give the system a trial. I have heard it condemned on the score that sufficient sun and light could not reach the trees, but that this is more imaginary than real is evidenced by the fruitful state of the trees at Carrow.—J. CRAWFORD.

**Sad end of a giant Apricot tree.**—The *Revue Horticole des Bouches du-Rhone* mentions the disappearance of an Apricot tree nearly a hundred years old, which was the pride of an orchard at Hyères. The stem of this giant measured 9 feet 2 inches in girth. Its branches extended over a circular area nearly 50 feet in circumference, and under their shade twenty-five

persons could shelter themselves from the sun. It has borne nearly four tons weight of fruit in a season, and the crop has often been sold, on the tree, for 500 francs (£20). The tree, which was of the variety named Abricot Royal, was a chance seedling, and was planted out seventy years ago. With advancing age part of the trunk had become hollow, and a colony of hornets took up their abode in the cavity. Lately, the owner, wishing to get rid of these troublesome tenants, placed some burning sulphur in the mouth of the cavity in order to smother them, and having finished the operation went away, thinking he had made a good job of it. Unfortunately, however, during the night the fire, which lay smouldering in the interior of the tree, being fanned into activity by the rising wind, totally consumed it, and next morning where the tree had stood nothing was to be seen but a heap of ashes. The owner is said to have been quite stunned by the occurrence, and he had good reason to be so.—*Revue Hortico.*

**Notes from Monmouth.**—With me, and I believe in Monmouthshire generally, this has been a somewhat peculiar year. Until the early part of May there was every prospect of a remarkably good season. Plums, Pears, Apples, Cherries, &c., were one mass of bloom, but frost suddenly appeared after an extraordinarily mild winter and destroyed our hopes. I escaped fairly well except with Cherries, Plums, Gooseberries and Currants, and wall fruit generally, which have been poor. Pears are an indifferent crop. Apples are fairly good, but they are falling off, the maggot having attacked them. Figs are abundant, especially the Brown Turkey, but they are later than last year; the same with Filberts and Nuts. Melons, thanks to the sun, have also done well, though I fear the cold, wet weather we are now having will injure the fruit which a week back looked so promising. Strawberries were good, but did not last long. I grew twelve sorts, but next year shall, from experience, confine myself and rest satisfied, I hope, for a while at all events, with the following six for outdoor: Royal Sovereign, Vicomtesse H. de Thury, Sir Joseph Paxton, Veitch's Perfection, Latest of All, and Waterloo; and for indoor forcing, Royal Sovereign and McLean's Wonder, though the latter was this year disappointing. Noble I have always found very poor and have discarded it. To my mind, the very best Strawberry I have or have seen in this county is undoubtedly Royal Sovereign. Late Potatoes at present show no signs of disease, though I fear the continuous rain we are now having will affect them. Globe Artichokes, which do so well generally with me, are not so good as usual. As a rule vegetables generally, especially Peas, have been most abundant.—*G.WENT.*

**Fruit at Kimberley Park.**—So far as shelter and position are concerned, few gardens are so favoured as the one at Kimberley Park. In spite of this, however, Apples are this year as scarce as in other gardens less sheltered. The only variety bearing a good crop is one called the Lyon, a local name most likely, as I never remember hearing of it before—a medium-sized Apple, of good appearance and colour, and useful for both dessert and cooking. At Kimberley, the smaller finely-flavoured varieties of Pears seem to find most favour, such sorts as Doyenné du Comice, Josephine de Malines and Glou Morceau receiving every attention, and paying for it by the prolific crops the trees are yielding. Pot Strawberries are well done. Mr. Wainwright making a rule of potting two plants into an 8-inch pot for successional work. I noticed a very healthy batch of Gunton Park treated in this way, and the results are most satisfactory. I have often thought that pot Strawberries intended for ripening their crops in April and May are generally confined in too small pots to give the plants the best chance, and that by having more soil to root into and being less pot-bound, better results would be obtainable. Of course, with very early batches that are introduced into heat say in November and December the case is different, as these are brought on

with less sun-heat, do not make so much top growth, and are far more easily kept moist at the roots. In the vineries at Kimberley, which are planted mostly with Hamburgs and Muscats, I noticed a remarkable Black Hamburg sixty-three years old with an enormous stem and carrying a magnificent crop of good-sized well-finished bunches, as good, in fact, as those borne by young Vines in adjoining houses. Filberts, as in most other gardens where they are grown in Norfolk, may be gathered by the bushel.—*C. C. H.*

#### SHORT NOTES.—FRUIT.

**Pears Beurré d'Aremberg and P. Sterckmans.**—Will some of your correspondents who have grown the Pears named below kindly give their opinion of them as to cropping, flavour, and if they ripen satisfactorily? 1, Beurré d'Aremberg (Pear stock); 2, Beurré Sterckmans (Quince).—*B. ADDY, Southport.*

**Plague of wasps.**—In this neighbourhood we are quite over-run with wasps. To-day I started five men in search of nests, and within the space of two hours they found no less than nineteen nests, all within a quarter of a mile of the fruit garden. To-day I was examining a Pear Beurré d'Amanlis and I found no less than twelve wasps inside of it. What can one do to protect the fruit under these circumstances? The wasps start on the fruit long before it is ripe.—*JOHN BUTLER, The Gardens, Normanton Park, Stamford, September 13.*

#### NOTES OF THE WEEK.

**Begonia gigantea.**—I send you one leaf, a spike, and a bud of this raised by M. Nouin. It is a most beautiful decorative plant, the truss of flower being double the size of that sent and very singular.—*D. GUIHENEUF, 48, Rue St. Merri, Paris.*

**Heliopsis lævis.**—For cutting, the well-formed blossoms, of a decided orange-gold, should prove even more useful than the larger Sunflowers, as the flowers are borne on good stems of a nice length, while the foliage is also smaller and neater generally.

**Fuchsia simplicicaulis.**—A large specimen of this old species in one of the greenhouses at Kew is at the present time loaded with trusses of its long drooping flowers. The tube is very small, of considerable length, and imparts a somewhat unusual appearance to the plant.

**Aster spectabilis.**—This is one of the North American Starworts, flowering in company with the Italian kinds. It is not quite 2 feet high, with masses of blue-lilac flowers, the latter of good size individually. It is a free grower and good bloomer for early September work.

**Lobelia splendens** (Winchmore Hill var.).—This is certainly a handsome as well as telling form, the colour of the blossoms a deep vermilion-scarlet, and freely produced on blackish purple stems nearly 4 feet high. It produces a most brilliant display when seen in quantity.

**Helenium nudiflorum** is now in its fullest beauty, and for the large border its fine panicles of bloom are very showy. It is surprising what a number of flower-heads is produced in one large panicle on a single stem, while the distinct shade of colour is very acceptable at any time.

**Asclepias incarnata pulchra.**—This pretty form has been in good condition in Mr. Perry's nursery at Winchmore Hill. In habit and general aspect of the inflorescence it resembles the species, while the much-branched heads of flowers are of a purplish rose hue and very distinct.

**Colchicum speciosum.**—This fine bulbous plant is flowering splendidly in the rock garden at Kew, the blooms of exceptional size and vigour, as may be expected from established bulbs. Not far away a bold group of *C. byzantinum* is also very effective, but in point of size and fine colour

all pale when compared with the handsome kit above named.

**Aster acris**, with its cloud of pale blue star blossoms, is certainly one of the finest of the race, the mass of blossom produced being real marvellous. Its full height is about 2½ feet, and coming early in September, is particularly valuable. In its flowering it is even before the Italian kinds.

**Aster Amellus.**—Apart from the intrinsic beauty and value of the flowers of this Starwort we have also the very important addition of new attractive foliage—a plant, indeed, in all its forms far removed from the weedy rubbish that for years was regarded as representative of the Starwort family. The above species deserves extensive culture and is effective for a long time.

**Dendromecon rigidum.**—This beautiful member of the Poppy family is in flower at Kew where it is planted against the wall of a green house. The blossoms are of a clear deep yellow and very attractive. Its perfect hardiness, however, in this country is doubtful, and for the time being a slight covering at the root during severe weather may assist in bringing it through winter of moderate severity.

**Anemone japonica Whirlwind** is a very distinct variety of the Japanese Anemone, possessing a sort of Hen-and-Chicken-like arrangement in its flower-buds in the way these last surround the central flower, which is of the same colour as in the well-known white form of the plant. These smaller buds are, moreover, quite numerous, while the complete head of blossom produced on exceptionally stout, vigorous stems each about 1 foot in length.

**Punica Granatum nana.**—The Pomegranate in flower in this country is not conspicuous either for its frequency or the number of flowers. At the same time, the colour is exceedingly brilliant and very showy if only a few flowers are open at a time. Just now the dwarf form mentioned above is giving a few blossoms. Kew on the Orchard house wall. Some years ago I remember seeing the taller form flowering freely in the Oxford Botanic Garden.—*E. J.*

**Flowers from a Surrey garden.**—Mr. Wilson sends us from his garden at Weybridge some remarkably fine flowers of the *Gentiana*, the sweet-scented *Linnaea borealis*. The soil Mr. Wilson's garden, as also the rains we have recently had, have no doubt helped these flowers, which, coming at the present time, are valuable in the open-air garden. Mr. Wilson also sends some leaves of *Shortia galacifolia*, which is very highly coloured for so early in the season.

**Rosa canina var. dumetorum.**—The splendor upon this variety are now very attractive. The collection of Rose species at Kew is nothing among this numerous collection to be compared to the variety under notice for the brilliancy of its seed-pods. I am not acquainted with the flower, but I certainly think it is worth growing if only for its beautiful fruit. The petals are of the clearest scarlet-crimson, oblong in shape and each about 1¼ inches in length.—*PILLOMET.*

**Agave vivipara var. nova.**—A beautiful marked plant of this scarce kind in the collection at Kew cannot fail to attract attention by reason of the nearly milk-white shade of its rather narrow leaves. This peculiar shade in greater or less degree is spread over the whole surface, though its greatest density is from the margin inward. In most kinds the variegation is of a yellowish golden hue, disposed either centrally or at the margin, or both, in which case much green appears. In the above, however, the white shade covers a good portion of the leaves.

**Berkheya (Stobæa) purpurea.**—A very distinct Thistle-like plant of South African origin that does not appear to gain much favour in gardens in spite of its many attractions. It is capital plant for a hot and dry soil. This species is now flowering at Kew, where the plant is nearly 4 feet high, much branched and freely flowered. The ray florets are of a lilac-purple

shade. The radical leaves are of large size, while the whole plant is very spiny. The species may be readily raised from seed, and if grown freely would make a capital plant for the wild garden.

**Gazania longiscapa.**—This species differs materially in the manner of producing its rich golden blossoms from the other members of this showy race by the exceeding length of the foot-stalks. These are each more than a foot in length, and bear at the extremity one very large and handsome flower of rich orange-gold about 3 inches across. The shade of colour is peculiarly striking and brilliant, and with many blossoms expanded very attractive. The flowers spring from a tuft of long linear leaves, each about 1 foot long, green above and silvery on the reverse side.

**Physalis Franchetti.**—Any gardeners who are in doubt concerning the value of this handsome Japanese plant should, if possible, pay a visit to Kew, where two beds in the herbaceous ground are devoted to it. The species is of erect growth and attains 3 feet to 4 feet high, flowering and fruiting profusely. A day or two since, when inspecting the plants, we noted that many of the earliest of the huge bladder-like calyces were already finely coloured, the rich orange-scarlet shade being very showy. Some of the larger calyces would be three times the size of those of the better-known kind.

**Kniphofia Nelsoni.**—In the whole of this arid and extensive family of hardy plants it is very doubtful whether any species or variety can surpass this in its brilliant colour, as also its great freedom of flowering. In these respects the plant appears almost unique. Less tall and robust than the majority, the established plants are not more than 3 feet to the tip of the tallest spike. The plant is quite large enough, however, to be extremely useful, the vermilion-scarlet of its long tubular flowers being most effective. In growth generally it may be compared with *K. laciniata*, though slightly taller, while the colour is unique.

**Coris monspeliensis.**—A miniature rock plant of procumbent habit, that bears some resemblance to the *Ethiomas* in the habit of growth, though quite distinct in flower. The violet-coloured blossoms are borne in elongated terminal heads, in which the orange anthers are conspicuous. It is only suited to the warmest and sunniest positions in the rock garden, requiring sandy peat and loam with ample drainage. The proximity of a portion of rock would afford some protection to a pretty, though not over-robust nature. Happily, it is readily raised from fresh seeds, and such when obtainable should be sown at once.

**Meadow Saffrons in grass.**—That the meadow Saffrons, as the *Colchicums* generally are properly called, should find a congenial home in the grass is not surprising; indeed, they appear content here as in the border. At the same time the grassy blades from which they spring in some degree compensate for the absence of their foliage at flowering time. Bolder in the masses of their blossoms than the *Crocus* in spring, these things give a welcome tone of colour in many spots that would otherwise now be empty and bare. The white and pink forms of *C. autumnale* are not only free-flowering, but may be had at a very cheap rate also, which permits of planting freely.

**Zephyranthes Atamaseo.**—A group of this pretty bulbous plant is now in flower near the orchid house at Kew. The plant is used as an adjunct to some rare bulbs and other things, and the pure white blossoms appearing so freely from the almost grassy bed of leaves make a very pleasing display. The blossoms individually are unlike those of the *Crocus*, only larger and spongy, while the dark green roundish leaves fling away from the blossoms prevent these being besmudged with dirt. The plant is so nearly akin to evergreen, that it is worth using much more freely in some such spots as this, either in the woodland, on grass, or in the rock garden. In any such position where it may re-

main permanent for three or four years and its blossoms receive protection, the snowy flowers at this time are always pleasing.

**Abutilon megapotamicum** (syn., *A. vexillarium*).—This very distinct species is now in flower at Kew, where a large plant is trained to the wall of the economic house. It is a singularly graceful and beautiful species for a position thus protected, though scarcely sufficiently hardy to succeed generally in the neighbourhood of London. In more favoured parts, as the Isle of Wight and the south of Ireland, this species is more content in the open, where it is invariably admired. The blossoms are quite distinct from those of the better-known members of this race, and inclined to a tubular or bell-shaped outline, the sepals of a dark crimson, and petals of a golden hue.

**Polygonum orientale.**—A very striking and effective species for planting in bold groups, particularly in newly-made gardens or the like where a quick effect is desired. Though only of annual growth, it is certainly one of the most showy of this genus. In lieu of the usual creamy-white flowers so common in the members of this family, the blooms are deep rosy-purple, and produced in long drooping racemes both terminal and axillary. The effect of a handsome group is very striking, the giant plants reaching to 8 feet high or more. A native of the East Indies, it has been known to botanists well-nigh 200 years, and is still a valuable plant for the mixed border. A fine group may now be seen at Kew.

**Encomis punctata.**—Three years ago I was given a plant of this. Until it flowered, neither the giver nor myself knew its name. Having been told that it was a kind of Orchid, I put it into a small stove house, where it grew vigorously and at last threw up its bloom. I divided the plant, and have now eight. This year it has bloomed out of doors, each of the two plants that I experimented on having flowered. I now have in my room one bloom picked August 12; it is a good 13 inches long, and still retains its colour to a certain extent. I have grown these out of doors against the wall of a conservatory facing south and west; the plants look perfectly healthy, and I believe, given a warm situation, they will do well out of doors.—*M., Haunts.*

**Amaryllis Belladonna.**—A grand display of this handsome bulbous plant is now to be seen in the Royal Gardens at Kew. Perhaps the most conspicuous, though not the only lot is that outside the Orchid house, where something like a hundred or more spikes in all stages are to be seen. Some of the strongest heads have close upon two dozen buds and blossoms, which in itself means a long season of flower. While some of the flower-spikes are only just clear of the soil, others are even passing out of bloom, while in intermediate stages there are numerous examples. Not the least pleasing and attractive feature is the infinite variety both of colour and size of blossom that is to be seen. In the irregular grouping as here seen the plants have a most lovely effect. In such a beautiful display it would seem impossible to desire anything further, and, so far as flowers go, nothing really is needed. At the same time in such an arrangement a little foliage of some kind at flowering time would be of great help, and, thinly disposed among the spikes, should give additional charm to the whole.

REMOVING A BOILER.

YOU very courteously in your number (August 28) of THE GARDEN answered my query about the expediency of removing my boiler, subject, however, to my describing the "kind of boiler in use." It is a plain saddle boiler, and the exact number of feet of piping is 640 feet.—*A. A. W., Holme Grange, Wokingham.*

\* \* \* A boiler of the size you have fixed, this being capable of heating several hundred feet more of hot-water piping than are already attached to it, cannot be quite so economically worked as one four sizes smaller. Much in any case, how-

ever, depends upon the stoking. There is no necessity to fill the interior of a boiler with fuel every night, thereby burning it to waste, overheating the houses, and doing more harm than good. Good stokers, or those who keep their flues clean and their dampers and ash-pit doors in good working order, can by a judicious use of the latter make 2 cwt. of fuel go as far as reckless stokers can 3 cwt. At the same time, I am of opinion that plain saddle boilers are not the best that can be selected, and if much larger than needed for the amount of piping attached, are decidedly extravagant. If "A. A. W." decides to have a smaller boiler in the place of the old one, I should recommend a "Chatsworth" or some other saddle boiler with a water-way back and flue through top. Size 10 would be equal to heating about 680 feet of 4-inch piping. This size would be 42 inches long, 20 inches wide, and 25 inches high, and could, therefore, be easily fixed in the position occupied by the old one. It would be found a somewhat expensive boiler, but the saving in fuel would soon compensate for this outlay. The amount of fuel it would burn in a year cannot very well be given. It is all a question of local circumstances. For obvious reasons no particular firm of hot-water engineers can be recommended. Any of them could supply and fix the boiler named.—*W. I.*

— If "A. A. W." (p. 168) will look up his old numbers of THE GARDEN he will find the question of boilers discussed in connection with the relative merits of anthracite coal versus coke in the autumn of 1896. If, however, these numbers are not to hand, it may meet the case to state briefly that too large boilers are just as great a mistake as when they are too small, and that even when the heating power of two particular types is guaranteed at about the same figure, he would find for the amount of piping stated that a 36-inch Chatsworth would answer his purpose better than a 48-inch plain saddle, although, if the smaller boiler is used, I should recommend the substitution of anthracite for coke unless the latter can be procured very cheaply. It is difficult for the best stoker to work an over-sized boiler economically, for the simple reason that sufficient fuel has to be employed to get a good heat all round, and a natural inference is, that the greater the interior dimension, the more fuel will be required.—*E. BURRELL.*

SOWING TULIP SEED.

HAVING saved a quantity of Tulip seed, I should feel obliged if you will inform me if I should sow it now or when. I should also be glad of full particulars as to treatment of seedlings.—*W. M., Bognor.*

\* \* \* Tulip seed may be sown at any time during the month of October or early in November. At the time when the bulbs are planted it is usual on the part of raisers of seedlings from fine rectified strains of the florist's late Tulips to sow the seed in large pots, deep pans, or boxes well drained, the compost a light and sandy one. There must be good drainage so that water can pass away. The seed should be only thinly covered with soil. As the seeds are as hardy as the bulbs, the pots or boxes in which they are sown may be placed in the open, but it is safer to winter them in a cold frame. Very little growth will appear the first year, only a thin thread resembling that of the Onion. In the second year one narrow blade-like leaf will appear, and in the third year a rather broader one, and this will go on for five or six years until a second leaf is produced, and then a flower may be expected. It is usual to allow seedling Tulips to remain in the pots in which the seeds are sown two or three years, and then when they have ripened their leaves to lift them and replant. There is a singular peculiarity about seedling Tulips which is not generally known. In the second year, and for two or three years after, the seedling plants do not content themselves with forming one bulb only, but two or three or more perhaps, and these are technically termed "droppers." They are to

be found not where the parent bulblet was planted, but at the end of a kind of underground pipe, or hollow stem, which the bulblet sends down below its level in the soil, and all that the raiser of seedlings can do at this stage is to select the longest of these "droppers," which is usually found deepest down in the soil, and grow it on until it ceases to send down "droppers" and has formed a blooming bulb. One only of the "droppers" should be selected; it is enough to prove whether the flower is of value when it opens. "W. M." gives no information as to the section of Tulips from which he has saved seeds. It is to be hoped the seeds are from a strain worthy of the expenditure on his part of time and attention.—R. D.

**Grub on Pear foliage.**—Would you kindly tell me what the grub I send is and its origin? I picked it from a Pear tree.—CONSTANT READER.

\* \* The grubs on your Pear trees are those of the Pear sawfly (*Selandria cerasi*). They will not do much harm at this season. They make their chrysalides in the earth. Spreading quicklime under the trees would kill any that happened to fall on it. If the attack has been a bad one, it would be worth while to remove about 2 inches of the soil under the trees and burn or deeply bury it.—G. S. S.

**Grubs in Cyclamen.**—I send you herewith some Cyclamen bulbs, and also some grubs which eat the roots of the same. You will greatly oblige me by throwing any light upon how they can be eradicated and where the grubs originated.—A. HUBBARD.

\* \* The Cyclamen roots you sent were attacked by the grubs of the black Vine weevil (*Otiorrhynchus sulcatus*) or its near relative the clay-coloured weevil (*O. pecifus*). The parent beetles feed on the foliage of various plants, vines, wall fruit trees, &c. They lay their eggs at the roots of Primulas, Cyclamens, Ferns, Strawberries, and other soft-wooded plants, on which the grubs feed. When present in large numbers, as they frequently are, they injure the plants very much. From their position at the roots insecticides are useless. The only way is to pick out the grubs from among the roots. The weevils only feed at night, and to catch them the best way is to spread a sheet under the plants attacked during the day, and after dark to enter the house with a bright light. This will startle the beetles and they will often fall; if they do not, give the plants a good jarring shake and search them well. Tie small bundles of hay or moss round the stems; the weevils will creep into them for shelter during the day, and can be caught in them.—G. S. S.

**The weather in West Herts.**—Since the present month began there has not been a single warm day with only two warm nights. Indeed, the past week was the first cold one since the middle of June. On the night preceding the 4th the exposed thermometer fell to within 3° of the freezing point. At both 1 foot and 2 feet deep the soil is at the present time about a degree colder than is seasonable. Rain has fallen nearly every day, and to the total depth of over an inch. Until the 6th the wind remained high and came entirely from some westerly point, but since then the weather has been much calmer, and on the 7th the average rate of movement was less than a mile an hour.—E. M., *Berkhamsted*, Sept. 9.

— Since the beginning of the month there has been only one day which was unseasonably warm, with but three warm nights. During this cold spell the exposed thermometer fell to within 4° of the freezing point on five nights. The temperature of the ground, both at 1 foot and 2 feet deep, is now about seasonable, but a few days ago the reading at the former depth was 3° below the September average. No rain at all has fallen since the 8th. Throughout the last eight days the weather has been very calm, the average rate of movement of the air at 30 feet above the ground being on an average less than two miles an hour—

direction mostly some point between north and east. On three consecutive days during the week the sun shone from seven to ten hours a day.—E. M., *Berkhamsted*.

## PUBLIC GARDENS.

### MUNICIPAL VANDALISM.

LORD LONDESBOROUGH sends the following note to the *Times*, and it reminds one of the good things that are destroyed in so-called improvements in towns now and then. For instance, the fine view of the Thames at Richmond is much marred by a kerbstone edge to the river. There may have been some need for a fixed margin to the river, but surely it was possible to have done it without making it like the edge of a London kerbstone! The absence of the sense of beauty in people responsible for the improvements of our towns is deplorable, and it surely should be possible in all large towns and cities to have a committee of men of artistic training or tastes to advise as to such changes.

I venture to ask permission to call public attention through your columns to the vandalism that is being committed on the Castle Hill at Scarborough. Some time ago, much against the wish of a large number of the inhabitants, it was decided to make a road round the base of the Castle Hill. These works have now been commenced, with the result that the north side is irretrievably ruined. Instead of the grand rugged rock to which one is accustomed, there is now what appears a monstrous railway embankment. The road will probably cost over £100,000, but the ratepayers are not, I believe, to be allowed to drive along it free, but are to pay a toll. Who but lunatics would pay for the privilege of driving by the side of a railway embankment?

**St. Paul's Churchyard.**—The most deplorable sight in the City for the past five or six weeks has been the once beautiful garden in St. Paul's Churchyard. No one, we suppose, could have prevented the destruction of the grass while the immense Jubilee stands were being put up, but it has been a matter of considerable surprise that no steps have been taken to lay fresh turf.

**New recreation ground for Richmond.**—We hear that the negotiations between the Town Council and the Crown authorities for the purchase of a large portion of the famous Old Deer Park as a public recreation ground are almost completed, and the hope is expressed that the "new lung for Greater London" will be ready for public opening on the 10th October. The Town Council will acquire nearly ninety acres of the park, and a deputation from the Council will this week wait upon the Chief Commissioner of Works in order to settle the final agreement. The new ground will meet a long-felt want of the local cricket and football clubs, in addition to affording one of the most picturesque open spaces on the banks of the Thames. During the week a meeting of the representatives of the local athletic clubs will be held for the purpose of forming a ground committee to assist the Town Council in regulating the park, and it is hoped it will be possible to secure a member of the Royal Family to perform the opening ceremony.

**Planting Carnations.**—Can any reader inform me whether it is better to plant Carnations from layers during September, or put them into pots and plant in the spring?—T. S.

**Juniperus compressa, creeping form of.**—I sent you lately a note on a supposed creeping form of *Juniperus compressa*. I now write to say this is a mistake. By some means a slip of *J. tamariscifolia* must have been sent me with a number of slips of *J. compressa*. It seems extraordinary that such a strong-growing shrub as

*J. tamariscifolia* should have remained almost without growth for nearly five years. During the last few weeks of heavy rainfall it has shown its true character.—E. C. BRXTON.

**The Ginger plant.**—"Winchester" asks what should be done to make a fine plant of the scarlet variety of the Ginger flower, which has been kept in a vinery in summer and in the Cucumber house in winter. The true Ginger plant is *Zingiber officinale*, which has a fleshy, knotted root-stock, leafy stems about a yard high, the leaves 8 inches to 12 inches long, narrow, spear-shaped, green and rigid. These leafy stems never produce flowers, the flower-stem, which springs direct from the root-stock, being leafless, from 6 inches to 12 inches long, clothed with sheathing bracts and bearing at the apex a small cone-like head, formed of imbricating green bracts, from which the comparatively small unattractive flowers are pushed out two or three at a time. They are greenish-yellow, with a purple spotted labellum. This plant is widely cultivated in tropical Asia and is the source of commercial ginger. Singularly enough, it very rarely flowers even in the tropics. It has only been known to flower once at Kew within the last twenty years. Of course, it is easily cultivated if kept in a warm greenhouse. If "Winchester" will kindly forward to Kew a specimen of his "scarlet variety," it may possibly be identified. Probably it is not the true Ginger plant, but some other species of *Zingiber*, of which some thirty are known. *Z. rubens* has bright red bracts and flowers, but is not known to be in cultivation. There are several species cultivated at Kew, but none of them is of any value for decoration.—W. W.

## OBITUARY.

### MR. JAMES COCKER.

THE news will be received with general regret of the death on Wednesday morning, September 15 at Sunnypark, Aberdeen, of Mr. James Cocker senior partner of the firm of James Cocker and Sons, nurserymen, seedsmen, and florists, Aberdeen. He had been ailing for the past two years and latterly had been unable to attend to business. Deceased was borne at Corse, parish of Forgue, in 1832. He entered the business of his father—who was founder of the firm—at the nursery at Sunnypark, and afterwards went as a journeyman to Cloncaird Castle, Ayrshire. He also spent several years in London studying the various branches of the nursery business. He went into partnership with his father and brother about twenty-six years ago, a partnership which continued until the death of his father sixteen years ago. He then started business on his own account, taking his three sons—James, William and Alexander—into partnership with him. His eldest son James predeceased him three years ago but William and Alexander are still actively engaged in the business. Mr. Cocker was a very enthusiastic and successful cultivator of Dahlias, Pansies, Pinks, and Carnations, while latterly herbaceous plants and Roses claimed his chief attention.

**Royal Horticultural Society.**—On September 21 the next meeting of the Royal Horticultural Society will be held in the Drill Hall, James Street, Victoria Street, Westminster, from 1 to 5 p.m. Lecture at 3 o'clock by Mr. W. Iggulder on "Cultivation of Cyclamen."

**Names of plants.**—*Constant Reader.*—Please send better specimens, and not single leaves, as in some cases.—*Col. ... and Gabriel.*—1, *Clerodendron fatiolum*; 2, *Vitis acouitifolia*; 3, *Berberis stenocephala*.—*A. B.*—*Mitonia Moreliana*, a good form.—*T. Scott.*—1, too shrivelled to identify; 2, next week; 3, *Polygonum Brunonis*.

**Names of fruit.**—*R. W. M.*—Pears: 1, *Jery Gratioli*; 2, *Beurré d'Arenberg*; Apples: 3, *Lord Suffield*; 4, not recognised; 5, *Waltham Abbey Seedling*; 6, *Warner's King*.—*N. B.*—*Pear Durondeau.*

## CHRYSANTHEMUMS.

### EARLY-FLOWERING CHRYSANTHEMUMS.

More than ordinary interest was felt in the display of Chrysanthemums at the September show of the National Chrysanthemum Society this year; at least, so far as the somewhat limited number of admirers of the early sorts are concerned. This season a step in the right direction was taken by the committee, who had appealed to the best known cultivators of the early flowering varieties for an expression of opinion as to the sorts which should be classified as "early flowering," and with which to make a special section in the Jubilee edition of their catalogue. As a result of this appeal the have been divided into two sets—(a) Japanese and (b) Pompons. The selections comprise thirty kinds of each type of the flower, and represent pretty well the best sorts now grown. The exhibition, held on September 7 and two following days, was confined to the varieties enumerated in the Jubilee catalogue, and considering the lateness of several of the best sorts, the committee have every reason to be satisfied with their first effort in this direction. With two exceptions, all the pompon varieties flower naturally during the latter part of August and the whole of September, and on this account there was plenty of material to select from. On the other hand, of the Japanese sorts included in the list, half of them were in bloom during September—several of these late in the month, and the second half during October. It will therefore be seen that the list is supplemented with novelties at present little known, the Japanese sorts will be represented in as interesting a variety of color and form as the admirers of the flower would wish. Such varieties of recent introduction as Barbara Forbes, Queen of the Earlies, and pure white, the former distinctly the

better of the two; Mme. Casimir Perier, white prettily tinted pink; Ambroise Thomas, crimson-red, tipped bright gold; Francois Vuillermet, pale rosy blush, very free and branching; Gladys Roult, a pretty little white flower for October; Mons. Levéque Père, a large bright bronze flower; Notaire Groz, a lovely lilac-mauve, very free, really an early James Salter; Rose Queen, beautiful shade of rose, free and dwarf; Ivy Stark, nearest approach to an early Source d'Or, though smaller, very dwarf; Mme. Armand Groz, pale primrose-yellow, flushed blush-pink, very pretty indeed, and exceedingly free; M. Regnault de Molmain, creamy-white shaded rose with a darker centre; and De la Guille, rich orange, passing to yellow, dwarf and bushy, may be considered desirable additions to the early blooming section, their period of flowering extending over a term of fully six weeks, commencing early in September and continuing well into October.

The early-flowering Chrysanthemum is essentially a hardy border plant, and is never seen to greater advantage than when freely used in large beds and borders, where it makes a bold and handsome display. In such positions little or no disbudding is necessary, and then useful sprays of handsome blossoms, although small or of medium size, may be had for quite a long time. Far better results may be achieved by planting out as suggested, as with very little attention a wealth of blossoms may be had when the majority of the late summer and early autumn flowers are past their best or have been crippled by a few degrees of frost.

Growers of high-class blooms are sometimes disposed to underrate the value of the early kinds, considering them unworthy of attention, because of the small size of their flowers, but to those who have to keep up a continuous supply of bloom these pretty little blossoms, if cut in sprays, are invaluable. It is a pity, therefore, that a really good exhibition of these sorts cannot be made. The first week in September is quite a fortnight too early, and although this is better than no display at all, there is no deny-

ing the fact that gardens would be far richer if facilities were given to bring the real merits of the early-flowering Chrysanthemums into prominence. D. B. CRANE.

### EARLY-FLOWERING CHRYSANTHEMUMS AT THE AQUARIUM.

THE display of these was as usual somewhat scanty. Whites, of course, are valuable at any time for the supply of cut bloom, because of the lasting quality of Chrysanthemums. These, however, must have the protection of glass to open them pure in colour and clean in petal. Kinds with bright tints are conspicuously rare; the lilacs seem dingy, the reds washed out. Mme. De-grange and the yellow sports G. Wermig and Mrs. Hawkins are especially beautiful. These lend themselves to the production of blooms of a good size. Those named were well shown at the Aquarium. A board composed of six bunches of the yellow sorts cut with long stems had a rich effect. Queen of the Earlies, exhibited in medium sized blossoms, appeared most chaste. This was probably opened under glass. Barbara Forbes is another white with a faint primrose tinge, well worth cultivating. Emily Silsbury, yet another white, may be had good in September, but must be opened under glass. Lady Fitzwygram is perhaps the purest white of sorts that will flower in the open border, and is a most useful kind as a pot plant. The habit is dwarf and bushy, the blooms shapely. Mme. Marie Masse (rose-pink) was seen bright in colour; so, too, was Harvest Home (red and gold). Ambroise Thomas (bronzy-tinted red) seems a pretty sort, of recent introduction.

Two sports from the variety M. G. Grunerwald were exhibited, the one a bronze, the other a yellow. They were not, however, in a condition good enough to judge of their merits. It was pleasing to note that the National Chrysanthemum Society awarded the prizes to really early kinds. More than one exhibit was disqualified because it contained naturally late kinds made to open their blossoms early by manipulating the flower-buds. Nothing could be more misleading to those who expected early flowers from such sorts in the ordinary way. W. H. Lincoln, for instance, is a

variety that may be forced into flower in August as well as be retarded up to January. H. S.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Buds on Chrysanthemums** (*Penlwyn*).—By the term "taking a bud on the third run" is meant retaining the third bud appearing on the shoot after the break is made. This latter break may have either been made naturally by the formation of the bud causing the new growths to break away from around it, or it may have been caused by pinching out the points of the shoots to effect the same purpose. A bud on the third run may be either a second or third crown bud, and it may also be a terminal bud. Varieties differ so much in this particular that no general rule can be laid down.

**Chrysanthemum Calvat's Australian Gold.**—I have noticed something wrong with this variety in several places this season. The tender tips of the growth appear as if scorched by the sun just as they are forming flower-buds. So much so has this been the case in one instance that the embryo blooms are quite destroyed. When first seen it looked like a case of over-feeding, but when noted in other gardens there seems something characteristic of the variety. Although this sort was not exhibited in good form last year, I fancy it will be this, and I still think it a magnificent Chrysanthemum—one that is easily grown.—H.

## KITCHEN GARDEN.

### RUNNER BEANS.

WHEN I compare the thick, old, hard, and too often dirty and stale Runner Beans Londoners have to purchase from greengrocers with the beautiful clean, fresh, tender Beans seen in such abundance in good gardens, I wonder naturally whether town consumers do ever partake of these Beans in a condition fit for food. That our market sample is, as a rule, the very worst of any form of vegetable put on to the market there can be no doubt. Very few market growers stake their Beans, and even if they do, only for very limited heights. Most of these Beans are dwarfed by pinching close to the ground, where the pods become crooked, hard, and dirty very quickly; and because the plants have no supports on which to climb the crop is far from being a continuous one. Then little or no care is exercised in the gathering. This is usually done by women who are paid per bushel, and who pull off young and old indiscriminately, clearing so many rows at one time and so many at another. Thus there is no sorting, and the market gardener makes no complaint. It is under such conditions as these town consumers have to take their Beans or leave them. No wonder if when sliced up, as they needs must be to get them edible when boiled, they show as much of flavour as boiled sticks, some being soft, some hard. Whenever I see, as I have of late, many grand rows of Runner Beans, especially of the newer selections, having tall stakes to support them, and in consequence running up to a height of from 10 feet to 12 feet, dense in growth, though the seeds were thinly sown, and full of handsome straight tender pods from top to bottom, I mentally ask whether growing runners on this method for market could not be made to pay. I believe it could, for the produce obtained from such rows as I have described is really marvellous, extending continuously for nearly three months. I have been into many good gardens lately, and in all have noticed the splendid Runner Bean crops. At Forde Abbey

Mr. Crook has splendid rows of the Best of All or Prize-winner type, fine selections from Ne Plus Ultra, and Mr. Bowerman has much longer ones of the same stock at Hackwood, carrying the longest and handsomest Beans I have seen, deliciously tender and crisp, really surprising crops. These are the product of the finest stocks, of thin sowing, 9 inches to 12 inches apart, deeply worked soil, well manured and tall well-secured supports. Would it not pay anyone engaged in market gardening to prepare say an acre of ground by deep trenching and heavy manuring, to get seed of the finest stocks, sow thinly in rows, not less than 6 feet apart, and furnish to the plants tall supports well secured against wind storms? The higher the Beans can run the longer will they bear pods. A liberal mulching of long manure should be laid between the rows, and a copious supply of water or sewage furnished in hot weather if needed. A. D.

**Crimson Globe Onion.**—This very handsome variety is so great an advance on the old Blood Red that those who have a strong preference for colour in Onions will highly appreciate it. This Onion, whilst always showing high flavour, is also a good keeper. Even when the plants are raised under glass and later dibbled out thinly into rich soil, the bulbs do not come to an inordinate size, but they are very richly coloured, solid and distinct. In shape, though termed Globe, it is rather round than spherical; indeed, gives very perfect deep form.—A. D.

**Potato Early Regent.**—I was glad to see such a favourable notice of this Potato by "A. D." in THE GARDEN (p. 175). I have grown it for several years as a second early, and can corroborate all your correspondent says about it. I have counted upwards of thirty usable tubers from a single root, and the quality was all that could be desired. Potatoes on different soils vary in cooking qualities to such an extent that it is not possible to satisfactorily recommend any one variety, but by growing a few sorts for trial, one will soon hit upon the variety suitable to his soil, and by changing the seed occasionally there need be no fear of any deterioration in productiveness or quality.—J. EASTER, *Nostell Priory Gardens*.

**Potato Up to Date.**—I lifted a few days since the whole of the rows of twenty-six diverse varieties of Potatoes grown by me for trial on an allotment plot at Surbiton. Up to Date from seed tubers kindly given me for the purpose by Mr. Sydenham, of Birmingham, gave much the heaviest crop, one that so attracted the attention of the allotment holders that there was much anxiety shown to secure stock. Next in cropping order came Syon House Prolific—seed being kindly given by Mr. Wythes—Chancellor, Prime Minister, Satisfaction, Windsor Castle, The Bruce and Renown. The tubers of Up to Date have something of the old Lapstone form and are of good general table size. So far it is the heaviest cropper I have seen this season.—A. D.

**The Bean beetle or weevil.**—Those who are engaged in the seed trade are familiar with dry seeds of Broad Beans, both Long-pod and Windsor, riddled by the Bean beetle. Sometimes a crop of English-grown Beans is much injured by it, and it is often found that seeds of imported Beans are badly affected. When Mr. Messrs. Hurst and Sons' seed grounds at Kelvedon a short time since, my attention was called to two rows of Seville Long-pod Beans, taken from a sample of imported seed returned from a customer, on the ground that they would not grow, being so much punctured by the beetle. Enough Beans were picked out from the bulk to sow two somewhat long lines: one lot consisted of the worst samples—those which appeared to be riddled through and through; and one of Beans only slightly so. Not a seed appears to have failed, and, though the rows were side by side, the worst Beans had actually produced the strongest plants.

This might have been simply a coincidence, there was no mistaking the fact. The lesson drawn from the experiment is that the operation of the beetle do not destroy the vital germ in Beans, and that to suppose their vitality is paired is a misconception.—R. D.

### MAGGOTS IN MUSHROOMS.

My Mushrooms grown in beds under cover in usual way—without being heated—are being infested with maggots. I have frequently found them in large ones, so I thought I would try smaller ones, and they are equally as bad. Can any dressing be used to prevent the disease without injuring the crop?—J. H.

\*\* Beds so affected are useless, and not worth any further trouble. It is strange that we grow the Mushroom to perfection from October to May, possibly June, in an ordinary Mushroom house heated or otherwise, with in the same structure during the summer, with as much care as possible and grown up, it is almost impossible to get clean Mushrooms. The maggot asserts itself, and once in evidence the crop is useless. "J. H." says beds are under cover. This is the evil; they are deficient in atmospheric moisture. No matter how much damped down and syringed, if the house above the ground level it is fatal. There have been cases of successful culture in such houses during cold, wet summers; but in a dry season with great heat like this year, Mushroom culture in the ordinary Mushroom house is out of the question. Very good crops are obtained in cellars where a regular temperature is maintained. You do not tell us the kind of house where your beds are, but I conclude it is an ordinary built with the roof exposed. This is the evil, as it is impossible to prevent dry air entering the house. I have for years discontinued the culture of Mushrooms in the ordinary Mushroom house from October to October. There will be no difficulty now if the atmosphere is charged with moisture. Next year you may succeed by having a ridge-shaped bed to the open under a north wall. A bed made thus in May will give you a good supply free of maggots, but even then you will need to use plenty of litter over the surface to keep the bed cool and moist. If you have a cool cellar, an old, deep, dis-stoke-hole, or any place where air and dirt cannot enter freely, you could make beds there and you would not be troubled with the pest. I cannot give you a remedy to prevent the maggot without injuring your crop; it is best to prevent the evil by adopting the advice given above. Drawings of any kind are out of the question—in fact, useless.—G. W.

**Ketchup-making.**—It is to me astonishing that many people are not poisoned by eating ketchup purchased from common hawkers in country towns. Perhaps the reason why the majority escape is because so little of it is taken of at each meal. In this neighbourhood men and women scour the country, and nothing in the shape of a Mushroom escapes them. I go home laden with a mixed lot. I recently saw an unscrupulous gatherer enter a meadow near my residence, top up his basket with common Toadstools, and go on his way. No doubt many who buy bottles of ketchup at the door are totally ignorant of its constituent parts, and think they ought to be warned against these unscrupulous vendors.—J. CRAWFORD, *Notts*.

**Late Vegetable Marrows.**—In many gardens where these are appreciated, as long a supply as possible is aimed at; a batch of plants being brought on for producing Marrows during the last half of August, September, and October. These being specially valuable, it behoves them to be in charge to afford some temporary means of shelter from early frosts, as few things are more susceptible to injury from such as Marrows. When the pits are plentiful and one can be spared for the late batch, it is a good plan to give the plants the benefit of it. If fairly wide it will generally cool

the growth made by these late plants, and the light can be drawn over them in case of cold nights. Filling pits, a rough framework of rails can be easily formed, this being covered as with the cooler nights necessitate it with mats of canvas. Any short-jointed, small fruiting varieties are better for growing for late supplies than more rampant large fruiting varieties, and a more free soil is best.—J. C.

**late market Peas.**—Many will agree with "Power's" note at page 136 on the short season market is provided with Peas. A large grower told me the demand after the London season is was insufficient to warrant having large quantities of late Peas. Possibly the growers have not paid sufficient attention to variety. I saw some of the kinds sold in June and July not worth cooking, and they get old so quickly. "Power" names a few good kinds. I could add several more to his list, and these are Marrows of first-rate quality. On the other hand, the seed is not cheap, and in quantity would be costly, and anyone could soon get over the difficulty by ordering for seed a year in advance. There has been great improvement in Peas of late years, especially in the dwarf section. I noticed this season a grower who had a few late rows for sale was overwhelmed with orders. I think there would be a demand. In the north there would be a difficulty in getting a late supply.—B. M.

**Asparagus at Gunton.**—Mr. Allan always raises his own plants, and now never plants berry-bearing ones, having proved from continued observation that the non-berry bearers produce not on finer grass, but much more of it. Mr. Allan told me to see his beds and pointed this out to me. All through the large beds I did not see a single exception to the rule. Plants raised from seed one summer produce seed the next if seed-bearers, and when the berries appear the plants are gone over and marked, so that the right ones are taken up for planting in spring, the others being discarded. Careful lifting, keeping the young, tender, fibrous rootlets moist while out of the ground, planting in shallow trenches, mulching, staking when sufficiently high, and watering several times in dry summers are the chief cultural details by which Mr. Allan lays the first season the foundation from which springs grass the second summer 5 feet and 6 feet high and as thick as walking-sticks.—J. C.

**Savoys New Year.**—Last year this new Savoy did well that I planted it again, and, from the appearance of the plants, I think it will be one of the best introductions of late years. As most growers are aware, Savoys early in the year are of greater value than in the autumn, as the flavour is superior, and the new one named above is mild in flavour that it is worth special cultivation. It is smaller than the Drumhead, and I suppose this latter point will not make it a market variety where size is the chief consideration. On the other hand, it will commend itself to private growers. Its value is greater on account of its lateness. With me it does not split in wet seasons like the older Drumhead. The plants are very close and of a deep green colour. There are few outside coarse leaves, therefore little waste. From its compact growth I should say it is one of the hardiest Savoys grown. I planted on an east border to get late supplies, and noted how well this variety stood the wet last season. It appears to be a cross between Late Drumhead and De Vertus, a late, good kind much grown on the Continent.—G. WYTHES.

**late Leeks.**—Few vegetables of late years have come into such favour as the Leek. In my earlier days I was in gardens where the Leek was not tolerated, but why I do not know, as it is one of our best late spring vegetables, and nicely cooked few can object to its flavour. Doubtless in severe winters we have had now and again in a measure shown us the value of the Leek. The winters ago it was one of the few things left in our gardens, and green vegetables were highly prized. Another point in its favour is its lateness. The Leek is the last vegetable to

run to seed in the spring, and if lifted and heeled in in a cool north border under a wall, it will be good well into May if the soil is kept moist and shaded. Having to supply vegetables in great quantities in the spring, I have planted Leeks largely. I do not attempt to grow the plants after the manner of exhibition roots, but in deep drills 2 feet apart. In the early part of the year, in suitable weather soil is drawn up to the stems to assist in blanching. For late supplies none can equal the Musselburgh. It is not so thick as earlier kinds, but the quality is good and it is one of the hardiest and latest.—S. H. M.

**FRUIT AND VEGETABLE CROPS.**

**WESTERN.**

**Sundorne Castle, Shrewsbury.**—Apples are a moderate crop, Keswick Codlin, Stirling Castle, Lane's Prince Albert, Cellini, Warner's King, and Ribston Pippin being the best. Of Pears there is an average crop, both on walls and bush trained trees. Beurré Diel, Winter Nelis, Glou Moreceau, Jargonelle, Beurré Rance, and Pitmaston Duchess are best on the wall. Damsons and Plums in this neighbourhood are quite a failure. Peaches and Nectarines outside are a splendid crop in this garden. Strawberries have been very good, but the season very short. Gooseberries and Currants have been good; also Cherries and Nuts.—G. PHILLIPS.

**Toddington, Winchcombe, Glos.**—The fruit crops in this district are much below the average with the exception of Strawberries, which were about an average. Plums are a very poor crop, and the same may be said of Apples, though in places fair crops may be seen. Against walls Peaches and Nectarines are fair crops, though the trees were badly affected with blister. Pears rather under average; Cherries much under. Of bush fruits, Red Currants were the best, Black Currants and Raspberries being much under. Aphid has been less in evidence than is usual, but a good many Plum trees in the neighbourhood have been attacked by the shot bore beetle (*Xyleborus dispar*), and are dead in consequence.—J. CLEAKE.

**Bowood Park, Calne, Wilts.**—Fruit crops are much below the average, Apples and Pears in particular, while Plums are a complete failure. Apricots are a fair crop, likewise Peaches and Nectarines, and there has been a fairly good crop of Strawberries and small fruits.

Vegetables on the whole are good. Potatoes up to recently were looking well, but I regret to say the disease has made its appearance all through this district.—GEORGE BROWN.

**Tregothnan, Cornwall.**—Apples are under average; Pears and Plums very scarce; Peaches only half a crop, as the trees blistered badly and the fruit dropped. Cherries (Morello) are almost a failure; Strawberries better than for several seasons and the fruit good, but the crop was soon over. All bush fruit is good.

Vegetables, considering the dry season, are very fair. Early Potatoes and early Peas good; mid-season varieties were badly infested with mildew. Early Cauliflowers were bad, many of the plants buttoning. Both autumn and spring-sown Onions and Shallots are good.—WM. ANDREWS.

**Forde Abbey, Chard.**—In early spring there was a promise of an abundant fruit crop. Pears set a heavy crop and swelled up to a good size. On some bush trees the fruit attained to a good size. About the time the Apples were on the point of setting we had a severe frost, which destroyed the greater part of the bloom and froze the Pears right through. This happened in some instances where they had double fish-netting over them. Plums are almost a failure; Magnum Bonum and Orleans on a north wall are the best; Jefferson's and Kirke's have a few. Morello Cherries are a splendid crop, and very fine from north walls. Our best cropping Apples are Lord Suffield, Domino, Royal Somerset, Lane's, Cox's,

and Mannington Pearmain. Of Pears, Winter Nelis, Durondeau, Beurré de Capiaumont, Old Cras-sane, Passe Colmar, and Grosse Calchasse are the best. Strawberries not half a crop, bloom killed by frost, Royal Sovereign and President the best. Gooseberries an enormous crop. Black Currants grand. Red poor.—J. CROOK.

**Haverholme Priory, Sleaford.**—Apples are a good average crop, especially Lord Suffield, Lord Grosvenor, Potts' Seedling, New Hawthornden, Beauty of Kent, Warner's King, Ecklinville Pippin, Keswick Codlin, Stirling Castle and Northern Greening; fruit fine and clean. Pears are very uneven; still we have nice crops of Louise Bonne of Jersey, Jargonelle, Beurré Bosc, Marie Louise, Brown Beurré, Marie Louise d'Uccle, Haeon's Incomparable, Glou Moreceau, Beurré Diel and British Queen. Plums, Cherries and Apricots are very poor; in fact, the worst crop for ten years. Strawberries were a good average crop, rather small, but flavour excellent. Gooseberries very good and plentiful. Currants (Red and Black) under average.

Vegetables good and plentiful. We have a good heavy subsoil, so the drought does not affect us.—J. COWARD.

**Stourton Court, Stourbridge.**—Stone fruit here is quite a failure, with the exception of Victoria Plums, which have a grand crop. Apples are a fair crop, especially Warner's King, Emperor Alexander, Lord Suffield, and Keswick Codlin. Beurré Diel, Jargonelle, Williams' Bon Chrétien, and Marie Louise Pears on an old wall facing south have splendid crops. Red Currants and Raspberries were above the average. Black Currants were not so good, with the exception of Carter's Champion, which bore well.—T. SIMPSON.

**Cirencester House.**—Apples are abundant, but injured by a terrific hailstorm, which occurred on July 20. Pears a fair crop; the fruit is clean and the trees healthy, also free from insects. Plums a failure. Apricots heavy crop and good. Peaches very good. Cherries half a crop. Strawberries excellent in every way. Bush fruit also excellent and abundant.

Vegetables good. Although I have not found any disease in Potatoes, I hear complaints and I notice the haulm of some varieties is attacked.—T. ARNOLD.

**MIDLAND.**

**Bostock Hall, Middlewich, Cheshire.**—In this district a few varieties of Apples are carrying good crops, including such sorts as Lord Suffield, Keswick Codlin, Manks Codlin, Ribston Pippin, Yorkshire Greening, Beauty of Kent, and Pott's Seedling. Other varieties are thin. Pears are generally very poor. We have a few nice Jargonelle, Aston Town, and Swan's Egg. Morello Cherries are very fine and plentiful; other sorts very scarce; Damsons, Plums, and Apricots are quite a failure; Strawberries and Raspberries good crops; Black Currants poor; Red Currants very good; Gooseberries plentiful.

In spite of the dry season, vegetables are very good. Peas, Scarlet Runners, French Beans, Celery, Cauliflowers, Onions, and Carrots are excellent crops; Potatoes also capital crops and of good flavour.—A. STATHAN.

**Coddington Hall, Newark.**—The fruit crops in our garden and this district generally are the poorest known for many years. The spring brought great promises in the way of abundance of bloom, but the bitter, almost unprecedented cold winds of April and May—not frost—shattered all hopes. Gooseberries, Black Currants and Raspberries were only half a crop; Red Currants average, La Versailles exceeding all othersorts. Were I planting for market purposes this is the variety I should choose. Superlative Raspberry seems to stand a cold spring better than the older varieties, and should be planted in exposed gardens. Strawberries were a light crop, many of the plants in rows of old well-tried sorts not showing a single truss of bloom. Of Apples we have but a poor crop. In young orchards where the wind had free access none but a few hardy

sorts, such as Duchess of Oldenburg, King of Pippins and Sturmer Pippin, have any fruit on. Old trees that are a complete thicket of wood are carrying half a crop. This is, I think, instructive, as proving the folly in our uncertain seasons of thinning out young Apple trees too much. On espaliers, Fearn's Pippin, a never-failing Apple here, has a capital crop, also Cox's Pomona and Stirling Castle. Other sorts are a failure. Pears, both on walls and espaliers, are half a crop, Pitmaston Duchess, Doyenné du Comice, Louise Bonne, Glou Morceau and Beurré d'Arenberg bearing the heaviest crops. Plums and Damsons are next to a failure, even the old Victoria in market gardens failing to yield. Peaches on open walls are the choicest I have had for years, Dymond, a splendid hardy outdoor Peach, of excellent quality, carrying the most fruit. Morello Cherry trees, which had borne well for the past ten years, have not a single fruit on them. Nuts are plentiful.

Vegetables have done well, except Peas, which were hurried on by the extreme heat and lack of moisture. Potatoes have yielded good crops, Ringleader, Snowdrop, Carter's Snowball being excellent under garden culture; late sorts in field promise a good return. I still keep to the Magnum Bonum as a main winter Potato, as it does well on the light soil. I change the stock of seed every few years.—J. CRAWFORD.

**Thoresby.**—The fruit crops are very erratic. Early in spring there was a promise of a plentiful crop of everything. Cold east winds, however, set in and continued all through the flowering and setting time. These caused most of the flowers to drop, and now Apples are but a light crop, also Pears, Plums, and Morello Cherries. Sweet Cherries are half a crop. Small fruits are good, except Black Currants.

Vegetables were late owing to such a spring, and since the end of June we had little rain, and required to water all the crops in the kitchen garden.—A. HENDERSON.

**Alton Towers, Staffordshire.**—The majority of hardy fruit trees blossomed well, but owing to the continued cold east winds and sharp frosts in May which killed the blossom, and even caused some of the fruit which was set to fall off, there is scarcely an average crop of anything except Apples, which are very heavy in some cases, especially those of the Codlin type. Pears are very thin; a mere sprinkling on some trees, on others none at all. Stone fruits are a total failure. Of Plums there are none. The Cherries set well, but dropped off wholesale at the stoning period. Currants and Gooseberries are fair. Strawberries small and soon over, owing to the dry weather.

Vegetables on the whole are fairly good here, but light crops are the rule in most cases in this district. Root crops are small and below the average standard, scarcity of moisture being the prevailing cause.—E. GILMAN.

**Impney, Droitwich.**—The fruit prospects here are not so satisfactory as they promised to be at the flowering season, particularly in the case of Apples. The cold east winds and late frosts crippled the bloom. The Apples bearing best with me are Keswick Codlin, Stirling Castle, and Lane's Prince Albert; Worcester Pearmain, Cox's Orange, and Fearn's Pippin are also carrying fair crops. Pears are a good average crop, both on walls and bushes. Plums are a thin crop; Early Orleans, Jefferson's and Kirke's are the best. Peaches outside, Apricots, Cherries, and Damsons are a failure. Gooseberries, Currants, and Raspberries have carried good crops, the fruit of good quality.

Early Potatoes are small; late Potatoes promise to be good. Vegetable crops generally have suffered owing to the long-continued drought.—F. JORDAN.

**Teddesley Park, Penkridge, Staffs.**—In this district in the spring there was a great wealth of bloom on all hardy fruit trees, but the continual cold from the north-east, coupled with late frosts in May and June, seriously damaged the prospect of good crops. Apples were very much below the

average, although some trees are carrying good crops, while others are a failure. Pears set well, but have dropped badly, leaving very few on some trees, while others have a fair crop. Peaches and Nectarines are a failure. The trees were badly blistered in the spring, but are now making good growth. Apricots are poor. Plums are a medium crop, Victoria and Jefferson's being the best. Morello Cherries are very good and fruit fine in quality. The Strawberry crop was a heavy one and the fruit large, the finest being President. Raspberries are good and of fair quality. Gooseberries a heavy crop; Red Currants medium; Black the worst we have had for the past nine years; Damsons very poor; Walnuts bad.

Vegetables have been very good this season, with the exception of Cauliflowers, a great many having gone blind. Peas have been very good. Chelsea Gem, William Hurst, and English Wonder grown on south borders for the earliest supply have been very good. The last-named I consider a grand dwarf Pea. Midseason Peas were soon over, owing to the spell of hot weather we had. Autocrat is a good dry-weather Pea. Ne Plus Ultra and Sturdy grown for a late supply are coming in earlier than usual this season. Runner Beans and the climbing French Bean are giving good results. Winter greens of every description are looking remarkably well, so are root crops. Early Potatoes have turned out very good. Late Potatoes are looking well and promise to be heavy crops. At present there are no signs of disease.—F. CLARKE.

**Chatsworth.**—The fruit crops in this district are under the average with the exception of Strawberries, which have been over the average and of good quality. Apples, Pears, and Plums are a poor crop. Cherries average crop. Bush fruits moderate.

Vegetables of all kinds are growing freely. Potatoes are a good crop and free from disease.—W. CHESTER.

**Aldenham Park, Bridgnorth.**—Apples, Plums, Peaches, and Apricots in these gardens and immediate district are much below the average, and Damsons, I might say, are a complete failure, though it is very seldom these fail here; you will find them growing in almost every hedgerow, and they seem to thrive better in this position than when planted in either garden or orchard. Cherries of every description are much below the average. Gooseberries, Currants, and Strawberries were very plentiful.

Vegetables are very good in general, and from what I have seen at local shows the quality is an advance on late years.—THOS. CANNING.

**Hardwicke Grange, near Shrewsbury.**—Fruit crops, on the whole, are below the average, Apples particularly so. Nine-tenths of the trees have no fruit. I notice a tree here and there carrying a crop. These are more or less early varieties. The cause of this, I fear, is a good deal owing to the maggot. Not only did it take the blooms and young fruit, but the foliage as well, and this has been going on for some years. Pears are somewhat better, still not good by any means; and what seems strange, with the abundance of fine hot weather, is that much of the fruit is scabbed. Worse still is the crop of Plums and Damsons. In the gardens here we have only a few Green Gages on walls, no others to speak of. No one can remember when fewer Apricots have been gathered in this neighbourhood. Many cottagers will be reminded of this when rent-day comes. Cherries have also been poor. I should be glad to hear if the Morello trees are noticed to be dying off badly the last few years. It is so with me. What can be the cause of it? I can write much more hopefully of the Peach crop. There is enough and to spare. The foliage at first was blistered very badly. I pull all such leaves off, apply the garden engine every evening with warm water, which soon alters matters, and if mildew puts in an appearance, we have now that excellent remedy, X.L.A.L. I gathered a fine lot of Early Alexander outdoors in July. I think, notwithstanding the long spell of hot, dry weather,

Peaches generally are later than usual. I think, may partly be accounted for by the early trees received early in the season by blight &c. Of Figs we have a good crop. Trees looking healthy after being killed to the ground a few years since. Cob Nuts are plentiful, Filberts are scarce and Walnuts but few. Currants are a failure, Black Currants or little better, and Gooseberries few and far between. Raspberries have been somewhat better, only the extra labour of heavy watering. Strawberries have been a good crop, but of short duration.—J. TAYLOR.

#### NORTHERN.

**Lowther, Penrith, Westmoreland.**—Apples are a very poor crop indeed, in many places a failure. Pears average crop. Cherries and Plums below average. No Peaches, Nectarines or Nuts grown outside. Raspberries, Gooseberries, and Red Currants average. Strawberries very good, fruit very fine, particularly James Veitch, Countess, Auguste Nicaise, F. d. Sovereign, and Empress of India. The above are the best varieties I grow, and for travelling I find Countess to be far the best, as it is not only fine fruit, of good flavour and appearance, but has the seed well on the surface, which is a great thing in the saving of the fruit from crushing.—F. CLARK.

**Abney Hall, Cheadle.**—As regards fruit crops, this year is the most unsatisfactory. Apples are the best. They are barely an average crop, though after these late rains they are setting up well, and we shall have some good kitchen Apples. The dessert kinds do not produce satisfactory results in our district, and there are not much grown. Pears are a failure, so are Plums. Cherries have been poor also. As regards bush fruit, Gooseberries were far below average; Black Currants a failure; Red Currants fair; Raspberries moderate.

The Pea crop looks well, having abundant pods. After William I. for early use I grow Plus Ultra mainly, and I find nothing better. Of course it requires long stakes, but it is certainly worth an effort to provide these. The only satisfactory way to do Onions in this part is to raise the young plants in boxes under glass in the spring, and then plant them out so that they have a good early start; then they give a good return. Crops of autumn Cauliflowers, Brussels Sprouts, Celery, &c., are looking well.—R. M'ELLAR.

**Elm Hall Gardens, Liverpool.**—Apples in this district are up to average. Warner's King, Ecklinville, Lord Suffield, Bismarck, Dumek Seedling, Peasgood's Nonsuch, Cox's Orange Pippin, Blenheim Orange, Ribston Pippin, and I believe Peach are carrying heavy crops. Pears are fair. The best are Jargonelle, Louise Bonne of Jersey, Marie Louise, and Clapp's Favourite. Plums, Cherries are very thin; Peaches, Nectarines, Apricots, and Figs excellent. Strawberries have yielded fine crops. Bush fruit has been plentiful with the exception of Black Currants.

Spring and summer vegetables have done well. They are doing remarkably well, while those in the winter quarters are just as promising.—JAMES BRACEGIRDLE.

**Allerton Priory, Liverpool.**—Strawberries have been fair. Bush fruits good on the whole, but Currants thinner than usual. Cherries poor. Plums and Damsons are a failure, the weather having been very unfavourable during the time they were in flower. Pears are moderate, the best being Jargonelle, a full crop, B. d'Amanlis, Durandean, and Thompson's. Apples as standard are the best, and include Warner's King, Lord Derby, Ecklinville Seedling, King of Pippin, Lemon Pippin, Keswick Codlin, and the Duke of Pomeroy, which I consider one of the very best of cooking Apples, although pushed into the background by its more showy rivals. Bush trees carrying good crops are Worcester Pearmain, Ribston Pippin, Lane's Prince Albert, and Potts' Seedling.—J. J. CRAVEN.

THE GRANGE, [ASKRIGG.

THE GRANGE, near Askrigg, Yorkshire, of which we to-day give an illustration, sometimes called by Hall and now used as a farmhouse, is said to have been built on part of the "Abbey of Fors," founded by Peter de Quincey. It is prettily situated near a waterfall on one of the mountain streams in Uredale, the garden, as will be seen from the illustration, occupying the front of the house.

**Heights of perennial Phloxes.**—While it is perfectly correct to say of the old or ordinary sort of hardy Phlox that growths increase in height as the plants become older, it should be evident that such heightening is due not to increased vigour, but to greater density of growth,

FLOWER GARDEN.

TUFTED PANSIES—A LATE DISPLAY.

It is some years since the Tufted Pansies were in such fine condition as they are just now. In the neighbourhood of London, in the middle of September, blossoms of phenomenal size and exceedingly rich colour may now be seen. This is ample compensation for a display of a less interesting character experienced early in the year, when in the first place, chiefly owing to cold and cutting winds, followed by drought, the plants suffered very considerably, and the display was not quite so fine as one would have wished for. The value of a good mulching was never more apparent. Especially during the

were treated to a compost made up of equal parts of sifted loam and rotten manure, with the addition of a sprinkling of guano, and these plants have attained quite large proportions, and are making an exceedingly free display. The quality of the flowers regarding size, colour and substance has been of a high standard of excellence. The plants are now simply bristling with numerous young growths, which will serve to perpetuate the different sorts, and these are easily detached with roots appended, or, to those who prefer the system, of a suitable size to make first-class cuttings.

With the introduction of so many fine novelties during recent years, there has been a constant inquiry for those sorts which commence to flower very early in the season, and those, too,

The Grange, near Askrigg, Yorks. From a photograph by Mr. G. F. Jones, Malton, Yorks.

largely excluding from the leaves and stems heat and air, and causing the growths, in fighting for the possession of these elements, to go higher than of them than would otherwise be the case. It is but a repetition of what is always seen in vegetation when plant growths are crowded. But with reference to the heightening of the growths of the really dwarf varieties, that is of an age but infinitesimal, because habit is as potent a force as tendency. Thus at Chiswick, where a fine collection of Phloxes of several years' standing may be seen, and also as seen at Long Ditton, true dwarfs remain dwarfs relatively to others. There is plenty of varieties, none of the highest excellence, whose regular height ranges from 12 inches to 18 inches.—A. D.

spells of very hot weather was this fact more noticeable: those plants which had been generously treated in this way grew away vigorously and blossomed profusely, although, owing to the great heat, the blossoms shrivelled long before they had attained their full size. The cooler and moister weather of the greater part of August, and also during the first half of the present month, has just suited these plants, and while other subjects in the hardy flower garden are looking anything but happy and comfortable, the Tufted Pansies have simply revelled in it. The rotten manure with which the beds had been mulched has been very valuable to the plants just lately. Some beds

which are seen at their best during the latter part of the season. At the present time the following sorts with me are in the pink of condition: each of the members of the Duchess of Fife family, which includes that already mentioned; Goldfinch and White Duchess; together with the original of this type of plant and form, Ardwell Gem, are as good as I have seen them for a long time. Devonshire Cream, the new creamy white flower; Ethel Hancock, purest white; Nellie, white; and Christiana, the last with a rich orange suffusion on the lower petal, are each literally covered with blossoms. Of the yellow sorts, Pembroke, one of the very best; A. J. Rowberry, Molly Pope,

rich butter yellow; Princess Louise, one of the finest bedding sorts; Mary Gilbert, and Lord Elcho, are a blaze of rich colour, and alongside the white varieties are making a most beautiful contrast. The delicate colouring of pale rosy blush as seen in *Rosea pallida*, one of the freest and best of the tufted sorts, appeals to almost everyone, and this in conjunction with the large oval rayless flowers of *Florizel*, a blush-lilac colour, forms a very welcome feature in the garden. Sir Robert Peel, a new variety distributed for the first time this year, is in excellent form, with its large oval blossoms, deep primrose with a very effective orange eye and a most delightful creeping form of growth, and those fond of very large flowers, with well-defined rays and strong growth, yet compact, will find in *Lord Salisbury* a typical flower. *Bartholdi*, a rich crimson-purple with neat yellow eye, has flowered in a wonderfully free manner, the brilliancy of its colouring standing out conspicuously. Of the blue shades of colour, *Britannia*, a deep violet-blue, stands pre-eminent. *Blue Gown*, *Magnificent*, and a charming little seedling named *Symphony* are three beautifully compact types of growth, while the profuse character of their flowering renders them almost indispensable at this season. The colour of the first two sorts may be described as mauve-blue, that of the latter sort being a pretty violet-lavender. Of the fancy type of flower succeeding well just at present is *Isa Ferguson*, with large purple-black flowers, paling off to light lavender on top petals. *Stobhill Gem*, a somewhat similar kind of flower, but not so dark and with more substance; *Cottage Maid*, alternately marked purple-violet and pale lavender; *Sunset*, pale yellow, with a broad crimson band on the upper petals, and very sweet scented; and *Butterfly*, very large white flower, with heavy margin of deep rose, form a very desirable and interesting quartette. One very fine sort named *Lucy Franklin* is free in its growth, and white, with sulphur-yellow suffusion of the lower petal. This has succeeded wonderfully during the last three weeks, and should be largely used where something unique may be wanted.

The foregoing sorts are well worthy of the attention of all wanting a striking and pretty display during the latter part of the season.

Higgate.

D. B. CRANE.

***Tropæolum speciosum*.**—For years I failed to grow this, but now it is an absolute weed with me. The great secret, I find, is uniform moisture for the roots to run in and the soil must be deep, sandy, and free. Where the *Tropæolum* now grows so freely was a corner of strong blue clay, absolutely useless. I cleared the space and carted on a mixture of soil collected in our woods. I made it about 4 feet deep, and the natural slope gave the required drainage. Various shrubs are planted here, up which the *Tropæolum* climbs. This year I trained some up spikes of *Yucca recurva*, which had a splendid effect on the north slope of this made soil. *Montbretia Pottsi* and *M. crocosmeiflora* make a complete hedge, and flower splendidly. The *Tropæolum* has been planted about six years.—J. R. HALL, *For Warren Gardens, Cobham, Surrey.*

It is to be hoped that few will venture to plant this beautiful creeper in their rock gardens, as, one would infer from a recent note, some are doing. It is difficult to establish at first, but once it gets a foothold, *Tropæolum speciosum* is only kept in bounds or eradicated with difficulty. In a rock garden it becomes a lovely object, but runs so rampantly as to be a pest. Like some of the *Convolvuli*, it requires to be planted where its naturally rambling and encroaching ways will do no harm.

Any readers of THE GARDEN who may wish to try *T. speciosum* will find March or April a suitable time for planting. The soil should be well trodden before and after planting. If snails or slugs are plentiful they are very troublesome until the creeper gets a good hold, which may be in two or three years.—S. ARNOTT, *Carsethorn, N. B.*

—In a recent issue "E. J." made some interesting remarks on this "when at home" gorgeous climbing plant. I have tried to grow it in this garden, but it only does moderately, and that behind a north wall where the growth takes possession of a Plum tree. It did very well in an old garden a mile from here in the stitish loamy soil of the Raspberry bed, the growth each season climbing amongst the canes in all directions—an undesirable position some may say—but I think the gardener had tried it in almost every other part of the garden and failed. The success he had with it leads me to think that my soil is too light for one thing, and does not retain sufficient moisture for its wants. "E. J." mentions its doing well further north, and as a proof that a cool, moist climate suits it, I may mention that in my employer's garden near Loch Awe, in Argyllshire, it grows and flowers quite freely.—J. CRAWFORD, *Coldhington Hall, Newark.*

**Carnation The Burn Pink** (p. 190) was raised at The Burn, near Brechin, many years ago by the late Wm. Lawie, gardener, who named it *Annie Lawie*. Many plants of it were given away, and some of the recipients who may have forgotten the name called it *The Burn Pink*. Years afterwards, when the Duke of Fife was married, a too enterprising nurseryman dubbed it *Duchess of Fife* and sent it out as a new variety. It will thus be seen that it has no claim whatever to be called by the latter name, and I think it should be known by its original name of *Annie Lawie*, if only as a souvenir of a very capable gardener who during a long service did much to enhance the many natural beauties of The Burn.—M.

***Helenium autumnale superbum*.**—This is now in flower, and I think it will prove a useful pot plant for autumn use. Grown in the ground it runs up very tall before it comes into bloom, but as a pot plant it may be had in bloom with a large head at from 2½ feet to 3 feet high, and younger plants will flower when about 18 inches high. It does not appear to throw up young shoots from the base so freely as most herbaceous plants, but cuttings root freely. The tops may be taken early in the spring. If they are taken after the plants have made a good growth, the old plants will branch out and a number of cuttings may be had from side shoots. Cuttings should be put in a hotbed or an intermediate propagating pit, a little bottom heat and sufficient moisture to keep the fleshy cuttings from flagging being all that are necessary. The tops produce the largest heads of bloom and come into flower earlier, but the side shoots will make nice plants and keep up a succession of bloom.—A.

***Gentiana acaulis*.**—For its bright display of blossoms in the early spring and summer, the old garden *Gentianella* is among the most prized of all hardy carpet plants, and on some soils is by no means difficult to please. In other districts, however, the plants are invariably unhappy, and while growing freely, or rather forming patches of rather diminutive growth, fail to give anything like an adequate flowering. This may be, of course, due to neglect rather than anything else, or, again, some deficiency in the soil may, in a measure, account for the poor growth. Too frequently the large patches are left too long without disturbance, which in this species is an error. It is equally wrong, inasmuch as only inferior results ensue when the plants are pulled to pieces and planted, as they are quite frequently, in spring at flowering time. During the latter period many hundreds of plants are sold because attractive, though the future of the majority of such plants would not prove very encouraging if followed up. Where the plant thrives it should be made much of, and no season in the whole year

is so well suited to dividing and replanting as the present. Planted firmly in good ground at any time during September or October, the losses are reduced to a minimum, the plants take readily to the soil, and continue making stoloniferous growth nearly all the winter, a fact that may be verified in the ensuing spring when the young shoots appear above ground. Over-dense patches often fail to flower freely, but with room for development they produce one of the brightest displays spring.—E. J.

#### ANNUAL ASTERS.

ANYONE interested in the annual Asters will find a large and complete collection in the gardens of the Royal Horticultural Society at Chiswick just now. But they are bewildering, as one sees the same thing under different names, and the matter is rendered more mystifying by reason of mere naming in this country of types which have originated in France, Germany and elsewhere. The trial at Chiswick may be said to furnish four types: the Quilled German, which has a tall branching and somewhat loose habit of growth but produces highly symmetrical and fully double flowers borne on long, stiff flower-stems; an admirable type to grow for cutting, because the flowers are produced freely and continuously, as they last much longer in a cut state than do the softer flat-petalled varieties. Next the Comet type, with its large, spreading florets, curving, and with a small centre of quilled florets. Of this type there are now several varieties ranging from blue to white. They are early bloomers, and when well grown produce very fine flowers for exhibition; indeed, they are driven all the other types of flat-petalled Asters from the exhibition tables. They, when well grown, reach a height of 18 inches or so, and the blooms are large, full and very handsome, and therefore is not to be wondered at they are becoming increasingly popular. The third type is that generally included under the head of *Chrysanthemum* flowered, embracing the tall *Victoria* and the dwarf *Bouquet* and *Mignon* types, all of which have compact, flat-petalled blossoms varying in size, all reflexing, but well filled in the centre, and singularly symmetrical. These are all very valuable garden varieties, most of them compact growth, and at the same time very free blooming. Until the *Comet* type came to the fore it was the favourite Aster for exhibition, and those who made a point of growing the *Victoria* Aster for show produced wonderfully fine blooms, thinning out the buds and mulching and watering the plants as needed.

The fourth type is that known as the French Aster, a fine form of which is known as *Truffaut* *Pleony*-flowered *Perfection*. This is a type of Aster requiring high culture to bring it to perfection; the petals incurve, and when fully developed form a compact half ball. But it is a long time to flower, and that is perhaps why it is not much grown as it should be. In the various exhibitions where French Asters are this should be the only one exhibited as such, but all flat-petalled varieties are now regarded as French Asters. The range of colour in the French flowered French Asters is greater than that observed in any other type, and this, added to their great beauty, makes them a desirable section to cultivate.

R. DEAN.

**African Marigolds.**—Some plants of both the orange and lemon varieties of these very effective autumn-blooming plants, grown by me in a very exposed field at Surbiton in small clumps and thinned, are blooming superbly and evoke the warmest admiration from all who see them. The seeds were sown on May 3 last, quite early enough for such tender things, especially as so soon the plants bloom profusely and finely all through the autumn, when some such bright colours are very welcome.—A. D.

**Canary Creeper.**—In the kitchen garden at Forde Abbey, Chard, Mr. Crook backs the kitchen garden flower borders with tall rows

of Sweet Peas. These, however, with the best of treatment soon become exhausted, and then a seed or two put in here and there beside the rows of Canary Creeper early in June produces sturdy plants that, getting hold of the Sweet Pea supports, run up them quickly, and as the flowers of the Peas give out they are

reason is that these Phloxes always show their finest form the first year when raised from cuttings. The second year they give several heads of bloom, but less fine. Does not that show that when it is so easy by propagation in the spring to have plants in plenty showing their finest form, it is undesirable to grow stock on in borders

now in great beauty in Messrs. Daniels' nursery, Norwich. The individual blooms are similar in size to those of auratum, but have a wide red band running throughout the entire length. It is pleasing to find Lilies receiving more attention, as when well grown they always pay for the labour and cannot fail to be admired. A large, round, elevated bed filled with *L. lancifolium rubrum* in the pleasure grounds at Blickling is now (the first week in September) a pleasing sight. The plants and flowers are much improved by giving a good mulch during the summer months. If the soil is allowed to become very dry, growth soon becomes weak and stunted. Unless in very sheltered positions, it is necessary to place neat sticks to the plants to prevent damage from high winds.—J. C.

*Acanthus mollis.* From a photograph by Mr. F. Mason-Good, Winchfield.

ACANTHUSES.

THE genus *Acanthus* occupies a prominent position among the best of the hardy fine-foliaged perennials, and for this reason, when well grown is worthy of special positions where the plants may remain and become a feature. Without previous knowledge of the plants it would scarcely be thought that the ordinary examples of these things obtainable in the hardy plant nurseries would in a few years develop into the giant proportions possible. Being of rather slow growth naturally, often three or four years elapse before the flowering stage is reached, even in the more robust kinds. One species, after a twenty-five years' experience among hardy plants, I have not yet seen in flower. I refer to the very distinct form known as *A. spinosissimus*, a plant by no means frequent in collections to-day. But while of slow growth generally, the *Acanthus*es are by no means uninteresting until the flowering stage is reached, for the handsome and picturesque leaves that are each year put forth are sufficiently attractive in themselves to merit attention. Nearly all the species are very robust, and for this reason require a rather strong loam or even clay soil occasionally, in which they find ample means of support. In proof of this I may state in passing an experience of some large examples that grew quite near the Crystal Palace many years ago. Much of the soil in the garden referred to was the output of the Penge tunnel, a soil of soft greasy clay, which, incorporated with the loamy soil of the garden, made an unusually deep-rooting medium for many plants. It may possibly have been more due to the increased depth of soil than to anything else that one of the most vigorous kinds (*A. mollis latifolius*) each year produced such a fine display of foliage and blossom. Planted in the foreground of a shrubbery having a belt of trees behind and a deep slope to a railway cutting near, the position was at once sheltered and well drained, the result being some of the grandest specimens I have seen, the fine leaves several feet in length, and the singular and striking flowering spike towering above all. It is in such positions and with a good depth of soil that the *Acanthus* or Bear's Breech, as it is called, invariably succeeds. As few plants provide such striking leafage, they are worth a little extra trouble. It is not that the plants are in any way fastidious as to soil or even situation; on the contrary, they grow quite freely in almost any good garden soil. But to make specimens of them, an extra depth of soil is needful, and the handsomest examples I have seen have not resulted either in a retentive clay soil or in one very hot and dry. Where a depth of 2 feet or 3 feet can be given, these plants will quickly make themselves at home, and in course of time hands me tufts 4 feet or 5 feet across, surpassing many of the

succeeded by the long growths and pretty yellow flowers of the *Tropeolum*, and thus a pleasing display, almost more beautiful than before, is furnished several weeks longer.—A. D.

**Perennial Phloxes.**—I am asked to explain why I think these hardy border plants should be lifted and either divided and replanted or thrown away after the second year's blooming. My

reason is that these Phloxes always show their finest form the first year when raised from cuttings. The second year they give several heads of bloom, but less fine. Does not that show that when it is so easy by propagation in the spring to have plants in plenty showing their finest form, it is undesirable to grow stock on in borders

**Lilium auratum rubro-vittatum.**—This new form of the well-known *Lilium auratum* is

so-called sub-tropical subjects in stately grandeur. Where space permits in the rock garden, one or two of these should be so planted that the deeply-cut and glossy leaves should cover portions of the rock. On the lawn, too, or a sunny slope a group of these would be effective; indeed, in almost any position where a good depth of soil is assured there need be little fear of success, and, provided they are well planted at the start, the plants may remain undisturbed for many years. Once they are well established they increase annually in beauty, and a few isolated examples six or eight years planted will constitute a feature in the garden. The majority of the species are quite hardy, or at least sufficiently so to pass through an ordinary winter with impunity. At the same time, in the case of fine specimens it will be best to give some slight protection in severe winters, as such things are not easily replaced. All the kinds may be increased by division, preferably in spring with returning growth; by seeds, if sown any time during the winter after being gathered; and thirdly, by cuttings of the roots. Of all these methods of reproduction, seeds when obtainable must take the first place always, as the root cuttings, while constituting a most prolific source of supply, and therefore great help in trade collections, considerably weaken any established plant. Young plants raised in private gardens for the further embellishing of the grounds should be planted in nursery beds for a year, or perhaps two, prior to placing them in permanent positions. Some of the best known and most worthy kinds are

**A. MOLLIS**, an idea of which may be gathered from the accompanying illustration. Not only is this one of the most showy and distinct, but it is also, when fully grown, a free-flowering species, the lofty spikes producing rose and white blossoms, very striking in the entire inflorescence. Native of Italy.

**A. MOLLIS LATIFOLIUS** is perhaps the best known of all. This is rather more dense and generally compact than the type, the flowers more closely arranged on the spike, and the foliage handsome in appearance. It is a vigorous and robust kind, and certainly the most imposing for purposes of sub-tropical gardening. This unique form should find a home in almost every garden. It is frequently grown under the name of *A. lusitanicus*, which is regarded as synonymous with the above.

**A. LONGIFOLIUS**—as may be inferred by the specific name—is very distinct, the leaves from 2 feet to 3 feet long, decidedly narrow in comparison, and when seen in the established clumps the whole tuft of leaves gracefully arching. This is especially valuable for the rock garden by reason of its characteristic habit of growth. The flowers are of a purplish rose in long spikes nearly 2 feet in length. Native of Dalmatia.

**A. HISPANICUS**.—This Spanish kind has large, shining, deeply-cut leaves and spikes of white flowers, and though an old species long known to botanists, is not well known in gardens at the present time.

**A. SPINOSUS** is a South European kind with purplish blossoms and deeply cut leaves, the divisions of which are terminated by a short, sharp spine.

**A. SPINOSISSIMUS**.—A very old, though still uncommon species in cultivation. It is perhaps the most distinct, as it is also the most spiny of the genus. It blooms in autumn, the beautiful rose-coloured blossoms being densely set on a long spike. The radical leaves are of a silvery hue, and the spines with which the deeply lacinated and pinnatifid leaves are clothed very acute and recurved. It is a handsome and striking species from South Europe—E. J.

—They have long been grown in English gardens, but it is now rare to find the plants well placed as regards effect—a point so little thought of by gardeners generally. Spending

many nights over wretched diagrams in which colour is treated as ignoble, flat colour only, the way the decorator has to look at it mostly, how few turn their thoughts to the far higher and more interesting question of how to place well, things that have beauty of form as well as colour. There are many instances in our gardens of plants of great beauty of form never being noticed owing to the thoughtless way in which they are crowded among other things or seen in single starved specimens. Among these plants we find the *Acanthus*, often starved and ill-placed and even flowerless, though well placed and in handsome bloom it is often striking for its beauty of flower. Indeed, we cannot get the best of it unless by putting it in conditions in which it flowers well, that is to say, sunny places and warm soils if we have any, although this it does not always exact, and we have it growing very freely on coldish soil. There are several kinds of *Acanthus*, but really not much distinction from the point of view of effect, and the best way is to take the boldest forms, particularly the one called *latifolius*, making, from the gardening point of view, always far more of their effect than of any botanical distinctions. As to where to place *Acanthuses*, they will do with the least care and give no trouble in cultivation round fountain basins, at the foot of stone walls or piers, or in sunny corners in court-yards. These are among the places in which the fine foliage will strike people most, and the plant will be still more interesting if it flowers finely. But wherever we place it it cannot fail to be noticed if the plants have room and good soil to thrive in, and, above all, are grouped together in visible quantity.

**Lilium lancifolium**.—The varied forms of this old-fashioned Lily are still hard to beat either for pot culture or for planting in open sheltered borders of nice, light, well-drained compost. The *rubrum* and *album* forms are now making a brave show in the Castle Gardens, Norwich. They are planted down the centres of narrow beds on well-kept grass, being margined on either side by *Rudbeckia Newmanii* and other similar height herbaceous plants. For placing in windows in front halls or at the foot of staircases in large mansions and grouping with other plants in autumn, these Lilies, grown into large specimens by placing some half-dozen bulbs in a 10-inch or 12-inch pot, are most useful. Two bulbs in a 6-inch pot produce just the right sized plant for dotting in convenient places in artistic groups at exhibitions, surrounded by graceful greenery to hide the somewhat rugged stems. Well drained pots, a good loam and a little decayed manure free from worms suit them well.—C. C. H.

#### FLOWER GARDEN NOTES.

**HERBACEOUS PHLOXES**.—I quite agree with Mr. Jenkins in his remarks as to the advisability of retaining herbaceous Phloxes in the same quarters for something like three or four seasons, and if the practice leads to good results alike at Hampton and here, where the soil is dry and light, there must be something to be said in its favour. Annual renewal is certainly not satisfactory if big masses of colour are required; individual pips are very fine, but the trusses are neither so large nor the growth made nearly so vigorous. Where plenty of time and labour is available to plant very carefully, mulch heavily and give occasional soakings of liquid manure should the weather prove hot and dry, I say nothing against annual planting, but if the plants have in a great measure to shift for themselves, it is certainly advisable to leave them in the ground. Naturally, a shift should always be given as soon as the clumps show signs of deteriorating. I find it advisable when planting to work in a little stuff a bit stiffer than the natural soil and mulch heavily.

**STATICE LATIFOLIA**.—I noted a week or two ago how seedling plants of this Sea Lavender vary in time of flowering, and have picked out several distinct things in a batch of seedlings so far as their season is concerned, and also in the size and

depth of colour of the tiny individual flowers. A decided boon in connection with flowers of this type is a batch of *Gypsophila* under a north wall, which comes in much later than plants in the open, and is just now (the second week in September) at its best.

**HYDRANGEA PANICULATA**.—Have any correspondents experienced a difficulty with this plant in the way of a sudden and mysterious collapse? My plants have kept all right as yet, but one or two friends chronicle disaster, and the worst part of it is the collapse seems unaccountable. Certainly it could not have been owing to any severe visitation of frost, as the winter was by no means hard. Where a number of large plants go off in prominent positions, a gap not easily filled late in the year is made. I wonder if the practice of very severe pruning, *i.e.*, taking out every bit of small, weakly growth and heading back the strongest shoots to one or, at most, two buds, has anything to do with the failure. We know that plants of vigorous habit are sometimes apt to resent such hard cutting in, and it struck me if such treatment was continued for many seasons, it might possibly be answerable for the collapse of the *Hydrangeas*.

**CHRYSANTHEMUM FLORA**.—This is one of the most useful of the early-flowering pompons for outdoor work and gives a bright mass of colour from the middle of July right away until nearly the end of the season, a speciality being the number of buds produced and the manner in which they are all developed. In its special colour it recommends itself to the notice of those who are supposed to keep the garden gay until the approach of frost, the other best things from this standpoint being yellow *Marguerites* and Mrs. Clibran *Tropeolum*.

**MARGUERITES**.—Large plants of these will be found extremely useful for standing about occasionally in glass porches, corridors, or in large greenhouses and conservatories, and, given care in watering and enough warmth to keep away frost, they will give a fair display the greater part of the winter. Plants in the open both of the white and yellow varieties that were put on early in fairly good soil will now be over 3 feet in height and as much in diameter, and if they are cut round at twice, say, a fortnight, and a week before lifting, taken up and put into small tubs, pans, or large pots, they will be found very serviceable. It is advisable to place them in partial shade for a week or two after lifting and when housed a sharp look-out must be kept for maggots. Touching this pest, the same care should be taken in propagating, any shoots showing a sign of the excrescence indicating the presence of the insect being cast on one side.

**PINKS**.—I never remember a better strike of Pinks than we have this season. Older sort always root well, but some of the newer kinds are not always so free, and it has sometimes been found advisable to layer in preference to propagating from cuttings, or rather to adopt the former method in case the latter was a partial failure. With Her Majesty, Ernest Ladhams and Snowdon plenty of good stock for another season is thereby secured. Albino, a new kind on trial this year for the first time, is very distinct, pure white in colour, petals smooth edged, habit free and vigorous. It is a grand white button-hole flower, the blooms very shapely and the calyx remain intact with no sign of bursting. Pinks of what ever shade are very acceptable border flowers, and may be introduced into the formal garden with the best results if something is planted to give a contrast with flower or foliage or with both. I know of nothing better for the purpose than *Lobelia cardinalis*.

**USEFUL FINE-FOLIAGED PLANTS**.—The mention above of *Gypsophila* and the Sea Lavenders, and the knowledge of the many uses to which they are put in connection with cut-flower work, remind me of several fine-foliaged things that prove very useful. The lemon-scented *Eucalyptus* probably I think, even a more powerful odour of this particular nature than the *Aloysia*, and side shoot of fair length mix well with many different

lowers. It is advisable to sow this early and grow it along quickly before planting, so that these same side shoots should be quickly developed. It would doubtless, like the *Aloysia*, come through an ordinary winter safely with a little protection. The experiment might be tried by planting close up to the angle of a wall, not that the plant should be confined at all to this through the summer, but that the branches are loosely tied up at the approach of winter they could be slung to the wall and protection more readily afforded. *Thalictrum aquilegifolium* is not so finely cut as the smaller variety, but it is much more vigorous, and good long sprays of the foliage are very acceptable. It will do very well in partial shade. *Tamarix gallica* does not grow so vigorously as in closer proximity to the sea, but I find an occasional plant in the shrubbery orders very useful. Of the scented *Pelargoniums* with finely-cut foliage, perhaps the best for the purpose under notice is *filiceifolium*. Fine long leaf-stalks, the better adapted for utilising with flowers, can be obtained by pinching back and occasionally removing side breaks.

E. BURRELL.

### AUGUST IN SOUTH DEVON.

During the month rain has fallen to the extent of 3.31 inches on 20 days, against 1.03 inches on 11 days in August, 1896, the average fall for the month being 2.75 inches. For the first 8 months of the year the rainfall has amounted to 23.84 inches, the average fall for the period being 2.81 inches, while in the corresponding 8 months of 1896 but 9.17 inches fell.

Of sunshine there have been 217 hours 35 minutes, which is considerably in excess of the average of 100 hours, and slightly above the amount registered for August, 1896—namely, 209 hours 25 minutes. For the past 8 months 1339 hours of sunshine have been registered, against 1364 hours 25 minutes for the same period of 1896, and an average of 162 hours 55 minutes. The mean temperature has been about normal, being 61.2° against 61.0° for August, 1896, and an average for the month of 61.5°. The highest screen reading was 72.1° on the 6th, and the lowest 49.5° on the 27th. The wettest grass reading was 47.4° on the same date, and the highest sun temperature 120.4° on the 9th. The total horizontal movement of the wind has been 7977 miles, which shows the month to have been considerably more boisterous than the corresponding month during the last 2 years, but not quite so rough as August, 1894. The windiest day was August 21, when 518 miles' run was recorded in the 24 hours, the highest hourly rate being reached between 2 and 3 p.m. on the same day, when a speed of 26 miles was reached.

In the wild garden the tall blue Monkshood (*Aconitum Napellus*) has been blooming in company with the Golden Rod (*Solidago ambigua*), while the great *Acanthuses*, with which are associated *Gumeras*, *Funkias* and *Canna Ehmanni*, have thrown up tall blossom-spires of white and pink. *Aemone japonica* Honorine Jobert, in large clumps over 5 feet high, is covered with its white golden-centred blossoms, dozens of which are cut daily for indoor decoration, their pure colouring and simple form rendering them eminently suitable for artistic floral arrangements. *Phillea ptarmica* fl.-pl. The Pearl continued in bloom well into August, and the white *Antirrhinum* is still in flower, while the pale blue of *Guthaea colestis* gives a pleasing note of colour to the border. *Astromeria aurantiaca* was in full bloom at the commencement of the month, in which time the hybrid varieties were flowering. The tuberous *Begonias* have done well, and a large bed of erect-growing scarlets has been a blaze of colour, the frequent rains having kept the plants growing, whilst not diminishing their flowering. *Marguerite* Carnations have been coming well, and those that are to be potted up this month, from which the flower-buds have been picked off as they formed, are healthy, bushy plants that will furnish a good supply of welcome bloom during the coming dark days. In potting these care should be taken not to use too large

pots, one of the secrets of success being that the roots should thoroughly permeate the soil before growth is finished for the year. The large-flowered *Cannas* are still beautiful, and show to the best advantage when associated with the dark-foliaged *Ricinus Gibsoni*. The fine-leaved *Canna Ehmanni* *iridiflora* is an object of beauty, but has not bloomed with such freedom as was the case in the preceding year. The tall flower-spikes of *Chelone barbata*, with their pendent scarlet blossoms, create a charming effect when a breadth a yard or so in diameter is grown. *Campanula pyramidalis*, with its tall spikes of white, purple and French-grey flowers, some 6 feet in height, has been a fine sight at the back of the herbaceous border, some of the plants that have been two years in the ground having thrown up as many as twenty flower-spikes. This *Campanula* is often seen growing well as a pot plant in cottage windows, the tall flowering stem being bent over till it arches from side to side of the lattice in a floral wreath. *Campanula turbinata* and *C. t. alba* have also been in flower. The strong-growing *Chrysanthemum maximum* has borne its white Daisy-like flowers in profusion, but is a plant that requires early and intelligent support, failing which it assumes an untidy appearance, that staking at a later date merely intensifies. This may also be said of the more valuable *Pyrethrum uliginosum* and of the taller of the perennial *Asters*, of which *A. Novi-Belgii* Harpur-Crewe is now in bloom, as are the dwarf-growing *A. dumosus* and the large-flowered *A. Amellus bessarabicus*. When tall-growing herbaceous plants are staked whilst making their growth, by several green-painted Bamboo canes being thrust into the clump and lightly looped together with tarred twine, the shoots growing naturally amongst them soon render them inconspicuous whilst receiving the necessary support. *Coreopsis grandiflora* has continued its display throughout the month, though giving signs that a limit will soon be set to its continued flowering. A bed of *Crimm capense* in the neighbourhood is now a striking sight, a dozen great flower-scapes rising above the wide curving leafage. *Cypella Herberti*, alluded to in my July notes, flowered continuously through the month, and is still expanding blooms. The rosy purple of the autumn *Crocuses* (*Colchicum autumnale*) is evident here and there, and on grassy banks the colour is set off to the best advantage, contrasting prettily with the vivid green.

*Cactus Dahlias* are now at the zenith of their beauty, and new and valuable varieties being added each year, there is now a lengthy list to choose from. It must be admitted that as regards form and colour, Juarez, the originator of the race, has never been excelled, but in habit this plant leaves much to be desired, being a sparse bloomer and usually having its short-stalked flowers hidden by foliage. Good scarlets are *Gloriosa*, *Professor Baldwin* and *Starfish*, while in *Mrs. A. Beck* the scarlet possesses a tone of orange. *Mayor Haskins*, crimson, and *Harry Strudwick*, dark crimson, are also good varieties. Nothing has yet been produced to beat the velvet-maroon *Matchless*, but *Bridesmaid*, sulphur and pink, appears to be an improvement on *Delicata*, the flowers of which latter are often hidden by its leafage, and occasionally revert in shape to the decorative type. Of yellows, *Lady Penzance* and *Blanche Keith* are excellent in form and colour, whilst *John H. Roach*, rather lighter in tint, is also good. Beauty of *Arundel* is a glowing lake in colour, but is surpassed in shape by the new *Cycle*, which is much similar in hue. Less progress has been made in whites than in any other colour. *F. C. Smale* belongs rather to the decorative than *Cactus* type. *Mrs. A. Peart* almost invariably comes with an open eye, and *Mrs. F. Fell*, though at its best a pleasing ivory-white of good shape, is often unsatisfactory. A few blooms of *Doronicum plantagineum* Harpur-Crewe have been forthcoming from time to time, and *Erigeron speciosus* in shady spots continued its flowering well into August, while the Mexican *Daisy* (*Erigeron mucronatus*) has been in full bloom throughout the month. *Galega officinalis*

*alba* produced its pea-shaped blossoms in profusion, associating well with late-flowering plants of *Lycnis chalcidonica*, while the stately beauty of the white *Caps Hyaenanthus* (*Galtonia candicans*) was enhanced by the glowing scarlet of *Gladiolus brechenleyensis*, and in another situation by the blue of *Salvia patens*. The orange and black of *Gazania splendens* and the crimson and gold of the *Gaillardias* formed bright breadths of colour in the border, while the scarlet *Genm coccineum* gave a high note of colour. *Gypsophila paniculata*, a fairy-like sight at the commencement of the month, with its myriad minute blossoms and delicate tracery of its thread-like flower-stems, was soon past its best, to be succeeded by the beautiful *Sea Lavender* (*Statice latifolia*), whose inflorescence, though perhaps lacking the exquisite refinement of the flower-lace of the *Gypsophila*, is very lovely and well adapted for decoration when cut. The *Hydrangeas* have throughout the month been flowering grandly, billows of pale blue bloom around the Elm tree boles, massive blooms varying in colour on different plants, ranging from bright pink to white, from grey to Forget-me-not blue, while on some large bushes flowers of various tints were to be seen. The perennial *Sunflowers* give the garden a golden glow, *Helianthus multiflorus* and *H. m. Soleil d'Or*, *H. latiflorus* and *H. rigidus* being in full bloom, while *H. rigidus* *Miss Mellish* has commenced to expand its fine blossoms, and *H. giganteus* has its tall line fringed with pale saffron. The glowing spikes of the *Torch Lilies* (*Kniphofia*) give fine colour to the garden, and appear to best advantage when seen afar against a background of evergreens. Of the *Lilies*, *L. pardalinum*, *L. canadense*, and *L. superbum* were in flower at the commencement of August, the former being especially fine, some of the stems reaching a height of 7 feet and bearing as many as forty blooms. The handsome scarlet *Turk's-cap* (*L. chalcidonicum*), with its vivid vermilion blossoms, has also flowered well, and its blooms having the desirable quality of lasting well, remained an object of beauty through the greater part of the month. *L. Humboldtii*, with its orange-purple spotted flowers, grew to a height of 6 feet and blossomed well, as did *L. auratum* from a batch of cheap imported bulbs planted in 1892. These from the first have done fairly well, though planted in ordinary garden soil with little care; whereas some fine home-grown bulbs procured at the same time, which were planted in a specially prepared bed, each bulb being surrounded with silver sand, disappeared entirely after the first year. *L. speciosum* has been flowering well, as has *L. tigrinum splendens*, while *L. tigrinum Fortunei*, the best of the *Tiger Lilies* with me, has just commenced its display. *Lobelia fulgens* is now the most brilliant sight in the garden, many dozens of tall vermilion flower-spikes rising out of a bed of *Salvia patens*. *Lobelia rosea* is also flowering well, but the soft pink has a washed-out look after the eyes have been dazzled by the vivid tint of its more showy sister. The old crimson *Bergamot* (*Monarda didyma*) concluded its flowering in the first week of the month, but its white variety and *M. hirta* were in bloom until its close, while the orange-scarlet *Montbretias* brightened the garden with their handsome flower-scapes during the greater part of August, and *Oxalis floribunda rosea* was still a breadth of bright pink. *Phygelis capensis* has produced its showy crimson flower racemes, and the dwarf *Polygonum capitatum* has carpeted a bank with its modest blossoms, while the calyces of the *Winter Cherry* (*Physalis Alkekengi*) are already showing an orange stain. *Plumbago Larpentea* has covered a portion of the rockery with its deep blue, and *Plumbago capensis* has shown off its charming light blue flower-clusters to the best advantage against a red cliff facing the south-west. *Oenothera Lamarekiana* has, after being relieved of its first flower-spike, bloomed freely from side shoots, and the single and double forms of *Iceland Poppy* (*P. nudicaule*), though not as showy as in the past month, have expanded a fair amount of blooms, while a

few fragile blossoms have appeared now and again on the clumps of *Papaver pilosum*, and the Welsh Poppy (*Meconopsis cambrica*) has borne occasional pendent yellow flowers. The Tufted Pansies are still blooming in shady nooks, while the herbaceous Phloxes, crimson, salmon, and white, have been fine masses of colour, and the yellow Paris Daisies, now large bushes, have been thickly studded with their clear saffron stars. The Sweet-scented Tobacco (*Nicotiana affinis*) still renders the fast-shortening evenings odorous with its

*Fritillaria kamschatcensis.*

sweet perfume, mingling its essence with that of the second bloom of the old double Rocket. *Rudbeckia Newmanii*, in masses a yard in diameter, has been covered with its orange, black-centred flowers, and the delicate blue of *Scabiosa caucasica* has acted as a foil to the gorgeous colouring of the *Tigridias*. *Sedum Sieboldi* is now coming into bloom, and *Tradescantia virginica* has produced a second crop of deep violet-purple blossoms, while *Zauschneria californica*, which grows strongly here, is bearing a good crop of scarlet flowers. The Plume Poppy (*Bocconia cordata*) has flourished amazingly this year, some of its shoots being 8 feet in height. Associated with Bamboos and fine-foliaged plants it is most effective, its glaucous leaves, with their white undersides, and the ivory and brown of its large flower-panicles being in marked contrast to its surroundings. *Erythrina Crista-galli* has grown over 5 feet high, and has produced a quantity of handsome crimson flower-spikes, some of them over 2 feet in length. This plant is very showy in the garden, and here passes the winter in the open air with impunity. The spikes, cut at their full length, make a telling arrangement for a tall vase. The Tea Roses have been rather spoiled by the rain storms and bluster-

ing winds, but sufficient have always been forthcoming for indoor decoration. The single white Macartney Rose is blooming freely, no day passing without some chaste blossoms expanding. The *Salmiglossis* still holds its place as the handsomest annual in the borders, but the scarlet *Zinnias* are at this season of the year most showy, and the Ivy-leaved *Pelargonium Souvenir de Charles Turner* has a delightful distant effect when hanging, a mass of cherry-pink flower-trusses, over grey stone. *Solanum jasminoides* has increased in beauty for the last three months, and now from eave to basement is studded with white flower-clusters swaying loosely from its pendent shoots. The scarlet *Tropaeolum Lobbianum* has had a brilliant effect, as has a late-flowering shoot of *T. speciosum*, while *T. tuberosum* is bright with its orange and scarlet blossoms, standing out on long stems from the blue-green leaves, and *T. canariense* threads a golden trail through a dark-leaved *Berberis*. *Eccremocarpus scaber*, though less striking than the climbers mentioned, is not unpleasing in colour, and is here a hardy perennial. The Everlasting Pea (*Lathyrus latifolius*) has covered an old outhouse with its white blooms, through which here and there the red and yellow flowers of *Mina lobata* show. *Physianthus albens* flowers and fruits abundantly in the open, and is now a mass of blossom on a perpendicular cliff wall. Tall specimens of *Aralia spinosa*, Palm-like in appearance, have been blooming freely, and large bushes of *Hibiscus syriacus* have been white with flower. The standard *Magnolia grandiflora* has generally eight to twelve creamy-white cups open above its glossy leaves, and in the neighbourhood *Catalpa bignonioides* has been in blossom. S. W. F.

## GARDEN FLORA.

### PLATE 1137.

#### FRITILLARIAS.

(WITH A COLOURED PLATE OF F. WALUJEWI.\*)

AMONG hardy spring-flowering bulbous plants, few genera possess so large a number of beautiful and interesting species. Some few kinds are well suited for naturalising in semi-wild or woodland gardens, and in such places, where the Bracken grows several feet high each year, various kinds of *Fritillarias* will grow, flower and increase admirably. For such purposes the Snake's-head *Fritillary* (*F. Meleagris* and varieties), also the Crown Imperial group (*F. imperialis*), are well suited. A mixed arrangement of white and coloured kinds of *F. Meleagris* in the grass in spring is very pleasing, while there are still a few that have an especial value when grown in pots. The group itself, though extensive and varied, even now affords great scope for improvement. The need for a series of kinds having brighter and even more attractive colours for the garden is apparent when one looks at the incessant green or dingy

purple tints in the hope of catching a trace of something whereby to identify a certain kind hereafter, though generally in vain. And when purple and green, or possibly a sort of leaden hue, are combined, it is difficult indeed to describe that flower. Even in the Crown Imperial section there is plenty of room for improvement in the rather dull red shades of some of the kinds, to which a pure white or good scarlet would prove decided acquisition. In respect to their

#### CULTIVATION,

the majority will grow quite freely in warm positions in sandy loam, and with soil of good depth also; indeed, most garden soils, provided these are not too cold and retentive, will accommodate a fair number of the ordinary kinds, such as *F. Meleagris*, *F. imperialis*, and others. The latter are, as a group, somewhat partial to a rich as well as deep soil, and in such not only build up bulbs of great proportions, but produce vigorous stems and handsome heads of blossom. Too frequently these are wrongly placed in the garden. Some attention should be paid to planting in a position where they are shaded from the mid-day sun. Frequently the Crown Imperials may be seen planted on south border near a wall, and in such places the flowers are not only small in proportion, but short-lived and generally disappointing. In the spring garden these Crown Imperials are a unique, and for this reason alone the bold vigorous heads of blossom are worth consideration. Worthy of special mention here is the *latifolia* section. Its bold, vigorous habit and varied inclination should render it a good parent, particularly so the variety known as *nobilis*, with its deep crimson-coloured blossoms. Indeed, in this group alone there is material for improvement that should not be lost sight of, the flowers being bold in many instances and of good substance, together with perfect hardiness. Only a few, and these t

*Fritillaria Meleagris.*

most precious, of the dwarf species appear to demand something more than ordinary care that is if we would have them in perfection. Refer to such beautiful kinds as *aurea*, *pubida*, *Moggridgei*, *recurva*, and such like species; t

FITILLARIA WALTERI EWING

These are dwarf, and among the most beautiful of this genus for pot work or the rock garden; but as some at least of these and others need more than ordinary care, it will be best referred

smaller-growing and rare species that they be planted in this or the following month. The following are some of the most beautiful species and varieties, some at least of

*Fritillaria imperialis.*

in detail later on. Among other things of primary importance in their cultivation is that of planting. Some species and usually their varieties may be kept a long time in the dry state with impunity. Among these, *imperialis* varieties and *Meleagris* also may constitute fitting illustrations. These kinds I have kept quite dry till very late in the year, and in the case of *F. imperialis*, which has been kept dry for the express object of its flowering late for a certain spring exhibition, the results have been as instructive as they were surprising. Of course, such a finely formed bulb has an abundance of stored-up energy that a week, more or less, in the dry state would mean nothing at all, and this, indeed, has been on more than one occasion abundantly proved. Kept perfectly dry and without emitting a single root in a year uniformly cool and airy, and therefore out of the soil for nearly two months after the majority of such things had been planted, it was hardly expected that less than a week would separate their time of flowering in both halves. Yet this is exactly what happened, and not only with *Fritillarias*, but with most bulbous plants it is the same, there being no comparison whatever between the time of retarding and that of actual flowering. The most noticeable feature with such things is a shortened growth, which is the least desired. It is very interesting, however, to note that while increased warmth will hasten flowering in such things, the cold as well as dryness at the root have not a retarding influence in like degree. And very singular is it that the stature of the plant only, and not the height of bloom or the period of blooming, should have been changed. In other kinds differently constructed, as, e.g., *F. recurva* and others, prolonged delay in planting is not only injurious, but almost fatal; and while one may recommend September for planting generally as a good and safe time, it is essential with the

which should be found in every garden. Taking them in alphabetical order—

*FRITILLARIA ALPINA* comes first. This is a neat and pretty species, of dwarf growth, and bearing drooping flowers that are chocolate on the outside and yellow within, while its margin of brighter yellow gives the flower a pretty effect. It blooms quite early in spring and is of easy culture.

*F. ARMENA*, from Asia Minor, is also a dwarf form, producing pretty freely its soft yellow bell-shaped blossoms on frail stems less than 6 inches high. This kind is best suited for sunny spots in the rock garden or for planting freely in pots or pans for very early flowering. A soil of peat and loam suits this admirably. Next in order is

*F. AUREA*, undoubtedly one of the gems of the whole race and certainly the best of the dwarf flowering species. As a pot plant in the cool house quite early in the year it will hold its own with any, while the lovely masses that have been grown at Kew of late years stamp this as one of the most exquisite of hardy spring bulbs. Equally good and effective is it in the open, though from its naturally dwarf habit of growth such beautiful plants appear to require a dwarf evergreen carpet through which they may spring and that would give protection to the lovely golden flowers of this handsome species. But such carpets must of necessity be plants of very dwarf creeping growth, such as some of the smaller mossy *Saxifrages* or *Anubrietas*, that do not mind frequent disturbance and are easily replaced. Of course, a neat grassy slope, where *Primroses*, *Snow Glory*, and *Snowdrops* abound, would be a veritable home for such a plant, though, failing this, a carpet of *Sedum aere* (not the golden form to clash with the lovely blooms of the plant in question), or, again, *Sedum hispanicum* or its variety *glaucum* would

make the most perfect carpet possible, taking the least from the soil and giving the least possible resistance to the plants below. No member of this genus is worth greater care than this one, and a free, rich soil of sandy peat and loam with a little manure added will be found the most suitable. It is a native of Silesia, with large drooping golden blossoms faintly chequered with brown.

*F. CYRINA*, as also its variety *reticulata*, have prettily formed flowers, distinctly bell-shaped, the former citron-green, the latter yellowish and striped with reddish-brown. It is about 9 inches high and flowers in April.

*F. IMPERIALIS* and varieties constitute, for the border at least, the showiest and boldest of this useful race of plants. The value of their free and quick growth in early spring cannot well be over-estimated, the established plants or strong bulbs rising to nearly 4 feet high, with handsome foliage and stout, fresh green stems, terminated by a cluster of handsome drooping flowers, and above all a feathered tuft of leaves at the summit of the stem. The blossoms, which in all the varieties are by far the largest of the genus, are of various shades of colour, and either in mixture or alone make quite an imposing display. Of considerable worth are such things in semi-wild places or in the shrubby border where the bold spikes of blossom will not fail to attract attention. Naturally such vigorous-growing subjects do best in a deep, well-enriched soil, and though somewhat opposed to frequent removal, should be replanted at least every three years. Replanting may be done in August and September, placing the bulbs about 6 inches deep, while bulbs in the dry state may be planted for some weeks longer. The shades of colour include yellow, sulphur, red, orange-red, and so on, while a variety with red blossoms and beautifully variegated foliage is well worth growing.

Another group that promises to assume considerable importance is

*F. LATIFOLIA*; indeed, already it contains a good variety of different shades of colour. Bo-

*Fritillaria Meleagris alba.*

tanically this is included under the Caucasian species *F. lutea*, a somewhat variable plant, while the variety *latifolia* has given many shades

of lilac, purple, yellow, and black flowers. Too numerous for the purposes of this note are the varieties that have already received distinctive names. One handsome kind, however, *F. latifolia nobilis*, has this year been honoured by the award of merit from the Royal Horticultural Society. This has handsome blossoms, deep blood-red in colour, beautifully tessellated internally, and quite hardy, as, indeed, are all the set, and about 9 inches high. This kind has been very noticeable both at Kew and Ditton during the past spring. Many varieties of this group attain to nearly a foot high, and by their bold varied blossoms are very attractive quite early in the year.

*F. MELEAGRIS* (Snake's-head *Fritillaria*), with all its beautiful forms, is from an all-round point of view perhaps the most useful for the garden, and likewise for cutting. To the British gardener this plant should prove doubly interesting on account of its being a native of some parts, though more particularly of the Oxford meadows and pastures, a fact alone that should at once indicate its value in semi-wild or grassy parts of the garden. Though becoming more and more scarce in the wild state in Britain, the important fact of its being found frequently in moist meadows should not be lost sight of when cultivating the plant in all its forms; while its fondness for a certain degree of moisture, or even shade in lieu of the latter, may frequently be noted in any garden where opposite conditions are afforded it. The whole group is of the easiest culture, growing and flowering freely in any good loamy soil, always bolder where shade and some moisture are at hand. Graceful and elegant in habit, and attaining to nearly 2 feet high when established, the species may often be seen in cottage gardens in spring-time, flourishing year after year with little or no care. Particularly good is the nearly pure white variety, which has scarcely any other marking when freely grouped in grassy spots in partial shade. In the garden proper or for vases this may be also used to advantage; and, further, it is well worth isolating and seeding freely in the hope of a still purer and better white being secured. Of the intermediate shades there are many, and these being obtainable at a very cheap rate, may be freely used in various parts of the garden. Planting at 4 inches deep may be done from August to end of October.

*F. MOGRIDGEI* is a beautiful kind fairly well known in cultivation, with handsome drooping blossoms of golden-yellow, prettily chequered with chestnut-brown on the inner surface. It is a dwarf and valuable kind, requiring treatment identical with *F. aurea* above noted. It is a native of the Maritime Alps, and one of the choicest of this family.

*F. ORANENSIS* is a pretty Algerian species, growing 8 inches or 9 inches high and producing rather small though pretty flowers of yellow and purple-brown.

*F. PALLIDIFLORA* is a distinct species from Siberia. It grows about a foot high, and has pale yellow blossoms prettily chequered internally. The flowers of this are more widely extended at the mouth and squarely shouldered, owing to the keel-like prominence of the base of the segments externally, the broad foliage being of a distinctly glaucous shade.

*F. PUBICA* is a chaste and lovely species, the blossoms of a clear golden-yellow, about three-quarters of an inch across and distinctly campanulate in form. For its small size the blossoms possess considerable substance, and when grown in frames quite early in the year last a long time in perfection. It is in every respect a superior plant to the greenish-yellow *F. armena*, the latter also more frail, while the above has a stiff, erect leafy stem about 6 inches high. For pot culture or the choicest positions in the rock garden this really delightful plant is well suited. During the past two years this species has proved one of the most attractive in the early spring exhibitions, while in the present year Messrs. Wallace brought up handsome masses of it to show its permanent

value when thus grown. Not the least attractive part of the plant is the pleasing fragrance of its golden bells which have a neat and pretty appearance at the summit of the linear and somewhat glaucous leaves and stems. The plant is a native of the Rocky Mountains and portions of California, where it forms a great attraction in the early spring flora. It is quite hardy, and, grown in a rather rich mixture of loam and leaf soil with plenty of sand and a little manure, makes a charming show of its blossoms, these appearing in profusion for some time. The species, which has several varieties little known in cultivation, is readily increased by the small offsets that occasionally spring up like seedlings about the base of the larger bulbs.

*F. PYRENAICA* is a distinct species, with handsome plum-coloured flowers, beautifully reticulated internally, which is also of a yellow shade. The flowers are somewhat reflexed at the mouth. It is an easily-grown kind, flowering in May and early June. Height, 1½ feet. Southern France and Spain.

*F. RECURVA* is one of the rarest to flower, and, perhaps, also one of the most difficult to manage. The stronger bulbs should be planted 4 inches deep in a perfectly drained position in the rock garden, where the proximity of a large stone will afford some shelter. The species is as distinct in its somewhat flattened bulbs, which in this kind is an aggregation of fleshy, roundish nodules, as it is in the scarlet recurving flowers, which are very beautiful when the plant becomes quite strong and established. In Mr. Barr's nursery at Ditton this year, in one of the many shelters that obtain there, the plant was growing nicely in a light peaty mixture, some of the stems bearing as many as five of the beautiful flowers. In its Californian home the plant is said to produce stems 2 feet high and as many as nine blossoms on a stem. The largest I have seen, however, were less than half this height, but doubtless in favoured parts of these islands where the plant may also be treated specially in a sandy peat and loam of good depth, with moisture during the spring months, an improvement may be noticed. Left alone for a year or two, the plants may eventually flower more satisfactorily. After flowering the bulbs incline to break up or to give offsets more freely from the fleshy granules which compose the root-stock in this species.

*F. SEWERZOWI*.—Though distinct in flower, the growth of this species is not unlike that of a small *F. imperialis* var., yet quite devoid of the robust character of the latter. In the different examples I have seen the flowers vary from bronze-green to vinous purple and of a greenish yellow shade within. The large drooping blossoms are disposed in a loose raceme and attain 2 feet high. It is a native of Turkestan.

*F. WALUJEWI*.—This, the beautiful and distinct species to which prominence is given in the coloured plate, belongs to the more recent additions to this group, though for some years known to botanists. This beautiful species was exhibited in April last before the Royal Horticultural Society, when it obtained the award of merit. It is worth a place in all collections. Externally the blossoms are whitish and shaded with dove colour, internally prettily marked with white on a crimson-brown ground. There are, however, varying degrees of these shades in the collected plants. The species is quite hardy, succeeds well in loam and peat, attains 15 inches high, and comes from Turkestan. The large, solitary drooping blossoms are distinct and handsome in appearance, and, as seen in a large group at Ditton in the past spring, produced a very fine effect.

*F. WHITTALLI*, another modern introduction, is not less beautiful than the last, from which, however, it is quite distinct, the blossoms, of a red-brown on a yellow ground, being beautifully tessellated on both surfaces. This very handsome kind, which at present is not perhaps generally known, received a first-class certificate from the Royal Horticultural Society during the spring of

1896. The plant is of easy culture and will for a good companion to the one above-named.

In the above list will be found some of the most worthy species, as also a few of the more recent novelties. A complete list has not been attempted, and of necessity many interesting and beautiful things have been passed over. Those, however, who desire fuller information of these important spring flowers should endeavour to arrange a series of visits to Kew or Ditton early in the year, where very full collections may be seen in bloom. At Kew Garden such distinct kinds as *tenella*, *plurifolia*, *rutemica*, *Thunbergi*, *conica* with others have been noted during the present year. In this way will be easy to avoid the dull and useless kind that possess little or no value for the flower garden or even the woodland. E. J.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

GENERAL WORK.—Although we are now experiencing a pleasant change in the weather, the season is too far advanced to expect a long continuance of balmy days and the absence of frost at night; therefore it is well to be on the alert, having spare lights or other protecting material ready for placing over tender crops, such as French Beans, Vegetable Marrows, and even Cucumbers growing in frames. Late sowings of French Beans will pay well for having a frame placed over them, as with this protection they will afford valuable gatherings for weeks to come and thus save to a great extent forcing them in houses for some time at least. On the approach of frost, good gatherings of these as well as Runner Beans should be made before they are injured, and if spread thinly in a cool, dry place will last in good condition for several days. Although the heavy rains of late have proved beneficial to most established crops the surface soil has run together, especially on sowing beds, and such as Onions, Lettuce, Spinach, Turnips, and the like, will be greatly assisted by having the Dutch hoe used between the rows, which will not only destroy small weeds, but the growth will be accelerated by loosening the surface. Most autumn sowings have come up well, but should there be any blanks in the rows of Tripoli Onions these should be filled up by lifting the plants carefully with a pointed stick when they have come up thickly. A showery day is best for doing the work, and the plants should not be buried too deeply.

WINTER SALADS.—It is not wise to wait until we get frost before half-grown Lettuce and Endive are lifted and transplanted into pits and frames. Such work can be done more satisfactorily when the ground is not too wet, and it also allows time for plants to make some roots while the weather is favourable. The plants do not keep well when crowded together, as a spell of wet or severe weather causes many of them to decay. Each plant should be lifted with a good ball and carefully planted with a trowel, allowing 1 inch or 2 inches space between each so that light and air can reach the soil. One watering may be necessary to settle the soil round the roots, but, if planted early the lights may be drawn off during showery weather, which gives the plants a start. As good salad is generally scarce during spring it is always worth the trouble and seed to make another sowing in a warm corner or frame at the present time, as the seedlings will form nice little plants, and when they stand through the winter they turn in more quickly and with far less trouble than sowing early in spring in heat. The Year Round and Lee's Immense are the most suitable varieties, as they are very hardy. Endive is not appreciated in the salad unless it is well blanched. The Moss Curled is very popular, it becomes beautifully white and is less coarse in texture than the Broad-leaved Batavian, though

quires more protection during hard weather. There are various ways of blanching Endive, some place a tile or slate over each plant, which is removed when there is an absence of frost. In small flower-pots are also used successfully so that light does not reach the plants, which is effected by putting pieces of slate over the drainage hole, but as it is desirable to keep the plants at an even temperature, a good thickness of litter should be spread over the pots, which assists in obscuring light, prevent the sun from acting unduly upon them, and at the same time ward off frosts. Mustard and Cress are always sown, and as they are grown so easily, a sowing once or twice a week, according to requirements, should be made during the winter. It will be too late to grow this in cold frames, as it comes off quickly in a low temperature, therefore shallow boxes filled with rich soil should be used, and these stood in gentle heat. Fresh soil should be added at each sowing or the results will not be satisfactory.

**WATER-CRESS.**—This is appreciated on most tables, while it is often required in the kitchen for garnishing, &c. I have also known gardens where a daily supply had to be maintained, and were the methods employed to have it in good condition throughout the winter. Here the means of obtaining it is by making frequent plantations at the base of a back wall in the fruit houses. Cuttings are dibbled into sandy soil about an inch apart and given abundance of water. Grown thus, the foliage is delicate in colour and flavour, and being tender is more appreciated than that found in watercourses, and it can also be produced when none is to be found in the open.

**CELIFLOWERS.**—Plants from seed sown during August of Waleheren will now be ready for pricking off into their winter quarters. Nine plants are generally set out under a handlight, and in the corner the four corner and centre plants are retained and the other four transplanted. A border should be selected where the ground is rich. Mark off the stations where the handlights will be placed in lines so that there will be not less than 2 feet of space between them. In planting, lower the roots so that most of the stems are buried, water the plants in and give the surface soil between them a dusting of soot or lime to keep off slugs. Where handlights are not available, a shallow frame must be used to winter the plants in. It is not necessary to place this on a bed of manure, it being better to stand the plants on a hard surface in a sunny position and about 6 inches of good soil; make this surface firm, then prick the plants out about 12 inches apart. I am not in favour of very close plants for this purpose, as they become crowded before spring, and they do not prove so satisfactory as dwarf sturdy ones. It is not too late now to make another sowing if one light of a frame can be spared. This should produce nice plants by the end of October. These, if carefully ventilated during the winter, will make a fine succession, and may be put out in March. Vandy's Autumn Giant will now be plentiful, and will keep up a supply until the early Broccoli is ready. The plantation should be looked over and the heads cut before they become too large. It is a good plan to bend some of the leaves well over the heads while in a young state as this preserves the colour and also protects them from frost. If it is found that they are coming on too rapidly a slight check can be given by heeling them over, heads facing north, and the number may be dug up and stored in a cool place.

**CABBAGE BEDS.**—One is tempted sometimes to destroy these as being unsightly, which is a great mistake, as they may be made to supply a valuable lot of sprouts most of the winter. In showery weather of late has just suited them, and if the decayed foliage is removed, and the ground between them hoed, they will soon be furnished with young heads. Having stood so long, the plants are naturally somewhat exhausted, and the produce will not be so tempting as

that produced on younger plants. This, however, can be met by feeding the plants, and nothing suits them better than a good soaking of farmyard liquid. If this is not obtainable, a dressing of nitrate of soda or sulphate of ammonia will prove valuable. This, if hoed into the surface, will be washed down to the roots by the first rain, and a prolonged supply of a most valuable vegetable will be the result. RICHARD PARKER.

FRUIT HOUSES.

**PEACH HOUSES.**—The trees in the early houses will be fast shedding their leaves, and although they should not be forced from the trees, no harm will be done by smartly tapping the trellis two or three times a day, which will dislodge all that are ripe and ready to drop. Beyond this, all other means should be discontinued, and the leaves should be left to mature and drop naturally. After the leaves are all off, the trees should be pruned and detached from the trellis to undergo whatever cleansing they may require. After this fill up any gaps by lifting, if possible, suitable trees from the outdoor walls, and, if the matter has not already had attention, lift and lay out afresh the roots of those trees demanding attention in this direction. If the house stands in need of repairs or requires to be painted, this had best be done before attempting to top-dress the borders, and to prevent the borders being trodden into a solid mass place boards on the surface for the workmen to walk upon. In successional houses proceed with root-lifting, making additions to borders, top-dressing, and planting fresh trees to make good deficiencies caused either by death or the removal of unsuitable varieties. Trees grown outdoors are the best for this purpose, as they give by far the best results, while time is saved when looking at the matter from a cropping point of view. Where much Peach-forcing is carried on it is an excellent plan to grow a reserve stock of trees outdoors against a wall, so that a full-sized tree is always ready to hand when a gap occurs in the houses. For this purpose I prefer to plant maidens, and if these are well looked after and properly trained, a fine lot of trees can be obtained in from three to four years from the time of planting. The initial outlay is small, and when compared with the expense incurred in the buying of a good-sized tree for making good a gap with there is a great saving. If but ordinary-sized trees are purchased, a season or two is lost before they commence to make adequate returns in the shape of a crop of fruit, whereas a full-sized home-grown tree will give a full crop of fruit the first year if carefully lifted and properly planted. This is also a good way of furnishing the trellises quickly in newly-erected houses, as a good crop of fruit results the first season. When a new house or several houses are to be erected, provision should be made the previous autumn for growing the trees at home, if only for one season, and if the houses and borders are ready, they can be lifted and planted early the following autumn. In this case three or four-year-old trees should be selected, and, in addition to planting them in heavy calcareous loam, which will adhere well to the roots at lifting time, pay them every attention during the growing season in the way of keeping the young wood thinly trained out and the foliage clean and clear of insects. In late houses cut away all the useless wood from the trees as they become cleared of fruit, and give them, if they need it, a good hosing or a wash with the garden engine. Any lifting or root-lifting may then be done, also renovating and top-dressing of borders. Keep the houses cool and well ventilated if the wood is ripening up well; if not, a little fire-heat by day will be a great help in conjunction with a free circulation of air. See that the borders are kept uniformly moist, and if the trees are in the habit of bearing full crops of fruit annually, diluted farmyard liquid or diluted sewage may be given with beneficial results each time water is required. The remainder of the pot trees should be attended to as soon as the fruits are gathered,

and should the unfavourable weather continue, keep them under cover until their leaves fall and afford them an abundance of air.

**EARLY VINERY.**—The leaves being off the Vines, they may be pruned forthwith, after which they should have a thorough cleaning. The loose bark may be removed, but nothing more than this unless that worst of all VINE pests has gained a footing—the mealy bug. A thorough search must then be made for these insects both on the rods and spurs. They are more likely to be found in greater numbers on the latter, therefore particular attention should be paid to the spurs on infested Vines. After clearing away all loose bark, thoroughly scrub the Vine with a warm solution of Killbright, mixed at the rate of 2 ozs. to a gallon of warm water, and work it well into every twist and crevice both on rods and spurs. When dry, paint them with a composition made of soft soap, clay, soot, and sulphur in equal parts. Mix the ingredients together with warm water until they assume the consistency of paint, and apply with a sash tool. The old mulch and all loose particles of soil on the surface of the border should be cleared off, whether bug is present or not, and after the house has been cleaned and painted, if found necessary, pick off with a fork as much of the surface soil as can be done with safety and then top-dress. Use good fibrous loam, with wood ashes, bone-meal, and a little lime rubble added, and make all firm by treading and beating it down with the back of a five-tined fork. On very heavy soils a little sand spread over the roots before applying the top-dressing works wonders by inducing them to send out a regular network of new roots into the sand, after which they quickly avail themselves of the fresh rich compost placed immediately above it. Should the weather continue wet, the border, if outside, had better be covered, as the continual rains will have the effect not only of saturating the soil, but will also lower the temperature of the same considerably. If fine weather should again set in, leave the border uncovered in order that the sun may again warm the surface. Indoor borders, after being top-dressed, should be mulched with horse droppings, and if there is much traffic over them, place boards for the attendants to walk upon, to save the surface being trodden into an impervious mass, through which water cannot percolate properly when the time again arrives to commence watering.

**BORDER-MAKING.**—The rainy weather has caused a suspension of this operation, but it should be resumed again the first favourable opportunity with a view to bring it to a speedy completion, as this kind of work is always best done in autumn when circumstances will allow. Lifting where the roots have got into a bad state, with the consequent making of new or partly new borders, also adding to existing borders, also come under the same heading, and the sooner they are done so much the better. The soil when thrown together in the border starts fermenting to a certain extent, and the slight heat generated gives the roots a quick start. Proceed with the top-dressing of older borders after removing as much of the old, inert soil as is consistent with safety, and make good all defects in turf walls at the outer edges of the borders when such are used in lieu of retaining walls of brick.

**PIXES.**—A final potting up of suckers should take place, the number varying according to the stock at command, also future requirements. If a good stock is potted up now there will be no further need for putting more in until the spring-time. The finding of room for plunging these will necessitate a rearrangement of the pit or house in which they are to be grown, and advantage should be taken of this to give all present inmates that are still in 4-inch and 5-inch pots a shift into pots two and three sizes larger. They will then take no harm until the time for spring potting arrives, when they will require the final shift. The plants in succession pits or houses intended for starting early in the year should be got to rest at the end of the present month or not

later than the beginning of the next. The batch that will succeed these should also be treated in like manner, allowing a further period of two or three weeks before growth finally ceases for the season. All shading can now be dispensed with. In the fruiting house a warm atmosphere will be necessary for the proper ripening of all fruits. Smooth Cayenne and other winter-fruiting kinds swelling their fruits must have liberal treatment both in the way of feeding at the roots and in the maintenance of a nice humid growing atmosphere, and to this end take every advantage of sun-heat. A. W.

## ORCHARD AND FRUIT GARDEN.

### STEWING PEARS.

STEWING Pears are not so much cultivated as they deserve. They keep without difficulty well into the spring, and are not fastidious as to storage, whilst there is a great scarcity of fruit from February to May for cooking, a time when these Pears are acceptable. In my earlier days there was no difficulty in finding a ready sale for the best fruits, and the smaller ones were kept for home consumption. The variety mostly grown was the

**BLACK WORCESTER.** I have seen it stated that this variety is inferior to Catillac, but I have not found it so—at least, in the fruit gardens and orchards in Worcestershire and Herefordshire it is much esteemed for its good keeping and cooking qualities; indeed, this fruit is represented on the City coat-of-arms, so that it must be of ancient origin. The fruits were cooked as follows: A quantity of fruit was peeled, cut in half, and put into large jars and baked in the oven. When cold they were delicious, no colouring matter being necessary. Pear pies were also a great feature. Black Worcester is also grown under the name of Vernlam. I have never grown a better fruiting kind, as it rarely fails to give a heavy crop. I now come to a kind in favour in most gardens—namely,

**VEDALE'S ST. GERMAIN.**—I have the Worcester and this on an east wall some 15 feet high, and the crops are always fine. The Uvedale is a larger fruit than the Worcester and a grand keeper, but with me a shy cropper. It is in season at much the same time as the Worcester, and is a very large, firm fruit, of good quality when cooked, and may be termed a perfect stewing variety.

**CATILLAC** (see illustration) is also another Pear of great merit, and being a large fruit well repays growing on a wall. A wall, however, is not necessary, as when grown in bush form or in a dwarf state it gives a good return, and is a late fruit, keeping good well into the spring. It bears well when young. There is a much wider selection of earlier fruits or those in use from October to Christmas. Many of the third-rate dessert kinds are only fit for stewing, but they lack the quality of these later kinds, and are

more difficult to get of a good colour when cooked. For early use

**GROSSE CALEBASSE** is a valuable stewing variety, that sells readily in the market if gathered before it is ripe. It does well in bush or standard form.

**GILOGIL** is much grown on the Continent. This, I think, is the best stewing Pear grown, the colour and flavour when cooked being first-rate.

**VICAR OF WINKFIELD** is also a good, sound, winter fruit, very large and of splendid quality when cooked. For pies this variety is superior to many, and makes a nice change when well served; besides, it is a heavy cropper, and a very fine fruit when grown on a wall and grafted on the Quince stock. The little-known

**DIRECTEUR ALPHAND** is a valuable baking Pear, but with me it is neither so free as those named nor so large.

**BEURRE CLAIRGEAU** well repays for growing in quantity and is a sure cropper. It is a good baking Pear for early use and always saleable, being in season from October to January.

*Fruiting branch of stewing Pear Catillac.*

The above varieties may be planted with no fear of failure, and are far more profitable than many of the very small inferior dessert kinds.

W. S.

**PEAR MARGUERITE MARILLAT.**—The above variety was figured in these pages last year and a brief account of it given. The fruit is so handsome that it is well worth adding to Pear collections in favourable localities. In size it is not unlike a well-grown Pitmaston, but the colour is different. With me it more nearly resembles a well-finished Louise Bonne of Jersey, the spots being bright, the skin a rich golden-yellow flushed with red, the flesh sugary with a rich aromatic flavour. It is a grand addition to our early September Pears. With me cordon trees only planted last year have borne splendid fruits. It appears to be a free grower on the Quince stock, and if it does well in bush form it will prove a valuable intro-

duction. It is of continental origin. I saw great specimens of this variety fruiting in pots a determined to give it a trial. This autumn hope to plant some trees in bush form, as it is a splendid variety to follow Williams' Bon Chrétien.—G. WYTHES.

**PEAR JERSEY GRATIOLI.**—Many growers do not place the above Pear in the front rank of flavour, but with me it is so good and free from grittiness, which is not always the case, that in light poor soil I think it one of the most reliable of our early autumn Pears. It always bears a fair crop even in adverse seasons, and the fruit matures quickly after gathering. They are about medium size, melting and very sweet. It has greenish-yellow, richly-flavoured flesh, the skin rough russet. I prefer this variety grown in bush form. Grown thus the fruits are superior in flavour and less gritty. On walls they do not come larger. It bears freely in the open on Quince stock, while on the Pear it grows freely and is not so well flavoured. I have seen this variety good grown as a standard in favour

able localities. In many catalogues its season is given as October, but with me it is ripe in September 11). In heavier soils it is late. S. H. M.

**FEEDING RASPBERRIES.**—These plants suffer much during June and July from drought, but made but slow progress during August, but they are making up for lost time and grow freely, especially where the canes which fruit have been cleared away as soon as the fruit is gathered. Now is a good time to arrest the growth, at the same time restricting the shoots to a limited number, only leaving those intended for fruiting next year. Raspberries are often allowed to remain so long in one place, that feeding is necessary to get the best results. Many canes take liberal manure at this date and the plants will take liberal supplies. Failing this, a good manure of stable manure will do good in pushing the new wood, as with cooler weather the plants will grow freely for some time. I have seen

that excess of food now, means a soft, pithy growth, but if the canes are well thinned out I never saw late growths injured. There is ample time to finish such canes, as I find the more vigorous the canes the heavier the crop next season.—S. H.

**Peach Violette Hative.**—As a good all-round variety for general use this should be freely planted. In the south of England in warm aspects it is ripe the second week in September, but here is not fit until the end of the month from outside. In an unheated house it is just ready. The tree is hardy and fairly vigorous, and the fruit always sets freely either outside or under glass. It is not one of the largest, but quite big enough, takes on a fine dark red colour on the sunny side, and the quality is excellent.—R., *Suffolk*.

**PEACHES AND NECTARINES ON OPEN WALLS.**

THERE are many varieties of these that do not succeed well on open walls in this district. They live for a few years and then die off altogether. The springs have much to do with this, for the sap is excited early in the season by the genial weather we often get in February and growth commences. Sharp frosts and cold winds follow, so that in a short time the young foliage is covered with blister. In some seasons this is much worse than others, though it is seldom we are free from it altogether. Some varieties are also much more subject to blister than others, but none are altogether free. The best are Early Rivers, Alexander, Royal George, Early Silver, Sea Eagle and Prince of Wales; while Nectarines Darwin, Pitmasnan Orange, Spenser, Prince of Wales, Victoria, Pine-apple, and several others suffer severely. There is always some difficulty in getting the wood to ripen thoroughly on cold heavy soils and in exposed situations, as growth is so late before being arrested, and when the trees are badly blistered it is often the end of the summer before they recover from the serious check received earlier in the season. When the summers are cold and wet, like that of last year, there is little wonder at the wood not ripening in such places, but this has nothing to do with blister, for trees that are healthy and bloom freely are frequently cracked in cold springs. Blister, however, is not the only enemy the gardener has to contend with, for often mildew makes its appearance, and this is almost as serious as the other. There is, however, more chance of coping with mildew than with blister, for so long as the cold winds prevail blister will continue, while sulphur remedies applied in time, will keep mildew in check. To show that cold winds are responsible for blister, if the same varieties be planted in a cold house and on a south wall close together, we will find that while those on the outside are wholly infested, the others will be quite free. In some gardens that are sheltered blister seldom makes its appearance, while in others that are not far distant, though more exposed, the trees are nearly killed. I have often noticed that young trees in a nursery are seldom cracked by blister. How is this? In the first place, such are usually pruned back and made to break from lower eyes, the consequence being they do not push so early in the season; then again, it is seldom they have the protection of walls to hasten the flow of sap in spring. Peaches, Nectarines and Apricots are far more difficult to grow in the south than in the Midlands and further north, and many are puzzled to understand how this is. The only explanation I can give is the one before mentioned, as on gravelly soil, chalk and stiff loam

the trees die off alike. Neither lifting, close summer pruning nor early pinching seems to save them. I have frequently seen the trees killed by the cold when the Apricots have been the size of Peas. Many advocate wiring the walls that a current of air may pass between them and the trees; others recommend leaving the trees away from the walls as long as possible in spring; but neither of these plans has the desired effect, though the last is beneficial in some seasons when we have no late, severe spring frosts. Wired walls have their disadvantages as well as their advantages, particularly if the wires are too far away, for then the walls are not of that service in protecting the flowers or maturing the wood as they are when the shoots are close to them. Before glass was so cheap good stone fruit was grown on walls—in fact, from accounts, far better than at the present time; then there was not so much extra work in summer to prevent proper attention being paid to the training of the trees. In those days young men took their turns on the walls; now all is changed. The rage for cut flowers necessitates far more labour in the glass department, even though there is no more glass. I am not complaining of this, for it shows what progress has been made in the cultivation of flowers during the last generation; but what in many places is most annoying is that so much is required from the limited means at disposal, and where so much time has to be spent on cultivating plants, trees on walls get neglected. It is not that seasons have so much changed, or that gardeners are not so well versed in the management of hardy fruits now as formerly, but, owing to the multifarious duties they have to perform, something must get neglected. If Peach trees could be protected from the cold winds in spring and the shoots regulated and nailed in during the summer, the foliage kept free from insects and other pests, and watering and syringing attended to, there is little doubt, with the improved varieties, that as good Peaches could be grown now on the open walls as in years gone by. Cheap glass, however, has altered our gardens, and those who in former days were content with a vinery or greenhouse have whole ranges of glass for different plants, amongst which are Peach houses to produce early fruit. All this has a tendency to cause trees on the walls to be neglected, as the finest flavoured late varieties may be had in midseason, but if late fruits are to be had, it is still necessary to pay special attention to trees on the open walls, for though Princess of Wales, Sea Eagle, and some other highly-flavoured varieties are excellent in cold houses, the fruit will not hang till October, when it is often appreciated, so that trees on the open walls are necessary to prolong the supply. Disbudding is one of those operations that get neglected; the young shoots are so crowded together that they lose some of their lower leaves, and when thinned out, many of those left make laterals, and as these are not checked in time, they spoil the chances of a crop the next season, for instead of the growths being studded with flower-buds they are nothing but bare shoots. The aim should be to disbud as early as possible and protect the trees from cold winds, to encourage growth by keeping the foliage clean, to lay in no more wood than is required for the next season, to remove any laterals as they appear, and during the summer to keep the shoots fastened to the walls that the wood may be thoroughly ripened. All this requires time, and where so much extra work has to be attended to it is often difficult to do things just when they need it; hence the reason that Peach trees in many places do not thrive so

satisfactorily as one would wish. Protection in spring is often out of the question, and when only half done it is as well left alone. Blister, aphids, and mildew follow, the trees fail to grow satisfactorily, and in time die off. Gardeners are not to blame for this, for where there is not sufficient labour the most pressing work must receive attention first. Peach cases were recommended, but in many instances they were worse than useless, for the tops were fixtures, and, where the foliage got near the glass, red spider and thrips soon made their appearance, so that the remedy was as bad as the disease. In many places water is so scarce and time is required for other things, that syringing is impossible. In many of the new gardens coping the walls properly has been neglected, and as the water runs down them the mortar soon perishes. A good stone coping that projects at least 4 inches on either side is the best possible kind. As the most frequent rains are from a southerly direction, the slope should be made on that side, that the trees may have the benefit of the water from the coping; by this means fruit hanging on the opposite side of the wall will be kept dry, for late Plums and Cherries are frequently grown on the opposite side of the wall from that on which Peaches are. With due care and attention good fruit may be grown in the open, but where labour is limited this is almost impossible. H. C. P.

*Busted Park, Uckfield.*

**Plum The Czar.**—This is not, I believe, usually classed as a dessert Plum, but in a season like the present, when Plums are scarce, it comes in very useful. I have been sending it to table since August 10, and it has been appreciated. Though smaller than Victoria, it is much superior in point of flavour, and it is equally hardy, constant in bearing and earlier. Three years ago I had occasion to move some trained cordon trees of it, and having no wall to put them on, cut away all the lateral shoots except a few at the top, and planted them in the open as standards. They have made capital heads and have fruited well this season and last. Although a good deal of rain fell after the fruits had finished swelling, I have not found one cracked.—R.

**Peaches at Blickling Hall.**—Fruit generally is well grown at Blickling, and during the first week in September I saw some remarkably fine samples of Sea Eagle and Princess of Wales Peaches. The former, Mr. Oclee considers should be fit for gathering not later than the last week in August. Fruit that ripens later is, as a rule, much inferior in flavour to August ripened fruit and lacks juice. It is doubtless one of the most prolific and profitable Peaches to grow for market, and fruits on the upper side of the trellis take on a very delicate and attractive colour. I have heard Princess of Wales spoken against as being second-rate in flavour, but Mr. Oclee thinks well of it in this respect. Desse Tardive, a fine showy late Peach, does exceptionally well on a back wall. This Peach is naturally a strong grower, and, if allowed a free root run, often refuses to bear in a young state, but the tree at Blickling is restricted in root space, which no doubt has much to do with its fertility. For a late Peach the flavour of Desse Tardive is excellent.—J. C.

**Melon Gunton Orange.** A correspondent recently noted that he had not been successful in fruiting this delicious scarlet-fleshed Melon, and asked if any reader could help him in inducing it to fruit. My experience is that it does by far the best when its roots are somewhat confined. A shallow restricted border will do, but the best results are obtainable from pot culture. The growth is then tolerably firm, more bloom-producing laterals are formed, and most of the flowers set well if artificially fertilised. Fertilisation is important with Gunton Orange, and if this is neglected most of the blooms will fall. It, how-

ever, repays a little extra trouble, as it is without doubt one of the very best scarlet-fleshed Melons ever sent out. Unless a few fruits only are taken from each plant and much feeding resorted to, the fruits grow only to a medium size, just the size in fact for table, but they are very solid, deep-fleshed, and deliciously flavoured.—C. C. J.

**Late frame Melons.**—Not unfrequently where frame Melons are grown in quantity, cold, ungenial weather overtakes the latest crop when about half grown, with the result, unless remedial measures are taken, that the foliage turns yellow and the fruits never swell to their normal size or ripen properly. The old linings to the hotbeds on which the frames stand will most likely by this time be trodden down and incapable of supplying any warmth to the interior. These linings should be entirely removed, being replaced with others made of fresh material and built well up to the tops of the frame to allow for a slight settling. Further, the glass should be covered each night with mats, and a minimum amount only of air given, this being removed directly after dinner. Root moisture must henceforth be given on fine sunny days only and in a tepid state. Overhead syringings must be slight and given only in sunny weather, as wet foliage during the night is injurious so late in the season.—J. C.

**Grape Mrs. Pince.**—In spite of all the cultural notes that have been written on this Grape, perfectly coloured bunches are very seldom met with. This is a great pity, as without doubt the flavour of well-finished bunches is unsurpassed by that of any other black Grape. Mr. Oclec grows this Grape well at Blickling, and it may interest readers to know that he employs very little fire-heat as compared with most gardeners: in fact, early closing with plenty of sun-heat is his practice until the berries are somewhat advanced in colouring, from which date until colouring is complete a circulation of air is kept up day and night, the pipes being warmed in dull sunless weather. There is no doubt that many growers give this Grape too much fire-heat, which it resents, the berries often shrivelling by December. Rather narrow, shallow, sweet borders, rendered very porous by the addition of abundance of lime rubbish, are the root run of Mrs. Pince, and indeed of all the Grapes at Blickling. There is no fear of over-moistening such borders, and the roots being in a small compass are easily reached by manurial waterings.—J. CRAWFORD.

**Apple Worcester Pearmain.**—I have tried for many years to grow Worcester Pearmain as an espalier, but cannot get it to make any quantity of wood or to bear more than about half a dozen fruits in one season. It forms very few fruit-buds when spurred back, and what few fruits I have secured have been borne on the extremities of short growths about 6 inches long, which were let alone when the trees were summer pruned. This showy early Apple is often strongly recommended for market, but my experience is that, unless the soil is light and warm and the situation extra good, the trees generally make very poor headway and frequently collapse altogether from canker. I should not advise planting it except on a very limited scale in cold midland and northern districts. One sees very few Worcester Pearmain exposed for sale in midland markets.—C. H.

**Grafting old trees.**—The remarks by "A. D." (p. 195) are interesting and instructive. Years ago I assisted in a good deal of grafting in an Essex garden, and the plan advised by "A. D." of putting a few strong grafts into strong stems was generally followed. The trees were headed well back, the smaller side branchlets being entirely removed, and, as a rule, a stronger and larger tree resulted in a given time than when numerous small scions were inserted in many-forked branchlets. Several years ago Mr. Allan served an old unprofitable specimen in the pleasure grounds at Gunton in the same way, the sort employed being Blenheim Orange. This

year when I saw it the new portion was carrying a good quantity of nicely sized fruit. Grafting in this manner is just what is wanted with the Blenheim Orange, as when one plants trees of it there is no telling when they will fruit.—J.

**Apple Adams' Pearmain.**—This is one of the very best of the Pearmain section, but one seldom meets with it. Its season is from December to the end of February. The fruit is conical, the colour pale yellow, flushed and streaked with red on the exposed side. It does well trained in espalier form or as an upright cordon on a wall worked on the Paradise stock. It may be safely planted in standard form where the soil is fairly warm, but in cold, heavy loam it cankers. The flavour is brisk, juicy, and refreshing. Some of the finest fruits I have seen were growing on an upright cordon on a wall at Blickling Hall. Mr. Oclec is very fond of it and it never disappoints him in cropping.—J. C.

**Apple Cobbett's Fall.**—This Apple was, I believe, raised in Suffolk, and is a fine, juicy, well-flavoured cooking variety. It is sometimes catalogued as synonymous with Warner's King, but I believe it to be quite distinct and a better bearer. The fruit, moreover, on young trees fully exposed to the sun colours up much more highly than Warner's King, and, as a rule, is of better shape. I have it both in standard form and as an espalier, and this year the former is loaded with good normal-sized fruit, the espalier tree having a fair crop. Warner's King, even in our light soil, grows strongly and refuses to bear for some years even if root-pruned, while Cobbett's Fall generally yields in a year or two after planting, and makes only moderate wood. An old Suffolk gardener assured me that the two Apples were distinct.—C. N.

**Apple Tyler's Kernel.**—This fine cooking Apple was known to Herefordshire growers for many years before it received a certificate from the Royal Horticultural Society. With me it proves equally prolific grown as a bush as it is when grown as a standard, and such being the case, it is a great acquisition, as in form and keeping qualities it takes rank before many varieties, such as Lady Henniker for instance. What little falling off there may be in point of size is more than compensated for by the regular outline of the fruits of Tyler's Kernel, which means less waste when being prepared for use, and also by a considerable gain in weight. It is a fine market Apple, the fruits being clean looking, with a handsome tush on the sunny side, while they are large and conical in shape, and evenly formed. Its season is from October to the end of the year.—A. W.

**Open-air Vines.**—In spite of a wet and cold August, Grapes in the open are ripening nicely, especially the white variety Chasselas Vibert and the old Sweetwater, the latter being very good this season on an east wall. Chasselas Vibert is a very good Grape and well worth more notice, as it is very sweet, of fair size, berries round, and of a fine golden amber when ripe. So far it has never failed to produce a crop every season if the growths are kept stopped back to allow sun and light to reach the fruit. It is a strong grower, ripens ten days earlier than the Muscadine; flesh juicy, rich, and very refreshing. The black varieties with me are a little later, and I fear will crack badly if the autumn is not favourable. On a south wall Black Cluster and Miller's Burgundy do well. The Claret Vine (*Vitis purpurea*) and the Parsley-leaved are pretty for covering, and beautifully coloured in the autumn.—G. W. S.

**Pear Dr. Jules Guyot.**—I recently staged this Pear and was told I had two kinds—viz, Williams' Bon Chrétien and the newer variety. In appearance they are much alike, the quality varies on different aspects, but there is a distinct flavour to the one named above. It is a Williams' without the musky flavour. Another point one may distinguish Dr. Jules Guyot by is that the fruits are more tapering at the stalk end than Williams', but this is not always the case. Some growers class it equal in cropping with the older

kind. With me in cordon form it has never failed. My trees are on the Quince stock and make a fair growth. It is in season at much the same time as the Williams'. On a wall it is the earlier of the two, and being a handsome fruit it will become a favourite for market. I should class it as an August fruit, and in bush or pyramid form it will be worth room in most gardens where early Pears are needed.—G. WYTHES.

**Scarcity of Doyenne du Comice Pear.**—This is a bad Pear year; only a few kinds are bearing an average crop, and it is strange that some of the shy fruiterers this year are better than those which usually crop freely. I notice some of the newer varieties of Pears this season are bearing much better than one could expect, seeing there are so scanty crops on older kinds. Doyenne du Comice in this part is only a poor crop, and this is a misfortune. On two walls south and east, I have none, whilst on a north aspect I have only a very few fruits out of a good number of trees. The worst of trees on this aspect named is that the fruits lack the clean skin those on a more favourable position have. I think by growing Pears on different aspects there is a great gain in such seasons as the present. In my case bush and pyramid trees of this variety this year are barren, and these trees in my opinion give the best flavoured Pear. Cordons are somewhat better.—G. WYTHES.

**Flavour in Damsons.**—I do not know many growers of these useful fruits have noticed the difference in the flavour of the round and some of the larger fruits compared with that of the oval kinds. I have this season tried several kinds to test flavour, and I must give the first place to the long-fruited oval kinds, those known as the Cheshire Prune in the north and a similar variety as regards its rich, piquant flavour, the Shropshire Prune. These fruits are oval in shape and the growth is quite distinct from that of the larger kinds. These latter in some cases have small stone, and doubtless from a grower's point of view would be more saleable than the oval kinds. Preserve made of the Hereford Prune, I think, no equal. The trees have small leaf and make a slender growth in comparison with that of the larger kinds. It is to be hoped that our large fruit tree raisers will not omit these varieties from their lists in favour of newer larger kinds. I am aware in the counties named there is no fear of the stock being worked out, many cottagers grow them largely, but in gardens they are not so often seen.—S. B. M.

**Apricot trees.**—As there seems to be a thing new under the sun, I presume it would be regarded as absurd to ask whether anyone has ever tried the effect of budding or grafting standard varieties, and notably Moorpark, upon seedling Apricot stocks. No doubt some one has, and now, and it would be interesting to learn the result. That there can be very good Apricots raised from seed there can be no doubt, but the same very few care to take the trouble. It is a wonder that some enterprising nurseryman has not striven to produce good varieties in this way, but presumably it is regarded as too great a lottery. Only a few years ago there was a huge tree, reputed to have been 100 years old, in the garden of Malshanger Park, but it died at last from sheer old age. But two or three years since I saw growing on the old stone walls that surround a portion of the gardens at Farnham Castle two very old trees, or remains of old trees, that had strange stems, one having been some 12 inches more broad, yet almost flat, yet from such support there were numerous branches cropping w. annually. These trees were, doubtless, 150 years old. They had really no border, only 12 inches of soil, then 12 inches of turf edging, then gravel path 5 feet wide, then grass again. The longest-lived Apricot trees seem to be the having no borders, but a gravel path or road over the roots.—A. D.

**Pear Marie Louise d'Uccle.**—Although, "C. C. H." remarks on p. 194, the title of improved Marie Louise is not by any means approp-

ble to this Pear, it may with advantage be grown or prolonging the season of the type. According to my experience it is harder than Marie Louise and a more certain cropper, and though the flavour is not so good, yet it is by no means to be despised, especially when fruit is scarce. I much regretted having to cut down an old tree here against the house, the station being required for vegetables. This bore freely every year, and the other day I saw a fine young tree at Melford Hall growing on a south-west aspect and loaded with fruits with the characteristic russet skin. On heavy soils the tree should be planted very shallow and well mulched, the production of plenty of young roots near the surface being of great importance. Here they have the advantage of air and sun, and the difference between the fruit from young trees so treated and that from old ones the roots of which have got down to an unsuitable soil is very marked. Most soils are warm enough and good enough to grow good fruit if the roots are running in a firm but well-ventilated surface medium, but on a cold, hungry soil it is quite different, this causing cankered trees and cracked, undersized fruit.—R.

I am pleased to see "C. C. H.'s" note (194) on the above, as I think its qualities much over-rated in fruit catalogues. In some lists—my own included—it is not worth much notice. Mr. Barron, in his useful report on Pears, No. 85, gives a very good account of its quality, having pasty flesh and inferior in quality, though a great cropper." Doubtless this last quality may make it valuable to many, but a poor pear is not worth room in any garden. For market it is often recommended, but buyers are beginning to know the qualities of a few kinds, and for flavoured ones will not command so good a price. When placed by the side of the older Marie Louise it is not worth eating, as "C. C. H." remarks. The tree is a vigorous grower, and on the east coast I have seen some remarkably fine trees on cordon trees. Doubtless soils may influence flavour, but so far I have never tasted a really good fruit of this variety. For exhibition it is a favourite on account of its size. The question of size is too favourably considered in the exhibitions. Another fine Pear much over-rated is Beurré Bachelier. This with me is anything but first-class, though a certain cropper.—S. H. B.

There is certainly a hope that florists will amend their ways and lean more to the informal and natural in the future. For notes on the various exhibits reference must be made to the detailed report which follows. There was also an admirable exhibit of autumnal Roses from the well-known Waltham Cross firm. This in itself was worth a journey to see as a lesson of what to plant for a late display. Hardly harder flowers too were shown in goodly numbers, notably Michaelmas Daisies and various allies of the Sunflower family. A few good and well-known plants, flowering and otherwise, were also staged. These added to the attractiveness of the meeting. The best of these were *Salvia splendens grandiflora* and the early-flowering *Chrysanthemums*. Orchids were not numerous, but those shown were of excellent quality, *Vanda cœrulea* standing out conspicuous. Fruit was not numerous on the whole. The competition for the flavour prizes was distinctly good, but no new variety of either the Apple or the Pear supplanted the older kinds.

**Orchid Committee.**

A first-class certificate was awarded to

*LELIA PRÆSTANS* (Gatton Park variety).—This is very much in the way of a variety previously certificated as *L. Dayana delicata*. The nearly white sepals and petals are slightly suffused with mauve. The front lobe of the lip has a deep blue tint instead of the usual red, the side lobes similar to the petals, shading to yellow at the base. The plant carried four flowers and buds. From Mr. J. Colman, Reigate.

Awards of merit were given to the following:—

*CATLEYA HARDYANA LOWLE*.—One of the finest forms of this lovely natural hybrid we have seen. The sepals and petals are deep rose mottled with white in the centre, the lip deep crimson-purple margined with rose, veined in the centre with white, and having very prominent yellow blotches in front of the throat. The sides lobes are rich purple, longitudinally lined with rich golden-yellow. The plant carried a raceme of four flowers. From Messrs. H. Low and Co., Clapton.

*VANDA AMGENA*.—A distinct and lovely addition to this family. It is supposed to be a natural hybrid between *V. Roxburghi* and *V. cœrulea*. The ground colour of the sepals and petals is of a silvery-grey, thickly covered with small blue-tinted spots, the lip bright blue thickly lined and spotted with a darker shade of blue; the side lobes nearly white, thickly covered with deep blue spots. The column is white with numerous dark blue spots. The plant bore a raceme of three flowers. From MM. Linden, Brussels.

*MILTONIA PEETERSIANA*.—Supposed to be a cross between *M. Moreliana* and *M. Regnelli*. The sepals and petals are similar in colour to those of *M. Moreliana*. The lip is light rose in front, veined with a darker shade; it has the rich purple disc and crest as seen in *M. Regnelli*. From Mr. R. J. Measures.

*LYCASTE DENNINGSIANA*.—A distinct variety; sepals and petals each about 3 inches in length, pale greenish white, the lip about 1½ inches in length, of a deep orange-red shade. From Mr. F. W. Moore, Royal Botanic Gardens, Glasnevin.

*ONCIDIUM PAPILIO*.—A good form of this well-known species of the Butterfly Orchid, which had not previously been certificated. The sepals, petals, and lip are bright yellow, with prominent bright brown markings. From Mr. D. M. Grimdsdale, Kent Lodge, Uxbridge.

Messrs. Hugh Low and Co., Clapton, sent a large and interesting group, prominent in this being some remarkably fine forms of *Vanda cœrulea*, several finely-flowered plants of *Cypripedium Charlesworthi*, and a dark form with three flowers of *C. Alfred Hollington*. *C. orphanum* and *C. Arthurianum* were also well represented. Amongst the *Odontoglossums* were good forms of *O. crispum*, *O. seeptrum*, and *O. triumphans*. *O. grande* and *O. Harryanum* were also conspicuous. A distinct form of *Dendrobium Lœanum*, the sepals and petals bright rose-pink, shading

to white at the base, the lip deeper purple in front, shading to a light shade of rose in the throat, was also shown. Prominent amongst the *Cattleyas* was a good bright form of *C. Ludemanniana* with two flowers. Several dark forms of *C. Harrisonæ*, *C. Gaskelliana delicatissima*, sepals and petals pure white, lip white, with a delicate rose blotch in the centre shading to bright yellow in the throat, *Lælio-Cattleya Aurora* with two flowers and its near ally *L.-C. Novelty* were also noteworthy. A silver Flora medal was awarded. Messrs. F. Sander and Co., St. Albans, sent a small group, in the centre of which was a large plant of *Odontoglossum grande* with eight spikes of flower. *Dendrobium Farmeri*, *Lælia Dayana* with ten flowers, *Lælio-Cattleya Vedasti*, in the way of *L.-C. Aurora*, a dark form of *Miltonia Moreliana*, *M. Lubbersiana*, *M. Lamarekiana*, a natural hybrid between *M. Clowesi* and *M. candida*, a grand flower of *Cypripedium bellatulum album* and *C. H. Ballantine* were also included. *Dendrobium Gratrixianum*, shown for the first time, is a distinct species with pure white sepals, the petals white with rose tip, the lip white with a slight tip of rose in front, having a distinct rose-purple disc at the base. Messrs. Collins and Collins, Willesden, sent *Odontoglossum Pescatorei* in variety and a form of *Odontoglossum excellens*.

Mr. W. S. McMillan sent a plant of the lovely *Cattleya Dowiana aurea* Mrs. F. Hardy var. that had previously been certificated; the sepals white, petals white, with a slight trace of pink at the apex, the lip having the deep crimson and yellow markings characteristic of the species. Mr. Grimdsdale sent a finely flowered plant of *Cattleya Harrisonæ*, and Sir F. Wigan sent a cut spike of *Houlletia Brocklehurstiana* with six expanded flowers.

**Floral Committee.**

First-class certificates were given to the following:—

*RETINOSPORA OBTUSA SULPHUREA*.—A distinct form of the type and of elegant and free growth. A pale green pervades the older portions, whilst the young shoots are tipped with sulphur-yellow throughout. From Messrs. J. Veitch and Sons, Chelsea.

*AFERA ARUNDINACEA*.—A remarkably distinct grass. The leaf growth is erect, about 2 feet or so in height, the leaf being of a pale green, whilst the stems are of a pale golden shade, the growth from the base being dense. Its attractiveness, however, centres in the drooping, extremely light and graceful plumes of quite 4 feet in length, these arching over and extending far below the soil line and quite self-supporting. From Messrs. J. Veitch and Sons.

Awards of merit were voted to the following plants:—

*CHRYSANTHEMUM MYTCHETT WHITE* (Japanese, early flowering).—A pure white variety, of good form and of medium size. It partakes of the reflexed character in the petals, which are of medium width also and fluted at the base. It is a distinctly useful variety and one to which three marks were accorded at the last meeting of the committee at Chiswick. From Mr. M. Russell, Mytchett, Farnborough.

*PRIMULA OBONICA FIMBRILATA*.—A very distinct form of this Primrose with larger flowers than in the type, and which in addition are prettily fringed. A rosy tint pervades the flowers, whilst the eye, which is of a greenish yellow, is considerably enlarged. The growth resembles that of the type, but the flowers lean towards the Chinese varieties. Mr. T. Lowton, Faversham.

*PHLOX MISS PEMBERTON*.—A variety of decided merit, with flowers of unusual size and good also in the truss, the colour a combination of shades of salmon and rose. Messrs. Paul and Son, Chess-hunt.

*CRASSULA COOPERI*.—An extremely dwarf species, of dense habit and growth, and completely covered with minute blossoms of a vinous crimson, the leaves quite fleshy. A useful plant for dwarf edgings and rockwork, but not hardy during the

**SOCIETIES AND EXHIBITIONS.**

**ROYAL HORTICULTURAL SOCIETY.**

SEPTEMBER 21.

The decision of the council to hold two meetings in the present month has been amply justified, and it must be very satisfactory to the governing body to know that this, the second gathering in the month, has met with so much favour and support. It would hardly have been possible, were the society dependent upon competitive classes with substantial money prizes, to have drawn together a more or more representative exhibition of autumnal produce than that staged on the present occasion. Such an exhibition reflects the greatest credit both upon the trade and private growers, and from time to time, as occasion favours them, bring together their various exhibits for the education of those who attend these fortnightly meetings. It may be safely said that never was the Royal Horticultural Society more popular with its Fellows and supporters than it is at the present time. No better proof of this is needed than that afforded in the extensive displays from time to time at the Drill Hall.

Dahlias at this meeting were excellent, and never before has such a display of this popular autumnal flower been made in the Drill Hall. Most of these exhibits were put up by the trade, and it was gratifying to note that fresh object lessons in staging Dahlias were to be seen. It is a great relief to see that the old and antiquated method of staging is being broken away from.

winter outside. *C. Cooperi*, as described in "Dictionary of Gardening," has white flowers. From Messrs. Paul and Son.

**DRACENA (CORDYLINA) RUSSELLI.**—A narrow-leaved form of *D. australis* and of similar habit to *D. Doucetti*, to which it will in all probability be a fitting companion; the colour is of a clear coppery shade. From Mr. J. Russell, Richmond, Surrey.

**DAHLIA HARRINGER (show).**—This is a pale lilac-coloured variety of beautiful form, having a close, compact centre. From Mr. Harris, Orpington.

**DAHLIA GREEN'S GEM (Cactus).**—A very small flower of fairly good quality, but having a rather loose centre. The colour is a dull salmon. J. Green, Dereham.

**DAHLIA MURIEL HOBBS (show).**—A clear golden yellow of good form, the centre good, and slightly tinged with chocolate. Mr. Hobbs, Bristol.

**DAHLIA MINNIE RICHARDS (pompon).**—A pretty flush-white variety, but inclined to be coarse and to open in the centre. The shape is good and very even. Mr. T. S. Ware, Tottenham.

**DAHLIA NELLIE BROOMHEAD (pompon).**—A very good exhibition bloom of excellent form, with a perfect centre, very even in the petal, and of a very pleasing lilac colour. Mr. J. T. West, Brentwood.

**DAHLIA ISLAND QUEEN (Cactus).**—A very pretty and compact flower of good Cactus form, rosy lilac in colour. Mr. J. T. West, Brentwood.

**DAHLIA MARY SERVICE (Cactus).**—A bloom of perfect form, the petals finely pointed and twisted, the colour a dull bronzy pink, more curious than pleasing. Messrs. Keynes, Williams and Co., Salisbury.

**DAHLIA LAVERSTOCK BEAUTY (Cactus).**—Another flower of good form; petals much twisted, colour pinkish terra-cotta. Messrs. Keynes, Williams and Co., Salisbury.

**DAHLIA KEYNES' WHITE (Cactus).**—The purest white Cactus Dahlia yet raised, of good form and apparently very reliable. Messrs. Keynes, Williams and Co.

**DAHLIA ARACHNE (Cactus).**—A striking scarlet and white-striped flower of perfect Cactus form, but rather small. Messrs. Keynes, Williams and Co.

**DAHLIA MALUMA (pompon).**—A fairly good yellow, but inclined to have a weak centre. The colour is pleasing and the shape and the petals even. Mr. C. Turner, Slough.

**DAHLIA MISS FINCH (Cactus).**—A beautifully shaped variety with finely pointed petals and excellent centre, the colour a rich purplish crimson. Messrs. Cheal and Sons, Crawley.

**DAHLIA MRS. T. GODDARD (Cactus).**—A beautiful crimson, perfect in shape and petal, one of the best of this season. Messrs. Cheal and Sons, Crawley.

**DAHLIA SALMON QUEEN (Cactus).**—A very striking flower, of good size and form, but with a tendency to flatness in the centre petals. The colour is a deep apricot, shading to salmon in the outer petals. Messrs. J. Burrell and Co., Cambridge.

**DAHLIA CASILDA (Cactus).**—A fine primrose-yellow of good form. Messrs. J. Burrell and Co.

**DAHLIA FALKA (Cactus).**—A very good flower, narrow in the petal, and of a rich ruddy magenta colour. Messrs. Burrell and Co., Cambridge.

Dahlias were greatly in evidence at this meeting, and a very gorgeous show they made, a large number of really excellent flowers being staged. A silver-gilt Flora medal was awarded to Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, for a large exhibit of Cactus Dahlias, among which were good bunches of Mrs. F. Fell, Harmony, Fusilier, Lady Penzance, and Chas. Woodbridge. The blooms were throughout of fine form and size. Mr. West, Tower Hill, Brentwood, staged a collection of Dahlias, comprising Cactus, pompon, and show varieties. In the first-named section many of the blooms were inclined to be coarse, this being particularly the case with Harmony and Earl of Pembroke. The best bunches here were those of Island Queen, the charming new mauve-coloured variety. Among

the shows were Duchess of York, Arthur Rawlings, Maud Fellowes, Virginale, T. W. Girdlestone, and Nellie Crامond. The pompons included good bunches of Gipsy, Nellie Broomhead, Nerissa, Mary Kirk, and Madge. A silver Banksian medal was awarded. A similar exhibit, but smaller, came from Mr. G. Humphries, Kington Langley, and included some splendid show and fancy blooms, notably Duchess of Albany, Goldsmith, Mrs. Saunders, James Cocker, Ethel Britton, and Duchess of York (bronze Banksian medal). A few splendid Cactus Dahlias, chiefly new varieties, were shown by Messrs. Keynes, Williams and Co., Salisbury. The best were Mary Service, Firebrand, a new crimson of good form; Arachne, the new scarlet-and-white striped flower; and Keynes' White, the best white yet certificated. A very extensive exhibit of Cactus Dahlias and Gladioli came from Messrs. J. Burrell and Co., Cambridge. The best of the Dahlias were Regulus, Mrs. F. Fell, Beatrice, Cinderella, Fantasy, and Mrs. Kingsley Foster. The Gladioli were throughout magnificent, well flowered, and the blooms of great size. A few of the best were At's, Mikado, Rayon d'Or, Jeannette, Grand Rouge, Carmen, Enchantress, and Horace Vernet. A silver-gilt Flora medal was awarded. A particularly fine exhibit of Dahlias came from Messrs. Cheal and Sons, Crawley, every bunch being remarkably fresh and perfect in condition. The best of the pompons were Fabio, Whisper, Lillian, Nerissa, Sunny Daybreak, Emily Hopper, and Ganymede. The Cactus varieties were very beautiful and constituted the chief feature of the exhibit. The best were Cinderella, Mrs. Kingsley Foster, King of Siam, Starfish, Harry Stredwick, Harmony, Cycle, Chas. Woodbridge (a superb bunch), and Mrs. Beck. The singles included some very beautiful things, especially Naomi Tighe, Miss Zulema, Donna Casilda, Mrs. Wythes, Victoria, Little Nell, and Phyllis. A silver Flora medal was awarded. Mr. Chas. Turner, of Slough, had a pretty collection of Dahlias, the flowers being shown in baskets. The best varieties were Starfish, Mrs. Barnes, Countess of Gosford, Chas. Woodbridge, Mayor Haskins, Harmony, and Fusilier. The pompon Hypatia, a new variety of good form and unique colour, was also shown (silver Flora medal). Mr. G. Mortimer, Farnham, Surrey, also staged Dahlias—Cactus, pompon, show, and fancy varieties. In this case the shows and fancies were particularly good, notable kinds being Joseph B. Service, Duchess of York, Perfection, R. T. Rawlings, Diadem, Richard Dean, Majestic, Shirley Hibberd, James Cocker and James Stephens. A silver Flora medal was awarded. Messrs. Jones and Sons, Shrewsbury, had a large exhibit of Dahlias, comprising arrangements in baskets, vases, &c., and also bouquets. A few of the best things were a charming bouquet of Harmony, tastefully arranged with grass and tinted foliage, a graceful basket of small blooms of Fusilier, another of Fantasy, and a huge trophy of Mayor Haskins and Lady Penzance. The whole group was of high quality and well staged, and fully deserved the silver Flora medal. Mr. J. Hudson, of Gunnersbury House, Acton, exhibited a large and interesting collection of Cactus, single, pompon and single Cactus forms of Dahlias. The single Cactus varieties were in good form, especially interesting as being the only ones in the show. The collection gained a silver Flora medal. Messrs. H. Cannell and Sons, Swanley, Kent, also staged Cactus and pompon Dahlias in good style, gaining a silver Banksian medal.

A very excellent and striking exhibit was a large collection of Asters and Sunflowers from Messrs. Veitch and Sons, Chelsea. A great number of varieties of Asters was shown, some of the most beautiful being F. W. Burbidge, Apollo, Candidus, Shorti, Acris, Mrs. John Wood, and Aurora (silver Flora medal). A collection of very lovely varieties of early Chrysanthemums was shown by Mr. E. F. Such, Maidenhead, and gained a bronze Banksian medal. A few of the best things were Harvest Home, Dorcas, Blushing Bride, Miss M. Massey, and Bronze Bride. A

silver Flora medal was given to Mr. J. H. Withy for a good and tastefully arranged group of Chrysanthemums, including some very fine Japanese varieties. Very attractive was a collection of autumn Roses from Messrs. Wm. Paul and Son, Waltham Cross, which was awarded a silver-gilt Banksian medal. A few of the best things were a new Tea, Souvenir de C. Guillot, a good colour deep rosy apricot; Cameos, George Nabonnand Mme. Pierre Cochet, Marie van Houtte, Enchantress, and Queen Mab. A silver Banksian medal went to Messrs. John Laing and Sons for a group of very handsome stove plants, chiefly well-grown Dracenas and Crotons. A similar group from Messrs. Peed and Sons was awarded bronze Banksian medal.

Messrs. Paul and Son, Cheshunt, staged a remarkably fine group of hardy herbaceous flowers, containing Aster Novæ-Angliæ pulchellus (very dark form), Funkia subcordata grandiflora (some charming hardy Cyclamens, Sanguisorba canadensis, Crassula Cooperi (a rich crimson flower for carpet bedding), Colchicum speciosum and Rosa viridiflora (silver Banksian medal). A charming group of early white Chrysanthemum Lady Fitzwygram and Liliums came from Mr. C. Wythes, Syon House Gardens. A silver Flora medal was deservedly awarded. A collection of huge blooms of Japanese Chrysanthemums came from Mr. W. J. Godfrey, Exmouth, Devon, at contained a box of lovely flowers of W. R. Prince a large, handsome yellow. Messrs. Cutbush and Son showed branches of Phytolacca decandra heavily fruited. A brilliant patch of colour was formed by a group of the dazzling scarlet *Salvia splendens grandiflora*, shown by Mr. J. Hudson.

#### Fruit Committee.

There were fewer exhibits before this committee than might have been expected. Hardy fruit were not numerous, but the Apples and Peaches staged for flavour made a good display. Ten minutes of a committee meeting held at Chiswick on the 8th inst. were confirmed. Potatoes were dealt with, between seventy and eighty kinds being examined. Several were noted for their cropping qualities, but only a few stood the test of cooking. Tomatoes were gone through, but awards were given. It was decided to examine them later. Runner Beans were also examined. One variety was thought excellent for use as a haricot, but the others were passed over.

Awards of merit were given to:—

**POTATO IVO.**—This, obtained from the Canals Islands, is a white-fleshed kidney, a good cropper and of first class flavour. From Major Curtis.

**POTATO CARDINAL.**—A very heavy crop, white round, inclined to be somewhat pebble shaped. It is of excellent flavour, flesh firm and dry. It is a good late variety.

**POTATO HORSFORD'S SEEDLING.**—A very profuse, white, pebble-shaped variety, of fine quality and a heavy cropper. From Messrs. Horsford, New York.

**POTATO WINDSOR CASTLE** was given three medals thus confirming the previous award given. The variety proved to be one of the best for crop and quality. Messrs. Sutton & Sons.

Mr. Empson, gardener to Mrs. Wingfield, Amptill House, Beds, staged a large quantity of Onions, taking up much table space. There were some very fine specimens of Carter's Record, Excelsior, Ailsa Craig, Holborn, Banbury, Magnum Bonum, with smaller specimens of other varieties arranged in groups and large mounts (silver Knightian medal). Some twelve Melons, mostly large specimens, but varying much in shape and colour, were staged by Mr. W. Keble Barnes. The variety was said to be Earl of Favourite, but there were doubtless several varieties. Mr. Woodward, Barham Court Garden, Maidstone, showed a fine dish of Beurre de Melon tillet Pears, receiving a cultural award. A seedling Apple named Sweet William was shown by Mr. Williamson, Daisy Bank, Conington. A very fine bunch of Grapes, stated to be a seedling, and not unlike a Sweetwater, but

uch firmer berry, named Bloxham Seedling, me from Mr. Bloxham, Brickhill Manor, Beds. ew Melons were shown by Mr. Bishop in three varieties, but none were thought any improvement older kinds. A fine dish of the new Late Denian Peach was staged by Messrs. Veitch, Ltd., nelsen.

The Veitch prizes for flavour brought forth a rited competition, there being eleven varieties Apples, the first prize going to Mr. Wythes, on House, Brentford, for an excellent dish of bston Pippin, grown on a bush on a south rder, Mr. Coleman, Gatton Park, Reigate, ing second with Worcester Pearmain. Gravenin, Maltster and Ribston Pippin were the other nds staged. Pears were represented by eleven shes, the premier award going to Mr. Herrin, opmore, for Souvenir du Congres, a very fine sh. The second prize was taken by Mr. Wythes th excellent Autumn Nelis; smaller fruits than e first, but we think of better quality. The her varieties staged were Beurré d'Amanlis by er exhibitors, Williams' Bon Chrétien, Jersey atiali, Marie Louise, Louise Bonne of Jersey, nd Fondante d'Automne.

There was a very good attendance to hear Mr. guldens lecture on "Cyclamens." He treated e subject in a very practical manner. The lecter gave the flowering season as October to arch. Of late years there have been some grand ditions both in colour, shape, and size of lwers. Only in a limited number of gardens are cyclamens grown well, and this is to be regretted, few plants are more useful during the winter ouths. They require much attention to keep em clear of insect pests, and if at all neglected, e. Iggulden's advice was not to grow them, unless done well it was best to leave them me. Seed was often sown early in the year, but ere was not sufficient time for the plants to evelop. Autumn sowing was much better, d details were given as to sowing, also e importance of sowing new seed, the latter havg more vigour and germinating freely. Young plants must not be checked in any way from the rt, but be kept growing and perfectly clean. e temperature the lecturer recommended was em 60° to 70° for the seed. It should be sown i pans covered over with sheets of glass, and ed to prevent drying of the soil. As soon as re enough to handle, the seedlings should be eefully lifted out of the pans and potted up ip 2½-inch pots. Here more care was needed up was at times given, as if the tender rootlets a broken in the operation, the plants receive sh a check that they rarely grow out of it. er potting up, the plants are best stood on a eash bottom on a stage in low houses or pits, ding from sun. A small house is advised, as e more moisture is retained. At the second sit the compost should consist of two parts len, one of leaf soil and one of coarse sand, and h pots are best, firm potting and ample drainage being necessary. Place again in the shetures advised till the roots reach the sides of el pots, and take care to spray the plants overbd twice daily, morning and afternoon, well daping the foliage. In summer the plants are e grown in low cool frames on an ash ecom, housing in September not far from th glass. These plants are best grown in a ese by themselves. It is best to water at th side of the pots. During the flowering eod he advised a lower temperature—45° by nght and 50° by day. Another point he strongly emphasised was thoroughly ripening the crowns afr flowering, as by so doing better growth folld. Two-year-old plants he found flowered in h better than one-year-old ones. He briefly eferred to the great strides Cyclamens had made e years. Few plants had shown greater imement. We now had such good varieties that th only thing needed was care in culture. eeling and other points of culture were also gone

r. Iggulden, in reply to questions by Mrs. Douglas and Sydenham, stated that old

plants were superior to seedlings if they were well ripened previous to being repotted. He gave old plants a thorough soaking after drying off before repotting and carefully removed old soil, not breaking the roots in so doing. Mr. Sydenham stated that with improved fumigators there was less difficulty in culture. He also pointed out the value of Cyclamen flowers when cut.

**National Chrysanthemum Society.**—On Monday evening last the general committee of this society held a meeting at Anderton's Hotel, Fleet Street, Mr. T. W. Sanders presiding. The minutes and correspondence having been formally disposed of, the secretary read out a list of the society's medals awarded at the recent early-flowering show. The question as to time and place of the annual dinner occupied some attention, a small sub-committee being appointed to eury out the details. A financial statement up to the 11th inst. was presented by the secretary, which appeared to be satisfactory when compared with that for the same period last year. Several new members were elected and the North Canterbury (N.Z.) Chrysanthemum Club was admitted in affiliation. Mr. Gordon drew the attention of members interested in the early varieties to the collection at present growing in the Royal Horticultural Society's gardens at Chiswick, and thought it would well repay a visit by any of those who paid special regard to varieties of that type. Mr. Harman-Payne announced that the French National Chrysanthemum Society intended to hold a conference and show at Orleans next November, and would be glad to welcome a deputation from the English Society. If it were considered feasible to organise such a deputation he would be pleased to give every information as the time drew nearer to hand.

NOTES OF THE WEEK.

**Dahlia Miss Irene Cannell.**—This is perhaps one of the most beautiful of the Cactus forms of this flower, and likewise a most pleasing kind in the rather unusual apricot shade that renders it such a useful addition to this favourite class.

**Potentilla fruticosa.**—This shrubby species after flowering freely for a long season is still gay with many of its golden blossoms, and a worthy subject for the higher parts of the rock garden or the shrubbery. Its neat foliage, too, is by no means common.

**Aster Novæ-Angliæ pulchellus.**—This is perhaps one of the finest of this section of Star-worts, the flowers large and of a useful shade of colour in the garden at this time; the plant is also robust and can care for itself for years when once planted.

**Aconitum japonicum** is welcome for its mass of deep violet-blue in the border at this time, and being dwarf-growing and of easy culture, should find favour on this account. One or two other late-flowering species have deep-coloured flowers, but the above is perhaps among the best.

**Lycoris radiata** or **Nerine japonica.**—Bulbs of this plant are now flowering in the open air in my garden. They were planted there some two years ago and left undisturbed. Has this plant flowered anywhere in the open ground in England?—ALEXANDER WALLACE, *Colchester.*

**Clematis coccinea.**—Flowering sprays of this remarkable and interesting species were included in an exhibit from Messrs. Paul and Son, Cheshunt, on Tuesday at the Drill Hall. Though of great interest, it has scarcely proved so useful as was expected when first introduced.

**Coris monspeliensis.**—This is a dignity relation of our garden and wild Primulas, and I should be most grateful to the writer of the note in THE GARDEN (p. 231) if he would kindly tell me where or whence fresh plants or seeds of it may be obtained. It is said to be wild in South Europe

and North Africa, but I have asked for seeds from Montpellier in vain.—F. W. BURRIDGE.

**Saintpaulia ionantha.**—This pretty little plant is now flowering freely in quite small pots, and by its many buds promises a long display of its richly-coloured blossoms. Of easy culture and free-flowering, it is worth attention where marginal plants are required for the conservatory and such places.

**Agathæa cœlestis.**—Though usually grown in pots for winter flowering, this plant is very useful in the flower garden. From cuttings that are rooted quite early in the year and grown on quickly good plants result, and these, if pinched once or twice before planting out, will make capital bushes and flower freely during the greater part of the year.

**Gypsophila libanotica.**—For its very distinct and pleasing growth as well as the dainty truss of pure white blossoms, this should prove a welcome plant for late summer flowering in the rock garden. The habit is compact and generally neat in appearance, the leaves of a distinct glaucous shade and each about 1½ inches long. The flowers are rather numerous, in a compact terminal truss.

**Crassula Cooperi.**—A species bearing this name obtained an award of merit at the Royal Horticultural Society's meeting on Tuesday last. The example in question was a mass of reddish crimson blossoms, though the species is recorded in the "Dictionary of Gardening" as "white" flowered. In the masses of its flowers and colour the plant bears some resemblance to *C. rubicunda*, though somewhat more dense than we remember the latter species.

**Begonia Lafayette.**—This remarkable kind promises, both by the fine colour and the great quantities of its blossoms, to surpass what are known as the bedding kinds. The intense crimson-scarlet hue is very telling, the more so when it is remembered that the season for such things is drawing to a close. The plants exhibited by Messrs. Veitch on Tuesday at the Drill Hall were lifted from the open ground the day previous, and were apparently little the worse.

**Sedum spectabile.**—Freely planted either in beds or groups in the rock garden this is very effective at this season, and cannot fail to be duly appreciated. There are times, however, when such a plant can be misplaced, and quite recently an instance came under my notice. Attracted by a large group of the *Sedum*, I found on the opposite side a fine clump of *Colecium* in flower—a rather unfortunate as well as unusual association. In the *Sedum* we have a colour safe almost anywhere in early autumn.—E. J.

**Potentilla nepalensis.**—This brilliantly-flowered species, which is not unfrequently referred to under *P. formosa*, is certainly in point of colour one of the most telling plants in the rock garden. The shade of colour is by no means common among hardy plants, and may be best described perhaps as brilliant reddish carmine. But though only medium-sized blossoms, the trailing stems produce a profusion of flowers that makes their presence felt. Where the rock garden is large enough to allow this plant to trail at will, it will produce a very unusual and brilliant array of its richly coloured flowers.

**Tropæolum speciosum** (Flame Flower).—This very brilliant climber is still producing its vivid blossoms. In some instances where the long trails have ascended into the adjacent shrubs and the lower branches of the trees, a very pretty effect has resulted. Usually in the southern counties at least a difficult or a slow plant to establish, it well repays all efforts in this direction, when at length success is assured. Where *Rhododendrons* abound it is a capital plant to grow among them, and when established and flowering away far into the autumn months above the plants named the effect is unique.

**Erodium supracanum.**—It is surprising what a profusion of flowers even quite small plants of

this will produce. Some nice plants of it in the rock garden have been pleasing for three months at least, yet never at any one time making a great show. Depending on the size of the tuft the number of flowers will be in proportion to the number of spikes or blossom, as only very few flowers on each spray expand at one time. In this way a long succession of bloom is kept up, and as the sprays are produced in great profusion the plants appear to be always in flower. For the rock garden the *Erodiums* are very useful, the blossoms prettily marked or veined, and the foliage pleasing in the extreme.

**Chrysanthemum Lady Fitzwygram.**—The good qualities of this plant are becoming better appreciated. The blossoms are of the purest white, and on this account are more highly valued than those of *Mme. C. Desgrange* with their yellowish shade of colouring in the centre. To see the variety under notice at its best it should be freely disbudded, and from eight to ten flowers allowed to develop. These attain to a good size, and are useful where a bold effect in vase decoration may be wanted. Plants in the open are just now looking at their best, the diameter of each being quite 2½ feet, and, owing to a slight disbudding, freely covered with blossoms of a useful size. This is one of the dwarfest of the early Japanese sorts, rarely exceeding 2 feet in height.

— This useful dwarf-growing kind, which in some districts is very difficult to grow, was shown in superb condition at the Drill Hall this week by Earl Percy, Syon House (gardener, Mr. Geo. Wythes). The plants, without an atom of training and no disbudding, were little more than 2 feet high, pots and all, and about the same in diameter, the compact little bushes being simply loaded with fully-developed, pure white blossoms, and almost endless buds that will carry on the display and yield material for cutting for weeks to come. There were about a score of plants from Syon, so much alike all round that they may have been grown in a mould, so perfectly uniform were they in every respect. Indeed, it would be difficult to surpass the standard of excellence attained in these plants, which, with buds and blossoms complete, constituted one of the best examples of natural growth and freedom of flowering I have seen. Many of the most useful and freest flowering of decorative *Chrysanthemums* are irretrievably ruined year by year by an over-rigid system of disbudding, but which, I am glad to find, does not find universal favour in all gardens.—E. J.

**Silene monachorum.**—Where a thin carpet is required either in the rock garden or elsewhere that would be specially suited to clothe the surface where small bulbous plants are grown, this plant should meet almost every want. Not in the slightest degree rampant, over-dense, or deep-rooting, it is nevertheless a perfect carpet plant, covering the earth with its small leafage and in summer clothed with a profusion of pure white flowers. Frequently carpet plants are too dense and, for the plants below them, take too much from the soil. A dense carpet should only be tolerated for deep-rooting subjects and strong growth, and it cannot be supposed that what is a good carpet for a bed of *Roses* would be equally suited for *Snowdrops* and other such things.

**Salvia splendens grandiflora.**—On Tuesday last there were two exhibits of this splendid plant at the Drill Hall, and of its great value there can be no doubt. Much the finest examples were those from Messrs. de Rothschild (gardener, Mr. Jas. Hudson). The plants in this instance, notwithstanding they were merely cuttings of the present year, were veritable specimens between 3 feet and 4 feet high, and completely loaded with long spikes of vermilion flowers. A more brilliant flowering plant in the open garden in September could not possibly be conceived, the spikes of flowers alone being upwards of a foot in length in numerous instances. These handsome bushes were grown in the open till about three weeks

ago. A year or so ago cut spikes came from the garden of Sir Trevor Lawrence, and these, foliage and all complete, were between 2 feet and 3 feet in length, thus showing their great value in a cut state. Such a plant as this will prove of the greatest service for filling large beds in the summer or in pots with a slightly altered method of culture for autumn and winter flowering.

**Lilium longiflorum eximium.**—Though somewhat late in the year, a very handsome group of this beautiful Lily may now be seen flowering in No. 4 greenhouse at Kew. Of its value there need be no two opinions, for in many respects it is quite unique. Large and handsome individually, and singularly pure and chaste in the snowy whiteness of the glistening flowers, it is perhaps one of the most valuable members of a genus replete with many of the choicest gems that are to be found among bulbous plants. Treated as at Kew, with three or more bulbs planted in a 9-inch pot, a very fine display is the result, several stems, each rather under 3 feet high, being crowned with some half-dozen of the spotless, trumpet-shaped blossoms. Such grown plants are eminently fitted for conservatory decoration, while the profusion of blossoms and pleasing and delicate fragrance are items that are always appreciated. Not least of its many claims to notice is the abundance of fresh green and shining leaves, the latter so very persistent as well as beautiful in this justly popular Lily. It is a kind, moreover, that by various methods of treatment may be had in flower for many weeks in succession.

**Notes from Baden-Baden.**—Notwithstanding cool and very rainy weather, *Colchicum giganteum* is in full flower just now. The flower is larger and the colour much deeper than in *C. speciosum*. *Linaria pancei* is a showy perennial, the flowers large, yellow and orange, set off to advantage by the broad, massive glaucous green foliage and the elegant habit of the plant. It is a native of Southern Serbia and quite hardy. *Gerbera Jamesoni* is very fine this year, throwing up flowers since May and likely to continue so until frost sets in. Every visitor admires the vivid scarlet of the Aster-like flowers. It is easily lifted now and replanted in March or April. *Delphinium caucasicum* is also showy with lax spikes of large sky-blue and bright blue flowers. *Delphinium speciosum* var. *glabratum* is a very showy plant from the north of Kashmir. It flowers in a panicle about 3 feet high, and the blooms very much resemble those of *D. cashmerianum*. It is a robust and distinct species. Since June *Incarvillea variabilis* has been flowering freely. It is a Central Asiatic species and has a half-shrubby habit like *I. Olge*. The flowers do not last long, but there is a constant succession. They are not so large as those of *I. Delavayi*, but of the same colour, and their constant succession in combination with the finely cut bright foliage gives the plant a peculiar charm. It comes close to *Amphicome Emodi*, but is more shrub-like, about 3 feet in height. *Kniphofia Tysoni* is also flowering now; it much resembles *K. caulescens*, but the foliage is more massive, broader, and of a glaucous bluish tinge. The flowers, not gaudy, yet striking, are brick-red, changing to white with a slight tinge of green. All in all, it is a stately plant.—MAX LEICHTLIN, *Baden-Baden*.

**The weather in West Herts.**—A week of very changeable weather as regards temperature. For instance, on the 18th the reading in shade at no time exceeded 54°; whereas three days afterwards the shade temperature rose to 66°. On the night preceding the 19th the exposed thermometer fell 1° below the freezing-point, making this the first frost, although a very slight one, of the present autumn. The ground at 2 feet deep is now about 2° colder, and at 1 foot deep about 3° colder, than is seasonable. Rain fell on three days during the week, but to the aggregate depth of less than half an inch. No rain-water at all has come through the heavy soil percolation

gauge for four days, showing that the soil is now in good working order and free from superfluous moisture.—E. M., *Berkhamsted*.

**Lily bulb disease.**—I have read Mr. Massey's paper (pp. 220-1) on Lily bulb disease with great interest, all the more because it corroborates the opinion I have always held, that, given a sound unbroken skin, plants and animals may by defiance to external fungoid germs. He writes "Germ tubes could not enter the tissue through the epidermis," and again, "The fungus cannot penetrate the unbroken tissue of the bulb, but gains an entrance through wounds, more especially broken roots." The same holds good with the Potato disease, and I have just now been observing, in a moist patch in my garden, Potatoes which had been bored into by worms or slugs, and had cracks in their skins, showed signs of disease commencing about the edge of the wounds, the sound-skinned Potatoes mostly escaping. (Of course the disease may enter through the epidermis of the leaf or stem after it has been attacked by the little insects which breed there, as I have shown many years ago, but till this year I never got the evidence of disease commencing in the tuber where the epidermis of the tuber had been destroyed.—DR. ALEX. WALLACE, *Colchester*.)

## PUBLIC GARDENS.

**The preservation of Highgate Woods.** In spite of the strong protests of the inhabitants of the neighbourhood and others interested in the preservation of the natural beauty of Highgate Woods, the Charity Commissioners some time ago sanctioned a scheme put forward by the Hornsey Charity Trustees for the demolition of the almshouses in Muswell Hill Road, Highgate, and the purchase of a piece of the Churchyard Bottom Wood, the whole of the land to be converted into sites for villa residences. It now appears that there is still an opportunity for preserving the wood intact, for, though the almshouses have been demolished, the Hornsey Charity Trust have not yet been able to let the land on building leases. If the movement which has been set on foot for purchasing the wood from the Ecclesiastical Commissioners for £25,000 could be carried out speedily, before the land above mentioned has been disposed of, it might also be possible to secure this land which forms the front of the wood to Muswell Hill Road. The Great Pit Wood, secured to the public some years ago, has a frontage to the other side of the road, that at present the two woods form a large stretch of open country. If a row of villa residences erected on the trustees' land, this continuity unfortunately be broken.

**List of Roses (Smith and Jones).**—We should think "The Rose Garden," by Wm. Paul, Waltham Cross, London, N., would answer your purpose.

**Names of plants.**—*T. Scott.*—2, *Oxalis Ortgi*—*A. C. Bartholomew.*—Looks like a Cassia, but far gone to be quite sure.—*Co. Cork.*—1, *Crataegus Pyracantha.*—*J. F. H.*—*A Bromelia*, probably *Æchmea*, but cannot name without flowers.—*E. Clark.*—1, *Lilium Kratzeri*; 2, *Helianthus decapetalus*; 3, *Veronica spicata*; 4, we cannot undertake to name Asters; 5, *Pyrethrum uliginosum*; 6, *Cypripedium Spicerianum.*—*W. C.*—1, *Ceanothus azureus*; 2, *Escallonia macrantha*; 3, *Ampelopsis sempervirens*; 4, *Rose China Cramoisi Superieur*; 5, *Eleagnus pungens variegatus*; 6, *Weigela aurea*; 7, *Diplazium chrysophyllum.*—*G. A. M.*—It is possible that *C. tatei* *Maid* or *Rosa Mundi* is the Tulip to which you refer.—*Southampton.*—1, *Virginian Poke* (*Phyllaea decandra*).—*W. Richardson.*—*Diplazium Brearleyana.*—*J. S. Stirling.*—1, probably *A. laevis*.

**Names of fruit.**—*J. E. D.*—Apples: 1, *Ribston*; 2, *Carlisle Codlin*; 3, *Blenheim Orange*; 4, *Alfriston*; 5, *King of the Pippins.* Pear: 6, *Autumn Bergamot*.—*Rev. J. C. Ross.*—1, *Old Keswick Codlin*; 2, *Hornsea's Pearmain*; 3, *Improved Keswick Codlin*; 4, *King of the Pippins*; 5, *Cellini Pippin*.

## ORCHIDS.

### NIGRO-HIRSUTE DENDROBIUMS.

This section of the genus is quite a distinct one, although the various species contained therein require somewhat different treatment, there is a certain affinity amongst them that they are easily recognised by. One and all are beautiful plants when well done, but it must be admitted at the outset that they are more difficult to cultivate than the majority in the genus, not from any weakness of constitution exactly, but such as *D. formosum* are really strong growers, but because of a habit they have of going back after a few years' growth in this country. The reason of this lies entirely in the atmospheric treatment; there can be no doubt of this, for it is easy enough to provide a suitable root-run. A few years ago I had several beautiful specimens of *D. Draconis* established through pieces of Apple wood. Hardly an inch of the block could be seen; it was simply covered with long white healthy roots in each direction, and had it depended upon the rooting medium then these plants were safe as long as the wood lasted. The first sign of a failure was a few of the young leads damping off with no apparent cause; the consequence was when the back breaks appeared the season was too far advanced for these to ripen properly, and after that their decline was rapid. To entirely prevent this kind of thing is impossible, and the most that cultivators can do is to study closely the habit and manner of growth of the individual species, shaping their treatment to meet this as far as practicable. Indeed, the plants themselves vary, even of the same kind, as anyone who has a large number of one species may see for himself, and this shows how little use it is giving stated times of such cultural operations as are necessary. It is a few of the more salient of these may be touched on with advantage. Watering at the root is an important point, as on it depends the

health of the plant in a great measure. Many of the species included in this group are in a state of Nature deciduous, or nearly so, but cultivators have long since found that in this respect, at least, it is unwise to follow natural conditions exactly. If we dried these plants at the roots sufficiently for the foliage to fall off every autumn, or whenever the bulbs ripened, in all probability there would be no foliage to fall the next season, or at all events the plants would be so weakened that they would cease to have any value. On the other hand, if we water the roots too heavily during the time growth is inactive we run the risk first of killing the roots, and also, if much heat is afforded, of starting the plants into a weakly, unseasonable growth; but by just giving enough moisture to the roots to keep the leaves fresh into the second season, it is possible to keep the basal eyes dormant without unduly wasting the energies of the plant.

This leads to the consideration of the compost, for if the roots are in an unsuitable class of material it is quite impossible to maintain the health of the plant. They are damaged by contact with soddened and soured material, the green feeding tips decay, and, in consequence, the root first fails to perform its functions of carrying moisture for the need of the plant, and ends by dying outright. Whatever is used, then, must be of such a character that it rapidly parts with water. Peat and Sphagnum Moss are both excellent material in themselves; in fact, indispensable to the Orchid grower; but too much of them, without division of the bulk by adding crocks, charcoal or some similar material, leads just to that condition we are trying to avoid. Better by far for any epiphytoid Orchid to be grown in a mixture that runs dry two or three times a day than for the progress of the roots to be hindered by a close and water-logged compost. Take the beautiful *D. infundibulum* as an instance; place it in a narrow pan, the depth of which only allows of about an inch of compost. In the growing season this will want watering daily at least,

but the roots will take hold of every particle of compost and every inch of the inside of the pan. This is the way to get healthy growth. Put the same plant in a large pot where the roots have several inches of material before they reach the sides, and they never get there, the plant always being unhappy. Temperature is another important point, and depends largely on the habitat of the species. Such as *D. formosum* and *D. Draconis* are found low down in Burma and Moulmein—in some of the hottest parts of the world, in fact. To grow these in company with *D. infundibulum* or *D. Jamesianum* that occur at an altitude of several thousand feet in the same country is obviously wrong. This then must be the grower's care with this beautiful section of plants—not to treat them all alike because they are all *Dendrobiums* and somewhat similar in habit and inflorescence, but take them individually and study the wants of each. They are all subject to the attacks of thrips and red spider if the atmosphere is kept too dry in the growing season. This must be avoided, and as soon as the first signs of insects are observed at once take means of ridding the plants of them, for with them they cannot be healthy for any length of time. R.

**Burlingtonia candida.**—A basketful of this pretty species with a dozen of its spikes of pure white blossoms has a nice effect just now, the little yellow stain on the lip being just enough to enhance the beauty of the snow white on the outer segments. It is a native of Demerara, and an Orchid that anyone might grow with a little care. The most frequent mistake in its management is allowing the rhizomes to extend and carry the roots out of the reach of the compost. It does well in the Cattleya house in a light position, a moist atmosphere and plenty of water at the roots being required while growing.

**Cymbidium Hookerianum.**—This I noted last week in good order, the large yellowish flowers with crimson markings having a very fine effect against the fine foliage. It is a good deal like *C. Lowianum* in habit, and like it does much better and flowers more profusely in a house kept

cool, airy and moist than in a very high temperature. It is rather a gross feeding plant for an Orchid, and likes abundant moisture during the growing season. Even when at rest the roots must not be dried, or the pseudo-bulbs soon shrivel badly. It is very subject to the attacks of a small brown scale insect, and this must be kept in check by sponging. It is a native of the Himalayas, whence it was introduced in 1866.

**Dendrobium leucolophotum.**—This is not a showy species or one that produces more than an average quantity of flowers, but these are chaste and pretty, and occur when not many others of the genus are flowering. It is not often seen in cultivation, and is an erect-growing plant upwards of a foot in height, the flowers occurring on racemes from the upper part of the pseudo-bulbs. They are small, almost pure white, with a greenish tinge at the base of the segments. Plenty of heat and a moist house are needed to grow it well, as it is a native of the islands about the Malay Peninsula, whence it was introduced in 1881.

**Oncidium roseum.**—The flowers of this plant are extremely useful for cutting, as they may be had almost any length and last a long time in good condition. It is one of the prettiest of the non-bulbous kinds, and not difficult to cultivate. It grows fairly strong, so may have pots of good size and an open compost, consisting of peat and Sphagnum, over abundant drainage. It does best in the Cattleya house in a light, almost unshaded position. During the time growth is active a very liberal supply of moisture is necessary, but during the winter months a good deal less suffices.

**Catasetum tridentatum.**—I recently noticed a fine spike of this singular Orchid in bloom at Melford Hall. It is one of the strongest growers and one of the most easily cultivated, the spikes containing a great many flowers, each about 4 inches across. The segments are all stiff and ungainly looking, and the singularly formed lip has the power of ejecting the pollen when the horn-like processes on the column are touched with a pencil. It requires plenty of heat and moisture while growing and to be potted in peat and Moss. After the pseudo-bulbs are fully matured it must have a long dry rest.—R.

**Galeandra Baueri.**—This is a very pretty species when well grown, the colour of the blossoms being an effective combination of greenish-brown, purple, and white. The lip is funnel-shaped, open in front, the white portion being outside. The flowers, each upwards of 2 inches across, are produced on drooping racemes from the top of the stem-like pseudo-bulbs. It is best grown in a warm moist house with plenty of water at the root from the time the growths start at the base until the flowers are over. Afterwards the plants may be gradually inured to cooler and drier treatment, the roots also being kept on the dry side. It likes a fairly substantial compost and to be grown in pots on the stage.

**Dendrobium superbienis.**—This beautiful Dendrobe I have just noted in good condition. Few kinds vary more than this in quality, the rich, warm crimson-purple tint on the sepals and petals of the best varieties being showy and fine in the extreme. The racemes occur at the upper part of the stems and bear each about a dozen flowers. It is not a difficult plant to grow, and the stems flower profusely if well ripened by exposure to sun and air. Although a strong-growing plant, very large pots are not necessary, the roots apparently preferring rather to coil about in a small area than push far away. It is a native of the islands in the Torres Straits, whence it was introduced in 1876.—H.

**Epidendrum inversum.**—This comes from a correspondent for a name, and it is an old, almost forgotten species. In habit and general characteristics it is not unlike the better-known *E. fragrans*, but larger. The peduncle rises from the apex of the club-shaped bulb and bears a dozen or more flowers, each being about 2 inches across and closely crowded together. The sepals, petals

and lip are all pale creamy yellow, the latter being freely marked with purple. It does well in the Cattleya house and is very inconstant in its time of growing, resting and flowering; consequently, it is not easy to recommend how it should be treated as to moisture, but when growth is active it of course requires more than when at rest. It is a native of Minas Geraes, in Brazil, and was introduced in 1839.

#### CATLEYA LUDDMANNIANA.

THIS species forms a useful connecting link between *C. Gaskelliana* and *C. labiata autumnalis*, but cannot be said to be a rival in any way of either. It is not so free-blooming, as a rule, as Gaskell's *Cattleya* or the older species, but, nevertheless, should be grown. Like all this section of plants, cultivation alters their habit to a marked extent, and it is often difficult to detect any difference between many of them when out of flower. The foliage of *C. Luddemanniana* is, however, often much thinner in texture than that of the species mentioned above, the stems, too, being straighter and smoother, and of a pale green tint. It is a very free grower, this fact, in some instances, accounting for its paucity of flowering, and it must be said of some plants of it that it seems almost impossible to get them to bloom. The most likely means of bringing the plants into flowering condition is growing them from first to last in an airy, light house where the atmosphere and temperature keep steady and the plant can be arranged far enough from the roof to do away with much shading. It should also be kept dormant after the flowers are past, or if the plants have not bloomed after the season's growth is complete. It is no use allowing sudden drops in the temperature and withholding water all at once, as some cultivators still persist in doing with refractory subjects. In one case out of a dozen it may be successful, but in nearly every one it predisposes the plants to the unsightly spot, to which they are subject, and weakens them materially in other ways. Let them have the change by all means, and keep the plant quiet if possible, but bring this about in a more natural and gradual manner, and it will be far more effective. The habit of the species is to bloom upon the young growths like *C. labiata*, not to rest in sheath, like *C. Trianae* or *C. Mossiae*. The blossoms are of medium size, the sepals much broader than the petals, of a delicate purplish rose, with a white suffusion. The lip has a deep purple front lobe, the base lighter in colour, with radiating lines of purple and a paler area on each side, like some forms of *C. Mendeli*. It needs a fairly large pot or basket, as the roots like to ramble freely over large rough lumps of charcoal or similar material, and otherwise it may be treated similarly to its relative mentioned. It is named after a French gardener, with whom it first flowered under cultivation, and presumably it was imported with a consignment of *C. Mossiae* or some other kind from the same locality. It first flowered in Britain in 1863 in the Meadowbank collection.

**Oncidium Kramerianum aureum.**—In this pretty variety, which I noticed in flower at Mr. Bull's recently, the greater part of the lip was of the clearest lemon-yellow, and the margin of chestnut-red, although well defined, is not so broad as usual. The pretty twist in the sepals adds very much to the beauty of the flower, and it is far superior, in my estimation, to *O. Papilio*. Both do well in plenty of heat and moisture and a light, sunny position.—H. R.

**Lælia monophylla.**—This is quite distinct from all the other *Lælias*, and a bright effective little plant. It consists of upright stems each about 6 inches high. The flowers, borne singly, are each less than 2 inches across and orange-scarlet in colour. It does not require much heat, as, though it comes from Jamaica, its habitat is high up in the mountains. The most convenient way of growing it is to plant it in baskets or

shallow pans of peat fibre and Moss, hanging these up in the lightest position at command the *Odontoglossum* house. The stage is too much shaded in this house, as a rule, for this kind to satisfactory, nor is too damp a condition of atmosphere any advantage to it, especially in winter. Moisture it delights in while making growth, but shade, moisture, and a very cold atmosphere combined are too much for it. I recently saw some nice plants in a house devoted principally to *Masdevallias* of the *Chimara* group where the temperature in winter never fell below 50°, and these appeared happy under the circumstances. It is not a novelty, having been so long home from Jamaica to Kew in 1881, where it flowered the year after.—R.

#### KITCHEN GARDEN.

##### PLANTING CABBAGE IN AUTUMN.

THIS is a simple matter in certain soils, but the reverse in light land deeply dug and well manured. I think the Cabbage much more tender if planted in light, over-rich soil. In the spring the plants bolt badly. "J. C." a few seasons ago advised a firm soil for spring Cabbage, and I quite agree with him, as though the autumn growth is less strong, the plants being more sturdy are in better condition to battle against our variable winters. I do not even dig and manure my land for the spring crop, and I need a good quantity. Cabbage follows spring-sown Onions. The land is well manured for the Onions, and is then merely hoed and raked and drills drawn. Many will not agree with me, and think such a grower will need food at the roots to promote strong growth. I do not foster a strong growth as though I am aware it is necessary for plants to get a good root-hold before the show days, a gross growth now means a severe check should hard weather follow. Of course, heavy clay soils my note may not be applicable. I am dealing with a light, old garden soil, just the kind where one fails on account of richness and loss of roots in severe seasons. For me in such a soil I was troubled with spring Cabbage running, but with a hard root-run a less food at planting there is no difficulty, as I have five plants in a thousand run. The Cabbages put out early in September are nice compared with the end of October. Previous to draining soil well up to the lower leaves to protect the stem, each plant is well trodden round to make it as firm as possible. It is an easy matter to feed young plants, say in February or March according to season, if growth is forward, as that date by using liquid manure, guano, or other fertilisers, the plant gets the food just the time new vigour is needed. I have used nitrate of soda in March to great advantage with strong plants and in soil none too rich. I vary the Onion quarters as much as possible with the result that in some years the land is much poorer. Nitrate of soda applied in showery weather as a fertiliser is a powerful manure, but I prefer to give two dressings to a strong one, and at the rate of 2 cwt. to 3 cwt. per acre. I plant rather closely, only 15 inches between the rows and 1 foot between the plants. A later lot is given 18 inches and 15 inches, but the varieties are small. Ellam's cannot be beaten, and Mein's No. 1 for succession is equally good. It may be thought Cabbages planted at distance named are too close. I do not allow the spring Cabbage to grow large. Cutting begins early, and it is an easy matter to thin out. The reason the later lot is given more space is to allow of hoeing freely between

rows, as being later there is more difficulty with weeds.

G. WYTHES.

**Lettuces failing.**—Will any of your readers tell me how to get rid of a parasite that has infested the roots of my Lettuce plants for the last two seasons? On pulling up a plant the root appears covered with white mould, among which are numerous yellowish insects, somewhat larger than cheese mites. The plant does not wither, but the effect is to completely paralyse its further growth and prevent its hearting.—W. L. A.

**Maize as a vegetable.**—This is not often grown for use as a vegetable, but it is well worth growing in any garden where variety is valued, and any persons who at first object to its taste in a short time appreciate it. This has been a grand reason if the plants were given an early start. In starting early I mean sowing the seeds under glass, and potting off singly, or pricking them into boxes. I am aware seeds may be sown in the open, as the plant is a quick grower, but though it makes a fair growth, in our variable climate it fails to produce good fruits, hence the importance of sowing under glass in March for a first crop. Well-cooked, it is a nice vegetable, and by some thought to be nutritious. There are several good varieties to select from.—G. WYTHES.

**Carter's stringless French Bean.**—I think I have seen this Bean mentioned in THE GARDEN before by Mr. Wythes, of Sion House. At any rate, it is an acquisition in more ways than one. I have grown it this summer, and just when it is in full growth the weather was very hot and dry. Yet in spite of this the haulm showed no signs of distress, was not affected by red spider, and I set a grand crop of pods. These, as its name implies, have no strings running up the sides of the pods, as all others have, more or less, even when not old. Consequently, they can be prepared in a very short time. Another good trait of its character is the long time the pods remain in a usable condition. The flavour is first-rate. Perhaps it is scarcely hardy enough for first early sea-air sowings, but for mid-season and later sowings it is certainly unsurpassed.—J. CRAWFORD.

**Autumn-sown Carrots.**—Small, tender, sweet Carrots seem now to be indispensable in all large gardens, as cooks are constantly asking for them. In warm sheltered gardens where the soil is light, and door sowings do fairly well, but the best results are obtained when a frame is given them. In cold, wet autumns the young roots do not always go away so freely as wished for, and are liable to be attacked by grubs. These pests need to a certain extent be guarded against by the use of wood ashes when getting the bed ready, and these are also a good stimulant. When sown in a frame, codling need not be practised, the plants being drawn off in fine weather and tilted over the young roots during heavy rain, snow, or frost. A little more thinning out of the young plants is needed from autumn sowings than from spring and summer ones, growth being less vigorous and the days darker and colder. Market Favourite is one of the best varieties for sowing at this time of year.—C. C. H.

**Autumn Peas.**—Those who have got a good supply of late Peas are to be congratulated, as in light soils on gravel it is very difficult to get a full crop in a hot, dry summer such as we have just passed through. In a good loam and in other localities there is no lack of good autumn Peas. When I lived in the north and midland counties I had fair crops well into October, but in the south, with more than ordinary attention, there is little return for one's labour. We certainly have an advantage in the earliest supplies, and such soil we can grow the best type of Marrow Pea, which would decay in colder districts. We have thus some advantages. On the other hand, our lot is now made easier, as some of the dwarfier types, such as Sutton's Latest of All Dwarf Mammoth and Michaelmas Peas are so robust, that these, if sown late, will give a good

return if a little care is taken in getting the seeds to germinate quickly. Many growers in poor soils do not think the extra trouble to procure autumn supplies worth taking, but I think the more variety of vegetables anyone can give the better, so that I am in favour of autumn varieties.—G. W.

**Tall v. Dwarf Peas.**—Many people wonder why market gardeners do not grow tall Marrow Peas in the same way as one finds them in the gardens of the wealthy landowners. The reason is simple enough. To buy stakes tall enough for British Queen or any other tall Marrow would entail a cost of several pounds per acre. Consequently, it is only dwarf kinds that are in demand for field-culture. This is no reason why good Peas should not be forthcoming much longer than they usually are. This season I have grown English Wonder for both the earliest and the latest crops, and during September Peas have been equal to any of the year. As the soil was dust dry in July when the last crop was sown I took out shallow trenches about a foot wide and 6 inches deep, and spread a good layer of quite rotten manure in the bottom, with just enough soil to make it when finished ready for seed, about 2 inches below the level. The seed was then scattered thinly all over the surface and covered, and one good soaking of water given. The Peas grew away rapidly and quickly came into flower, and have yielded excellent gatherings for a long time, although the haulm was very short. In this locality English Wonder has, to a great extent, supplanted American Wonder and William Hurst, and as Pea-sticks in suburban districts cost about as much as the Pea crop would realise, I need hardly say that the demand for tall Peas gets less every season. I think it is only a question of time, when tall Peas will disappear from the neighbourhood of large towns altogether.—J. G., Gosport.

#### THE CARTER SPINACH.

No doubt readers of THE GARDEN have come to the conclusion that the declaration of Messrs. James Carter & Co. re the above Spinach (p. 222) is correct, and settles the matter. The note at page 222 says "that an award of merit was granted to the variety by the fruit committee on July 11, 1895." I thank the firm greatly for furnishing me with these data, because I am enabled to turn to the Royal Horticultural Society's Journal, which it would be well if all gardeners could have; and in the issue of August, 1895, in the report of the proceedings of the fruit committee on June 11, p. 36, I find this: "Award of merit to Spinach Longstander (or Lent à Monter of Vilmorin), votes unanimous, from Messrs. Carter and Co. A very fine variety grown at Chiswick; the leaves large, pale green, very late in running to seed." How the firm can claim that the award was made to a variety named The Carter, I, as also every reader, fail to see. Turning now to the meeting of the same committee, held June 25 (p. 39), that is, two weeks later, I find this: "Messrs. Carter and Co., High Holborn, submitted examples of Longstander Spinach and of a variety named The Carter. These seemed to closely resemble each other. It was recommended that a trial of Spinaches be made at Chiswick next year." Here, as is seen, The Carter as a new variety comes first on the scene, and the fruit committee for I remember the circumstance well—at once resolved to ask the council to have a Spinach trial the following year. Now we will see what came out of that trial, which took place in 1896, and which was, too, as good a trial as could have been furnished anywhere in the kingdom. Here is the prelude to the result of that trial, as determined by the fruit committee when examining the varieties on May 23, 1896: "Thirty-three stocks of Spinach were received for trial, and all were sown on April 4. In spite of the dry weather, the seed germinated freely and the plants grew well. The result of the trial proved that there are really only a very small number of varie-

ties, and also that the round, dark-leaved sorts are the true Longstanding, and the light green are not." The varied nomenclature was astonishing, and showed great confusion. The so-called varieties were divided into round-seeded and prickly-seeded, but it cannot be too widely known that mere presence or absence of spines on the seed does not constitute a variety, for the Longstander, for instance, with its thick, round, dark green leaves, is just the same plant whether from round or prickly seed. So also with the Flanders and the Virolay. The trial is reported in the August number of the Journal for 1896, commencing at p. 69, and shows in detail exactly the true section or variety to which each so-called one belongs. Thus I find No. 29, The Carter, is the same as No. 12, Longstanding Round (Sutton and Sons), this being similar to No. 20, which is Heinemann's stock of Longstanding, the best stock of the variety grown; so also are Lent à Monter (Vilmorin) and many others. Thus it is seen that after all in asking how far The Carter Spinach was distinct from others in commerce and was amply justified, I leave to others to draw their own conclusions. As a member of the fruit and vegetable committee who knows thoroughly the value of trials at Chiswick, I feel it to be my duty to hold loyally to the results of those trials. If the work done at Chiswick is to be entirely ignored, then the gardens might as well be closed.

A. D.

**Winter Spinach thinning.**—The thinning of winter Spinach is at times overlooked, owing to late sowing or press of work, but it is an important matter, as the plants when at all crowded do not make a firm growth, with the result that with sharp weather or cutting winds the leafage is much injured. In thinning, each plant should be given ample space, so that the leaves do not touch each other. The Victoria and Long Standing require more space than the older forms, the leaves being stouter, and, if much crowded, the plant becomes naked at the base and is damaged by winds, the leaves turning yellow and decaying. I find when Spinach is given plenty of room there is less trouble with slugs and a better return. Early thinning is important to secure a good growth, and I think the old theory that the non-thinning of winter crops with the idea that thickly-grown plants protect one another will not find much favour in these days. When the best culture is given there will be fewer losses. A sturdy plant can battle against our variable climate, whereas a weak plant goes to the wall.—L. H. B.

**Peas and green fly.**—My experience is quite different from that of "S. F." (p. 175), who says that dwarf Peas are more subject to the attacks of green fly than tall ones. Much depends upon the soil and cultivation, and I think the 3 feet to 4 feet Peas suffer more from insect pests than the taller ones. I admit varieties with a stout haulm, such as Eureka, Maincrop, Marrowfat, Peerless, and Magnum Bonum—all 3 feet Peas—are better able to resist mildew than the 6 feet varieties, and my plants are free from green fly. On the other hand, the old Ne Plus Ultra and Criterion, taller varieties, were badly infested. A mistake often made with Maincrop Peas, especially these robust 3 feet to 4 feet varieties, is thick sowing, as, if at all thick, they are soon attacked by insects, and, having more succulent leaves, are more liable to attacks. At p. 155 Mr. Tallack gives us a good note on the medium growers. He notes the value of Autocrat, one of the 4 feet kinds, and also others of a dwarfier type. I think we have a splendid selection in these kinds, and so far I have not found them so subject to mildew as the tall ones. Of late I notice there have been several interesting notes mostly on this class of Pea in these pages, showing how well they have done in an adverse season.—L. M.

**Parsley growing for sale.**—I have always thought Parsley a good paying product. Everybody uses Parsley, and in gentlemen's kitchens it is indispensable. As to price, even in the summer

months from 3s. to 4s. per dozen bunches wholesale are easily realised, the bunches, by the way, not being very large. It is, however, in the winter months that it pays best, the price per bunch then usually rising to 4d. or 5d. Even if the weather is open and in times of severe frost a fabulous charge is often made in large towns. I maintain that were market gardeners of the smaller type to grow more for a winter supply it would pay them well. If sown in long narrow beds and a rough wooden framework erected over them, these being covered in severe weather with home-made straw hurdles, exposing them again in fine weather, the crop could be preserved in good condition and the hearts of the plants saved from ruin, so that an early and good start would be made in February and good fronds produced during April and May, a time when after a trying winter Parsley is at a premium. The large growers have, as a rule, no lack of this commodity, but it is the smaller country growers who seem to be behind in the matter, thus standing in their own light. Then there is something in variety, as Parsley is graded as well as other market products, a dwarf, dense, true strain always being eagerly bought up for garnishing. Occasionally one meets with a small grower who disposes of his Parsley privately to first-class greengrocers, thus saving the fee of the middleman and pocketing the whole of the profit himself.—J. C.

## FLOWER GARDEN.

### HERBACEOUS PHLOXES.

THE statement by "A. D.," at page 239, that "these Phloxes always show their finest form the first year when raised from cuttings," is altogether wrong. A large number of the plants are not distributed from the nurseries till more than a year old, unless it be the most recent novelties. And if the above statement were true, the first and, according to "A. D.," therefore the "finest" flowering is for ever lost. But it is not so. Equally wrong is the additional statement made by "A. D." that "the second year they give several heads of bloom, but less fine." Anyone who has "intelligently grown" these Phloxes for only three years would be able to refute such a statement, so utterly opposed to facts. It is very true that Phloxes do "severely eat up plant food and absorb moisture"; so does an Apple tree or an Oak; but this is not evidence that the time has come for rooting them out and discarding them as being of no further use. And if it be so impossible for the minor roots of a three or even four year old Phlox to find support, what may be expected of many other perennials, to say nothing of numerous shrubs and evergreens, that in these respects could easily outstrip the plants in question? What more voracious things have we than Aster *Novae-Angliae* vars., Helianthus *orgyalis*, or Plantain Lilies, while the very aspect of some species of the last tends to direct even the rainfall away from the plant. Yet few things are more satisfactory, even when six or ten years planted. Equally true, only in a less degree, is this of Phloxes; indeed, I have taken some handsome heads this season from a bed planted six years ago, that would compare very favourably with the finest I have seen at the Drill Hall this year. Briefly as to height, as here also "A. D." appears to have gone astray. At page 189 *Aurore* and *Syphilde*, among others, are said "to be very dwarf," and "blooming at 15 inches in height." Messrs. Barr's list gives these at 2½ feet, and as the latter, which is a capital white, has been even taller at Kew this year, it will at once be seen it is not so "very dwarf" after all. And if a like proportion be added to

those "A. D." describes as "20 inches to 30 inches," it will bring the herbaceous Phloxes to much the same height as they have been for some years. Twenty years ago *Coccinea*, *Edith*, *J. K. Lore*, and *Independence* were reputedly dwarf varieties, and were so, in fact, in the first year. But if these were planted 4 feet apart and left three years in good deep soil, the first will be nearly 4 feet high and the others upwards of 3 feet. I say at 4 feet apart because I note "A. D." imagines height to be caused by overcrowding, which is not likely to ensue at 4 feet apart. I have occasionally seen the well-known *Coccinea* at 18 inches high, though usually poor, puny, and small-flowered, and, like all else where this dwarfness is but the outcome of want of culture, and not natural habit, quite unrepresentative of the beautiful class to which it belongs. Recently divided plants after such a summer of heat would be just of this class unless special means had been taken to prevent it. In many directions there is room for improving these plants, which around London do not receive the attention they did twenty-five years ago, when Mr. Robert Parker, Downie, Laird, and Laing, Forest Hill, and Henderson's, Wellington Road, grew them nearer perfection than I have seen for some time. The Phloxes in all these places were a feature. Many of the best then are the best now with very few exceptions. Phloxes at 12 inches high are not wanted in the garden, and as a fact, happily, do not exist. For years past the tendency has been to elaborate and embellish the beds on the lawn, while the garden all around has been ignored. For this latter purpose these Phloxes are most valuable, and raising their heads aloft are best suited for effective grouping as also for distant effect. For these purposes we do not want them a blaze of colour level with the lawn; rather should they be sufficiently tall to be fittingly associated with other things equally desirable and capable of similarly beautiful and varied effects in the landscape of any good garden. E. JENKINS.

Hampton Hill.

### NOTES ON HARDY PLANTS.

**Clintonia umbellata.**—Those who have grown this interesting herbaceous plant will just now be reminded of the best aspect in which it presents itself in British gardens, because it is now bearing its umbels of large fruits of a bright and light blue colour. Those who have not grown it may be assured of its hardiness, and may perhaps better realise what it is like when it is stated that it is equally correct to call it a *Smilacina* as a *Clintonia*. It does well in an open border if there is a deep moist soil of a black or vegetable nature.

**Shortia galacifolia.**—Charmed as we were in spring by the lovely flowers of this humble, but effective plant, no one can be less so on seeing the highly-coloured foliage at this season; besides yellow there is rich mahogany colour in more or less pronounced shades, which, with the dividing lines of the midribs and veins in paler yellows or on green, is enough to content the most exacting, and the fact that this oval foliage is arranged in pretty tufts, almost rosette-like in many cases, further enhances the value of the plant for autumn, especially where grown quite exposed, as certainly it may be. Indeed, it is my fully exposed group that tempted this note, the more shaded plants being as yet comparatively green.

**Arenaria gothica.**—This is still in bloom, and how large and striking the flowers are for so small a plant! They are pure white, star-shaped, and of a glassy or glistening nature; indeed, the whole plant is notable for its shining character. It is quite a thing to put into chinks in the rock garden, and it evidently can take care of itself, provided rampant neighbours are kept

from reaching it, or, better still, not allowed to be there.

**Primulas—the alpine species.**—I can say that I know for a fact that the mealy root does much harm. I do not like to see it, and some of the healthiest plants I have seen are infested with it, and though I always wash the roots of plants I work at for propagation, I have seen pest propagated with the plant without apparent harm. This uncertainty is not quite satisfactory, but there are points on which I do feel certain. First, that the aphid is not a pest of general origin or peculiar to the plants in a state of captivity, because I have frequently seen its roots newly collected in the Alps, and just when I am importing my usual supplies, and the pest is conspicuous on such species as *minuta carnolica*, *Wulfeniana*, *calycina*, *oenensis*, *venensis*, and *Dumoulini*. The more porous the rooting medium, the more liable the plants are to be infested. This brings me to another point, also, I think, beyond doubt, that the aphid cannot long exist if not near a circulation of air. The porous soil just hinted at is an instance. Another is the fact that you always find the densest colonies at the collar of the plant, and if deeper it is pretty sure to be in loose soil or *débris* as many of us have a fancy for setting the *Primula* species amongst. And again in the case of pot-cultivated specimens this is emphasised by the fact that there may be a colony at the collar and another at the bottom and near the hole of the pot. In stiff, adhesive soils you rarely find this pest, but, of course, if soils are not practicable for all the species. Given, however, the correctness of the air theory, if one wishes to destroy the pest, we have an obvious advantage in knowing such simple facts.

**Muhlenbeckia complexa.**—Properly planted, this is capable of growing to a most attractive specimen. On the outside of a greenhouse facing south it has grown into a wide mass and had a delicate and Fern-like effect. It acts as a foil to some *Tritomas*, and as such its distinct effect will be better imagined than described. It makes a striking hillock of sombre foliage when grown in a border or on rocks, or it may be employed as a cimber of considerable vigour. Of course, a position named is an exceptional one, and may be said to indicate the want of hardiness which I have found to be the case. My experience is that in severe winters it suffers in the open, but is killed. Anyhow, it is one of those good and effective things that are worth some care in winter, and often a small armful of dry Bracken will answer for protection in winter. I notice a crop of beautiful fruits setting on twigs that have rambed into the greenhouse. J. WOODVILLE.

Woodville, Kirkcubbin.

**Single Dahlia Scarlet Defiance.**—I have grown this Dahlia this season, and find it to be very vigorous, free-flowering variety, producing blooms of a most intense scarlet colour and extra large size. These are borne on very long stems and are just the thing for cutting. Given as all the types of Dahlias are for the flower garden, none are so useful for cutting as the single varieties. One mistake which is often made is placing too many in a single vase or bowl. A space of a few inches between each flower should always be given, thus allowing for the spare contribution of some suitably coloured autumn foliage.—J. C.

**Asclepias tuberosa.**—This fine plant, which was introduced from North America some three hundred years ago, has come before the flower committee of the Royal Horticultural Society two or three times this season in the hope it would obtain an award; but, good and valuable as it is, the limit of age was very properly applied in its case. It is a grand old plant, and the season appears to have suited it. The dry, warm sunning brought it to a high state of perfection. It needs a light warm soil to come to perfection, and this it is found to do well in a mixture of peat and loam. It is seldom met with, and that, perhaps, because conditions of soil and climate may affect it.—R.

## ANDROSACE LANUGINOSA.

the whole, this may be considered the best of its race. Left alone it is rather straggling in growth, but this may be considerably modified by regulating the shoots with a few wooden pegs, thus forming it into more compact masses. The majority of the species in this beautiful genus have a caespitose habit of growth, this leading to make them rather short-lived in our temperate climate. The plant under notice is an exception, being easily grown and readily propagated. The stems reach a length of about 2 feet and are furnished with silky white leaves, the flowers rose-coloured with a yellow centre. There should be no difficulty in forming large clumps, as in the illustration, preferably in positions where the trailing stems could fall over a ledge of rock. It will also do well on a level, but to be successful grown thus the ground should be carpeted with small stones for the growths to rest on. A soil composed of

years to perfection in heavy damp soil and in a shaded situation. In sun or shade, in light or heavy soil, cottagers seem rarely to fail with this exquisite Lily, and one is large-hearted enough to be glad of their success even if such does not attend one's own efforts. After reading the exhaustive and interesting article (p. 220) on the disease which has lately attacked the Japanese Lilies, one feels a strong desire that those who have worked so ably to elucidate that question would turn their attention to the disease, that so often works havoc in the ranks of *Lilium candidum*, which is *par excellence* our Lily, and yields the palm to none in pure beauty. Many reasons have been assigned for this visitation and many remedies have been recommended, but, as far as I know, all are more tentative than authoritative.—S. W. F.

**Seedling scarlet Lobelias.**—I send you a few side spikes of Lobelia seedlings having for parentage *L. syphilitica* and the forms of *L. fulgens*. The result of such hybridising is to give greater hardiness to the race, and it also tends to make them bushy. My large bed of

200 feet in length, which have lately been filled with double Violets. The plants were looking particularly strong and healthy, and on not one could a trace of red spider be seen, the foliage being of a uniform dark green throughout. These Violets were grown in the full sun, and no watering was required from the time they were planted out in the spring, while the heavy rains that fell immediately after they were moved to the pits settled them well in their new quarters and prevented them flagging even for an hour.—S. W. F., *South Devon*.

**Muhlenbeckia complexa.**—A note from Mr. Wood on the charming effect of the above associated with *Rhexia virginica* appeared on p. 159. It is, indeed, valuable for clothing blank or unsightly places; here hanging like a curtain before a bare rock; here filling the interstices of a worn-out hedge with its wiry stems and minute leaves, and here again acting as a foil to some brilliant flower. In my garden it has this year overgrown the corner of a bed where *Lobelia fulgens* lives, and a few brilliant spikes have shot up

*Androsace lanuginosa* at Totley Hall, Sheffield. From a photograph sent by Mr. W. A. Milner.

sandy loam with either peat or leaf soil added, and also some burnt clay, answers well for it. The illustration was from a photograph taken by Mr. Milner, Totley Hall, Sheffield, in his garden on July 29 of the present year. Mr. Milner says that the plant was given to him about three years ago, and that it seems to increase and be thoroughly at home. He also tells us he has never pinched it back, and that he grows it in a mixture of light soil and limestone chippings.

**The Madonna Lily.**—On page 159 reference is made to the healthy conditions of the above Lily in cottage gardens. The writer of the note is inclined to attribute this success to the sandy soil in which these bulbs were grown and to the high and sunny situation of the bed. The fact of these Lilies thriving nowhere as they do in cottage gardens has often been alluded to in the columns, but it is not alone in dry positions that they flourish in such gardens, for I know of more than one place where they have grown for

these has been quite a sight, being a mass of bloom. The plants were put out as miniature seedlings in the middle of a large field, with no protection whatever, in the early spring. I have other crosses, and for next year I hope to get a greater range of colour. The Gaillardias also are the result of careful hybridising in order to get a distinctiveness to the strain.—B. LADHAMS, *Shirley, Southampton*.

\*\* They are very interesting and such experiments may lead to some useful varieties, but we think that all crossing of *L. syphilitica* and the splendid scarlet kinds is a step the wrong way. What we ought to seek are fine varieties of the scarlet kinds, than which there are no better.—Ed.

**Violets.**—I see that on p. 190 "J. C." speaks of the present season as having been trying for the double Violets on account of the encouragement given by the drought to the red spider. Fortunately for us in the south-west, we have had a fairly moist summer, only one of the summer months being below the average as regards rainfall. I have just seen a range of pits, over

through its dark green maze. It must, I think, be judged perfectly hardy in the south-west, as one plant, which grows here at the lip of a small cascade and hangs down towards the water beneath, was in the severe winter of 1895 a solid sheet of ice for many weeks, from root to furthest leaflet, with the incessant sprinkling of the quickly freezing water. After the departure of the frost it looked very miserable for a time, but with the return of spring threw out fresh shoots and leaves.—S. W. F.

**Notes from Almondsbury.**—It is wonderful and delightful to notice the growth of the love of gardening and the rapid spread of flowers into small and out-of-the-way places. On Monday I was at Aust, one of the many places connected by tradition with the meeting between St. Augustine and the Welsh bishops. Just opposite the fine old church is a farmhouse, and the garden is full of white *Anemone japonica*. Yet it seems to me only a few years since the gardening world was rejoicing over the possession of this treasure. One day last week a lady, who had spent many hours in the study of gardening books, came

to me, and, though knowing very little as yet, was enthusiastic on the subject. Down in the village little greenhouses are madly springing up, and wild purchases at ruinous prices are made of bulbs that will never grow to perfection. One can often give here a helping hand. *Physalis Franchetti* is looking very fine. My advice is, give it a good place in the vegetable garden and grow it freely; it is a most excellent fruit. I think it superior to the ordinary Cape Gooseberry in flavour, and a dish full of these gorgeous monsters would delight the eye as well as the palate. Sun and rich soil are all it needs, and once planted, never think to be free of it. *Rudbeckia Golden Glow* is a fine thing, but mine went up to 9 feet high and then bloomed profusely. Put it with a *Silphium* and see which will beat. My hardy *Cyclamens* are over—how charming these are! A race of *Streptocarpus* from Messrs. Sanders is good, to my mind, but rather difficult to bloom. These things want heat, but not a stove. In the stove they come out waxy and lanky. Everyone should grow the tall *Tydeea fragrans*—pure white, long tube—most useful just now, yet I seldom see it.—C. O. MILES.

***Tropæolum speciosum*.**—This brilliant climber, a note on which appeared on page 189, is difficult to establish in the south-west. I have tried to introduce it into my garden for five years, and only succeeded in acclimatising it last year after four unsuccessful attempts. It is now growing in leaf-mould and loam in a bed which the sun's rays rarely touch, though, after the plant has reached a height of 5 feet it gets plenty of sunshine. It has flowered abundantly this year and has also seeded freely, yet in the summer great lengths died off suddenly without any apparent cause. As "E. J." pointed out, its vigour in Scotland is marvellous. No careful selection of site and exposure is needful there. It is almost sufficient to drop a piece of the root on a bed for it to occupy the whole of the surrounding soil in a year's time. I have seen barrowfuls of the roots dug up and thrown away in the north, with which we in the south would have been only too glad to experiment.—S., *Tarquay*.

#### BORDER CARNATIONS.

PERMIT me to make a few additions to what I said the other day, as I seem not to have made myself understood. No one has a greater appreciation of the excellent work Mr. Martin Smith has done in raising and giving us his beautiful and vigorous modern Carnations. What I did say, and say again, is that "no flower has been more killed by kindness," because the florists, in their search for smoothness of petal and symmetry of form, overlooked the cardinal points of vigour and hardness. To me—and I venture to think to most "picture-loving" gardeners—a bed of Carnations from last year's autumn layers is an unsightly thing, with its single-stemmed plants, probably stifflly tied up, and with a ring of cropeared layers around the central stick. What I must have is a fine bold mass, full of growth and flower, as little tied up as possible; for preference, not on the flat, but hanging down over a bank or a wall and covering it, perhaps for 4 feet or even 5 feet with a curtain of flower. Will anyone contend such an effect is possible with one-year-old plants? It certainly is not in the north, and therefore I only call such Carnations as will endure and thrive for three years at least true border Carnations, because they only can give the rich effect of luxuriance and flower that I desire. Those who have not seen the beauty of Carnations grown in this way have a treat before them if they will try it. I shall never forget a striking instance I saw years ago in a stable yard at Tarifa, in the south of Spain. Hung on the walls of the inn yard where the diligence stopped were large pockets of cork bark, filled with soil and planted with Carnations which hung down in a blaze of beauty. Such artistic stables do not, I think, reach as far north as England, but we certainly may diversify the usual Carnation bed of

an English garden by a raised bed of Carnations hanging down over Larch poles where the soil is sufficiently holding to grow Carnations really well. One of the many merits of Mr. M. Smith's Carnations is that their flowers are so bold and so large, that they are improved by being slightly smaller and so perhaps refined, while the gain in the mass and quantity is enormous. I mentioned one florist's Carnation as a type of what is unsuitable from my point of view; let me add another—Mrs. Eric Hamöro, which is so formal that it is to me positively ugly, and I have discarded it. No doubt it may be a first-rate florist's flower, but then I am not a florist.

EDWARD H. WOODALL.

***Zauschneria californica*.**—In my garden in South Devon this plant grows very freely in heavy loam, even in a spot which is not well drained. It is now bearing its brilliant vermilion blossoms, and is a pretty sight. It is quite hardy here and is given no protection during the winter, having borne the long cold of 1895 with impunity. A small root soon makes a large plant, and as it spreads abroad considerably, it is well not to plant any weak-growing subjects in close proximity. In some gardens it refuses altogether to thrive, although everything is done to humour it.—S. W. F.

**Dahlias and earwigs.**—The note on the above subject (p. 147) reminds me of a time, many years ago, when I planted out a new Dahlia in sunny weather and propped up an old sack over it by way of protection. The next morning I found, to my horror, that the leaves had been all but demolished, and on removing the sack, the better to examine the work of destruction, found it teeming with earwigs. At that time I was growing a few hundred *Chrysanthemum* plants for exhibition blooms, and had already lost many a promising shoot owing to the same pests. I trapped largely with inverted 2½-inch pots filled with hay, sections of hollow cane and crumpled up pieces of brown paper, but felt that the tale of the slain was too inconsiderable to cause any appreciable diminution in their numbers. The sack episode, however, seemed to point a method by which the enemy might be annihilated wholesale, and a search being made for every available piece of old sacking, some thirty or more were found. These were lightly folded and placed on the grass and around the *Chrysanthemums* and Dahlias before nightfall, and on examination the next morning were generally found to contain from a dozen to a hundred earwigs; on some occasions an even larger number than the last-named was trapped in a single sack. Towards the end of the summer the captives were fewer, and the following year the earwigs appeared in diminished numbers. A few weeks ago I was in a garden where a white ensign had inadvertently been left at the truck of a flagstaff through the night. As the proprietor wished to substitute another flag, I hauled down the ensign, and as it touched the ground I noticed that some fifty or more earwigs were running about over the bunting. The night having been absolutely calm they had taken advantage of the hanging folds of the flag for shelter.—S. W. F.

**Herbaceous Lobelias.**—I was glad to read on page 124 that a correspondent found herbaceous Lobelias perfectly hardy with him. That this is not the general experience may be inferred from the numerous letters that have appeared in THE GARDEN during the last few years, dealing with various methods of preserving these plants through the winter months. In my present garden, the soil of which is a heavy loam, both the dark and green leaved varieties are so hardy that, though I often divide the clumps in the autumn, I never have, as in "B. C.'s" case, to place a mulch over the divided plants. The chief group of these Lobelias is situated close to water, and in the severe frost of 1895 the freshly divided clumps were frozen solid for months, this garden, with its low-lying and water-surrounded position, being some degrees colder than any other in the neigh-

bourhood, yet not a single plant perished. The brilliantly coloured flower-spikes, some exceeding 4 feet in height, are thrown up in great profusion, and the other day I cut four dozen without their loss being noticeable. This year they are associated with *Salvia patens*, and very beautiful is the effect of the vermilion spires shooting up from the deep gentian-blue of the *Salvia Lobelia rosea* also does well, and has proved hardy under the same conditions during the last two winters; but whether it would withstand prolonged frost such as that of 1895, with impunity, remains to be proved. When I reside in a warmer and far more sheltered spot on the banks of the river Dart, where the soil was light and shady, I could never keep these Lobelias healthy in the open through the winter, and I had the greatest difficulty, though I wintered some frames and others potted up in gentle heat, preserving sufficient for a yearly display, would seem that, in a damp and holding soil to gain a hardiness to withstand disease and the clemency of wintry weather, that in a lighter soil and more genial surroundings they fail to acquire.—S. W. F.

#### NEW DAHLIAS.

AT the two exhibitions—the Crystal Palace and Aquarium—lately held, fresh varieties of Dahlias were numerous. This was more especially the case among the Cactus flowers. They were many cases improvements, too, both in shape and colour. There appeared to me, however, rather a tendency to award certificates to sorts of somewhat similar tint. Thus, shades of ruby-red were so honoured in Falka and Ruby. Now *Cycle* last year is perhaps better than either, and *Regulus* is not so fine a crimson as is *Chari Woodbridge*. To multiply varieties indefinitely is certainly not a gain unless distinct advance and I fear the cry will soon be with *Cactus Dahlias* as with *Chrysanthemums*, that we are getting too many.

One could wish for some means of judging a new flower in other respects besides the bloom itself. Thus, *Fantasy*, which struck one last year as absolutely new and out of the common shape, is a complete failure as a plant. Its blooms without severe disbudbing are tiny; they have footstalks so short that the leaves hide them entirely. Now one has to pay a considerable price for these novelties, and the many failures are disappointing. As seen at the shows,

**DAFFODIL** is quite ahead of any of its colour, and its shape is most perfect. It is of medium size and its petals are narrow, these standing out quill-like and graceful. The shade of yellow is also very pleasing.

**NIGHT**, as the name implies, is very dark, almost black. In shape it is an improvement on the variety called *Matchless*.

**TILLIE** is a charming shade of salmon-rose; its shape is of the approved type.

**ISLAND QUEEN** has a distinct shade of coral heliotrope-pink will describe it. It is free blooming and has long stems, and is sure to become esteemed.

**ALFRED VASEY**, salmon-rose, is a charming flower quite one of the best of the year. The tint is fresh and rich, and the shape most desirable.

**MARY SERVICE** is another exquisite flower in tint of salmon and pink. Its petals are narrow and pointed.

**ARACINE** will be grown because of its distinctive colouring—white and red. Its petals are very narrow and have a most pleasing curl.

**E. J. DEAL** has bright scarlet crimson flowers. These are forked or pointed and light in appearance.

**ANNIE TURNER** has a charming Cactus-like form and the shading of cerise is most distinct.

**TRUE FRIEND** is a dark-coloured taking bloom. Its petals are spiky and narrow. It is a distinct advance.

The above-named are all Cactus Dahlias. They appeared to me the best among others which gained certificates of merit. *Hypatia*, terra-cotta-yellow, and *Nellie Broomhead*, lilac, are two pompons of very pretty form and colour.—S.

**Physalis Franchetti.**—"F. W. B." (p. 17) notes how easily this is grown, though he admits

ere are failures. Last year I failed, not getting a dozen perfect fruits. This year, without any attention, I have a large quantity and of large size. I think last season the culture was at fault. I raised the plants in strong heat, finally cutting out at the end of May or early in June. The plants soon became infested with red spider, making but poor progress. Being on a Vine border I expected better things. This year the plants came up again very strongly, and instead of a few weakly plants I have grand bushes covered with fruit. This *Physalis* may be raised in a cold frame, and, given ample moisture, will grow freely. Treated thus there is no check. I have this season raised it by sowing in the open ground.—G. WYTHES.

ORCHARD AND FRUIT GARDEN.

BLACKBERRIES.

The accompanying illustration (from a photograph by Messrs. Scott and Sons, of Exeter) shows the value of the Blackberry for covering rustic garden arch. Not only is it effective in furnishing shade for a garden seat, but it breaks the monotony of a long wall-enclosed garden, and furnishes a considerable quantity of fruit of superior quality. The variety is *Alison, Jun.* The garden, belonging to Mr. Sargent, Prospect Park, Exeter, has a moderately favourable situation.

A. HOPE.

UNFRUITFUL PEACHES.

I have a lean-to Peach house having a west gable, the front is 4½ feet high, back wall 10 feet, with 9 feet. The south gable is of stone, and the house on that end is shaded by Beech and Ash trees which grow to within 10 yards or 12 yards. The rafters are 11 inches apart and 3½ inches deep under the glass. During the summer the sun does not begin to shine through till about 1 o'clock p.m. The trees grow in an inside border and are in splendid health. For the past two years they were covered with bloom in spring, but with the exception of four trees at the north end of the house they have quite failed to set a crop. They are not forced, there being no artificial heat. Could you suggest the possible cause of failure?—GARDENER.

\* The cause of failure is evident enough—immature wood. The house was badly designed at the wrong position for it chosen in the first instance. If a Peach house must face the south, as I often visit a garden where Peaches and Nectarines are successfully grown in a lean-to house facing the west, the least that could have been done would have been to construct a glazed south gable, to have light sash bars, these also serving the purpose of rafters, arranging them 15 inches to 18 inches apart, and to provide artificial heat. Even with these improvements it is doubtful if the shade of the Beech and Ash trees would still have an injurious effect upon the Peach trees at the south end of the house. Neither Beech, Elm, nor Ash trees are desirable adjuncts to a garden, and if "Gardener" can get permission, he ought to destroy those shading the Peach house under his charge. If he could further turn on fire-heat, that would partially compensate for the insufficiency of sunshine that reaches his trees. Seeing that they flower freely, root-lifting is not necessary, but he ought to do all the thinning out needed directly what fruit ripens is gathered. Freely thinning out, in particular removing much of the wood that has recently produced fruit, or which ought to have done so, gives the reserved young growths a better chance to harden, as they then get the full benefit of what little sunshine penetrates through the roof. Immature wood may flower freely, but the flowers are imperfect in form and feeble, few or no fruits resulting from them. Trees in pots

would do better under the conditions that prevail in "Gardener's" Peach house, as these after the first season rarely form soft growth, added to which they could be shifted to a sunny, open spot directly the crops are cleared off. Well-managed pot trees produce surprisingly heavy crops. W. I

**Fruit tree in plant house.**—I have a small span-roofed plant house, used in winter for *Cinerarias, &c.*, one end being a brick wall. In spring and summer there are *Pelargoniums* and *Begonias*. Would a Nectarine or a Fig do on the wall satisfactorily? What is the best practical book on fruit culture under glass and outside?—X. Y. Z.

\* \* \* In all probability the house runs from north to south and the wall is at the north end. This being so, either a Fig or Nectarine tree ought to succeed well against the wall. If a Fig tree is preferred, Brown Turkey is the variety to plant. Confine the roots in a border about 6 feet wide,

of a normal-sized Winter Nelis, but less russetty in the skin than that variety. How seldom one meets with Gansel's Bergamot nowadays; this, no doubt, being accounted for by the fact that it requires a good climate and warm soil to do it justice. It used to grow freely and fruit well at Rendlesham, in Suffolk, and I remember a capital tree on a south wall in Essex, worked on the Pear, as it is not naturally a robust grower.—J. C., Notts.

**Figs.**—Figs, especially the Brown Turkey, are abundant with me, and, though somewhat late, are now (the middle of September) ripening well; other sorts, though equally prolific, are not ripening at all well. The Fig is a very gross feeder; I feed mine (some two dozen trees, half of them standard, the other half trained on walls) with blood and fish manure, cow manure, and lime rubble from old buildings. The trees are cut round late in the autumn so as to keep the roots within bounds; manure is put into the trench,

and then a good coating of farmyard rotten manure as a mulching, on top of which a layer of sifted coal ashes is placed to exclude the frost during the winter. In the spring the coal ashes are removed, but the manure mulching is left and well saturated with strong liquid manure. No amount of frost seems to affect them. I never lose a tree from the effects of frost and have almost invariably good crops, especially with the Brown Turkey, which rarely or ever fails, and keeps me well provided with delicious fruit from August till November. I have given up growing the Brown Turkey under glass. True, it ripens earlier, but it is not nearly so prolific or the flavour, to my palate, so good as the outdoor grown fruit. Several of my trees are thirty years old. I prune the wall trees, but not the standards.—GWENT.

**Strawberry Loxford Hall Seedling.**—This, when well grown, excellent late Strawberry appears to be very popular in the eastern counties, judging from the large stock of runners I saw this autumn in the Norwich nurseries. Although, perhaps, not sufficiently prolific for planting in large breadths for market, it is when at home a grand variety for private use, and, when well ripened, of good flavour for a late Strawberry. It is of no use trying to grow it in gardens where the soil is light and hot, as red spider, which is particularly partial to it, is sure to infest the foliage badly. It requires a cool moist loam and liberal mulching.

I have had no experience with it on a north border where such sorts as Elton Pine, Frogmore Late Pine, and Helena Gloede do well, but on ordinary beds exposed to the sun I have had very large fruits, these ripening after all other sorts were past. The fruit is cockscomb-shaped, dark crimson, with prominent seeds.—GROWER.

**Growing Plums for market.**—As with most other things in the fruit and vegetable line, too many midseason varieties are grown and too few early and late kinds; consequently in most seasons there is a glut of such sorts as Victoria, which everybody grows on account of its productive character, as low as a penny a pound and two pounds for three-halfpence being sometimes accepted. Of early and late Plums, however, there is in most market towns a scarcity. Were growers to turn their attention to the production

The Blackberry on a trellis in Mr. Sargent's garden at Prospect Park, Exeter. From a photograph sent by Mr. A. Hope.

narrower if the wall is not more than 10 feet high at its highest point, and a mixture of fresh loam, garden soil and old mortar rubbish in equal parts would answer well. If an early Nectarine is desired, Rivers' Early can be recommended. Humboldt is a fine midseason Nectarine. For Nectarines use less mortar rubbish. "Fruit Culture for Amateurs," by Mr. S. T. Wright, would prove of good service to you.—ED.

**Pear Bergamote d'Esperen.**—This, one of the freest bearers of the Bergamot section, is worthy of more extended cultivation, as quite young trees worked on the Quince fruit freely. In this district it does well, and in fairly sunny seasons is juicy and refreshing, being apt to show a slight grittiness near the core after a wet, sunless summer and autumn. I have it in upright cordon form both on an east and west aspect, and it does well, the fruit being about the size

of August and October ripening varieties they would doubtless find it remunerative, particularly in seasons when Plums are plentiful. Early Prolific, Prince of Wales and Orleans would be good Plums to grow for early supplies. The Sultan, an improved Prince of Wales and a very free bearer, might also be included, also Oullin's Golden, a large, oval, rich yellow Plum, ripening in August. July Green Gage, Early Transparent Gage, Mitchelson's, Monarch, two fine dark very prolific Plums; Grand Duke, ripening in October; Belle de Septembre and Winesour, the latest of all Plums, would be a good selection for producing late market supplies.—J. C.

#### PREPARATIONS FOR PLANTING.

ALTHOUGH it is too soon for planting, when the trees have to be procured from a distance, yet much may be done in the interval to forward matters. The foremost and most laborious work is the opening of the holes and getting them ready for the trees, particularly when a great deal of planting is contemplated. There is a great advantage gained by getting this done early, as not only does it save time when the actual planting has to be performed, but the excavated soil will become warmed by the sun's rays, and the mass and the sides of the holes will also become sweetened in the meantime. The soil thrown out in the process of digging becomes disintegrated on the outside, if not throughout the whole mass, and, as every planter knows, these finer particles are of the greatest value for placing directly over the roots, as they fill up all the interstices between them and leave no hollow spaces, as is the case when freshly-dug soils of an adhesive nature have to be dealt with. In some gardens it is necessary to concrete the bottoms of the holes where the subsoil is cold and wet, or where it is apt to be charged with water at certain seasons of the year, and when this has to be done it is almost superfluous to add that it should be done in good time. In this case short drains must be provided for carrying the moisture away from these concreted holes to the nearest existing drain, but if there are many holes—and they should be contiguous to one another—the quickest way would be to lay a drain purposely, and in such a manner that it will collect all the moisture from each hole. This drain should have a good fall, and be laid just below the level of the concrete floor to ensure the latter always keeping dry, and if placed just at the outer edge of the concreting with some rubble placed on top, the necessity for short drains will be obviated. In cases where the soil is merely cold and damp through the situation being low, the difficulty, and likewise expense, of concreting may be got over by putting a good layer of brickbats or stones at the bottoms of the holes, with a thin layer of broken metal on the top. This will ensure the roots of the trees lying much warmer, and often leads to their succeeding when they would otherwise be quite a failure. When this method is adopted, the precaution should always be taken to place either a layer of turves over the drainage or a sufficient quantity of long litter to keep the soil from getting amongst it and choking it up. For orchard planting the site should be thoroughly and systematically drained if the situation is a low-lying one and the subsoil cold and apt to become water-logged, for to plant fruit trees in such a soil without draining it is simply courting failure. Draining is of course best done, when convenient, early in the season, so that the disturbed portions of the field or pasture, as the case may be, have time to settle down before planting is done. But matters of this description cannot always be performed just at the right moment, and if undertaken at once a great deal of this kind of work could be done between now and the time that nurserymen would be in a position to commence lifting their trees. Another method of overcoming the difficulty of dealing with heavy retentive soils is to plant on mounds or stations. This is of course less expensive than draining, but the latter is the more lasting and

effectual remedy, and should always if possible be adopted. Of course there are numerous cases where no drainage of any description is needed, the subsoil being so porous that all superabundant moisture passes away readily, and all that is necessary in dealing with these is simply to open out holes of sufficient diameter and depth. Where a considerable sized tract of land is to be converted into a mixed orchard or fruit farm, the soil should either be trenched two spits deep or otherwise deeply ploughed after the draining is completed. Unless this can be done early in the autumn it is best to defer planting until the following season, taking a crop of Potatoes from the land in the meantime, after which the soil would be in good working condition. The diameter of the holes will vary according to the class of tree to be planted, but, as a rule, they should not be less than 4 feet, but in orchards 6 feet is none too much, and every particle of old roots should be picked out of the soil if the new tree has to occupy the same site that the old or dead one did. In forming an orchard the soil for which has been trenched, holes 4 feet in diameter and from 18 inches to 2 feet in depth will suffice, but if the trees are to be planted on grass or arable land which has received no previous preparation whatever, the diameter of the holes should certainly not be less than 6 feet, 2 feet in depth, and the bottom well broken up in addition. If this little extra trouble were only taken instead of merely digging a hole just large enough to hold the roots, and sometimes barely that, so many stunted, half-starved-looking young trees would not so frequently be seen in orchards. The next question is that of

#### SOIL,

of which a little should be spared for placing over the roots when the staple is of a poor description. In gardens the soil in which Melons or Cucumbers have been grown answers well if maiden loam is too precious, an article to use first hand. With this may be mixed turf parings from walks and drives, trimmings from the sides of roads, road scrapings, wood ashes, and burnt soil, and when the whole is mixed together it will form a compost congenial to the wants of any kind of fruit tree. The same kind of compost, even if minus the loam, answers remarkably well for placing about the roots when planting orchards, and when much planting is contemplated, a good heap should be got together and turned once or twice some time previous to its being required. Road scrapings, ditch cleanings, and trimmings from the edges of roads can generally be had for the hauling in country districts, and when thrown together and a little lime added at the time of turning, to sweeten the mass, a valuable compost is soon formed. Hedge trimmings, if collected and taken to where the compost heap is being formed and burnt on the spot, will supply a crude form of potash, and this should be intimately mixed with the other ingredients. By exercising a little care and forethought in this way a valuable heap of compost is soon formed, and the labour and expense entailed thereby are amply compensated for in the fact that the trees become the more quickly established, and as a result commence bearing sooner. Whether required in the garden or orchard, this soil should be either wheeled or carted and a sufficient quantity of it placed ready for use by the side of each hole. This should be done as early in the autumn as convenient, for, generally speaking, the ground is then firmer and the wheeling or carting can be done with greater facility than after it becomes saturated by autumn rains.

In addition to preparing the holes and placing a fair medium of compost when required by the side of each, there is the question of

#### STAKING,

as each tree, particularly standards, after being planted must be kept firmly in place by being tied to a stout stake. Staking should be well done at the outset, for if the tree once gets loose at the surface of the ground and a funnel-shaped cavity is formed, in consequence of the stem waving back-

wards and forwards through the action of the wind it will never do much good afterwards. In staking extra care is needed in staking, for the reason that the roots being on a level with the surface, or only a little below it, they have not a firm hold as when planted in the ordinary way consequently, winds have a greater power over them. The stakes in all instances should be driven firmly into the subsoil, and this is best done before the trees are planted, and then no mutilation of roots will take place, as is likely to occur when staking is done after planting. The requisite number of stakes had therefore better be prepared and to render them more durable the butt end after being sharpened, should be charred and then dipped in gas tar, or otherwise be boiled for a few hours in creosote. As a protection against ground game, galvanised wire mesh netting forms a cheap and effective guard for the trees. For this, the light stakes are needed to tie the wire to, and these should be placed triangular fashion round and at some little distance from the stems. The wire netting should be let into the ground to a depth of 2 inches or 3 inches. This same netting makes a good cattle guard if stout and long stakes are used, reaching well up to the heads of the trees. The end corner of the netting should be let into the ground and then wind it round the stakes in spiral fashion until the top of the stake is reached. It should then be cut across, which will leave the netting in the right form for letting into the ground and winding round the stake placed about the next tree. The netting should be held in place with a single strand of barbed wire fastened to one of the stakes near the ground, which should take the same course as the netting does, and fasten it at the top to one of the stakes with a staple. After finding how much wire and netting are required for one tree the necessary number of lengths of both can be cut and had in readiness for use. This is the most inexpensive form of guard for fruit trees that I am acquainted with, and it has the additional merit of being very durable. A. W.

**Japanese Wineberry.**—I was glad to read a note from "Grower" (p. 229) in praise of *Rubus phoenicolasius*. Here it has fruited abundantly this season. As "Grower" says, it makes a very palatable preserve. It is also useful for tea and when fully ripe is a pleasant dessert fruit. In 1896, owing to the abundantly dry spring and summer, the berries were small and comparatively tasteless, but this year they plumped up well and were more than double the size of those borne in the preceding season. If this Wineberry were valued less from an economical point of view, it would still be worthy of a place in the garden for its ornamental qualities.—S. W. F., *Torquay*.

**Wasps' nests.**—The hopes of gardeners in this locality in early summer that wasps would give them no trouble this season have not been fully realised. Up to the middle of August, half-a-dozen wasps had been seen in this district, and one would have thought that the copious cold rains we have had since that date would have done away with them. For the last fortnight, however, the pests have come in upon us in great numbers, attacking not only Grapes, but also Pears and Apples also. The fact is, the cold weather of May kept the nests backward, and of small size of the wasps proves. Another point that climatic influences have much to do with is forwardness and numbers of wasps is found in fact that in Norfolk and Suffolk the pests were this season fairly numerous by the middle of August. Fixing tiffany over ventilators in the old-fashioned way incurs much labour, but the contents of a bottle of Davis's wasp destroyer poured over some damaged fruit—this being kept out of the reach of anyone—seems to clear them off in short time.—C. C. H., *Notts*.

**Pears Beurre d'Aremberg and B. Stermans.**—In answer to Mr. B. Addy's query respecting these two Pears, Beurre d'Aremberg is a success on the Pear stock, either as a bush in the open or as a cordon on a west wall. With

the fruit ripens satisfactorily, the flavour is excellent, closely approaching that of Winter Nelis, while its cropping leaves nothing to be desired. Consider it an excellent Winter Pear, and should be like to be without it, as it comes in so useful after Glou Moreceau. Moreover, it is a Pear which remains in good condition for some days after having arrived at maturity, and it does not rot at the core. The individual fruits are large enough for table or ordinary use. The same variety is quite as satisfactory when worked on the Quince stock. I wish I could give Mr. Adley a good account of B. Sterckmans. This I consider to be but a second-rate Pear, and do not think it worth growing, and have discarded it some time since. It is a good cropper, but I never knew it to ripen properly; in fact, it was only fit for stewing. I have seen it classed among Pears possessing a melting flesh, but my experience of it is quite the contrary. On some it may be a success, but I have never yet met with it in first-rate condition.—A. W., Hereford.

#### CUTTING OFF VINE LEAVES.

Is it injurious to the Vine to cut off part of the shoot with the Grapes? Is it bad for the future of the Vine to pull off for the table some six or eight leaves daily during the period that the Grapes are being cut down?—INQUIRER.

\* An early and excessive removal of the first-formed leaves must, to a certain extent, prove injurious to the Vines. All the while the leaves remain healthy they are performing their natural functions. After the wood is matured, buds formed, and crops ripened, the storing up of sap is still going on, while the roots are particularly active just before the fall of the leaf. It follows that a wholesale loss or destruction of large must paralyse the action of the roots and do bad for the future of the Vine. When this question cropped up some six years ago, I closely observed the behaviour of Vines that had been rather hardly used in the direction of early and severe removal of leaves. The crop was nearly marketed, and for several reasons bunches of Grapes that are sent to the market must be cut with wood attached, this meaning shortening the bunch-bearing laterals to near the third or fourth joint. All the laterals were at the winter pruning shortened back to either the first, second, or third bud from the old wood. Only a few long spurs or with three buds showing were left, and these by way of experiment, and any laterals that had not been allowed to bear a bunch, also a few that had not been shortened when the bunches they bore were cut were with the majority rather badly pruned, one, or at the most two, buds showing on the spurs formed. The results were somewhat strange. We will take the spurs where the laterals had been early shortened when the bunches were cut. Where only a single, plainly discernible bud was left the break was weak, and the laterals gave either a small bunch or none at all. The spur with two buds on it broke more strongly, and none of the laterals failed to give serviceable bunches, while those shortened to the third or fourth joint more plump buds broke the most satisfactorily, and would each have produced two bunches if permitted. In the case of laterals that had produced bunches, and which were not shortened when these were cut, these, when hard pruned, all broke moderately strongly or better than their neighbours which had been less severely dealt with when the bunches were removed, and each gave a bunch weighing about one pound. Those shortened to the second and third buds, as might be expected, did even better, and the greater number of finer bunches resulted from the growths springing from the spurs left when pruning the laterals that carried no bunches the previous year. This points rather conclusively, I think, to the fact that premature and severe shortening of the laterals should be avoided if possible, though it does not follow that the Vines are irreparably injured by this early pruning.

Last season I once more took note of the consequences of early shortening of laterals, and also of pruning in relation to over-cropping. The variety was Gros Colman, and a bunch had been produced by nearly every lateral. Many of the bunches were cut with wood attached late in September, or while yet the foliage was comparatively green, and if at the winter pruning these quite young vines had been hard pruned, or the spurs shortened to the first or even second bud, the crops this season would have been thin and the bunches small. Luckily many of the laterals were shortened to the third bud from the old wood, and these turned what might have been a failure into a creditable success. The moral of this is: Never resort to hard pruning in the case of vines very heavily cropped during the previous season; the same rule holding good, though in a less degree, in the case of vines that had much of their best foliage removed with the bunches.

Personally, I would rather not gather many leaves from my Vines, but then I do not leave so many on them as do some growers. In my case the greatest value is attached to the primary leaves, and of these, two, or at the most three, beyond the bunches are considered ample, all lateral growths not carrying bunches being stopped at about the same length. The sub-laterals are usually strong and are kept stopped at the first leaf. But for their acting as so many safety valves they would be dispensed with altogether. As it is, they are preserved because they serve as outlets for superfluous vigour, and if they were removed early, the new buds on the laterals would burst into growth. I never hesitate about gathering these secondary leaves, but should not think of pulling off the primary ones. "Inquirer" may safely gather leaves freely from all superfluous or sub-lateral growths, the value of which so many gardeners over-rate, but if Vine leaves must be forthcoming for the dessert, why not grow a hardy Vine against a wall or shed for supplying them? W. BURGLEN.

**Pear Triomphe de Vienne.**—This handsome richly-flavoured Pear is becoming very popular, and will no doubt be planted by many in place of Williams' Bon Chrétien, as the musky flavour so characteristic of this is objected to by many people. Not only is the fruit of Triomphe de Vienne handsome and of excellent flavour for an autumn Pear, but the tree is an early and very free bearer, the fruit keeping some time in good condition if stood in a cool place. It appears to be at home in the midlands, as at the Derby show last year it turned up in several collections of fruit, and in the class for a single dish of Pears was awarded the first prize, the fruit in each exhibit being large, tapering and very handsome. It is in season during September.—C. C. H.

**Pear Souvenir du Congrès.**—I am surprised, in walking round gardens noted for fine Pears, that in many of them the above kind has not yet a place. Too many of that bad-keeping variety, Williams' Bon Chrétien are planted. Souvenir du Congrès is a seedling from the foregoing variety. The fruit is larger, sometimes enormous, from wall or espalier, and does not decay so quickly after gathering. Fruit of Williams' Bon Chrétien grown in midland gardens, is poor in quality as compared with those fruit trees in the south of England. Souvenir du Congrès has much more juice in it, and the tree is hardy and usually sets a good crop of fruit even in unfavourable springs. During the past few years a great many trees of it have been planted in Kent and Sussex for market.—J. C.

**Plum Stint.**—At p. 185, in an interesting note on Plums, "E. B. C." asks what is the difference between Stint and River's Early Favourite. Stint is a small fruit reddish in colour; indeed, my fruit may be termed marbled with red on a greenish-yellow ground, whereas Early Favourite is rounder, of a purple colour, a freestone, and with me ten days earlier than Stint. Both are excellent early varieties. Of Early Favourite there is a grand tree in the Royal Horticultural

Society's Gardens, Chiswick, which I notice always crops freely. Stint is equally prolific, as even in adverse seasons it fruits freely. Some growers may object to Stint on account of its being a small fruit, but its earliness is a gain, and it is of good quality for an early Plum. This variety will fruit freely on a light soil where others fail. My soil is very similar to that of "E. B. C." I get my best crops from cordon trees given a little freedom in side shoots.—G. W.

**Cordon Plums.** I was specially interested in "A. W.'s" practical note on the above (p. 193), as a few years ago I adopted this mode of culture. Having a very light soil I made a narrow border, giving 2 feet of heavier soil, planting cordon trees. From these I get the best fruits and regular crops. I am obliged to vary my treatment in the case of certain varieties, and here, I fear, it cannot strictly be termed cordon growth, as I allow the trees to make a few inches of side growth. By this means more young wood is secured and a certain amount of older wood may be cut out annually. I found by adopting a rigid cordon growth some kinds failed to crop, and by giving a little more freedom at the sides I get a good return. I do not encourage breast wood. In such soil as mine certain varieties when young make far too much growth trained as fan-shaped trees, and are poor croppers. Here, I think, the cordon system is of great advantage. In many cases the Plum is so gross that it needs different culture. In my opinion the wood should be trained nearly horizontally when the trees are young.—G. WYTHES.

**Apple Waltham Abbey Seedling.**—This Apple betrays its parentage by its colour, which, if a trifle paler, is yet sufficiently golden to at once suggest that it must have originated from Golden Noble, which is really the case. It has not quite such a clear skin as the parent, the small pale russet dots with which the surface is marked showing out rather conspicuously, and in exposed situations the fruits sometimes become marked with patches of russet. As a garden tree the fruits are clean-looking and quite free from blemishes, and then the fruit equals Golden Noble in its handsome appearance. The fruits are very evenly formed, and the stalk, which is rather short for so large a fruit, is inserted in a rather deep basin. When cut open the flesh is found to have a yellowish tint, much resembling a well-ripened specimen of Wormsley Grange Pippin, while it is tender, juicy, sugary, and pleasantly flavoured. It is a capital cooking Apple, and one that requires but a small amount of sugar. Its season is from September until the end of the year. The tree makes a capital bush or pyramid and is very prolific. Both growth and foliage are quite distinct, the former being of medium strength while the leaves are small. Altogether it is a very desirable Apple, and intending planters would do well to make a note of it.—A. W.

**Apple Golden Russet.**—This fine old-fashioned English Apple is seldom met with now unless it is in old orchards. This is a pity, for when well grown and thoroughly ripened it is hard to beat for flavour. I came across a fine old standard tree a few years ago, growing in the dividing hedge between two orchards, and the fruits were the finest, best coloured and the highest flavoured ever seen or tasted. On making inquiry I found the tree to be of great age, it having been planted in all probability early in the present century. It was noted for its bearing continuous and heavy crops of fruit. When last passing that way I found the old tree was gone, whether it had blown down or not I cannot say, but most likely this was the cause of its disappearance, as many other fine old trees in the adjoining orchard seemed to have met with the same fate. Golden Russet is not a large Apple, the skin yellow, thick, and irregularly coated with russet, the more shaded the fruits the more dense is the russet. Where the fruits experience full sunshine the skin is much clearer, and they then take on a beautiful colour. The flesh is yellowish, firm, sugary and highly flavoured. It is a fine keeper and can be had in good condition as late

as April; in fact, should not be sent to table until after Christmas. The tree is a healthy, vigorous grower and suitable either for garden or orchard culture.—A. W.

## CHRYSANTHEMUMS.

### THE GROWTH OF CHRYSANTHEMUM PLANTS.

THE sole object of the exhibitor is to obtain fine well-developed blooms, and the habit of growth of any particular kind, if its flowers can be produced to win prizes, is of secondary importance, but to the general grower, and especially to the amateur, the height a sort will grow to is a consideration. A. H. Fewkes is a variety of model growth; it is dwarf, that is about a yard in height if cultivated for large blooms, and has plenty of well-shaped and closely-grown foliage. Australian Gold is a capital grower; so, too, is the old variety Avalanche. Col. W. B. Smith, Commandant Blussett, and Dorothy Seward are all of sturdy habit, but the last-named must be topped in the spring if more than one large flower on a plant is desired. G. C. Schwabe, Geo. Seward, Golden Gate, John Neville, Kentish White, Lady E. Saunders, L'Emindra, Louise, Mme. Ad. Chatin, Mme. E. Capitant, Mme. Gustave Henry, and Mlle. Marie Hoste are all first-rate in the matter of growth. So is Mlle. Thérèse Rey, but this has of late years exhibited a tendency to produce bloom-buds that will not swell, a habit which will soon cause it to be discarded, for, however fine the bloom, uncertainty is disappointing. Miss Elsie Teichmann is a sort not unlike the above, and may be grown in place of it. Mr. A. G. Hubback has a capital habit combined with good flowers. Mrs. H. Weeks, too, has growth of the right kind if the plant be topped in spring, as it must be to give more than a single large bloom to a plant. Mrs. J. Lewis is a new white variety that will be prized for its growth as well as its flowers. Mrs. J. Shrimpton, treated as advised in the case of Mrs. H. Weeks, has a most desirable dwarf and well-foliated growth. M. Edouard Andre is a particularly sturdy grower; so, too, is Modesto, one of the best of Chrysanthemums. Mutual Friend produces splendid blossoms on plants about 3 feet high. Nyanza bears fine crimson blooms and has the best of growth. It would be difficult to find habit and flower combined finer than the newer variety Oceana gives, and Phœbus is perfect in every respect. Pride of Madford, Pride of Exmouth and Pride of Swanley are all excellent growers of a dwarf nature. Nor must I forget M. Chenon de Léché, perhaps the dwarfest of all, which produces large blooms. Surprise is a newer kind with nice growth. Souvenir de Petite Anie is well known as a variety with an excellent habit. Viviani Morel and its sport, Charles Davis, are also first-rate. Wm. Tricker and W. H. Lincoln are also of capital growth, but not so highly esteemed as formerly for show. They must, however, still be grown for other purposes, the last-named being one of the very best yellow sorts for a late supply of bloom.

That splendid white Chrysanthemum Mme. Carnot as a plant is not pleasing. It is tall, and few can cultivate it throughout a season without its foliage becoming spotted and yellow. Australia grows to a great height. I have this year cut down the plants of this, and the buds look promising on specimens 4 feet high. Edith Tabor, grandest of yellows, has an ungainly habit; the leaves are far apart and the blooms come in an irregular manner. Eva Knowles, Graphic, Mme. Marius Ricoud, Mlle. A. de Galbert, Miss D. Shea, and Mrs. W. H. Lees are fine kinds that run up too tall to make comely plants. Western King, among newer kinds, has first-rate growth, sturdy and strong. This is likely to become a most popular variety, probably surpassing the fine white Niveum. Mme. E. Roger, a rare novelty, with green-tinted blooms, is a

splendid habited plant, and others of M. Calvat's later sorts, notably one called N.C.S. Jubilee, Mlle. Laurence Zede and Mlle. Lucie Faure, leave little to be desired in respect of growth.

H. S.

### CHRYSANTHEMUM NOTES.

#### TREATMENT WHEN UNDER GLASS.

FAILURES often occur just before flowering through faulty management of the greenhouses in which the Chrysanthemums are placed. If, for example, air be not admitted in abundance, the tops of the plants will run up spindly and soft and the flowers resulting will be wanting in substance. A like growth follows when the buds are a long distance from the glass. It is wise, therefore, to raise the plants to get them up to the light when the flowers are expanding. When first housed, doors and top and front ventilators should be kept wide open night and day. During bright sunshine, when evaporation is so rapid, I find that good results are obtained by damping the floors, and even syringing among the foliage, if the position of the house, such as a lean-to, is particularly hot. This damping is done in preference to giving much water at the roots, at least for a few days. It is well also to withhold manure for a week or so, the object being to keep the plants quiet, as it were, until they have recovered through the changed conditions from the moist and cool open air. Fumigating the houses once or twice is advisable, whether or not green-fly is seen. If this is not done at first this pest is almost sure to come in great numbers later on, when fire-heat must be applied. A safe and effectual method of fumigating is to use the XL All Vaporiser. It does not hurt the most tender leaves and is easily managed. The old practice of employing tobacco, or tobacco rag or paper, is decidedly clumsy compared with this later invention. I think the blooms of Chrysanthemums are the better for a slight shade. This should be put on at the first opening of the florets. Blinds which roll up and down at will are much better than fixed shadings, such as painting the glass, because light apart from bright sunshine is desirable. A temporary shade may be provided for the few blooms that always open before the bulk, so that the latter may have the advantage of full light whilst the buds are yet swelling. Less air may reach the blooms as they open. The florets are easily cramped and spoiled by cold draughts; ventilation at this stage should therefore be guided by the front lights. A little top air should always be allowed, and as the danger from frost and damp becomes apparent, fire-heat may be applied in such quantity as to keep a dry and pleasant atmosphere. For example, I do not like to notice the pots damp or the leaves moist the first thing in the morning. This tells me that not enough heat has been given at night to dry up condensed moisture. This latter is sure to settle on the blooms and cause decay. A temperature much over 50° is not beneficial to the Chrysanthemum. Some of the Japanese kinds—especially when early buds have been retained—require more heat perhaps to open them properly, but this heat is given at the expense of substance and colour. Incurved kinds open much more satisfactorily in a temperature just warm enough to expel damp. Fire-heat tends to make the florets so thin that they reflex instead of turn inwards, thus failing in the more important quality.

Some little may be done in assisting the opening blooms. The curling and curiously arranged florets of many of the Japanese cling together; if parted when opening there is a gain in form. As they are developing, again, the incurving varieties may be assisted. A short or damaged petal can be pulled out, which would otherwise block the way for a perfect one. This, in fact, is the best time to "dress" the blooms, as it is called. Attention in this direction must, however, be constant. I would go over the blooms every day or two. The labour

is necessary and repaid if exhibiting be an object. All decaying foliage should be removed. Yellow bottom leaves do not add to the beauty of plant. Side shoots usually come in all directions after the plants are under glass. These may be removed; they must rob the blossoms if left. Stimulants, which were withheld at first, should be given until the flowers are nearly open. When in good health, roots are seen running over the surface of the soil in the pots. Encourage them by every means. Weak doses of liquid manure and small quantities of fertilisers in the concentrated state will do this, but strong quantities will kill them. Quite recently I have seen a striking instance of this. A lot of exceptionally well-grown Chrysanthemums has been almost ruined by one application of nitrate of soda. It was sprinkled over the surface of the soil during showery weather. The leaves, which were of healthy green, gradually assumed a sickly yellow hue, and the flower buds remained stationary. All the small roots were burnt. The late strength of these plants will enable them to recover slightly, but with far different results the shape of blossoms that would have been secured had all gone well. Nitrate of soda and sulphate of ammonia require most careful handling. They are effective in pushing growth and giving brilliancy of colour to the flowers, but I never either above the strength of an ounce to ten gallons of water. Damping of the blossoms gives trouble to many. Some sorts, notably Mlle. Marie Hoste, Mutual Friend, Col. W. B. Smith and the very dark-coloured varieties are liable to such decay as they open. Very bad cases, I am certain, are caused by the plants being overgrown. The stems, which may look pleasing to the eye, become stout, are often hollow in centre, and the promising buds fail when they have arrived at a certain point. We rarely notice damping when Chrysanthemums are grown of than for huge blooms.

If the precautions noted in this article be followed, a satisfactory finish should be the reward of a year's labour, but gross unripened wood never yet produced handsome blooms. H. S.

## GARDEN FLORA.

### PLATE 1138.

#### THE CROWFOOTS.

(WITH A COLOURED PLATE OF *RANUNCULUS CARPATICUS*.)

THE Ranunculus, or Crowfoot, family is an important one in the hardy plant garden. Large and extensive as the genus undoubtedly is, the number of really good species that are worthy of being included in a selection is comparatively few. These, happily, are in many instances not only of easy culture, but may be beautiful when seen in good condition on the richer soils of our lowland gardens, whatever the altitude at which many of the choicest of the alpine forms grow—those that struggle for existence on the very verge of perpetual snows, scarcely any that I can call to mind have been in any way difficult to grow either in pots or in the rock garden where suitable positions and soil can be afforded them. I will refer to their culture in the enumeration of the species themselves. In place of the usual alphabetical arrangement of the kinds I have roughly grouped them as follows: (1) alpine forms, (2) herbaceous, (3) moisture-loving, and (4) florists' kinds. For the first of these the first group here given is not only numerous, but a very beautiful one, many of them worthy of every care as being among the most lovely of mountain plants, and forming

\* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Goffart.

RANUNCULUS ACRIS

their native haunts a veritable carpet of glistening white and yellow cups, so abundantly do their flowers appear. If less numerous, the second group yet contains several really good and first-class kinds; while the third, also small numerically, yet contains sufficient good kinds to render the moister spots of our gardens, as also the margin of lake and pond alike interesting. The last group, though not so much grown as formerly, is well worth attention from the great variety therein contained.

#### ALPINE SPECIES.

I have arranged under this head in alphabetical order the best of the true alpine species, a large number of which, by their dwarf stature as well as freedom of flowering, are especially fitted for the rock garden. It is, however, worthy of remark that, notwithstanding so large a number of the true alpine species are in their native mountain homes very dwarf, given liberal culture and deeper soils, not a few kinds grow to a much larger size and produce larger blossoms in many instances. This is, however, only achieved when planted out. I have grown many of the true alpine species in rich soils similar to those used for *Chrysanthemums*, and with only sufficient grit to keep the whole open. If freely grouped in good deep soil, light, gritty, and rich for the most part, it is surprising what beautiful results can be obtained. Many of the kinds are essentially adapted for grouping in this way, and being easily divided in some cases, and in others easily raised from seeds, advantage should be taken of this fact.

*RANUNCULUS ALPESTRIS*.—Is a true alpine of from 4 inches to 6 inches high. In its native mountain home this species is usually found in a calcareous soil, though this is not an absolute necessity under cultivation. Indeed, many of these dwarf alpine forms may be grown and flowered well in cocoanut fibre rather tightly placed in boxes or pots, a fact alone that at once removes the notion that for years prevailed, that the soils of their native mountain regions should be closely imitated. Now, however, the notion is fairly well exploded, and scores of the choicest alpinists may be grown with as much success in a border of well-prepared soil as in the most elaborate combination. The pure white flowers of this species are large, and with a conspicuous cluster of yellow stamens in the centre. Usually the flowers are produced singly. With a fair amount of moisture in the season of growth, and planted in loam, peat, and leaf-soil with grit, this species is a success. The rock garden is the best place for it, where it flowers in the early part of June. It is a native of the Pyrenees and other parts.

*R. AMPLEXICAULIS*.—This may be regarded as one of the best of the whole genus, and happily one of the easiest to cultivate. In soil that is deep and rich the plant will attain to nearly a foot high. A prevailing idea with many is that for mountain plants the merest scrap of earth is sufficient, the cultivator too frequently ignoring the fact that these alpine gems often send their root fibres to great depths in rocky crevices where drought is quite unknown. Planted in the drier parts of the rock garden, the plant is never seen at its best. The pure white glistening blossoms, each an inch or more across, are borne on the branching stems, and these in company with the greyish tint of the leaves are very pleasing. Moisture, or a good depth of soil, must be assured for this plant, which is freely distributed through the Alps of Europe, Provence, the Pennines, Ireland, the mountains of Leon, Spain, always in high, moist, rocky situations.

*R. ANEMONOIDES*.—Another true alpine, frequently not more than 3 inches high, though occasionally when well grown it may be seen double this height. This species is of more delicate and frail growth than many, and for this reason deserves to be treated somewhat specially.

Once established, it is one of the most charming of all alpinists. What it appears to love best is a deep fissure of gritty loam, leaf soil, and peat. Species such as this are assisted by being placed in contact with pieces of sandstone just below the surface. An exquisite mixture is the lovely white and rose-pink blossoms, and when a nice tuft has been formed it constitutes one of the choicest bits of any rock garden flora.

*R. CARPATICUS*.—This is the beautiful and showy species to which prominence is given to-day in the accompanying coloured plate. This mountain Buttercup is a free-growing kind with large blossoms  $1\frac{1}{2}$  inches across that are borne singly on rather leafy stems about 12 inches or 15 inches high. The species is, I believe, by no means common or even frequent in cultivation, though it is likely to prove a most desirable kind and a free and easy grower withal. In the nearly pedate and deeply notched radical leaves it is quite distinct, as it is again in the short rhizomatous or creeping rootstock. The plant succeeds perfectly well in a rather rich and moist loamy soil, and begins to flower quite early in April.

*R. CRENATUS*.—A very pretty and charming kind with pure white blossoms not unlike those of *R. alpestris*, but differing from that species in the crenate petals and also the scape, which is always one-flowered. It is a native of moist positions in the mountains of Hungary, flowering from June to the end of July, and grows about 6 inches high.

*R. GLACIALIS*.—This is about 4 inches high, having fleshy, dark green leaves, the upper ones covered with soft hairs, while the calyx is exceedingly hairy. The flowers are of a reddish hue and suffused with purple. This species does best in the higher parts of the rock garden in loamy soil, but rejoices in plenty of moisture during summer; but while inhabiting the highest mountain ranges it is quite possible that under cultivation in the lowlands quite moist spots would suit it best.

*R. GRAMINEUS*.—Though scarcely an alpine in the truest sense, this species is included here by reason of its dwarf habit. It is usually 1 foot high, the stems surmounted by two or three bright yellow blossoms. This species is better suited for the woodland or grassy spots, where it may be naturalised. It is sometimes found in Wales, though always in dry pastures, and occurs frequently in the mountain pastures of Southern Europe.

*R. MILLEFOLIATUS*.—A distinct and pretty kind with blossoms of a clear yellow. It is about 1 foot high, with erect, hairy, almost leafless stems and solitary blossoms. In some respects it is not unlike *R. chærophyllus*, though quite distinct in its roots and other essential details. This is not a true alpine, but is placed in this group by reason of its stature. The treatment recommended for such as *R. amplexicaulis* will in all probability make it even more vigorous than here given. If planted in the rock garden, the soil should be deep and fairly good.

*R. MONTANUS*.—This is easily grown in sandy loam and in spots somewhat shaded and cool. It is about 6 inches high, with bright yellow blossoms, each three-quarters of an inch across. The solitary blossoms are produced on somewhat downy stems, but near the ground this pubescent character is wanting. This species may be freely increased by division.

*R. PARNASSIIFOLIUS*.—The specific name of this kind alone shows features quite distinct that will prevent its being confounded with any other. The thick, entire, rather heart-shaped leaves are very distinct. The plant inhabits high elevations in the Alps and Pyrenees, and is usually found in granitic or calcareous soils in the fissures of rocks contiguous to perpetual snow. The flowers are snow-white and about the size of those of *R. amplexicaulis*, and produced several on a stem 6 inches high. This species may be successfully grown in quite moist loamy soil in much the same way as recommended for *R. anemonoides*.

*R. PYRENEUS*.—Another equally distinct kind growing about 1 foot high. *R. plantagineus*, from the Piedmontese Alps, and *R. bujaleurifolius*, usually found in moist valleys at a much lower

level, are varieties of this species. All have white flowers that appear in May and continue to July.

*R. PEDATUS*.—A yellow-flowered species nearly a foot high and rather abundantly distributed in parts of Hungary, Tartary, and about the river Volga, in Siberia. The leaves are smooth, the radical ones stalked, flower-stem erect, with from three to five flowers.

*R. RUTEFOLIUS*.—Another species from the higher Alps with unmistakable foliage characteristics. In common with other species from these high elevations, this one is only 4 inches or 6 inches high. In the plants I have seen the blossoms are white, but I notice they are described as yellow in the "Dictionary of Gardening." In "Alpine Flowers" they are also described as pretty white flowers with orange centres, which quite agrees with the plants I have grown from time to time.

*R. SCUTATUS*.—A distinct species, with large yellow flowers and very smooth kidney-shaped, crenate leaves. It is a native of the mountain woods of Hungary, and grows, when established, nearly a foot high. This latter is perhaps rare and only obtained by the best culture.

*R. SEGUERI*.—This distinct species grows about 6 inches high, having three-parted leaves and is more nearly allied to glacialis and alpestris, though very distinct from either. The flower-stem is erect and the flowers usually solitary. The blossoms are pure white, with distinctly rounded petals.

*R. THORA*.—A yellow-flowered species, closely related to *R. scutatus*, but differing in its always long-stalked and very smooth radical leaves. Both kinds require plenty of root-room to allow of full development, and with deep and good soil give little trouble once well planted. The more vigorous character of this kind renders a deep soil rather more needful.

The above selection will be found to contain most of those worthy of cultivation, while such as *cortusifolius*, *isopyrioides*, *bilobus*, *Trausfelleri* and *uniflorus* are others worthy of note in this extensive genus. Many of these dwarf alpine kinds are very pretty when grown in pans of rich soil by those who do not possess a rock garden, and in this way a large number of the choicest gems may be fully enjoyed. Thus grown, too, the protection of a cold house or frame at flowering time may be given, and in those gardens where many of the best kinds already exist seedlings should be raised. Some readers of *THE GARDEN*, too, may have opportunities of receiving collected plants or seeds from friends abroad, in which case seeds may be sown at once in fine sandy loam, and just covered with the same, placing a sheet of glass over all. Collected plants are often a source of much trouble and loss, and after many attempts—varying considerably in degree so far as success is concerned—I know of no better method than that of planting the roots in cocoanut fibre instead of soil. Give one good watering and place in a sheltered place in the open. Once the new roots push forth, there is some hope of success, and the plants are quite safe in this material till the following spring. Shallow pans or boxes are the best for this purpose, and not only for these, but for a large number of choice alpinists that suffer considerably in transit.

#### BORDER SPECIES OR VARIETIES.

*RANUNCULUS ACONITIFOLIUS*.—While I have placed this plant among the border sorts, it may be well to state that it is equally at home in quite wet or boggy spots, and in such yields a great mass of its dainty white flowers. The plant is well known, and grows quite 2 feet high when given moisture. A better known form is the double white kind called the Fair Maids of France (*R. aconitifolius* fl. pl.). Though not in any way difficult to grow, it certainly prefers, like the type, a quite moist position, or, failing this, good and deep soil.

**R. ACRIIS FL.-FL.** (Bachelor's Buttons).—This, though pleasing in colour and free flowering, does not possess the charming grace of the last-named.

**R. MONSPELIENSIS.**—Though a fairly good and distinct border kind, this is not common. A native of the Mediterranean region, it is apt to start into early growth, only to be cut down by spring frosts when these are severe, for which reason a northern or western position may retard its growth. It bears yellow blossoms on erect stems nearly 2 feet high in April and May.

**R. SPECIOSUS.**—This is a first-class border perennial of dwarf habit, and by no means so common as its merits justify. Individually, the blossoms are nearly the size of those of the Marsh Marigold. The plant delights in a deep and moist as well as rich soil, and gives freely of its handsome double flowers. Little more than 1 foot high and of tufted or semi-procumbent habit, the plant is well suited for grouping in or near the front of the border, or the drier margins of the bog garden, or even the lake.

#### MOISTURE-LOVING KINDS.

Though by no means a numerous class, these strictly moisture-loving kinds are not only a very beautiful class, but are also decidedly ornamental when given suitable positions.

**RANUNCULUS AQUATILIS** is abundant in many parts of Britain, particularly in ponds or wet and marshy ground. The plant flowers for many weeks in profusion, and, growing and spreading rapidly, should be kept within desired limits.

**R. LINGUA** is likewise a British kind, and, while not so abundant as the last, is much more valuable. Indeed, it is not too much to say it is among the handsomest of waterside plants. In water a foot deep or less it revels. Attaining 2 feet or sometimes nearly 3 feet high, it is easy to understand what may be accomplished with such a plant yielding so great a profusion of golden blossoms, each about 2 inches across. Many buds also appear in company with the erect golden cups, so that a brave show results when a group of several feet across exists. It may be readily obtained and increased, and once planted gives little trouble after.

**R. LYALLI** (Rockwood Lily) is one of the noblest of this race. Happily, too, in several districts the plants have survived the winter unharmed, a circumstance in some degree due to the quality as well as the temperature of the water in which it is grown. The large waxy-white blossoms, each often 4 inches across, and the cluster of yellow stamens render it a most conspicuous object. The handsome broad and leathery foliage, too, is produced on stout petioles, the branching stems reaching sometimes 3 feet or 4 feet high. It requires more care than the usual run of water-loving species, as so far success is not always ensured even when seeds are forthcoming. No plant is worth greater care, however, to make it a success.

#### FLORISTS' VARIETIES.

**RANUNCULUS ASIATICUS** has given rise to the various sections of garden Ranunculi, so much esteemed by the old florists. It is only in the more favoured parts of these islands that the roots or claws, as they are termed, can with safety be left in the soil all the year round. Where the soil is well drained, light and warm, this may be done; in all others it is necessary to lift them each year in the month of July and give a thorough drying before planting again in October or November. In heavy soils it may be best to defer planting till February or even March, the ground having been roughly prepared during the previous autumn. A perfectly drained as well as light soil is important, the same being deeply worked and well enriched with manure. On soils that are very hot and sandy, cow manure six months old will be best, by reason of its cool, moisture-holding propensity. The addition of soot and lime in winter and a dressing of bone-meal broadcast in the drills at planting will be of great value.

Where grown in quantity, shallows drills will be found the best, pressing the claws into position, making the soil above fairly firm. The French kinds are the strongest growers and very free-flowering. The Persian kinds are somewhat dwarfer and with smaller flowers, though containing many fine varieties, while the Turban forms include some of the most highly coloured of this race. The position best suited to these is a somewhat shady and sheltered one. The whole of this tribe possesses the additional advantage of being remarkably cheap, so that a large number may be planted at small cost. E. J.

## THE WEEK'S WORK.

### HARDY FRUIT GARDEN.

**ROOT-PRUNING.**—This operation is best undertaken at the same season as that of root-lifting, and the earlier it is performed within reason the better, as the wounds on the roots then heal over before winter sets in. Root-pruning is, however, a drastic remedy, and should be resorted to only in extreme cases and where the more rational method of root-lifting is found to be impracticable. Generally speaking, root-pruning would become unnecessary if gross-habited trees were to receive the needful check at the roots to induce fruitfulness while in a young state. The neglect of this, coupled with the annual close pruning practised in gardens, tends to keep such trees unfruitful, and the only way out of the difficulty in the end is to root-prune them. The operation of root-pruning differs from root-lifting, inasmuch as when opening out the trench all the larger roots found are severed, but although this is so, I always advise that roots from the size of a lead pencil downwards should be saved and laid out again when refilling the trench. The trench itself should be taken out 2 feet in width, and the distance from the tree will vary according to its size and age; but, as a rule, 6 feet is quite near enough, and in some cases it may be necessary to go quite 9 feet away from the stem. The trench should also be taken out deep enough to find all the roots, and the larger of these should be severed, and the smaller roots, as indicated above, saved and fastened back with pegs out of the way until the excavating is completed. All the mutilated portions of the roots should then be trimmed with a sharp knife, after which the trench can be filled in again. In some cases a little fresh soil may with advantage be placed about the more fibrous of the roots as the filling-in proceeds, as these are the kind of roots the trees should be encouraged to make and multiply. Root-pruning is best spread over two or three seasons, doing one side of the tree now and the other in two years' time, otherwise the trees would receive too great a check, if it did not cause actual death. Wall trees may be operated on in the same manner, and in their case a modicum of fresh soil should always be placed in the trench near the top when filling in again to encourage the roots to feed upwards.

**ASSISTING OLD TREES.**—It often happens that old and favourite trees get into a weak, debilitated state and cease to bear either altogether or only very inferior fruit. When such is the case and it is desirable to keep such trees, they may often, with a little care and attention, be brought back to a healthy condition if some new compost is placed about the roots. The surface soil should therefore be removed until plenty of roots is found, and then replace it with a compost of loam, burnt soil, wood-ashes, with a fair proportion of thoroughly rotted farmyard manure added, or plenty of bone-meal may be used instead. This compost should be trodden firmly and evenly over the roots, mulching afterwards with litter. If the soil about the roots is found to be dry, give a good soaking of water before applying the compost. The new soil will stimulate and incite the roots to renewed action, and growth, though weak the first year, will be stronger the

next, and by the third season a wonderful improvement will be perceptible, with the ultimate result that the trees will eventually become re-established in health. The same method may be pursued with regard to orchard trees, and grass orchards the turf on the surface may be chopped up and utilised for mixing with the top soil, as the surface can soon be made green again by raking it down and sowing some grass seed thereon. Old, but valuable trees can also be kept in good health for many years simply by repeated applications of liquid manure, which should be poured on the surface under each tree and as far as their branches spread. This is best applied during the autumn and winter months as liquid can be the better spared then, while also prevents waste taking place, as is generally the case when cesspools and pits get filled during the autumn and winter months.

**PLANTING.**—Where a reserve stock of Gooseberries, Currants, and Raspberries is grown at home and it has become necessary to make new plantations of either or all of them, the work may be undertaken at once, as both bushes and stock may be moved and transplanted without the slightest fear as to the result if carried out with all due despatch. It may be necessary in some localities to water the soil home about the roots before finally filling in the holes when planting, but after the rainfall of the latter part of August this will be the exception rather than the rule. Do not omit placing a little good compost of some description about the roots of the bushes if the staple is poor, if only gaps are being made in existing plantations. When forming new plantations plenty of manure should be trench in when preparing the site, and too much emphasis cannot be laid on this point when preparing a plot for Raspberries, as not only are they good feeders, but they generally occupy the same site for a good many years, hence the necessity of paying extra attention to this matter. The ground for these should be bastard-trench worked in old rubbish-heap material in the bottom spit if sufficient manure cannot be spared for both layers of soil, breaking up the hard bottom and leaving it there. Home-grown Apples, Pears, Plums, Peaches, Nectarines and Apricots may also be lifted and transplanted during the month, provided they are kept out of the ground as short a time as possible. All of these should be well watered home when the holes have been partly filled in with soil. Leave them an hour or two to drain before finishing off, and then mulch the surface with litter, as this will both conserve warmth and keep out cold and frost. Walls should be tacked or tied back to the walls rather loosely, and both these and other transplant trees should be syringed once a day. On very bright days a mat hung on the walls, or suspended on two stakes in front of trees out in the open, will prevent the foliage flagging to a great extent. When the trees have to be purchased, planting will of course be out of the question for some time to come, but holes and compost for placing about the roots can both be dug and prepared. When convenient to do so, a visit should also be paid a nursery where the growing of fruit trees is made a speciality, and then the purchaser can select the trees on the spot.

**DISTANCES FOR PLANTING.**—For the information of intending amateur planters the few following rules with regard to distances at which to plant the various kinds of fruit trees may be useful. Bush Apples, Pears, Plums, and Morello Cherries may be planted 6 feet apart and 3 feet from the edge of the walk. The first three mentioned may require to be lifted the second year after planting, but after this if due regard be paid to close pinching, this and the fact of their bearing fruit will keep them within bounds. This advice is given under the assumption that space is restricted, and that there is a desire to plant as many trees as can conveniently be accommodated. Where more space can be allowed, the trees may stand 8 feet apart, and this distance will also suit bushes of sweet and Kentish Cherries. If pyramid trees of the above-mentioned fruits are wished for, the

low a distance of from 8 feet to 10 feet between them, varying the same according to the height they are to be allowed to attain. Peaches, Nectarines, Apricots, Plums, and Morello Cherries are walls should be planted from 14 feet to 16 feet apart, and on high walls a standard trained tree could also be planted midway between each two of the latter to furnish the upper portions. Pears, Plums, and Cherries as cordons may stand from 18 inches to 2 feet apart: fan-trained Pears on the Quince 12 feet apart, on the Pear stock 18 feet, allowing 2 feet more for diagonal trained trees. Sweet Cherries as fan-trained trees may stand 14 feet apart, but allow 4 feet more for diagonals. Spaliers for the sides of walks may be planted from 15 feet to 20 feet apart, and low cordons for the same position 6 feet if single trained, if double with two stems 12 feet apart. Upright cordoned Plums or Pears may be planted between every two trees of either Peaches, Nectarines, Apricots, Plums, Cherries or Pears, to remain as a manucy. Bush Apples should be on the paradise stock and Pears on the Quince, as far as practicable for small gardens on account of their occupying less room. Gooseberries and Currants may be planted 4 feet apart and 6 feet between the rows.

A. W.

### KITCHEN GARDEN.

**MUSHROOMS.**—It is found in many gardens that these can be more freely produced and of better quality during the summer and autumn months on outside beds than from the Mushroom house proper. Under the most skilful treatment the beds will not always do well, the house being often ill-adapted for producing them at the season named. A dry atmosphere, together with too high a temperature, is more often the cause of failure than the spawn or the way in which the fermenting material has been prepared and the beds made up. Where any difficulty was found last winter in maintaining a continuous supply, it could be well to study what disadvantages the grower laboured under with a view to rectify such matters before the winter beds are made up. It is a common occurrence to find that the Mushroom house is in close proximity to that in which the boilers are fixed, and, further, that several of the hot-water mains are brought through this under the pathway and merely covered with flagstones. The heat arising from this would be greatly in excess of what is required for the well-being of the crop, while it is almost impossible to maintain any humidity in the atmosphere; and, further, if evaporating pans are used to supply steam, the steam condenses, causing the "buttons" to damp off before they attain a serviceable size. The evil of this kind is best overcome by placing 6 inches of gravel over the pathway, which will not only prevent the heat rising, but will assist to conserve moisture in the house. Failing suitable gravel, fine ashes or even ordinary soil could be used, covering this with a plank to walk upon. The end wall abutting on the boiler house should also be treated in a way to prevent heat passing through. The best plan would be to build up the boiler wall  $4\frac{1}{2}$  inches thick, but several inches on the permanent one. A pipe should be carried through the highest point in the roof immediately over the hollow space to allow the heat to pass off. Treated in this way a house which has previously proved unsuited for Mushroom culture may be found all that could be desired. I have seen many houses in which, though Mushrooms have been produced plentifully up to a certain age, they damp off wholesale before they become ready for use. This shows that there is not sufficient ventilation, and it is not a good sign to see the wall running with moisture when the door is opened in the morning. A few holes, if only an inch in diameter, made at the top of the door would allow much of the steam to pass off without creating a cold current of air, while, should it be deemed necessary, further means should be afforded for ventilation from the roof, always placing perforated zinc over the apertures. Such details as these if carried out may save much disappointment.

**PREPARING THE MATERIAL.**—It is always better to have several cartloads of suitable droppings in hand at one time than to try and prepare them in dribbles, though this has often to be done during wet weather. By having a good body of manure it is more easily brought into a suitable condition both as regards heat and moisture for forming the beds. Where a shed is not available to prepare a large quantity the manure should be carted to a sheltered position, such as against a wall, where it can be turned over as required and protected with shutters or thatched hurdles during rain. I strongly recommend mixing a good portion of leaves with the manure, as this not only increases the bulk, but the heat produced is less violent and more lasting, while by the addition of say one cartload of rich fine loam to six of manure the beds can be made much firmer and it encourages the spawn to spread, the Mushrooms being more fleshy and of better flavour than those produced in manure alone.

**WINTER TOMATOES.**—The warm weather of late, with an absence of frost at night, has proved favourable for plants under glass, as, being able to admit plenty of air, the growth made has been sturdy, while flowers have been produced freely and a good set of fruit obtained. Under these favourable conditions the plants, too, have kept free of disease. It is surprising what a small quantity of soil is required to establish really strong plants, so long as they receive careful attention in the way of watering. The most of our winter fruiterers are in 9-inch pots. The plants are about a yard high, with eight to ten trusses of fruit set on each, and yet the pots are barely half filled with soil. Had they received more root-run, no doubt the plants would have been much taller, but I doubt if they would have set a corresponding amount of fruit. Top-dressing will now have to be resorted to, as the strain of fruiting will prevent undue foliage being made. Not more than an inch of material will be afforded at one dressing, and this will be made quite firm to further induce the formation of short-jointed growth. The compost will consist of fresh turfy loam, to which will be added a sprinkling of bone-meal. I prefer the latter in the meal state, as it is more quickly assimilated by the roots than when used in a coarser condition. The plants should have plenty of room and be arranged near the roof, so that they will receive all the light possible when the short days come. It is best to devote a house to these plants, so that they can receive suitable treatment. Where other plants of a tender nature are grown with them, the treatment afforded seldom suits both, and more than probably the humid atmosphere maintained for the latter will soon weaken the constitution of the Tomatoes and disease will quickly appear. Even when wet or frosty weather overtakes us, a certain amount of ventilation will be necessary, together with a gentle warmth in the pipes to prevent a sluggish atmosphere in the house, and as a further means of warding off fungoid disease the pipes should be frequently painted over with sulphur mixed to the consistency of paint with the aid of milk. Strong doses of manure should be withheld, as the plants if grown in good loam will swell the fruit off quite large enough for winter supplies. Soot water is beneficial to the plants, but during sunless weather it is apt to give the fruit a bitter taste. If the plants are well cared for, they should continue to produce flower-trusses most of the winter, and though, of course, they will not be numerous, they will provide some late dishes towards spring before the summer-fruiterers turn in. It will be necessary, however, to assist the fruit to set by going over the bloom with a soft brush or rabbit's tail, at the same time exposing the flowers by removing or tying back the foliage immediately over them.

**SUCCESSION PLANTS.**—As it is always desirable to turn out winter-fruiterers the following spring directly they cease to yield, a good batch of strong plants should be ready to succeed them. These are best obtained by sowing in the autumn,

and if not already done a pinch of seed should be put in at once. As a rule, the seed germinates very freely. A great mistake is made in sowing too thickly, causing the seedlings to become drawn before they are barely ready for pricking off into pans or boxes. This should be particularly guarded against at the present sowing, or the plants may remain in a weak state all the winter. Keep them near the glass, and better allow two dozen plants plenty of room than endeavour to raise a larger quantity in a crowded state.

**OUTDOOR TOMATOES.**—It is seldom these do well after October comes in, as the cold nights and heavy dews cause the fruit to crack when the sun reaches them the following day. Where the plants are growing against a fence or wall and are still laden with fruit approaching maturity, a few odd lights placed over them will assist their ripening, or the fruit may be cut and placed in a warm, dry position.

RICHARD PARKER.

### NOTES FROM GUNTON.

ANY gardener happening to be in Norfolk would find Gunton well worth a visit just now. The hot, dry summer has of course left its mark, but the crops generally, both of fruit and vegetables, are looking well. In common with most gardens, Apples are the scarcest crop that has been known for many years, but Pears are plentiful and promise to swell to a good size. Almost every gardener has heard of the Gunton Pears, and while such second-rate flavoured sorts as Marie Louise d'Uccle, Beurré Clairgean, and Beurré Diel are found room for, the smaller sized, first-rate quality varieties receive every attention. Marie Louise, Thompson's, and Glou Moreceau all do well at Gunton, and the new President Barabe is bearing a heavy crop of medium-sized, russet-looking fruit. This Pear is sure to make a mark, as few late varieties possess such excellent flavour. Mr. Allan is working it on to old trees of inferior varieties. His enthusiasm in Strawberry culture is as great as ever, his latest achievement in the way of new varieties being Lady Sulfield, of which "D. T. F." recently wrote in terms of high praise. Latest of All is thought well of by Mr. Allan, but Monarch he regards as a coarse, rather washy variety. Gunton has long been noted for its good Grapes, and the crops this year are no exception to the rule. Muscat Hamburg has large bunches without a single shanked berry, and the Duke of Buccleuch worked on Alnwick Seedling has given such satisfaction, that Mr. Allan is extending it yearly, intending to fill the whole house with it. The bunches are of good size and the berries beautifully clear, with an entire absence of the spot which so often mars this otherwise fine white Grape. One thing that particularly struck me in these vineries was the fine lot of Lady Downe's on Vines trained up the back walls. The finest lot was in the Muscat house, the temperature of which Mr. Allan considers it requires. Not a damaged berry was to be seen, which can seldom be said when the Vines are trained in the ordinary way beneath the roof glass. In the early Peach house is a magnificent tree of Dymond, which is in great favour at Gunton, as it possesses every good qualification, the fruit, which sets very freely, being extra large, beautifully coloured, and most deliciously flavoured. In the same house is a fine young tree of Early Rivers Nectarine. Mr. Allan is delighted with this variety, as in his opinion it supersedes all others of the early section. I was much interested in a new Tomato growing in several houses side by side with Frogmore Prolific and Flam Green. The two latter were much affected by disease, while the new variety, named Powley's Up to Date, and raised by a market gardener near Norwich, is quite free from it. The fruit is of medium size, very symmetrical, and is produced in great numbers. It will no doubt make a fine market variety. Amongst the numerous sorts of Figs grown under glass, that deliciously flavoured, deep coloured fleshed variety Bourjassote Gris is re-

presented by a fine healthy bush now loaded with fruit. This Fig is not so well known as it should be. As seen at Gunton the tree is a strong, short-jointed grower, and where variety is wished for in early forced Figs, it should be associated with Brown Turkey and St. John's, as it does capitally in pots. As a rule, late Peas are in strong force at Gunton, an autumn supply being important. This year, however, mildew is very troublesome amongst late rows, Autoerat withstanding it better than any other variety. This is accounted for by its exceptionally robust growth, which stands it in good stead in times of drought. A good dry weather vegetable proving itself very useful just now is the New Zealand Spinach. If kept well picked down it continues to yield large quantities of its fine succulent leaves over a very long period without running to seed. Amongst Beet, Veitch's Selected Red finds most favour, being just the Beet for a gentleman's table. The roots under ordinary cultivation are of medium size, the colour a delicate red, with an entire absence of woolly rings so prominent in many of the much advertised varieties, while the flavour is excellent. The Chrysanthemums grown for large blooms are looking well this season, the wood being stout without grossness and apparently well ripened. The Belladonna Lily does wonderfully well at Gunton, growing in a narrow border of loamy compost close to the wall of a plant stove, the hot-water pipes running along close inside the wall. In a length of 9 feet of border I counted thirty-eight fine flower-stems, each bearing several extra large flowers. Evidently it requires a well-drained, warm root-run similar to the one described, as for years it failed at Gunton in an ordinary sunny border.

J. C.

## TREES AND SHRUBS.

### OLD HAWTHORN AT ST. COLUMBA'S COLLEGE.

A SHORT distance from Dublin, on the slopes of Kilmashogue Mountain, lies St. Columba's College, an ideal spot for a boy's school, and commanding superb views over Dublin Bay. In the grounds are many fine old trees, especially Beeches and Hollies; of the latter, many were evidently growing there long before the hand of man had touched the place. Amongst other ancient denizens is the Hawthorn shown in the annexed illustration, which in May last, when the photograph was taken, was a charming sight with its gnarled trunk and mass of snow-white blossoms. The Hawthorn—we do not call it "May" in Ireland—flourishes in abundance about Dublin, and many fine old specimens are to be seen in the Phoenix Park and elsewhere.

GREENWOOD PIM.

**Clerodendron foetidum.**—This *Clerodendron* is, from a flowering point of view, widely removed from the Japanese *C. triehotomum*, for the blossoms of this last are white, and protrude from large red calyces after the manner of the indoor kinds, while they are disposed in an open panicle. Those of *C. foetidum*, on the other hand, are packed closely together in a terminal head after the manner of an *Ixora*, but the blossoms are much more crowded. *C. foetidum*—of which I have lately seen some good examples—is one of Fortune's introductions from Northern China. In the milder districts of the country it is quite hardy, but elsewhere a certain amount of pro-

tection is necessary during severe winters. Unlike the commonly cultivated members of the genus, the stems of this species are only of annual duration, but of a stout, sturdy nature, and will reach a height of 4 feet to 5 feet. The large heart-shaped leaves are decidedly ornamental, while the flowers are of a bright rosy red tint, and deeper coloured in the bud state than they are after expansion. When the conditions are favourable to its well-doing this *Clerodendron* will quickly spread underground. It is also known by the specific name of *Bungei*, that of *foetidum* being derived from the fact that it gives off a very unpleasant smell if bruised in any way. At the close of a hot summer it, as a rule, flowers with greater freedom than at any other period. The Japanese *C. triehotomum* is also now in full flower, and is decidedly ornamental and quite distinct from anything else in flower, or in fact from any other hardy shrub, irrespective of the flowering season. This is a free-growing species, quite hardy, and can be readily increased

Abbotsbury, Dorsetshire, and remarks upon the amount of iron in the soil. Yet of the many *Hydrangeas* grown there, only, I think, in two cases have the plants blue flowers. These blue-flowered plants are growing in the shade, but blooms from cuttings from them have reverted to the pink shade. This fact would seem to point to shade being the prime factor in producing the blue colour, but I know of many cases where plants growing in shade bear pink or flesh-coloured flowers, and the brightest blue *Hydrangea* bloom that I ever saw were borne by plants growing in the full sun on the edge of a cliff overlooking Start Bay, where there was no particle of shade. Many of these blossoms were of almost a Forge-me-not blue. S. W. F.

### HARDY HEATHS.

I WAS pleased to see the note in *THE GARDEN* on page 191 respecting the *Erica vulgaris* HAR

An old Hawthorn at St. Columba's College, Dublin. From a photograph by Mr. Greenwood Pim.

to almost any extent from cuttings of the roots.—T.

**Colour in *Hydrangea hortensis*.**—The blue shade so often seen on the massive flower-heads that cover the great *Hydrangea* bushes in the south-west is, when it is clear in tone, very beautiful. On many plants the blossoms are of one uniform light blue tint, on others a portion may be blue and the remainder pink, while some blossoms exhibit a not very pleasing shade, in which both colours are mingled. At present the reason of this blue colouring seems but indefinitely understood. By some it is attributed to the presence of iron in the soil, by others to the plants being grown in the shade. It is true that many plants growing in soil heavily impregnated with iron bear blue flowers, but, on the other hand, many plants in the same soil have pink blossoms. In Canon Ellacombe's paper on "The Great Drought of 1896," a reprint of which appeared on page 204, he makes mention of the gardens at

mondi. It is one of the best white Heaths, and to see it at its best it should be planted in masses. One reason why we do not see more of these beautiful hardy plants is due to the treatment they receive at the hands of the planter. Another reason is that the best are often overlooked or left out through not knowing what to plant for effect. Where the *Rhododendron* and *Azalea* grow well there need be no difficulty in growing varieties of the hardy Heath. I would advise all who are so situated and real lovers of hardy flowers to add these to their list, for there is nothing more effective and beautiful than a bed of Heaths in bloom. I am well acquainted with them, and send you a list of eighteen of the best for massing and making a good show. There should be no less than fifty or more plants of each sort. The varieties of *E. cinerea* should be put 9 inches from plant to plant, and the *vulgaris* sort

inches apart. I also add time of blooming.

" " <i>Hammondi</i>	Aug. and Sept.
" <i>tenuis</i> (scarlet)	" "
" <i>Alporti</i> (crimson)	" "
" <i>aurea</i> , golden foliage, for winter and summer effect.	" "
" <i>cuprea</i> , similar to <i>aurea</i> , but more upright and quite distinct.	" "

*E. Alporti* and *E. Hammondi* would look well together, their growth being equal, also time of blooming. *E. rigida* and *tenuis* would also look well mixed, their growth and time of blooming being the same. By making a careful selection it is possible to have *Ericas* in bloom for quite six months. To show the reasons for the best advantage I select a gentle slope. There is no need to be particular as to the aspect so long as it is fully exposed to the sun. What hardy Heaths require is a suitable soil for the roots and free from shade. If the soil is likely to become too dry, a mulch of spent Hops or rotten manure would help them, and the ground should be trenched 12 inches deep, some leaf-mould or rotten manure being worked into it, and all made firm before planting. When once they are established they will last for years. If they become too large or straggling, cut them off close to the ground at the latter end of May or beginning of June. Give them a mulch of rotten manure, and they will soon grow and become vigorous again. *E. cinerea* requires to be divided every three or four years, as the plants become straggling. Add to the soil some leaf-mould or rotten manure, also mulch them with the same after planting. The best time to move Heaths is in September or the first week in October.

Two Dales, Matlock. C. REEVES.

STOVE AND GREENHOUSE.

ANTHURIUMS.

These bright and effective plants are deservedly popular, both the fine-foliaged species as *A. crystallinum*, and those with showy spathes as *Andreamm* finding plenty of admirers. The many hybrid forms, too, raised from the latter and other species are a good deal grown, but it must be admitted that there are many of these that are sent out with fancy names that are not worth the trouble of growing. Dull, slaty-looking purples and washed-out tints of pink and rose are certainly not an improvement on the old form, but the highly-tinted large spathed hybrids should be grown by all who have room for them. It is a fact worth noting in connection with these, that they will, if planted out or well watered so that the roots have a fair run, do very well with a good deal less heat than when grown in pots. Their additional strength has apparently the effect of making them more hardy, and only a few weeks since I saw in a very moderately heated conservatory a large number of healthy specimens growing on the walls. The leaves were broad, of that deep shining green that betokens robust health, and the spathes were very

large. Wherever a place suitable for these plants exists they should be planted. On rockwork it is very important that water easily drain away from the base of the plants, for though they all like a liberal supply of moisture, it is detrimental when lying stagnant about the roots. They should be planted in rough peat, broken up into lumps as large as a hen's egg, half the quantity of Sphagnum Moss and plenty of rough pottery ballast, charcoal or similar material. Their position in the house has a good deal to do with their successful treatment. In shady corners they are not satisfactory, nor will they stand the full glare of the sun; but if, by the interposition of climbers on the roof or the leaves of large plants a nice broken light is produced, they will be well suited in this respect. In such structures there is usually a nice genial temperature kept up, and the slight rise and fall in summer and winter are easily arranged. Anyone planting them and giving a little care is sure to be successful with them, and they make a welcome change from the ubiquitous *Begonias*, *Tradescantias* and others.

To grow *Anthuriums* in pots is not difficult, provided a warm temperature is maintained all the year round, and plenty of atmospheric moisture. Cleanliness is an important point, both the pots and compost needing careful attention in this respect. Young plants are usually more satisfactory than large old specimens, the latter, owing to the almost climbing habit of some of the species often getting leggy and bare of foliage below. Some of the kinds may be cut back with safety, but it is not always an improvement, as the side breaks form smaller leaves and spathes than the leading growths. Some of the varieties of *A. Scherzerianum* are neat, compact growers, and these make fine well-balanced specimens that for many months in the year are indeed bright and effective. A compost similar to that mentioned above suits pot plants, but the material will not of course be used in quite so rough a condition. When well rooted they may with advantage be allowed occasional waterings with well diluted guano or soot water, either of these helping the foliage considerably. In potting, keep the compost a little higher in the centre of the pot, this helping to throw the moisture away from the stem. No old sour peat should be allowed to remain about the roots, but otherwise disturb them as little as possible when renewing the compost. In a suitable atmosphere, and with clean plants for a start, insects are not usually very troublesome, but a small brown scale sometimes affects them. This should be at once removed when seen and kept in check by frequent sponging.

R.

**Leaky conservatory.**—I have charge of a small conservatory facing south and overhung with trees on the north, which leaks all over, carrying with it on to the roof more or less of the green matter which falls from the trees as well as possibly some portion of the white lead used in the paint. Can plants under such circumstances be kept in health?—CONSERVATORY.

\*.\* Drip, whether owing to defective glazing or the fact that the roof is too flat for the moisture that collects on the underside of the glass to pass away into the gutters, is most injurious to plants of all kinds. The heavy shade and drip from overhanging trees would be particularly detrimental to flowering plants and not to the liking of Palms, Ferns, and other plants grown for the beauty of their foliage. Conservatories are too often designed by architects who study only external appearances, and gardeners take charge of them only to find that they are so many "slaughter-houses." It is bad when the roofs are high enough for tall Palms to luxuriate under, but if added to these drawbacks a leaky

roof has to be contended with, nothing short of a range of plant-houses and plenty of labour can keep them properly "fed." Drip, with its accompaniments, a damp house and a moisture-laden atmosphere, is the very reverse of what we expect to find in a conservatory and where possible ought always to be remedied.—Ed.

TROPEOLUM TRICOLOR.

SEPTEMBER is a good time to pot up bulbs of this elegant and useful greenhouse *Tropeolum*. I have grown it trained both on rustic pieces of Larch and wire balloon and oval trellises painted green, and it is very effective in both ways. Old gardeners used to turn the bulbs out of the soil after the growth had matured in spring, and store them in a cool, dry place in silver sand, examining them occasionally towards autumn, so that potting could be performed immediately new growth commenced. A 6-inch pot suits them well, although I have known, say, three bulbs placed in an 8-inch or 9-inch pot for growing on into large specimens. A light loamy compost and plenty of leaf-mould and silver sand are the best rooting medium, and little water must be given till a foot or so of new growth is made. A soddened soil rots the base of the bulb before it has a chance to emit new rootlets. Some little trouble is needed to secure an evenly furnished trellis, as if the twining growths are left to themselves they soon get entangled, and no amount of patience will separate them. The best way is to insert one, two, or three small Hazel sticks, according to the number of growths that are emitted from the parent bulb, taking the leading points of these to the base of the sticks and letting them twine round these until the top is reached, when they may be gently unwound, tied to the trellis, and the points again taken to the sticks. *T. tricolor* and *T. Jarratti* used to be considered distinct, but are now catalogued, and rightly, so I think, as one and the same. The flowers, scarlet-yellow and black in colour, are produced in great abundance, and last a long time in perfection. When the bulbs are kept in the pots until repotted in autumn, they should be stowed away in a perfectly cool position, otherwise they are liable to shrivel and soften. The new growths must be watched, for slugs and small snails are very partial to them.

J. CRAWFORD.

**Lilium Krætzleri in pots.**—Reference was recently made to the value of this chaste Lily for open air. I can also speak in its favour as a grand pot Lily. Few, in fact, do better in pots than this variety, the plants when grown in, say, 10-inch or 12-inch pots coming in most useful at the end of August, and, if brought on behind a north wall in September, for standing in front halls, corridors, and conservatories. The flowers also, if cut with long stems, which the growth more than that of any other sort allows, look chaste and beautiful arranged in tall glasses in the drawing-room. Used sparingly with delicate Fern fronds or flimsy-coloured foliage, they are very welcome on the dinner-table, their fragrance, too, being of moderate strength only, giving no offence, as is the case with some Lilies when confined in living-rooms. One great secret in pot culture is repotting the bulbs directly the foliage dies down in autumn instead of waiting till spring, as formerly.—J. CRAWFORD.

**Myrosma canæfolia.**—Would some of your correspondents kindly inform me the treatment of the above plant? I have three plants in a conservatory which have made strong growth, but have never flowered.—W. J. R.

\*.\* This, like many other Gingerworts, is not very free-flowering, unless it is treated in a particularly liberal manner, such as planted out in a good open compost in a warm structure. If in pots the compost should consist of good turfy loam, leaf-mould, peat and sand, plenty of water being given during the growing season. Then, on the approach of autumn, the water supply

should be lessened, and throughout the winter the soil must be kept moderately dry so as to give it a period of rest. With the return of spring more water should be given and the plant then encouraged to grow away freely. It is essentially a stove plant, though it may be wintered in an intermediate temperature. Being grown altogether in a conservatory may have something to do with the non-flowering of the plant in question, and I should advise that after a winter's rest it be grown in a structure kept at a higher temperature than a conservatory. It is now generally known as *Phrynium Myrosma*.—H. P.

#### WINTER-BLOOMING CARNATIONS AFTER FLOWERING.

THE following treatment I find successful. As soon as the plants have done blooming, say in February or later, the old stems should be cut back to a healthy shoot as near the base as possible. Shake off carefully about half of the old soil and repot into a larger pot, using good sound loam with a portion of sand, well-rotted manure, and leaf-mould. Stake out and give the plants an occasional syringing. With many of the newer varieties a good crop of blooms will follow in June, especially if the plants are kept in a slightly heated house. The plants after blooming may have the shoots shortened, giving the plants a little fresh soil and standing the plants in the open. These will give another crop during November and onwards.

If no summer blooms are required the plants should be kept well topped to the end of June and the shoots tied out. After the second year Carnation plants are, generally speaking, not worth house room.—W. J. GODFREY, *Ermouth*.

— At page 218 "R. D." complains that so very little information has been forthcoming as to the best treatment of winter-blooming Carnations after flowering, and thinks that a few remarks occasionally on the subject would be of much service to amateurs, who frequently keep their plants for two or more years. Probably why so little has been written on the treatment of old plants is because so few gardeners care to keep them, preferring to propagate a fresh batch annually, and certainly, so far as my experience goes, this is, except in the case of a few sorts, the most satisfactory plan. I have, however, grown Miss Joliffe the second year into large bushes, which have borne plenty of blooms, and I have thought the colour of the flowers, as a rule, brighter than in those from yearling plants. My treatment is as follows: As soon as blooming is over, or, say in March, the plants are placed in a small house and fumigated once or twice to rid them of any greenfly that may be lurking about the tips of the shoots. The growths are then carefully thinned out, those on thick bushy plants reduced to one half—this is important—as if left unthinned they get crowded before the end of the next summer, and spoil one another. One-year-old plants, generally being in 6-inch pots, are then potted into others one or two sizes larger, according to their individual vigour, and placed in a perfectly cool, light house, which is freely aired by day and night. A pit is a very good place for them, as then they can be placed

close to the glass. A light fibrous loam containing abundance of natural grit with a sixth part leaf-mould grows them well. All manures are best excluded from the soil. In May, if the weather has become settled, the plants should be stood out of doors in a sheltered spot, on a bed of rough coal ashes—fine ashes are an evil, as the pots in course of time sink into them, and a water-logged condition is likely to ensue. Careful watering, eradicating by means of tobacco powder any greenfly which may appear, and laying the pots on their sides for a time, if heavy rains prevail, comprise the chief summer treatment. I never give manure water. About the first week in October remove the plants to a light, airy house, elevating them near to the roof glass, fumigate lightly occasionally, and water carefully, keeping a uniform night temperature of 45° in mild weather and 3° lower when the pipes have to be

#### THE SPOTTED GLOXINIAS.

SINCE this form of the *Gloxinia* was first introduced, now several years ago, there has been a decided improvement in form, in habit, and colour. In form the flowers have advanced breadth of petal, and also in the more expanded tube; in habit the advance is quite marked the more compact growth and in the great freedom of flowering, for which the best strains of the spotted form are now most remarkable. The leaf growth, too, has shown a distinct advance, being more vigorous, with the foliage not so pointed as formerly. In colour the improvement has been chiefly in the brighter and more varied spotting, and in the clear margin lines of pure white now so apparent in the best kinds or strains. The spotted *Gloxinias* a

*A seedling Gloxinia with spotted flowers.*

warmed to exclude frost. More heat than this weakens growth, encourages aphid, and is a sure forerunner of poor cuttings in spring.—J. CRAWFORD, *Coddington Hall*.

**Fuchsia Ballet Girl.**—This is one of the finest of the double varieties with white corolla. The flowers are large and full and the plant of good habit. It is becoming a great favourite with market growers, as it makes a capital plant in a 5-inch pot and blooms freely. Messrs. Veitch and Sons obtained an award of merit for the above in July, 1894.—A. H.

specially adapted for small pot culture. It is quite needless to exceed in size of pots those 6 inches in diameter, while plants fit almost for any purpose may be grown in one size less. They may also be flowered in still smaller pots. The substance of this form was at first quite flimsy, but it is all that one could wish. Altogether the *Gloxinias* are most beautiful subjects for the stove.—H.

— The majority of these will now have finished flowering, and gradual drying off of the bulbs must take place. Withholding water at once, as is sometimes done, will cause

orms to partly shrivel, a weak growth next year being the result. When the foliage turns yellow just enough water should be given to keep the soil from becoming dust-dry. In November the pots are best stood in a dry place at a temperature of about 50°, care being taken to keep them away from hot-water pipes. I saw a great lot of bulbs last spring which had been much injured by being stood on a shelf immediately over a hot-water pipe. Gloxinias are often lost in winter by being placed in too cold a house close to the glass, and, on the other hand, the bulbs are often excited to growth and their vitality greatly weakened through too much heat and moisture during the wintering season.—C. C. H.

—By many it is considered absolutely necessary for Gloxinias to be grown in heat, that is to say, treated generally as intermediate house plants, and while it must be done in order to flower them early, yet for late blooming very different treatment will yield highly satisfactory results. From the end of May onwards they may be grown without any heat whatever, and under such treatment will not begin to flower till the early part of August or thereabouts, when for six weeks or so they will yield a fine display in the greenhouse, and that, too, at a time when many of the summer-blooming plants are on the wane, when the fresh, brightly-coloured flowers of the Gloxinia are all the more valuable. In raising Gloxinias from seeds it is necessary to sow them in heat early in the year; hence for this cool treatment one-year-old tubers are required. I flower a considerable number in this way and find them particularly valuable for maintaining a display at the end of the summer. In the autumn the tubers are laid in boxes of sand and wintered at a temperature of 45° to 50°. During that period an occasional sprinkle is given to prevent the soil becoming too dry, and under such conditions the young shoots will commence to push up about the end of March. This year, owing to stress of work, our plants were not potted till a month later than that, and were then kept in the greenhouse till nearly the end of May, after which they were removed to an ordinary garden frame without any heat whatever. There they made slow, but sturdy progress, with a perfect immunity from insect pests, and by the latter part of June were ready for a shift from 2½-inch into 5-inch and 6-inch pots. The plants were shaded during bright sunshine, and the frame shut rather early in order to husband the fire-heat, while as the pot became filled with roots, occasional doses of liquid manure were given. Grown in this way the foliage is healthy and well coloured, thus seeming to show off the bright-tinted blossoms to the best advantage. A mixture of loam and leaf-mould, with a dash of rough sand, will just suit the Gloxinia, as it needs a good porous compost. If the flowers are cut when just expanding they remain fresh and bright for some days.—H. P.

**Aschynanthuses.**—The different species of Aschynanthus are all very beautiful when in flower, and in the case of most of them their usual season of blooming is during the autumn months. *A. speciosus* is one of the showiest members of the genus, the curved scarlet flowers marked with brown at the mouth being borne in large terminal clusters. One of the commonest, *A. Lobbianus*, is a general particular widely removed from the preceding, but in its way it is, I think, equally beautiful. In this the stems are slender and purple in colour, while the ovate leaves are small and more than an inch long, and of a deep, bright green, while the thimble-shaped calyx, which is quite 1 inch in length, is hairy and of a deep purple tint. Protruding therefrom we have the right scarlet corolla, curved as in the others, and about a couple of inches long. As the calyx is developed some little time before the corolla, the plant then presents the appearance of being studded with dull-coloured thimble-shaped blossoms, but as the corollas develop they impart an additional feature to the specimen. There are several other species, but the above

may be taken as a good representative couple, while a third species is well worth a place in any garden where facilities exist for its culture. This is *A. Hildebrandii*, a native of the Shan States. This was introduced to Kew in 1894, and up to the present I have not seen it anywhere else, though it is a charming little kind and quite the pigmy of the genus, for it only reaches a height of about 4 inches. The comparatively large scarlet flowers are borne in terminal clusters as in the others. This will succeed in a greenhouse temperature, but needs a fairly moist atmosphere such as a cool Orchid house. The other members of the genus are essentially stove plants. They are all more or less epiphytes, and do well treated as basket plants, particularly the slender yet free growing *A. Lobbianus*. A mixture of peat, Sphagnum, charcoal, and leaf-mould will suit them well, as they require a porous compost such as this. They need a liberal amount of water, of course more during the growing season than in the winter, but at no time should they be allowed to become dry. Throughout the summer frequent syringing is also very beneficial. Propagating is effected by means of cuttings which should be put into a light peaty compost with plenty of sand, and in a close propagating case will soon root.—H. P.

#### GARDENIAS.

I SHALL be much obliged if you will let me know in your columns what compost suits Gardenias best, also a little information upon their treatment. I shall also be pleased if you could tell me the best manner to pack the cut flowers to undergo a journey from twenty-four to thirty hours, and the composition used by florists to steep the flowers in when cut to ensure their lasting.—G. G.

\*\* The compost suitable for Gardenias will of course, to a certain extent, depend on the size of the plants, as when potting into large pots it must be much rougher than for small ones. In growing Gardenias many cultivators prefer to propagate their own plants, and this is generally done by cuttings of the half-ripened shoots put singly into small well-drained pots of sandy soil and kept in a close propagating case till rooted, which will be in about three weeks or so. When rooted they must be hardened off, by being inured to the air of an ordinary stove, when they can soon be shifted into larger pots. The points of the shoots must be pinched out from time to time in order to ensure a bushy habit of growth, and the structure in which the plants are kept should during the summer have a night temperature of 70° with a corresponding rise during the day. The plants should be so situated as to get as much light as possible, but at the same time they must be shaded from bright sunshine. By the end of June the plants will if they have done well be ready for their final shift, which may be into pots 6 inches or 7 inches in diameter. After this, if they are kept well syringed and the structure in which they are growing is shut up early in the afternoon in order to husband the sun-heat, they will make rapid progress. By the end of August they must have more air in order to harden them off, and very little, if any, shading will then be needed. During the winter a minimum night temperature of 55° with a rise of 10° or so during the day is very suitable for them. As the spring advances the flowers will quickly open in the higher temperature. Throughout all stages of growth, except during the winter, Gardenias are greatly benefited by a liberal syringing, as it tends to keep the foliage green and healthy, added to which the plants are often attacked by insect pests, and a liberal use of the syringe will help to keep them under. If bug or scale effect a lodgment on the plants, they must be laid on their sides and syringed with one of the many insecticides which are effectual in destroying these pests. After flowering any straggling shoots may be shortened, and the plants shifted on into pots about 3 inches

larger than the others. They must again be encouraged to grow freely during the summer, and be hardened off towards autumn. The flowering season in the spring may be regulated by the temperature maintained at that time, and it is generally the custom to bring them on in batches in order to ensure a succession of bloom.

The flowers should be packed in shallow boxes, as they travel much better in this way than when in layers. To send by rail several of these shallow boxes may be put into a deeper one for convenience. If a little fresh Moss nearly dry or the finest wood wool is put over the bottom of the box in a thin layer and covered with tissue paper, which must also extend around the sides, the flowers must be arranged thereon as closely as possible, and the box finished off with a few layers of tissue paper on the top. In packing flowers many make the mistake of being too cautious, that is to say, they put them too loosely together, the consequence being that they move about and become bruised beyond recognition. A firm hand is necessary in packing flowers, and practice is most essential. Flowers that are intended for travelling should be cut a few hours before they are packed and placed in jars of water, and they will then be well charged with moisture and better able to bear the journey than if cut and packed at once. I know of no composition to steep the flowers in in order to ensure their lasting.—H. P.

#### Variegated Pelargonium Mrs. Parker.

This Pelargonium is on page 198 referred to by "R. D.," who states that he is not sure if it is in commerce. It has been grown for years, and by some is much appreciated, not only as a pot plant, but also for the flower garden. It is a sport from a one time popular variety, Leamington Lassie, which is of especial interest to the readers of THE GARDEN, as it is the only semi-double zonal Pelargonium of which a coloured plate has been issued, and that was as long ago as April 23, 1877. The flowers of Leamington Lassie are a kind of lilac-pink, and the variety Mrs. Parker does not differ therefrom in any respect, except that the leaves are deeply margined with white. There is a second variety of this section, that is with variegated leaves and double or semi-double blossoms, which is often confounded with the variety in question. This is Chelsea Gem, whose leaves are not so flat as those of the other, and though the variegation is of a purer white it is not so broad. The colour of the flowers, too, is different, that of Chelsea Gem being a clear deep pink. Both are free-branching, low-growing kinds, the variety Chelsea Gem being the more vigorous of the two.—H. P.

**Boronia serrulata.**—The recent note regarding this beautiful New Holland plant reminds one how difficult it has been to obtain it for some time, till a few years ago it was taken in hand by Messrs. Balchin, of Hassocks, who may be said to have rescued from oblivion the charming blue-flowered *Boronia serrulata*. They have been equally successful in the culture of the *Boronia*, and as recently as the last Temple show numerous flowering examples were exhibited by them. The colour both of the *Boronia* and the *Leschenaultia* is decidedly richer on the plants grown at Hassocks than it is in most places. This is presumably owing to proximity to the sea, combined with the clear, pure air of the Southdowns, for this feature is by no means confined to the two plants in question. Crotons, Dracenas, Acalyphas, and various indoor plants grown for the beauty of the foliage are all unusually bright throughout the district in question, while out of doors the variegated forms of *Euonymus*, *Hollies*, and *Privet*, as well as the tricolor and bronze-leaved Pelargoniums all attract particular attention from the richness of their colouring. The flowers, too, of the different zonal Pelargoniums are from the same circumstance very noticeable.—H. C.

**Richardia albo-maculata.**—This cannot for one moment be compared with the large showy species of *Richardia* such as *R. aethiopica*, *R.*

Elliottiana, and R. Pentlandi, yet for all this it is very pretty and particularly free flowering. It is a small growing plant, as if kept out of doors it is little more than a foot high, but under glass it of course grows somewhat taller. The leaves are narrower in proportion to their length than those of the common Calla, while they are blotched with white on a green ground. The flowers are creamy white, with a reddish blotch at the base of the interior. This species often produces a double spathe, while occasionally the inflorescence is particularly curious, consisting as it does of a half spathe, half leaf. This *Richardia* grows with great freedom, and towards the end of the summer a plentiful crop of blossoms is pushed up. It differs from the common Lily of the Nile in being totally deciduous during the winter; indeed, it forms a solid tuber which needs to be kept almost dry throughout that season. This latter remark will apply to all the *Richardias* except the universally grown Lily of the Nile, *R. aethiopica*.—H. P.

#### FUCHSIAS WITH WHITE COROLLAS.

In the early sixties the varieties of Fuchsia with white corollas were but few, and very few of that limited number are now in cultivation. Still, a couple of them may be occasionally met with, viz., Madame Cornelissen, which is still a very desirable form for flowering out of doors during the summer, the growth being compact and sturdy and the plant free flowering. The second, Princess of Prussia, is somewhat in the same way, for in both of them the corolla is single. The variety Princess of Prussia occurs in a catalogue of Messrs. Rollisson for the spring of 1858, when it was described as a novelty, having received a first class certificate at Regent's Park during the preceding summer. Of varieties with double white corollas, Avalanche held its own for a very long time, and it is still grown to a certain extent. There was a second variety of the same name the flowers of which were dark, and both being popular at the same period often led to a good deal of confusion. At the present time quite a long list of varieties, both single and double, is to be met with; indeed, they are so numerous that it is difficult to make a selection therefrom. One of the very best is Ballet Girl, which was given an award of merit by the Royal Horticultural Society in the summer of 1894. This variety is of good free growth, very free-flowering, with a large double white corolla veined with red at the base. The bright coral-red sepals are longer than in several others and reflex gracefully, a feature which is frequently wanting in many of the newer large-flowered varieties. Besides this a couple of new varieties from M. Lemoine, of Nancy, have pleased me very much, and they are certainly worth a place among the most select of this section. The varieties in question are Due d'Annale, with a large globular-shaped white corolla, marked with red on the lower part of the petals. The sepals are short and broad, the flowers reminding one to a considerable extent of those of the once universally grown Miss Lucy Finnis, which, however, is a weak grower, while in this newer kind the style of growth and habit altogether leaves nothing to be desired. The second to be mentioned is De Goncourt, in which the corolla is single and of an exceedingly pure white; the sepals, too, which reflex beautifully, are long and of a bright coral-red tint. The edges of the petals are somewhat wavy, hence the corolla is less formal in outline than in many of the others. The habit of the plant is good, and the flowers, which are supported by long stout stalks, display themselves to the very best advantage. Another of M. Lemoine's varieties, Madame Carnot, will commend itself to the lover of huge blooms, for, in addition to this, it is free-flowering. The leaves of this are rather small and roundish, and the habit of the plant more upright than in most of them, but the weight of the flowers causes the branches to partially droop, for the massive blooms are thickly clustered near the points. Other good

varieties are Molesworth, Flocon de Neige, Duchess of Edinburgh, Colonel Dominé, and Mrs. Hill. As an illustration of the prominent position that the Fuchsia occupied for a time may be mentioned the fact that out of the seventy varieties acknowledged by the Royal Horticultural Society from 1859 to the present time fifty of them obtained their awards between the years 1865 and 1875. GROWER.

#### LILY OF THE VALLEY.

REFERRING to the article on the Lily of the Valley (page 182), though it has not, as far as I am aware, ever received a first-class certificate, yet the particular variety, of which a coloured plate accompanied the article in question, was given an award of merit on March 25, 1890. Fontin's var. is undoubtedly a very superior form, the large open bells being characteristic of the German type, from which it has doubtless sprung. Of the immense numbers of the Lily of Valley which are sent to this country during the winter months, the greater portion of the single crowns or eyes is obtained from the Berlin district, while, on the other hand, most of the clumps come here from Holland. The flowers of these last are totally different from the German ones, being very much more contracted at the mouth; hence they appear a good deal smaller. For early forcing the Berlin crowns are preferred, as they respond to heat more readily than the others, but for the embellishment of the greenhouse as spring advances the Dutch clumps are by many regarded as superior, for, being taken up with the ball of earth adhering to them, their roots receive but little mutilation, and therefore when the bright spring weather sets in they do not flag so readily as the German crowns, whose roots are shaken entirely clear of soil before they are sent here, and the flower-stem is pushed up previous to the roots establishing themselves in the new soil. Despite the fact that we get nearly all our supplies of the Lily of the Valley from abroad, Mr. Jannoch has shown us that with care and attention its culture in this country can be made remunerative. Such being the case, the question is suggested whether a good deal of the money that we pay to the foreigner for *Spiraeas*, *Dielytras*, and different bulbs might not be kept in the country, for we have many wide districts well suited for their culture. The use of the refrigerator has given a great impetus to the culture of the Lily of the Valley, and beautiful flowers of it may now be seen in the florists' shops of London at all seasons of the year. About twenty-five years ago I was connected with a market nursery where the Lily of the Valley was made a special feature. In those days a few spikes of the very earliest blooms were ready for market by the first or second week in December, and it was considered particularly good culture to have an ample supply by Christmas, and those that were fortunate enough to obtain flowers by that time found the Lily of the Valley a very remunerative crop. In those days its culture was very limited compared with what it is at the present time. H. P.

**Richardia Pentlandi.**—Though the early part of the summer is the usual flowering season of this *Richardia*, yet several plants in full bloom have come under my notice of late, and at this time of the year the bright golden-coloured spathes are particularly welcome. The plants, which are thus blossoming out of their season, were imported from South Africa in a dormant state late last spring, and having been potted and placed under conditions favourable to growth, in due time some of them flowered. This and *R. Elliottiana* are certainly two beautiful golden-flowered *Richardias*. They are both a good deal in the same way, the principal points of difference being that the flowers of *R. Pentlandi* have a blotch of crimson at the bottom of the tube, and this is wanting in *R. Elliottiana*. Besides that the leaves of this latter are marked with irregular

translucent spots, while those of *R. Pentlandi* of a uniform deep green. The blade of the leaf, too, is rounder in *R. Elliottiana* than in the other and this character alone is sufficiently pronounced to distinguish between them. Among the late importations of these golden-flowered *Richardias* that now reach this country two forms are represented—firstly, *R. Pentlandi* itself, and secondly a variety of the same, in which the leaves are marked as in *R. Elliottiana*. It is, however, quite distinct therefrom, being, in fact, a counterpart of *Pentlandi* except that the leaves are spotted. I have met with it under the name *Richardia Pentlandi maculata*, which has the advantage of expressing its prominent characteristics.—H. P.

**Lilium Harrisii.**—When this was first sent to this country in quantity, about a dozen years ago, a good deal of interest was aroused as to what it was really a particularly early flowering form, or owed this feature only to the conditions under which the bulbs had been grown. This latter theory is now proved to be the correct one, for the open ground, at all events in the second season, it will flower at the same time as the rest of the longiflorum section; indeed, *L. Harrisii* from Bermuda cannot under such conditions be distinguished from *L. longiflorum* from Japan. Planted in the open ground it makes sturdy growth and flowers profusely, so that a mass of *Lilium* with its countless trumpets of dazzling whiteness forms a very attractive feature. I have with numerous examples of it this season in particularly good condition both by itself and associated with other subjects. A mass of this interspersed with the scarlet spikes of *Gladiolus brenchleyensis* was particularly showy when in its best. As *L. Harrisii* is often brought on considerable heat for early flowering, the idea that it is a tender Lily is very widespread, but such is not the case, as our average winters do not produce any effect upon it. It succeeds best in a good open loam, fairly sandy, and where the drainage is good, though not in a spot dried up during summer.—GROWER.

#### FRUIT AND VEGETABLE CROPS

##### NORTHERN.

**Lambton Castle, Durham.**—The Apple and Pear crop in our county, I am sorry to say very poor. During the time the trees were in bloom we had strong winds and frosts that seem to cut the blossoms all to pieces; consequently very few set their fruit except in sheltered places and on the walls, where a fair crop exists. Bush fruit is fairly good, although not a heavy crop. Gooseberries are clean and a good medium crop. Currants are a fair crop; Raspberries medium crop and clean.

Vegetables are good upon the whole. Green of all sorts are clean and healthy, and look finishing satisfactorily. Onions are small, owing to the want of rain during their growing season. Potatoes are good and free from disease, and the varieties have done well here. Peas and Beans are doing well and free from mildew. J. HUNTER.

**Castle Howard.**—Apples, on the whole, rather a thin crop. In situations well sheltered from north winds there is nothing to complain of and such varieties as Keswick Codlin, Cock, Lord Suffield, Domino, Lane's Prince Albert, and Duchess of Oldenburg are well loaded with fruit even in rather exposed positions. Provided rain comes soon, the yield will not be so bad as was anticipated a short time ago. Pears on walls a good average crop, so also are some varieties the open where well sheltered. Those exposed are almost a failure. Plums may be regarded as a total failure; even Victoria and Rivers' Early Prolific, varieties which are among our sure croppers, are barren. Apricots are also almost a failure, and the few fruits have suffered from drought, some falling, and the remainder being

all. Cherries, both sweet and Morello, are under the average and smaller than usual. Gooseberries and Black Currants have been about a crop, whilst Red Currants and Raspberries are an average crop. Outdoor Peaches and Nectarines may be regarded as a failure, and Strawberries have been both small and few in number. The poor crops of fruit in this neighbourhood are attributed to the late frosts and cold, cutting winds which prevailed in spring and early summer, and the long spell of drought and excessive heat from which we are now (August 7) suffering.—J. RIDDELL.

**Kirklevington Hall, Yarm.**—The fruit crops in this district are not heavy, but on the whole there is not much to complain of. The crops in spring were not so thickly covered with bloom as they were last year, and although we had no May frosts to destroy it, yet the cold, dry winds we had during May and June did great damage. Apples are a thin crop. Pears a fair average crop, especially on old trees. Plums are up to the average on old trees, but on standards a failure. Morello Cherries are a good crop, but rather small. Strawberries have also done well, but the fruit is small. Raspberries have been very scarce. Currants, Red and Black, and Gooseberries have been very plentiful and good. Potatoes are turning out well. Peas have been good; in fact, all vegetable crops are good where they have been watered and properly attended to.—ALEX. CUNNINGHAM.

**Widd Hall, Ripley.**—In this district Strawberries, Currants, and Gooseberries have been an average crop, but the fruit has been rather small. Raspberries, Pears, and Apples are below average, and Plums are a total failure. The varieties that bore the best crops are, Apples: Lee's Prince Albert, New Hawthornden, Cellini, Kewick Codlin, Lord Suffield, Potts' Seedling, Summer Pippin, Scarlet Nonpareil, Golden Nale, Ecklinville; of Pears, Louise Bonne of Jersey, Marie Louise, Durondeau, Doyenné d'Été, Berré Giffard, Bergamote d'Esperen, and Winter Pear. Apricots are a very scarce crop. Onions are small. The vegetables that have suffered most are the Brassicas and Peas and Beans. The principal cause is the cold winds that prevailed in the early part of this year and the absence of rain for so long a period.—W. DINES.

**Met Hall, Leeds.**—Owing to severe frost on the night of May 11, with cold winds and a drizzle the following day, fruit trees suffered severely, as the majority were in full bloom. Some large Horse Chestnuts breaking into growth were completely blackened and have not yet recovered. Then the gale on June 16 shattered nearly everything to atoms. Some Oak trees and a timber hedge adjoining the kitchen garden looked as if they had been scorched with fire. Fruit trees in some cases were stripped of their fruit and foliage, and vegetables, such as Peas, French Beans, Scarlet Runners, Potatoes, Lettuce, and Jerusalem Artichokes were torn to pieces. This year will long be remembered for the destruction wrought by wind at York gala. There is a complete wreck of tents and produce I never witnessed, and a worse season, I think, I have never experienced. Nearly everything here appeared about a fortnight later than usual. Apples, Pears, and Plums are below average; Cherries, Gooseberries, Currants, and Raspberries poor; Strawberries very good.

The kitchen garden here is very much exposed to the north-west and rests on a strong clay, so that most vegetables have wonderfully improved during the recent hot weather, and do not suffer from drought so much as in some gardens, although we had only 1.04 inches of rain during July in eight days, two of which measured 0.84 inch, so that the remainder was only like dew. Up to date of writing (August 12) we have registered 0.40 inch for the present month, with continuous hot weather. Peas are very good, especially Ne Plus Ultra. Early Potatoes are all, but late ones appear very promising.

Beet, Onions, Turnips, Carrots, and Lettuce have not been so good for years, but Cauliflowers are small. Brussels Sprouts and Savoys are looking very well, but Broccoli and autumn Cauliflowers are suffering from continued drought and water here is very scarce. I heard some farmers remark that they never saw Turnips in the fields looking better than at present.—THOS. BONSALE.

**Grimston Park, Tadcaster.**—Fruit crops generally are very light in this district, stone fruits particularly so. It is some years since I had such thin crops of Apricots and Plums as there are this year. On an Apricot wall nearly 100 yards in length in these gardens there is only one tree that has even a fairly good crop upon it. I have tried to account for this. Up to now I have come to no logical conclusion on the point. There are other trees of the same variety on the wall quite fruitless; it is Hemskirk. The tree has not been lifted in recent years, nor yet root-pruned, nor in any way treated differently from the rest. There has been no branch-dying on Apricots this summer, as is too often the case. To my mind the sunstroke theory of the cause of branch-dying breaks down completely now, as it is some years since our trees had so much hot sun shining upon them, as during the past two months. The trees generally are very healthy, foliage being good and free from insects. Even if we do get some sharp frosts at blooming time next year I venture to say, with the protection of a double herring net, there will be some Apricots. Peaches are very thin, but the trees in this case are healthy and fairly free from insects; Plums the same. Even that free fruiting variety Victoria is all but fruitless this year. Apples are partial. There is a nice crop on some kinds, but as a whole the crop is not more than a third of a good average one. Keswick Codlin, Lord Suffield, Improved Cockpit, Irish Peach, Warner's King, Yorkshire Greening and Rose Hill are the only kinds that have anything like a crop of fruit on them. In this case also the trees generally are healthy and fairly clean. Pears, too, are a thin crop; Doyenné d'Été, Citron des Carmes, Beurré d'Amanlis, Urbaniste and Jargonelle have good crops. The same remark applies to some old trees of that well-known excellent Pear Marie Louise. In this case they are planted on the north side of a wall. Some twenty-five years ago I trained branches over to the south side of the wall, which they now cover for some 6 feet of its upper surface. I generally get some good fruit from this portion of the trees; this year there is a very good crop. Cherries are a thin crop. For some cause not known to me I never get good crops of dessert Cherries here. I have tried fresh soil, &c., but have not yet succeeded as I could wish. Some two miles off as the crow flies there are some fine fruitful trees of Bigarreau. I do not even get the trees to grow well against walls. The soil is a stiff holding one, about 3 feet in depth, overlying magnesian limestone. Can anyone throw light on the subject? Morello Cherries grow and fruit very well. I have had good crops of bush fruits, though not quite so abundant as in some years. Gooseberries were fine in size and flavour, but owing to the very dry July soon past their best. Red and White Currants were a good crop, but not so large in berry as usual from the same cause. The same remarks apply to Black Currants. Raspberries were but a thin crop, except that very excellent variety Superlative, the best cropping variety I have, and the fruit of a good size. It has one drawback as to increasing the stock, viz., it throws suckers up very scantily. I hardly dare put into figures the amount of fruit an acre of land would produce if covered with this Raspberry in rows 4 feet apart, judging by what the one row 20 yards long gave me this year. There are good crops of Walnuts and Hazel Nuts hereabouts. I had excellent crops of Strawberries, but owing to the drought they were soon over.

Speaking generally, vegetable crops have been under the average hereabouts this season. Even the most self-satisfied and up-to-date cultivators are more or less under the influence of the weather

in this part of gardening. With the exception of 1879, this season has been the worst I have had to deal with in my twenty-five seasons here. We had a wet winter, a cold, ungenial spring; then in June came a spell of hot sunshine, which somewhat baked the surface of our stiff, cool soil. All through that month and also July we had continued drought with plenty of sunshine. The good effects of the latter were much counteracted by two or three sudden lowerings of the temperature with cutting winds of some duration. All newly-planted-out stuff, such as bedding plants, vegetables of kinds, &c., started very badly. Early Peas were good, but a week later than last year in coming in. I still grow a few rows on a south border of what our kitchen garden man calls bullet Peas, viz., such kinds as Ringleader, First and Best. They come into use sooner than Exonian and William I., which are two good early kinds both for cropping and table use. Gladiator grown on the same border succeeds the latter kinds well. I follow on with Advancer, Premier, and Dr. Maclean. It may here be mentioned that after growing the Maclean family of Peas for thirty years I have nothing but good to say of them. Veitch's Perfection is an old, well-proved friend for midseason use. Then comes one row each of Criterion, Champion of England, and Ne Plus Ultra, Ebor, a very excellent selection from Ne Plus Ultra, and last, but not least either in height or usefulness, the good old British Queen. It is only fair to add that only those who can command tall Pea sticks should grow the kinds named above. Hawfinches have troubled us a lot this year. It is surprising what harm a few of them can soon make in a row of Peas just coming into use. Nothing but shooting them early in the morning or late in the evening is effectual. Early Potatoes have been a good crop as to quantity, but owing to the drought much smaller than usual. I have seen no sign of disease in the garden as yet. Veitch's Ashleaf, Sandringham Kidney, and Racehorse are my standard kinds for early crops. I have grown the two latter kinds over twenty years in these gardens without changing the seed. A new kind of Potato named English Beauty promises well. I have tried another so-called new kind called Fore-runner, but think it is our old friend the Walnut Leaf under a new name. Anyhow I shall be pleased to have a stock of that good old kind once again under any name. For early forcing in pots some thirty years ago it was considered indispensable. I do not grow any late kinds in the garden. French Beans have been very good in crop, but short-lived, causing more occasional sowings than in more moist seasons. Osborn's Forcing, Ne Plus Ultra, Fulmer's Forcing, and Negro Longpod are the varieties I grow. Scarlet Runners are very late coming into use this year. Veitch's Mammoth Scarlet and Scarlet Champion serve me well for abundant long-continued crops. Onions are not so good as usual owing to the dry season; they are healthy, and bulbs are firm but small. I generally sow about 300 square yards of land with this useful crop. The treatment from first to last has been the same for over twenty-five years. In some seasons I have taken over 160 stones of Onions from the area named; this year there will not be more than a third of that quantity, if so many. Other tuberous and bulbous-rooted vegetables promise to be fairly good. Green vegetables, such as Cauliflowers, Cabbages, &c., are now growing away well after the grand rains we have had. They are more or less riddled by the larvae of the white butterfly, which were very numerous in July. Celery is now growing away very well. Whenever able I give a good watering of diluted house sewage to this. At present there is no sign of damage done by the Celery fly. Last year it injured the crop very much.—HENRY J. CLAYTON.

**Hurworth Grange, Darlington.**—Fruit trees generally were full of bloom, but owing to the cold east winds we had in spring the crops vary very much. Strawberries were a fair crop and of average size and quality, but soon over. Gooseberries, Black, White and Red Currants

are a good crop. Raspberries poor. Cherries dropped three parts of their fruit in stoning and are thin. Pears vary. Jargonelle, Beurré d'Ananlis, Clapp's Favourite, Bergamots, and one or two others have good crops; the rest are thin. Apples are thin generally, as also are Apricots. Peaches in case a good crop. Plums are the worst crop I have ever had.

Potatoes are a good crop, but a great many small ones. Peas, Beans, and Cauliflowers have taken a lot of water and go off very quickly. Carrots, Turnips, and Onions are small. Winter greens have required a lot of attention both in watering and filling up. Our land here is strong loam on strong clay, and cracks and bakes very much in dry weather.—JOS. SIMPSON.

**Wiggantheorpe, York.** This is one of the worst seasons I have had for this time both for fruit and most kinds of vegetables. There was every prospect of a good crop of Pears and Plums as far as the show of bloom was concerned. Apple trees were not so full of bloom. Plums are almost a failure, Victoria being the only kind carrying a crop. The better kinds on walls are a total failure. Though there was a good show of Pear blossom only a few kinds are a good crop on walls. Jargonelle, Marie Louise, Beurré Clairgeau, and Passe Colmar bearing best. Bush trees have hardly a fruit upon them. Apples are a light crop; only a few kinds are bearing fruit, these being Keswick Codlin, Cellini, Manks Codlin, Burr Knot, New Hawthornden, Stirling Castle, Lane's Prince Albert, and Cockpit, the last-named the only one carrying a heavy crop. With the exception of Royal Sovereign, Strawberries have done badly. Gooseberries and Currants have been plentiful, but the former did not ripen properly, which I attributed to the very dry season. Raspberries are very few and small; Morello Cherries an average crop. We had a very dry time as well as strong, cold winds when the trees were in bloom. Whether the failure of the fruit crops is due to this cause or to the wet autumn it is difficult to say.

The greatest sufferers, owing to the prolonged drought, amongst vegetables are Peas and Celery. Early Potatoes are good and quite free from disease; later sorts will be small. Owing doubtless to the cold spring, all crops came into use later than usual.—J. S. UPEX.

**Eden Hall, Langwathby.**—Apples in this part are a fair average crop, whilst Pears are heavy, most trees carrying fine crops. Cherries are an average crop, but Plums considerably under average. Apricots are very poor. Strawberries, Currants, Gooseberries, and Raspberries have all been very heavy crops.

Vegetables have done well, French and Runner Beans exceptionally good. Peas suffered considerably from the long spell of drought experienced here, so have not been of long duration. All winter crops look very promising after the rains we have had during the last fortnight.—ARTHUR SMITH.

**Seaham Hall Gardens, Seaham Harbour.**—Apples are under the average, although the sorts that flowered late are better crops. Such as Lord Sutfield on walls and in sheltered places that escaped the sea-fogs have a fair crop. Wellington and an old sort called Pine-apple have fair crops. Pears are under the average owing to the cold weather when in flower. Plums are a failure from the same cause. Cherries are under the average. Gooseberries and Currants have about a quarter of a crop, except on those trees that I do not prune. The close branches protect the blossom and fruit just after it has set. Raspberries have fair crops, but suffered from the dry weather.

Potatoes look well both in gardens and fields and there is no disease. Peas did wonderfully well, considering the dry weather.—R. DRAPER.

#### SCOTLAND.

**Dalkeith Palace.**—The fruit crops in this district vary considerably in different places. Where the garden or orchard is favourably situated and the fruit trees and bushes receive due

attention, the crops, as may be expected, compare to advantage with those grown under less favourable circumstances. On the whole, where the trees are well-sheltered and properly cultivated the crops are a fair average. Apples are a fair crop; Pears abundant; Plums irregular; Cherries light; Peaches and Nectarines on walls very good; Apricots light; Gooseberries fair; Currants good; Raspberries and Nuts very good; and Strawberries abundant, but late. All kinds of fruit are better in size and quality than usual, owing probably to the warm and genial weather experienced since the middle of June, and the absence of insect and fungoid pests in the early part of the season. Fruit trees have made a fine, free, and clean growth, and with good ripening weather in autumn they promise well for a good crop next season.—M. DUNN.

**Dunrobin Castle Gardens, Sutherland.**—Fruit crops here are decidedly under the average, with the exception perhaps of late Strawberries, which were a good crop and of good quality. Standard Apples inside the walls bear a very thin crop—many trees none at all. On a south wall facing the sea Keswick Codlins are a medium crop. Plums and Pears are scarcely half an average crop. Raspberries under average. Bush fruits are about half a crop; Gooseberries very thin—the poorest crop for many years.

Vegetables are good. Carrots and Onions have stood the drought well, and have not been so good for several years. French Beans were very backward for some time, but the warm weather of July has brought them round. Peas have been plentiful and good, but the drought of July has caused them to come in too much together. Potatoes were later than usual in getting to be of good quality. They are a good crop, and at the present date free from disease.—D. MELVILLE.

**Tynninghame Castle, East Lothian.**—Apricots are practically a failure. Plums and Pears, on the other hand, are so heavy as to require severe hand-thinning. Both are much later than usual, and the latter are not swelling to an average size. Apples are a fair crop with me, but in some gardens they have failed. The fruit of the Codlins is spotted, and late kinds much smaller than usual. Figs are a fair crop, but fruit small. Peaches none. Small fruits have been good, though Strawberries did not turn out so well as expected on light soils. On heavy land the crop was a good one, though of short duration. Brambles are an extraordinary crop, so also is the Japanese Wineberry, both small fruits that are valuable late in the season.

The most remarkable feature in the vegetable department has been the erratic behaviour of many of the kinds. This began with early winter and spring Broccoli, and ever since, perhaps largely owing to the lateness of the season, one has been unable to depend on crops turning regularly in. All crops, however, are very good, though Onions will not be so large as usual, and Celery is also backward. No doubt the last-named will make up. All winter crops are doing well. Potatoes have been very good and up to date no disease, but the humid weather we have experienced for some time has destroyed the foliage, and it will not be surprising if later sorts suffer from disease.—R. P. BROTHERSTON.

**Balcarres, Fife.**—The fruit crop suffered much from late frosts and cold east winds during the month of May. Apples are only a moderate crop. Pears very good where sheltered. Plums, Peaches, and Cherries much below the average. All small fruits are good, particularly Gooseberries. The early Strawberries were very light, but late varieties and Elton Pine very good, the best we have had for years.

Vegetables are three weeks later, but very good. Potatoes small and late and now attacked with disease.—EDWARD TATE.

**Blackadder, Edrom.**—The fruit crop in this district, although most promising in the early spring, proves now, taking it all over, to be rather below the average. Apples are very much under, owing chiefly to the great destruction

wrought on the buds by bullfinches in spring; the small percentage of buds remaining further reduced when in flower by a hard frost the first week of June. Pears, Plums, and Cherries are an average crop. Some varieties of the two former are considerably over, notably Jargonelle Pear and Victoria Plum. Buds of latter seem to be less palatable to birds than other sorts of Plums, as this was the only variety that escaped their ravages. Green Gages were completely stripped and only show a few fruit per tree. Had the repeated attempts to keep birds in spring been successful, I venture to say that the Plum crop here would have been an enormous one. Peaches and Nectarines are much under the average. Apricots slightly under, but of very good quality. Small fruits mostly average, Currants being rather under, but Raspberries greatly over, all of good quality. Strawberries promised well, but were, unfortunately, just in flower at the time of the frost already mentioned and were all blackened; small flowers which opened later gave a few small fruits of poor quality.

Vegetables made little progress in the early part of the season, but with cooler nights and plenty of moisture a rush has taken place, and to a great extent made up for the time lost earlier in the season. Peas at several places have been exceptionally good, and all other vegetables, to my knowledge, are a fair crop. Potatoes are now suffering badly from disease.—J. IRONSIDE.

**Brechin Castle, Forfar.**—The fruit crops in the gardens here I consider a fair average. In the case of Apples, the majority carry a fair quantity, which promises well, and, having got plenty of rain lately, should swell to a useful size. Stirling Castle, Ecklinville, Beauty of Moray, Lane's Prince Albert, Lord Grosvenor, King of Pippins, and Warner's King are among our best croppers this season. Pears seem more plentiful than last season, but not more than an average crop. Both Apples and Pears are good and healthy. Plums are under, while Cherries are a good average. Peaches I do not grow of doors. Small fruits have been plentiful. Strawberries, although late in ripening, were a good crop and of fine quality; late sorts ripen late. Everything is much later this season.

Vegetables, although very slow to start in the earlier part of the summer, are now doing well, but there was little genial weather before the month of July; indeed, on July 8 the thermometer was down to freezing point. Peas have done well with shorter straw than we generally have. French Beans are good. Early-planted Cauliflower made little progress or else butted soon after planting, but later batches are turning in splendidly. Potatoes are a fine crop of good size and quality, and there is no appearance of disease.—WILLIAM McDOWALL.

**Tulloch Castle, N.B.**—In regard to fruit I beg to state that small fruit is very plentiful; grand crop all over. Cherries and Plums are only exceptions. Apples are a fair crop and abundant.

Vegetables (all kinds) were never better. The weather this season suits our soil, consequently vegetables have done extra well.—DAVID HUNTER.

**Lennox Castle, Lennoxtown.**—In the neighbourhood Apples and Pears are good. Plums very fine. Cherries of all kinds very good. Bush fruits, such as Gooseberries, Currants, and Red, White and Black Currants quite up to the average. Strawberries in the early part of the season were very good, but suffered badly from the wet weather at the end of the season.

Vegetables are a good average crop.—J. TINSLEY.

**The Gardens, The Glen, N.B.**—Small fruit are an abundant crop, except Gooseberries, which are a light crop in most places owing to frost when they were in flower. Apples on walls are a good crop; bushes and standards are thin. Cherries and Plums are very light. Victoria Plum only is good. Raspberries have been good and the fine. Strawberries, although late, are a heavy

## ORCHIDS.

### RHAMMATOPHYLLUM SPECIOSUM.

The flowering of this remarkable species in the collection of Sir T. Lawrence has been an event of considerable interest to Orchid growers in the country. A cut spike of this plant was exhibited at the Drill Hall meeting on August 24 on which occasion it was awarded a gold medal. It is truly a giant of its race. The plant has been grown for a number of years in the Burford collection, and has been a subject of special care to Mr. W. H. White, who has been rewarded for his pains in successfully rearing one of the rarest Orchids in cultivation. The growth of the plant varies from 7 feet to 10 feet long. There is no doubt that it is owing to its gigantic size this species does not get the attention it deserves. It is a native of the May Archipelago, and to illustrate its dimensions it is interesting to note particulars recorded by Mr. J. H. Veitch in "A Traveller's Notes" of a plant under Mr. Curtis's charge at P. Lang which was, with careful measurements, 12 feet in circumference, the stems from 6 feet to 7 feet long, the capsules with their stalks 7½ inches long, without them 5 inches, and 2 inches in diameter. One of the previous year's capsules, of which there were thirty, measured 7 feet long. The same writer also gives particulars of a still larger specimen in the Botanic Gardens, Java. This plant had forty-six capsules, some with twenty-four flowers open and many more buds to expand. The plant was 15 feet through, with stems 9 feet long. When it is considered that the individual flowers of Sir T. Lawrence's plant measured over 5 inches across, one cannot but agree with Mr. Veitch's remark that it must have been a splendid sight.

There are very few collections in this country that can afford accommodation for such plants. The plant in the Burford collection is accommodated at one end of a large span-roofed stove. There is also another large specimen in the

south-west corner of the Victoria tank at Kew, where it is thriving well, and should not be long, judging from its dimensions, before it flowers. This plant was imported by Messrs. F. Sander and Co., of St. Albans, in 1893, and was afterwards presented by them to the Royal Gardens. A particular characteristic of this species may be noted in the habit it has of producing numerous erect branching roots round the base. There was recently a smaller plant in Messrs. Charlesworth and Co.'s nurseries at Bradford which was developing the same characteristics. There does not appear to be any great difficulty in the cultivation of this species beyond the question of room. It requires hothouse treatment with a liberal supply of moisture during the growing season, with only sufficient shade to prevent the sun scorching it. It was introduced by Messrs. Loddiges, and flowered for the first time imperfectly in their Hackney nurseries in 1852. In 1859, in the collection of Mr. W. G. Farner, Ewell, Surrey, it flowered well. Later it bloomed with Mr. G. Staunton at Leigh Park and in the collection of the late Mr. J. Day. STELLIS.

**Cypripedium Lowi.**—This very distinct plant I noticed in flower this week, the bloom-spikes being over 2 feet in length, and bearing each four and five flowers. The dorsal sepal is yellowish lined below with purple, and has often a greenish area at the base, the light green petals being spotted with pale rosy-purple. It is a vigorous grower, liking a fairly large pot and plenty of heat and moisture.—R.

**Epidendrum vitellinum.**—This is now flowering in many collections, and is a useful Orchid for keeping up a display over a long season. It may be grown by anyone having a cool, moist house, and should be planted in pots, these being well drained, and a compost of good peat fibre and Sphagnum Moss used. Although possibly most of the plants now sold in this country are *E. v. majus*, there is no doubt that a much larger form than the majority of these exists. This should be looked out for among imported plants, for it is one of the very best red-flowering Orchids

in cultivation. It is a native of Mexico, and first flowered in England in 1839.

**Cattleya bicolor.**—Flowers of this *Cattleya* come from "S. M." for a name. It is an old species, not so showy as some, but very distinct. The growth is erect and the spikes contain a dozen or more flowers varying in size, the largest being about 4½ inches across. The sepals and petals are olive-brown, the lip crimson on the front and side lobes. It is a free-growing, easily-cultivated species requiring the usual *Cattleya* treatment, and flowers abundantly every season. The compost may consist of rough peat, Moss, and charcoal over good drainage, and medium-sized pots should be chosen. It is a native of Minas Geraes, in Brazil, whence it was introduced in 1838.

**Pleione lagenaria.**—This is one of the earliest of the genus to bloom, and one of the most useful. The flowers are each 3 inches across, the sepals and petals rosy lilac, the lip similar in ground colour, with many bright purple stripes, and a pretty wavy margin. It grows freely in an intermediate temperature, the young pseudo-bulbs being repotted early in spring in a compost consisting of fibrous loam, peat, and chopped Moss, the drainage coming in for especial attention. When the growth gets well away and the young roots are running freely in the new compost plenty of water is required at the roots, but during the early winter, after the leaves have fallen and the flowers are past, keep them quite dry. A light sunny house and a temperature that does not fall below 50° suit the plants well at this stage. *P. lagenaria* is one of the introductions of the late Mr. T. Lobl, who sent it to Messrs. Veitch in 1849.

**Trichosma suavis.**—A nice form of this pretty Orchid comes from a correspondent, the flowers having been apparently cut from a spike thrown well up, as they are not all crowded together in the way often seen. *T. suavis* is for this reason rather a disappointing Orchid, but when the growths are strong and healthy, and the compost well filled with roots, there is not much to complain of as a rule. It does well in a rough compost, with plenty of Sphagnum Moss and charcoal mixed with the best peat fibre. Owing to the fleshy nature of the roots, they cannot

thrive if the material is at all close. It is better not to let newly-imported plants flower during the first season or two, and until they have formed one set of growths, keep them in an intermediate house. After this they will thrive well in company with *Odontoglossums*. *T. suavis* is a native of the Khasia Hills, and was sent to Chatsworth in 1836.

**Cattleya Mendeli and C. Mossiae.**—I have plants of *Cattleya Mendeli* and *C. Mossiae* showing flower-sheaths at top of new bulb. Should they be kept dry now till spring, or will they be better kept growing longer? None of my Orchid books tell me what to do in this case. The plants seem quite strong and healthy.—A. R. W.

\* \* \* Keep the plants growing in the *Cattleya* house until the young pseudo-bulbs are quite made up, when a slight reduction in the water supply may be made. *C. Mendeli* should by now be finished, but *C. Mossiae*, flowering rather later, usually requires a little more time. They have both the same habit, viz., resting in sheath during the winter and making up the young growths after the flowers are past. In this way they differ from *C. labiata autumnalis* and *C. Gaskelliana*, which bloom on the current year's pseudo-bulbs. A good deal depends on how all these *Cattleyas* are watered during the winter. If well ripened by exposure to light during the autumn they will do with much less water than if green and succulent, but in no case must they be kept dry too long, this causing the bulbs to shrivel and the buds in consequence to start weakly in spring.—R.

#### CIRRHOPEALUMS.

This genus is rather a large one, but at least two-thirds of the species known to botanists are not in cultivation, or at all events are so little known, that few Orchid growers trouble about them. The structure of the blossoms is remarkable and beautiful, quite as much so as that of the nearly-related *Bulbophyllums*, and they are more useful than these from a garden point of view. They are all dwarf-growing plants, of a pseudo-bulbous habit, the bulbs springing from a scaly rhizome at various distances apart, and each bearing a single leaf. Anyone who has a house suiting *Dendrobies* well, should, with a little care, manage *Cirrhopetalums*. None of them like a great amount of compost, and I have seen excellent examples grown on blocks of Tree Fern stem suspended not far from the roof in a hot, moist house. The growths were large and healthy, and roots had been freely produced, almost entirely covering the blocks referred to. But this material is not always at hand, and fine plants may be grown in the small hanging pans so often recommended for dwarf Orchids. These may be almost filled with clean crocks, and, a suitable size having been chosen, the plants firmly fixed in position by dibbling in peat and Moss with a few bits of charcoal. Keep the plant high in the centre and the leads as far from the edge of the pan as possible. Plenty of light and air, an atmosphere saturated with moisture and abundance of heat are necessary while growth is active, and the strong buoyant atmosphere, created by shutting the house early on bright days and allowing the sun to shine full on the plants, is also much to their taste. The blinds of course would not be taken up before every part of the house had been thoroughly damped, as this causes a film of moisture on the glass that prevents any possibility of the foliage being burned. This must be continued as long as growth lasts, but when the pseudo-bulbs are well filled out, increase the ventilation and lessen the moisture both in the atmosphere and at the roots. I have likened their treatment to that for *Dendrobiums*, but during the winter they will not stand so much drying at the root as the long-bulbed deciduous

section of that favourite genus. The treatment they like is more that given to *D. aggregatum* or *D. Jenkinsi*, viz., just water enough to keep the foliage fresh and the pseudo-bulbs from shrivelling. Then many *Dendrobies* stand a very low temperature, but it is not safe to keep *Cirrhopetalums* much below 55° at night even when quite at rest. The species mentioned below are the most generally known, but several recently introduced kinds are not included.

**C. CUMINGI** is a dwarf-growing plant. The flower-spikes are very thin and wiry, and each bears on the top a circular umbel of about a dozen flowers. These have the outer segments of a reddish-purple, the lip similar in colour, and so lightly hinged that the least movement in the air sets it in motion. It is a native of the Philippine Islands, and was sent by Cuming to Messrs. Loddiges about 1840.

**C. MEDUSE** is a native of Singapore. In habit it is not unlike the last named, but the blossoms are very singular, the sepals being much elongated, and, owing to the large number of flowers, the umbel appears like a head with long, dishevelled hair. The colour is creamy white, with pinkish spots upon the segments. This was also introduced by the Messrs. Loddiges about the same time as the last-named.

**C. ORNATISSIMUM**, although a small grower, is a bright and effective plant when in flower. The spikes are each about 6 inches high and the flowers are brownish yellow, spotted and striped with purple. The lower segments are long and tail-like, the upper ones shorter, with a fringe of hair-like processes on each. This species is a native of the Himalayas, and was introduced in 1879.

**C. PICTURATUM** is perhaps as popular as any in the genus and a distinct kind, bearing many-flowered umbels upon a tall wiry scape. These are each about 2 inches in diameter, varying in colour, but usually some tint of greenish yellow, spotted with bright red. It was introduced many years ago from Moumein, and again lately by collectors in Burma.

**C. THOUARSI** produces small, smooth pseudo-bulbs at some distance apart on the rhizome, and one-sided racemes of flowers of a tawny orange colour, spotted with bright red. It comes from various parts of the Philippine Islands, and also as far west as Madagascar. It is named after a French botanist, who discovered it about 1836. R.

**Epidendrum cuspidatum.**—A fine plant of this useful and pretty old species was recently in flower at Melford Hall. It is one of the oldest kinds in this extensive and variable genus, having, it is said, been introduced late in the last century from the West Indies. In habit it very closely resembles a *Cattleya* of one of the dwarf *labiata* kinds; in fact, it has often been imported with them. The spikes bear about half a dozen flowers, the sepals and petals of which are nankeen-yellow with a bronzy reverse, the lip usually pure white and deeply fringed. Its culture is not difficult, the plants requiring a medium sized pot with a nice open compost of good texture. The drainage must be well attended to, and the plants elevated only slightly above the rims. Place the plants in a light, almost unshaded, part of the *Cattleya* house where they can obtain abundance of fresh air. During the time growth is active, and until the flowers are past, keep the roots nicely moist, but as soon as possible afterwards reduce the water supply and place the plants in a cooler and very airy house, where they will be entirely at rest until the spring. So treated, it flowers annually and freely, but if allowed to grow during the winter months it is more shy.

**Odontoglossum tripudians.**—There are few more variable *Odontoglossums* than this, some of the best of them ranking almost as high as the better-known *O. triumphans* so far as beauty and usefulness go. In habit it resembles the *crispum* set, and the flowers are similarly produced, viz., on long arching scapes from the base of the

pseudo-bulbs. In colour the typical form has yellow segments, more or less blotched chestnut-brown, the lip being sometimes yellow (*xanthoglossum*) or white (*leucoglossum*), variably blotched with crimson or brown. It comes the centre of the *Odontoglossum* region in Grenada at a considerable elevation, and its treatment does not differ materially from that of *crispum* and *Pescatorei* forms with which associated in a wild state. Grow it as strong as possible in a cool, moist, and shady house until all these plants delight in. During winter must be kept as near the light as possible, never allowed to remain dry at the root for any length of time. The pots used should be large enough to show a narrow margin all round the plant, and an inch of compost is sufficient for medium-sized plants. It was discovered by late M. Warszewicz in 1849, and has since been imported by many of the principal growers in this country and on the Continent.

#### ONCIDIUM GARDNERI.

The flowers of this *Oncidium* are handsome, lasting, and I noted it this week thriving in a house with the coolest section of *Odontoglossums*. I have found it to succeed better with rather warmth, such as *O. Forbesi* and one or two of the *crispum* set like, but the instance above shows it is not a very fastidious species. In habit it is strong, the pseudo-bulbs, each 3 inches high, dark bronzy green, with fine dark green leaves, occurring at intervals on a creeping rhizome. The spikes are long and branching; the flowers, each about 2 inches across, have chestnut-brown sepals and petals margined with bright yellow. The lip is yellow, the brown spots being principally disposed around the margin. A mistake often made in its culture is growing it on a low stage away from the light, and in a deep, poorly-drained, pot and a thick compost. A much more satisfactory in shallow baskets filled with drainage or on teak rafts, either which should be suspended as close as possible to the roof-glass in a position where it can have ample light without being exactly exposed to the full glare of the sun. This, with the constant circulation of air that usually goes on in such a position, causes a hard, solid growth. In fixing the plants on the rafts thin strips of cork may be cut and laid across the rhizomes, a wire being passed over them and brought between the rods, where it can be fastened. If the plants are newly imported only partly established, no compost need be used for the first year, but a little *Sphagnum* must be worked in for established plants. The roots are strong and fairly large, and disclose medium, but if plenty of air reaches through the rods of the basket or raft they will be healthy and long-lived. For baskets about 4 inches of compost suffices, the remainder of the depth being filled with crocks. Even more is necessary here in fixing, for the roots can get a hold if the plant is so loosely fixed that the basket about when the basket is moved. A close observation of the roots is the best guide as to the quantity of water needed, these being frequently very active while the spikes are forming. Syringing overhead is not desirable as a rule, most likely time for it to do good being at the time of the hot, dry days in summer. Plants that are growing freely must be watered daily, but when at rest keep the roots well on the side, only watering sufficiently to keep them in good order. *O. Gardneri* grows naturally at great elevations on the Organ Mountains, and was introduced in 1843.

**Cattleya Schofieldiana.**—In its best form this is one of the most striking of *Cattleyas*, the section to which it belongs, the yellow sepals, prettily spotted with crimson and purple, having a very fine effect when arranged with suitable greenery. Botanically it

most *C. granulosa*; indeed, some botanists treat it as a variety of this species, but it is far preferable to some of the older varieties of the kind. It is an erect-growing kind, each pseudobulb bearing a pair of dark green leaves, from between which spring the flower-spikes, the individual blooms being about 4 inches across. *C. Schfieldiana* may be grown in the usual Cattleya temperature, a light and airy position being best for it, where it is only shaded from the direct rays of the sun. During the early part of the season it should be liberally treated and grown as thickly as possible, and after the flowers are kept a little on the dry side to cause it to ripen. Very little trouble will be found in keeping its annual periods of growth and rest. It likes a rough open material and not too much potting, the young growths being kept as near the surface as possible. It first flowered in 1882 with Mr. W. L. Schofield, of Manchester.

NOTES OF THE WEEK.

*Fucus speciosus* is now very beautiful in the rock garden, where the dark-coloured blossoms are very striking, though appearing to greater advantage perhaps when mingling with the pure white form of the Meadow Saffron (*Colechicum autumnale album*).

*Primula Poissoni* is an interesting as well as a showy flowering species with blossoms of a lilac shade, and growing quite a foot high. Individually, however, the flowers are not large, and for this reason the plants should be set rather closely together and in groups of about a score.

*Phlox Cochineal*.—A very fine and showy variety of a crimson-scarlet hue, the blossoms being well lifted up and supported on stout footstalks. Another excellent kind, equally free and striking, is the General Gordon, of a most brilliant shade of vermillion-scarlet. Both are planted at Kew with a view to their effect on the grass.

*Hydrangea Novi-Belgii densus*.—Despite the fact that this is one of the most free-flowering, as well as among the finest of the blue kinds, it is, nevertheless, rather formal, the great mass of blossom appearing all on one level at about 3 feet high. A different aspect may be obtained by planting such on a somewhat rugged or uneven surface.

*Artemisia arborescens*.—Even with a wealth of blossom in the rock garden this is a showy plant by reason of its distinct appearance. At the present time, however, it is perhaps more conspicuous than it appeared a short time since. A catal bush some 2 feet or 3 feet high is very striking when the silvery hue of the leaves is at its best.

*Asperula sitchense*.—This tall and extremely elegant North American plant is now very fine in my garden. It is very striking at the back of a herbaceous border, its curious cream-white spikes of flowers being uncommonly numerous. The plant is of strong habit and a very hardy perennial.—E. E. ST. PAUL, *The Woods, Ripon*.

*Colechicum autumnale album plenum*—It is very curious to note how slowly some of the best plants appear to increase. The above is a case in point, a plant above the average in merit, and still, as it was thirty years ago, very scarce. A good clump of this on a grassy slope where the soil has been prepared for it is not easily to be often if once seen in good flower.

*Geranium aurantiacum*.—Though quite an early grown plant in almost any position, there is a rather early value in this species when planted on the sunny banks or similar places, especially where the plants get the early morning sun. In full sun the plant blooms profusely for a long season, and the colour also is distinct. The flowers quickly close when the warmth of the sun is at its best.

*Gegetes signata pumila*.—As an edging or carpet to taller things this is a very useful

plant, that flowers profusely for a long time. Shorn of its pretty blossoms, the plant has been largely used in carpet bedding in the past because of the neat and pleasing habit. There is a much wider field open for such useful things when allowed to grow and flower naturally, as they certainly should.

*Hibiscus moscheutos*.—A very distinct species from North America bearing this name is now flowering near the entrance to the Orchid house at Kew. The plant is quite erect and between 5 feet and 6 feet high, freely branched from the base, and producing its creamy-yellow blossoms profusely on the several branches. The blossoms are large and bell-shaped, and in this instance quite self-coloured, which is not usual.

*Anemone Whirlwind*.—The earliest flowers of this were not particularly good, but during the past three weeks the plant has been quite a feature in Messrs. Barr's Ditton Nurseries. Essentially an autumn flower, its blossoms are now very fine, rejoicing in the cooler nights and days and lasting a long time in capital condition. Quite near, a large group of the pink variety *A. j. elegans* is also charming, the blossoms very large and handsome.

*Linum narbonneuse*.—This is still laden with its lovely blue flowers, and though somewhat frail and delicate-looking when only a single plant is seen, it makes a most delightful object when freely grouped either in the border or the rock garden. In whatever position it is planted, the best results are secured when the plant is allowed to grow naturally. In this way half a dozen plants make a really charming and graceful group, and the bright sky-blue blossoms a fair picture.

*Hippeastrum aulicum*.—If lacking some of the fine form, massive appearance, and rich colour of the newer hybrids of this race, this species is at least striking and effective. More than this, it possesses an additional value by reason of its usually flowering in the autumn at a time when not many species are in bloom. The scape is fully 2 feet high and the finely coloured flowers somewhat numerous from large bulbs. Some plants of this Brazilian kind are now flowering at Kew.

*Gazania nivea latiflora*.—This is a very distinct and beautiful plant, still flowering profusely at Kew. The flowers are whitish in colour, perhaps more cream coloured even than this, while the florets are broad and imbricated. The plant is regarded as fairly hardy, and, judging by the many buds still appearing, would make a fine addition to autumn flowers for the warmer positions in the rock garden. A good sized patch of its handsome flowers would make a quite unique display at this season.

*Coreopsis grandiflora*.—Judging by the fine display of its blossoms, and also their size individually, as seen in Messrs. Barr's nursery recently, one would imagine that seedlings were flowering for the first time. But in place of this the plants have been blooming continuously for fully three months past and are still giving splendid blossoms. The thin wiry stems of this plant are of great service when the flowers are used for cutting, while in the border it is one of the most showy of plants still in bloom.

*Phlox amœna*.—Among the dwarf Phloxes, that is the true alpine forms and other allied kinds, this pretty species should always be freely grown if only for its value in spring and autumn. Naturally enough, the finest display is in spring, but where the plants are divided and replanted after this flowering it frequently happens that quite a rich display is secured in the early autumn. At the latter named date the rock garden is by no means gay, and this easily grown plant should in no wise be lost sight of. Its free growth and abundant flowering at all times render it a desirable species for the rock garden. In any position deep and fairly rich soil is always appreciated.

*Androsace lanuginosa*.—Both the type and the variety known as *oculata* still give many

heads of beautiful and pleasing blossoms. In the rock garden the plant is usually most happy, though in many gardens the inclination is to give far too little soil for the support of these dwarf alpine, and in this instance the plants never appear to break freely into growth. What may be accomplished with such lovely alpine as this may be gathered from an illustration in THE GARDEN at page 257. Rarely indeed does this species without pinching or pruning form so dense a covering of its soft silken leaves and numerous heads of blossom. Evidently soil and position have suited it, and I would like to know the exact position occupied by so fine a tuft.—E. J.

FLOWER GARDEN.

NARCISSUS CALATHINUS.

MUCH has been written about this pretty little plant, although great confusion prevails still on the subject, so much so, that, according to the "Index Kewensis," *Narcissus calathinus* does not exist at all, whilst there are several members of the genus bearing such a name. Even Linné (spec. plant, ed. 2, vol. i., p. 347) says *Narcissus calathinus* is found in Southern Europe and in Orient, but we know that at that time Linné was not very particular about the true habitat of the plants, and that in several instances he assigned them the locality of the correspondent who sent them to him. Delarbre in 1800 (*Flor. Auver.*, vol. ii., p. 591) writes: "*Narcissus calathinus* is the same as *N. heminalis* (Schult.), which is plentiful at Orcival, in the mountainous districts of Auvergne, and at the Mont d'Or." Loiseleur Delongchamps ("Recherches Botaniques sur les Narcisses Indigènes," p. 33, Paris, 1810) writes: "*Narcissus calathinus* (Linné) is found in the neighbourhood of Montpellier and Avignon, and is synonymous with *Narcissus dubius* (Gouan)"; whilst at page 42 he says, "*Narcissus reflexus* (Nob.) is native in the Glenans," and there he gives probably the first accurate description of the plant, from a sample received from M. Bonnemaizon at Quimper; but in "*Flora Gallica*," p. 723, he says, "*Narcissus calathinus* (Linné) is native of the Glenans," which is in contradiction with the first assertion. However, on his authority the name *N. reflexus* was accepted. Loureiro ("*Flora Lusitania*," vol. i., p. 551) writes: "*Narcissus reflexus* (Loiseleur) is nearly the same as *N. odoratus* (Linné) and is found in mountainous districts at Gerez, near Amaranth. According to "*Index Kewensis*," this is synonymous with *N. triandrus* (Linné). *Narcissus calathinus*, described by Loureiro, is very uncommon; he says it is cultivated in gardens and found in a wild state in mountainous localities of Unhaes and Loriza, and is very similar to *N. odoratus* and *N. tazetta*. Wilkomm and Lang ("*Prodromus Flora Hispanica*," vol. i., p. 153) say: "*Narcissus calathinus* (Linné), synonym *Narcissus reflexus* (Loisel. non Brotero), is much like *N. juncifolius* (Lag.), and is found wild at Goditano, a Spanish town"; but they add, "The true species is found in *Gallia armoracia*." According to "*Index Kewensis*," this Spanish plant is *Narcissus triandrus* (Linné). Redouté, who was a celebrated painter and plant lover, gave two coloured plates of this *Narcissus*. His paintings are generally considered strictly made from Nature, but either these figures were drawn from memory or from wrong specimens, they are not accurate, and do not represent the true *Narcissus calathinus*. In his "*Liliacées*," vol. iii., t. 177, the figure shows a bulb too large, wrongly shaped, the leaves erect and lorate, the flower citron-yellow,

and the corona too short. He adds, the drawing was made from a plant collected in the Glenans, and given to him by M. Bonnemaison, of Quimper; but this must be an error, as I am sure that such a plant has never existed in the Glenans. The second figure (vol. vii., t. 410), given as a variety of the former, is more natural and almost correct, excepting the colour of the flowers and the erect leaves.

Above particulars show the great confusion which has always existed respecting this plant, and I believe that the plant has been seen growing in its wild state by the three late botanists only, viz., Messrs. Bonnemaison, of Quimper, Blanchard, of Brest, and Lloyd, of Nantes.

In conclusion, the following names and synonyms—*Narcissus calathinus*, Delarbre; *N. c.*, Lin. ex. Wilkomm and Lang; *N. c.*, Lin. ex. Redouté, t. 177; *N. c.*, Lin. ex. Redouté, t. 410; *N. c.*, Loureiro; *N. c.*, Loiseleur, all which have been attributed to the true *N. calathinus*—are wrong or erroneous as regards either description, figure or habitat, and consequently ought to be discarded, as well as *Narcissus calathinus odoratus* and *N. c. albus* of catalogues, which can only lead to confusion, and the plant known under the name of *Narcissus calathinus*, Lin.—synonyms, *N. reflexus* (Loisel.), *N. triandrus calathinus* (Hort.), *Ganymedex reflexus* (Herb.).

The true *Narcissus calathinus* (Lin.) has some affinity with the Spanish *N. triandrus* (Lin.), which is often mistaken or sold for it, but the specific characters are so distinct that no mistake is possible. The former has the cup or corona always as long as the reflexed perianth segments, therefore belongs to the group *Magni-coronati*, whilst the latter has the corona always shorter than the perianth, and consequently is of the *Medii-coronati* group; besides, the foliage is more erect and broader in the Spanish plant. The true *Narcissus calathinus* (Lin.) is indigenous in the Islands of the Glenans, about thirty miles off the coast of Finisterre. It grows there on a small granitic island about 100 yards across amongst grasses, and in the interstices of the rocks at an altitude of 6 yards to 10 yards above the sea level, in a sloping spot, protected from the north and east winds; the soil is a mixture of half very light peat and half very fine sea-sand; it has never been found elsewhere. It seems strange, and no one can account for such a small plant being localised on a similar wild spot, but it must be observed that on the west coast of France, a large area of the sea, from Cape Finisterre to the Isle of Noirmoutiers, on a width of about forty miles, is only a few yards deep, and full of rocks emerging above water, which indicates that in remote times this portion of the sea was above water and attached to the French continent, and probably at that time *N. calathinus* was more plentiful and widely spread, unless bulbs of *N. triandrus* might have been accidentally imported into the Glenans in the same manner as the Guernsey Lily, and that the plant, owing to the special soil and climate, has assumed its distinct specific characters; but now, in spite of all controversy, the plant must be considered as a distinct species. *Narcissus calathinus* has a very small round or pear-shaped bulb of the size of a large Snowdrop, with a short neck and brown tunics; the leaves, three or four in number, are dark shining green, very narrow, channelled with two nerves above, erect when appearing, then spreading on the ground, 10 inches to 16 inches long; the stem is erect, terete, slender, 8 inches to 15 inches long, bearing one or two, rarely three, nodding

flowers of self ivory-white colour, produced from an erect spathe; the perianth is formed of six lanceolate, perfectly reflexed segments, the three outer a little larger; the cup or corona is nearly cylindrical, faintly six-lobed on the edge, always as long as the perianth segments (hardly 1 inch); the stamens shorter than the corona, but the style protruding; the flowers are produced about April 20, and last two or three weeks. It is one of the prettiest members of the genus, and may be considered a perfect gem owing to its scarcity; but one must be very careful when buying such a rare plant to get the true species, as bulbs of spurious plants are often sold for it, which has caused many disappointments.

#### CULTURE.

Although this plant has been considered somewhat difficult to grow, it is very easily managed and increased under proper treatment. I have always found that after one or two years' cultivation my collected bulbs greatly improved both in size and vigour. It dislikes moisture more than cold, as a temperature of 10° Fahr. will not destroy it if slightly protected. The best time to plant is September. The best soil to use is a mixture of one part of sandy peat, one part of well decayed leaf mould, and two parts of fine sand. Select a warm, sunny spot, at the foot of a south wall if possible, protected from north and east winds, drain thoroughly, and plant the bulbs 2½ inches deep and 4 inches or 5 inches apart. In winter protect with dry leaves, cocoa fibre, or other material, or cover with a frame until sharp frosts are over; never give any water. If necessary, the bulbs may be lifted at the end of June, but it is safer to leave them undisturbed for years, allowing them to get as dry as possible in summer. In pots plant from four to six bulbs in a well-drained 5-inch pot 2 inches deep, using the same mixture as above. Winter under frame, keeping almost dry until the leaves appear, and never give any artificial heat. When the flowers are over plunge the pots in a sunny border until the soil is quite dry, and do not give any water. This plant likes perfect drainage, sandy soil, and dryness, although I have grown it for several years in pure granitic light soil with perfect success. Sometimes it is grown as a hardy alpine. This plant is easily increased by division of the bulbs and by seeds, which must be sown as soon as ripe in pans, using the same mixture as above. They germinate in two or three weeks. Winter the seedlings in a frost-free frame. The following summer these seedlings may be transplanted or left alone. The strongest will flower the third year. It hybridises well with other sorts.

Unfortunately, the plant is disappearing fast from its native habitat owing to the depredations of fishermen, who lift these plants when they are in bloom with a ball of earth, thus destroying a quantity of small ones. Last winter, during disastrous tempests, the sea ran several times over the island; the soil got thoroughly impregnated with sea water, and a quantity of bulbs was destroyed.

A few years ago I planted some of these bulbs in another part of the Glenans. They have succeeded admirably. This season I have rented the small island where they originally grew, and landing or collecting being strictly forbidden, I trust, in leaving them alone for a few years, the stock will increase sufficiently to satisfy every amateur. D. GUIHENEUF.

48, Rue St. Merri, Paris.

**Carnation The Burn Pink** (pp. 190 and 238).—This Carnation was raised by William

Lawie about twenty-five years ago. So far as I am correct; the rest of his story is erroneous. The Carnation was never named Maggie (or Annie) Lawie until long after William Lawie's death, and the name was never approved by the chiefly concerned, including the present gardener at The Burn, a son of William Lawie. The only legitimate name for this Carnation is The Burn Pink, and this has been acknowledged by the Carnation Society, whilst most growers have been very civil on the mistake being brought to their notice, the only exception being the party referred to by "M." as an "enterprising nurseman," who procured the cuttings unauthorised and advertised the variety as "Duchess of Fife," quite new, 2s. 6d. per plant.—C.

#### VIOLET MARIE LOUISE DISEASED.

TO THE EDITOR OF THE GARDEN.

SIR,—In the issue of THE GARDEN of May 1900, a note of mine appeared respecting the late Violet, which had been a failure here during the previous winter owing to what I presumed was a disease, and soliciting advice and information respecting it, also a remedy, whether I could safely rely on increasing stock from what remained of the affected plants. Several of your correspondents kindly responded to my inquiries, to whom my sincere thanks are tendered. I am very pleased to learn the disease is unknown to most of them. Mr. Crawford May 15 writes to the effect that the culture treatment may be at fault, or some unsuitable ingredient in the soil may be accountable for their deplorable state, and strongly advised obtaining runners from a fresh source. In following week's issue "W. S.," who sympathises with me, as he had a visitation apparently the same malady some years ago, remedy also being a fresh stock. On the same page "D. T. F." attributes it to the presence of gas in the frame from over-fermentation, a carbonic atmosphere, &c., and agrees with the preceding correspondents as to the desirability of an exchange of stock. Before most of the notes alluded to appeared I had planted out my stock. Probably my cultural treatment may be faulty in some particulars, thus causing failure, but I followed on similar lines to those I had practised here for eight years, annually resulting in abundant bloom tending over a long season. I do not winter them on any heating material, but in low pits 1 foot above the level of the soil, having ample drainage and the foliage almost touching the glass. They get no coddling or artificial heat, the lights being placed over them in wet or frosty weather and protected when necessary with Bracken mats. My stock has been but partly replenished. A generous friend kindly supplied me with 1000 rooted runners and old plants. As this number is not quite half my stock (4000), I made up the remainder with the best available of my old stock, which now, however, I believe to be a mistake. Both lots have received exactly the same summer treatment, but anyone can see a difference at a glance between the fresh and the old, for the latter lacks the luxuriance and deep green foliage of the former. As regards bloom, both are about equal in this respect—abundant and commenced flowering the latter part of July. The whole are now being put into pits, but I fully expect the collapse of the diseased lot this winter and have prepared for next year's stock from new-comers, as I trust they will be free from the dreadful malady. The blooms and pale leaves sent you are from the old stock.—J. ROBERT Tan-y-bulch.

\* \* \* As far as the flowers are concerned, we can see very little difference between the two lots, both being excellent, but in the case of the foliage the disease is quite visible, the leaves being pale and flimsy. We should be glad to know how these pale-leaved plants come through the winter.—Ed.

## IRIS GATESI IN SURREY.

ENCLOSE a photograph of *Iris Gatesi* which I think may interest you. The plant was grown on a raised bed of pure road scrapings, the roads being of a sandy gravel. *Iris Susiana* does well in the same position. I have almost entirely carried out Mr. Ewbank's suggestions as to the cultivation of these plants in *THE GARDEN*, vol. xliii., p. 395.

NORMAN RUSHWORTH.

Beechfield, Walton-on-Thames.

*Begonia semperflorens*.—All soils and situations are not suitable to the outdoor cultivation

cient room to develop, they grow into nice bushy plants some 12 inches to 15 inches in height, the different shades of flowers showing to great advantage against the highly-coloured foliage. They are seen at their best on a dwarf carpet of *Mesembryanthemum*, *Manglesi Geranium* pegged and kept close, or dwarf *Ageratum*. They are very easily propagated from cuttings, by division and from seed, and can be recommended for all gardens where there is a quantity of small beds.—E. B.

*Eceremocarpus seaber*.—The hardiness of this plant, judging from some recent notes, is not generally recognised. As a proof that it is thoroughly hardy, I may say that it came safely through the very severe weather of the first

the *Belladonna Lily* which is flowering at Kew, and which far eclipses any variety I have previously seen. It differs from the ordinary kind in the flower-spike being nearly double the height and a great deal stouter, the blooms much richer in colour and far more numerous, as from twenty to thirty blossoms are borne in one head or umbel. It is certainly a really magnificent variety, but as far as I know it cannot be obtained from nurserymen, and it will doubtless be years before a stock can be worked up. Still, it is one of those good things that will be appreciated by everyone.—H. P.

## THE ACANTHUSES.

I was very much interested in the excellent article on these handsome fine-foliaged and flowering plants in *THE GARDEN*, page 239. Nothing can be finer than these when well placed. We generally find far too much bare stonework, bases of vases or columns, or formal terrace walls and buttresses that would be all the better if garnished by the glossy foliage of the *Acanthuses*. Near rocks or stones or sunny walls they seem peculiarly at home, and they all have a peculiar knack of fitting themselves to their formal surroundings. In the College Park at Dublin I have planted all the kinds, and they are thriving even in dry places under overhead balconies and in gravel walks near to walls and buildings, but in such extensive places one can never, as it seems to me, have enough of them. Apart altogether from their own peculiar grace and beauty, the *Acanthus* forms a foil for lighter and brighter flowers, and being evergreen in sheltered sunny nooks and corners, the noble leafage is most suitable for flower vases at a season when foliage is not too abundant. Their propagation is of the easiest kind. Large clumps are readily divided, and I prefer to do this in May or June and during wet weather, when scarcely any check is experienced by the plants themselves. In dividing great masses the thick, carrot-like roots are all collected separately and laid or planted 6 inches deep or so in a broad trench under a warm wall. So treated every bit soon grows and forms a plant before the winter.

In thanking "E. J." for his appreciative notice of these noble garden plants, I send you specimens in flower of the rare and beautiful *A. spinosissimus*, which is much admired here, as it grows on a cinder walk at the foot of a big Ash tree, where it flowers every year. I see Mr. Nicholson gives nine or ten species or varieties and synonyms, but those mentioned by "E. J." are, so far as now known, the best for garden uses. If one kind only be grown, then let it be *A. mollis latifolius*, which has leaves 5 feet high and spikes over 6 feet high when well grown, as at St. Anne's, Clontarf, Co. Dublin, a place that may fairly boast of the finest herbaceous borders in Ireland, even if not in Europe as well. In "Index Kewensis" sixty species and synonyms are given under *Acanthus*. The probabilities are that as in the gigantic *Gunneras*, so also in this genus *Acanthus* there are at least some, if not many, fine species or wild forms worthy of introduction to our gardens. But the epoch of hardy plant collecting has never been fulfilled, and even in the 19th century hardy plants are collected in a desultory and amateurish kind of way.

Will no lover and cultivator of hardy flowers send a good collector to the highlands of the Caucasus, to the higher mountains of New Zealand, to the great snow-capped ranges of N. India, or to the cloud-capped Andes and Cordilleras of Chili and Peru? For the species and wild forms of *Acanthus* at least this would not be necessary, since with one or two exceptions they are S. European or W. Asian kinds. As "doctors are said to differ," so also do authorities as to the colour of the flowers of the rare old *A. spinosissimus* I send you to-day. But as we all know, authorities are often like the proverbial sheep; they follow each other, as can be proven by the copying not only of the truth, but even of clerical

*Iris Gatesi* in Mr. Norman Rushworth's garden at Beechfield, Walton-on-Thames.

uberous *Begonias*; the plants seem to barely exist, instead of making the free, vigorous growth that is indispensable towards a good display, and for this reason the *sempervirens* type is very acceptable, as being invariably thoroughly at home and helping to make bright and attractive beds. Some years ago the small-flowered tuberous *Begonia* *Worthiana* was a first-rate outdoor summer plant. It was, however, one of the first to succumb to the *Begonia* disease, and for the last six or seven years I have been unable to do anything with it. Certainly the different forms of *sempervirens* do not attain to the dimensions of the more vigorous of the tuberous section, and are consequently more suited for smaller beds. Given, however, suffi-

months of 1895 when the thermometer fell 7° below zero. It has been in the same position for about seven years now, and has never had the slightest protection in any form. Seedlings come up by the hundred every spring; indeed, one of the greatest faults the plant has is its freedom in seeding, which makes it necessary to remove the pods every few days during the late summer months. I find the plant a thoroughly vigorous and showy climber.—J. C. T.

*Amaryllis Belladonna* at Kew.—A week or two ago there was a note in *THE GARDEN* calling attention to the grand display of this beautiful bulbous plant to be seen at Kew. In the note just alluded to no mention is made of a form of

or printers' errors. Nearly all the books state that the flowers of *A. spinosissimus* or Hedgehog *Acanthus* are rosy in colour. Those sent to you are sometimes nearly pure white; indeed, I know of no other *Acanthus* having white flowers.

F. W. BURBIDGE.

#### DOUBLE VIOLETS FROM CUTTINGS.

ALTHOUGH a few growers annually raise their stock of such double Violets as Marie Louise, Neapolitan, and Comte de Brazza from cuttings, the majority of gardeners still continue the old practice of planting out ordinary runners which the parent plants produce while yet in their winter quarters in frames and pits. The latter plan I still believe to be the best from a quantity point of view, plants raised from cuttings and kept to a single crown producing fewer, though finer blooms. About the superior size and quality of blooms grown on the latter class of plants I have not the slightest doubt, some of the very best I have seen being at Blickling Hall. Mr. Sawyer at Elston Hall, near Newark, also grows magnificent Violets, and I fancy this method of culture suits the old Neapolitan even better than Marie Louise. The plan at Elston is to take off the cuttings in March, pricking them into light, gritty compost in a frame standing on a mild hotbed, and as soon as rooting takes place air is increased and the plants gradually exposed to the atmosphere. By the beginning of May they are in good condition for removal to their summer quarters, and when growth commences in earnest, a good stout crown is selected, all others being removed and all runners closely cut off. The foliage under this treatment is large, dark coloured and leathery, provided of course that watering is properly attended to to keep down spider. Violets are often, through press of work, left out in borders later in autumn than they should be, consequently do not get established in their new quarters early enough. This makes all the difference to the supply of bloom during winter. As a rule, particularly in midland and northern districts, the end of September, or at the latest first week in October, is late enough for placing the plants in frames.

J. CRAWFORD.

**Myrtles in tubs.**—In reference to Mr. Easter's remarks in a recent issue about Myrtles in tubs, we have here four growing in square tubs, their height being 12 feet from the bottom of the tubs, and the plants are 10 feet through. Two of them have been in full bloom for the past three weeks, and being covered with their lovely white flowers, have been much admired by all who have seen them; the other two are just coming into flower at time of writing. They are put to the same use as Mr. Easter's during the summer months, being stood by the side of a path with Orange trees in the same sort of tubs, and have large vases of Geraniums between them. The greatest drawback to such plants is the housing of them during the winter months, as they take more room than many can find for them.—H. BEAN, *Betteshanger Park, Dorset.*

**The Snapdragon.**—Plants of *Antirrhinum* raised from seeds sown at the end of last summer and planted out in the spring quickly grew into size, and gave an abundance of bloom from the main shoots. Then came the summer spell of dry weather, when the drought so affected them that they ceased to flower for a short time, but with the rain came an abundance of side shoots, and they are now producing spikes of bloom most abundantly. I have bushes which are 3 feet through and bearing dozens of spikes of bright flowers. They supply plenty of cut bloom just as summer is gliding into autumn and when we most need it. I do not expect to keep the plants through the winter, and do not desire to do so, as I have young ones to take their place. The early spring-sown *Antirrhinum* are now getting into fine flower. The great majority of these will pass

through the winter in safety, unless the weather is unusually severe.—R. D.

**Scarlet Lobelias.**—It is unfortunate, so far as these beautiful hardy flowers are concerned, that they do not produce seed in this country. There are the flowers and organs of fertility, but apparently pollen is lacking. Were they seed-producers, how rapidly might even the beautiful varieties that we have now be improved and varied in colour, whilst how much more easily might plants be increased. I have just been admiring that lovely variety *Carmine Gem*, and although there are already evidences of new growths from the roots, the hoped-for seed produce is not found. It is interesting to find that these plants are again so popular in gardens. The *Victoria* variety I saw in several gardens recently, though perhaps nowhere in finer form than at Bickton, Devonshire, where Mr. Mayne uses it largely, especially for dotting in beds of silvery *Pelargoniums*. He has plants that carry half a dozen flower-stems, and so grown it is very effective. Once a good stock is obtained, of course propagation may go on rapidly by division of root growths. In cold or wet soils it is wise to lift the roots and get them into boxes of soil or large pots singly, just keeping them cool and moist, without unduly exciting growth or over-watering. So far down as Devonshire doubtless the plants are perfectly safe during the winter, and even may stand very well higher up, but ordinarily it is best to have them under cover of some sort for the winter. Seed can be produced on the Continent, but it is rather dear. Still, good seed sown properly should always well repay the outlay, as some diversity in colouring may be hoped for.—A. D.

#### NOTES ON HARDY PLANTS.

**Viola obliqua.**—Why is not this species much more used where good flowers (practically true Violets) are wanted. Nothing as a plant could be harder, and it can take care of itself for half a dozen years or more without any cultural attentions. This is soon explained, as its root habit is quite distinct. The roots are a sort of half fleshy rhizome and half tuberous or knobby. Thus the plant can be found after many years exactly at the same place where it was originally planted, *i.e.*, there are no bounding stolons and no smothering of neighbouring flowers. The leaves are each 3 inches to 6 inches across, with stalks over a foot long.

**Polygonatum verticillatum.**—Now that the tops of this tall and distinct Solomon's Seal are turning a bright yellow, with the leaves still held at right angles with the almost erect stout stems, the bright scarlet berries (also just at their best colour) are best displayed for autumn effect. It may be stated that the leaves are in more or less distant whorls, as in the case of the Panther Lilies, and not in pairs, wing-fashion, as on most of the genus, and the berries being in whorls, too, immediately at the junction of leaves with stem, their effect just now is that of a string or ring of coral beads loosely hung round the stem at every set or whorl of foliage; stature 3 feet; a splendid waterside plant.

**The Skunk Cabbage.**—It appears this is not much known, and this name is not likely to lead to a correct conception of what the plant is really like. As the plant is now being more employed in company with other bog subjects a note may be of use. It is really as beautiful as it is singular, but it is no Cabbage as we know Cabbages, but an Aroid, called *Symplocarpus fetidus*. It has big leaders of 1 foot to 2 feet, and a robust habit when near water. Culturally, it may be termed a bog plant, and prefers peat. It is perfectly hardy and attractive to look upon when seen in a mass and doing well, but it should not be placed too near a path owing to the fetid odour implied by its common and scientific names.

**Primula Forbesi.**—This charming species has been flowering all summer in a moist position, but never have its flowers been so large or so deep in colour as now. Plants stood several degrees of

frost without harm in very sandy soil, but I have not yet tried it in the open all winter. Anyhow it flourishes and flowers outside all summer and nearly the end of the year plunged in damp cocoa fibre or short rotten peat.

**Dianthus Knappii.**—I venture a further note on this, as it seems to be quite a late bloomer. The flowers are larger and of a richer yellow than earlier in the season. Its hardiness is beyond doubt, and what is equally a good feature, it robust without being coarse.

**Pheasant Grass** (*Opera arundinaria*).—This most beautiful out-of-doors now. It is, however one of those things to be seen to be known. Scarcely can one do justice in words to the grass part of the plant even by the aid of the name which so justly hints at the rich colours, but is impossible to convey an idea of the loveliness of the sprays of bloom, so long and elegant. The grass should be noted by all who are fond of choice material for vase decoration. I have tried it the open, it stood last winter without the loss of a single plant, which is more than I can say for batch kept in a cool greenhouse. I could imagine nothing more seasonable and decorative as a tall plant.

J. WOOD.

Woodville, Kirkstall.

#### TAKING UP AND STORING DAHLIA ROOTS.

SINCE the mild weather during the two last weeks in September set in, Dahlia plants of all types have made a free growth and bloomed freely. There is no knowing how soon a frost may come. Last year the plants stood unharmed until about the middle of October, the weather being mild and open, as at present. The Dahlia is a tender plant and very susceptible to frost. As soon as the young growths become blackened by the frost, rapid decay sets in, and in two or three days most the main stalk should be cut away to within 9 inches or so of the ground. If the weather keeps fairly open, the roots may remain in the ground for a time longer, and then advantage should be taken of a sunny, drying day to cut the roots up. By using a pointed stick, get rid of a good deal of the soil adhering to the roots, and then turn them upside down on a garden mat, so that any moisture can drain from the hollow part of the stem, and also dry out of the soil remaining on the tubers. If left in the open for a night or two, they should be covered securely from harm by frost.

Another point worth attention is to see that every variety is securely named. It is usual with many growers to tie to the top of the stake supporting the main stem of the plant a wooden label with the name of the variety upon it. The label should be securely fastened to the root by using flexible wire, as the loss of a name is sometimes annoying. When the roots are sufficiently dry to be housed they can be placed in a dry shed or outhouse, uncovered on fine days, until an external moisture is got rid of, and when winter should be out of the reach of frost.

There are various ways of preserving Dahlia roots during the winter. Some dry them roughly and stand them on cool, airy shelves from the inroads of frost, but here rot will afflict them, some sorts being much more difficult to keep than others. On the other hand, some place them on the floor of a warm house under the plant stages, and though drip falls upon them they yet come through the winter in comparative safety. Some place their roots on shelves and cover them with dry sand, others hang them in a cellar, they are also put into boxes with sand, sawdust or cocoa-fibre. Let them be kept from frost and damp, and then there need be little fear as to their wintering in safety. But whatever way the roots may be stored for winter let them be thoroughly dry when put away; put away damp there is always danger from rot.

R. D.

**Exhibiting Cactus Dahlias.**—At a recent exhibition of the Midland Counties Dahlia show

TREES AND SHRUBS.

HYDRANGEAS.

THE striking panicles of *Hydrangea paniculata* and its variety *hortensis* have during the past month or six weeks been the most prominent features among hardy shrubs. In the home counties this is the most valuable of the Hydrangeas, but in the south-western counties in Ireland, and in places with a similar climate, the old *H. Hortensia* is the most beautiful. Quite recently I have seen it very finely in flower in various parts of Ireland, and a few years ago I noted it as one of the most effective of autumn-flowering shrubs in Cornwall. In

our less favoured districts further north it is chiefly known as a cool greenhouse plant, and it is only occasionally that it flowers with anything like its natural freedom. There are, however, several other species which are well worth growing and which are perfectly hardy, although none of them can be said to equal either of the species just mentioned.

The greater proportion of our hardy species comes from Japan, but they are found also in China, the Himalayas, and in North America. The most noteworthy characteristic of the flowers is that they are of two kinds—the one large and showy but sterile, the other fertile and seed-producing, but small and comparatively inconspicuous. In the wild specimens the showy, sterile flowers are, as a rule, confined to the margin of the inflorescence, but under cultivation there is a tendency towards their increasing at the expense of the others, and in some varieties the whole inflorescence consists of these showy abortive blossoms.

Of their cultural requirements little need be said. Their chief wants are a free open soil of good quality and plenty of moisture. The plants bear

pruning well, and several of the species, when cut back pretty hard in spring and the young shoots subsequently thinned, produce much finer racemes and foliage. The *Hortensia* group, however, breaks freely from the base, and all it requires is an occasional clearing out of old stems.

**H. HORTENSIA.**—The specific name of this shrub, which so frequently is transformed into "hortensis" even in works of authority, is really an old generic name given to some of the Hydrangeas by Jussieu in honour, I believe, of Queen Hortense. The species has never been found in an undoubtedly wild state, but is one of the plants the Chinese and Japanese have cultivated from time immemorial, and it was from China that it was originally introduced to the King's garden at Kew towards the end of the last century by Sir Joseph Banks (according to Loudon). The accompanying illustration shows admirably how beautiful and striking a plant it is. The flowers

Wellingborough, *Cactus Dahlias* were shown on boards in the same manner as the large showy fancy varieties. As large, well-developed blooms were staged, they were really very attractive, and they appeared much less formal than did the larger flowers of the show type, and they were altogether more varied in colour, as well as showing considerable range of variety in form. Such a method of exhibiting is desirable to the part of those who grow only limited collections and who might find it difficult to get six or three blooms of a variety. That the culture of *Cactus Dahlia* is rapidly extending there can be no doubt. The present season has witnessed the production of more new varieties than any previous one, and now improvements in the habit of growth, in freedom of blooming, and strong,

*Eucalyptus globulus* had flowered during the summer, which is, I believe, an unusual occurrence in England. The fine and symmetrical specimen of *Paulownia imperialis*, 30 feet in height, had blossomed in the spring, and a cutting taken from the same tree is now 12 feet high. The small sheet of artificial water, which in my first notes on this garden (p. 383, vol. xlix.) I mentioned as being in course of construction close to the Bamboo plantation, is now finished, and is already a further attraction to the beautiful garden. At its margin a colony of Bulrushes was flowering, Gunneras, *Eulalias*, *Arundos*, and *Dracenas* adding their beauty of form to the picture, while large clumps of the vivid-hued *Tigridia grandiflora* and of the orange-scarlet *Montbretia Pottsi* brightened the scene with their high notes of colour. I

*Hydrangea Hortensia* bearing nineteen flowers in a 12-inch pot at Holmdale, Leicester. From a photograph sent by the Rev. W. Bell, Knighton Rectory, Leicester.

flower-stems thrown well above the foliage in necessity.—R. D.

NOTES FROM ABBOTSBURY, DORSETSHIRE.

OPENING to be at Weymouth during the last week in August I took the opportunity of renewing acquaintance with the attractive sub-tropical gardens of Abbotsbury Castle. The large bushy rather tree, of *Clerodendron trichotomum*, a representation of which appeared on page 320, *foli.*, was in full flower and scented the air for miles around, and *Oxydendron arboreum* was also in blossom. A fine specimen of *Catalpa bionoides*, some 30 feet high, at the side of which stood an Evergreen Beech, was in good bloom, and large bushes, 8 feet in height, of *Hiscus syriacus*, both the white and purple variety, were smothered in bloom, as were the double Myrtles, of which there was a goodly array at the sides of the wide grass walks.

should hardly have thought the margin of a pond a situation best suited to the needs of these two flowers, but never have I seen such vigorous examples of either as I did here. The lowest-planted clump of *Tigridias* was nearly 3 feet high and bore enormous flowers, while some of the *Montbretias*, whose corms were almost at the water-level, had thrown up great leaves almost as wide as those of *Gladiolus brecheleyensis* and correspondingly long, and were flowering grandly. I had always been of opinion that *Tigridias* and *Montbretias* did best in a dry soil, but at Abbotsbury their abnormal vigour is apparently due to the exact opposite. *Montbretia crocosmiflora* is also grown, and, in the neighbourhood of the water, *Cyperus natalensis*, the Tree Tomato (*Cyphomandra betacea*), and the Japanese Wineberry were to be found, with many fine *Hydrangea* bushes in full bloom, *Pampas Grasses*, *Bocconias*, and flowering *Clematises*, while on the trunk of a tall Palm the climbing *Rhodochiton volubile* was blooming. S. W. F.

are usually of a pale pink colour, but under certain conditions and in certain soils they are blue. The exact cause of the change has not been clearly ascertained, and has been variously ascribed to the presence of iron, potash, or alum in the soil. Although usually killed to the ground each winter near London, it is never destroyed outright. After unusually mild winters it will sometimes flower. The following are the more noteworthy of its numerous varieties: *Otaksa* has sterile flowers at the margin of the corymb only; it probably approaches the true wild type of the species more nearly than any. *Var. nigra* has very handsome purplish brown stems. *Var. Thomas Hogg* is a very valuable plant for indoor cultivation, having pure white flowers. *Var. Lindleyi* (figured in THE GARDEN for December 1, 1894) has only the marginal flowers of the corymb sterile; they are pale rose. *Var. japonica rosea* (coloured plate, GARDEN, August 15, 1896) has also pale rose flowers, but the whole of them are sterile. *Var. stellata* has the segments of its sterile flowers frequently toothed.

*H. PANICULATA* is a Japanese species of robust growth and perfect hardiness. Its leaves are ovate, each from 3 inches to 6 inches long, and they are frequently borne in threes at each joint, instead of the usual pair. The flowers are produced on huge erect panicles, and in the typical plant the great proportion of them are fertile, but in the variety *hortensis* (or *grandiflora*) the whole of them have become sterile, and each flower consists of four petal-like segments—really a development of the calyx—and nothing more. These panicles are naturally about 8 inches long and of pyramidal outline, but under high cultivation, when grown in rich soil and the shoots reduced considerably in number, they may be obtained as much as 1½ feet long and of proportionate width. The flowers are white at first, afterwards pink, and lastly pale brown. It was introduced in 1874.

*H. PETIOLARIS* (*scandens*) is a climber and a native of Japan. It is perfectly hardy, and at Kew is grown on a large tree stump, which it has completely covered. Its habit makes it interesting, and its luxuriant growth renders it handsome, although it does not flower very freely out of doors. The corymbs are large, but with only a few flowers of the sterile kind, and these of a dull white. In Japan this *Hydrangea* climbs the trunks of trees such as the Ivy does in this country, covering them up to a height of 60 feet or more. It may also be grown on a sunny wall, where it will flower more freely. Two other Asiatic species that may be briefly mentioned are

*H. PUBESCENS*, a very strong-growing shrub with narrow, pointed, finely-toothed leaves each 3 inches to 5 inches long, and large flat corymbs produced at midsummer, the flowers of which are white at first, afterwards rosy; and

*H. THUNBERGI*, a rare plant of dwarf stature, with small leaves and corymbs 3 inches in diameter, whose flowers are sometimes pink and sometimes blue, the species evidently being subject to the same influences as *H. hortensis*. The North American species are not such valuable shrubs for the garden as the Asiatic ones. The most ornamental of them is

*H. QUERCIFOLIA*, a native of the Southern United States, and, unfortunately, not so hardy as could be wished. In hard winters it is always cut back more or less. The foliage is very distinct and handsome, the large leaves being deeply lobed and unlike those of any other species. The flowers are borne in large erect panicles, the barren ones being white. It should be given a well-sheltered position, and the soil should be deep, rich, and moist, so that the leaves may be developed to their fullest size.

*H. RADIATA* is of no particular merit as a flowering shrub, producing dull white flowers; but its leaves, on the other hand, differ from those of any other *Hydrangea*, being of a beautiful bluish-white colour underneath. The species is often grown under the name "*nivea*," which refers to the snowy whiteness of the leaves.

*H. ARBORESCENS* is a strong grower with large coarsely-toothed leaves of quite a brilliant green, but it has no value as a flowering plant. The flowers, of which only a few are sterile, are of a dull white. It is a variable plant, and between it and *H. radiata* there are several intermediate forms, some showing a whiteness beneath the leaves, but never of the purity of the true *radiata* or *nivea*. W. J. B.

#### SHORT NOTES.—TREES AND SHRUBS.

*Eueryphia pinnatifolia*.—This has been flowering finely here the last six weeks. It has been growing on a sheltered bank for eight years, and is still doing well.—J. TAYLOR, *Hardwicke Grange*.

*Cratægus Pyracantha*.—In the Fulham recreation ground, where the conditions are none too favourable, there are numerous bushes of the *Pyracantha* from 4 feet to 6 feet high and as much through which are profusely laden with their brightly coloured berries. They are disposed at regular distances along a belt of shrubs, and in this way they form brilliant patches of colour. The *Pyracantha* is so generally seen and so universally admired as a wall plant, that its merits when grown in bush form are apt to be overlooked. It should, however, be more often planted in this way, as it is of a neat, yet free habit of growth, while the little flattened clusters of white blossoms are earlier in the year decidedly pretty.—T.

### KITCHEN GARDEN.

#### SUMMER CAULIFLOWERS.

MR. TALLACK points out the value of Cauliflower Eclipse and I am sure those who need this vegetable during the summer months will do well to adopt the advice given. It is an excellent variety and the heads are of just the size for home consumption. Market growers may not think it good enough. The value of Eclipse is its good qualities in dry weather at a season it is difficult to get Cauliflowers worth cutting. In many gardens summer Cauliflowers are not needed, but in others they are in constant demand, and though there is a wealth of Peas, Beans, and other choice vegetables I find good Cauliflowers are much liked and daily required. For years I grew the true Walcheren to give a summer supply, and it rarely failed. As Mr. Tallack observed, Eclipse is more compact than Walcheren for summer supplies; I mean during July and August or for earlier use. To follow the Broccoli in May and June I still rely on Walcheren. The value of Eclipse grown in summer is its mild flavour. I am aware Autumn Giant may be had at the season named, but with me the heads are strongly flavoured if cut before the middle of September.

There are other excellent varieties for early summer use. I find the Pearl a good variety to follow the late Broccoli. Pearl is earlier than Eclipse and by sowing these I get a succession; indeed, I make two or three sowings of Pearl, one in frames in February to give heads early in June, another in the open early in March to form a succession, and a later one if needed. If Eclipse is sown in March it will give a July, August, and September supply by making two or three plantings. A few years ago I paid great attention to summer Cauliflowers, having some half dozen varieties from the Cape and Italy, but none were equal to our own kinds. A few were early, but lacked the pure white curd and compact habit of Pearl and Eclipse. Snowball is one of our most useful kinds on account of its quick growth, but I class it as a late spring Cauliflower, as sown in heat in the early part of the year it will mature early in May. It is one of the best to take the place of the Broccoli should the latter fail or run short, as it may be had in three months fit for table. A summer Cauliflower which never fails is *Magnum Bonum*. This appears to me to be distinct from Walcheren

and superior for summer. It is larger than Eclipse and one of the best for affording a supply from June to October. It is a broad-leaved variety, but the head is well protected by the leaves. I do not know of any variety which keeps so long after being fit for table. This variety is very sturdy and is equally good in tropical weather as in more favourable seasons. I do not advise it for first crop, but as a summer variety especially in soils where Cauliflower does not always thrive. In my light soil it never fails. In heavy soils it is well to pay attention to the selection of summer Cauliflowers, and I have found Eclipse and *Magnum Bonum* the best. On the other hand, in poor land, it is necessary to grow vigorous kinds in hot, dry seasons, as the first earlies button at times and a crop is lost. Even this last season, with every attention to keep up a good supply, I was obliged to milk freely. I found it an excellent plan to give the surface-soil a good covering of spent Mushroom manure. This I obtained from a large grower at a small cost, and it was a great saving. A thorough watering once a week kept the plants growing freely. Few vegetables find drought sooner than Cauliflower, and if the plants are checked they soon become a prey to caterpillar, and take on a bad colour. I do not advise at getting large heads, but those with a compact white curd. The four varieties named are all good grown to form a succession. Doubtless other growers may have found others quite as reliable in diverse soils, and some may like larger kinds. G. WYTHES.

*Potato Syon House Prolific*.—I think "H. C. P." (p. 221) must have made a mistake when he classes *Syon House Prolific* as a variety. I am pleased to see the writer's comments on the same. I note on the same page Mr. Tallack writes favourably of this variety as its free-cropping qualities. This Potato was introduced last year. I am more pleased with this year than last, as I regret to say my *Potato* crop is a poor one in the case of some varieties. *Windsor Castle* was grand and *Satisfaction* excellent, but not so even as usual, some of the tubs being very large. My best cropper is the one in question, and though in this case there are coarseness, the general quality is good and quite free of disease. Though a late Potato, it boils fast as soon as lifted. My *Magnum Bonum* this year is poor. This I much regret, as it is my favourite and the seed was new and planted early. A few other older kinds are light crops. The new *English Beauty*, a very early kind, came in just in advance of *Windsor Castle*. The whole I do not think the *Potato* crop will be a heavy one. Drought crippled the plants in their early stages, and with so much rain disease will be prevalent in clay soils.—GROWER.

*Disease in Kales*.—At a recent meeting of the fruit and vegetable committee at the Royal Horticultural Society's gardens, Chiswick, I was grieved to see some Kales much diseased. The plants some two months ago were much admired for their splendid leafage. Many at first sight would think that the roots were attacked by disease, but this is not the case, and I am penning this note hoping that some readers may give us some information how to combat the disease. At *Syon* the Kales, though not quite so bad as at Chiswick, are suffering from the same disease. I have tried various remedies all to no purpose. The roots are strong and clean, but the leafage is badly attacked by a kind of mildew or fungus, which curls up and withers. The plants lose their centres, smell badly, and present a miserable appearance. They first showed the pest in June, and I hoped with a good rainfall later they would grow out of it, but the reverse is the case. They are much worse; in fact, a few rows have been destroyed, as the plants looked so unsightly. Another curious point is that the disease or fungus only affects the very latest kinds, such as *Bude* or *Asparagus*, the *Cottager's Kale*, *Ragout Jack*, *Chou de Milan* and similar kinds.

otch Kales adjoining are quite free. At Wiswick the land was new for the crop, at least I did not had a similar crop for years, and I think various remedies have been tried in the way of plates and dressings. A late sown and planted appears to have escaped, and some may say, why not rely on such plants? but they are too small to give large supplies. I think the evil is owing to drought in the first place. It is a loss, these late Kales are so valuable during March and April, and produce so freely.—G. WYTHES.

**Beet seed.**—"A. D." (p. 221) may easily be wrong as to his surmise that the mixed seed he sowed was due to negligence or want of care after sowing. For many years I have been in the habit of saving seed from a selected stock, and the result is not always what it should be in spite of every care being taken in isolating the seed-bearing roots. In some years the plants come perfectly true; in others a small percentage of Mangolds comes with them, and it is curious to note that the latter are of a red or yellow type according to the kind of Mangold grown for seed in the neighbourhood the same year, though none are grown within a quarter of a mile of the garden. Of course, this is due to cross-fertilisation and not to the seed being mixed after harvesting or to wrong roots being saved for planting. Last year the percentage of Mangolds was higher than I had ever known it, while this year the case is entirely different. When one comes to think of it there is no cause for wonder at this being so, for the farmer who is saving Mangold seed may have just as good reason to complain of the gardener's Beet as the gardener has of the Mangold. The one thing I do not understand in the case is why the Mangolds were not pulled out at an early time. They can easily be seen, and will be much advanced in growth beyond the garden plot at that time, so the only excuse for their being left would be too thin sowing. Beets are easily transplanted that there is no excuse for mixed lot being grown on through the season if only a fair quantity of seed was sown, so that late would be available for filling gaps by sowing out the bastard plants. The stock itself is uninfected by these rogue plants, the percentage of which is never large.—J. C. TALLACK.

#### CABBAGE SPROUTS.

Though "J. C. T." (p. 221) thinks Cabbage sprouts superior to young Cabbage, his note does not convince me of their superiority. Growing of Cabbage stems to produce sprouts is not an advance in the right direction. We have now such excellent quick-growing varieties that it is not worth while to keep an untidy bed of old stumps cut from. I may be told they can be kept dry. They rarely are in many gardens, and in some cases the old stumps remain well into the second year, being cut over and over again. This is not gardening. I would ask "J. C. T." if such produce is worth sending to table? I do not think much of it would be appreciated in the dining room, and my contention is, that by growing young Cabbage the ground is better occupied and the quality of the Cabbage is superior. I admit it is a practice generally followed, and old cabbages die hard. I think we may with advantage follow a regular system of cropping and clear the ground, as when good autumn Cabbage can be grown in a few weeks there is no need to leave old plants to produce a second crop, when the time is taken into account the plants have occupied the soil. My plan is to give the soil a change as soon as possible. Vegetables, like individuals, need change of food. Summer Cabbages after heat and drought are not free from insect pests, and if sown there is less fear of adjoining crops being attacked. With an ample supply of Coleworts I fail to see the need of old Cabbage sprouts. I do not think the comparison made between Brussels Sprouts and Cabbage a happy one, nor would I think of destroying Brussels Sprouts if they had matured the crop. When Cabbage has matured one crop, why demand a second and what is the soil? I have for some years taken

special measures to prevent grub and destroy insects. To this end I find it advantageous to clear crops as soon as possible, and, in the long run, I am the gainer both in quality and, I may add, quantity, with freedom in a great measure from insects. Another strong point is neatness, and I think we cannot overlook this latter, as it is an important one. I do not think "J. C. T.'s" point with regard to labour needs much comment. Cabbages are planted so quickly with certain success, even in dry seasons, that there will be less cost in the end. The young plants in clean ground will give little trouble after planting unless in very dry weather watering may be necessary. S. M.

## STOVE AND GREENHOUSE.

### GLORIOSAS AND THEIR CULTURE.

THE genus *Gloriosa* (so named by Linnaeus from the superb colouring of the flowers) consists of two species of annual, tuberous-rooted, climbing liliaceous plants, natives of the tropical parts of Asia and Africa, and named *Gloriosa superba* and *G. simplex*. These, although introduced into cultivation many years since, are not often found in gardens, possibly because they are old-fashioned plants, but being neither costly in price nor very difficult to grow, they deserve the attention of all amateurs who are seeking for handsome flowers.

**GLORIOSA SUPERBA (L.)**.—A native of Malabar, Ceylon and Nepal; introduced in the year 1690. Stem from about 7 feet to nearly 10 feet long. Flowers pendent, of a fine orange or yellowish red colour, golden yellow at the base, with six reflexed divisions which are very much crimped and undulated at the margins, blooming from July to October, and remaining persistent on the flower-stalk after they have withered. Each flower continues a long time in good condition and presents different shades of colour as it advances in age.

**G. SIMPLEX (L.)**.—A native of Mozambique; introduced in 1823. Similar to the preceding species in habit of growth, but with longer stems. Flowers of a greenish-yellow colour, with a yellow claw; the margin and extremity of the divisions of the corolla are also yellow and are not crimped, but are slightly undulated. The variety *G. simplex Planti* (Loud.) has reddish-yellow flowers, and *G. grandiflora* (Methonica grandiflora) is a form of it which has very much larger flowers. Miller, in his "Gardeners Dictionary," mentions a species named *G. cerulea* with blue flowers, but he adds that no one of his acquaintance had seen it in flower. Is anything now known about this species? Up to the present *G. superba* is the finest known species.

Gloriosas are tuberous-rooted plants with an annual growth, which require to be replanted after a certain period of rest. At the commencement of the new growth the repotting and multiplication of the plants are carried on simultaneously. At the end of the growing period the tuber that was planted will be found to have produced two other tubers, having disappeared itself by absorption into the new tubers. These two tubers are then to be divided and planted with the lower end uppermost, a peculiarity of the *Gloriosas* being that the new growth is made from the lower end or bottom of the tuber. When dividing the tubers, the cuts should be sprinkled with fine-powdered charcoal. It occasionally happens that the old tuber will produce only one instead of two fresh tubers, and, contrary to what is stated in books which treat of the culture of *Gloriosas*, I have never found any bulbils at the base of these plants. As regards the

### CULTURE.

In February the roots are potted in low-sided pots or pans (such as are used for *Caladiums*) of suitable size or, preferably, in flat seed-pans, in which the roots are placed horizontally, one root in each pan; the potting soil should consist of fresh heath soil alone, or else leaf-soil and the pans should be well drained. The roots should be placed so that the part from which the stem will issue may be at the surface of the soil or very slightly covered by it. A slight watering is given, after which the surface of the soil is covered about half an inch deep with live *Sphagnum*, which is to be kept in a moist condition by occasional slight waterings. The pans are then removed to the propagating house where they are given bottom-heat by plunging them in the tan or ashes of the frame over the hot-water pipes. The only attention they require is to keep the soil moist, and the layer of *Sphagnum* is almost always sufficient to do this until the growth commences. This is rather capricious in making its appearance sooner or later. The stem as it issues from the soil is leafless for a considerable portion of its length and grows more rapidly in proportion to the higher temperature of the house. It should have the support of a stake when this becomes necessary, and the plant should be more frequently watered as the growth progresses. The pans in which the roots were planted cannot long supply sufficient food to the plants, which should be repotted as soon as the rootlets become abundant. In repotting it is necessary to be careful, as the roots are very sensitive and suffer much when they are disturbed. It is best to use pans from 10 inches to 16 inches in diameter and from 6 inches to 10 inches deep, according to the strength of the plants, placing the roots in a slanting direction in a compost formed of one-half fresh heath-soil or leaf-soil, one-fourth well-decomposed hotbed material, and one-fourth vegetable mould, all well mixed together and prepared beforehand. It is advisable to mix a little sand with the compost. In removing the plants from the pots great care should be taken, and this operation will be more easily effected when the roots have been started into growth in small-sized pans.

The plants when repotted are watered and then removed to the warm house where they are to complete their growth, and for some time after they have been repotted moderate watering is advisable, and this is to be increased gradually. The stem, growing rapidly, must be supported by a stake, and cords running parallel to the glass of the house must be arranged so that the tendrils of the plants may take hold of them and so help to support the stem. These cords should be placed at a distance of from 6 inches to 8 inches from the glass. The plants may also be grown on trellises or other supports. If it is desired to grow these plants in a cool house in summer, this may be transformed into a warm house by admitting as much solar heat into it as possible, and, if necessary, giving a little fire at night to prevent too great a lowering of the temperature.

Further attentions consist in keeping the soil in a proper condition of moisture, and giving once a week a watering of liquid manure, composed of night soil and cow manure in a 10 per cent. solution. The training of the stems should also be attended to, tying them here and there with strips of raffia. Flowering commences in July and continues until October. I have remarked that the plants bloom much better in houses where there is a free circulation of air than they do in houses where the atmosphere is moist. The reek or steam from fermenting materials should be avoided, and also syring-

ing, which spots and spoils the flowers. Two interesting particulars should be noted: the flowers being marcescent, it is a good plan to pick off the faded corollas, which otherwise would detract from the appearance of the plants, and unless it is intended to gather the seeds, it is best to remove the flowers entirely as they wither. In well ventilated houses impregnation of the flowers sometimes takes place naturally, but they can be easily impregnated artificially on a fine day. The seed takes a rather long time to ripen, and should not be gathered until the seed-vessel opens of itself and the seeds are of a deep red colour. Once the plants have perfected their growth and are in full bloom, they should only be moderately watered. As the flowering approaches its termination watering is still further diminished, and should cease entirely about the first week in October. The stems of the plants are then to be cut down to 3 inches or 4 inches from the soil, and the pans are to be placed on the hot-water pipes in a warm or a temperate house, where they are kept dry until the following February, when growth recommences and re-potting takes place. Raising plants

#### FROM SEED

is easy enough, but is tedious in its results, as it takes five or six years before a seedling plant comes into flower. The method, however, is as follows: The seeds, which are pretty large, should be sown from January to March in a hothouse or on a hotbed in good-sized pots or pans (6 inches or 7 inches in diameter) and about half an inch deep in the soil, with a distance of nearly an inch at least from seed to seed. They germinate pretty quickly and regularly, but the young plants cannot be pricked out during the first year. Pots of seedlings are kept undisturbed through the winter, and in the following spring each root is potted off into a small pot of a size suitable to the strength of the root, which is afterwards re-potted like a grown plant. The stems of young seedling plants do not begin to climb before they are two or three years old.—JULES RUDOLPH, in *Revue Horticole*.

**Cupressus torulosa as a pot plant.**—This elegant little conifer is wonderfully well adapted for growing in pots for room and conservatory decoration. For mixing with flowering plants in ornamental baskets it is also most useful. Of easy culture, and, of course, very hardy, it succeeds well in a good stiff loamy compost, given a firm root run and well-drained pots. Small plants will, if assisted with manure water occasionally, remain in good condition in  $4\frac{1}{2}$ -inch and 6-inch pots for several years.—C. C. H.

**Rooting double Primulas.**—It is not always so difficult to induce double Primulas to send out tiny rootlets into the compost with which they are earthed up in spring as to get them to take a free hold of the new soil when detached and potted off. If the weather is bad a cold frame does not always suit them, the weather even in June sometimes being anything but warm and genial, and an airy greenhouse not just the right medium. A friend of mine who succeeds with double Primulas always makes up a small hot-bed of leaves, and gives the newly-potted double Primulas the benefit of it. He does not plunge the pots, but merely stands them on the surface of the bed, taking care to admit a little air almost continually in order to allow of the escape of superfluous steam. In this way he usually manages to root 90 per cent. of the plants.—C. C. H.

**Solanum jasminoides.**—The flowers of this charming creeper are freely produced, and very useful at this time of year. In general it is grown

as a greenhouse creeper, and has a pretty effect trained across the principal rafters of span-roofed houses, the flowers being allowed to hang down in a natural way. In favoured localities of course it may be grown outside. I saw several fine plants of it at Kings Weston in August, where possibly the proximity of the Severn has something to do with its thriving condition. There are also plenty of conservatories with high and bare back walls that this plant would cover rapidly and be very useful. I once had a fine plant on a conservatory roof, and the border for this was about 2 feet deep to the drainage, which was carefully laid. Three parts of loam, one of decayed horse manure, one of leaf mould, and plenty of charcoal and rough sand were the compost used. After the plant had covered the space the shoots used to hang down a couple of feet or more, and these after flowering were either laid in in vacant places or cut back, and the effect of the large clusters of pure white blossoms was remarkably telling. Wherever such positions as those noted exist, then I would strongly advise the planting of this Solanum, for the effect of the plant is certainly not to be judged by the miserable, starved specimens one often sees in hot, dry greenhouses. It must be fed, and it delights in moisture both in the atmosphere and at the roots, and the more freely it is allowed to ramble the better will be the effect when in flower.—R.

**Gladioli in pots.**—Although not generally grown in pots, Gladioli are most useful for conservatory and general decoration during September. All the varieties of the large-flowering type are good for the purpose, but none surpass in brilliancy the good old *brencleyensis*. One bulb in a 6-inch pot, this being well drained and filled with good yellow loam, a little well-decomposed manure, and a good sprinkling of rough sand or road-grit, is the most useful way of growing them, April being the best month for starting the first batch, a second lot being potted up in May. A cool frame is a good place for them until the new growths are a few inches high, air being admitted freely in fine weather, and the lights entirely removed during the day in May, little water being given till new roots commence to work freely in the soil. In June the plants are best plunged in ashes in a sheltered sunny position, and when growing freely, weak liquid manure given, say, twice weekly will assist in building up strong flower-stems and spikes. When high enough to take harm from winds, neat sticks painted pale green should be inserted in the pots and the stems carefully tied to them, leaving plenty of room for expansion. If desirable, a few plants can be removed from the plunging material to a cool glasshouse, where the flowers will quickly open. I have seen them used to great advantage in artistic groups at exhibitions, the great thing being to use them sparingly. Some might, perhaps, think pot culture unnecessary, supposing that the plants could be lifted from the open ground and potted when required, but, apart from the early date at which they may be had in flower in pots, they never do satisfactorily when lifted and potted up.—J. CRAWFORD.

#### SHORT NOTES.—STOVE & GREENHOUSE.

**The Tubarose in the open air.**—This is so generally seen brought on under glass, that a bed of it in full flower in the open ground at Kew at once attracts attention, owing to its being so seldom met with treated in this way. The plants are flowering profusely. When in the open ground and fully exposed to the sun, the flowers, which under glass are of the purest white, become slightly suffused on the exterior with a reddish tinge.—H. P.

**Nicotiana affinis poisonous.**—Probably many of your readers are not aware that the leaves of this sting the flesh severely. Lately when carrying a few plants in a pot the leaves came into contact with my bare arms, and I felt a sharp, stinging pain. The marks spread out into large patches of red, and now, after six weeks, they are still quite red.—J. G., *Gosport*.

## GARDEN FLORA.

### PLATE 1139.

#### RHODODENDRON KEWENSE VARS.

(WITH A COLOURED PLATE.\*)

AMONG hardy evergreen Rhododendrons there may be noticed two distinct types of inflorescence. In the commoner and hardier group the trusses are composed of numerous closely packed, bell-shaped flowers, arranged in a more or less cone-shaped mass. In the other group the flowers are flatter and more saucer-shaped, fewer in number, but individually larger and arranged loosely. To the latter group belong *R. Thomsoni*, *R. Fortunei*, *R. campylocarpum*, *R. Griffithianum* (*Aucklandi*) and *R. Hookeri* and belonging to the same set also are the hybrids figured in the accompanying plate. *R. kewense* was raised in the temperate house at Kew in 1875 by the late Mr. Binder from a cross between *R. Griffithianum* and *R. Hookei*. Of the numerous plants raised, none flower until the spring of 1888, since which time they have flowered every year, and, as a rule, with great freedom. At first grown in the temperate house, they were afterwards planted outside a peat bed, where they could be protected by canvas covering during hard weather. For the last two years they have at Kew been grown in the Rhododendron dell, with no other protection than a naturally sheltered position such as this affords. Never during the ten years that the hybrids have flowered have they been so beautiful as during last May, when Mr. Moon made his drawing. Most of the bushes some of which are now 8 feet across, were literally covered with trusses of the type here figured, although as a rule much larger. Most of the flowers measured between 4 inches and 5 inches across. Although the whole of the plants came from a single pod of seed, they vary a good deal in the colour of the flowers. Some on first opening are white, with pale rose tinge, becoming almost pure white after a few days; others are of a more decided rose; whilst the richest colour of all is the smaller truss here figured, whose buds are of a rich rosy crimson and the flowers of a deep soft rose, which never loses its warm tint. But all the forms are beautiful and the different hue of the one only serves to bring out more vividly the loveliness of its neighbour.

When its parentage is considered, the hue of *Rhododendron kewense* is remarkable. Little appears to be known of *R. Hookeri*, as I have not heard of its being grown out of doors in the London district. *R. Griffithianum*, which can only be grown here as a cool greenhouse plant, yet there are plants of *R. kewense* (the bulk of them) that have been grown with any artificial protection in the dell at Kew for five or six years, and have withstood, consequently, amongst others, the winter of 1897 without any injury. This hybrid proves that the genus *Rhododendron*, although it has so long been a field where many noted workers have successfully laboured, has not yet had its beauties all revealed. For the hybridiser who has the time and opportunity, and who will leave the beaten track, there are many chances of creating new varieties which shall not only be distinct from those we already possess, but quite as beautiful. W. J. B.

\* Drawn for THE GARDEN in the Royal Gardens, Kew, by H. G. Moon. Lithographed and printed by J. L. Goffart.

## THE WEEK'S WORK.

## KITCHEN GARDEN.

**BEETROOT.**—It often happens that there is more attention over the qualities of this crop between the grower and those who have to prepare it than any other vegetable sent into the kitchen. The usual complaint is that the roots either lack a rich colour, or that they are too large and coarse and tough in texture. These are matters which it behoves the grower to guard against as far as possible, though even when the roots are well grown in every respect, a great deal depends on how they are prepared after they have left his hands. Where the seed was sown too early on rich land the evil of so doing will now be too apparent, as instead of medium-sized spely roots with corresponding foliage, they will have become far too large for general use, and they will increase in size for some weeks to come. Overgrown roots are not only coarse in texture, but they seldom possess that deep rich colour which is appreciated so much when sent to table. Such as this may be regretted, nothing can be done to check growth, as early lifting would result in the roots shrivelling prematurely, and they would become useless. It is not until November in some seasons that growth is checked by frost sufficiently to necessitate lifting and spring. However carefully this may be done, the roots never cook so well afterwards as when lifted direct from the ground. For this reason it is a good plan to leave a portion of the crop undug and protect it with straw litter on the approach of hard frost. It can often be preserved in this way into the new year and later, when by sowing early in frames the season of stored roots is considerably shortened. Beet requires most careful treatment in getting it out of the ground, the least bruise or breakage of roots leading to loss of colour. A fork should be used to assist in drawing the roots out of the ground, and in removing the foliage twist it off, not quite an inch or so away from the crown, or it will prove as harmful as breaking the main root. Of the several ways of keeping Beet as long as possible during the winter, I prefer to stack the roots up in cone-shaped heaps in a cool cellar. They should be arranged so that the crowns all point outwards, and no covering is necessary. As a rule it is the crowns which commence to decay first, and when the roots are drawn together into one large heap rot quickly spreads and many of them are spoilt. By being arranged in the way described a certain amount of leaf growth takes place, and by having sand not too dry—packed between them, small white fibres are formed, which prevent shrivelling, and they last for months in the best condition. Of the several varieties I have grown this season, Dell's Crimson is still the best, being uniform in size and of excellent quality and colour.

**CARROTS.**—What roots may remain from early sowings of the small varieties should now be lifted and stored away for winter use. Instead of turning these up at once I find it better to place them in a bin by themselves, and they invariably keep much better than larger roots which form the main crop, and they come in most useful in spring when Carrots are scarce. I am not in favour of leaving Carrots in the ground until late in autumn, as the heavy rains cause many of them to split, while after a time they lose their colour, and pale rings form in the centre. If they can be lifted before the ground becomes soddened, and when wet the roots come out much cleaner, and even large quantities have to be stored they should be well dried previously. Only the perfect roots should be placed together, as a few bruised or cracked ones soon decay. Imperfect roots should be used up first, as they answer the same purpose as sound ones. It is only where there is another convenience in the way of a suitable pit store that Carrots should be buried in the open, and though they may keep well thus, it is not so convenient to get them if required

during severe weather. A large quantity may be stored in a small compass if made up in heaps as described above for Beet. In this way they can be easily examined at short intervals, and they keep in good condition when carefully placed in sand.

**GLOBE ARTICHOKE.**—I advised raising a batch of plants from seed early last spring, and where this was done a good supply of heads will now be obtained, and the plants will continue to produce them until cut off by frost. It is certainly preferable to have beds well furnished with young, vigorous plants than to see the plantation, as one often does, irregular and patchy, owing to the plants being killed by frost or too much wet. This year's plants will be protected with long litter as the season advances, which will give a supply earlier next season, and by raising another batch in February a long succession is maintained. A few dishes of these for the next few weeks prove very acceptable, as they make a variety when Scarlet Runners are cut off.

Goodwood.

RICHARD PARKER.

## FRUIT UNDER GLASS.

**FIGS.**—The season for these is fast drawing to a close, and never do I remember Figs having been more plentiful and in finer condition than they have been this year. Some March-started trees are still carrying a good second crop, but these will be over in a week or ten days; and with this exception, all trees are now bare of fruit and taking a well-earned rest. All late-fruited trees should get plenty of air as soon as the crops are cleared. Much less moisture will also be required at the roots, and this, with a free circulation of air, combined with the ripening influence of autumn sunshine, should lead to the wood becoming thoroughly consolidated and in the best possible condition for fruiting next season. If any of these trees have been allowed to develop fruits within the past six weeks, they should be pulled off at once, as there is not the remotest chance of their attaining maturity this year, while to allow them to remain will only distress the trees. Such work as root-pruning, and curtailing the root-run of unfruitful trees should be pushed on with while the dry weather allows of carting and wheeling being done. Although Figs are now grown much more extensively than was formerly the case, it is astonishing the number of inquiries that are made as to their culture, more particularly with regard to borders. There seems to be an impression with many people that extensive borders are necessary, and that the soil must be rich, whereas the opposite is the case. Figs fruit best when their roots are restricted, and when planted in loam, to which lime rubble or some such calcareous matter has been freely added. (Growth made under such conditions is always firm, of medium strength, and an embryo fruit will be found at the base of each leaf on every shoot by the time autumn arrives. The roots may be confined by brick walls, but if they are below ground the joints should be pointed with cement to prevent the roots escaping. Even when this precaution is taken, it is always wise to throw out the surrounding soil every autumn, in case any roots should have made their way through a faulty joint. The plan I favour most is to build a pit of brickwork from 3 feet to 4 feet long, 3 feet wide and the same in depth, on the ground level, using as a base paving stones, which are laid in cement so that the roots cannot penetrate through the joints. Six inches of drainage are placed in the bottom of the bins, and the water escapes through small apertures between the bricks in the lowermost course. Trees planted in these pits or bins will cover a large area of trellising and carry heavy crops of fruit annually. Feeding is done from the surface, and the mulching and a certain amount of the surface soil are removed every autumn to allow of a top dressing being applied. Another method is to grow them in square beds of soil enclosed with turf walls, built upon brick floors or paving stones: but of the two I prefer the brick pit, and give the above details for what

they may be worth. In the early house the permanently planted trees will have shed their leaves. Whatever pruning is necessary can therefore be done at once, and then the necessary steps for cleaning the trees and the house, should insects have gained a footing, can be undertaken during wet weather or when a suitable opportunity offers. Early pot trees, if they were moved outdoors a few weeks ago to undergo a thorough rest, should be taken under cover again. Before doing so the house they are to occupy had better be cleansed, and the trees taken to a shed to undergo a thorough cleaning, if needed, before taking them indoors. Scale is the principal insect pest which attacks Figs, and no pains should be spared to rid the trees of it. After cleansing both house and trees and putting all in order, keep the house perfectly cool until the time arrives for starting, either in November or December.

**CHERRIES.**—Pot trees outdoors will be shedding their leaves if they have not already done so. They should now be looked over, when if any pruning should be found necessary get it done at once, in order that the wounds may heal up before there is a likelihood of a severe frost occurring. Strictly speaking, pruning should be unnecessary if due regard was paid to the stopping with the finger and thumb of all young shoots during the growing season. A free use of the knife on Cherry trees, either in the autumn or winter months, leads to gumming, and should therefore be avoided. After this general look-over, get all necessary potting and top-dressing done, if these have not already had attention, after which stand the trees in one block, with a sufficient space between each to allow of Bracken or such like material being packed between the pots or tubs in a few weeks' time, as a protection against frost. Planted-out trees will be going to rest, but additions to borders, lifting, transplanting and top-dressing should be completed as early as circumstances will allow. Borders in newly-erected houses should be made, and the planting done forthwith, if trees have been grown at home for one season with that end in view. If the trees have to be purchased, a delay of a few weeks will occur in the planting, but this need not prevent having everything in readiness for their reception.

**PLUMS.**—As soon as the fruits are gathered from the late varieties, such as Golden Drop and Jefferson's, look to the trees, potting or top-dressing them as may be necessary. Then turn them outdoors, and if the foliage has become infested with insects take steps to eradicate them before placing the trees with the others turned out a few weeks ago. This moving of the trees outdoors will leave the houses at liberty for the housing of Chrysanthemums where large numbers of these are grown, an arrangement which generally works well, while the Plums will be all the better for a few months sojourn in the outer air. These, like the Cherries, should be so arranged that some non-conducting material can be placed between the pots later on.

**PEARS.**—As the fruits are gathered from these take them to the potting shed and treat them as advised for Plums, after which place them outdoors in the full sun, on a hard foundation, so that worms cannot gain an entrance through the crock holes. As winter approaches these must be protected in the same way as advised for Cherries and Plums. Trees on which the fruits are ripening must be carefully watered, as too much moisture will lead to the flavour being flat and insipid, while the contrary treatment will cause the fruit to drop prematurely. A happy medium must, therefore, be hit on which will keep the roots supplied with just a sufficient amount of moisture to enable the trees to perfect their fruits. Continue to feed trees of later varieties until the fruits are full grown or on the point of ripening, and then give pure water only, observing the foregoing conditions.

**ARTICHOKE HOUSE.**—This house cannot possibly be kept too cool; therefore ventilators and doors should be opened to their fullest extent. This free volume of air continually passing through the house and circulating among the trees, together

with the sunshine we may reasonably expect for another four weeks, will assist the trees to plump up their buds and lead to the thorough ripening of the wood, without which it is useless to look for good crops of fruit. Although the trees must have free exposure as far as possible, the roots, or rather the borders, must not in any way be neglected, and they must be kept in a properly moist condition right through the winter months. Inattention to this matter will lead to the buds dropping in a wholesale manner next spring, and this is more often than not the stumbling block in Apricot culture under glass. A. W.

## FRUIT AND VEGETABLE CROPS.

### SCOTLAND.

**Caprington Castle, Kilmarnock.**—All the fruit trees in the early spring looked promising, but owing to the cold cutting winds and frost in May, wall trees especially were badly crippled. Peaches with four ply of netting on them are all but a failure, the first miss I have had for a number of years. Plums, with the exception of Victoria and Magnum Bonum, are all blank. Pears shared the same fate with the exception of Marie Louise, Duchesse d'Angoulême, Winter Nelis and Hessel, which are all heavily cropped. Standard Apples were late in flowering and escaped the cold winds. Some are laden to the ground, especially Keswick Codlin, Stirling Castle, and Irish Codlin. Hawthorn den has splendid crops, and there is a fair sprinkling on the others. Raspberries are an abundant crop. White, Black, and Red Currants are very heavy, also Gooseberries. Cherries light.

Vegetables, though late in the early part of the year, made rapid progress when good weather set in. Midseason Peas are very poor owing to the drought we had some time ago. Early Peas were a splendid crop, and the late ones are looking well. Potatoes are fine crops and clean, but the disease has started amongst them.—WALTER YOUNG.

**Gattonside House, Melrose.**—The Apples and Plums here are much below the average. Pears and Cherries average. Apricots none. Gooseberries are above average in quantity and of splendid quality. Currants average; Black Currants in some places poor crop. Strawberries splendid crop and of good quality. Raspberries above the average.

Vegetables are above average. Peas have done well. Cauliflower has been very good with me, but I hear complaints from different parts as to its doing badly. Potatoes are very good, both in quantity and quality; Sutton's Satisfaction is the best second early that I have tried.—ROBERT WEDDELL.

**Hopetoun Gardens, Queensferry, N.B.**—The autumn of 1896 being cold and wet, as a rule fruit trees in this locality did not ripen their wood very satisfactorily. Nevertheless, an abundance of flower-buds was formed. They, however, looked small and not so plump as in former years, consequently when the flowering season came round the flowers were weak, and the cold, raw, wet snap we experienced during that period checked the natural flow of sap; this, coupled with occasional gales of east wind (prevalent here) and an absence of sunshine, I have no doubt caused the damage. The only varieties with anything like a crop are the various Codlins. The bright warm genial sunshine of the past month has improved the trees, and I have no doubt the fruit will swell to a nice size, the trees being in good health and now free from insect pests. The Pear crop on walls is certainly better than the Apple one, but the same may be said of Pears as of the Apples—weak buds and weak flowers, the result being about half a crop, and with the lateness of the season they may not swell to size as in former years. Apricots not plentiful, but good. Sweet Cherries are barely an average crop, and the

Morello Cherries are not so good. I do not grow many Peaches on the open walls, but those I have are good. Plums all but a failure, both on walls and standards. Gooseberries are plentiful, but small. Currants abundant. Strawberries very good and abundant.

Vegetables are strong and vigorous, and I have no doubt the supply will be quite equal to the demand.—J. SMITH.

**Culzean Castle, Maybole.**—The fruit crop in this neighbourhood has been very poor. Gooseberries, Pears, Plums, and sweet Cherries, also Black Currants in some gardens, have been quite a failure. Apples in some gardens are very good, but late; I have a heavy crop in the gardens here. Morello Cherries are also good.

All the early vegetables were very poor, especially Cauliflower and French Beans; the later crops are looking more promising. Onions are very bad with maggot.—DAVID MURRAY.

**The Gardens, Orchardton, Castle Douglas, N.B.**—Although we had abundance of bloom, Apricots, Pears, Plums, Cherries, and Damsons are almost a failure. Cherries fell wholesale at the stoning period, late spring frosts being the cause. Apples are rather under average. All small fruits are a good average crop. Raspberries, Red and Black Currants extra good both in quantity and quality.

All vegetable crops have done well. Peas are extra good, although mildew has been troublesome. I am growing Autoerat this year for the first time. It appears to be a good mildew-resister and a good all-round Pea. Early and second early Potatoes did very well indeed, no disease, but later kinds are showing disease badly.—P. WILSON.

**Carron Lodge, Stirling.**—Fruit crops which are most abundant in this locality are Apples and all small fruits. Of Apples, all the Codlin class, especially Lord Suffield, Keswick Codlin, Lord Grosvenor, Potts' Seedling, and Golden Spire are the best. Stirling Castle, Cellini, Northern Greening, Yorkshire Greening, Seaton House, Sandringham, Wellington, King of Pippins, Worcestershire Pearmain, Irish Peach, Red Astrachan, Golden Pippin, and Kerry Pippin are loaded with fruit and have had the crops thinned. The trees are mostly young and kept dwarf. They are resting on a bed of broken bricks and lime rubbish, the roots kept on a level with the surrounding soil. The situation being low and damp, it is necessary to keep the roots well up to receive the benefit of the sun.

Vegetable crops never were started under greater climatic difficulty, and made slow progress till July; then they grew rapidly, and are now, without exception, all one could wish. Potatoes have been good, but disease has been in evidence. Earliest sorts were very good. Sharpe's Victor (the yellow variety) was first and best. Snowdrop is a favourite. Its small haulm allows sun and air to reach the soil freely, which is much in its favour on our damp soil. Onions are late, but of capital quality. The most useful Peas have been Chelsea Gem, Dr. McLean, Telephone, Veitch's Perfection, Autoerat, and Ne Plus Ultra as latest.—M. TEMPLE.

**Galloway House, Garlieston.**—The fruit crops in this county are considerably below the average of the last few years, but with the exception of Pears, which are very poor both against walls and in the open, there is not very much to complain of, for what is lacking in quantity promises to be recompensed to a great extent in the size and quality of the fruit. This applies especially to Apples, which are very clean, large and well shaped. Of these, the Codlins and other early sorts are bearing full crops, while later sorts, as Eeklinville, Warner's King, Lane's Prince Albert, Loddington and a few others, are very satisfactory. Plums are below average, the best being Rivers' Prolific, Czar, Kirke's, Victoria, Lawson's Golden Gage and Pond's Seedling, which are growing against walls with various aspects. Standard trees are very thinly cropped, and Damsons are a complete failure. Figs are heavily

cropped. The sorts grown are Castle Kenned and Brown Turkey. The former has ripened quantity of very fine fruit, but owing to the lateness of the season, it depends upon the weather during the next few weeks as to the success of the latter. Peaches and Nectarines are a light crop and the fruit much smaller than usual. Apricots were a light crop, but of very good quality. Cherries of dessert sorts were fair good, but Morellos both in quantity and quality are much below the average. Strawberries were very good, and the dry weather that prevailed when the fruit was ripening enabled the crop to be secured in excellent condition. Gooseberries, Currants and Raspberries were good crops and the fruit very fine. Pears, with the exception of Jargonelle, Beurré Rance, Williams' Bon Chrétien, Beurré d'Amanlis and Ne Plus Meuris which are against walls, are almost a failure.—JAMES DAY.

### IRELAND.

**Charleville Forest, Tullamore.**—I have never known the hardy fruit crops here so poor. The long, severe spring, which lasted almost to the end of May, was simply ruinous to them. Apricots, Morello Cherries, Damsons, and I might almost add Plums, are a failure. Sweet Cherries a few. Apples and Pears about a quarter crop. Strawberries good. Currants and Raspberries fair.

The Potato crop has got a very early touch of blight, which will give late sorts not much chance for a return. The leaves are almost all cut. Champion, just at the season when the tubers ought to be swelling. The half of early kidney and second varieties is now rotten. Peas were never better. The same applies to all other vegetables except Onions, which would have been benefited by more sunshine.—ROBT. McKENNA.

**Castle Upton, Templepatrick.**—The fruit crops here are much under average, with the exception of Raspberries, which were very heavy and fine. Strawberries are very poor. Other bush fruit is a fair average. A few Apples, such as Warner's King, Keswick Codlin, Small's Admirable, Irish Peach, Duchess of Oldenburg and Ribston Pippin, are a fair crop; others poor. Pears, Plums and Cherries are poor.

Midseason Peas have been good. Early Potatoes clean, but small.—E. TAPPING.

**Stradbally Hall, Queen's Co.**—After the wet, sunless weather we experienced here last autumn, fruit trees, especially Pears and Plum made a good show of bloom. Consequently, we anticipated a grand fruit year, but the May frosts blighted the bloom. This garden being low and late escaped better than most in the district, some of which have scarcely an Apple, Pear, or Plum on the trees. Here we have very few Pears or Plums, but a very fair crop of Apples. Of dessert sorts, Devonshire Quarrenden and King of the Pippins are fairly cropped. Of kitchen sorts, Tower of Glamis, Fillbasket, Cat's-head, Warner King, and a local sort named The George are the most plentiful. The last-named Apple is by far the heaviest cropper we have this season. It is a beautiful fruit and a good cooker. Of small fruits, Red Currants were good; Black poor. Gooseberries medium. Raspberries showed plentifully, but many of the fruits failed to swell. Strawberries, Noble and Vicomtesse H. de Thury were heavily cropped and good; Sir Joseph Paxton and Latest of All were poor in crop, but of good quality.

Vegetables, although late, are quite up to the average in quality; Onions are especially good with me, but I sowed the main crop on a hot-bed in February, and planted out between young Strawberries in April. On our cold, wet soil we have never been able to get really good Onion by the ordinary system of sowing, and would strongly advise anyone in a similar position to try the frame system. There is no loss of time as there is no after-thinning to do.—J. TWENDALE.

**Headfort Gardens, Kells, Co. Meath.**—We had a fine show of bloom, but owing to the wet and cold season we have very little fruit

ples are under average; Pears the same; bush fruits scarce. Strawberries promised well, but the fall here for the month of June was 6.56 in., the result being that all the best fruit rotted. The kinds I favour are Royal Sovereign, Noble, Hogg, and Latest of All. I grow others, but the above-mentioned do best with us.—JAS. BUNSLAW.

**Castle Macgarrett, Claremorris.**—The fruit crops in the gardens here are much below the average. Apples and Pears very light. Plums and Cherries on walls fair. Filberts good. Small fruits were plentiful. Gooseberries and Currants all kinds very good; also Strawberries.

Vegetables of all kinds satisfactory. The following Peas have done well this season: Telegraph, Fillbasket, Alpha, Prizetaker, and Champion (England). We have beautiful green Peas now (October). Telegraph is a splendid Pea and does well here. Potatoes not so heavy as last season; quality poor. Potatoes planted early in March much better than late-planted ones; the latter diseased before they are fully grown and marketed.—J. QUAA.

**Straffan House, Straffan Station, Co. Kildare.**—The fruit crops in this neighbourhood are much under average, brought about by the severe frosts of March 30 (14°) and April 2 (11°), each of 10 hours' duration. Peaches, Apricots and Plums all failures, and the Peach trees nearly all killed outright. Of Apples, we have good crops of Lord Suffield, Blenheim, Northern Greening, Fearn's Pippin, Loddington, Cellini, Bess Pool and Bramley's Seedling, and in each case these kinds bore very heavy crops in 1895 and 1896. Pears are early an average crop. Marie Louise, Winter Nelis, Passe Colmar, Knight's Monarch, Ne Plus Ceris, Beurré Rance and Alexandre Lambre have all good crops. Strawberries were an extra heavy crop, Royal Sovereign, Vicomtesse Hélicart de Lury, Waterloo and President being the best. Gooseberries, Raspberries and Currants of all kinds were excellent, but much damaged by wet. Vegetables, on the whole, have not been a success. Runner Beans good and Veitch's Criterion was extra good, but other kinds poor as regards produce.—FREDERICK BEDFORD.

**Fota, Cork.**—Fruit crops in the south of Ireland are much below the average. February was warm and dry month, which unduly excited the sap of fruit trees. In March and April there were heavy gales of wind and rain. The Plum blossom opened first, only to be cut off by the wind as fast as every bud expanded. Pears followed, and were treated the same; Cherries also. The mean temperature of the three months was the same, except that of February, which was about half degree warmer than the two following months. Small fruits were very partial; in one garden, as here, Gooseberries were a full crop, in others in the neighbourhood none; other small fruits under average; Strawberry season short. Apples are an average crop and fruit clean, but not so well coloured as last year. The following are bearing heavy crops: King of Pippins, Blenheim range, Cox's Orange Pippin, Worcester Pearmain, Kerry Pippin, Ashmead's Kernel, Queen of Glamis, Lord Grosvenor, Lane's Prince Albert, Small's Admirable, Sandringham, Stone's Farmer's King, Tom Putt, Winter Hawthornden, Lady Henniker, Gascoigne's Seedling, Alfriston, Golden Noble, and Bramley's Seedling, a constant and heavy bearer. I mention this because any may be deterred from planting it, in consequence of the few unfavourable reports we read from time to time as to its bad growth and shy bearing; here it commences to bear after two years. It is a splendid grower, and bears heavy crops of fine clean fruit every year. The old favourite, Wellington or Dumelow's Seedling, is less here, so the heads have been cut off and affected with Bramley's, branches of this being now bent to the ground by the weight of fruit. I mention this to show that there cannot be any fixed and fast line drawn as to the best varieties of fruit for every garden; other fruits are influenced in like manner by soil and locality. Pears are scarce, and these cracked and malformed; Peaches

a very heavy crop under glass copings and well coloured, but lacking sugar in consequence of the sunless August. Figs and Mulberries are fine crops, but destroyed by birds and wasps.—W. OSBORNE.

#### SUPPLEMENTARY.

**Addington, Winslow.**—The fruit crop is disappointing. Apples may be said to be a complete failure, the very heavy crop carried last year may partly account for this. Pears are also a thin crop with the exception of Fon Chrétien, Marie Louise d'Uccle, and Crassane. Plum trees showed a great deal of blossom, but during the time they were in flower we had a long spell of dry, east wind, which did much damage. Some young espaliers are, however, bearing a fine crop, particularly one named The Czar, also Prince Englebert and Monarch. Small fruits of all sorts are abundant and good.

Vegetables of almost all kinds have done well this year, the exception being the Pea crop, which was soon over. All the Brassicas are now looking strong and healthy, so the prospect for autumn and winter is good. Of early Potatoes I find Sharp's Victor a really good kind, both for produce and quality, and it has been perfectly free from disease. Among later kinds I have a suspicion that disease exists, but I have not proved it yet. I may say a word in favour of Veitch's Climbing Bean, it is most productive and of excellent quality.—A. MATHIESON.

**Ashwellthorpe Hall, Norfolk.**—Fruit crops in this garden are far below the average, Apples being a total failure. Pears are a very poor crop. Plums are very thin on the walls and on the standard trees. Damsons are almost a failure. Apricots are the best crop we have. Peaches and Nectarines on unprotected walls are a fair crop. Gooseberries, Currants, and Raspberries were a very thin crop. In this neighbourhood Raspberries are grown largely for market, and the crop was only about a third of what it usually is.

Vegetables of all kinds have done fairly well, Peas better than usual. The Potato crops are very good indeed, and Onions in this garden have never been better.—T. B. FIELD.

**Osterley Park, Isleworth.**—The fruit crop is much below the average. Apples are very scarce with the exception of the early and soft varieties, such as Keswick and Lord Suffield, which have carried fair crops. Pears and Plums are a failure. Bush fruits are much below the average, while Peaches on the open walls are carrying heavy crops. I gathered the first dish of Hale's Early on July 20, ten days later than last year. The trees suffered badly from blister early in the year, owing to cold winds and late frosts. Strawberries have been excellent with me this season. Walnuts are a failure and Cob Nuts a good crop.

Early Potatoes have been a good crop and free from disease, but I find it spreading in the later crops. Peas did well in the early part of the season, but after the heat and drought they were badly attacked with mildew and thrips. Such sorts as Daisy, May Queen, Veitch's Perfection, and Antocrat bore the best crops. Beans have done well. Root crops look remarkably well since the recent heavy rains.—JAS. HAWKES.

**Tedworth, Marlborough.**—Fruit crops in this neighbourhood are very disappointing, especially stone fruits. Plums and Apricots are almost a failure. Cherries a light crop. Apples partial, early varieties being much better than late ones. Lord Grosvenor, Lord Suffield, Cox's Pomona, King of Pippins, Yellow Ingestre, Worcester Pearmain, Beauty of Bath, Irish Peach, Stirling Castle, Ecklinville Seedling and Lane's Prince Albert are carrying good crops. Some later varieties are carrying half crops, although all blossomed well. We certainly had some late frosts, but I think the cold winds did the mischief. Pears in some places are satisfactory, but in others light. Our best varieties are Clapp's

Favourite, Seckle, Thompson's, Brown Beurré, Beurré Rance, Glou Morcean and Josephine de Malines, with a fair crop of Doyenné du Comice. Peaches and Nectarines inside have been very good, but are very unsatisfactory on outside walls, suffering more than usual from blister. Strawberries have been very satisfactory, both forced and in the open. Raspberries were also a good crop, but suffered somewhat from drought. Superlative is a fine fruit. Black Currants were a heavy crop of fine fruit, Red and White Currants very scarce. Gooseberries were also a good crop and troubled little with caterpillar. Nuts of all kinds are plentiful; in fact, I never recollect such a heavy crop of Hazel Nuts.

Vegetable crops are good. There are heavy crops of Potatoes and very little disease at present. Peas have done better in than the past two seasons. Sutton's Climbing French Bean Epicure is very good, being a heavy cropper and the flesh delicate.—G. INGLEFIELD.

**Tring Park, Tring.**—Fruit crops here and in the neighbourhood are generally unsatisfactory. Apples are very light, having borne heavy crops for two years previously. There are a few kinds I might mention carrying fair crops; these are Ecklinville, Duchess of Oldenburg, Lady Sudeley, Lane's Prince Albert, Winter Hawthornden, King of Pippins, Dumelow's Seedling, Hanwell Souring, and Court Pendu Plat. Pears are a good crop and above average, quality very good. Plums on standards and bush trees are quite a failure. Some kinds on walls are carrying fair crops. Cherries quite a failure, including Morellos. Bush fruits have been very good. Strawberries, Nuts, and Filberts are carrying very heavy crops.

Vegetable crops have required much watering, the season being a very dry one. Mid-season Peas were badly affected with mildew. Early Potatoes are small in consequence of the drought, and late ones were a long time coming through the ground from some cause. As yet I have not found any disease.—EDWIN HILL.

**Ottershaw Park, Chertsey.**—Pears on walls have a fair crop, and a few sorts in the open have a few fruits. The following Apples are bearing the most fruit: Grenadier, Lady Henniker, Keswick Codlin, Lane's Prince Albert, Lord Suffield, Annie Elizabeth, Red Juneating, Stirling Castle, Gloria Mundi and Fletcher's Prolific. Apples, Pears, Plums and Cherries are poor. Peaches and Nectarines average and good.

Early vegetables have been very good, but late ones have suffered in places from want of water. Early Potatoes were very good. The second earlies are yielding good sound tubers and the late ones are looking very well.—T. OSMAN.

**Crowsley Park, Henley-on-Thames.**—The fruit crop in this neighbourhood is very poor indeed. Apples here are very indifferent. On many of the trees there is no fruit whatever, while just a few are carrying a small quantity. In most of the orchards round here Apples are a complete failure. Peaches and Nectarines are excellent. The fruit required a good deal of thinning out. The trees are healthy and clean, although they were much injured by blister in the early part of the season. Pears thin. Plums and dessert Cherries almost a failure; Morellos thin. Currants, Gooseberries and Raspberries a fair crop. Strawberries good. Filberts and the common Hazel Nuts very abundant; Walnuts poor.

The vegetable crop was very satisfactory in the early part of the season, but a great falling off took place after the drought had well set in.—W. GLASSEY.

**Ripley Castle.**—There was a splendid show of blossom on all fruit trees, but a long spell of cold north-easterly winds followed by severe drought has materially altered the promise of spring. Apples are erratic, some trees carrying good crops, others very thin indeed. Of kitchen sorts, the best cropped are Lord Suffield, Ecklinville Seedling, Alfriston, Norfolk Dumping, Councilor, Annie Elizabeth, Mère de Ménage, Nelson and Keswick Codlins; of dessert kinds, Irish Peach, Early Harvest, King of the Pippins

and Devonshire Quarrenden are bearing most freely. Pears also are erratic; those bearing most freely are Citron des Carmes, Jargonelle, Louise Bonne of Jersey, Pitmaston, Glon Morceau, Althorp Crassane and Moorfowl's Egg. More rain is badly needed in this district, otherwise Apples and Pears will not attain much size. Plums are a failure throughout. Apricots are very thin and many branches are dying off. Cherries, both sweet and Morello, are thin crops and gumming is more prevalent than usual. Strawberries were a heavy crop, but suffered through drought. Gooseberries, Red and Black

ful and over average. Strawberries promised well before the disastrous frost in the early part of May, which blackened all the first and strongest flowers, which alone can be reckoned on to produce a heavy crop. The later flowers, though they came on and did fairly well, the season being in every way favourable for their development, did not yield more than an under average crop. Apples are generally scarce; here and there a fair sprinkling may be seen on some trees, our best being Duchess of Oldenburg and Blenheim. Irish Peach and Lord Suffield are fairly good. Plums are a light crop, Victoria and

## FERNS.

### FILMY FERNS.

(TODEAS.)

FILMY FERNS form two distinct groups, one having large and bold coriaceous fronds, the other having fronds thin and pellucid in texture. *T. africana* is the plant upon which the genus was established. It was introduced into this country from the Cape of Good Hope about the year 1805. The well-known Australian ex

*Todea pellucida.* From a photograph by Miss Willmott, Warley Place, Essex.

Currants are heavy crops. Raspberries average, but soon over. Filberts good.

The vegetable crops have suffered from the dry summer. Early and midseason Cauliflowers were very unsatisfactory. Peas are bearing good crops of excellent quality, but each sowing quickly failed. Brussels Sprouts, Broccoli and other winter greens look well. Root crops are good. Potatoes are good and perfectly free from disease.—J. TUNNINGTON.

**Clarendon Park.**—The whole of the fruit crops here in South Wilts must be regarded as under average except Nuts, which are very plenti-

Rivers' Early Prolific being the best bearers. Apricots were thin, as also Cherries, except May Duke, which bore a light crop. Currants and Gooseberries were about an average with me, but in some gardens near Gooseberries fell from the trees after the frosts in May. Nuts over average.

Vegetables of all kinds have done well, early and mid-season Peas especially so, but late sorts were checked by the dry weather. Potatoes are good and promise well almost everywhere here about, and up to middle of August but little disease was to be seen.—C. WARDEN.

plorer, Allan Cunningham, sent home from that country a similar plant under the name of *T. australasica*, also known as *T. rivularis*, but the Australian and African plants are now considered to be identical. Notwithstanding this decision, however, under cultivation the African plant does not attain to anything near the proportions that the Australian plant assumes, nor is it such a vigorous grower; its fronds are more triangular in outline, and the plant altogether is more spreading in habit. The Australian plant produces fronds from 3 feet to 6 feet

length, or more. In damp ravines in Victoria it attains gigantic proportions, masses of it measuring some 6 feet in height, more than 12 inches in diameter, and over a ton in weight.

(LEPTOPTERIS) HYMENOPHYLLOIDES, also known by the name of pellucida (see cut), produces fronds triangular in outline from 12 inches to 18 inches long, and from 6 inches to 9 inches wide in the broadest part; they are, however, frequently of smaller dimensions; the fronds, which are twice divided, have elegantly-cut segments, whilst the texture of the pinnae is thin and membranous, and the colour deep green. It comes from mountain ranges in New Zealand.

SUPERBA is also a New Zealand plant, popularly known as the Ostrich-feather Fern, from the resemblance of its fronds to the curled plumes of the bird. In outline it is vasiform; the fronds are some 18 inches to 24 inches in length, tapering at each end. The point of the segments curls upwards, giving the fronds a peculiarly beautiful crepe appearance; they are bright green when young, but become dark green when old.

INTERMEDIA is a magnificent Fern, partaking in some of the characters of both the two previously named kinds, but it does not possess the vase-like form of *superba*, although its fronds are somewhat recurved.

FRASERI resembles the last in general outline; its pinnae are alternate, the segments more distant, and the lip finely divided. It comes from New South Wales.

WILKESIANA is a very beautiful plant. It usually grows from 3 feet to 5 feet in height; the stem is very slender, not larger than an ordinary walking-cane, but occasionally stouter. The fronds are some 2 feet in length.

Plants are not difficult to cultivate; they thrive in moist spots in a tropical fernery, and are equally at home in a cool house; we have seen them growing vigorously in an unheated conservatory with the protection of a mat in sharp, frosty weather; whilst as ornaments in a Wardian case in well-lighted-rooms the filmy-fronded kinds are unequalled. Wherever grown, however, the sun's rays should never reach them, but do not shade them with green glass, or the beauty of the elegant fronds will be destroyed. These plants enjoy moist air; their fronds like to be frequently bedewed with the syringe, whilst the roots must be kept wet, but water must never stand about them. The soil should be good, peaty peat, a little loam, and some sharp river sand.

#### GYMNOGRAMMA SCHIZOPHYLLA.

This is one of the most beautiful Ferns in cultivation, and very pretty in a young state. In a warm house it is of the easiest culture and thrives either in pots or baskets, its habit fitting it well for the latter. It should, if possible, be suspended where the fronds cannot be touched or broken, as when grown on a stage with other plants they are apt to be. The fronds on well-grown specimens grow from 18 inches to 2 feet in length, and the pinnae are deeply cut, the dark, wiry stems showing plainly through them. It is a good practice to syringe this Fern much overhead; a light dewing may do no harm on hot drying days. If required for table decoration it may easily be kept in small pots; in fact, it is much safer under than over-potted in any case, but when a plant becomes very much potted it is wise to give the roots a chance to get free from the old ball before repotting. This may be done by turning it out of its pot and laying it for a time in a little loose Fern compost. The young rootlets soon begin to run out into this, and the plant may safely be potted, with a little of the new material clinging to the roots. If placed in a fresh pot without this precaution the old ball often gets dried up, while the soil around it is moist, the consequence

being that the roots perish before they have a chance to get out. Very pretty baskets may be made by placing a strong plant in the centre, and, as the young crowns appear on the tips of the fronds, pegging these down to the sides of the basket. In about three years they will be at their best, and another set should be planted to take their place when they become too thick, for the beauty of this Fern lies in its lightness and airy character, and this is to some extent lost in a thick mass of fronds.

The best way to propagate *G. schizophylla* is by means of the young crowns referred to, these being laid on small pots of compost near the parent plant until rooted. They come away with more freedom than divided portions of an old plant, as these cannot be separated without losing many of the best roots. If only the latter are at command, place them in as small pots as possible in a moist house, so that they may be kept fresh without very much root moisture. Once let the roots get hold of the soil they are all right, but the latter soon becomes sour and unsuitable for them when the moisture is not taken up. This fine species is a native of Jamaica and was introduced in 1880. There is a garden form called *gloriosa* which is stronger in growth, but the type is as often as not sold for it. R.

#### THE HARDY FERNERY.

Now that autumn has come, with its fine days and cool nights, the best time of the year has arrived for the formation of new ferneries outdoors or the re-arrangement of old ones. This, therefore, is an appropriate time to bring forward the

##### MODE OF PLANTING.

The planting of Ferns is often done without any system, in a sort of haphazard style, and thus the effect is considerably minimised. While system however is necessary for the production of the best results and effects, it must not be supposed that a symmetrical and artificial style is advocated. One thing which is perhaps more noticeable than any other in the natural habitats of the Fern family is the manner in which they grow. As a rule, where Ferns are abundant they are found growing in masses or clumps of each individual kind, and although stragglers are found outside of these clumps, they are as it were colonisers, which have by some means become isolated, but which will proceed to gather around them a progeny by offshoots or spores, which will in course of time form equally effective masses as those existing in their immediate neighbourhood. For instance, on the mountain sides are seen square yards covered with nothing but the Parsley Fern (*Allosorus crispus*); in other places dense masses of the Lady Fern (*Athyrium filix-femina*); elsewhere even larger masses of the Male Fern (*Lastrea filix-mas*). In some places the mountain Buckler Fern (*Lastrea montana*) abounds, forming long, irregular masses; and the same remarks may be made in reference to most of the British species. When these things are considered they serve to guide Fern cultivators in the style they should adopt in the planting of Ferns in their gardens, whether in rockwork or otherwise. Far too frequently Ferns are dotted about and intermingled one with another, so that there is nothing definite in the effect, all individuality of species being lost. To prevent this, and at the same time to come as near as possible to Nature's ways, Ferns should be planted in clumps, say half a dozen or so of a kind together. By this means each kind will be kept distinct, and an effect produced at once pleasing and natural. By a judicious arrangement of the different genera and species or varieties, the peculiarities of each may be made

prominent, the clumps of the heavier-foliaged kinds serving to show up those of the lighter and more graceful kinds. The colour also, or the shades of green, should be considered, and thus another feature of interest utilised in the arrangement to produce improved effect.

##### TIME FOR PLANTING.

Autumn is the best time of the year for the planting of Ferns out of doors, as, their season's growth having been made, they will bear removal then better than when in growing condition, and there is little risk of injury provided reasonable care is exercised. When replanted in September or October the plants have an opportunity to make roots and become established by the spring. They may, indeed, be safely removed any time before growth commences, but the longer the interval between their removal and their commencing to grow, the better it will be for them. All Ferns should be removed and replanted with as many roots as possible; if the whole of the living fibrous roots they have made are left intact there is far more certainty of their making vigorous and satisfactory growth the following season than if a number of these feeders are broken off and the plants deprived of their assistance. At this season also division of the crowns and rhizomes may be most safely accomplished, and thus an increased number of plants be secured for extension of the fernery.

Many people have a clearing up when the leaves have fallen from the trees and the Fern foliage becomes brown, but in the interest of the Ferns this should be postponed until spring. The fronds of the Ferns and the fallen leaves when left on and about the plants serve materially to protect the crowns and slender creeping rhizomes of such as the Oak Fern, the Beech Fern, and similar kinds from the frosts and cold winds. They also serve to retain moisture about the plants, which is very beneficial during even the dormant season. In spring, when the new fronds begin to start and growth is on the point of becoming vigorous, it is advisable to remove the old fronds, as they are not then of much further use to the plants, and they can be dispensed with and the fernery cleared up ready for the new season.

An important matter in the making of a new or in the reconstruction of an old fernery is the supply of proper compost for the Ferns to grow in. When possible some good fibrous turfy loam should be procured, and after the removal of any growing material, the fibrous portion should be chopped up so as to form a nice rough mass. To this should be added an equal proportion of good partially decayed leaf-mould, another equal quantity of good fibrous peat, and about an equal proportion of sharp sand. These mixed together will form a compost in which almost any Fern will grow luxuriantly. Of course, some of the kinds require a little variation. For instance, the Polypodies will be better with a double quantity of leaf-mould, the *Osmundas* a double quantity of peat, the *Scelopendriums* will also be benefited by a free admixture of lime in the form of old mortar, broken oyster shells, or tufa dust. *Blechnums*, however, cannot do with lime at all, hence it is a good plan to mix up the general compost first, and then, taking this as the foundation, provide the various kinds with anything special which they may require. There are many very beautiful varieties among the hardy Ferns which, unfortunately, are far from being as well known and as extensively cultivated as they deserve. Some of the North American species are exceedingly hardy and their style of foliage quite distinct from anything among British Ferns, while, on the other hand, some of the varieties of our native Lady Fern, Poly-

body and Shield Fern are exquisite in their finely divided fronds and delicate shades of green. B.

## ORCHARD AND FRUIT GARDEN.

### APPLE LORD DERBY.

THIS variety is well known and worth a prominent position in the garden. I well remember at the National Apple Conference at the Royal Horticultural Society's Gardens at Chiswick in 1883 this variety was shown in no less than forty-three collections from all parts of the country, and a dish from Messrs. Lane and Sons, Berkhamsted, was specially fine. Mr. Barron describes it as a large, oblong, angular, greenish-yellow, mid-season fruit of first quality for cooking, a fine handsome Apple and a great bearer. These, remarks everyone will admit, are very appropriate. It appears to have had no synonyms at the congress noted above, and this is strange, as many of our most popular Apples have numerous synonyms. The congress alluded to is now bearing excellent fruit, as we have at the present day evidence of better cultivation, and growers now grow the better fruits which were less known at the time noted.

This variety is often mistaken for Gloria Mundi and Belle Dubois, but if the fruits are placed side by side it is soon distinguished, as Gloria Mundi is the less angular of the two, much paler green, and in my opinion not nearly so good as Lord Derby. In the north the Apple illustrated is one of the most popular kinds grown, and in cooking Apples size is not despised. Though a midseason fruit, it may be kept well into spring in a cool store. The flesh of this Apple is greener than is often seen in many of the large cooking varieties, and to this may be attributed its good keeping, as the dark green skin is hard and very bright at the time of gathering. Few Apples are better for exhibition than Lord Derby. This season I had fruits nearly 5 inches in height, and I noticed at the Royal Horticultural Society's show at the Crystal Palace on Sept. 30 some grand specimens of this variety exceeding the dimensions given above. No less than twelve lots were staged in the single dish class, and the fruits were very fine indeed also in the collections of dishes of cooking varieties.

As regards soil it does not appear fastidious, as I have it in very poor soil resting on gravel, and even thus the trees make a strong growth, indeed too strong, unless the roots are curbed. If on the Paradise stock there is less rank growth, and the trees rarely fail to crop freely. In suitable soils the fruit colours up well if not gathered too early, assuming a golden colour. It is at times used for dessert, and anyone who likes an acid flavour will find this to his liking, as at the season named the flavour is brisk and pleasant. It makes a grand orchard tree, as in this way the tree is given more liberty, making an erect growth, and is most valuable for market work. In all selections of Apples for cooking, keeping, and profit, I would give this a place if only a dozen of the best were selected, on account of its free-cropping qualities and absence of small useless fruits. For cordon culture I do not advise it, as it grows too strong, and if not frequently root-pruned the wood is gross. Lord Grosvenor, one of the Collins, is far better as a cordon.

G. WYTHES.

**Pear Comte de Flandre.**—I have only met with this Pear on one or two occasions, yet when gathered just at the right time and stored in a

cool room the fruit ripens up well and the flavour is very good. The fruit, moreover, keeps some time in good condition. One thing I have always noticed in connection with this Pear is that if grown in a shallow, light soil, or not supplied with water in a dry season, the fruits are almost sure to fall. Where it does well, gathering should be postponed till as late as possible, or the fruit will shrivel. In cool, moisture-retaining soil it does best, the foliage being large and of a very dark shining green colour. I have a healthy tree in upright cordon form on a west wall. This bears well in five seasons out of six. The only fault I have to find with this Pear is that it casts a portion of its fruit if allowed to get too dry at the roots.—J. CRAWFORD, *Coddington Hall.*

**Apple trees on mounds.**—Having a rough grassy bottom with a hard chalkstone base near to his kitchen garden at Lockinge, on which it was desired to plant Apple trees, Mr. Fyfe, having broken up roughly the bottom where each tree was to stand, carted in a load of rough soil to each one, put it down as a mound, then planted the tree on to it. The trees did remarkably well, and since then their root area has been added to

with advantage, as in finally transplanting where to remain and fruit, there need be little exposure of the roots, and the work can be done early in the autumn. In transplanting it is wise to prune back the roots of yearlings somewhat, the result is for the second transplanting clump of nice fibrous roots close home. Towards the spring the heads should be hard pruned also unless it be done when the roots are pruned at planting.—A. D.

### DAMSONS.

THE notes on Damsons by "S. B. M." (page 24) are well worth reading. He prefers the long fruited, oval-shaped varieties from a flavour point of view. On this point I am at one with him and think that no variety equals the well-known Shropshire or Michaelmas Plum, as it is sometimes called. There is a peculiar richness about the sort that one finds in no other. My opinion is that there is more deception attending the sale of Damsons than any other of the Plum tribe, and this neighbourhood and the midland counties generally a small blue Plum almost as large as

Apple Lord Derby.

by carting or wheeling to the mound all sorts of garden refuse or soil, which, decomposing, forms material into which the roots run. None can strike downwards, as the base is too hard and impervious. For that reason, no doubt, there is no evidence of canker. There are many trees of good varieties, and there was for the season on them recently very fine fruit. On the south-west side a dense Yew hedge offered needful shelter from occasional fierce winds that come from off the Berkshire downs.—A. D.

**Propagating bush fruits.**—The earlier in October good stout, straight shoots can be taken from the bushes of Gooseberries and Currants for the making of cuttings, and the more quickly planted, the better prospect of a good take and the forming of strong young bushes next year. The market growers, in putting down breadths by thousands, prefer yearlings, as cheaper and more likely to root quickly. In private gardens where a few dozen only may be grown in this way yearly, to keep the fruit garden or orchard well furnished, transplanting yearlings into a fresh nursery bed, giving more room and growing on into larger bushes a second year, may be done

by the Early Violet, and known to growers as the Damsene is often palmed off as a real Damson. The flavour is inferior to that of any of the Damsons, the fruit generally eating dry. I believe, however, that the flavour is much influenced by the soil in which the trees are grown and although I suppose no good reason could be given, it is a fact that the trees are in more gardens than not planted in shaded positions near large trees. Perhaps the hardy character of this fruit tempts people to plant thus, reserving the more open sunny positions for the larger sorts of Plum. Perhaps the most profitable Damson for market because the freest bearer, is the Farleigh Prolific Kent Cluster or Crittenden. It is well the planters should be made aware of these various aliases, as no doubt this Damson has in more than one instance been planted under all the names with the idea that they were distinct varieties. From a sale point of view this would not so much matter, but where difference of character and flavour is looked for it is disappointing. To prove that new Damsons are taking a much larger form, I may mention that a small Plum sent out by a leading firm has

ers been dubbed a Damson, as it partakes, as they think, more of the character of the latter than the former. This is now known by the name of the Prolific Damson. It bears wonderfully freely, carries a beautiful bloom, hangs a long time on the trees, being ready for use in August, and is of good flavour. I do not care for a sweet Damson, preferring that pleasant bitterness so prominent in the old Shropshire, but for those who would appreciate one as sweet as the choicest dessert plum, Frogmore Damson, an early variety and good yielder, is such. One great characteristic feature of Damsons of all sorts is their exceptional firmness, this no doubt being the reason why so many advocate planting in hedgerows and similar places. The thing is right enough in purely rural districts, but in the vicinity of towns it only leads to be so inclined to break the law of trespass, destroy the hedges, and steal the fruit.

J. CRAWFORD.

## SOCIETIES AND EXHIBITIONS.

### FRUIT SHOW AT THE CRYSTAL PALACE.

SEPTEMBER 30 AND OCTOBER 1 AND 2.

The general consensus of opinion with respect to this exhibition was that it fully maintained the high degree of excellence attained in previous years. There may not have been anything very startling as compared with previous shows, but the average quality throughout was remarkably good. Those exhibitors who a few years back would not hesitate to stage second-rate produce would find it quite useless to do so, hence there is a decided absence of second-rate fruit of any kind. With respect to the Apples, the general impression was that the size was rather under that of last year, but in compensation for this the fruit was as regards colour and firm, weighty fruit was all that one could desire. The same applies generally to the Pears, but there was an absence of spot, whilst they gave every indication of thorough good ripening. Peaches and Nectarines were fully up to the average in quantity and quality. Plums were present in good numbers too. Evidently most of the dishes were from walls, and, taking into consideration the lateness of the season, remarkably good. Grapes as a whole were no better, if so good as at previous shows. There were no bunches of abnormal dimensions, but there was a decided tendency to relinquish exhibiting the more inferior kinds. It was a treat to see the highly-finished bunches of Mrs. Pince's Bek Muscat. These were beyond any question the three best bunches in the show. The trio of Bek Hamburgs from the same source were also of splendid quality and finish. The three bunches of Chasselas Napoleon were beautiful examples, the clear pellucid appearance of the berries being most attractive; this is a fine Grape when in good condition. Of Madresfield Court there were two remarkable bunches, highly coloured and fine in berry. The winning three bunches of Muscat of Alexandria were models of good culture in every respect. The competition in the classes for collections of fruit was very much better than last year in all instances except in the nurserymen's classes. The two chief classes for general collections brought out some most commendable produce, and greatly in advance of last season. The taste also was evinced in the staging than previously shown. The same remarks also apply to collections of hardy fruits grown entirely in the open and those grown partially under glass; in both these classes some excellent produce was staged.

It is a pity the competition in the classes set up for nurserymen is not more keen than it is. This, in one class there were three competitors, but in all the rest it was more of a walk over. It may not be inferred by this that the exhibits in any case did not come up to the high standard of the best-known exhibitors, for they were of splendid quality in each case. Taken as a whole, the majority of the prizes for Apples and Pears

still continue to go to Kentish growers, but exhibitors from Sussex, Surrey, and other southern counties now bring up some first-class examples; hence the contrast between Kent and other districts is not, on the whole, so much in evidence as it has been. Special note should be made here of the magnificent exhibit of Apples from Monmouthshire. These betokened high-class quality and cultural skill to a remarkable degree. The miscellaneous exhibits were numerous and quite representative of our British-grown fruit. Most of this, of course, comes from small trees, but it indicates what may be done in the earlier stages of fruit trees. As regards the extent of the exhibition, it should be noted that there were in use nearly 1000 more plates than at the last show. This will afford some idea of the increase on the present occasion. This increase was not perhaps to many so apparent as it really was by reason of the more scattered character of the show this year in consequence of the, for a time, permanent exhibition of other industries. This resulted in different arrangements being made, which in nearly every case met with the approval of exhibitors. Those who staged in divisions 1, 3, and 4 had better positions most decidedly, more light and more convenience in every way. Mr. Wright and his assistants worked hard to make the arrangements as complete as possible, and it is gratifying to note that the results met with general approval by the exhibitors.

On each day of the show a lecture was delivered on various branches of horticultural industries. These will receive comments later on when more detailed reports are at hand.

#### DIVISION I.—COLLECTION OF FRUIT.

In the first class for twelve dishes of ripe dessert fruit there were three competitors, the premier award being rightly made in favour of Mr. Harris, gardener to Lady Henry Somerset, Eastnor Castle, Ledbury, who had a remarkably even exhibit and of excellent quality, whilst the arrangement was well balanced. These dishes consisted of fine Muscat Grapes and Gros Maroc, also good; the Pine-apple was Smooth Cayenne, an excellent fruit; Prince of Wales and Sea Eagle Peaches, both well finished, the former being specially well coloured. Apples Ribston Pippin and King of the Pippins were both represented in good condition. Pitmaston Duchess Pears and seedling Melon added to the effect. Of Nectarines there was a good dish of Albert Victor, and others of Coe's Golden Drop Plums and Brunswick Figs. Mr. Goodacre (gardener to the Earl of Harrington, Elvaston Castle) came in a good second, he having as his finest dishes a well-ripened Queen Pine and excellent Muscat and Black Hamburg Grapes, fine Pitmaston and Souvenir du Congrès Pears, and capital well-coloured fruits of American Mother Apple, with a good example of Hero of Lockinge Melon, Sea Eagle Peaches and Brown Turkey Figs. Mr. McIndoe (gardener to Sir Joseph Pease, Hutton Hall, Yorks) had on this occasion to be contented with third place. In the smaller class for eight dishes of ripe fruit, Mr. Reynolds (gardener to Messrs. de Rothschild, Gunnersbury Park, Acton) came well to the front, there being in all some six competitors. His dishes were, of Grapes, Muscats, well coloured, and large clusters of Gros Maroc, a fine-looking seedling Melon, Gladstone and Princess of Wales Peaches, capital fruits of Ribston Pippin Apple, with Coe's Golden Drop Plum and Pine-apple Nectarine. Mr. Empson (gardener to Mrs. Wingfield, Amphil House, Beds) was second.

#### GRAPES.

For six distinct varieties, two bunches of each, Mr. Reynolds was first, staging three white and three black varieties. Of the former, the Muscats were well coloured and of good size. The Chasselas Napoleon formed a striking dish, very fine in berry and clear in colour, and Buckland Sweet-water in its best condition; and of the latter, Black Hamburg, kept well and good in berry; Gros Maroc, large bunches and berries; and Ma-

dresfield Court, slightly over-ripe. Mr. Taylor, gardener to Mr. C. Bayer, Tewkesbury Lodge, Forest Hill, was a good second, having a splendid bunch of Madresfield Court and another of Muscat, with Gros Guillaume well finished; a weak pair of Trebbiano, however, detracted from this exhibit. For three varieties, in pairs, Mr. Cole, gardener to Sir George Russell, Swallowfield Park, Reading, won with comparative ease, having very superior Muscats, with colour and form of bunch at their best; Foster's Seedling, fresh and clear, and Alicante for a black. Mr. Jones, Ridgway Vineries, Cradley, Malvern, was very fortunate in being placed second with Gros Maroc, Gros Colman, and Alicante, all of good average merit, against fine Muscats, finer Gros Colman, and Gros Maroc from Mr. Harris. For Black Hamburg (three bunches) Mr. Mitchell, gardener to Mr. J. W. Fleming, Chilworth Manor, Romsey, was easily first with ideal bunches, finely coloured, Mr. Taylor in this case being second with bunches not so well coloured. For Madresfield Court, Mr. Taylor won the first prize in a most creditable manner, the bunches of medium size, but large in berry. Mr. Tidy, gardener to Mr. W. K. D'Arcy, Stanmore Hall, came in a good second. His bunches slightly lacked colour. For Gros Colman or Gros Maroc, Mr. Jones won with the former variety, both bunches and colour being first-class and the berries of extra size. Mr. Reynolds was second with good bunches of Gros Maroc. For Black Alicante the competition was very keen, there being but little to choose between all three prize-winners. Mr. F. Cole was placed first with handsome bunches, well coloured, Mr. J. Bury, Petersham Vineries, Byfleet, second, and Mr. Tate, gardener to Mr. Henry Tate, Park Hill, a very close third. For Lady Downe's Seedling Mr. Tidy was first with neat bunches of medium size but fine in berry, and Mr. Empson second with bunches a trifle deficient in colour. For any other black variety Mr. Mitchell was first with noble bunches of Mrs. Pince's Black Muscat, remarkably well coloured, and Mr. Smith, gardener to Mr. R. Ovey, Badgemore House, Henley-on-Thames, second with good clusters of Alnwick Seedling. For Muscat of Alexandria the competition was again very keen, but Mr. Cole won the first prize with ideal bunches of large size, long and tapering, with the beautiful clear amber finish so much desired but not always to be had; Mr. Goodacre was a good second, showing fine clusters, but with a slightly perceptible difference in colour. Mr. Reynolds followed closely for third prize. For any other white variety Mr. Reynolds was first with Chasselas Napoleon, fine in bunch and berry, Mr. Taylor taking second place with Buckland Sweet-water.

The competition in the one class provided for Figs was much better than last year, whilst none of the fruits was any too ripe, a most essential point in showing the Fig. Mr. Messinger, gardener to Mr. C. H. Berners, Woodverstone Park, Ipswich, was first with very fine Brown Turkey, of the ideal colour and of full size. Mr. H. Folkes, gardener to Mr. C. E. Strachan, Gaddesden Place, Hemel Hempstead, was second, again with Brown Turkey, whilst the third prize went to the same variety yet again, and that against larger and fine fruits of Brunswick. Quality with the judges had its proper weight. For a collection of hardy fruit grown entirely in the open, and to consist of not more than fifty dishes, Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, showed a remarkably fine even lot of fruit, which in addition was tastefully arranged with suitable foliage and other useful adjuncts to attractiveness. This exhibit comprised of Apples, fine dishes of Cox's Orange Pippin, Wealthy, Warner's King, Alfriston, Ribston Pippin and Cellini, and of Pears there were very good examples of Beurré Bachelier, Beurré Bultet père, Beurré Sterckmans, Doyenné Boussoch, Louise Bonne of Jersey, Beurré Diel and Brown Beurré, with Pitmaston Duchess. The Peaches comprised Sea Eagle, Golden Eagle, Nectarine, Barrington, and Late Admirable, with Walburton Admirable. Other dishes

comprised Coe's Golden Drop, Pond's Seedling, and Washington Plums, with the Shropshire Prune, Morello Cherries, Walnuts, and Nuts, as well as Sweetwater Grapes, making in all a well-varied exhibit. Mr. Powell, gardener to Colonel Brymer, M.P., Ilington House, followed closely, but not with so varied a collection. The finest dishes were those of Apples and Pears; of the former the best were noted as being of the well-known and approved varieties.

For a collection of not more than thirty-six dishes of hardy fruits grown partly or entirely under glass to illustrate orchard-house culture, Mr. R. Potter, gardener to Sir Mark Collet, Bt., St. Clare, Kemsing, Sevenoaks, was placed first, he having several remarkably fine dishes, notably Rond Noir and Brown Turkey Figs, Lady Palmerston, Golden Eagle, and Princess of Wales Peaches, Coe's Golden Drop Plums, and of Apples, Ribston Pippin, King of Tompkins County, Baldwin, Lady Henniker, and Emperor Alexander, with grand Pears, of which Marguerite Marillat, Pitmaston Duchess, Doyenné Boussoch, Doyenné du Comice, and Duchesse d'Angoulême were the finest; and the Grapes did not, however, add to the quality of this exhibit. Mr. McIndoe also showed well.

#### DIVISION II.—NURSEYRYMEN.

In the collection of fruit trees bearing fruit, though there was less competition than might be expected, the trees shown by the Messrs. Rivers and Bunyard were splendid, and illustrated what may be done by pot culture. In this class baskets of fruit were admissible, and here was seen the cream of the fruit staged in the building. Much of this was grown under glass, and was of splendid colour and finish. In the cases of these large collections medals were the awards given. The judges gave a gold medal as first prize to Messrs. Rivers and Son, Sawbridge-growth, for a magnificent display. The centre was a large pyramid tree of Cox's Pomona, with a number of trees dotted at the base of the collection. Of the less known and newer kinds, Bijou was laden with fruit, brilliant crimson in colour; Bramley's Seedling was very fine, and Bismarck appears to be a favourite pot tree. There were some superb Cox's Orange in baskets, also Peasgood's Nonsuch of great size. This Apple was well shown by most exhibitors. Of Pears, Pitmaston Duchess was shown 2 lbs. in weight, but we preferred the smaller Princess. Conference, Doyenné du Comice, Lebrun, Durondeau, Souvenir du Congrès, Duchesse de Mouchy, and Louise Bonne of Jersey were specially good. Peaches were less numerous, but Lord Palmerston and Golden Eagle were very fine. Plums were also excellent, Coe's Golden Drop, Primate, Grand Duke, Jefferson's and Decaisne being the best. There were some interesting fruiting trees of Crabs in variety and excellent fruiting Vines in pots, the varieties being Gros Maroc, Black Alicante, Muscat of Alexandria, Golden Queen and Hamburg—truly a superb collection. For a collection of hardy fruits grown partly or entirely under glass to illustrate orchard-house culture Messrs. Bunyard and Co., Maidstone, had no rival, but rarely has the firm made a grander display, the quality and variety being much admired. This collection occupied a large space, and was noted for the splendid fruiting trees of Apples in pots. Duke of York, a new Apple of 1895, was specially good, also the new Wagener, an American variety. Cornish Aromatic was fruiting freely. Of Pears, Le Lectier, a new late Pear of great merit, Beurré Fouqueray, Conference, Vicar of Winkfield, Durondeau, Marguerite Marillat, Pitmaston Duchess, Doyenné du Comice and General Todleben were excellent. The groundwork was composed of grand baskets of The Queen, Twenty Ounce, Emperor Alexander, the new Allington Pippin, Wealthy, and Washington Apples. Pot Vines were well represented, Gros Colman, Foster's Seedling, and Black Hamburg being staged, with Lord Palmerston Peaches, the little known Reculver Figs in pots, and baskets of Grapes, well meriting the silver-gilt medal awarded. Indeed, a gold one would have been more in keeping for the excellent culture and variety.

In the next class for 100 baskets or dishes of fruit there was more competition, and here Messrs. Bunyard and Co. received the coveted gold medal. Some of the finest fruits were staged here. A pyramid of Apples formed the centre, and the table was dotted here and there with light, fine-foliaged plants, the base being mounds of fruit. Some excellent Sweetwater Grapes represented fruit grown in the open. The fruits of Bismarck, Gascoigne's Scarlet, James Grieve, Stone's, Castle Major, Twenty Ounce, Rivers' Codlin, Royal Jubilee and Ribston were excellent. Pears were equally good, the best being Beurré Hardy, Nouvelle Poiteau, Conference, Doyenné du Comice, Jean Van Geert and Marie Louise. Mr. H. Berwick, The Nurseries, Sidmouth, Devon, came second with mostly baskets of fruit. This exhibit was noticeable for the high colour of the Apples. The fruits most prominent were the varieties named above, but Tyler's Kernel, Beauty of Kent, Bismarck, Annie Elizabeth and Cox's Pomona deserve special mention for their size and colour. The Pears were smaller. Some fine Dutch Medlars, Brown Turkey Figs and a few Plums were staged. The third place was taken by Messrs. Hartland, Louth Nurseries, Cork, and this firm is to be congratulated on their excellent exhibit, some of the kinds being rarely seen at shows. For not more than fifty varieties, Mr. J. Colvill, Sidmouth, was awarded the silver-gilt medal with excellent fruits, and tastefully arranged with fine-foliaged plants. There was more variety in this exhibit than usually seen, the large square baskets of fruit and small round ones making a nice display. There were very nice Pitmaston Duchess, Beurré Clairgeau, Brockworth Park, Marie Louise, Grosse Calebasse and Catillac Pears, very fine Lane's Prince Albert, Mère de Ménage, Cox's Pomona, The Queen, and Newton Wonder Apples, and good Plums, Medlars and Peaches. Mr. A. Wyatt, Hatton, Middlesex, was second with smaller fruits, but of good quality. For a collection of not more than fifty varieties of Pears there was only one competitor, and here Mr. Berwick, Sidmouth, secured the silver-gilt medal. The fruits lacked the size of those of last year's collections. We think this is a class which might with advantage be altered if made into two, one for gardeners. It would be well contested, as the largest class for gardeners is for twelve varieties only. One of the best exhibits was that of Mr. John Barham, Fair Oak Nurseries, Bassaleg, Newport, Monmouth, for not more than fifty dishes of Apples. Here there was no attempt to decorate, but the fruits showed special culture, and that Wales can produce fruit little inferior to that of Kent. The colour was equally good: indeed some kinds were even brighter (silver-gilt medal). Messrs. Hartland, Cork, took the silver medal with a very excellent collection, the fruits smaller. Munster Pippin (a very showy fruit), Stone Peach, White Square, Bank's Exhibition, Scarlet Tiffin and Kilderskin were very fine.

#### DIVISION III.—GARDENERS AND AMATEURS ONLY.

Here there was no lack of exhibitors, and, as is usually the case, the Kent growers had the lion's share of the awards. The strong competition from all parts of the country showed that cultivators are alive to the importance of good fruit culture, and this in a measure is due to the splendid conferences held at Chiswick a few years ago. For twenty-four dishes, sixteen cooking and eight dessert, Mr. Woodward, Barham Court Gardens, Maidstone, was first. Mr. A. Bayford, gardener to Mr. Lee-Campbell, being second with smaller fruits. Mr. G. Goldsmith, gardener to Sir E. Loder, Bart., was an excellent third, there being six competitors. In the class for twelve dishes, eight cooking, four dessert, six lots were staged. An excellent lot from the Bishop of Bath and Wells was disqualified, Baumann's Red Reinette being shown as a kitchen Apple. Mr. Pragnell, gardener to Mr. J. R. Wingfield Digby, Sherborne Castle, Dorset, was first, having very heavy Lord Derby, Warner's King, Peasgood's Nonsuch, Allrison, and Annie Elizabeth, with fine Ribston, King,

Cox's Orange, and Sturmer Pippins. Mr. W. Miller, gardener to Mr. T. W. Startup, West Farleigh, Maidstone, was second, some of the cooking fruits being very fine. For nine dishes, six cooking, three dessert, there was a poor show only two lots being staged. The first prize lot was excellent, there being grand Warner's King, Peasgood's, Sandringham, and Stone's, with Cox's Orange, Worcester Pearmain, and Washington. These came from Mr. Slogrove, gardener to Mrs. Crawford, Gatton, Reigate. Mr. Herbert, Nutfield Court, Redhill, was second with smaller fruit. For six dishes, cooking, there were six competitors. Here Mr. Woodward was first with highly-coloured Mère de Ménage, very fine Peasgood's Nonsuch, Warner's King, Stone's, and Lord Derby. Mr. W. Lewis, gardener to Mr. T. Oliverson, East Sutton Park, Maidstone, was second. For three dishes of Apples, cooking seven entered the list. Here Mr. Goldsmith was an easy first with grand fruits of Lord Derby, Peasgood's Nonsuch, and Warner's King, Mr. Powell being second with fine fruits, the weakest being Lord Derby. For six dishes of Bramley's Seedling Apple, Mr. W. King was first with fair fruits, well coloured; Mr. Turton, Maidstone, was second. For six dishes, dessert Apples there were nine exhibitors. Unfortunately, one was disqualified for showing Peasgood's Nonsuch as a dessert variety. Mr. Woodward was a good first, having very fine Baumann's Reinette, Gascoigne's Scarlet, Washington, Ribston, Cox's Orange, and Mother Apple. Mr. Miller second, having a splendid dish of Worcester Pearmain. For three dishes there were eleven lots, all good, Mr. Bayford securing premier honours, Mr. Kemp, gardener to Mr. C. R. Scrase-Dickens, being a close second. In the class for twelve dishes of Pears six lots were staged, and Mr. Woodward secured the premier award with splendid fruits of Durondeau (well coloured), Pitmaston Duchess (very large), Beurré Superfin, Ballet Père, Emile d'Hey, Duchesse d'Angoulême, Doyenné du Comice, Doyenné de Merode, Princess, Beurré Hardy, Gansel's Bergamot, and Marie Benoist. Mr. Goldsmith was a close second, his best being Souvenir du Congrès and Pitmaston Duchess. Mr. Powell had excellent Doyenné du Comice in the third lot. For nine dishes there were five lots, and all good. The premier award was well deserved. Mr. C. Terrell, gardener to Sir W. Geary, Tonbridge, having fine fruits, very clear in skin, and of the best possible varieties. Pitmaston Duchess was very fine, as were Beurré Hardy, B. Superfin, B. Bonne, and B. Rance. Mr. Jones, Wallington Bridge, Carshalton, was second, but we failed to see what others failed in this class if quality, not measure, was considered. For six dishes there were six competitors, and Mr. Messenger was first with good Beurré Ballet, Doyenné du Comice and Louise Bonne. Mr. Slogrove was a good second with similar varieties. For three dishes eight entered, and the first prize went to Mr. G. N. Field, gardener to Mr. R. Edward Sevenoaks, he having very large fruits of Doyenné du Comice, Mme. Treve, and Pitmaston this collection being noticeable for the clear skin and good colour. The second award went to Mr. G. Fennell, Fairlawn, Tonbridge, he having an excellent dish of Marguerite Marillat. For three dishes of cooking Pears only four staged. Mr. Woodward was first, Mr. Goldsmith being a close second. For one dish there were seven lots, Mr. Harris, East Grinstead, being first with Catillac. Mr. Barnes, Rutland Lodge Gardens, Petersham, was second with Uvedale's St. Germain, very large fruits. For Peaches, Nectarines, and Plums the competition was much stronger than last year, and the fruits very good. No less than ten staged for three dishes of Peaches, and Mr. Woodward again led, having very fine Sea Eagle, Prince of Wales, and Nectarine Peaches: Mr. Harris, Eastnor Castle, second, with Gladstone and Sea Eagle both excellent, but a poor dish of Lord Palmerston. For one dish there were thirteen exhibitors. Mr. W. Mitchell, gardener to Mr. J. Fleming, Chilworth, Romsey, being first with a grand

Sea Eagle, and Mr. Lane, Englefield Green, close second with excellent Stirling Castle. In his class Mr. Wallis, Keele Hall, Staffs, had a grand dish, but probably by accident the fruit was not named, or it would have been given an award. Nectarines were a weak class, the season being too advanced for these. Mr. Harris, East-pr, was first for three dishes, showing medium-sized fruit of Elruge, Albert Victor, and Pine-apple. The other prizes were not awarded. For the dish five entered, but they were wanting in colour and finish, the best being Victoria, from Mr. Strugnell, gardener to the Right Hon. W. Long, Rood Ashton, Trowbridge, Mr. Hill, Babram, second. The class for Plums brought forth more entries than one could have expected owing to the short supply this season. Mr. H. Folkes, gardener to Mr. C. Strachan, Hemel Hempstead, was first with four dishes of dessert varieties, giving good Golden Drop, Reine Claude de Bayay, late Transparent Gage, and Cloth of Gold, Mr. Vert, gardener to Lord Braybrook, Audley and, Saffron Waldon, being a good second, he giving a grand dish of Coe's Violet. For a single dish Mr. Vert was first with excellent Golden Drop, Mr. Turton being second. Twenty-two dishes were staged in this class. Five competitors entered for the four dishes of cooking Plums, Mr. Goodacre being first with Pond's Seedling, Polliath, Archduke, and Monarch, Mr. Sims, gardener to Mr. Gooch, Hemel Hempstead, being second. There were eleven competitors in the single dish class for cooking Plums, the Rev. G. Palmer (gardener, Mr. Osborn) being first with grand dish of Le Molt Lang, and Mr. Sims second with Monarch. For Gages, one dish, Mr. Messenger was first with excellent Reine Claude de Bayay, Mr. Herrin being second with Brady's late Gage. For Damsons or Bullaces there was only one entry, Mr. G. Fennell, Tonbridge, taking st with the Prune Damson, Crittenden and Bullaces.

## SINGLE DISHES.

## APPLES.

The single dish classes produced as usual some keen competition and the quality generally was high. A few of the classes failed to induce more than one or two exhibitors to come forward, this being simply a repetition of last year's faults, and the reason for including in a limited list varieties which never are shown in any quantity, to the exclusion of others that would make a better display, is not quite apparent. Dessert apples come first in the schedule, commencing with Adams' Pearmain. The first-prize dish came from Mr. W. Camm, gardener to the Duchess of Cleveland, Battle Abbey: second, Mr. G. Goldsmith, gardener to Sir E. G. Loder, Leonardlee, Dorset. Seven dishes in all were shown, and the first three were all excellent. Allen's Evering was a weak class, only three lots being shown. The first prize dish, a very good lot, came from Mr. J. Powell, gardener to Col. Lymer, M.P., Hsington House, Dorehester. Lumann's Red Winter Reinette was finely shown, all the fruits being well coloured and even. Mr. J. McKenzie, gardener to Mr. F. S. W. Cornwallis, Linton Park, sent the first prize dish; Captain A. J. Carstairs, Welford Park, Newbury (gardener, Mr. C. Ross), was second, and Viscountess Portman, Buxted Park (gardener, Mr. J. C. Prinsep), third. All three prize dishes were very fine. Ten dishes in all were shown. Blenheim Orange was not quite so good as usual. Fifteen dishes were shown, but only one or two of these were as well coloured as we are accustomed to see them at this show. The best dish came from Mr. W. H. Godden, gardener to the Hon. W. Buxton, Herts, and Mr. G. Chambers, Moorcocks Farm, Mereworth, Kent, came second with a nicely coloured dish of smaller fruits. Ewnee's Russet was shown in good form by seven exhibitors, Mr. Woodward being first with a nice dish, followed by Mr. H. C. Prinsep. Claydon Pearmain produced five dishes, the first and second prizes going to Mr. Woodward and Mr. Prinsep in the order given. Court Pendu Plat was well shown, fifteen dishes being staged. The first

prize went to Mr. J. C. Tallack, gardener to Mr. E. Dresden, Livermere Park, Bury St. Edmunds; second, Mr. C. Ross. Cox's Orange Pippin was, as usual, largely shown, twenty dishes being staged, and of these a dozen were really good, the best dish coming from Mr. W. Messenger, gardener to Mr. C. H. Berners, Woolverstone Park, Ipswich. This was an excellent dish of large, shapely, and well-coloured fruit; second, Mr. W. King, Gatton Park, Reigate. Only two exhibitors showed Egremont Russet, the first prize going to Mr. B. Miller, gardener to Mr. T. W. Startup, West Farleigh, Maidstone, and second, Mr. G. Goldsmith, whose fruits were a little smaller than the first prize lot, but very shapely and attractively coloured. Fearn's Pippin was a good class, fifteen lots being shown, the first prize going to Mr. Tallack, Livermere Park, for a good dish; second, Mr. McKenzie, Linton Park. This was a very even class, and most of the dishes highly coloured. Gascogne's Searlet was shown by seven exhibitors, and the highly-coloured fruits made a very attractive exhibit. Mr. McKenzie, Linton Park, came first with a handsome dish; second, Mr. J. Hudson, gardener to Mr. Leopold de Rothschild, Gunnersbury House, Acton. King of the Pippins was largely shown, nineteen dishes being staged and mostly good fruits. The first prize went to Mr. Tallack, Livermere Park, for a grand dish of large, well-finished fruits: second, Mr. J. Powell, Hsington House. King of Tomkins County was not largely shown, only five dishes being staged. Mr. T. Turton, gardener to Mr. J. Hargreaves, Maiden Erleigh, came first with a highly-coloured dish; Mr. Tallack followed with large fruits not yet coloured. Mabbot's Pearmain was shown only by Messrs. McKenzie and Prinsep, who took the prizes in the order here given: both dishes were very good. Mannington's Pearmain was rather poorly shown, though the prize dishes were good, that shown by Mr. Woodward especially. Mr. McKenzie came second. Margil was shown by ten competitors, the fruits being rather larger than usual, but except in one or two cases not well coloured. Mr. Woodward was first, Mr. McKenzie second. Of American Mother only six dishes were shown. Of these the first was very good indeed, and was staged by Mr. C. A. Bayford. Mr. McKenzie's second prize dish was also good. Of Ribston Pippin twenty-two dishes were staged, and a very even lot they were with one or two exceptions only. The first prize went to Mr. Woodward for highly coloured and shapely fruit; Mr. McKenzie second, with larger fruits, but not so ripe. Scarlet Nonpareil was not largely shown. Mr. Hudson, Gunnersbury House, was first with a very nice dish, Mr. C. Ross second. Sturmer Pippin was represented by nine dishes, and the first prize went to Mr. W. G. Pragnell, gardener to Mr. J. K. D. Wingfield Digby, Sherborne Castle, Dorset; R. Chamberlain second. Williams' Favourite was only shown by one exhibitor, Mr. J. Powell, who had a nice dish of fruit. Worcester Pearmain was largely and well shown, nineteen dishes being staged, Mr. W. King, Gatton Park, being first, Mr. G. Woodward second. In the any other variety class twenty-one dishes were staged and numerous varieties shown. This class is more or less of a seramble, such a large variety being brought in. The first prize went to a nice dish of St. Edmund's Pippin shown by Mr. McKenzie, second to Mr. G. Goldsmith for Gravenstein, and third to Mr. Woodward for a beautiful dish of Washington.

Kitchen Apples commence with Alfriston, Mr. McKenzie, who was very strong throughout these classes, came first with splendid fruits, Mr. Woodward second. Seven dishes were shown. With Beauty of Kent, Mr. R. Chamberlain came first with a fine dish, Mr. Woodward second. Nine dishes were shown. Eleven good dishes of Bismarck were shown, Mr. McKenzie being well in front with a fine dish; Messrs. Woodward and Ross followed. Bramley's Seedling was not strongly shown, only four lots being staged. Mr. C. A. Bayford was first with a fine dish; second, Mr. W. Lyon, gardener to Mr. J. H. Salmon,

Holly Bank, Rowton. Thirteen dishes of Cellini, a very even lot, were shown, Mr. G. Goldsmith coming first, Mr. Bayford second. Cox's Pomona was also finely shown; seventeen dishes of large and highly coloured fruits were staged. Mr. McKenzie was first with a heavy dish. Duchess of Oldenburgh was not very well shown, the first prize going to Mr. Culton, Diklawn Gardens, Castle Douglas, N.B., who was well ahead of the other competitors. Dumelow's Seedling was well shown; sixteen dishes were staged, and none were weak. Mr. McKenzie was placed first for a nice dish; Mr. Pragnell second. Ecklinville Seedling made a good class of fifteen dishes, Mr. McKenzie being first; Mr. J. Spottiswood, Queen's Park, Brighton, second. The first prize dish was a very good one, clear-skinned, and fine. Emperor Alexander was not quite so largely shown or so well coloured as on former occasions, but ten dishes were staged, and all very good fruits. Mr. McKenzie was first with a very fine dish, and Mr. Woodward second. Mr. McKenzie was again placed first for Frogmore Prolific, and Mr. Bayford second. Six dishes were staged. Golden Noble made a very attractive exhibit, and the fruits have seldom been seen in better form. The first prize dish, from Mr. G. Chambers, Moorcocks Farm, Mereworth, was a very handsome one. Mr. Woodward came second with heavier fruits. Golden Spire brought out six exhibitors, and the first prize went to Mr. G. Woodward for a very fine dish. Only three exhibits of Grenadier were made. Lady Louisa Fortescue, Dropmore, Maidenhead (gardener, Mr. C. Herrin), was first for a good dish. Hawthornden (New) only brought out four exhibitors, and among these Mr. Woodward was first for a very good dish; Mr. A. Brooks, of Latter's Farm, Mereworth, was second. Mr. McKenzie was first of two exhibitors only for Hornead's Pearmain, and staged an excellent dish. Lane's Prince Albert brought out a fine exhibit of fourteen dishes, the best coming from Mr. C. Ross, of Newbury, followed by Mr. Bayford and Mr. Woodward. Lord Derby was another good class in which Mr. G. Fennell, gardener to Mr. W. M. Cazalet, Fairlawn, Tonbridge, was placed first. Lord Grosvenor was a weak class, only four dishes being shown, but that from Mr. Woodward, taking first prize, was fine indeed. Lord Sutfield brought out fifteen competitors, and most of the dishes were very good, Mr. McKenzie's, which was placed first, being excellent. The second prize fell to Mr. Woodward for a fine dish. Mère de Ménage was shown in fine condition and colour by seven exhibitors, and of these Mr. McKenzie was placed first. Smaller samples, but of the deepest colour, from Mr. C. Ross, Newbury, were placed second. Of New Northern Greening an excellent dish was shown by Mr. C. Ross and placed first; only three competitors came out for this class, and no third prize was given. Two classes were made for Newton Wonder to prevent clashing between northern and southern growers. The best dish in either class came from Mr. J. Hill, of Babraham, who, under the conditions, was placed among northern growers. Mr. R. Edwards was first in the southern section. Only six dishes were shown in all. Peasgood's Nonsuch was as usual finely shown, Mr. McKenzie being placed first out of nine competitors, the Lord Bishop of Bath and Wells (gardener, Mr. A. W. Mackenzie) being second. For Pott's Seedling Mr. Turton was placed first, eleven dishes being staged; Mr. Woodward was second, and Mr. Hudson, Gunnersbury House, third, for the heaviest dish shown. Only one dish of Royal Jubilee was shown. This came from Mr. C. Ross, and fully merited the first prize it obtained. Eight dishes of Sandringham were put up, and were mostly good, but varied considerably in form and colour, only one or two dishes showing the characteristic mottling. Mr. McKenzie was placed first, Earl Percy, Syon House (gardener, Mr. G. Wythes), coming second with smaller fruits, but in excellent character. Four good dishes of Spencer's Favourite were shown, the first coming from Mr. Woodward; second, Mr. W. Jones, gardener to Mr. G.

R. Brougham, Wallington Bridge, Carshalton. Stirling Castle brought out ten dishes, Mr. McKenzie being placed first with a very good dish; second, Mr. W. Strugnell, gardener to the Right Hon. W. H. Long, Rood Ashton, Trowbridge. Of Stone's, six dishes were shown, Mr. McKenzie coming first with fine fruit, and Mr. Woodward second. In the class for The Queen the same exhibitors took first and second prizes in similar order. Tower of Glamis, of which eight dishes were shown, was not a very strong class, except for the first prize dish from Mr. McKenzie. The same exhibitor was first for Tyler's Kernel, a first-rate dish, only three lots being staged. Warner's King was a strong class of twenty-three dishes, and here again Mr. McKenzie led with a splendid lot, being followed by Mr. G. Chambers. A well-filled class was that for "any other variety" of kitchen Apples, and the prizes went to good dishes of Dutch Codlin, Lady Henniker, and The Major, respectively shown by Mr. McKenzie, Mr. W. Camm, of Battle Abbey, and Mr. G. Fennell, the Dutch Codlins from Linton being grand fruits. Seventeen dishes were shown in this class.

#### PEARS.

These generally were good, but the classes were not so well filled as were those for Apples. Eight dishes of Bergamot d'Espere were shown, and the prizes fell to Mr. J. Powell, Ilslington House, Mr. C. Ross, and Mr. Woodward in the order given. Beurré Bosc was fine, four dishes especially so; one exhibitor showed in this class a nice dish of Doyenné Boussoch; the first prize dish came from Mr. G. Goldsmith; second, Mr. W. Cotterell, gardener to Sir W. N. M. Geary, Bart., Oxon Heath Park, Tonbridge. Mr. Woodward showed the only dish of Beurré d'Anjou—very good fruits. Thirteen dishes of Beurré Diel were staged, and here there seemed to be some error of judgment, as Mr. Wythes's dish, placed second, should have been first, the fruits being finer and clearer than those of Mr. Woodward placed first. The best dish of Beurré Dumont was staged by Mr. Woodward, only two lots being shown. Beurré Hardy was represented by seven dishes of very clean fruits, Mr. Woodward being first with a grand dish, and Mr. Prinsep second, only a little behind. Eleven good dishes of Beurré Superfin were shown, Mr. Woodward and Mr. Goldsmith being first and second. Only one good dish of Williams' Bon Chrétien was shown, this coming from the Earl of Galloway, Galloway House, Garlieston, N.B. (gardener, Mr. J. Day). Mr. Turton was first in a weak competition for Comte de Lamy. Conference was staged by five exhibitors, the first, very good, coming from Mr. Woodward, who was followed by Mr. W. Slogrove, gardener to Mrs. Crawford, Gattou Cottage, Reigate. Six dishes of Conseiller de la Cour were shown, that from Mr. Tallack being a fine lot and well ahead of the others. A grand dish of Doyenné du Comice secured for Mr. Powell the first prize out of ten exhibits. Mr. Goldsmith had the best dish of Duchesse de Bordeaux, two dishes only being shown. Eight good dishes of Durondeau were shown, Mr. Woodward taking first place and Mr. Pragnell second. For Easter Beurré, first place was taken by Mr. B. Calvert. Emile d'Heyst was a weak class of three dishes only, Mr. Woodward securing first place. Fondante d'Automne secured four entries of very fair fruits, a good dish from Mr. A. Basile, gardener to Rev. G. L. Powells, Woburn Park, Weybridge, taking first place. The first and second prize dishes of Fondante de Thirriot, which came respectively from Mr. Woodward and Mr. Messenger, were excellent examples of a very fine Pear. Nine good dishes of Glou Moreceau were shown, the first prize going to Mr. Powell for excellent fruits; Mr. Woodward was second and Mr. Calvert third. Mr. Powell was again first for Josephine de Malines, Mr. J. W. Herbert second, and Mr. Calvert third. There were thirteen dishes staged in all. The class for Louise Bonne of Jersey was a very attractive one, as all the fruits shown were very clean and highly coloured. The first prize went to Mr. J. Coles (gardener to Mr. H. F. Walker,

Higley, Balcombe, Sussex); Mr. Messenger was second. Ten dishes in all were shown. Only three dishes of Marie Benoist were staged. Mr. Woodward came first with a fine lot, Mr. Messenger second. Marie Louise was a good class of ten dishes. As was the case last year, colour secured the principal awards. Mr. B. Osborn was first and Mr. Woodward second. For that very poor Pear Marie Louise d'Uccle, Mr. Cotterell was placed first out of seven exhibits with a very fine dish. Marguerite Marillat was finely shown by Mr. G. Goldsmith and Mr. Edwards, of Beechy Lees, and the prizes were awarded in the above order. Three out of the five dishes of Nouvelle Fulvie were very good, and these were shown by Mr. Woodward, Mr. Goldsmith and Mr. Wythes. A weak entry only was secured for Olivier de Serres. Mr. G. Goldsmith showed a nice dish, which secured first prize from three other exhibits. Twelve fine dishes of Pitmaston Duchess were shown. Mr. Cotterell was first for an excellent lot, Mr. Woodward second with rather smaller and riper fruit. Three nice dishes of Seckle were exhibited, the best a very good lot from Mr. C. Ross; second, Mr. Turton. Messrs. G. Goldsmith and G. Fennell were the only exhibitors of Souvenir du Congrès and were placed in the above order, the first prize dish an excellent one. Five dishes of Thompson's showed no very great merit, except the one from Mr. Powell, placed first. Of Winter Nelis there were twelve dishes, Mr. Woodward being first and Mr. Goldsmith second. The "any other variety" class brought out nice dishes of various Pears, Mr. Woodward being placed first for a grand dish of Gansel's Bergamot, Mr. Spottiswood coming second with Doyenné Boussoch, and Mr. Goldsmith third with Princess. Other excellent dishes among the nineteen exhibited were Mme. Treyve, Chaumontel and Brockworth Park.

For the Veitch prizes for flavour over forty dishes of Apples were staged, the majority being Ribston and Cox's Orange Pippins. Many varieties were included that stood very little chance of winning under present rules, and the necessity for eliminating varieties that have won a certain number of times becomes more apparent at each meeting. Mr. H. C. Prinsep repeated his success of last year, again showing Ribston Pippin in prime condition; and Mr. Herrin was second with Cox's Orange. In the corresponding class for Pears, Mr. B. Osborn was first for Louise Bonne of Jersey, and Mr. Cotterell second with Fondante d'Automne. Over thirty dishes were shown, and the judges' palates must have been much tried in testing for flavour so many Apples and Pears at one time.

#### MISCELLANEOUS EXHIBITS.

A much greater space was filled this year with miscellaneous exhibits, and some were most attractive, the plants and flowers giving a bright finish to the lines of fruit. First in the order of merit must be placed the collection from Mr. Thomas, The Royal Gardens, Frogmore. Here were grand Pine-apples, excellent Muscat of Alexandria Grapes in baskets, Peaches, Melons, Black Hamburg Grapes, Plums in variety, hardy fruits, and Tomatoes. From the Royal Horticultural Society's Gardens were sent forty-four varieties of Pears and some twenty kinds of Grapes, including a bunch of Gros Guillaume weighing 8 lbs., Black Hamburg, Muscat Hamburg, Mrs. Pince, Alicante, and Alwick Seedling. Pears were staged in quantity, the best being Princess, Thompson's, Beurré Bosc, Doyenné du Comice, Flemish Beauty, Emile d'Heyst, Napoleon, and Uvedale's St. Germain. Messrs. Veitch, Lim., Chelsea, staged a large quantity of fruit, 160 dishes in all. The Apples were excellent and the Pears good, the bright Physalis Franchetti being largely used in decoration, also Rosa rugosa, the fruit being nicely arranged. The same firm had a charming group of Nerine Fothergilli major nicely arranged with Ferns. The plants were the finest we have seen of late; many of the small pots had bulbs carrying three or four trusses. Messrs. Cheal and Son, Crawley, Sussex, had large groups of Dahlias and a good

collection of fruit, 180 dishes of Apples and Pears, the centre of the table being fruit trees in pots laden with fruit, the base filled in with baskets of Apples some twenty in number, and comprising the best varieties in commerce. This formed a pleasing exhibit. Messrs. Laing and Sons, Forest Hill, staged ninety dishes of Apples and Pears in variety, the centre of the table being filled with Orange trees bearing fruits freely. This firm also exhibited a fine collection of herbaceous plants, Dahlias, Chrysanthemums, Begonias, Streptocarpus, and Nephentes Mastersiana. Mr. T. S. Ware, Hale Farm Nurseries, Tottenham, had a splendid exhibit of hardy flowers in great variety, and Dahlias well arranged with Begonia seedlings lifted from the open air. Messrs. Paul and Son, Cheshunt, had Roses in great variety, both in pots and as cut flowers. There were baskets of hardy Cyclamens and other herbaceous plants in variety. Fruit was likewise staged largely, including Apples, Pears, and Plums. Messrs. W. Paul and Son, Waltham Cross, had a splendid collection of cut Roses arranged in baskets and boxes. The new China Rose Queen Mab, Enchantress, Cramoisi Supérieur, Marchal Niel, Sylph, Medea, and Marie van Houtte with numerous hybrids, and twelve varieties of Roses raised at Waltham Cross were in good condition. Messrs. Harkness and Sons, Bedale, sent a large collection of herbaceous plants, Roses in variety and of excellent quality, Lilliums, Chrysanthemums, and Carnations, the chief feature of the collection being some fine seedling Gladiolus from Messrs. Williams, Holloway, came a nice group of fine-foliaged plants, including grandly coloured Crotons, Dracenas, Palms, and Ferns. The beautiful Croton Emperor Alexander was in fine form. From Reading, Messrs. Sutton sent fine display of Tomatoes arranged in baskets perfect fruits of the best varieties. Perfection Golden Queen, Eclipse, Sunbeam, The Sutton A 1, Peachblow and Pomegranate were the kind staged, and, being shown in quantity, were much admired. Messrs. Fisher, Son, and Sibray, Handworth, Sheffield, sent a good collection of Apples and a few Pears. The former were excellent, at the whole well set up. Mr. W. Horne, Per Hill, Rochester, had good Apples and Pears in groups. Messrs. Spooner, Hounslow, had large collection of Apples and Pears, including twenty baskets and about sixty dishes of the best varieties of Apples and Pears. Mr. B. Well Crawley Fruit Nursery, had a small collection of Apples and Pears in variety. Mr. W. Well Earlswood, sent cut Chrysanthemums arranged in glasses. The Horticultural College, Swanley, arranged a table consisting of preserved fruits in bottles, with Grapes in variety, Melons, Apples, Pears, and Tomatoes. Messrs. W. Gaymer, Atterborough, had fine Apples of a few varieties on a stand erected on a table. Messrs. Peed and Sons, Streatham, had 120 dishes of Apples and Pears, Grapes Gros Maroc, Madresfield, and Alicante, and excellent hardy fruits in great variety. Messrs. Cannell and Sons, Swanley, had several groups, one composed of Cannas in pots, also one of Physalis Franchetti nicely arranged. Mr. A. W. Young, Stevenage, sent Dahlias, Aster Lilliums, and hardy herbaceous flowers, with collection of Gourds and Tomatoes.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, October 12, at the Drill Hall, James Street, Victoria Street, Westminster, 1 to 5 p.m. A lecture on "Some Curiosities of Orchid Breeding" will be given by Mr. C. C. Hurst at 3 p.m.

**Names of plants.**—*Countances.*—Virginia Poke (Phytolacca decandra).—*E. Cecil.*—1 and probably forms of Dendrobium Wardianum; 3, Dendrobium primulinum; 4, Epidendrum vitellinum.—*W. L.*—Cannot undertake to name Crotons.—*H. B.*—1 and 2, forms of Impatiens glandulifera; 3, Chelone obliqua.—*D. C.*—1, Aster paniculatus; 2, A. laevis var.  
**Names of fruit.**—*J. W. Burns.*—Pear, probably Beurré Rance.—*W. L.*—Conical fruit Adams' Pearmain, the flat fruit Fearns' Pippin.

## CHRYSANTHEMUMS.

### COLOURS IN CHRYSANTHEMUMS.

NOTWITHSTANDING the number of new varieties there are being introduced each year, I think it may be said we are advancing but slowly in the matter of rich, highly-coloured kinds. Whites and yellows are fairly plentiful, and it hardly seems possible to improve them. They may be had in various and beautiful types of form, but good reds would be most welcome. It was about ten years back that the variety E. Molyneux started the Chrysanthemum world by the colour of the blossoms then exhibited, and even now there is nothing to approach it. This variety, however, appears to have had its constitution impaired by the high culture necessary to obtain large blooms, and is rarely seen in anything like good form. Time after time one comes with plants of E. Molyneux having small crumpled foliage where it should be well developed and leathery, and the flowers refuse to put out on long peduncles away from the leaves—a sure sign in the case of this sort that excellent blossoms will follow. Several growers whom I know have from various sources changed the stock with the hope of a return to former vigour, but this has not assisted them.

In late years Mr. Seward's seedlings have given us more of the needed colour than have those of other raisers. One can imagine he has used Mrs. Falconer Jameson as a parent plant pretty freely, as many of his varieties partake of that kind in habit of growth. Many of them, too, have a similar tendency to produce the bloom-buds late in the year, hence a number of failures with them. Dorothy Seward, Mrs. John Shrimpton, of last year's notes, and John Neville, of this, must be topped in early spring to obtain buds soon enough to develop into large flowers. To return to highly-coloured Chrysanthemums. William Seward was a splendid gain, but this somehow is not seen in good form very often. It loses its rich crimson tint very quickly, and as large

blooms take a considerable time to open, the lower portion becomes dingy before the top florets are out. Apart, however, from large blooms, there is no other variety to equal the sort named in its rich dark crimson tint. Jeanne Délaux, which was known before William Seward, appears to be quite gone out of cultivation, but if well grown there would yet be room for it. The growth is not of the robust order; this, no doubt, caused many to discard it. William Holmes, Cullingford and John Shrimpton are all flowers of extra good colour for medium-sized blooms, but they cannot be produced large enough for exhibition. I thought by the blooms which M. Calvat first exhibited of C. H. Payne that a rich vivid crimson sort of surpassing beauty was obtained. This, again, has been a failure in the hands of British growers. Mr. A. G. Hubbuck gives us a nice shade of crimson-brown, and the habit of the plant is very sturdy. I am, afraid, however, that the sort will not take the place of E. Molyneux. M. Geo. Biron has flowers of a good crimson hue. The fault of this, however, is that it loses its leaves in most cases, and is therefore an ungainly plant. Dorothy Seward is a richly-tinted sort; terra-cotta-red. It keeps the colour well, and is in form and size most desirable. John Neville promises well. The colour, light crimson with buff reverse, is bright and taking. This is a handsomely-formed blossom, with long, trailing florets. Joseph Brooks is not yet open. This sort was one of the richest coloured of last year's new ones. That old variety Miss Dorothea Shea supplies a very nice deep terra-cotta shade when well grown, and is most attractive in a collection.

Pride of Madford is by far the best variety of a violet-crimson tint; but, like others of that colour, it sometimes exhibits too much of the lilac shade on the back of its petals. This is an Australian variety. I believe a crimson-coloured sport from it exists. This will be welcome when introduced generally. Nyanza has blossoms of the deepest possible crimson shade,

and is a magnificent sort when seen at its best. It is rather uncertain, but I fancy it will be esteemed for the supply of late blooms when better known. That dwarf-growing kind M. Chenon de Léché has most distinct colouring, and Col. W. B. Smith is a variety by itself with its lively shade of bronzy yellow. Mme. Marius Ricoud has rose-coloured flowers of a brighter tint than is to be found in any other sort, and Vivian Morel is distinct in its mauve shade. Golden Gate must be grown for its shade of tawny-yellow colour; it is a splendid variety. Thomas Wilkins has blooms of a somewhat similar shade, and is an excellent kind. Mrs. John Shrimpton gives us a most distinct shade of bronze, but there is a dead look about it that does not please me.

Yellow Chrysanthemums are very charming. I know of none so perfect in finish as is Edith Tabor. We have a deeper yellow in Modesto. The petals of this, too, have first-rate substance, and it is certain to become popular. Phœbus and Oceana are also two very fine yellows. The former reflexes its petals; the other is an incurving kind. They are models of different types. I am looking forward to seeing fine blooms this year of Calvat's Australian Gold; it is now most promising. Being widely distributed, the variety will have a better chance this year than it did last. It seems to grow well under any conditions. The variety Mme. Carnot will not be easily surpassed as a show flower among whites. This and Mme. Ad. Chatenay are grand types, the one drooping in form, the other incurving. They will have plenty of rivals this year in such as Mrs. J. Lewis, Baronne A. de Rothschild, Simplicity, Western King, and Mme. Gustave Henry. Then Mutual Friend, Mlle. A. de Galbert, Souvenir de Petite Amie, and other older kinds are too fine to be discarded. H. S.

Chrysanthemum W. G. Newitt is a first-rate white kind. It is of American origin, and is a failure if the plants be grown in the natural way. The points of the shoots must be topped

in March, this causing the formation of early flower-buds. From plants so treated blooms are each 6 inches across and of similar depth. The florets droop gracefully, making a fine show on stems not 3 feet high from the pots.—H.

**Chrysanthemum A. H. Fewkes.**—This Japanese variety not being one of the huge-sized ones has caused many to discard it, but it is an exceedingly fine sort for general culture. It is yellow, of a rich dark shade, and the flowers are of capital incurving form. Its growth is dwarf and sturdy, the foliage being retained to the last. The flowers are borne close to the leaves, a point of some importance when they are used for cutting.—H.

**Chrysanthemum Mychett White.**—This is a new variety which is sure to be in demand. Plants which were freely disbudded have developed a goodly number of large and handsome flowers, and others grown with very little or no disbudding are covered with charming little blossoms. They may be cut in sprays or individually, and each flower has a footstalk of a useful length. The blossoms are of the purest white, with fairly long fluted petals, and under glass are beautifully pure. I am growing this new sort in the open border, and here it is doing well, being a mass of bloom.—D. B. C.

**Chrysanthemum Mrs. H. Weeks.**—I am afraid there will again this year be no end of failures with this variety, because many growers did not top the plants in the spring. In early October I noted instances where the flower-buds were not showing, and certainly in such cases there will not be time for blooms to develop into large ones. This is essentially a show flower, and a very handsome one, its pearly white blooms having been grown to enormous proportions. Probably the best way to cultivate it is to strike the cuttings rather late, say February, and allow it to grow on with one stem in a pot not more than 8 inches across, selecting the first flower-bud.—H. S.

**Chrysanthemum Ivy Stark.**—The blossoms of this sort should be welcomed by those who complain of want of brightness in the early-flowering varieties. Just now it is coming into bloom, the colour being a very bright shade of golden orange; in fact, when freely di-budded it is not unlike a bright flower of the well-known mid-season variety, Source d'Or. In the border it is succeeding very well, each of the plants, owing to its fine branching habit, being of large size and blossoming most profusely. Each flower has a good footstalk, so that individual ones may be cut, or, if preferred, handsome sprays of four or five pretty flowers make an effective display for a small vase. The constitution is robust and the height from 2½ feet to 3 feet. This variety should be in demand for market work.—D. B. C.

**Chrysanthemum Piercy's Seedling.**—I saw this most useful autumn-flowering Chrysanthemum in fine form at Kelham Hall a week ago. The colour (a bronzy yellow) is very popular just now, and trusses sell well. The plant is of exceptionally dwarf habit and a most prolific bloomer. Mr. Webb (the gardener at Kelham) considers it one of the very best for market during September. The flowers stand damp weather and rain much better than those of some of the autumn-blooming varieties—Mme. Desgrange, for instance, which soon decays if damp settles on the petals. In various lists of autumn varieties I have looked through, no mention is made of Piercy's Seedling, so that I do not think it is as yet very generally known. The private gardener will find it as useful as the grower for market.—J. C.

**Chrysanthemum Mme. Desgrange and its sports.**—I was not aware until reading the remarks in THE GARDEN on the display of autumn-flowering Chrysanthemums at the Aquarium of the existence of Mrs. Hawkins, described as a yellow sport from the original straw-coloured Desgrange, but I am acquainted with Mrs. G. Wernig, also a golden sport from the same variety. As seen at Kelham Hall just now it appears to be quite as free as

its parent, and is much appreciated, as good yellows always sell well, particularly in autumn, when few sorts of that colour are obtainable. I particularly noticed the effect housing the old Mme. Desgrange as soon as the buds began to open had on the colour of the expanded blooms. The large batch at Kelham was arranged in a long span-roofed house and beneath the partial shade of Tomatoes. The few blooms that were open at the time of my visit were white enough for wreath-making, and Mr. Webb informed me that in an ordinary house, even when no shade was given, the blooms came of a good white shade. The original Desgrange is still a favourite with market growers. At the beginning of September I saw near Norwich 3 acres or 4 acres of this variety in the pink of condition. Care is taken not to plant too thickly so as to encourage mildew, and towards the end of the month the greater part of the blooms is cut and sold in bunches in Norwich market, this extending over several weeks, while a small proportion of the plants is lifted and sold cheaply for window plants. In this particular neighbourhood land is very high priced, yet I was informed on good authority Chrysanthemum growing paid far better than any corn crop that could be grown.—J. C.

## ROSE GARDEN.

### ROSE MARECHAL NIEL.

ALTHOUGH not always reliable in the open, who of us cannot recall more than one grand plant upon a house or wall, especially when the position was partly sheltered? I have seen it in magnificent form in all aspects, even facing due north, but the safest and best position is one due south and provided with partial shelter against strong south-west winds. This season I have several maiden standards that have given a really good autumn crop of bloom, and very welcome the flowers are; indeed, Maréchal Niel is never out of place. Occasionally we get a few good flowers late in the summer, but as a rule this grand old favourite only gives one good crop, and that upon wood made the previous summer. This fact is partly my reason for giving a few notes at such an apparently unsuitable date.

Surely such valuable wood is worth a little care and protection; and if we should be visited by severe frost, especially if bright sunny days accompany the frost, I would warn against the serious harm accruing to wood that is alternately frozen and thawed. At night everything is frozen hard, while when the sun rises a warmly-situated front of a house is often several degrees above freezing point. I am convinced that many a good crop of blossom has been lost through these extremes following one another so closely and being repeated so many times during a spell of severe weather. I would meet it by fixing a mat over the wood as the sun sets, removing this again directly the air has felt the influence of sun warmth once more. It is not so much that Maréchal Niel is tender as the fact that it does not seem able to withstand severe fluctuations. If tender, how is it we so often find a grand old specimen upon a north wall? Here we frequently get some of the grandest flowers, they coming a little later and escaping the sudden changes of temperature experienced by those in the front of the house.

Unfortunately, this Rose is more subject to canker than others. It is a puzzling disease. Among plants that have been treated exactly the same and are of similar age we may find canker on one, while the others will continue to grow away healthily for many more seasons. Then, if we put in a second specimen in place of the affected plant, it is quite as likely to grow away in a healthy and vigorous manner as

it is to develop canker similar to its predecessor. I feel sure that all observant Rose growers will be in accord with me when I say there is much to be learnt before we can successfully battle with this terrible disease. We may be convinced of several facts that apparently conduce towards this disease, but when we are so frequently confronted with specimens under the same conditions, and yet absolutely free, it would be rather bold to state with any degree of certainty what is the cause, or remedy for, canker. My advice is to root out the plant immediately after its next crop bloom has been secured and plant afresh. The variety will soon cover a large space, and the blank is not of long duration. On the other hand, we sometimes find an old plant bearing many cankered joints, and yet annually producing good wood and blossom. But this is an exception rather than the rule, and I believe wiser to replant at once. Give it good soaking and thorough soakings while in flower and bloom, also when making its first summer shoots. Do not prune away more than can be helped of last season's wood, and take little trouble as regards protection from sudden extremes of temperature.

When we come to the cool conservatory slightly heated greenhouse, what more generally favourite for the back wall or roof can possibly have? Here it may be depended upon to give a good crop of bloom, and such bloom as we very seldom see in the open. Do not restrict the root-run, treat it generously, keep free from insect pests from the first, and above all do not start it into fresh growth too early. Many start a plant early in the year, perhaps during a spell of brighter and milder weather and are not able to keep up a suitable temperature during the end of February and through March, a time when new growth is abundant and we are often experiencing most trying weather. Retard the plant as far as possible and when it will grow in spite of this treatment, give it every assistance. You will be surprised at the rapidity with which such a plant will overtake one that was started some weeks earlier, but which received a slight check at it had made growths of 3 inches or 4 inches. I would always severely summer-prune this Rose under glass, cutting out the wood as soon as it has flowered. This severe pruning also admits more light for other subjects at a time when such is indispensable. If a plant is growing the border near an outside wall, cover over the outside soil with short litter or light stable manure, as many of the roots are certain to penetrate below the foundation of the wall and get into the outside soil. R

**Mildew on Roses.**—At page 216 "Amateur" asks for a remedy for mildew on Roses. I can confidently recommend the following, which I learned from Mr. Tallack, Livermere Park: Three pounds of unslacked lime, 4 pounds of sulphur, and 1 gallon of water. Boil all together for forty minutes, leave standing till clear, then bottle into the clear liquid. Dilute when wanted from ¼ to ½ pint in 3 gallons of soft water, and use through a spray. Do not bring the solution into contact with painted surfaces. It is advisable to make several gallons at a time.—J. CRAWFORD.

**Rose William Allen Richardson.**—I have seldom seen this pretty Rose bloom so continuously and well as it has done this season. During the great heat in the middle of the summer it was almost the only one here I could cut even fairly good buds and flowers from, and although since the weather has been cooler many other kinds are in better order, this is still full of flower, the individual blooms having the deep orange tint well developed. It is one of those Roses that will

if the shoots are cut hard back every year; the more it is left alone in reason the better.—H. R.

**Rosa rugosa Blanche de Coubert.**—A group of Rose at Kew is particularly pleasing. The one is equally as handsome as that of the *Rosa rugosa*, while the blooms are of that constant white common to *R. rugosa alba*. Instead of being single, they are, however, semi-double, light in outline, and really charming. *Rosa* and its varieties are very ornamental, flowering as they do throughout the season, and brightly-coloured fruits may be found on bushes at the same time as the later blooms. It is sometimes difficult to get the varieties of *Rosa* on their own roots, in which case it is better to plan to layer the shoots as soon as they are sufficiently long, when they will push out roots of their own, and in time form quite a mass or bush.—T.

**Death of Roses.**—Will you kindly tell me why Roses require such frequent renewal? The gardener says many of the kinds must be renewed every year. My soil is heavy, and such is called a good Rose soil.—S. H.

It is simply a vicious system that is to be avoided—that is, grafting all sorts of beautiful and tender Roses on standards of the Dog Rose, because it gives the nurseryman a better chance in a short time. Some kinds are so nearly of the same nature to the Dog Rose that they take on the stock, while others do not. You are suffering from what thousands of gardens in England are suffering from, blind faith in what the nurseryman does for you. The remedy is a different system. Try and get Roses—any Roses you like—on their own roots; and as the nurseryman seldom supply strong Roses in this way, a good plan is to get all the Roses “worked” quite low down so that the union of the stock and the graft is near the ground level, and is so protected, and the graft may even strike root. If you have to have delicate Roses, like some Teas, which do not in all cases on our cool country’s cold soil grow well on their own roots, then you may purchase them on the Dog Rose; but the union between the graft and the scion should be so placed that it may be covered by the earth, and in a complete sense protected against our ordinary frosts. In light soils, in which the Dog Rose does not thrive, Rose troubles will be often greater than those you describe, as on these we compel the Rose, however vigorous, to grow on a stock which only thrives on heavy soils. One evil result of the system in vogue is that all who have to do with the struggle suppose they cannot grow Roses and are obliged to the struggle.—Ed.

IN THE ROSE GARDEN.

NOTWITHSTANDING a lot of wet and rather rough weather the Rose garden is still one of the most beautiful outdoor features. I recently saw many splendid beds of Teas and Hybrid Teas that were one mass of blossom. The best were *G. G. Grand*, *Papa Gontier*, *Safrano*, *Mrs. W. J. R. Marie van Houtte*, *Souvenir de la Malmaison*, and *Marquis of Salisbury*. As a matter of course we do not get a quantity of good autumnal roses from full and double-flowered varieties; but such as those named above are perfect for the season when hot suns do not cause them to expand and even premature expansion. A few of the roses that are doing exceptionally well this autumn are *Marjorie*, *Mrs. W. C. Whitney*, *Charles*, *Maman Cochet*, *Edith Gifford*, *Jardins*, *General Jacqueminot*, *Princesse de Saxe*, and *Mrs. Ramsey*. The last-named is at its best in the autumn, being mildew-free, a very free bloomer, bright, but not so full as is desired by the exhibitor. It is a fine Rose for decoration. The new Tea *Empress of Russia* is also very good with me. The first week in July until the present time (October) my Roses have been in bloom. There has been a short and sharp spell of red rust, which has appeared almost as rapidly as it invariably

attacks during the seasons it appears. Insects and mildew were not quite so troublesome as usual, and the Rose season of 1897 has been one of more than average pleasure, although fewer grand flowers than is sometimes the case have been obtained.

The budded stocks look well, and I find fewer failures than usual. The growth of both Rose and stock has been vigorous without being coarse and rampant, and there is every appearance of the wood ripening well. Much work must be done soon. Summer pruning needs finishing, vigorous shoots secured, buds loosened, and the ground cleared and mulched. We must also decide soon if protection shall be afforded or not, and get the necessary material to hand, so avoiding any delay at the rush which always accompanies severe frost. Then we have Rose cuttings of partially ripened wood to insert, also those of such dwarf stocks as the *Manetti*, *De la Grifferaie* and *Brier*. These must be seen to at once if the best results are to be obtained. Pot Roses must be overhauled and some means taken to keep away superfluous wet. Plants may be lifted from the open and potted as soon as they exhibit signs of ripening; such will get a partial start before frost arrives, and this is a great help in the future, especially as a safeguard against the drying and shrivelling of wood from keen winds. The ground intended for new beds should be dug and manured now, so as to get a little settled before planting.

ORCHIDS.

ZYGOPETALUM MACKAYI.

THERE is a good deal of confusion respecting this species and *Zygopetalum intermedium*, but so little difference that one is often grown for the other. *Z. Mackayi* as known in gardens is a fine species, free blooming, easily cultivated, the blossoms long-lasting, sweetly scented and very handsome. It is always more satisfactory in large than small plants, as when the pseudo-bulbs attain their full size they produce immense spikes of flower. The delicate colouring on the lip contrasts well with the more neutral tints of brown and green upon the sepals and petals. The plants are usually most satisfactory in an intermediate temperature, but in this respect they are not fastidious. Bright sunlight is very injurious to the foliage, so the house in which they are grown must be somewhat closely shaded during the summer. Some very fine old plants in a neighbouring garden have been for many years grown in quite a dark old-fashioned house, principally occupied by Maiden-hair and other greenhouse Ferns—not an ideal place for either perhaps; still both get along well, the Orchids flowering freely every season. Wherever a nice growing temperature is kept up during the spring and summer and a winter temperature of about 50° maintained, this species will, if well treated in other ways, be generally satisfactory. The roots are large and fleshy, of a far more brittle nature than those of most Orchids; consequently a rough compost is needed, and one that will not too often require renewal. Being rather gross-feeding, the staple must be good, and there must be thickness enough to ensure a thorough roothold. There is no doubt that good loam fibre lasts a good deal longer in good condition in the moist heat of the Orchid house than does peat. It is also more holding, and though some species of Orchids will not thrive in it, this *Zygopetalum* will. Mix it in equal proportions with Sphagnum Moss and peat and add plenty of rough opening material, such as pottery ballast, crocks, or charcoal, and it will form an ideal compost for this Orchid. Large plants such as would fill pots each a foot or 18

inches across would require at least 6 inches of compost to grow them well, but smaller or badly rooted bits must have much less. A good deal of care is required in pulling about old plants, as, for reasons above mentioned, the roots are very easily damaged; yet some at least of the old material will be found to have got sour and close, and this must be got out. Sometimes they get bare of leads, and naturally of foliage in the centre, and the best thing to do in this case is to divide them into two or three, either remassing them or setting them going separately on their own account. Some of the older leafless pseudo-bulbs may be cut right away, but the less of this the better, always provided a well-furnished specimen is the result. Plants that have the compost silted away from about the roots may, if in good order below, have a little new material packed around the bases of the bulbs and made firm. The line of compost may finish a little above the rim in a convex mound. The young growth usually starts away some time during the summer months, the tips of the flower-spikes appearing in the young growths when a few inches high. From this time until the pseudo-bulbs are well made up an abundant supply of moisture will be necessary; in fact, few epiphytal kinds require a more regular supply the whole year through, and any slackness is usually followed by shrivelled bulbs and puny flower-spikes. The long, strap-shaped leaves of this plant have a very fine appearance when they are kept quite clean and free of insects. The worst trouble comes from red spider and scale, but neither of these need occasion any mischief if reasonable care is taken in sponging and the atmospheric conditions of the house kept right.

**Oncidium zebrinum.**—This I recently noted in good condition, the long branching spikes bearing a large number of the singularly striped flowers. It is not a difficult plant to cultivate, and thrives well on trellised blocks or in baskets suspended in a light, moderately cool house. During the time that growth is active a free supply of moisture to the roots is necessary, and this is as often as not for the greater part of the year. Even when at rest, enough moisture to keep the pseudo-bulbs plump should be given, any shrivelling being assuredly followed by weak, puny growths and flower-spikes. The compost may be of the usual description for this class of Orchid, and as it dislikes being pulled about, only a little of this should be allowed, a little fresh being added yearly about the time the spikes show just before the young bulbs begin to emit roots. The present is its usual flowering season, and it is a native of Venezuela.—R.

**Vanda cœrulea.**—Very beautiful just now are the blossoms of this favourite species, especially the deeply-tinted, broad-petalled forms. When really well grown this is one of the very best in the genus. It does not thrive in every place, but this is more often than not owing to the unnatural and needless amount of heat to which it is subjected. As a matter of fact, it is often exposed to frost in its native habitat, but, of course, no one would think of doing so under cultivation. In the lightest part of a house kept at an intermediate temperature, and especially if placed near a ventilator, it is usually satisfactory during the growing season, and while the plants are at rest a minimum of 50° is ample. Watering requires care, as the roots are easily damaged by too much moisture. Plants only semi-established are especially liable to injury from this. It does not require a great amount of root space, nice little specimens being grown in pots or baskets about 6 inches in diameter. Single-stemmed plants do well in the 4-inch size, with a little Sphagnum Moss and charcoal about the roots. *V. cœrulea* is a native of the Khasia Hills, where

it grows on the bare bark of the trees at an elevation of about 4000 feet.

**Lælia Dormaniana.**—This pretty species sometimes throws a second lot of flowers at this season, and their bright tints make them very acceptable just now. Usually about three blossoms occur on the spike, which rises from the top of the slender bulb. They are each  $3\frac{1}{2}$  inches across, the outer segments varying in colour, the brightest being almost entirely rose-purple, the lip brighter in colour with deep port-wine coloured veins. *L. Dormaniana* presents no especial difficulty to the cultivator, yet in only a very few places is it usually well grown. It is often placed in too large pots, and, because the roots fail to get a good hold of the compost, they are surfeited and yet starved. Some very fine examples I noted in the spring of this year were growing in small wooden baskets, these being suspended from the roof of a warm house, and the roots not kept unduly moist. The plants might be said to be squeezed into them, for there was hardly any space between the bases of the bulbs and the rods of the basket. The usual *Cattleya* house temperature and general treatment suit it well, and it flowers very freely in spring.

**Cattleya guttata.**—Several forms of this species are now blooming, better known than the type, perhaps, being the variety *Leopoldi*. This sends up a stout flower-spike with a dozen or more blossoms, and when these are of a good form they make a fine display. *C. guttata* is not a difficult plant to grow, requiring to be potted in fairly large pots in a rough open compost of peat and Moss. The growths start in early spring with the advancing light and rest during the winter months, and all such plants are much more easily kept in condition than those that grow while the days are short and dark. The variety mentioned above is apt to damp off when the young bulbs are about half formed, the mischief commencing in a discoloration of the sheath and spreading to the underlying tissues. Doubtless it is more due to external conditions than to constitution, and it is wise to be on the look-out that a low night temperature does not occur at the same time as undue moisture. The roots are strong and vigorous and are usually emitted when the young bulbs are forming, this being a good time to attend to repotting. Water must be very carefully applied afterwards and until the roots have regained their hold on the new compost. The plant is widely distributed in Brazil, the type having been introduced as far back as 1827.

#### DENDROBIUM CHRYSANTHUM.

Few Orchids in bloom just now are prettier than this species, provided it has been allowed to grow naturally over and around its basket or block. From a mistaken idea of smartness too many growers are in the habit of tying the stems up to stakes placed erect in the compost. This is bad enough if the stems are tied up as they grow, as it makes a stiff-looking plant of what may be a very beautiful one; but when the flowers are allowed to open and the stems tied up afterwards it is infinitely worse, as the blossoms lose all natural carriage and grace. Although *D. chrysanthum* is deciduous, it requires a rather different mode of treatment from that given to the usual deciduous species. It is not exactly constant in its flowering season, and, as a rule, begins to grow at the base soon after the flowers are past. As often as not this is in early winter, so to dry the plants off just then is obviously wrong. They should be kept as warm as possible and grown not far from the roof glass. The atmosphere must be kept moist, as if allowed to get dry the plants are perhaps checked when only half grown, the stems begin to harden, and a healthy, free growth is out of the question. If grown on strongly without any check the flowers usually appear while the leaves are still green and fresh, and naturally this adds to their appearance. The young shoots grow several inches in length before they commence to

root, and just when a thickening roundish process appears at the base is by far the safest time to repot or rebasket. Then the older roots have to a great extent fulfilled their functions and the plant is pushing out fresh ones to keep it going. Let these have nice clean new compost to run in and the plants will thrive the better for it. For this use peat and Sphagnum Moss in as rough a condition as possible, and mix these with plenty of broken charcoal and crocks to ensure aëration. Being a very vigorous rooting plant, the pots or baskets used may be fairly large. They must be well drained and clean, and over the crocks spread a layer of rough Moss. Finish the line of compost well above the rim and trim off neatly.

The only resting season *D. chrysanthum* takes seems to be just before the flower buds show at the nodes along the young growth. It seems to be one of those plants one can hardly grow too strongly, provided the growth is made in a good light and is in consequence ripened to a certain extent as it is produced. The stems vary from 2 feet to as many yards in length, the longer ones having a zigzag appearance when fully developed. The pretty golden yellow blossoms, with deep maroon eye-like blotches on the lip, are delicately scented and are produced in racemes of three or four all along the growths. Unfortunately, they last but a short time in good condition, seldom more than a fortnight. It is a native of Burmah and the lower Himalayan regions, whence it was sent home by Dr. Wallich in 1828, and it first flowered in England soon after at Chiswick.

#### ORCHIDS FOR AMATEURS.

I WRITE as an amateur, without any of the ordinary appliances for Orchid growing. I have no Orchid house—not even hot-water pipes—where I grow them, but an old-fashioned flue, which is no doubt a great hindrance in many ways to the proper supply of heat. Nevertheless, I grow Orchids and flower them with very great satisfaction to myself and to those to whom I am able to send flowers. There are certain Orchids which seem to adapt themselves especially to circumstances and surroundings altogether unusual for Orchids. My house is a good-sized vinery, with a pit in the middle, originally constructed for Pines. This pit is used for Chrysanthemums in autumn and during the Christmas season, so during that time the house is kept quite cool and airy, with only frost excluded during the months of October, November, and December; therefore the Orchids have to be removed into very close quarters in a small greenhouse, where they share their space with Primulas and Geraniums, and such other plants as are usually to be found in a house of that kind. This is the trying time, and I almost gave up in despair pulling *Cattleyas* and *Lælias* through such an ordeal. Of late years, however, I have been quite successful with this, and a foreman from a large Orchid nursery who has lately inspected my Orchids noticed what fine large sheaths were at the present time growing on the plants of *Cattleya Trianae*.

I have an idea that many Orchids are still nursed too much as a general rule. They do not get air enough, and the coddling does not suit them. A gardener who grows Orchids largely told me that it was quite useless to attempt keeping *Cattleya citrina* for any length of time, because it invariably went back with him from year to year. My experience is the exact reverse of this. The bulbs of this *Cattleya*, instead of growing smaller, actually increase in size, and they are always plump and healthy-looking. I attribute this to the bed of peat and moss to which I always fasten the bulbs when they arrive or want a new board. This is, I am sure, of the greatest importance. I often see *Cattleya citrina* growing on a naked board, but I have never seen it healthy under such conditions. It requires an immense amount of moisture, so that I consider the second necessity for the healthy cultivation of this beautiful Orchid is constant watering with tepid water all the year round. I never spare the

syringe with these plants. Then I never them much fire-heat. They are kept as cool as possible all through the winter, and in spring when they flower, it is specially necessary to keep the plants cool, or the buds quickly yellow and go off. I believe if these three things attended to there are few plants more easily grown than *C. citrina*, and certainly there are few things more deliciously fragrant when at the flowers are in perfection. I have heard of *C. citrina* being grown in a frame, and I can easily imagine that it would adapt itself to that treatment, and perhaps flourish even better in a house. With me it has to hang anywhere out of the sun, while Ferns and Palms and matoes and a great variety of other plants occupy the house.

Another Orchid with which I have been successful in the same house is *Zygopetalum Gautieri*. I have had this for some years, and usually flowers twice in the year. It is grown on the stem of a Tree Fern. At first I hurried up in order that it should take less room; but I found it hard to give sufficient moisture to the plant when growing in that way, so I stuck the end of the Fern stem into a pot of soil and set the earth very moist. This, of course, helps to promote moisture throughout the whole plant, and my *Zygopetalum* immediately began to grow; that it approved of the treatment. One difficulty in flowering this plant on the Fern stem is that it speedily arrives at the top, and then the roots are in the air. I proposed to an Orchid grower who was looking at the plant to turn it upside down and so let the *Zygopetalum* creep up the stem again. But he would not hear of it. He said: "The plant is a wonderful success; you have had it so long. I would not meddle with it." I was strongly inclined to turn it upside down, nevertheless, for otherwise I do not see how it could grow on well from lack of moisture.

*Odontoglossum Harryanum* is now in flower, and truly beautiful it is. This plant has no more trouble than other *Odontoglossums* in a mixed house. The trial is with *Cattleyas* and *Lælias*, which have to be very carefully watched to see that they do not suffer from cold. It is they like a rapid advance of heat in January when the vinery is started. *Dendrobium* flourish remarkably well. I put them out of doors in July and August, and that seems to strengthen them and give them great vigour. *Dendrobium* floriferum seems to depend on such thorough ringing in an autumnal sun for maturing its blossoms. This is a fine Orchid when it is covered with Horse Chestnut-like flowers, but it lasts a very short time—a defect unusual in the Orchid tribe. *D. infundibulum* and *D. suavisimum* also do well under this rough treatment, but I have not succeeded so well with *D. Jamesianum*; it seems to me more crotchety. *Vanda corulea* grows vigorously and seems to enjoy its treatment, putting forth its large fleshy roots as the plant gets gradually higher. I give it nothing to grow in except Moss. In this it seems to thrive.

If Orchids can be grown successfully in any way—and I have not, of course, mentioned all the varieties in my house—who that has a greenhouse need fear attempting to grow this beautiful and interesting tribe of plants? It seems to me that no conditions could be more unlike the ordinary surroundings of Orchids than those in which the plants are grown.

#### A GLOUCESTERSHIRE PARSON.

**Palumbinum candidum.**—This is a delicate and pretty little plant not so often seen as it deserves. The habit is tufted and the flower-spikes occur in the centre of the young growths. The individual flowers are about  $1\frac{1}{2}$  inches across, nearly pure white, only a slight tinge of purple being present. It does well in the cool house and from the time growth starts in the spring until the flowers are past the roots must be kept very moist. During the winter less moisture suffices, but no dry rest is necessary.

GRASS WALKS.

The grass walk in the illustration is one of the most attractive features in the picturesque garden of which it forms a part. There is a very small portion of the year in which it is not more or less gay with flowers, mostly old favourites, though some newer and rarer kinds are from time to time added. In the spring it is a brilliant sight with Oriental Poppies, large Scillas, white and coloured Pinks, great clumps of Irises of all colours, perennial Lilies, Tufted Pansies, &c., soon to be followed by Delphiniums, Daisies of various colours, Pyrethrums, and other things too numerous to name. One great feature is the Yews and ornamental Hollies, which are planted at intervals and make a pleasing contrast to the flowering plants. Just at the moment while Dahlias, Asters, &c., make the walk gay, the fruit trees are heavy with

spaces; to its shady retreats, where the Ferns grow high; to the Vine-covered pergolas, whose leafy covering scarcely suffices, thus early in the summer, to exclude altogether the sunbeams, which daily find the interstices of the canopy becoming less in size and fewer in number, and to the green grass walks with their charming vistas, their flowering plants, some tall, some lowly, on either side, and the sense of the nearness of Nature that encompasses them. In the accompanying illustration we have a happy representation of one of the latter. At the back of the border the tall, light blue Delphiniums stand with the Madonna Lilies, whose first pure chalicees are as yet unopened. *Spiraea Aruncus* has perfected its feathery inflorescence, the Campanula bells show white, clearly defined, against a dark evergreen background, and the Pansies bloom above the grassy verge, while cluster Roses

preferable, with its breadths of hardy flowers, that from spring to autumn succeed each other in brightening the confines of the green way, to the level brilliancies of the bedding plants that ostentatiously display their massed colours from quaint plots in the full sunshine that falls upon the shadeless lawn.—S. W. F.

FLOWER GARDEN.

LOBELIA CARDINALIS.

This bright red Lobelia and its many varieties are among the most beautiful of herbaceous perennials now in flower. The bright blossoms on the long erect stems are fine at midday when the sun shines on them, while the morning dews give it an even greater beauty, the blossoms looking as though they were crystallised. The plant is not supposed to be strictly hardy, but it has stood the past three winters here in various positions, and also in neighbouring gardens, without the least protection of any sort. It requires good cultivation, and few repay it better. The site chosen for a group of plants ought to be taken out to the depth of a foot or more, according to its staple, and plenty of half-decayed manure laid in the bottom and mixed with the upper spit. If planting is done in spring the soil should be made very firm, the plants well watered home, and covered with a mulch of short material. Being kept moist by these means the growth will be vigorous the first season, and the plants will get thoroughly established before winter, and such plants rarely take much harm from frost. There are certain positions, perhaps, where *L. cardinalis* will not stand the winter, but they are fewer than is generally supposed, badly rooted and weak plants often succumbing where well established clumps would come through all right. It is worth while to give it a little extra care the first season and see what effect this has upon its hardiness. The usual method of propagation is by division of the roots, but, as is well known, the roots often die back considerably even without being cut when the plant is lifted for the winter. Seedlings of most of the varieties, or at least 90 per cent. of them, may be depended upon to come true. The seeds should be sown in fine, well-prepared soil in boxes or pans, these being placed in a gentle moist heat until the plants are well up. They may then be kept slightly cooler for a time, and as soon as large enough pricked out singly about 4 inches apart into cold frames. If the seed is sown about midsummer, the plants will be large enough to partly show their herbaceous character the first winter, and they should be left in the frame until spring and then planted as described. Plants raised earlier in the year may, of course, be planted out during the summer, and a large percentage of these will flower the first season, but for reasons indicated above I prefer the later-raised plants. The fine-foliaged variety Queen Victoria nearly always comes true from seed, but the paler-leaved forms usually show more variation. Cuttings of the young shoots may also be taken, and will form flowering plants the first year, either of these methods being more satisfactory than division of the roots. For late summer and autumn decoration *L. cardinalis* is very beautiful. Single plants may be grown in 6-inch pots, or larger ones may be used for grouping several plants in. They come in very useful at a time when the summer-flowering Begonias and others are getting past their best, and look exceedingly well grouped in company with double white Petunias or

A grass walk in Fairfield Gardens. From a photograph sent by Mrs. Deane.

Apples and Pears. There is nothing in a more satisfactory than a good herbaceous border, but, like everything else, a good judgment is required to ensure a successful and properly supporting rampant growers smart in itself.—D.  
—Fortunate are those whose gardens, with smooth drives and well-kept gravel paths, contain grass walks, for these, edged with various groups of hardy flowers, are a delight to the artistic eye. The green sward has on summer days a pleasant feeling of elasticity to the foot which gravel lacks. True it is that in wet weather the latter forms the best ground for walking upon, but during the long days, ere the year has reached its meridian, it is irresistibly drawn to the garden; to its corners rather than its more open

hang from the trellised arch. On either side foliage of many-tinted green rises aloft, fit harbour for the feathered songsters that make the morns and eves of early summer musical with their notes, and beyond the tree bole, that stands out at the end of the walk, a glimpse of the level lawn appears. Varied are the plants that add by their colours to the beauty of these grass walks; here Irises, purple, white, saffron, and lavender, interspersed with the apricot of *Papaver pilosum*; here the gorgeous Oriental Poppy, with its flaming vermilion; here pale pink and white Paeonies; and here, again, Lilies, white, scarlet, and orange.

Year by year, with but a little attention in cutting away an encroaching bough or adding a few plants here and there, the grass walk remains a delight, and to the lover of Nature, far

similarly habited plants. They are little trouble to grow, the crowns being potted up in spring, plunged outside in plant protectors in ashes or similar material until the stems are lengthening for flower, when they may go inside. Good rich soil must be allowed, and after the plants take on their second growth occasional soakings of liquid manure are beneficial. R.

**Crocus speciosus.**—This beautiful species, to my mind the very finest of the autumn-flowering Crocuses, is already in bloom from bulbs which have remained in the ground undisturbed for several years past, and the blossoms appear to be finer than ever. I have patches next to the Box edging of a border, and also under a west wall. The former, by reason of being in a warm and sunny position facing south, are always the first to bloom; in a north border, which the sun does not reach, the flowers come much later. The peculiarity of flowering successively is a good one; and the blooms are so beautiful that one can wish for them to be preserved as long as possible. Beautiful as this Crocus is, it is rarely seen, and yet if once seen its beauty must of necessity create a desire to possess and grow it.—R. D.

**Carnation Uriah Pike.**—In a recent issue of THE GARDEN one writer stated that Uriah Pike Carnation was of little value in the outdoor garden. When I was at the Carnation show at Birmingham my attention was called to a mass of Uriah Pike by the side of one of the main walks. Here it had grown vigorously and was blooming profusely, throwing large, full, and rich dark blossoms of fine quality, and if anything more free in producing its flowers than in the case of plants grown in pots. The plants were about 3½ feet in height, and the numerous flowers were admirably displayed. It was a model Carnation bed, and all the lovers of the flower present at the Midland Carnation show were invited to see it and were greatly delighted. Uriah Pike was quite at home here. Mr. Latham, the curator of the Botanic Gardens, grows Carnations largely for house decoration, and especially Uriah Pike and Germania, and no doubt he puts out in the open strong, vigorous plants, and they made the very fine and effective display to which allusion has been made.—R. D.

**Colchicums.**—In the short note on these on page 196, through some error I appear to say that the blooms of *C. autumnale* and those of some of the other Meadow Saffrons look magnificent in size beside those of *C. Bornmulleri* and a few others referred to by name. The word magnificent should have been insignificant. *C. Bornmulleri* is the largest of all the Colchicums with which I am acquainted, and a clump of it at the base of the rock garden here is very effective at the present time. On their first appearance above the soil the flowers are ivory-white. The outside of the outer segments is afterwards flushed with rosy purple, which extends in a few days until the outside of the flower is entirely coloured. The interior is of the same rosy-purple hue, but has a very broad white zone at the base. According to the Kew Hand-List of Herbaceous Plants, *C. Bornmulleri* comes from Asia Minor, Haussknecht being the authority for the specific name. It is not included in Mr. J. G. Baker's Synopsis of Colchicaceae in the Journal of the Linnean Society, vol. xvii., No. 103.—S. ARNOTT, *Carsathornie, Dumfries, N.B.*

**American Carnations.**—In THE GARDEN of August 21 (p. 147) Mr. H. W. Weguelin remarks, concerning American Carnations, "They all have papery petals, with the roughest possible edges." As a class for winter blooming, American Carnations are a long way ahead of the similar class grown in Europe, and I have often thought that they might be profitably grown in England somewhat on the American plan by selecting a locality that enjoys more than the average amount of winter sunshine—Torquay, for instance. What Mr. Weguelin means by "papery" petals I fail to

understand, unless he infers lack of substance, in which case his remark is not just, for in form, fulness, and substance the flowers will stand comparison with the best. But the "saw-edged" petal, I know, is the bugbear and the ground of offence to Mr. Weguelin and others. Why should we be forced to accept the florist's flower as the only true type while there is another form more natural, and withal possessed of rich fragrance? Mr. Weguelin talks about a winter Carnation show. If he will walk along the principal streets of any large American city on any day from early October till June he will see more Carnations every day than ever were on exhibition at one time at an English show, flowers of bright self colours, perfect in calyx, with strong self-supporting stems up to 2 feet in length. The Carnation here is a winter flower of the masses, but the extent of its culture and the number daily disposed of must be seen to be believed. The best American Carnations are certainly up to the standard of the best English varieties in every respect, their sole difference being in that form of petal which relieves the flower of formality and adds to it more beauty. If they are unacceptable to a limited few, it can only be because they are "saw-edged," as there is no other real or reasonable cause for "discarding" them, whilst one can but smile at the verdict of such judges as would pass them over, all other points being equal, because they happen to possess a characteristic trait of their original parent.—A. HERRINGTON, *Madison, N.J.*

#### FLOWER GARDEN NOTES.

**PYRETHRUMS.**—If an early display as well as an increased stock of Pyrethrums is required autumn division is desirable, especially if the coming spring, as in several past seasons, prove hot and dry. The clumps need not be split up any more than is absolutely necessary, a safe rule being to practise division, so as to avoid mutilation as much as possible. A deep, fairly holding soil is the best for Pyrethrums. If naturally on the light side, a liberal dressing of cow manure should be worked in. The plants are very sensitive to a prolonged spell of dry weather, and, so far as my soil is concerned, I find autumn planting, liberal treatment, and heavy surface mulching indispensable to successful culture. Given the two last-named points, the plants may remain in the same position for three seasons, but at the expiration of that time the crowns are pushed up a considerable way above the surface, and when these conditions are apparent they should be lifted and replanted. They are among the hardy perennials that may safely be recommended for permanent beds, for only for a very brief season are they without a fair display of foliage, and any rusty look about them, sometimes in evidence after the first flowering, can be quickly remedied by a bit of good manure on the surface and a thorough soaking, preferably with liquid manure. Perhaps some reader who grows largely will advise as to the best and most economical way of staking. It is one of the most awkward plants we have from this point of view, that is, to stake so that the blooms shall be well seen and the flower-stems fairly straight without undue formality, and with due regard to the amount of time expended in the operation. I mean, of course, where there is a mass of flowers together, small single plants throwing some two or three flowers each are easily dealt with. I notice a rather sharply defined liking as to the single and double types. Personally, I think both are beautiful, and there is hardly any difference in their duration either on the border or in vases. Good singles noted last year were Beatrice Keilway, Lorna Doone, Mr. Santley, Mrs. Bruce Findlay, Princess Charlotte and Empress of India; the two last-named, respectively first-class in the crimsons and whites, being exceptionally good for cutting. Among the older kinds, Tempête is welcome for its very finely-cut foliage. Half a dozen good doubles in different shades are Aphrodite, Solfaterre, Florentine, Celia, Ormonde, Mebon and Pericles.

**PROPAGATION OF HARDY PLANTS.**—Besides propagation by division, commencing with Pyrethrums, and continued right down through the various subjects until the flowers of the last Starworts are over and one is able to deal with them a considerable amount of stock can be secured from cuttings, that is, unless an equally good result is obtainable from early spring sowings, which it hardly seems desirable to resort to the cutting. The best strains of Phlox, Pentstemon and Antirrhinum can, however, be perpetuated in the latter way. With the decline of flower and foliage forms of herbaceous Lobelias can be divided and replanted; that is if it has been decided where sites they are to occupy in the coming year. A hard-and-fast line can be laid down as to the division and replanting of the many forms of Starflowers and Starworts. Some varieties may remain in the same position for years retaining splendid vigour, whilst others are seen to the advantage with annual, or, at most, biennial division.

**DAFFODILS.**—I should like to remind readers who are commencing the culture of Daffodils one or two important points essential alike for good and a long-sustained display the first season, and for after results. Firstly, that September or, at latest, the early part of October, is the time to plant, and that, given a rather light soil the bulbs should be inserted deeply. Secondly, that a careful selection is necessary to ensure a long display with no intermediate break. Thirdly, does not, as a rule, receive the consideration it deserves, but is a very important point when one remembers that the season extends from the end of January until the middle of May. Thirdly, the planter should make sure where he wants his different varieties, for once planted the bulbs should not be disturbed, that is, unless he is prepared to go to the trouble of early annual lifting, selection of best bulbs, close planting, and the necessary preparation of soil. The ordinary private grower whose chief aim is a big display of flowers rather than the increase of stock, will find the unturbed bulbs increase in strength with each succeeding year until the solitary bulb becomes a fair-sized clump yielding from twelve to eight bulbs.

**VIOLETS.**—We are getting nice outdoor plantings now from Amiral Avellan and Wellsiana, the former one of the big types, a large flower with stalk from 10 inches to 12 inches in length, yielding only a faint perfume, for which reason, despite its size, I shall have no more to do with it after the present season. Unless the unusually long stalks are deemed essential, it is doubtful if one can have a better single Violet than Wellsiana, flowers of a good colour, freely produced, and very strongly scented. The offering of Marie Louise for transfer to pits has been performed this week, and I do not remember a better lot of stuff, the plants large and vigorous, bristling with buds, and, best of all, free from spider. Few plantings have been made in for years without the preliminary dipping.

*Clairmont.*

E. BURRELL

**Sweet Williams which have flowered.** Any particularly fine varieties of these which have bloomed in the summer, and were marked on account of their fine properties, may during the present month be lifted, divided, and replanted. In dividing it will be found that most of the shoots which are thrown out from the roots at soil level will have small root fibres attached to them, and if they are planted out with some sandy soil at their bases they will soon root. This care is only necessary in the case of very fine and extra marked varieties, as seedlings from fine strains, such as the marked plants alluded to above, are certain to produce the best for the purpose. Seeds may be sown as soon as ripe, which is a matter in the matter of time, or in the spring. I prefer to sow thinly in shallow boxes, placing them in a cold frame, where they soon germinate, keeping the boxes in the frame all the winter when the seeds are sown in the autumn, in the spring placing them in the open as soon as

young plants have formed their second leaves, and taking care they do not suffer from want of water. They can be planted out to flower as opportunity offers.—R. DEAN.

GLADIOLUS TRISTIS.

The *Gladiolus* figured is a quaint and somewhat uncommon species, sent to me two years ago as the Night Scented *Gladiolus*. The name

*Gladiolus tristis*. From a photograph sent by Mr. Greenwood Pin, Dublin.

very suitable, as towards evening it exhales a perfume somewhat resembling that of the Night Scented Stock (*Matthiola*), while by day it has scarcely any smell. The colour is peculiar—a kind of lemon-buff, with dottings and pencillings of black; not strikingly pretty, but pleasing to such as like quiet colours. As noted in THE GARDEN (vol. xlix., p. 416), it has exceedingly curious leaves. These are for the greater part of their length apparently square, as occurs in *Iris tuberosa*, &c., but on cutting across the section is seen to be an almost perfect Maltese cross—a form of leaf met with in no other plant with which I am acquainted. It grows freely in ordinary garden soil, and in general style resembles *G. Colvillei* rather than the autumn-flowering section.

GREENWOOD PIN.

*Campanula isophylla*.—Is this species to be planted? The white variety is abundant, for almost everyone who grows plants owns it. But the blue, does it exist? I have had two blue forms sent me as *C. isophylla*, but they are not like the white variety in the shape and size of the leaf. Their leaves are broader and more rounded, more rounded, dark green, as opposed to the grey-green of the white, and on much longer foot-stems. I take one to be *C. fragilis* and the other *C. Barrelieri*, which is probably but a variety of the other. Neither of the blue-flowered types occurs near the white one for freedom and density of growth or profusion of bloom. I shall be glad if anyone can inform me if the true *C. isophylla* exists, and if it is obtainable. What comes nearest to the white is the green-leaved hybrid

obtained, it is said, from a cross between *C. fragilis* and *C. isophylla alba*, and from which the beautiful variegated form known as *C. Balciniiana* sprang. This is a free grower, singularly profuse of bloom, the pendulous shoots furnishing quite a cataract of blossom, as in the case of *C. isophylla alba*. My plant of the cross came beautifully variegated at the points in early summer, but not altogether variegated, as in the case of the new *C. Balciniiana*.—R. D.

PLANTING CARNATIONS.

IN answer to the query (GARDEN, September 18, p. 232), Carnations may be planted in September or early in October, always provided the layers are well rooted. If this is not the case they should remain on the parent plants until the spring. Under no circumstances would I advise "T. S." to pot up his layers and keep them under cover during the winter. The operation is quite needless. It seems a pity the idea still prevails that winter protection is necessary for Carnations. As a matter of fact they are among the hardiest of plants, and in the exceptionally severe winter some two or three seasons back, when the glass dropped to zero and the frost was very protracted as well as severe, the loss was very trifling. As mentioned above, it is emphatically a question of well-rooted plants, and this being so, an important factor in Carnation culture is early and careful layering, and close attention to the layers to see they do not suffer from want of water. Granted, however, all this, there are some varieties that root much more slowly than others, and with, for instance, Countess of Paris and Ketton Rose I have always had the best results from deferring the planting until the spring. The question of careful consideration as to the proper time for planting is applicable to many hardy things besides Carnations, and will depend, as with them, on the time of striking and the amount of roots made. Early struck Pinks, for instance, can be planted at any time, but tufted Pansies, if not inserted until September, will be just as well on the propagating border until early in spring. So, too, with any seedlings of hardy plants that have been obtained by autumn sowing. Although there may be no possible question as to their hardiness, it is hardly advisable to put them out as very small stuff on the open border. The better way is to prick them off in some enclosed space where they are likely to be under fairly constant supervision, and where measures can be taken to accelerate growth and to keep off any enemies.—E. BURRELL.

—A reader has lately asked whether he might safely plant layered Carnations in September, or had better put them into small pots and plant them out in spring. More Carnations are planted during September than at any other time, but the sooner in the month the work is done the better. Much, however, depends upon circumstances—how the layers are rooted, what kind of soil they are to be planted in, and what the situation is. Layering is often postponed till too late in the season for fear of spoiling the beauty of the plants; consequently should a wet, cold time follow the operation, roots are formed but slowly and transplanting cannot be done till October. I have seen plants do very well transplanted the first week in that month where the soil was warm and well drained, and fine weather followed till the end of the month, but, as a rule, those who have a strong retentive soil to deal with run a great risk by planting in October. The young plants, if not too numerous, had far better be put into as small pots as will hold them and be placed in cold frames or pits, being all the better if plunged in ashes and transplanted to the open border in April. Last autumn I saw a number of Carnations being planted in a private garden in October, the young plants being small and indifferently rooted, and the soil, moreover, cold and stiff. I am sure that if I could have seen the plants this summer they were a poor lot, but many are slow to learn that a little extra care and trouble at the outset often save loss and dis-

appointment in the end. Had the plants above referred to been not even potted, but merely planted closely together in frames, they would have stood the winter well, have increased the number of their roots, and have, after removal to open quarters in April, made good headway and bloomed fairly well. In cold gardens, a spit of the border or bed should be taken out and replaced with a light loamy compost; this gives the roots a chance.—J. CRAWFORD.

—"T. S." inquires (p. 232) as to the wisdom of planting these now in the open or potting them. Had your correspondent given particulars of locality and the kind of soil he has to deal with, a more definite answer could have been given. In the absence of these important details, perhaps the following may be helpful. I would unhesitatingly plant out freshly-rooted layers in any fairly light, well-drained soil, and provided also the locality is not troubled with rabbits in winter. Where there is a danger from rabbits, or again, where the soil is retentive or cold and badly drained, the Carnations will be best in quite cold and well aired frames till early in March. If possible at planting time, use a good handful or two of fresh loam and bone-meal about the roots, plant firmly, without burying any of the side shoots and avoid too much gross manure in the soil. If planted in autumn the plants should be gone over after severe frost is past, and see that all are firm in their respective positions. Many things besides Carnations are lost or injured through neglect of this very simple matter. If the Carnations are potted for the winter, give pots of fair size, at least 4½ inches in diameter, or, better still, where a shallow frame is at hand, plant all layers in this till March in a good mixture of soil, at which time they may be given their permanent positions in the garden. Lifted in this way with good balls of earth and the roots virtually intact, a good bloom may be expected. Autumn-planted Carnations are benefited by frequently stirring the soil during winter.—E. J.

PROTECTING IRISES FROM WATER RATS.

As I know many people find great difficulty in protecting their Japanese Irises from water rats, I send a photo of how I have here completely

Mode of protecting Japanese Irises. From a photograph sent by Mr. Geo. Dixon, Astle Hall, Chelford, Cheshire.

defeated them. Last year all my beautiful blooms were nipped off just as the buds were bursting, and I could not stop the rats, trap and shoot them as much as I would.

The accompanying illustration will describe better than words how the rats are kept out. I grew the Irises in clumps in the water at the edge of my lake, where they do very well, better than on land, although in a wet place. Although there is a little expense attached to this

method, the flowers are so beautiful that I consider one is well rewarded for the expense.

GEORGE DIXON.

*Astle Hall, Chelford, Cheshire.*

### THE HOLLYHOCK.

THERE appears to be the promise of a revival in the Hollyhock. It does appear that the dread disease which caused such havoc among the Hollyhocks for a long time is less hurtful than it was a few years ago, and perhaps it may yet depart as mysteriously as it came. Very few of the remedies recommended to cure the disease were of much avail; there were times when its virulence appeared to defy, and that successfully, any efforts to stay its progress.

Those who contemplate planting, especially in cold and damp localities, will do well to obtain plants in pots at this time of the year and onwards and winter them in a cold frame previous to planting out in the spring. There is scarcely any soil and situation in which the Hollyhock will not grow. I have seen it doing finely in the midst of somewhat thickly planted shrubs and at the backs of flower borders, in odd corners in the semi-wild garden, in the sun or in the shade.

To do well, the plants should be in a good garden soil trenched to the depth of 1½ feet, and into which has been worked some well-rotted manure. Then planting can be done early in November if it be done in the autumn, placing the plants a yard apart, so that they may have room in which to develop. A plantation of Hollyhocks with dwarfier things fringing it, such as Phloxes, Pentstemons, Gladioli, Hyacinthus candicans, the dwarf growing forms of Chrysanthemum maximum, and such like, would all be appropriate. Spring planting out of pots may be done at any time up to the middle of May. The Hollyhock is often slow to start into growth, but once it becomes vigorous it rapidly makes headway.

Mulching with good manure, watering when necessary, and then copiously, and staking as the plants gain in height, are all necessary summer details having much to do with the well-being of the plants. Staking is very important, as rough winds may snap off an ascending shoot, and then it is of no value for decoration. Good culture is the best antidote to the disease, and by such means a good deal of its virulence may be prevented.

R. D.

**Pyrethrum (or Chrysanthemum) uliginosum.**—I have found it quite easy to propagate this fine autumn-flowering Daisy by taking off tops 6 inches long just as the crowns of terminal shoots are forming, rooting them under glass, and thus have pretty and free-flowering plants to bloom in pots at some 20 inches in height in the autumn. Even by layering I have obtained the same results, as, although the stems are pipy, yet when layered and notched slightly roots are soon emitted. That plan, however, is much more troublesome than is the rooting of tops as cuttings. This plant, like so many more of the herbaceous hardy flowers, increases in height each year if left in the same ground undivided, because of the struggle of the shoots or stems to obtain as much light and air as possible.—A. D.

**Tropical Nymphæas in the open air.**—In the garden at Sandhurst Lodge, near Wokingham, adjoining one of the warm houses, a tank was made some two years ago. It is against a south wall, and so placed that a small pipe is taken from the pipes in the house through the wall into the tank to warm the water. In this are growing plants of *Nymphaea cyanea*, *Nymphaea Devonensis*, and *Nymphaea scutifolia*. They are thriving grandly. There were as many as eight to thirteen blooms open in one day on *N. Devonensis*. This is sufficient to show that it will thrive satisfactorily in the open air if the water is kept warm. The plants also stood in the open all last winter. From the success that has attended

the first trial, it has been decided to enlarge the tank and plant out other tropical kinds.—J. CROOK.

**Some native flowers in the autumn garden.**—If our September weather were always fair, garden flowers would be very happy; but with the sudden rains and storms that often come to us at this time of the year, bedding and other tender plants, and even hardy exotics, are saddened very soon by it. Then it is pleasant to see how some native plants are refreshed rather than disheartened by the rains and come into welcome bloom. In many country places where there is room enough these take care of themselves; for instance, the Harebell and the purple Vetch (*V. Cracca*) add much to the beauty of the autumn and late summer, and are often seen. So, too, the Heather is common in places and very pretty, but in others it is worth while taking a little care to get the less common kinds. For instance, although the Heather may be very common, and its fine varieties may be planted, the less known Heaths, such as the Cornish Heath (*E. vagans*) and Dorset Heath (*E. ciliata*), may be planted in rough places, and no plants are more deserving of it. The little Furze, too, which is so abundant in many upland wastes, is, we find, a very pretty plant, if not in the garden, not very far from it, helping to form foregrounds to drives, and in low coverts just at this time blooming very cheerfully and freely while other things are beginning to fade. As we write it is quite full of beautiful fresh blooms. It is easily raised from seed like the common Furze. Forget-me-not is still very fine by water, and where the soil is rich and deep the effect in broad fringes is very pretty, though its best time is the summer. The berries of the wild Roses begin to colour, and the various Blackberries also add to the beauty of the coverts and hedgerows. By the waterside, one of the handsomest bushes we have, the Water Elder, begins at this time to show the fine colour of its fruit, and the Orpine on banks and the Golden Rods in the coverts also make a show.—*Fidd.*

### NEW DAHLIAS.

WRITING on new Dahlias in last week's GARDEN, "S." remarks that the tendency is to grant certificates to varieties of too much the same tint of colour, and singles out the varieties Falka and Regulus as being too much like Cycle and C. Woodbridge. As grown and seen here in the open air, all four are very distinct from each other, and I forward you blooms of each for inspection. At the two exhibitions "S." refers to the new seedlings are carefully examined by a committee of Dahlia experts, men having a thorough knowledge of their work and of existing varieties, and when an award is made to a new seedling by such a body of men, it may, I think, be taken as correct that the variety has some merit of distinctness or shape beyond varieties already in commerce.

The same writer, commenting on the variety Fantasy sent out last spring, says it is a complete failure as a plant, that its flowers are tiny, and that the footstalks are so short that the flowers are hidden in the leaves. I send you half a dozen blooms of this, cut from a plant carrying at the present moment about four dozen blooms. You will see from the blooms sent that they have an average length of about 6 inches of clear stem from the bloom to where the two side flower-buds have been nipped off, and a length of about 11 inches to the point where they have been cut, just above where the topmost laterals are formed. This variety was sent out not so much as an exhibition or garden variety but as one specially suited for supplying abundance of small or medium-sized flowers for cutting of an elegant and new shape in Dahlias, and as such I believe it has given much satisfaction. With a little

judicious thinning of the branches and buds necessary for the Cactus varieties generally, it can be made an effective garden plant: in habit of growth it is equal to at least four-fifths of the varieties classed as true Cactus Dahlias.

I fear too many people who plant Cactus Dahlias neglect the little necessary thinning out of the branches requisite to make them effective garden plants. Out of about three dozen varieties grown here, Matchless, Beatrice, and Regulus throw their flowers above the foliage best, the stems of these being both long and stiff; but this is not always an advantage, as after a storm of wind and rain these cut a sorry appearance compared with a variety like Bertha Mawley, which throws its flowers close to, but just above the foliage. Many others have stems equally as long as those named, but are not so erect, causing the flowers to hang more or less among the foliage, but varieties of this description with a little thinning of the top laterals become most effective garden plants, as instance the variety Starfish, perhaps the most beautiful Dahlia ever sent out.

Cambridge.

J. BURRELL.

### ASTER TRIALS AT MORTLAKE.

IN the 310 varieties of Asters now being grown for trial by Messrs. Carter and Co. in their grounds at Mortlake there must of necessity be some duplicates and others too closely akin to be distinct yet on the whole the trial is a remarkable one, the varieties ranging from 3 inches high to nearly or quite 2 feet in the tallest kinds. No effort is made in these trials to produce prize flowers but with good culture all round to test the natural habit and relative value of each kind side by side. No excessive manuring or rigid disbudding to produce flowers of special quality is indulged in, with the result that these trials become a standard of reference and afford the most reliable information it is possible to obtain.

There are some dozen or eighteen types of Asters here besides others not yet sufficient fixed, but which will prove acquisitions well deemed reliable. In one instance some half-dozen years had been spent in growing, selecting and forth with a fixed ideal in view, but which is very slow in being realised. Particularly attractive is the Porcupine strain, with pointed quill-like petals, that resolve into a more or less Thistle-like head. Here, as in other classes, there is much variety, while the more brilliant shades are very charming. The Cockade or Crown Aster is very distinct and usually of two colour an outer whorl of a deep hue with a central crown of white; these attain 1½ feet high. The strains of the Peony-flowered, as also the Chrysanthemum and Victoria, are alike meritorious. A similar remark applies to the Comet Aster, which all in all is perhaps the most elegant of the family. Other noteworthy types are Queen of the Market Dwarf Bedding and Dwarf Bouquet. The Emperor type is readily distinguished by its producing one magnificent flower of fine proportion at the summit of a sturdy stem 15 inches high a grand exhibition kind, or for growing singly in pots. Some Swiss novelties were very striking and in addition to the primary features of the Comet group these possess a whorl of leaf bracts that materially adds to their beauty when cut. The Giant Branching is all the name implies—a strain at once remarkable for its vigour as also its great abundance of large handsome blossoms on branches nearly 12 inches long. The new yellow Aster is a light tone of yellow, pleasing in its shade and very distinct, and while as young in its infancy, will doubtless prove the forerunner of deep shades of yellow and improved forms. White Plume is the finest of all the pure white and the flowers of remarkable purity and finely built and one that by special culture might easily be mistaken for a pure white Japanese Chrysanthemum, so exactly do the overlapping petals convey the

dea. The plant is vigorous and reaches about 15 inches in height. The endless shades of colour it is impossible to depict in words, but the rose and pink shades are lovely in many instances, and restful, too, amid the fiery shades of scarlet and the richest of purple and blue, the more so when to large a space is devoted to the flower, as here obtains. E. J.

**Physalis Franchetti.**—Some beds of this are very striking and conspicuous at Kew just now. The plants have made good growth and are carrying plenty of healthy leaves, also a full crop of fruit. The growths have been tied up to light stakes, which are well hidden, and the immense calyces are thus better exposed to view than they would be if the plants were allowed to assume their natural habit. The calyces are well coloured and impart quite an unusual glow to the beds when seen from a distance. The plant will scarcely do for beds which are required to look right during summer, but it is well suited for rowing in less prominent positions or in corners where it can get ample sunlight and a rich soil.—T.

—Reference has been made to this several times lately, and certainly, where dried flowers and grasses are appreciated in winter for drawing-room decoration, they come in most useful. There are one or two points in its culture that need special attention if well-furnished stems and old, fully developed, and highly coloured pods are to be had. To grow them crowded is to court failure, as not only do the growths become stunted and weakly, but the flowers are few and far between. Moreover, if September and October should turn out wet, many of the calyces will rot. What is required is to thin out the growths early in spring so that plenty of sun and air can reach them, and to support them, when some inches or 12 inches high, with neat sprigs. The pods that are cut from Pea sticks are good for the purpose. The orange-coloured calyces look well mixed with Honesty, and placed in large vases or ornamental bowls.—J. C.

**Delphinium nudicaule.**—This attractive and dwarf-growing Delphinium is now flowering with ease, the plants raised from seeds sown in April, seems, therefore, that this species of Delphinium, in common with some other perennials, can be carefully treated to be made into an annual if it is early and proper treatment as soon as the seedlings are large enough to handle; say, potting each singly as soon as large enough, and growing on into size in a cold frame previous to planting in prepared ground. It should be a raised pot on which this Delphinium is planted, and when it becomes perennial, a little care being necessary to keep the roots well covered with soil during the summer. When planted in damp, low ground the roots are apt to perish. It is well deserving of culture on account of its colour.—J. D.

**Bouvardias in the open.**—A really good way of employing the large, ungainly plants is to plant them in the mixed border in spring and allow them to grow and flower at will. That large-flowered variety, *B. corymbiflora* Humboldtii, is especially good for this work, as by placing three plants in a group and allowing them to flower at will, quite a beautiful lot of blossoms will result. Plants a year old that flowered in pots the winter previous are the best for this purpose, these being cut back or pruned in March and planted out at the end of May. By starting the plants in frames in good soil, such may be duly hardened and transferred to the border with good results. No pinching will be needed after the plants are pruned in March, the object being to have as much bloom as possible during summer and early autumn. A warm border and good soil will not be given in vain.

**Cosmos bipinnatus.**—If only on account of the lovely pyramid of its unique foliage, this would prove invaluable in many parts of the garden, more particularly where it is possible to form large groups here and there. Indeed, so

far as its flowering is concerned, even in hot summers one has to be satisfied with foliage alone, unless special precautions are taken, or a special mode of culture is indulged in. Above the abundance of its beautiful leaves the elegant rose, mauve-shaded flowers are very showy, and in sunny or favoured localities it would repay for prompt and early attention. In other districts—and these perhaps the more numerous—it would be well to treat it more in the way of a biennial. By sowing the seed at the end of July and growing the plants on, a start would be made that would find its reward the following year, not only in larger bushes, but in a free and prolonged flowering also. It should always be planted in the hottest situations quite removed from shade, and in good condition is a fine plant indeed. Though strictly an annual, its rather late flowering minimises its value, though this may be altered by starting the plants in the previous year.

**Show Dahlia Mont Blanc.**—This is a magnificent pure white show Dahlia, and when well grown takes a lot of beating. Unlike some of its class, it usually opens its centre before the outer petals begin to decline, especially if shading is practised. I recently saw some grand blooms of it in the garden of an old Dahlia grower, who, by the way, does not believe in growing from old roots. Not only does he find that growth is more vigorous and free-flowering from cuttings, but also that tubers of many varieties kept through the second winter often die right out. I have heard people say they would try their hand at Dahlias, but should have to grow them on the same plot of ground every year, which they think would not answer. I know several enthusiastic amateurs so situated who grow excellent Dahlias of all kinds, not by heavy manuring altogether, but by biennial incorporation of a little fresh loamy compost and the use of a little approved fertiliser when the buds commence to form.—J. C.

#### POLYGONUM BALDSCHUANICUM.

VARIOUS foreign horticultural journals have lately published laudatory notices of this fine plant, which, two years ago, I described and recommended in *Le Jardin*, and which was then figured in that journal from a fine specimen in flower amongst the collections at the Muséum. The plant has well fulfilled all that it then promised. Since it was figured in 1895 it has increased greatly in size, and in the present year its long twining stems are not less than 26 feet in length. About the middle of June it commenced to expand its large and elegant clusters of white flowers tinted slightly with pink, and has continued in bloom ever since. At the present date it is still covered with bloom, and at the same time displays its handsome seeds, which are tinged with red and are as ornamental as the flowers.

This original specimen is not the only one at the Muséum. There is another very fine and pretty strong one (18 feet or 19 feet high) on the slope of the Labyrinth, and a third, about the same size and in full bloom, in the nurseries of that establishment, not to mention the young plants which have been propagated from the larger specimens.

*Polygonum Baldschuanicum* was introduced from Turkestan in the year 1882 by Dr. Regel (who was then director of the Botanic Garden at St. Petersburg), and was described and figured by him in the eighth volume of the "Actes du Jardin Botanique de Saint Petersburg" (p. 684, pl. 10). It was also figured in the "Gartenflora" for 1888 (p. 409, pl. 1278). From Dr. Regel the Muséum received the first specimen about the year 1885, and a second one in 1892, and this establishment first invited public attention to this remarkable species by exhibiting a specimen in bloom at a meeting of the Société Nationale d'Horticulture de France on September 13, 1894, and again on September 26, 1895. On the occasion of this last exhibition Professor Max Cornu

gave the history of the plant, and dwelt strongly on its ornamental value. In 1893 the Muséum was in a position to distribute seed of it, and in May, 1893, sent a growing specimen to the Royal Gardens at Kew, and this is very probably the same plant which is now so much admired by English amateurs. This very handsome *Polygonum* is quite hardy in our climate. The stems, it is true, suffer more or less from frost, according to its intensity, and may even be cut down close to the ground (as they were last winter), but they come up again vigorously in the following spring. In any case, the root will pass the winter in safety under a mulching of dead leaves.

The plant appears to find itself especially at home in well-drained, and even dry, soils, and shows no dislike to soil of a calcareous nature. It seeds abundantly, but many of the seeds are sterile. It can be multiplied by layering, but is tedious in taking root. Multiplication from cuttings succeeds well only when done in a propagating house and under special conditions.—L. HENRY, in *Le Jardin*.

#### SHORT NOTES.—FLOWER.

**A good dwarf blue Ageratum.**—This will be found in a very dwarf, compact, tree-blooming variety, grown at the Chiswick Gardens, the flowers silvery blue and produced in a dense head. Some would probably term the colour a bright violet-blue, but much depends upon whether the flowers are seen in the sun or in the shade. A large number of plants were in bloom, and they were singularly uniform in character. It is named *The Zoo*.—R. D.

**Erigeron speciosus superbus.**—This well-known border plant is still yielding a large number of its showy blossoms, much larger than the largest of the Michaelmas Daisies now flowering in such numbers. Few plants are more easily grown than the above, and fewer still provide such a profusion of blossoms from June to October.

**Aster St. Brigid.**—This variety belongs to the *Novi-Belgii* group, and promises to be among the most useful of this beautiful family. The name will not be familiar to many at the present time, as it is a new variety of the present year. But we were struck with its distinctness and beauty in Messrs. Barr's collection the other day. The flowers are produced in an erect, freely branched panicle, and pure white save for a flush of delicate pink near the tips.

**Aster vimineus.**—It is impossible to describe the beauty of this kind, which is undoubtedly one of the gems of this large genus. The plant is about 3½ feet in height, of a singularly neat habit of growth throughout, while its numerous pure white blossoms possess a perfectly natural spray-like arrangement on the slender branches and twigs. In the open border when left alone the plant inclines outwardly with a singularly pretty and graceful effect when in flower.

**Anemone japonica alba.**—As seen at Kew this is one of the best of autumn flowering plants. The growth made this year is dwarf in comparison with that of other years, but the freedom with which it is flowering leaves nothing to be desired. The plan of massing the plants in beds by themselves is good, as they require only the setting of grass to make them effective. The old single white form is still as good as any and better than most of the newer ones.

**Two old plants.**—I allude to that fine old *Calceolaria*, *C. amplexicaulis*, than which no *Calceolaria* ever raised is more beautiful, and to *Verbena venosa*, full of flower and hardier than most bedding plants. Beds of the latter in the distance gave the effect of large patches of Heather. The *Calceolaria* was mostly seen dotted about among other things, and would look better in a mass, its clusters of soft yellow flowers, borne on tall stems, requiring no better setting than its own foliage.—J. C. T.

**A fine single Dahlia.**—A very brilliant single Dahlia is one grown largely at Kew and appropriately named *Huntsman*. It is particu-

larly free flowering, and the flowers are borne on long straight stems; they are also shapely enough to please the most exacting florist. This stands out very conspicuously from all the others, the shade of scarlet being so telling. One wants to see Dahlias growing, and not set up as at shows, to judge of their value, as habit has so much to do with their effectiveness.

## FRUIT AND VEGETABLE CROPS.

### SUPPLEMENTARY.

**The Duffryn, Mountain Ash, S. Wales.**—On the night of May 13 we experienced severe frost, completely blackening all expanded Strawberry blossoms: even hardy Ferns that grow wild in the woods and mountains were burnt black. This night, no doubt, proved destructive to all fruit blossoms. Apples are an average crop, Keswick Codlin, Blenheim Orange, and Worcester Pearmain being the best. Pears light; Passe Colmar, Jargonelle, Bergamote d'Espereu the best. Peaches scarce, a light crop on Barrington, though covered over with greenhouse blinds. Plums a failure. Raspberries a heavy crop of fine fruit. These are tied to wires stretched from post to post. I head them back to the height of 6 feet. A thick mulching in the autumn of good manure seems to answer their requirements. Gooseberries fair crop. Currants under the average.

Potatoes small, but clean. Up to Date and Clanceller proved the heaviest croppers; Satisfaction proved rather unsatisfactory. Peas excellent, early and fine, especially Gradus, Duke of Albany, and old Fillbasket; May Queen cropped well. Runner Beans have cropped heavily, and will continue if the weather keeps favourable.—J. E. DAVIES.

**Munches, Dalbeattie.**—The fruit crop of 1897 has not been quite a satisfactory one here. Strawberries, considering the ground occupied, were a poor crop, flavour better than in some previous seasons; sorts that cropped best, Garibaldi, Noble, and President. To my taste, President had the best flavour. Gooseberries very plentiful, but the fruit generally small. The same may be said of Red and White Currants. Raspberries were abundant, but under the average size. Black Currants under the average crop. Cherries total failure. Plums very few, with the exception of Victoria (good crop), Kirke's fair, and a small early one (not sure of variety) which bore an average crop. The only Apple trees that have borne a crop this year are some old espalier ones; Warner's King, Lord Sutfield and another of the Codlin tribe being the best. But in other gardens in the district many trees have been heavily laden. Pears (and on walls only) have been under average here. Damsons very scarce.—A. MURRAY.

**Waddesdon Gardens, Aylesbury.**—The fruit crops in this locality may be said generally to be very poor. Amongst Apples, the Codlins have a half crop of small, imperfectly-set fruits, while Ecklinville, Stirling Castle, and Cellini have partial crops of good fruit, and the same may be said of isolated trees of Cox's Orange Pippin and Margil. The most of the standard late kinds are a failure. Of Apricots, Pears, Plums, and Damsons a total failure may be recorded. Of small fruits, Gooseberries had half a crop of good fruit, and Raspberries, Strawberries, and Currants had full crops of very good quality, but which, in consequence of the intense heat, ripened quickly.

Vegetables of all kinds have been abundant and good. The weather during the early spring was unfavourable and crops made but slow progress for some time. The earlier cuttings of Cabbage and Cauliflowers were a week or more later than usual: the best results of these for early crops were obtained from sowings made in gentle heat, about the end of January, of Veitch's Earliest of All Cabbage and the Early Forcing Cauliflower. Turnip Extra Early Milan and the Parisian

Forcing Carrot in sheltered positions are both doing well. The earliest gatherings of Peas grown in the open were a week or ten days later than the average; these were from sowings made in pots, and planted when 2 inches or 3 inches high, of Veitch's Extra Early Selected, a reliable variety for first crop. All successional crops have done well and stood the intense heat of July without causing a break. Asparagus was unusually plentiful. Globe Artichokes, a vegetable much in demand here, were more freely produced and of better quality than ever before noticed. Salading very good, the heat and drought of July were too much for the Cauliflowers, all the kinds grown suffering equally. Sharpe's Victor and Veitch's Improved Ashleaf Potatoes are good crops and sound. Later plantings look well.—J. JACQUES.

**Madresfield Court, Great Malvern.**—Apples are a good half crop, taken altogether, but much of the fruit is unsound owing to the depredations of the Codlin moth. There are many promising young orchards of choice fruit on this estate, especially on small holdings, the result of supplying gratuitously a choice selection of good trees. Pears on walls are good and clean crops, slightly undersized, possibly owing to early drought followed by the absence of sun during August and September. Stone fruit is under average, Plums especially being very scarce, consequently prices rule high. Bush fruits abundant and good in quality.

Vegetables, with the exception of Peas, abundant and good. The early and continued drought caused the late Peas to mildew, which baffled the best efforts to check. Although I grew the late varieties of Peas in trenches as for Celery, I never had greater failures. Hitherto this system of cultivation had given abundance of late Peas, of that best of all late Peas, British Queen and Ne Plus Ultra, the only fault being the tall sticks required, but more than compensated for by the perpetual or continuous bearing merits of such excellent Marrowfat Peas.—W. CRUMP.

**Coolhurst Park, Horsham.**—The Apple crop is almost an entire failure in the orchard here. In the two previous years there were exceptionally heavy crops, so that may have something to do with this season's failure. What blossom came was soon over, never developing into full form and had the appearance of being insect-eaten, and latterly rolled up like wool balls. In this quarter Apples are variable, as there are places where the crop is fairly good, while in other parts they are thin and, generally speaking, small, owing no doubt to the great drought that prevailed for the most part of the season. The trees are clean and healthy generally, so that may lead to a good crop next season. Pears are poor generally, only a few with anything like a crop, and these are Beurré Superfin, Beurré Rance, Beurré Clairgeau, Williams' Bon Chrétien, and a few others. Plums, with the exception of Blue Gage, Belgian Purple, Jefferson's, and Pond's Seedling, are a failure. There are no Cherries, but in no season do they do well here, the soil and situation do not seem to suit them. All about this locality there is a great scarcity of these fruits, and the failure in most cases is put down to the severe frost in May, which varied from 6° to 8°, and took clean off all blossom that happened to be out at the time. Black and Red Currants have been abundant and fine in quality. Gooseberries are excellent all through. The trees have all been healthy and clean, having been gone over with the engine early in the season to keep insects in check, then well washed with clean water before the fruit began to colour, so that all dust might be removed from it before the nets were put on. Figs are excellent on the open wall, but slightly under-sized owing to the dry state of the ground. Mulberries plentiful and fairly large. Cob Nuts a good average crop. No Walnuts. Raspberries were small in berry and under an average in crop. To have these good they must have plenty of moisture at the roots and slight shade.

Vegetables have been variable owing to the drought. Peas were good up to the end of July,

by that time those that were coming on were attacked with mildew, which cut them down so that a break in the supply occurred. Later crops will now give a supply, as the rains lately and still falling have been beneficial to these. Cauliflowers have suffered equally as bad as they did in 1893. Now we look hopefully for the autumn and early winter supply being good from the present moisture giving them a new start. Cabbages were good in the early part of the season, now they are totally eaten up with fly. Early summer planted Coleworts are now in fine condition for use. Brussels Sprouts promise an excellent crop. Carrots and Onions are clean and healthy, being perfectly free from maggot. Potatoes are quite free of blight and a plentiful crop. Early Puritan, Snowball, Beauty of Hebron and Red skin Flourball have all been excellent in quality. All Potatoes here are grown on ground that has been well manured the previous year, only a dressing of burned ashes being given at planting time. Celery has made fine growth and promises well for a full crop. It has been occasionally watered at the roots and over the head with soap-suds, and immediately after being done the plants were all dusted overhead with lime and soot mixed which stuck on the wet leaves, and the result that no fly has attacked the plants in any way, which is a common occurrence in hot, dry season.—A. KEMP.

**Englefield, Reading.**—Gooseberries an excellent crop. Currants, red and white, good black, not so good. Strawberries good. Raspberries poor. Apricots good. Peaches and Nectarines good. Apples very poor. Pea fair. Plums half a crop. It has been a bad season again for the gardens in general about here. The earlier part of the year was most favourable, as we had some very nice rains at the end of April and the beginning of May, but since that time we have had a continued drought through which kitchen garden crops have had great difficulty to exist.

Asparagus was very good indeed, and Broccoli and Early Cauliflower remarkably good. Early Peas were very good, but ripened off early. Through drought, later crops poor. Early Cabbages good. Potatoes are looking well, but when rain comes I am afraid they will make a second growth. Celery and winter vegetables are bad in need of rain.—JAMES COOMBE.

## GARDEN FLORA.

### PLATE 1140.

#### HYBRID COCCINEA CLEMATISES.

(WITH A COLOURED PLATE.\*)

THE new hardy Clematises recently introduced by Messrs. George Jackman & Son, Woking, and figured in this number, are the most complete break-away from all existing garden varieties which has come before our notice in several years. They have been obtained by hybridising the old herbaceous variety *C. coccinea* with some of the leading hardy climbing varieties now seen in nearly every garden. The three varieties figured are Countess of Cornwall, Duchess of York and Duchess of Albany, all of which have been certificated by the Royal Horticultural Society, and were greatly admired at the Temple show last May. They are quite distinct one from the other and are of compact late form, with four to six petals to each flower; the blooms are particularly thick in substance and stand out well from the foliage, and have one distinct advantage over the other climbing varieties in being suitable for cutting, the blooms lasting for several days in water. They are strong growers and flower freely from the

\* Drawn for THE GARDEN by H. G. Moon, Messrs Jackman and Sons' nursery at Woking. Lithographed and printed by J. L. Goffart.

HYBRID CLEMATIS

CULTIVATED BY THE GARDENERS OF THE GARDENS OF THE UNIVERSITY OF CALIFORNIA

young wood. Countess of Onslow is a bright chery purple, with a broad band of scarlet down the centre of each petal. Duchess of York is a delicate flesh-pink, with a deeper tinge down the centre, and Duchess of Albany, a beautiful bright pink, deeper down the centre, the edge of the petals softening down to a lilac-pink. This new race is sure to be a great acquisition to the already long list of hardy fruiting varieties.

## THE WEEK'S WORK.

### HARDY FRUIT GARDEN.

**FRUIT TREES.**—With the exception of the very best kinds, such as Salway and Walburton Admirable, trees are now clear of fruit, and should be looked over, when every particle of food not required for another season should be cut out to give the remainder every facility to become thoroughly ripened. After this, root-lifting and such like matters should have attention, and the old summer muleh, if any still remains on the alleys, should be removed. With regard to the above-named Peaches, they will be valuable in districts where other hardy fruits are scarce, and to ensure their better ripening a few sashes placed against the wall in front of the trees will bring this about. A little protection in this way works wonders, and I have seen equally as good results obtained from the employment of the tops of handlights placed at intervals over the trees.

**FRUIT GATHERING.**—In districts where Apples and Pears are plentiful much time will now be occupied in the gathering and storing of the mid-season varieties. The latest keeping kinds will, of course, not be ready for some few weeks; in fact, they should be allowed to hang—weather permitting—until the second week in November. Great care should be exercised in the gathering, and none should be pulled unless they part readily at the stalk, particularly Pears. If this simple rule is ignored, the fruits will neither keep nor ripen properly, and with Pears premature gathering generally results in the shrivelling of the skins, which renders the fruits valueless. The fruits in all cases should be carefully gathered by hand, and not shaken down, and they should be placed in baskets padded with soft hay or moss to prevent the wicker-work from marking or bruising them, and conveyed at once to the fruit room. If possible, the Apples should be stored in a separate room from that in which the Pears are placed. Apples merely require the best kept from them, and, failing a fruit room proper, they will keep well enough in cellars, provided these are not too warm or too dry. Barrels and boxes may be used in this case, and if care be taken to see that none but sound fruits are stored and that this is done by hand, placing each fruit carefully one on the other, there need be no fear at that they will keep well. Avoid the use of raw hay, or such like material, as this imparts bad flavour to the fruit; and if the boxes and barrels are perfectly clean and dry, nothing whatever is required, and the fruits may be placed directly into them without further preparation. When storing Apples in a fruit room, they may be placed several layers thick if the room is not large, but Pears are best kept in single layers, as they can then be the more easily inspected. If Apples and Pears have to be stored both in the same room, keep the former at the coolest end, and place the Pears in the warmest portion. Even if there are two fruit rooms set apart, one for each kind of fruit, it is an advantage to place some kinds of Pears in the Apple room at a time, as their season of use is then lengthened considerably, and they can be removed to the warmer room for a few days to finish ripening. By placing part of the crop of Marie Louise in the cool atmosphere of the Apple room, this Pear may be had in good condition for a much longer period than if placed altogether in

the Pear room at the outset. There are several other kinds which can also be subjected to the same kind of treatment, such as Althorp Crassane, Knight's Monarch, Seckle, Dama's Hovey, &c. After the trees are cleared of fruit, get any root-lifting or lifting and transplanting done. Other work which comes under this heading will be the harvesting of Walnuts. These should be thrashed or beaten from the trees, as the husks are now bursting open. Gather them up, lay them out thinly in an open shed, and when the husks part readily from the shells, clean and dry them, and store away in a cool but not too dry a place. If wet weather should set in, late Plums may be gathered, and kept in good condition for some time if laid out thinly on a shelf near the window in the fruit room. This will enable the netting, muslin, or whatever kind of protection was used to secure the fruits from insects and birds, to be taken down, dried, and stored away for future use.

**MANURING.**—Once more attention must be turned to this important matter in connection with fruit culture, and those who are fortunate enough to have plentiful supplies of manure should take time by the forelock and get Gooseberry, Currant, and Raspberry plantations dressed forthwith, unless early pruning of the two former fruits is in contemplation, when it may then stand over for a week or so. But where birds are troublesome and the question of pruning cannot be entertained until the turn of the year, then the manuring should be done at once. The manuring of Morello and Kentish Cherry tree borders is best done now, and where there is no prospect of the pruning of Apples, Pears, and Plums being done until the close of the year, all that stand in need of food may have a surface dressing now, when the autumn rains will carry its fertilising properties down to the roots. In all cases clear the surface from weeds before applying the manure, and the latter should be spread evenly over the surface and left so, as it can be pointed in after the turn of the year, or when the trees have been pruned and winter dressed.

**PRUNING.**—Currants and Gooseberries are fast shedding their leaves, and as soon as all are down, the bushes may be pruned at once, provided they are considered safe from bird attacks. Where much fruit growing is carried on, an early commencement goes a long way towards securing an early finish in these matters, and the work can also be got through with much greater expedition now than when the weather becomes colder and daylight is shorter. After being pruned, measures should be taken for dealing with insect pests, particularly the chrysalides of the Gooseberry and Currant sawfly, where the caterpillars of the latter have been troublesome during the past season. The soil under the bushes should accordingly be removed to the depth of 3 inches or 4 inches, and should either be taken away to be burnt with other garden refuse, or be buried deeply in some other part of the garden away from the bushes. Then put a little fresh lime under the bushes and make good the deficiency with soil from between the rows, after which give the plot a good dressing of manure.

**STRAWBERRIES.**—These should be gone through once more both to relieve the plants of all late-formed runners and to get rid of weeds before winter sets in. Plants set out early in August have made splendid crowns and good foliage, and look like yielding excellent results next year. Forced plants of Royal Sovereign set out earlier in the season produced an abundance of flower-spikes during the latter part of August, which, had they been allowed to remain, would have produced a fine second crop of fruit, rivaling, if not surpassing, in this respect V. H. de Thury, which does so well in many places as an autumn fruiter. Two and three-year-old plants have made good growth during the past few weeks, and are now amply provided with leaves for the protection of the crowns during the winter months. If the manuring of old plants in the shape of a top-dressing either of manure, old hotbed materials, spent Mushroom manure, or soil from under the potting-shed bench has not been done, it should

be no longer deferred. This should be worked close up to and around the crowns, which in the case of old plants stand considerably above the level of the soil in which they are growing. This will give them a new lease of life, particularly if the soil has become impoverished through neglecting to top-dress in previous years. A. W.

### KITCHEN GARDEN.

**FORCING VEGETABLES.**—In most gardens choice vegetables have to be produced throughout the winter, and very often under great disadvantages as regards convenience. The modern forcing pit has been the means of reducing the labour required in forming fermenting beds made up with leaves and litter, but there is still much to recommend these when properly prepared, as the heat produced is of a mild character and in every way suited for bringing on such things as Asparagus and Seakale. Where unheated pits or frames have to be used, a good body of leaves should be got together as soon as possible, so as to allow time for them to become warm before they are placed into the frame. If sufficient leaves can be obtained, they will give a more lasting warmth than when manure is added, but they must be prepared by turning them over several times and watering, if necessary, to encourage them to heat. The greater the quantity of leaves, the longer they will give warmth; therefore in filling up the pits they should be trodden as firmly as possible, and by bringing them well up to the top, such things as Asparagus and Radishes will be close to the glass, which is very essential, especially during the short, sunless days.

**STORING ROOTS.**—The Potato crop is not a heavy one this year, and, what is worse, the disease appears to have shown itself more or less in most districts. It is therefore necessary that extreme care be taken in storing the tubers, as a few affected ones might lead to great loss when they are placed in clamps, which probably would not be opened for many weeks. The dry weather has assisted in detecting unsound tubers, as they have come out of the soil in a clean condition. Unless large quantities have to be stored it is more convenient to place them in a frost-proof shed and cover with a good thickness of straw. In this way they are easily examined, and afford useful work during inclement weather. In clamping Potatoes, it is a great mistake to select a site under large trees, as the drip from these keeps the covering in a wet condition. At the same time they should not be exposed to the north or east winds, as when frost accompanies these it soon penetrates to the tubers unless a large amount of covering is used. The soil should only be thrown out a few inches to form the base, and if sloping ground is selected, there is less danger of heavy rains reaching them. A careful selection of suitable tubers of the different kinds should be made for seed. It is better to do such work at once, and store them, if possible, in single layers so that they can be easily examined; they keep better, and there is less danger of them sprouting than is the case when placed in heaps. The tubers of the early varieties especially should have immediate attention in this way, or they soon commence to grow. A free amount of ventilation is necessary to keep the tubers in a good condition, but it must be so managed that frost does not reach them. Provision should be made for storing other roots, such as Carrots and Beet. The latter may be lifted at any time, it being, however, better to do so early than allow the roots to remain in the soil after the autumn rains have commenced, as it not only becomes more difficult to get them out of the ground in a clean, dry state, but many of them may split and become practically useless.

RICHARD PARKER.

**Wasps.**—I used to be greatly infested with wasps, especially in my vineries, until I purchased two or three sixpenny butterfly nets, in which about April and May I caught all the wasps I

could come across (females, I imagine), the result being that I had not a tithe of these Grape and Plum destroyers visit me. This spring I killed from thirty to forty taken in this way, and I have since scarcely seen a wasp in any of my houses. No doubt this has been a bad year generally for the wasp family; why, I know not, for the winter was mild and the summer fairly warm. At all events, I think this is about my eighth year of the butterfly net process.—GWENT.

## ORCHARD AND FRUIT GARDEN.

### NOTES ON STRAWBERRIES.

WE have to thank our readers all over the country for so kindly replying to the following questions, and we hope that the notes will prove valuable:—

*Will you kindly aid us in throwing some light on Strawberries of best quality for the use of private growers, as market growers have a different standard from that which applies to the private gardener, and favour those kinds that bear carriage, rather than those that are remarkable for flavour and quality? For those who use their own fruit we think that a different standard should be in use.*

1. *What kinds do you consider the best for flavour in your district, i.e., as grown in gardens, not taking into account those grown in the open field for market?*

2. *The best early and late kinds for the open air in your district?*

3. *Which of the newer sorts do you find most worthy of cultivation from a garden point of view?*

4. *The best time to plant so as to secure the best and most regular crops?*

— These were an exceptionally fine crop. Sir Joseph Paxton last year was very fine in point of finish, but this season it was much larger and the colour of berry finer, indeed more so than I had ever seen it in former years. Vicomtesse Héricart de Thury came next in point of quality and abundance of crop. President has borne out in a high degree all its former character as a first-class cropper with berries of excellent flavour, and, like Paxton and Vicomtesse, travels well. Royal Sovereign was grown in the same brake in parallel rows with the above, and its weight of crop in all respects was equal, if not a shade heavier, but in point of flavour it is behind, and the berries are softer and lighter in colour, and on that account it is not so acceptable as a first-class dessert fruit. There is always an uncertainty about British Queen; it seems fastidious as to soil, for, although grown along with the others here in well-cultivated land, the Queen is uneven in its growth, some of the plants doing well, while others in the same row never make free healthy growth. Still, it is one of the best flavoured, and can ill be dispensed with. Empress Eugénie—or, at any rate, one under that name—bears well, but the flavour is only second-rate; the berries are large and mostly wedge-shaped. It comes in later than the foregoing, and is useful in that respect to lengthen the supply. Many of the varieties recommended in these pages have been grown here with every care to prove their fruiting and flavour qualities along with the standard kinds, and yet they are wanting in some important points to be worth growing in a private place for high-class dessert fruit. It must be very conflicting to many to decide which are the best for general use, for there are too many kinds mentioned, and particularly these very large-berried ones are all more or less deficient of flavour, however well they may look as individual fruits. The three kinds named at the beginning of this article are unquestionably in the front rank of all grown

at the present day, either for the market or the private gardener, as good all-round kinds that can be thoroughly depended on in all soils and situations. I have grown them on stiff tenacious clay on the north side of the Pentland Hills in West Lothian, and in Forfarshire, where the soil was light and thin, resting on gravelly rock; in Sussex on deep loam, with a dash of clay in it; and the crops in all these cases never failed to be satisfactory. Keens' Seedling does not do well here, and is now discarded after repeated trials. There is no better plan to get at which is best than growing many kinds together of the newer sorts with every care; and the same plan should be followed in forcing, to get at which are best. These large-berried kinds are not suitable for preserving in private establishments. Royal Sovereign is not suitable for preserves, always being thin. The second and third gatherings of Vicomtesse make splendid preserve, the berries being small and firm, and parting freely from the husks, and not so sweet. It makes a preserve almost equal to what the old Grove End Scarlet makes, and no kind grown equals it in that respect.

To grow the Strawberry well, it wants deeply cultivated soil well enriched with manure. The cultivator at all times should aim at vigorous, strong, healthy plants that will bear freely fruit of fine quality; and to get that there is no better way than trenching and putting a good supply of vegetable refuse of every kind into the bottom of the trench. This is of great importance when a dry season occurs such as the past one has been here. The surface should be made level and firm, and then the plants put out in rows 2½ feet apart, and 2 feet from plant to plant in the rows, and that distance apart each way will give ample room for three years, which is long enough for the plants to stand under the best cultivation. On thin, light soils, resting on gravel, two years are long enough for the plants to stand. The selection of the runners is a very important part of the culture, for on this depends much of the future success of the crop. When the fruit is being gathered, I note all the plants of each kind that possess special properties as to vigour of constitution and fine, symmetrical, well-coloured fruit. Of these the runners are taken with the view to maintaining a similar constitution in the future plant, as heavy cropping and much propagation have a deteriorating influence. Layering into small pots is much the best plan for the private gardener, whether these may be for forcing or planting out in the open as soon as rooted; but in my case I only root enough for forcing, as these are planted out as soon after fruiting the following spring, as they are well hardened off in a little shade, and ground can be got ready. There is no better plan where it can be adopted than that of sowing the Spring Onions 2½ feet apart, and planting between the Strawberries does not in the least interfere with the maturing of the Onion crop. In this way they can be got out early in the season, so that they can be well established before the autumn sets in. No planting should be delayed longer than the latter end of July if a full crop is expected the following season. Small plants put out in August have not the same chance of getting established before the winter sets in, and may suffer if it happens to be severe. To keep the ground thoroughly clear of weeds at all times is one of the cardinal points of success. There should be no digging or deep hoeing of any kind among the plants in case of cutting the surface roots. Runners should never be allowed to gain a footing, as they only exhaust the plants at a time they should be forming matured crowns for the next year's crop, but to let these grow until they form a thicket between the rows, as is to be seen in some cases, means the crop will just be in proportion to the strength that is left in the fruiting plants. The earlier the plants are mulched after the crop is gathered the better, as they derive benefit from it, the rains washing the goodness of it into the soil to feed the surface roots. The material on the surface retains the moisture in the

spring. Free growth of the foliage is of great advantage if late frosts and cutting cold winds occur. This spring I had no loss of bloom from the full, healthy foliage that protected it. Year or two ago a similar late frost happened, when much loss was the result in the neighbourhood, and thin crops of fruit followed. The full, heavy foliage here saved the bloom, and I had an excellent crop of fine fruit. Watering becomes necessary if the weather should be dry after planting to prevent the plants getting dry, which would check the growth and possibly lead to an attack of red spider. The plants are very much benefited by a good soaking of manure water after they come into bloom.—A. KEM, *Coolhurst Park, Horsham.*

— I would say that Héricart de Thury, Keens' Seedling, President and Royal Sovereign are all good-flavoured kinds. I have a difficulty in getting any of the British Queen family to grow well on this soil, consequently they are not fruitful. Dr. Hogg does the best and is of a fine flavour. On a south border containing about ten kinds, Laxton's Noble and Royal Sovereign were the first to ripen, followed by Héricart de Thury and Keens' Seedling, which were only about ten days behind the first-named. Jubilee and Newton Seedling do well with me for late crops on north border. Frogmore Late Pine is the best late one, but, as with the Queen family, it grows badly under good ordinary culture, hence I have great difficulty in getting runners to keep up the stock. There are so many good kinds grown nowadays that it is best to find out what suits each soil and climate, and keep to them for the principal supply. Royal Sovereign is the best of the newer kinds. I had some splendid fruits of it this year from plants put out of small pots last August. I find it is somewhat more disposed to mildew and red spider than the thicker-leaved kinds. I am trying Monarch, Leader and one or two others, and hope to report on them another year. I generally plant at two different seasons. Those for the earliest fruiting are grown on south border in three ages thus—two years planted, one-year planted, and this autumn runners. The last-named always follow early Peas. I give the border a dressing of good rot horse manure as soon as the Peas are over and cleared away, dig a good spade depth, and break up the soil well. I plant from small pots in rows 2 feet 6 inches apart and 9 inches from plant to plant in the row. I firm the soil well round each plant, give a good watering, and if the weather is very dry, mulch the surface with some old Mushroom manure. I invariably get good crops of fruit the following season from plants thus treated. I cut up the oldest of the three lots each year. I have main crops of Strawberries for preserving, & are generally produced from old forced plants. These generally follow second early Potatoes any other crop which is cleared off by the end of July. In this case I arrange to have the ground double dug and well manured the previous winter. As soon as the Potatoes or other crop are removed, I give another slight manuring, and dig it in if it is all dry, tread the ground well over to firm it, and plant in rows 2 feet 6 inches apart and 15 inches from plant to plant in the row. It will be noticed that in planting the ones on south border 9 inches apart in the rows was the distance given. I ought to have added that after the first year's fruiting I generally cut out each alternate plant. The old forced plants invariably give good crops of fruit the year after planting and the two following years, when I cut them up. It will be seen that in both cases I clear a portion off each year, and make a new plantation, thus ensuring that plants are more than three years planted. After clearing away the old foliage and runners from between the rows of the older plantations, in August, I generally give a dressing of well rotted manure, with some wood ashes or charred refuse mixed therewith. The manurial portions of the dressing get washed into the soil during the early autumn months, which being taken up by the roots, go to the formation of stout embryo fruit-trusses for the following season's crop.

spring, before putting betwixt the rows of plants the necessary material for keeping the fruit dry, I generally give a good sprinkling of some manure rich in potash. Some of the fish manures advertised answer for this purpose well.—H. J. VYTHES, *Grimston Gardens, Tadcaster*.

—I think the Pine varieties the best flavoured, so far British Queen cannot be beaten. Of these we have had several good things in the way of seedlings from the Queen, and I may in time be able to give a longer note on the best flavoured varieties. Veitch's Perfection promises well, and Mr. Allan's Empress of India is a grand flavoured fruit of the Queen family. Latest of All another of its offspring, in my soil is superior to the Queen, more robust and equal in quality, and the most valuable late Strawberry flavoured. Royal Sovereign is the most reliable early fruit and this crops grandly. For years I grow the much abused Noble, and with fruits at the end of May one does not expect British Queen quality. Few will deny that Royal Sovereign will grow in is of good quality. I class it as the most useful early variety. Mid-season croppers are not named so far, few kinds in this soil are superior to the old President, and for preserving I rely upon Vicomtesse H. de Thury. To follow these we have British Queen, and I have stated these are none better, but it is not a heavy cropper and needs good cultivation. I grow Latest of All largely, this is excellent from a north border and young plants. I find Royal Sovereign, Lord Sulfield, Empress of India, Gunton Park, Linton's Leader, and Latest of All the best for garden culture. On the other hand my soil is light, and I give good culture, and with the most growers rely upon young plants, only taking one crop. The best time to plant is as soon as the runners can be obtained, that is usually from the middle of July to the middle of August. I grow special plants for runner production, not allowing these to bear fruit, as it is impossible to get early runners from plants in full bearing. I rely upon young plants, and by so doing get fruit earlier and plenty of it. I layer all the plants into pots and give deep culture, plenty of manure and firm soil. After the Strawberries are cropped I use the land for a winter green crop, and digging, only cleaning the surface. By growing in young plants I find I get the best and most regular crops.—G. WYTHES, *Syon Gardens, Brentford*.

—Of this important fruit we have had an excellent crop, but its duration has not extended so long a time as usual in consequence of the intense and long-continued heat of July. For the fruit supply out of doors I depend on Noble, La Grosse Suerée, and Royal Sovereign. I have grown all other known early sorts, such as Laxton's No. 1, Black Prince, J. Ruskin, and a few others. These may turn in in a few days before the mentioned above, but they are so small, ofapid flavour, and poor in crop, that it is a waste of time and space to have anything to do with them. Lack of flavour I know may justly be imputed to Noble, but its earliness, fine size, good cropping qualities, and handsome appearance entitle it, in my opinion, to be grown to a limited extent in every garden. La Grosse Suerée with us is nearly as early as Noble, and for all purposes is one of the most satisfactory Strawberries. I agree with most of the good things said of Royal Sovereign, but for forcing its growth of foliage is too ample, causing it to take up nearly twice as much valuable space on the forcing shelves as La Grosse Suerée or the other dwarfed growth kinds. Out of doors Royal Sovereign is a few days later than La Grosse Suerée. Without doubt Countess is the best flavoured as well as one of the handsomest Strawberries known at the present time. British Queen does not succeed with me; therefore I do not include it in my list, but Dr. Hogg, one of the same breed, does. The colour of this variety is very pleasant, and although the colour may be against it, still it is one of those that should be grown for its good flavour by everyone. Vicomtesse H. de Thury is one of the best flavoured, best coloured, and best croppers

we have, fine for preserving. La Grosse Suerée is, as mentioned before, indispensable, combining good flavour with all the characteristics of a good Strawberry. Sir Joseph Paxton should not be omitted. Aromatic is another variety which succeeds well here, and is of excellent flavour, but as it is rather a soft fruit, it will not do to send long distances by rail or post. There is no question as to the new variety certificated by the Royal Horticultural Society last year, Veitch's Perfection, being of exquisite and sweet flavour, and if it proves to be a good grower and bearer it is sure to find its way into every garden in the United Kingdom. The earliest of all here is Sir Trevor, a new seedling, raised in the Royal Gardens three years ago, Noble comes next, then La Grosse Suerée and Royal Sovereign. The best late varieties are Frogmore Late Pine, A. F. Barron, Waterloo, and Latest of All. For its cropping qualities Laxton's Leader should prove a splendid variety for cottagers, as it is the surest and heaviest cropping sort I know. The best time to plant is as early in August as possible to have strong-rooted runners previously layered into small pots. If these are planted on a well-prepared and manured border at this time a splendid crop of fruit will result the following season.—O. THOMAS, *Royal Gardens, Frogmore*.

—The system pursued here in the cultivation of the Strawberry is to have the beds in three divisions; one is destroyed and a new one made each year, so that I never have a bed in bearing more than three seasons. A piece of ground that has been cropped with early Peas or Potatoes is selected, heavily manured and trenched. About the last week in July, strong runners of the different varieties are got and planted 2 feet apart from row to row, and 1 foot in the row, and from these in the following season I always succeed in getting my finest fruit. I have not the labour to enable me to follow out my inclination, otherwise I would treat them as annuals. The varieties grown here are British Queen, Dr. Hogg, James Veitch, La Grosse Suerée, Lord Napier, John Ruskin, Noble, Royal Sovereign, Sir Charles Napier, and Vicomtesse Hericart de Thury. British Queen does well here; the fruit is of large size. It is in my opinion still one of our very best flavoured Strawberries, but it is not a heavy cropper. Dr. Hogg is a first-class sort, combining size and flavour, and is fairly prolific—one of the sorts a private grower should not be without. I must also include La Grosse Suerée, Lord Napier, and Royal Sovereign. My best early kinds are Noble, Royal Sovereign, and La Grosse Suerée. For late use I like Lord Napier.—G. TAYLOR, *Shrubland Gardens, Ipswich*.

—Dr. Hogg and President are the two best flavoured Strawberries I have. British Queen is not satisfactory, and I do not grow it, although it is undoubtedly the finest flavoured variety grown. Vicomtesse Hericart de Thury is much liked here, also Keens' Seedling; both are old varieties, but still very good. La Grosse Suerée is both early and good. John Ruskin is early and the fruit good in colour and size. Sir Joseph Paxton is useful where quantity is wanted, and Noble makes a fine dish, and on our gravelly soil, in a hot and dry season like this last, the flavour is fairly good. Waterloo gave some extra fine fruits and was much appreciated, as it came in when all the other Strawberries were over. John Ruskin, Noble, Vicomtesse H. de Thury, and La Grosse Suerée all do well as early varieties here, Waterloo being the best late one. As regards the newer varieties I cannot speak from experience, as I have none of them at present. Planting is best done as early as the runners can be got and the ground prepared, the runners to be layered in small pots as if for forcing. Plants that have been forced and taken care of may be used, if they have not been allowed to suffer from drought. These will give good results the following season. Where a particular or new variety has been forced and a bed of it is wanted, planting out the forced plants answers well.—Geo. RINGHAM, *Wrotham Park Gardens, Barnet*.

#### NOVEL METHOD OF FORCING STRAWBERRIES.

PRIVATE gardeners are often surprised when visiting market-growing establishments to see certain plants or fruits, which in ordinary gardens require considerable time and labour to bring them to perfection, grown well in a very simple way, and ripened or bloomed in a minimum of time. A somewhat novel yet very effective way of producing good early Strawberries for sale was recently brought under my notice. An East Anglian grower owned several long, low, lean-to houses, which in summer were occupied with Tomatoes and Cucumbers, these being planted in shallow beds of soil, the pathway being along the front of the house. In June, runners from yearling plants of free-cropping, good-travelling varieties of Strawberries were pegged down into the soil of the bed, five or six of the stoutest runners being selected and the rest removed. I should mention that the parent plants were planted some 3 feet apart all ways, so as to give the pegged down runners in question the benefit of a good amount of light and air. After pegging, or rather laying a heavy stone on each, no more trouble was taken with them with the exception of keeping down weeds. At the end of September these young plants were carefully lifted with a trowel, just after rain if possible, and taken into the lean-to house for forcing. The shallow bed of soil named was forked over, a little artificial manure worked in, and after being made firm, the young Strawberries planted fairly closely together, the most being made of the space at command. A good soaking of water was then given, and the lights, which were portable, as all fruit house lights should be, removed till the second week in November, the plants getting a few frosts on them to perfect maturity of foliage and crowns. With very little assistance from fire-heat, the bloom trusses of such sorts as Vicomtesse, La Grosse, and Keens' Seedling soon made their appearance, a dry atmosphere being maintained when in bloom, and the syringe used but sparingly, and that on fine days only after the fruit was set. The heat being raised as the various stages of growth were reached, ripe fruit was secured by the end of February and first week in March, Tomatoes or Cucumbers being then again planted. GROWER.

**Pear Emile d'Heyst.**—This is one of the most regular croppers we have, as in any form it bears freely. The fruits on the Quince stock are earlier and of a brighter colour. The season is given as November, but in my light soil the fruits do not keep till that date, and on a warm wall are ripe early in October. They are of a greenish yellow, flushed with crimson on the sunny side, flesh tender and very juicy. I am aware Pear lovers would not class this as a first quality fruit, but it is not bad by any means. For early autumn supplies it is an excellent Pear and well worth space in any collection. For regular crop I would advise the Quince stock. Fruit from trees on this stock colours grandly. The tree will succeed in any form. As a cordon it is very fine and the fruits are earlier. It is not a gross grower in bush form, and is a good Pear for light soils.—G. WYTHES.

**Peach Marquis of Downshire.**—I was not aware until lately that this Peach was one and the same as Royal Ascot. On a back wall in one of the Peach houses at Kelham Hall, Newark, a tree of Royal Ascot has for many years produced fine crops of large, richly-flavoured fruit, Mr. Webb (the gardener) thinking very highly of it. It shows much more red at the stone than most Peaches. It used to be much grown in gardens in Oxfordshire, Berkshire and Buckingham, and it was from seeing it do so well in the first-named county that Mr. Webb was induced to plant it at Kelham. I believe this Peach was raised at East Hempsted Park, the seat of the Marquis of Downshire, in Berkshire, and was sent out by the late Mr. Standish, of the Royal Ascot Nurseries, which would account for its being called by both names. However, it is a very profitable variety

and has a good constitution. The house at Kelham is unheated and in a somewhat damp situation, Royal George planted by the side of Royal Ascot often becoming mildewed, while its companion escapes.—J. C.

**Gross Plum trees.**—I was not fortunate enough to hear Mr. A. H. Pearson's lecture on Plums a few weeks ago at the Royal Horticultural Society's meeting, but look forward to seeing the same in the society's journal. My difficulty here in a poor, light soil is that young trees are unfruitful, and the difficulty is how to make them bear. With young trees more growth must be allowed to form the leaders, and I find these, again, in their turn produce gross shoots and little fruit. This note refers to wall trees, those grown as standards being more prolific after a certain age. The note by "A. W." (p. 193) is opportune, as it shows what may be done to make wall Plums more prolific in their earlier stages. I may be told root-pruning or lifting is needed; I agree with the latter done carefully before the leaves fall, but root-pruning in my case means gumming later on, with canker, and finally death. I have tried training these gross growers so that more vigour or sap is sent to the lower branches by growing the leaders more horizontally. This I find advantageous with young trees inclined to make much wood.—G. W. S.

#### AN AMATEUR'S VINERY.

The illustration is that of an amateur's greenhouse rather than a vinery, which it appears to be. The measurement is 10 feet by 4 feet 6 inches, and 7 feet high at the centre. In winter, as Chrysanthemums and other plants are housed in it, an oil lamp is used, but there is no artificial heat all through the late spring, summer, and autumn. The Vine was planted six years ago, and has borne fruit these last two years. This season there are fifty-nine bunches on the Vine, all being of fair size, excellent colour, and good quality. The situation of the house is not a happy one, for it is almost north-west. All goes to show, however, that, given a suitable variety (and that Black Hamburgh certainly is) and a little care and judgment, a fair crop of Grapes can be had with but little expense and meagre accommodation. Mr. Sargent, whose house it is, resides in Prospect Park, the higher suburb of the city of Exeter.

A. H.

**Apple Eve.**—A small flattish red Apple, known as Eve, ripening in October and remaining in an eatable condition several weeks, is frequently met with in the midland counties, especially in Nottinghamshire. I do not think it is much known in the south, as I have looked in trade lists, but could find no mention of it. The Apple is not sent out under any other name so far as I am aware. Though small, it is a very great favourite amongst lovers of sweet dessert Apples; moreover, the tree is a constant and prodigious bearer, and would pay as a market Apple. In many private gardens in this neighbourhood fine old trees of it may be found. I should be glad to learn if this Apple is really known in the south or west of England, as I think it is a pity such a good flavoured, fairly long-keeping October Apple should not be generally grown.—J. C.

\*\* An Apple under this name was shown at the Apple Conference in 1883 by Messrs. Pearson and Sons, of Chilwell. This, no doubt, is the variety referred to by "J. C." The committee considered it synonymous with Trumpington.—E. v.

**Mulching late Vine borders.**—Mulching the surface of late inside Vine borders is often neglected in autumn. If applied in September, or even earlier, it preserves the surface roots, which are of great importance, in a moist, cool condition, and later on—say in November and December, when the days grow shorter and darker, and border waterings have to be done cautiously

—the mulching reduces the need for these, as what moisture there is in the border is prevented from evaporating. Various materials are used for the purpose, some using very short litter or old Mushroom manure, and others straw. The two former are apt to cause mischief by the dust rising from them when in a dry condition and settling on the Grapes. Straw or dry Braeken is as good as anything, and no dust can then reach the Grapes. I think it is a good plan, when inside late vinery borders are found to be at all dry, to give them a good moistening in October, while as yet the days are fairly long and the sun strong enough to warrant the admission of abundance of air to dry the atmosphere again. This watering, except in cases of very shallow borders, will carry the Vines on till January.—GROWER.

**Strawberries for market.**—Many writers seem to think that market growers are very slow in taking up new varieties and adopting new and improved methods of culture. Everyone knows Royal Sovereign to be a splendid Strawberry for

that they have something superior in every way.—JAMES GROOM, *Gosport.*

**Pear Marie Louise d'Uccle.**—As an attention to the notes that have recently appeared in THE GARDEN on the above-named Pear, I should like to record a curious experience and invite attention of fruit growers to what is to me an explicable part of Pear culture. When plantations seven years ago I was strongly advised to give this Pear a trial as being of fair quality and a tremendous and consistent cropper. The tree gave a few fruits the first year and from that capital crops have been taken from them, until the present season the fruit from a quarter standpoint was absolutely worthless, there an immediate transition from the green to a mealy stage, and it was only useful for stewing. This year there is a remarkable change the fruit ripens gradually, keeps well, and of very fair quality—not, of course, first class, but close up to Louise Bonne form, quite equal to such Pears as Passe Colmar or Napoleon, and

Grape Black Hamburgh in a greenhouse. From a photograph sent by Mr. A. Hope.

private gardens. As a pot plant I do not know any variety to equal it, and for the earliest outdoor crops it is splendid, for it has a robust constitution, makes fine plants that carry a good crop the first year, and as to flavour I have always found it first-rate. I feel sure, however, that as a Strawberry for market it will never supplant Sir Joseph Paxton, for the simple reason that it is too good to stand the rough-and-ready handling that market Strawberries get. During the Jubilee season Royal Sovereign realised a good price up to the time when Sir Joseph Paxton came in, but as soon as it did, the superior travelling qualities of Sir Joseph Paxton made it the only sort asked for, and my impression is that the variety is not yet in commerce that is to supplant Sir J. Paxton. At the same time there is plenty of room for both, and my only object in writing is to warn those who have good bearing beds of Sir Joseph not to root them up until they are fully convinced

fairly be described as very juicy, melting, and of fair flavour. Now I can understand one combined conditions of improved cultivation, youth, vigour or situation being answerable for better quality in Pears, having noted the same connection with Beurré Diel, B. Bach, Triomphe de Jodoigne and Alexandre La but how the difference comes about with no apparent cause is, as I have said, to me one of the mysteries of fruit culture. If any reader has a similar experience, perhaps he will kindly give me an opinion on the matter.—E. BURRELL.

**Keeping Grapes (Geo. Kent).**—Chloric calcium, as you were informed, is the same as chloride of lime. It is said to be extremely useful in attracting moisture from the atmosphere also are lumps of quicklime, though in a degree. Grapes will be found to keep best in a darkened room where an equable temperature of 40° to 45° can be maintained with the expenditure

a minimum amount of fire-heat. A very dry atmosphere is undesirable, this causing the berries to shrivel, and damp is even more to be feared. The room ought to be kept rigorously closed during very cold and also foggy weather, and ventilated freely whenever the weather is mild and fine. The most critical periods are the changes from very cold to mild weather. If the ventilators are suddenly opened while yet the berries are very cold, the warm, moist air admitted will collect on them in much the same way as it does on the cold walls of churches and schools that have had no fires in them for several days past. Immediately after frosty weather is over the want of a little fire-heat is most felt in makeshift Grape rooms. If the pipes could be gently heated and a top ventilator or outlet for damp, one of which ought to be found in every Grape room, set open, a good circulation of warm, dry air would be promoted, this effectually dispelling damp. Grapes keep best in rooms with blow walls and thatched roofs. The most freely thinned bunches ought to be reserved for spring, and all gone over two or three times a week in search of any odd berries commencing to decay. The fungoid growth complained of is the result of and not the cause of decay.—I.

### PRUNING FRUIT TREES.

The pruning of fruit trees in its manifold forms is not even in this fruit-growing age so well understood as it should be, nor are those who practise the pruning knife confined to amateurs, professional gardeners often erring in that direction, and nurserymen who prepare the trees can lay the foundation of future evils by an injudicious use of the pruning knife. How many Peach, Plum, and Apricot trees do we still see planted in private gardens which while in the nursery plantations had been subjected again and again to hard cutting back, the result being that with more than half of them gumming and canker set in in a year or two, and if they live they are never what they should be. It was this difficulty which made many even of the old school bud their own Peaches and Apricots on only maiden trees, being then able to prune as they liked in laying the foundation for the future tree. No doubt a desire to economise space is the main reason why trade growers cut back their unsold trees so hard, but in reality there is no gain, but rather the reverse, in shortening young fruit trees beyond the point where the wood is well ripened. Peach, Plum, and Apricot trees generally break well back on when long growths are left, but should there be any fear on that point in the case of very vigorous young trees, these can be gently cut in a downward direction when the trees are tied or nailed, raising them to their proper position when the shoots have grown an inch or two. This course would only be necessary for the first and perhaps second season, and if it pays to do this with young Vines, why not also with Peaches? Then, besides warding off canker by this longer pruning system, the wall or trellis space is secured in much less time—in fact, about one third. Summer pruning is also often badly performed. In the case of weakly trees, the best way often is to let them alone the first summer, withholding the knife and allowing all the upright growths to advance to their full length. This gives the tree a chance of making headway; whereas when pruned rigidly back in summer the trees often receive a check from which they do not soon, if ever, recover. With robust trees the case is very different. But some may say, what is the use of allowing even a weakly tree to make in summer wood that is to be cut away in winter? Roots are formed in strict proportion to top growth, and when the growths of the weakly tree, which have been the means

of its establishing itself the first summer, are removed after the leaves fall, the roots will be there to induce a good and perhaps fruitful growth the second year. Summer pruning or shortening back is often done too soon. With some, neither locality, weather, nor soil is considered, a certain day in a certain month, often in June, being the one on which they commence summer shortening their fruit trees. Even in the south of England it is not wise, as a rule, to proceed with summer pruning until July even in hot summers, from the middle to the end of it being quite soon enough in wet, sunless ones. I saw only this season a lot of wall and espalier Apples and Pears growing in a midland garden in a strong, clayey loam that received their first summer pruning in June, rapid growth necessitating a second one in July and a third in August. Thus the trees were induced to grow on too late in the season, many of the lower eyes starting, which, had the trees been let alone till the beginning of August the first time, would never have moved at all. This treatment is all against the formation of bloom-spurs and tends to grossness generally. The barrenness of espalier and wall trees is frequently attributed to the soil or season, when a crowded state of wood and foliage is the real cause. Many who are careful to prune in the orthodox fashion seldom think of limiting the number of spurs so as to permit of the ingress of a minimum amount of sunshine and light. In removing these, however, it should be done piecemeal, say half one year and the rest the next. The best plan is never to allow too many spurs to form from the outset. Root-pruning likewise is often done in a haphazard manner, young trees being allowed to form strong tap roots several years in succession, the whole of these being then severed at one time, to the detriment of the tree. Strong young trees should be lifted and root-pruned the first autumn or winter after being planted if growth is gross, the remaining roots being laid in very near the surface. It is not safe to rigidly root-prune all round in one year old Pear or Apple trees which have gone down into the subsoil, the safest way being to do half the roots one year and the remaining half the following. If, however, stations consisting of slates or tiles were placed beneath trees at planting time, especially in strong, cold soils, the necessity for root-pruning would be reduced to a minimum, and would be more easily accomplished if necessary.

JOHN CRAWFORD.

**Pear Magname.**—If this Pear proves to be as good in flavour as it is handsome, it will indeed be a grand addition to the list of October ripening varieties. Were it not known that it is a seedling from Louise Bonne, its parentage would at once be stated to be so, as the fruits carry the markings peculiar to that variety, although in not quite such a pronounced form, also in the crimson flush on the exposed side of the fruits. I planted several trees two years ago which are carrying a few fine fruits this season. As a cordon on the Quince stock it is a healthy, vigorous grower, and if the flavour should prove to be good I shall certainly give it a trial as a bush tree in the open garden.—A. W.

**Pear Backhouse's Beurre.**—A further acquaintance with this variety has led to its being placed in the front rank of September Pears, so exceptionally good has it proved this season. The fruits have been extra large and of first-rate quality, the flesh being melting, juicy, and richly flavoured. In appearance the fruit resembles that grand Pear B. d'Amanlis, but it grows to a larger size, and of the two I prefer the flavour of Backhouse's Beurre. The tree has very distinct foliage, and when comparing the leaves with those of other varieties

recently I found them to more closely resemble those of the old stewing Pear Vicar of Winkfield than any other. The wood is also very bright and clean looking, and growth is sufficiently robust without being gross. As a cordon on the Quince it is first-rate, and crops heavily. Altogether, I look upon Backhouse's Beurre as being a fine addition to the list of September Pears, and of those which have been added to the collection in recent years none has given me greater satisfaction.—A. W.

**Thinning late Grapes.**—While summer Grapes are often thinned to such an extent that the bunches sprawl about when laid on the table, late winter varieties are often under-thinned, with the result that many of the largest and best bunches are spoiled by the berries decaying. In modern-built, tightly-glazed vineries very liberal thinning is not so imperative, but where there is the least liability to drip, leaving the bunches the least too thick is very risky, to say the least. Many gardeners—and I think rightly, too—like to thin each bunch so that each berry stands clear of the other, such being easily examined in bad winter weather, any mouldy berry being then detached. It is astonishing how quickly a bunch becomes a mass of mould, the worst cases being when an inside berry decays first, gradually working outward through the rest. The mischief is not then discovered till too late. In thinning late Grapes, all inside berries should be removed if possible. Of course much depends on inside management during the winter months, as where careless treatment is given, loss through damp is sure to occur even in the best constructed house.—GROWER.

### SHORT NOTES.—FRUIT.

**Scarcity of Doyenne du Commerce Pear.**—My sympathy is with Mr. Wythes in the loss of his crop of this most excellent Pear. I have a good crop on trees on south and west aspects. I do not expect Pears to bear every year, and this variety is no exception. The tree on the west aspect, however, bore a good crop last year. I can do little with it in the open.—J. TAYLOR, *Hardwicke Grange.*

**Pear Triomphe de Vienne.**—I am much surprised by "C. C. H.'s" encomiums on this variety (p. 361), for with me it is not merely flavourless, but downright nasty. The tree is pretty healthy, growing and bearing well. This year, however, it has failed to crop, which is rather a relief, as I do not know what use to make of such detestable fruit. Perhaps if Triomphe de Vienne does so well in the midlands, it may require a cool climate to develop its good qualities (?). I have it planted in a very warm and sunny corner.—SOUTH OXON.

**Boiling water for yellows in Peaches.**—An Early Crawford Peach tree in the western part of Rochester, N.Y., says the *Democrat and Chronicle*, has borne three bushels of fine fruit. Two years ago the tree was smitten with the yellows, and the owner thought it was doomed, but, following the advice of a friend who had tried the remedy, he poured boiling water on the trunk and branches and threw it on the upper limbs, repeating the operation four or five times at intervals of five or six days. New growth soon started, and the tree was shortly covered with green and healthy foliage.

**Solanum jasminoides.**—I saw when recently at Bieton, Devonshire, this beautiful climber doing well outdoors. On a south aspect it is quite hardy. That is too much to expect of it in Surrey, but were plants grown on in pots and then planted out against warm positions in June, it is possible that success might attend upon that effort. It is a most graceful and beautiful plant. The finest one I have seen anywhere was at Cricket St. Thomas. Lord Bridport's place at Chard, where it grows with wonderful luxuriance on the back wall and roof of a glass corridor. This plant was put there six years ago, and now it covers an area of 40 feet long by several wide. It was indeed a beautiful specimen and showed how finely it does in a cool house.—A. D.

## TREES AND SHRUBS.

## THE WISTARIAS.

No Wistaria is more beautiful than the familiar *W. sinensis*, which flowered so splendidly last spring. There are others, as *W. multijuga* and the white *W. sinensis alba*, but the former, whilst having longer racemes of the same pleasing colour as *W. sinensis*, is not very free blooming. The white variety of *W. sinensis* is very pleasing, the flowers being pure white, but it is unfortunately too tender for general planting. We have received the accompanying note about the Wistaria shown in the illustration:—

I send you a photograph (taken on the 18th of May) of a very fine Wistaria in full bloom, growing on the house of a market gardener in this village. The tree covers a space of wall 63 feet by 14 feet, and being on the side of a high road, has attracted much attention and admiration this year.—R. C. LYNCH BLOSSE, *Stinchcombe Vicarage, Dursley.*

**Cratægus Crus-galli.**—A fine tree of the oval-leaved form of this covered with clusters of bright scarlet fruits and with leaves that were changing to all kinds of autumn tints, from yellow to scarlet and bronze, is very effective at Kew just now, and, taken from all points of view, it appears to be one of the best of trees for effective planting. Another very effective tree is *Pyrus baccata*, of which there is a large healthy specimen not far from the Palm house. This has a full crop of brilliant red crabs, each about the size of an ordinary Cherry.—J. C. T.

**Hydrangea paniculata.**—Reference was recently made in THE GARDEN to the fine display this plant was making at Kew. This reminded me of another brave show I saw in the pleasure grounds at Gunton. Some of the trusses would compare for dimensions with those mentioned by the writer in question. Had the flower-stems been supported by sticks, the effect would to a great extent have been spoiled, a too stiff and formal appearance being the result, but as seen at Gunton the trusses were allowed to fall about naturally, yet the stems supporting them were sufficiently stout to keep them from bending near enough to the ground to get splashed in wet weather. On a well-kept lawn the group had a very fine effect.—C. C. H.

**Hamamelis virginica.**—The bright weather we have experienced of late seems to have been particularly favourable to the flowering of this North American Witch Hazel, as in some places it has been almost as showy as its Japanese relatives, *H. arborea* and *H. japonica*, are early in the year. The species under notice, *H. virginica*, forms an irregularly-shaped bush, clothed rather densely with deep green leaves, which hide many of the curious, yet pretty blossoms. They are of a singular starry shape, with narrow twisted petals of a bright yellow colour. Generally the flowers open in an irregular manner, but such is not the case this year, and the plant is certainly far more conspicuous in this way than when a succession is kept up, as the blossoms are not sufficiently showy to give much of a display unless they are freely produced.—T.

**Rhus cotinoides.**—During a recent visit to Kew the brightest bit of autumn leafage that was observed among the hardy trees and shrubs was furnished by a few plants of this *Rhus*, which were conspicuous for a very long distance owing to the decaying leaves being of a vivid yellowish scarlet tint. The foliage was not of one uniform colour, as in some leaves the yellow predominated and others were quite scarlet. From its great beauty at this time of the year one might reasonably have expected this *Rhus* to be pretty generally met with, instead of which it is very rarely seen, and good plants of it are difficult to obtain. It is a native of North America, having been first

discovered by Nuttall as a large shrub on the banks of the Grand River, a branch of the Arkansas, in the Indian Territory, in 1819. It is said in America to attain to the dimensions of a tree, with a trunk 8 inches to a foot in diameter and a height of 30 feet. The leaves are in shape a good deal like those of the Venetian Sumach (*Rhus Cotinus*), but larger, while the plant is less spreading than in the better-known kind. Beside the above two many other species of *Rhus* are remarkable for the bright tints of their decaying foliage, notably *Rhus glabra*, whose pinnate

rich blue colour in dark, peaty soil, but only some 30 yards distant, where the soil is stiff and has in it strong loam, the flowers keep of the typical pink colour. All the plants are in the sun. Mr Miller mentioned that the longer the plants remained untouched the more the blue developed. Some planted twelve years were but just becoming blue in colour. There is no attempt to introduce artificial aid. At Basing Park I saw last year numerous small plants in pots from spruce cuttings carrying fine heads of blue flowers that the gardener informed me were produced by using

*Wistaria sinensis* in a Gloucestershire village.

leaves are at times much flushed with scarlet and yellow, and *R. Toxicodendron* (the Poison Ivy of the United States), which is of a vigorous climbing habit of growth. This species also occurs in Japan, and is often met with under the name of *Ampelopsis japonica*. The sturdy-growing *R. Osbecki* is another bright-tinted kind, and so are *Rhus venenata*, from the United States, and *R. succedanea*, a native of China and Japan.—H. P.

**Blue Hydrangeas.**—At Ruxley Lodge, Esher, *Hydrangea Hortensia* produces blooms of a

dissolved alum in watering: that may have been the case or not. Evidently, whether the blue colour is due to iron or other constituents in the soil, it seems to be furnished naturally in many places, and is usually found in boggy or black soils.—A. D.

**The Scarlet Oak (*Quercus coccinea*).**—The autumn tint of the foliage of this tree is very rich. The leaves are more deeply cut than those of the common Oak, and they take on this rich colour early in autumn some weeks before the

all. They are each from 6 inches to 8 inches long, and easily distinguished from those of most other species by their deep shining green in summer. Many beautiful arrangements of foliage of this class may now be made in the house, that of the amachis in variety, Ampelopsis and Berberis being especially beautiful in the combinations of rich brown, green and scarlet.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

OCTOBER 12.

THERE was a full display again on the above date, better even than one could have expected when it is taken into consideration that another traction was afforded at the National Chrysanthemum Society's October show. The Drill Hall could possibly have contained more Chrysanthemums had there not been any counter-traction, but, as it was, there was a highly edible exhibit of first-class blooms from Syon, which were set up in a very tasteful manner by Mr. Wythes, who does not evidently believe in the orthodox methods of staging. Michaelmas daisies made a brave show from Chelsea and from denham, the former being staged in pots and cupped as growing plants, by which means the effect was greatly enhanced. The latter consisted of the finest kinds in the best possible condition, the arrangement being likewise good. Late roses, still fresh and bright, were to be seen, but Dahlias were absent, as we might expect after the rather severe frosts. Of other plants, the most noteworthy exhibits were a finely-grown collection of Begonia Gloire de Lorraine, models of good culture and free-flowering, and a choice collection of small, well-coloured Crotons. Orchids were not numerous, but fruit was fully represented by Pears and Apples from Barham Court and elsewhere. There was also very good competition for the flavour prizes for Apples and Pears, but no new kind was able to beat the choicest of the best older varieties.

#### Orchid Committee.

Awards of merit were given to—

**VANDA CERULEA ROCHFORDIANA.**—A distinct and lovely variety with nearly white sepals and petals, the lip rosy purple, the upper portion of the raised ridges of the lip pure white. The plant cried a raceme of four flowers. From Mr. T. Lefford, Turnford Hall Nurseries, Herts.

**VANDA MOOREI.**—A supposed natural hybrid between *V. cerulea* and *V. Kimballiana*. The sepals and petals are nearly white, the lip a deep violet-blue, with a white line running through the centre towards the base. The habit of growth is intermediate characters, and there can be little doubt of its origin. From Mr. J. W. Moore, Lion Place, Bradford.

**ODONTOGLOSSUM GRANDE** (Pitt's variety).—Sepals and petals bright yellow, the usual brown bars being entirely suppressed by deep orange-yellow. The lip is nearly white, with yellow spots and bars in the centre. The plant carried five spikes of four flowers each. From Mr. T. P. Stamford Hill.

**ODONTOPETALUM JORISIANUM.**—A pretty form with pale green sepals and petals, barred with deep brown, the lip white, heavily fringed at the margin, the upper lobes canary-yellow. It has several large reddish-brown lines at the base. From Mr. W. Cobb, Tunbridge Wells.

**LILIA PRESTANS** (Low's variety).—This form is superior to the variety certificated as *L. prestans* (Gatton Park variety). The sepals and petals are larger, but similar in colour; the lip much larger and with a broader band of blue on the front lobe, which is also much deeper in colour. From Messrs. Hugh Low and Co.

Statistical certificates were awarded to *Dendrobium taurinum* var. *ambinense*, a distinct form, with yellowish brown sepals and petals, the lip

brown, with yellow lines at the base (from Messrs. J. Veitch and Sons, King's Road, Chelsea); and *Cryptophoranthus Dayanus*, represented by a large finely-flowered plant of this well-known Orchid. From Sir T. Lawrence, Burford Lodge, Dorking.

Messrs. J. Veitch and Sons sent a large and interesting group, prominent in which were some remarkable forms, finely flowered, of *Cattleya labiata autumnalis*, good forms of *C. Bowringiana* and a fine form of *C. bicolor* with five spikes of flowers. Among the hybrid *Cattleyas*, *C. Chloris*, *C. Eros* and *C. Minucia* (*C. Loddigesi* × *C. Warszewiczii*), intermediate in character between the two species, were noteworthy. Amongst the *Laelio-Cattleyas* were a fine *L.-C. Pallas*, good forms of *L.-C. Nysi* and *L.-C. Endora superba*, a dark form, with larger flowers than the type. Among the numerous forms of *Cypripediums* was a good form of *C. insigne Sanderæ*. In *C. Arete* (*C. Spicerianum* × *C. concolor*) the dorsal sepal is white, shading to greenish yellow at the base, spotted with purple, and having the characteristic purple band down the centre, the lip and petals yellow, spotted and suffused with purple. *Oncidium tigrinum* and *O. phymatochilum* were represented by large, well-flowered specimens. A silver-gilt Flora medal was awarded. Messrs. H. Low and Co. sent a neat and interesting group. Prominent among these were fine forms of *Vanda cerulea*, *Cattleya labiata*, finely-flowered plants of *C. Loddigesi* and *C. Harrisonæ violacea*, a good form of *C. Dewiana aurea*, and a grand plant of *Oncidium ornithorrhynchum album* with 9 spikes of flower. Amongst the numerous *Cypripediums* were a very dark form of *C. William Lloyd* (*C. bellatulum* × *C. Swianum*), *C. insigne Laura Kimball*, a yellow form with a bronze tint over the petals and lip, and *C. i. Millie Dow*, another yellow form with prominent spottings on the dorsal sepal. Numerous fine forms of *Odontoglossum crispum* were also included (silver Flora medal). Messrs. B. S. Williams and Son were awarded a silver Banksian medal for a neat group consisting of fine forms of *Cattleya labiata*, several forms of *Cypripedium Pitcherianum* (Williams' variety), good forms of *C. ananthum*, and a new hybrid between *C. Harrisonianum superbum* and *C. Sallieri aureum*, the dorsal sepal pale green, suffused and heavily spotted with brown. A good form of *Pescatorea Lehmanni* was also included. Messrs. F. Sander and Co. sent a small group consisting principally of finely-flowered *Cattleya labiata*, the most distinct one amongst them being a variety with nearly white sepals and petals, the lip white with a crimson blotch in the centre, the side lobes white suffused with rose, lined with crimson and yellow at the base. Good forms of *Cattleya Bowringiana* and *Cypripedium Leeanum* were also included.

Mr. R. J. Measures, Cambridge Lodge, Camberwell, was awarded a silver Flora medal for an interesting group consisting principally of forms of *Cattleya labiata*, the best being *Cattleya labiata* (*R. J. Measures' variety*), which received a first-class certificate last year. The sepals and petals are white, lip white, with numerous lilac veins down the centre. *C. labiata superba* is one of the darkest forms we have seen, the sepals and petals large and dark in colour, the lip of fine form and substance, heavily fringed, and deep crimson-purple on the front lobe. *Laelio-Cattleya Sallieri* has the sepals and petals delicate rose, lip rose-purple in front, shading to a lighter colour and yellow in the throat. The plant carried a raceme of five flowers. A grand form of *Laelia elegans Schilleriana* (the crimson-purple of the lip being very prominent) and a good plant (finely flowered) of *Dendrobium anreum* were also shown. Amongst numerous forms of *Cypripediums* were the original plant of *C. Chapmani*, *C. tessellatum porphyreum* with two flowers on the spike, and a new hybrid named *C. calloso-Mastersianum*, raised from the two species indicated in the name. Mr. C. J. Ingram sent *Cattleya Eclipse* (*C. maxima* × *C. Skinneri*), *Laelio-Cattleya odorata* (*C. Eldorado* × *L. xanthina*), *L.-C. Firefly* and *L.-C. Epicasta*

Mr. J. W. Temple, Leywood, Tunbridge Wells, sent *Laelio-Cattleya* (Temple's var.), the sepals and petals pale rose, lip rose, shading to white at the base, the centre lined and suffused with rose. Mr. Bradshaw, The Grange, Southgate, sent *Cattleya Mantini nobilior*, one of the best forms we have seen.

#### Floral Committee.

Awards of merit were made to—

**VERONICA SILVER STAR.**—A very distinct and attractive variety, and one which bids fair to be valuable as a decorative plant, especially for marginal lines or groups. The growth is exceedingly dwarf and compact, whilst the foliage, by reason of its distinct variegation, makes it a showy plant. The predominating colours are silvery white and creamy yellow, the silvery suffusion appearing upon a pale green ground. From Messrs. J. Veitch and Sons, Chelsea, S.W.

**NANDINA DOMESTICA.**—Not a new plant, having been introduced as far back as 1804, but one none the less worthy of the recognition it received. The examples shown were quite dwarf and compact, but it grows to a fairly good height. The prevailing colour in its autumnal tints was a bright red, which makes it a very showy subject. The leaflets possess a deal of consistency and should remain for a considerable time ere they fall. Of its hardiness we are not certain. From Messrs. J. Veitch and Sons.

**MARANTA PICTA.**—A dwarf-growing variety in the way of *M. Warszewiczii* to a certain extent, and one which possibly throws up its flowers in the same attractive manner. The foliage is somewhat narrow and pointed, the ground colour a dark green with pale olive-green featherings, and the reverse of a pale chocolate hue. From Mr. Wm. Bull, King's Road, Chelsea.

**CHRYSANTHEMUM MRS. WINGFIELD.**—Of this several very well-grown plants were shown, dwarf in habit of growth and with flowers of medium size, which in colour were a blush-pink, shading to white with age. From Mrs. Wingfield, Amphil (gardener, Mr. Empson).

**CHRYSANTHEMUM MME. G. BRUANT** (large-flowered Jap.), in which the petals are of considerable length, drooping gracefully, thus giving the blooms a pretty effect. The colour is a lilac-rose towards the tips and white (or nearly so) at the base. From Messrs. Pearson and Son, Chilwell Nurseries, Nottingham.

**BEGONIA (TUBEROUS)** (for strain).—In this the distinctive feature is the creasing on each petal, thus making a singular, but very pretty contrast to the ordinary type of singles; this creasing is most pronounced and the variation of colour good. From Sir Trevor Lawrence, Bt. (gardener, Mr. Bain).

A surprisingly large number of exhibits was brought together on this occasion, the chief things being Michaelmas Daisies and Chrysanthemums. A very fine collection of Asters came from Mr. E. Beckett, gardener to Lord Aldenham, Elstree, Herts, containing upwards of eighty bunches of really well-grown material. A few of the finest varieties represented were *A. cordifolius major*, *A. Novi-Belgii Proserpine*, *A. levigatus*, *A. Amellus bessarabicus*, *A. ericoides elegans*, *A. N.-B. Nancy*, *A. versicolor Themis*, *A. N.-B. Harpur-Crewe*, *A. puniceus pulcherrimus*, *A. vimineus*, *A. Madonna*, *A. Amellus*, *A. Novæ-Angliæ roseus*, *A. Linosyris*, the curious but very effective yellow variety, and *A. N.-B. Top Sawyer*, a large and very beautiful mauve flower (silver-gilt Banksian medal). A small but very excellent collection of Asters was staged by Mr. Wm. Potten, Camden Nurseries, Cranbrook, Kent. The best bunches were *A. N.-A. pulchellus*, *A. laevis Ariadne*, *A. cordifolius Diana*, *A. N.-A. ruber*, and *A. laevis formosissimus*. Mr. H. Deverill, of Banbury, also put up a collection of Asters, comprising good bunches of *A. N.-B. ruber*, *A. Amellus*, *A. Amellus Riverslea*, *A. acris*, *A. Robert Parker*, and *Boltonia asteroides* (silver Banksian medal). A magnificent group of Asters in pots, shown by Messrs. Veitch and Sons, Chelsea, contained good examples of *Aster polyphyllus*, a pretty and

free-flowering white; A. N.-B. Pluto, A. ericoides, A. N.-B. Arcturus, A. formosissimus, A. horizontalis, A. vimineus, A. Amellus bess-arabicus, and A. Shorti (silver-gilt Banksian medal). Excellent Asters and Sunflowers were also shown by Messrs. Paul and Son, Cheshunt. The chief feature of their exhibit was, however, the charming collection of Roses, which included Caroline Testout, Gustave Regis, Marquise de Salisbury, Bridesmaid, and Souvenir d'un Ami. Some handsomely berried Pernettyas were also shown (silver-gilt Banksian medal). A very beautiful group of cut Roses, most artistically staged and consisting chiefly of button-hole varieties, was shown by Mr. G. Prince, Oxford. The colours were very rich and admirably disposed, and nearly every bloom was in good condition (silver Banksian medal). Messrs. Cutbush and Son were represented by a pretty group of *Pyraeantha Lælandi*, freely fruited Orange trees, and thickly berried plants of *Skimmia japonica*.

Mr. G. Wythes, gardener to Earl Percy, Syon House, Brentford, staged a very pretty group of cut Chrysanthemums, the blooms large, well developed, and in fine condition, and very tastefully staged in a ground-work of Maiden-hair Fern. Some of the best varieties were Mlle. Thérèse Rey, Louise, M. Ch. Molin, W. H. Fowler, John Lightfoot, Comte de Germiny, Louis Boehmer, Lady Selborne, Lady Randolph, William Seward, Elaine, and W. H. Lincoln (silver Flora medal). A very delightful exhibit was that of Mr. H. B. May, of Edmonton, consisting of some thirty plants of the lovely pink *Begonia Gloire de Lorraine*, one of the most useful and beautiful of the winter-flowering Begonias. Every plant was finely grown and flowering profusely. They were very symmetrical in growth, and all remarkably even in quality. The effect of this mass of brilliant colour was very striking, and called forth great admiration (silver Flora medal). A small collection of cut Chrysanthemums came from Mr. Robert Owen, Maidenhead. Messrs. Veitch and Sons had examples of *Caryopteris mastacanthus*, brilliantly tinted plants of *Vitis Coignetia*, *Vitis vinifera purpurea*, and well-berried boughs of *Crataegus orientalis*. Messrs. Hawkins and Bennett had plants of a new double scarlet *Geranium Duke of Fife*, and Mr. Godfrey, of Exmouth, boxes of very fine cut Chrysanthemums. Sixteen fine bunches of Violet The Czar came from Mr. Harris, of Chippenham, and a group of plants of *Begonia Gloire de Lorraine* from Messrs. Peed and Sons. A group of very good Crotons, well grown and finely finished, was staged by Messrs. B. S. Williams and Son, Upper Holloway (silver Banksian medal).

#### Fruit Committee.

Fruit on this occasion filled a goodly portion of the building and was shown in splendid condition, notably the gold medal collection from Barham Court. Seedling Apples and Pears were numerous and above the usual quality.

Awards of merit were given to—

**MELON CROXTETH JUBILEE.**—A medium-sized, deeply ribbed and slightly netted fruit; flesh bright scarlet, of good depth and fine flavour for so late in the season. From Mr. B. Barkham, Croxteth Hall Gardens, Liverpool.

**PEAR DIRECTEUR HARDY.**—A very handsome medium-sized fruit; skin yellow, bronzy red on the sunny side. It is of first-rate flavour and a valuable addition to the October Pears. From Messrs. Bunyard and Co., The Royal Nurseries, Maidstone.

**APPLE JAS. GRIEVE.**—A medium-sized fruit, not unlike a large Cox's Orange; skin yellow, flushed with bright crimson. It is of splendid quality, and a valuable addition to the dessert at this season. From Messrs. Bunyard and Co.

Probably the finest 100 dishes of Apples and Pears ever staged in the Drill Hall were put up by Mr. Woodward, gardener to Mr. Roger Leigh, Barham Court, near Maidstone, on this occasion, as it consisted of the cream of the Crystal Palace fruits which had taken prizes in their several classes. The fruits were now staged in long rows

on a wide table. Apples were about half of the exhibit. Such kinds as Yorkshire Beauty, Peasgood's Nonsuch, Stone's, Lane's Prince Albert, Potts' Seedling, and Warner's King were enormous fruits, and few people have ever seen Tyler's Kernel, The Queen, Alexander, Lady Henniker, Washington, Mère de Ménage, and Cox's Pomona so large and highly coloured. Of dessert kinds only a few can be noted, such as Ribston, immense—in fact, too large for dessert; Margil, Cox's Orange, Wealthy, Mother, Allington Pippin, a new fruit of great merit of the Golden Reinette type, and Adams' Pearmain. Pears were equally good, Princess, Magrate, Conference, Marie Benoist, Beurré Ballet, B. Superfin, B. Diel, and B. Hardy being the best. There was a grand dish of President d'Osmonville. Doyenné du Comice was also fine, the collection well meriting the gold Banksian medal awarded. With such a collection as the one named as a standpoint to judge from other collections appeared poor, but exception must be made in the case of that sent by Mr. Offer, gardener to Mr. John Warren, Handcross Park, Sussex. Here was remarkably good fruit, some of the dessert Apples being superior in colour and equal in size to Mr. Woodward's. Some sixty dishes were staged, Pears predominating. There were very fine examples of Doyenné du Comice, Pitmaston, Beurré Diel, Beurré Hardy, Beurré Bosc, and Doyenné Boussoch, fine Marie Louise and the largest Gansel's Bergamot we have seen, with Princess, Magrate and Nouvelle Fulvie. Apples were notable for their grand colour. Cellini was very rich, also Cox's Pomona and Peasgood's Nonsuch. Dessert varieties, such as Cox's Orange, Fearn's Pippin, Duchess' Favourite, Duchess of Gloucester, Calvilles in variety, and Russets, made a splendid collection (silver Knightian medal). Seventy dishes of fruit were staged by Mr. Rickwood, gardener to Lady Freake, Fulwell Park, Twickenham. Of the Pears, Beurré Diel, Beurré Superfin, Beurré Bachelier, Beurré Hardy, Beurré Bosc, Durondeau and Pitmaston were good. Apples, both dessert and cooking, were also good (silver Banksian medal). Many of the visitors would be surprised to see a small collection of fifteen varieties from Mr. J. Easter, gardener to Lord St. Oswald, receive a similar award. The fruits were not large, having been grown in the smoke-begrimed district of Wakefield. This was considered. The dishes of Lane's Prince Albert, Warner's King, Ecklinville, with Blenheim, King of the Pippins, and Cox's Orange were good.

Messrs. Jas. Carter and Co., High Holborn, sent a collection of thirty varieties of Cabbage. Some kinds were specially good. Mein's No. 1 was noteworthy for its compact habit. Ellam's Early is not so good in autumn as for spring use. The older Enfield Market, Little Pixie, and Nonpareil still hold their own as summer varieties. Rainham was a fine type, and Dwarf Nonpareil was very good (silver Knightian medal). The Messrs. Young, Stevenage, Herts, staged a quantity of Gourds of various shapes and colours, but none named. An exhibition of this kind is useless without names (bronze medal). Smaller exhibits were very numerous. Mr. Ross, Welford Park, Newbury, staged several new seedling Apples and Pears, but most of these were reserved for the next meeting, not being sufficiently ripe. The Horticultural College, Swanley, staged bottled fruits of 1896 growth, Cherries, Plums, Gooseberries, Currants, and Raspberries. The fruits were of good quality and colour. A seedling Grape named Edward Lord was sent by Mr. Lord (gardener, Mr. J. Wright), Belmont, Rawtenstall, Lancashire. The berries are large, oval, and not unlike those of Black Morocco in shape, but of distinct flavour. Unfortunately, the colour is bad, skin very thick. Even if distinct the colour is a drawback. Messrs. Wells, Crawley, sent a new Apple not unlike Lane's Prince Albert in shape and colour, but different in quality. It is a very late cooking fruit and good. This the committee asked to see next spring.

The flavour competition for the Veitch prizes brought forth a spirited competition and proved

that a good dish of Thomson's Pear can hold its own with Comice. Mr. Powell, Isington House, Dorset, was a good first with the variety named second, the Rev. H. Golding Palmer, Holme Park, Berks, with good Marie Louise. There were nine dishes staged, the varieties being Beurré Bosc, B. Superfin, Seckle, and Doyenné du Comice. There was the same number of Apples and of course Cox's Orange will be difficult to beat for the next few meetings. Some excellent dishes were staged, Mr. Woodward being first with this variety, and Mr. Powell second with Ribston Pippin. The other varieties staged were Cravenstein, American Mother, and Charlestown Pippin.

The members of the floral committee on Monday, the 4th inst., examined for the second time the early-flowering Chrysanthemums growing at Chiswick. The trial is certainly a most satisfactory one, many excellent sorts hitherto little known being brought into prominence. The majority of the pompon varieties were past their best, the bulk of the display being made by very interesting lot of Japanese sorts, showing pleasing diversity both in colour and form. The plants have been grown quite naturally, no dibbudding or stopping having taken place, and on just a stout stake used for the purpose of supporting the taller growing sorts and an others of abnormal size needing some support of the kind. The trial should make known the excellent qualities of the early and semi-early flowering Chrysanthemums for making a bright display in the open border, when many other autumn-flowering plants have succumbed to the first severe frost. The plants vary in height from about 2 feet to 5 feet, the majority of the sort being about 3 feet in height. Three marks were accorded to each of the following varieties:—

**EDIE WRIGHT.**—This is a Japanese variety with incurving florets of good width. Colour rosy-pink, free-flowering, and of strong constitution; height from 2½ feet to 3 feet. From Messrs. Dobbie and Co., Rothesay, N.B., and Mr. H. Jones, Lewisham, S.E.

**LA VIERGE.**—Compact habit of growth, racemes exceeding 18 inches in height. Flowers white slightly tinted blush, of Japanese form and freely produced. This sort would have been better developed a week later. From Messrs. Dobbie and Co.

**ALICE BUTCHER.**—This, one of the prettiest of the pompon flowers, is a reddish orange spec from Lyon, a rosy purple flower. It attains height of about 2½ feet. From Messrs. Dobbie and Co. and Messrs. Barr and Sons.

**ORANGE CHILD.**—A Japanese variety raised by the late Mr. W. Piercy, and very useful as a de yellow flower for the open at this season. Some of the flowers are tinted orange. It is a strong growing plant from 2½ feet to 3 feet high. From Messrs. Dobbie and Co.

**MME. EDUARD LEFORT.**—In this the flowers are neatly notched at the ends, giving the quite a fimbriated appearance. Colour bronzy gold, slightly veined crimson; height about 18 inches. From Mr. W. H. Divers, Belvoir Castle Gardens, and Messrs. Barr and Sons.

**LADY FITZWYGRAM.**—This was in capital condition and profusely flowered. The blooms are pure white, of Japanese form. It grows from 18 inches to 2 feet high. From Messrs. Cannell and Sons, Swanley, and Mr. W. Divers.

**IVY STARK.**—This, one of the very best sorts recently introduced, is a Japanese variety, raised from seed saved in this country. The flowers very much resemble those of the popular autumn season variety Source d'Or. The earliest buds were developing flowers of an orange-yellow colour, while the later flowers were of a rich shade of the same colour. Height about 3 feet. From Mr. H. J. Jones.

**BRONZE PRINCE.**—Another English seedling of Japanese form, with florets of medium width colour a pleasing shade of bronzy salmon, the flowers being very rich in colour. Height about 2½ feet. From Mr. H. J. Jones.

**Mlle. Guindeau.**—Another Japanese flower, of deep pink, paling with age. It is free-fering and distinct. From Mr. H. J. Jones.

**BERTA.**—This is a bright little pompon flower of golden yellow colour, and borne freely on long stalks. Height about 2 feet. From Mr. H. Divers and Messrs. Barr and Sons.

**MARTINUS.**—This was specially noticeable for its nice bushy habit of growth. The colour may be described as pale pink, the centre florets edged white. The flower belongs to the pompon section. From Messrs. Barr and Sons.

**HARVEST HOME.**—This popular market variety is past its best. It is the earliest of the crimson and golden yellow flowers and blossoms somewhat fully. It is of Japanese form, with a spare habit of growth, and in height from 2½ feet to 3 feet. From Messrs. Barr and Sons.

**BLANCHE COLOMB.**—This, of stiff Japanese form, has creamy white blossoms; height from 18 inches to 2 feet. From Messrs. Barr and Sons.

#### ZONAL PELARGONIUMS.

At the same meeting the following zonal Pelargoniums received a similar recognition:—

**REV. H. H. D'OMBRAIN.**—A plant bearing splendid trusses of rich salmon colour, with well-defined individual pips.

**ULES LEMAITRE.**—A huge truss of rich crimson-scarlet, with large pips of good form and substance. From Mons. Lemoine, Nancy, France.

**ADOLPHE BRISSON.**—A pretty flower and a distinct advance upon the fancy types of the zonal pelargonium. Colour rich carmine-pink, having a white blotch at the base of the two upper florets. From Mons. Lemoine.

### UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.

#### THE ANNUAL DINNER.

The annual dinner of this benefit society, reserved entirely to gardeners, was held at the Albion Restaurant on Tuesday last. Although there were several horticultural engagements fixed for the same evening, the Venetian room was crowded, about 120 guests being present. We have never been present at a dinner of this society in which the proceedings passed off with greater zest.

The chair was taken by Mr. H. B. May, who was supported by Mr. Nutting, Mr. G. Bunyard, Mr. James H. Veitch, Mr. Harry Laing, Mr. G. Laram, Mr. H. Williams, Mr. Peter Kay, Mr. S. T. Wright, Mr. Walker, Mr. Wythes and many others.

After the usual loyal toasts, the chairman proposed "Success to the United Horticultural Benefit and Provident Society." In the course of his speech he said: "This society has for its motto 'Unity is strength,' but its pioneers, mindful of the stability is not obtained by numbers alone, have raised it upon an enduring basis of self-help. The society is conducted by gardeners for the welfare of gardeners, and so great is my admiration for its objects, and particularly its methods, that I venture to think it is unsurpassed, if indeed it is equalled, by any similar institution in the kingdom. The advantages it offers its members, especially those advanced in age, are certainly most liberal. The society is indeed a happy combination of a benefit society and savings bank."

It may be useful to point out the following information recorded by the chairman, as likely to promote increased membership. He said: "The members are of two grades, those on the higher scale paying 9d. and the lower 6d. per week to the sick and deposit fund; 3s. and 2s. a year to the benevolent fund, and 2s. 6d. a year by each member to the management fund. Members are entitled to 18s. and 12s. a week sick pay respectively for a period of twenty-six weeks, and 9s. and 6s. for a further period of twenty-six weeks, and may then be transferred to the benevolent fund, receiving such weekly payment as the committee deem advisable. The balance to the credit

of the sick fund, after deducting payments to members, is annually divided *pro rata* and placed to the credit of each member. This sum, with compound interest, is carried forward until he reaches the age of seventy, when he is entitled to withdraw the amount standing to his credit. A member, too, who has allowed his subscription to lapse does not forfeit the amount, but is entitled, on reaching the age of sixty, to withdraw the sum standing to his credit at the time of his default."

Mr. May said that the society had made decided progress, sixty-three new members having joined since the last annual dinner, the total number on the books being 684.

Mr. Hudson (the treasurer of the society) responded, and urged its claims strongly upon gardeners who had not joined. He mentioned that only the previous evening a sum of 30s. was voted from the convalescent fund to enable the member to stay a week or two at the seaside.

The toast of "The Honorary and Life Members and Visitors" was proposed by Mr. Nathan Cole, who gave a short history of the early days of the society. This was responded to in an excellent speech by Mr. George Bunyard. The health of "The Chairman" was proposed by Mr. Peter Kay. The toast of "Kindred Institutions" was proposed by Mr. W. J. Nutting, and Mr. G. Ingram (secretary of the Gardeners' Royal Benevolent Institution) responded. Mr. G. W. Cummins also spoke to this toast.

The remaining toast was "The Press," proposed by Mr. James H. Veitch, and responded to by Mr. Curtis. Mr. W. Collins (secretary of the United Horticultural Benefit Society) proposed thanks to donors of fruits and flowers, Messrs. H. Williams, J. Laing, H. Cannell and a few well-known gardeners having kindly given liberally to make the tables gay. Miss Hudson decorated the tables.

We can add little more about this society. It should appeal to every gardener in the land, in whatever circumstances, and the wish expressed by the treasurer, that the roll of members should soon reach 1000, we hope will soon be realised.

**National Chrysanthemum Society.**—Owing to want of space, we have been compelled to hold over the report of the show held on the 12th inst. and two following days till next week.

### NOTES OF THE WEEK.

**Aster ericoides.**—As implied in the specific name, this is the Heath-like Starwort, and certainly it deserves such distinction. The small pure white blossoms are produced in the most elegant sprays.

**Aster Amellus Riverslea.**—Apparently a selected seedling form, and differing from the majority of the Amellus varieties in the violet self tone of the ray florets, this being of a more decided shade than is usually seen.

**Jacobinia magnifica.**—Where a good display is required to be maintained in the warm greenhouse this plant should not be overlooked, for its showy heads of pink are most serviceable. By adopting a variety of methods, plants may be had in flower for a long period.

**Violet The Czar.**—When one sees this very handsome Violet in fine condition, it is doubtful whether the much-lauded new kinds are really acquisitions after all. On Tuesday at the Drill Hall some sixteen bunches of this old favourite were shown in splendid condition.

**Chrysanthemum W. H. Fowler.**—This promises to be one of the best yellow kinds, a fact amply illustrated by several splendid blooms at the Drill Hall on Tuesday last from Earl Percy, Syon House (Mr. Wythes, gardener). The flowers are very full to the centre and rich golden yellow.

**Passiflora racemosa.**—This very showy Brazilian species is among the most attractive of

the genus now in flower. The rich scarlet blossoms are produced with great freedom in an intermediate temperature, and, trained loosely to the rafters, the plant is an object of great beauty for weeks in succession.

**Sedum Borderi.**—While there are many inferior species catalogued from year to year, this striking plant rarely finds a place. It is a native of the Pyrenees, flowering quite late in summer and into the autumn months, at which time the heads of crimson-coloured flowers are most effective. It is a capital plant for the rock garden.

**Nerine pudica.**—This is a neat and chaste species, easy of culture and free flowering. The slender spikes bear some eight or more blossoms nearly pure white, with a faint rose streak on the midrib externally. Associated with the more striking species of this genus and where the plants are freely flowered the effect is distinctly pleasing.

**Chrysanthemum Mrs. Wingfield.**—A seedling variety of very dwarf growth, the plants as shown at the Royal Horticultural meeting being under 2 feet high from the pot. Indeed, as a pot plant from a decorative point of view, the variety would appear well suited. The flowers are of medium size, some almost pure white, and others flushed with pink.

**Aster puniceus grandiflorus.**—While the flowers of this are large and numerous and showy for the border or in groups, they are not so useful in a cut state as many, as they are produced in a somewhat cylindrical form, at least on the main spike. In colour the flowers are of a lilac-blush tint. It is a strong and vigorous grower, and does well in deep soil.

**Lilium speciosum eruentum.**—Even after the severe frost this vigorous-growing Lily still expands its richly-coloured flowers. It is a handsome form that should be abundantly grown in gardens, and a great improvement upon the ordinary forms of roseum and rubrum. It is equally good as a pot plant, and where late flowers are desired this should always be found.

**Chrysanthemum Klondyke.**—This promising variety, with deep golden yellow flowers and petals slightly drooping, was exhibited by Mr. Davis at the Aquarium show this week. The flowers are not large, but when seen in sufficient quantity very striking. Of its habit we know nothing, as for some reason the stems were divested of all leafage, and in this way the beauty of the blossoms was lost.

**Gladiolus Raphael Collin.**—This is perhaps one of the finest varieties of the Lemoinei section of these beautiful flowers. In greater part the flowers are of a deep salmon-pink, scarlet-crimson on the lower petal. The spike is large and the flowers numerous. Another very handsome form, also of the Lemoinei type, is Goliath, the flowers slightly hooded and of a purple-wine shade, lightened by a faint white central band.

**Pelargonium Duke of Fife.**—Whether this is any advance on the best double scarlets now in cultivation or not matters but little. It is undoubtedly a most vivid colour, the rather semi-double flowers large and in well disposed heads, and produced on stout stems nearly 10 inches in length. Some fine baskets of it were quite a mass of colour at the Drill Hall this week, when it was shown by Messrs. Hawkins and Bennett.

**Chrysanthemum Etoile d'Or.**—At the present time, when frost has blackened all Dahlias and other tender short-lived things, it is refreshing to see broad patches of this several feet across quite fresh and unharmed. The abundance of its foliage and the number of its soft yellow blossoms render it a most useful plant for the open garden in summer. Groups of old plants yield a surprising amount of flower, and are attractive over a long season.

**Antirrhinum Hendersoni.**—Snapdragons are now largely used in the flower garden, and this is one of the types which is most desirable among the spotted and variegated kinds. All these spotted, variegated and dwarf forms, how-

ever, make us long to see more of the pure distinct self colours which are now found in this family. The beauty of the Snapdragon is lost in the dwarf kinds which are now being largely planted. Mr. John Forbes, of Hawick, has just sent us some spikes of this.

**Begonia Gloire de Lorraine.**—This singularly beautiful and free-flowering kind was exhibited in the most perfect form on Tuesday last by Mr. May, of Edmonton, the plants being as remarkable for their good culture as for their abundant flowering. Though growing in pots only 5 inches in diameter, the plants were about 18 inches high and 15 inches through. These perfect little bushes were most attractive, the two dozen or more plants making a good display amid a setting of various beautiful Ferns.

**Kniphofia Nelsoni.**—In the kind under notice the rare beauty and worth are not in its giant inflorescence or even the vigour of the plant, for in *K. Nelsoni* the growth is less vigorous than in most kinds; at the same time it is so perfectly hardy and so free flowering as to make it well-nigh unique. It is a slender, graceful kind, the long tubular blossoms almost vermilion-orange in tone. Of all the tribe, this slender kind is the most suitable in a cut state, and for brilliancy is not surpassed by any of the more massive and robust forms.

**Kniphofia Woodii.**—This is a very distinct and interesting species from Natal now flowering in the Royal Gardens, Kew. The species is of rather tall and meagre growth, the attenuated inflorescence rising to 6 feet high and freely furnished with blossoms, each some three-quarters of an inch long. In the bud stage these are yellow, but expanded, of a creamy shade, and therefore quite distinct from all else. Unfortunately, its native habitat precludes the idea of its perfect hardiness—a fact that minimises its value considerably so far as British gardens are concerned. In the Cape house it will doubtless prove an acquisition.

**Schizostylis coccinea.**—In those gardens where some attention is paid to this plant in spring and summer the reward will now be forthcoming in the profusion of its vivid scarlet spikes. It is somewhat difficult to fully understand why so useful a subject is so generally either neglected or ignored altogether, as few plants give such a return for the little trouble expended. Planted out in good ground in early spring at a few inches apart, it is surprising what a number can be grown on a few yards, and in rich light soil even the small growths furnish flowering stems by the autumn. At this season it is best to lift and pot them for flowering. In a cut state the spikes are most attractive.

**Outdoor Grapes from Wales.**—I have sent you a box containing three bunches of Grapes cut from the vineyard at Swanbridge. They are typical of the whole crop in that vineyard. The fruit is well coloured, but not so sweet and palatable as usual, which of course is accounted for by cold, wet weather experienced in August and early part of September. The Grapes are juicy and in good condition for wine making. I anticipate making from that vineyard alone about thirty hogsheads of wine that will, I think, not be inferior to that of some of the best seasons. "La vendange" was commenced October 7, and will probably last for four or five days. The Castell Coch vineyard, on account of mildew, is nearly a failure again this year. Despite frequent applications of the Bordeaux mixture and the employment of all the latest continental methods for combating mildew, it still remains unchecked at Castell Coch. The Vines at Swanbridge are entirely free from it. —A. PETTIGREW.

**The weather in West Herts.**—The weather remained warm until the 4th inst., but since then colder conditions have prevailed. During the night preceding the 6th the thermometer exposed on the lawn showed 5° of frost. Notwithstanding

this low reading, neither the petals nor the foliage of any single Dahlias were in any way injured. At 2 feet deep the temperature of the soil is at the present time about seasonable, but at 1 foot deep it is about 2° below the average. On the 29th ult. about half an inch of rain fell during a thunderstorm. Previous to this thunderstorm no measurable quantity of rain water had come through either percolation gauge for more than a week, but since then small measurements have each day been made. There has been a good record of sunshine during the week, and on the third the sun was shining brightly for nine hours. During the past nine days the wind has been mostly very light, the average rate of movement for this period amounting to less than two miles an hour.—E. M., *Berkhamsted*, October 7.

—During the past ten days there has not been a single unseasonably warm day and only three moderately warm nights. On the night preceding the 6th the exposed thermometer showed 5° of frost, but my Dahlias were in no way injured, not a leaf or petal being touched. But with 8° of frost on the following night the upper half of the plants was killed and their flowering ruined for the year. Both nights were equally calm and bright, but on the second there were 3° more frost and the temperature remained at its lowest point for a considerably longer time. The ground at 2 feet deep is now about seasonable in temperature, while at 1 foot deep the reading is only about 1° below the October average for that depth. No rain worth mentioning has fallen since the 2nd, and then the amount registered fell short of a quarter of an inch. The sun shone on an average during the week for four hours a day, and on two days the record exceeded seven hours.—E. M., *Berkhamsted*.

## PUBLIC GARDENS.

**Surplus bedding plants in the London parks.**—Arrangements have been made for the distribution to the public, on the days named, of any surplus bedding plants that may be at the following places: Brockwell Park and Maryon Park, October 16; Myatt's Fields, Peckham Rye Park and Waterlow Park, October 19; Finsbury Park, Meath Gardens, Bethnal Green, Royal Victoria Gardens, North Woolwich and Victoria Park, October 20; Kennington Park, October 21; Battersea Park and Dulwich Park, October 22.

**Barnes Common.**—A new scheme has been prepared by the Board of Agriculture, under the Metropolitan Commons Acts, for placing the future regulation and management of Barnes Common in the hands of the District Council, who are to maintain the area free from encroachments and to frame bye-laws for the prevention of nuisances, the preservation of order, the regulation of sports and games, the exclusion and removal of gipsies, &c. The council will also be empowered to execute drainage and improvements, to repair footpaths, to cleanse Beverley Brook and the pond on Barnes Green, to preserve the turf and grass, and to plant or otherwise make the common more pleasant for exercise and recreation, but nothing is to be done that will otherwise alter the natural features of the common.

**The Metropolitan Public Gardens Association.**—At the first monthly meeting after the vacation of the Metropolitan Public Gardens Association, 83, Lancaster Gate, the Earl of Meath, chairman, presiding, the opening in July of the gardens of St. Matthew, Bethnal Green, and St. James's, Pentonville, was announced, and progress was reported in the laying out by the association of Guy's Hospital disused burial-ground in Bermondsey and of a site in East Street, Walworth. Resolutions were passed agreeing to lay out, if funds permitted, Christ Church disused burial-ground, Blackfriars Road, and a similar ground in York Street, Walworth, subject to proper provision being made in each case for their permanent up-keep. It was stated that the asso-

ciation, through the generosity of some of its members, was about to erect drinking fountain in Homerton and on an open space in Brooke Market, Holborn, and had made grants of seat for certain public thoroughfares in Wandsworth, Paddington, and other places; that the Act of Parliament authorising contributions from various public authorities for the purchase of Churchyard Bottom Wood, Highgate, had received the Royal Assent, and that £31,500 required for the purchase of a riverside ground of 20 acres in Wandsworth had practically been secured by means of grant from the London County Council, the local authority, and private subscriptions, including one of £5000 from Dr. Longstaff. The secretary reported the steps that were being taken with a view to the acquisition of a portion of Golder's Hill Estate formerly owned by the late Sir Spencer Wells, an addition to Hampstead Heath.

## OBITUARY.

### WILLIAM SCOTT.

WE regret to announce the death, at the age of 67, of Mr. W. Scott, Director of the Royal Gardens at Forests, Mauritius, at Stirling on the 3rd inst. after a short illness. He was home on leave after an unbroken residence in the tropics extending to sixteen years. After serving as a gardener several estates in Scotland, he came to the Royal Gardens at Kew. After six months' residence there he was appointed in 1881 to be assistant to the Mauritius gardens and forests at Pamplousses, being appointed director nine years later.

**Campanula patula.**—Can any of your readers kindly inform me where, if anywhere, I can obtain seeds of *Campanula patula* (annual)? It is in my opinion, the most beautiful of a beautiful family. I have never seen it offered in any catalogue, and I have never been able to gather seeds of it abroad.—A. D. G.

**Todea superba.**—I am sure you will excuse my pointing out that the illustration on p. 288 last week's GARDEN represents *Todea superba*, not *T. pellucida*. The latter is a very different plant. Of less consequence, but still worth noting, is the name Ostrich Feather Fern, which on the following page (289) is said to be applied to the Fern, *Todea superba*. This name, however, usually applied to *Struthiopteris germanica*, not to *S. pennsylvanica*. According to Field, in "New Zealand Ferns" the common names *Todea superba* are Prince of Wales's Feather Fern, Chenille Fern, and Grape Fern.—J. BIRKENHEAD.

**Irish-grown wood for Wales.**—A new development of the Irish export trade is, according to the *Pull Mall Gazette*, in evidence in Cork. During the earlier months of the year, occasional consignments of Irish-grown timber were carried to Welsh ports by the coaling boats, to be utilized as pitwood in the mines of the Principality. Previously to this, the coasters, when their coals had been discharged in Cork, made the return trip with cargo of any kind. But within the last few months almost every boat has been freighted with its homeward voyage with this wood, as the results obtained from its use were such as to induce the colliery proprietors to continue the trade. One contract just entered into is for 2000 tons of wood, which will be taken from the timber growing in the neighbourhood of Glanmire, and this is only one of many. The work of preparing such much timber and putting it alongside the steam affords employment to many hands, and the wood industry is one that should prosper.

**Names of plants.**—Henry P. Goodbody. *Vanda cœrulea*, very good form.

**Names of fruit.**—A. J. Williamson.—1, Launceston; 2, Rymer; 3, not recognised; 4, folk Beaufin; 5, Manks Codlin; 6, Hawthornden. *Country Gardener*.—Plum not recognised.

## ORCHARD AND FRUIT GARDEN.

### ROOT MANAGEMENT OF CORDON PEARS.

Every fruit tree that I am acquainted with gets out of health sooner than does the Pear when grown as a cordon if the roots are neglected and means allowed to take their course. The trees not only resent such neglect by failing to produce profitable crops of fruit, and in some cases rot at all, but they quickly give signs of it in the unhealthy appearance; also by making little or no growth, and once they get into this condition it takes two or three seasons to get them round into health again. As a rule, border for growing cordon Pears in are seldom constructed more than 3 feet wide, and often not so wide as this, while the depth varies from 2 ft to 2 feet 6 inches. Very often no special preparation is made for them, and the trees are planted in the existing soil with the addition, perhaps, of a little fresh compost to cover the soil with to give them a start. A border of the above-named dimensions provides a sufficient quantity of soil for the requirements of the trees for some time after being planted, but as the majority of them are worked on the Queen stock, which emits a multitude of hungry feeding roots, it follows that the soil in the border soon becomes exhausted. When the trees are planted in the staple with little or no preparation beyond a modicum of fresh soil placed about the roots, they soon get into a sorry plight unless the natural soil should be of good quality and suitable for Pear culture. A little attention will avert this if the roots are afforded a top-dressing of rich compost every two or three years, and if this is regularly attended to cordon Pears may be maintained in a healthy bearing condition for a number of years. I have seen trees of this description that were planted twenty-nine years ago, and which are in fine health and bear regular crops of fine fruit. Many may object to devoting so much time to

these cordon Pears, but as the fruits produced by them are invariably of large size and of exceptionally good quality, they amply compensate the owner for any little extra trouble he may be put to. Unless anyone contemplating planting cordon Pears is prepared to afford them this amount of attention when the trees become established and in full bearing, I would advise him to abandon the idea. Of course there are a few varieties of Pears which will not succeed do what one may, but they are the exception, and this is more often owing to physical defects than to faulty culture, and does not, therefore, come within the scope of this note. Cordon Pears are as equally deserving of extra attention in the way of root management as are Peaches and Apricots for instance, and they always give excellent returns when it is accorded them.

The proper method to pursue in Cordon Pear culture is not to wait until the roots have exhausted the soil in which they are planted, and for the trees to assume an unhealthy appearance, but to examine the border annually and so ascertain when the roots are in need of aid in the shape of fresh compost. With a properly constructed border this would not be necessary until the trees were well established and bearing annual crops of fruit, but after this a top-dressing every second or third year will maintain them in a state of efficiency. In the absence of a proper border a stricter surveillance would be necessary, and, as before mentioned, unless the staple is of good quality, the trees will need assistance the third year after planting. My method of dealing with these trees is to remove as much surface soil as can be done with safety, or until plenty of roots is found, much in the same way as when preparing a Vine border for top-dressing, and then replace it with a compost consisting of good fibrous loam, with which have been mixed a little lime rubble, wood ashes, and a plentiful addition of bone-meal. The compost is placed evenly all over the roots, trodden firmly and afterwards mulched. If virgin loam cannot be

spared, a compost such as was recommended in these pages in the issue of THE GARDEN for October 2 for planting fruit trees in will answer admirably if the bone-meal be added to the other ingredients. In the seasons when top-dressing is omitted the border receives a winter mulch of half-decayed manure spread over the surface about 3 inches thick. During the summer months two applications of superphosphate of lime and muriate of potash are given. This is mixed in equal quantities and sprinkled on the surface at the rate of 2 ozs. per square yard. This should be applied just before rain or immediately before watering the border, as, like all other chemical manures, it is useless if left lying on the surface. Other good manures are guano, dried blood and bone-meal mixed together, but I have abandoned their use in favour of the above, as this combination I find supplies constituents more suitable for the Pear. Trees which have got into a bad condition should be partially or wholly lifted and replanted in fresh compost, and then top-dressed afterwards to keep them in a healthy state when they have recovered. This will keep the roots in an active condition. A. W.

**A spider-resisting Strawberry.**—Amongst a good many varieties of Strawberries grown here (Notts) in a light warm soil, which quickly suffers from drought, not one has stood the indifferent summer so well as the new Monarch. I think this will prove to be a capital Strawberry for amateurs, and, indeed, all who have a shallow hot soil to deal with. While more or less spider is visible on other sorts, not an infested leaf can be found on Monarch. Moreover, it is a prodigious yielder, although perhaps the flavour is not first-rate. Many of the sorts, however, having in them the Queen blood, will not do at all satisfactorily where the soil is either shallow or light, but Monarch will, and I recommend it to all who have such gardens to deal with.—GROWER.

**Pear Beurre Bachelier.**—I think it was Mr. Wythes who this season referred to Beurre Bachelier as a sure cropping, handsome, fairly flavoured

Pear, which did well in most seasons on his light soil. With me in upright cordon form it never fails, and is this year carrying a heavy crop of handsome looking fruit. It will hang on the trees later than most sorts, and when placed in the fruit room comes on slowly, ripening here about the end of November. If this Pear would succeed in open market gardens and orchards as a standard, pyramid or bush, it would make a capital market fruit, as its bright and handsome skin is very firm and not easily damaged by pressure. It perhaps is grown largely in some districts, but I have never, so far as I remember, seen it quoted in lists of market sorts.—J. C.

#### MEALY BUG ON VINES.

Will any reader of THE GARDEN kindly give me a remedy for this troublesome pest on Vines? I have it here in a very acute form. Is sulphur of any use if the house be filled with the fumes after the leaves are off? I have tried going over the rods weekly with paraffin and other insecticides, but have only succeeded in keeping the pest out of the bunches. The house is to be painted this autumn.—C. EDWARDS.

\* \* C. Edwards will have a good opportunity of reducing, if not entirely exterminating, the mealy bug in his vineyard during the autumn and coming winter, and no time should be lost after the leaves fall in commencing operations. Sulphur fumes, if arising from burnt sulphur, are too dangerous to be recommended for use in a house where there is any plant life, dormant or active, and simply painting the hot-water pipes with a mixture of flowers of sulphur and water or milk mixed together will have no effect whatever on the bug. A cheap and very effective remedy is easily obtained by mixing 6 ozs. of paraffin (petroleum) with 3 ozs. of soft soap and adding to this 3 gallons of soft water, which should be used at a temperature of about 130° Fahr. This mixture should be forcibly applied to every part of the interior of the house by the aid of the syringe or garden engine, keeping it well stirred while using. The best way of mixing is to stir the paraffin into the soft soap before adding any water, as it then becomes more soluble and the danger of injury to any Vine buds touched by the solution is lessened. This mixture will form a solvent that will penetrate the woolly covering with which the female insects protect their eggs, and will destroy both the latter and any live insects with which it may come into contact. I need hardly say that it is absolutely necessary to penetrate with the mixture all crevices and holes in the woodwork and walls. The next step should be to strip off from the Vines all the bark which can be removed easily with the thumb and finger-nails, and it will be found that this can best be done when the Vines are wet. It will be found convenient to carry out the work immediately after the syringing above recommended has taken place. No scraping with a knife or any other forcible means of removing the bark should be allowed. I never use the clogging mixtures of clay and gas-tar and the like which are sometimes recommended for smearing the rods, but prefer washing them with a solution of Gishurst compound mixed in accordance with the directions, and in the case under notice I should recommend this being done two or three times between the times of pruning and starting the Vines.

In addition to the painting of woodwork which is to be carried out, and which should follow the cleansing operations, an application of hot lime-wash should be given to the walls and all available surfaces not painted. Two or three inches of soil from the top of inside borders should also be removed and some new soil put in its place, after which the floors and all surfaces which have not been already dealt with should be scalded down with very hot water. Strict attention to the above directions must be given and nothing overlooked. Cases are frequent in which remedies are rightly applied up to a certain point, only to over-

look some odd corner or space underneath the pipes or some other spot not easily reached, and which may be teeming with insects in all stages, only waiting for the genial warmth of a vineyard at work to bring them again into vigorous action. When the Vines again get into growth they should be closely and frequently looked over for stray insects, which are then easily killed, for it may be that in spite of care a small colony here and there will escape under the protection of an old snag on the rod, and in this case a touch of a small brush which has been lightly dipped in spirits of wine will kill a whole colony, as the spirits will spread to some distance round the spot touched with the brush. It must be understood that such a remedy must only be applied to the old wood on the Vines and must not come near the buds or new growth. Of course no infested plant should be admitted to the house after the cleansing is over, it being impossible to keep clean Vines if any fresh stock is admitted to the house.—CORNUBIAN.

**Late Melons.**—Melons ripened during October, unless that month is exceptionally sunny, and the beginning of November, are, as a rule, deficient in flavour. For this reason many gardeners do not agree with certificates for new varieties being awarded during October. Much may be done, however, towards improving the quality of these late crops of Melons by general management. Very little air will now be needed, a chink being sufficient even on the sunniest days, this being removed at 2 p.m. Overhead syringing also had now better be entirely discontinued, and even damping down confined to the forenoon of fine days. Root moisture, too, in the case of fruit now turning should only be of such a nature as will prevent actual flagging. Ordinary treatment now not only causes indifferent flavour but wholesale cracking of some varieties.—C. H.

**Pine-apple Prince Albert.**—Although Pine growing in private gardens has dwindled very much during the last twenty years, one occasionally meets with healthy batches of plants, and to me they are always interesting. There is no variety that can equal for flavour the Ripley or Moscow Queen, but these are, strictly speaking, summer fruiting varieties, harder varieties being necessary where fruit is wanted in the winter months. The Smooth Cayenne is very suitable for the purpose, but the variety I wish to draw special attention to is Prince Albert. Both foliage and fruit are very distinct, the former being of a very dark purplish hue, carrying a dense bloom, the fruit being long and conical in shape, good fruits often being as many as twelve and thirteen pips deep. The plant does well grown in rather small pots, and enjoys a strong bottom heat when swelling off. The flavour is not unlike that of that other good winter Pine Black Jamaica.—J. C.

**Alnwick Seedling Grape as a stock for Gros Maroc.**—With many gardeners, myself included, Gros Maroc on its own roots is anything but satisfactory from a productive point of view, neither are the bunches of any length. Like many other Grapes it seems to do better when grafted on to some other stock. A striking proof of the good effects of this operation may be seen at Hill-side, Newark, where Gros Maroc was several years ago inarched on to Alnwick Seedling. One rod on its own roots still remains, but the inarched rod produces bunches nearly twice the size, the berries also being much larger. The narrowness also of the border is worth a passing remark, this, which is inside of the house—a span-roofed one—being only some 3 feet or 3½ feet wide. Beside the Gros Maroc referred to, Alicante, Muscats, and Hamburgs occupy the border, and have done so for at least half a dozen years. The vigour and productiveness of all these Vines are all that could be desired, feeding, it is true, being practised rather liberally when the Grapes are swelling, good top-dressings being given annually. The above is a proof of what can be accomplished in both narrow and shallow borders, and, although

this is perhaps an extreme case, deep wide V borders will soon be a thing of the past.—N.

**Young Strawberry beds.**—Strawberry planted in July or August are, as a rule, look less vigorous this autumn than usual. This is to be wondered at, especially in gardens that suffer from drought, as runners were hard to find last June for layering. I notice that on the ground, as, for instance, where the plants were put out between rows of spring sown Onions, they have made more progress than where growing in a quarter that had been loosened by digging previously. July in most parts being very loose, open ground, no matter how freely trodden down after being dug, lost the moisture more soon than the solid root-run of the former position, and roots were made more quickly, to say nothing of the freedom from spider the plants enjoy. In any case where the slightest looseness is acceptable, the best way is to now go over the beds and firmly tread round each plant in the same manner as Carnation growers treat their plants in spring, removing all runners, passing the Dutch hoe through the surface once more, and refraining from putting on any mulching for the present, so that not only top growth but roots also may partake of the fullest benefit of every ray of sunshine between now and the end of November. Certain varieties have even this season seemed to defy the drought and attacks of spider, on account of their vigorous character. Amongst these is Monarch. Its constitution and the fact that any quantity of runners may be had from the parent plants in June, and that in unfavourable Strawberry seasons, are sure to make Monarch a favourite with market growers, as it is also a prodigious cropper.—

#### PEAR DOYENNE DU CONICE ON NORTH WALLS.

It would not do to advise everyone to grow Doyenné du Conice on north walls in every garden. I have this year obtained my only crop from trees on this aspect, trees in the open had failed to bear fruit. My trees on the aspect are well sheltered from rough winds, a belt of tall trees protecting them. There is a great advantage in having fruit trees in different positions as the season is prolonged, and as there be no question as to the good qualities of this variety, it is well to have as long a supply as possible. I find the best fruits are those grown in cordons. Trees on north walls are inclined to produce fruits covered with russet; this does detract from the flavour. I am aware a skin is much the best and more presentable with so good quality this is overlooked. The chief point with north wall trees is to have roots in well-drained soil. In heavy land year I grew this variety in raised borders, and, to say the best fruits were secured from a that had its roots under a hard walk, where digging and heavy traffic were constantly going. The trees produced grand fruit, and I attribute the success to the trees not getting an excessive moisture in the heavy clay soil, as the water drained away from the surface. The trees bore a sturdy, fruitful growth and no rank wood were on an east wall on the Quince stock I think it a profitable plan to plant a tree or two of the best-known fruits in out-of-the-way places as it often happens such trees thrive, and are most serviceable. I recently saw a wall fence covered with cordon trees of this variety and a few others, the fence being used to some stables, and it was most ornamental, at the same time profitable, as it was the only place in a large garden that had trees cropping well. More interest is secured by what is termed haphazard planting—a tree here and there where there is room. By growing trees in different aspects a crop may often be secured.

G. WYTH

**Apple James Grieve.**—This promises to be a valuable addition to the dessert Apples was given an award of merit on the 12th inst.

Royal Horticultural Society, but as several of the members had no knowledge of its cropping qualities, the higher award, a first-class certificate, was withheld. Its season is October, but I should say it would keep much longer, as the fruits were firm, the flavour brisk and refreshing. In appearance it resembles a large Cox's Orange, but of a brighter colour and with the good eating qualities of the older variety. It comes from Scotland and is said to bear there when the Orange fails. This will be a gain, and though we have no lack of Apples, a good fruit such as James Grieve is always welcomed.—G. W.

**Apple Lemon Pippin.**—In a season when the dessert Apples are scarce, it is pleasing to find the free-cropping qualities of this old variety. Not only are the trees bearing freely, but the fruit in most cases are finer than usual. For the few years I have never failed to secure a fair crop from bush trees of this variety. I have seen it grown as a standard tree, but do not advise it as such as there is too great a percentage of small fruit. The fruit of this variety is readily distinguished, the knob at the stalk end being peculiar. It is of first quality and in season from November to April. Being a late fruit it should be given a cool store and gathered late. It is less so than formerly, the larger showy Apples being more in favour, but it is well worth including in all lists where good late dessert kinds are needed as there are none too many good ones early in the season.—S. H.

#### NOTES ON STRAWBERRIES.

We have to thank our readers all over the country for so kindly replying to the following questions, and we hope that the notes will prove valuable:—

Will you kindly aid us in throwing some light on strawberries of best quality for the use of private growers, as market growers have a different standard from that which applies to the private owner, and favour those kinds that bear large, rather than those that are remarkable for their colour and quality? For those who use their own beds we think that a different standard should be used.

What kinds do you consider the best for your district, i.e., as grown in gardens, making into account those grown in the open field for market?

The best early and late kinds for the open air in your district?

Which of the newer sorts do you find most worthy of cultivation from a garden point of view?

The best time to plant so as to secure the best and most regular crops?

The really excellent flavoured varieties of strawberries are, as far as my experience goes, very few indeed, and in discarding all others from the notes one must perforce throw over both the very early and very late varieties, for none of them come up to the requirements. British Queen has been for many years the standard variety when judged by flavour, but neither it nor a few other good varieties which claim it for one of the parents are suited for a variety of soils, and the soil here is too light to suit them. The best flavoured varieties I grow, taken in rotation as they ripen, are Royal Sovereign, Keen's Seedling, Vicomtesse Héricart de Thury, Auguste Nélot, President, and Latest of All. Though I have included Royal Sovereign in this list, I cannot say that I have been quite satisfied with it this year on flat beds, for though the season has been propitious, I found that very many of the fine fruits turned mouldy before thoroughly ripening, and this, too, on one-year-old plants set well apart. On raised sloping borders it was all that could be desired, as it has been in former years,

but I shall hesitate to advise planting it largely until after another year's trial. Among newer varieties which I have so far tried there are none that I can conscientiously recommend for their flavour, but as my trials have only included eight or ten varieties, they have not been exhaustive by any means, and others may have been more fortunate. One thing is certain, there are many varieties sent out on the strength of their handsome appearance which never should have left the raisers' hands. The best time to plant is as early as it is possible to obtain well-rooted runners, as this ensures a good start, and most varieties will give a good crop of their best fruits in the following year. Later-planted runners do not get well anchored before winter and fail to make good crowns, while those kept over in nursery rows until spring give no fruit the first year.—J. C. TALLACK, *Livermere Park, Suffolk.*

—The best flavoured kinds I have grown are Keen's Seedling, President, Empress of India, Latest of All, Dr. Hogg, British Queen, Oxonian, and Waterloo. The early kinds, as far as I have grown them, have not much to recommend them as regards flavour. Royal Sovereign is an immense cropper, the fruit of fine appearance but soft. Noble, much as it has been decried, is fairly good if well ripened in a sunny spot, and quite as good as, though earlier than, Sir J. Paxton. Dr. Hogg and Latest of All are my best late kinds, the former requiring the same treatment as British Queen. Royal Sovereign is, I find, the best kind from a garden point of view, as it combines with fair quality a good constitution and freedom of fruiting. The better flavoured new kinds I have tried are poor growers in this garden. As soon as it is possible to get well-rooted layers is the best time to plant, always provided the ground has been well prepared and the plants are well attended to. If these are ready by the middle of July they should be planted before the roots have time to coil themselves thickly in the pots, and if well watered both at planting time and during dry weather afterwards there is no fear of their flowering prematurely, as starved plants sometimes will. Such plants fruit freely the season after planting, and go on improving for two or three seasons according to the variety.—H. R. RICHARDS, *Coldham Hall, Bury St. Edmunds.*

—The Strawberry crop in this part of Devon has been heavy. I find the best for general use are Keen's Seedling, Noble, Vicomtesse Héricart de Thury, Auguste Néaise, Sir J. Paxton, Sir C. Napier, Impératrice, and Waterloo. Many of the newer kinds have British Queen blood in them and do not grow well on the light soils of the shaly water stone of South Devon. I have grown Royal Sovereign one year. The fruits are fine, but the leaf stalk is too long, requiring so much space under glass. The above eight kinds are hardy and with one exception are of good flavour. I find deep cultivation is not necessary: 12 inches to 15 inches, with a liberal supply of cow and horse manure not too much rotted, the plants grow satisfactorily. Before planting the ground is well trodden. The last week in July is a good time to plant, and two years is long enough for them to remain. At the end of February of the second year a good top-dressing of stable manure is given them.—G. BAKER, *Menblaud, Devon.*

—The best flavoured Strawberries in this district are Sir Joseph Paxton, which is handsome in berry, very solid and richly flavoured, also forces well. Keen's Seedling is one of the best in every way. President is one of the best for general use, highly flavoured and splendid in colour. Royal Sovereign is, I think, a Strawberry that may displace Sir Joseph Paxton in time. It is free-growing, fine in berry, and of a rich vinous flavour. British Queen is an extra highly-flavoured kind; however, the plant is tender and requires the best cultivation. Vicomtesse Héricart de Thury has the one good point of thriving in most soils and situations. It is very hardy, an abundant cropper, richly flavoured, and one of the best for forcing in large quantities. Dr. Hogg is a first-class Strawberry in every re-

spect, and should be grown where British Queen does not succeed, owing to its hardier qualities. Waterloo is a most distinct and first-class sort, of excellent flavour. Laxton's Latest of All is a sort worthy of cultivation; fruit extra large and of good flavour. A useful sort is Lord Napier, handsome and of good flavour. The best early and late kinds are—First earlies, Keen's Seedling, King of the Earlies, Noble, Vicomtesse H. de Thury, La Grosse Sucrée, Sir J. Paxton. Second earlies: Royal Sovereign, James Veitch, Lucas, British Queen, Dr. Hogg, Gunton Park. Late sorts: Waterloo, Latest of All, Lord Napier, Frogmore Late Pine, Elton Pine, Helene Gloele. Leader is of splendid colour and flavour. Veitch's Perfection is a first-class flavoured fruit; in fact, I think it as fine as British Queen. Monarch is rich-coloured, firm in the flesh, and of good flavour. I cannot too strongly recommend layering into small pots as early as runners can be procured, say by middle of July, and planting at the end of July in well-prepared beds. A capital crop of Strawberries will be procured the following June. I treat several sorts as annuals, with the best results as to size and flavour.—J. W. McHATTIE, *Strathfieldsay.*

—On the black clay subsoil of this locality some of the finer flavoured Strawberries are difficult to cultivate, and must be grown as biennials to obtain good fruit. The kinds which stand best are La Grosse Sucrée, Royal Sovereign, President, Elton Pine, and Bieton Pine. The newer variety, Stevens' Wonder, also promises well. The best flavoured kinds are British Queen, La Grosse Sucrée, President, and Royal Sovereign: the best early kinds, Royal Sovereign, La Grosse Sucrée, and Noble; the best late kinds, Jubilee, Laxton's Latest of All, and Waterloo. Of the newer kinds Royal Sovereign and Leader are the best. The best time to plant is the second and third weeks in August. With me the indispensable kind is President, which crops well, forces well, and bears carriage better than any other kind.—J. JACQUES, *Waddesdon, Bucks.*

—On the rather retentive soil in this locality Strawberries of all kinds do well. After trying various sorts I still cling to President as the best all-round kind; it is a general favourite, and unsurpassed for flavour. British Queen, Dr. Hogg, Vicomtesse Héricart de Thury, and Keen's Seedling are also of excellent quality, and do well with generous cultivation. Viscountess, La Grosse Sucrée, and Royal Sovereign are the best early kinds here, either for forcing or the open air; and Oxonian, Frogmore Late Pine, and Elton Pine the best late kinds. Of the newer kinds of Strawberries, none have "caught on" so well as Royal Sovereign, either for market or private garden; Lord Suffield and Gunton Park are both good sorts for the garden, the latter rather too dark in colour to be attractive. No plan can beat layering early runners into small pots and planting them out the first week in August on well-prepared ground so as to ensure a good root-hold before winter sets in. Forc'd plants, cared for when turned out from under glass, and planted out in rows 3 feet apart and 2 feet apart in the rows, give splendid crops the following season, but they must be copiously watered to induce quick root action.—WILLIAM NASH, *Bulminster Gardens.*

—The best flavoured Strawberries grown here are Vicomtesse Héricart de Thury and Duc de Malakoff. Scarlet Queen is also excellent, but although of brilliant colour, I understand it does not maintain it when preserved. La Grosse Sucrée is still one of the best, this and Royal Sovereign making a handsome pair. The best early varieties are Vicomtesse H. de Thury and Royal Sovereign, the best late being Waterloo, which is first-class in this district. Royal Sovereign is the best of the newer ones I have tried. Monarch and Leader were not in good form and no opinion could be had. I always endeavour to plant early, a good time being the end of July or early in August; in fact, earlier if the ground can be cleared and prepared for their reception, as then the plants get well established

before the winter, the soil being warm and conditions favourable to rapid growth.—J. J. CRAVEN, *Allerton Priory Gardens, near Liverpool.*

## FLOWER GARDEN.

### NOTES FROM FILLINGHAM CASTLE, LINCOLN.

It would be scarcely possible to exaggerate the brilliancy of the autumn flowers on this lovely October morning. The garden suffered much in August from the long drought, and even the deluge that began about August 21 and lasted a fortnight failed to save the Phloxes, which simply never bloomed. They were, however, almost the only real victims, and now the late autumn flowers have come successfully through these climatic ordeals, and the long borders devoted entirely to plants flowering from July to November are a blaze of colour. The very tall late single *Helianthus rigidus elegans* towers 10 feet high at the back, with the much dwarfier *H. rigidus semi-plenus* below. At least fifteen different sorts of Starworts give varying shades of purple and pale lilac, from the tall waving branches of *Aster Novi-Belgii* Robert Parker to the brilliant *Amellus* (over which the lovely butterflies hover) and the very free-flowering *A. acris* and *A. vimineus*. The early *Chrysanthemums* are gorgeous, masses of different colours, and never so good as this year. The *Pentstemons* are quite at their best, and better this year from seed than cuttings. *Rudbeckia Newmanii* is very gay, and so are *Gaillardias* and *Montbretias*, these last flowering very late this year. The graceful form and crimson colouring of leaf and seed of the *Mountain Spinach* come in lovely contrast to the lower tones of the *Statice*s, and show well near the snowy white of the *Japanese Anemones*. The starry flowers of the *Nicotiana affinis*, grown for the sweetness of its evening perfume, now look up as if to welcome the autumn sun, instead of hanging as if dead under the summer rays. A lovely effect is produced by a mass of *Golden Rod* and the blue-grey of the tallest *Starwort*, all forming a background for the brilliant crimson and yellow spikes of the *Tritomas*. Turning down a side border devoted to rarer plants, which are therefore less massed and stand more out in detail, I can show you a beautiful picture. In the foreground is a large plant of *Funkia grandiflora* or *F. japonica*, undisturbed for several years and throwing up tall spikes of lovely pure white scented flowers above its pale tender green leaves. Just under it the bright blue flowers of the *Plumbago Larpentæ* contrast well with their foliage of dark green, changing to metallic-red; at the back, *Helenium grandicephalum striatum* grows 4 feet high (and never more gay than at the present moment with its red and yellow striped flowers); whilst a little further on a new note of colour is struck by the glowing pink of *Sedum spectabile* side by

side with a plant of white-leaved variegated *Mint*, a late spike or two of *Veronica sessilis*, the whole carpeted by some of the lovely *Tufted Pansies*, which, after suffering severely by the summer drought, are now flowering freely, and none better than *Border Witch*, *A. J. Rowberry*, *Duchess of Fife*, *Christiana*, *W. Neil*, and *Sheba*, which I can only describe as a rayless *Son of the Rock*.

In other parts of the garden the Ivy-leaved *Geranium Charles Turner* and the dark blue *Lobelia* still show in lovely contrast, the bushes of scented *Geraniums* grow 2 feet high in places, and the *Begonias* blaze under the October sun. *Salvia patens* is flowering most profusely, and its brilliant blue was never more effective than, as now, backed by the greenhouse *Tropæolum Fireball*, with its sea-green leaves and crimson flowers. I may mention that *Tropæolum speciosum* is thoroughly at home here and grows in wreaths of scarlet and green 20 feet high up grey stone pillars carefully faced with coarse wire netting for it to cling to, and it also throws its lovely wreaths over the hardy *Fuchsias* growing under the north wall. The *Dahlias* also deserve notice this October morning, being just now at the very height of their glory. Amongst the best here are *Aphrodite*, *Gloriosa*, *Matchless*, *Bertha Mawley*, *Mrs. Peart*, *Ernest Cheal*, *Purple Prince*, *Countess of Pembroke*, *Miss Irene Cannell*, *Delicata*, and *King of the Cactus* (now most splendid), and the gay little old favourite, *Glare of the Garden*. I again make a note of the superiority of cuttings over old roots, the cuttings flowering most profusely, whilst the old roots have produced an immense growth of leaves.

The *Roses* seem to have stood well both drought and deluge, and many are the lovely blooms to be found down the *Rose border*, both on the dwarfs and also on the climbers up the rustic 7-foot trellis at the back. Passing to this border under an archway covered with *Gloire de Dijon* *Roses* and purple *Jackmani Clematis*, I find nothing better at this moment than *Marie d'Orleans*, *Mme. Hoste*, *Souvenir de S. A. Prince*, *Catherine Mermet*, *Beauté Inconstante*, *Duc A. de Luxembourg*, *Comtesse Riza du Parc*, *Marie van Iloutte*, *Camoens*, *Distinction*, *Anna Olivier*, *Mme. de Watteville*, and *Marquise de Salisbury*. Amongst the climbers at the back, *Ophirie* has never flowered so well or continuously as this year. Alike in sunshine and rain it has been a mass of bloom. *Celine Forestier* has also been very good, and a few late flowers are still to be found on *Mme. Alfred Carrière*, *Bouquet d'Or*, *Cheshunt Hybrid* and *No. 1* and *No. 3* (sweetest of *Roses*) *Waltham Climbers*. I must not conclude these few notes on a *Lincolnshire garden* without naming the *Limber Clove Carnation*. A few of its lovely crimson flowers are still to be found, and will continue in all their beauty till killed by the frost.

October 15. MRS. PORTMAN-DALTON.

***Tropæolum speciosum* on the Pentland Hills.**—This *Tropæolum*, which so many people

try to grow, but fail, I saw growing freely other day at one of the shooting lodges belonging to Mr Charles W. Cowan, of Valleyfield, *Northlothian*. The lodge stands on one of the beautiful green slopes of the *Pentland Hills* in the *South county*, at about 1000 feet above sea-level. *Tropæolum* is trained on sheets of wire netting fully 5 feet wide and over 15 feet long, attached to a portion of the south front of the building making in all a sheet over 25 feet wide and 15 feet in height. The border in which it grows is only about a foot wide, and contains, I am told, small stones to which the roots love to cling. It has been watered at times with sheep manure water, which it seems to enjoy. Besides the wonderful *Flame Flower*, with its thousand bright scarlet flowers, I observed well-trained plants of *Gloire de Dijon* *Rose* and *Clematis Jackmani* in fine bloom.—W. L. M.

**Storing Dahlia roots.**—Many people would have more success with their *Dahlias* had they more suitable place for storing the roots during the winter months. The plan adopted by me of suspending from the roof of a dry, airy shed is not a good one, as shrivelling, more or less, and weak growth in spring are sure to follow. As long as actual frost is kept from them, the best storing place the better. I have found a place better than a cool underground cellar, where shutters could be put to the window in case of severe frost. Here the temperature is uniform one, and the roots remain in a pleasant and sound condition. In places that fluctuate regards temperature, dry rot often sets in. The best display of *Dahlias* I ever had was on plants that were not lifted from the border in autumn, but merely covered with mounds of fine cinders; but the position was a dry, well-drained one and the winter not severe. The fact, however, goes to prove that the roots are far harder than many suppose them to be.

**Michaelmas Daisies at Trent Park.**—These useful autumn flowers are well cared for here. None of the sorts could be considered the least dowdy in appearance, the selection being confined to the best of each type. The plants are growing in a long border with a northern aspect and seem to do extremely well. By a careful arrangement when planting, the tall-growing sorts form a splendid background, following with those of intermediate growth and finishing off in front with dwarf varieties. One especially noted was the easy way in which the plants were staked and tied, so that the graceful beauty of the plants were prominently set forth. The varieties in the pink of condition were *Amellus bessarabicus*, *Aster Novi-Belgii* de *la Roche* with grand heads of blossoms, on compact growth not exceeding 3 feet in height; magnificent plants of *A. N.-B. Robert Parker*, the lavender-colored blossoms making an effective contrast with those of the white and darker shades of colour in the background. *A. N.-B. Mrs. John Wood* is one of the best white flowers with a yellow centre, and was very free, branching and distinct. *Aster cordifolius elegans* was much admired with its long graceful sprays of soft lilac flowers. The best of the collection was *Aster N.-B. levigatus*, in some gardens labelled *A. formosissimus*. It bore grand heads of rosy-lilac flowers. The height of the plants was about 2½ feet. *Aster Areturus* was very distinct, its long individual footstalks giving it increased value as a cut flower. *Aster multiflorus* with close heads of pure white flowers was developing fast, and appeared in better condition than in past years. Single-stemmed plants of *A. Coombefishaere*, with its medium-sized flesh-coloured blossoms were unique. *A. vimineus nanus* with its beautiful graceful sprays of tiny white flowers was just past its best, but *A. vimineus* was developing lovely growth to follow on. Other good kinds were *A. polyphyllus*, pure white, yellow disc; *A. puniceus pulcherrimus*, bluish white, yellow centre; *A. Lindleyanus nanus*, rosy-lilac; and *A. N.-B. Maia*, possessing large full, rosy-lilac flowers with golden centres. D. B. C.

LILY OF THE VALLEY IN FRUIT.

The Lily of the Valley is so well known as one of our most beautiful native wild flowers, and is so extensively cultivated for its spikes of pretty bells, that one rarely, if ever, even thinks of it as sometimes producing very handsome racemes of fruit in autumn as well as the flowers of spring. *Convallaria majalis* is a monotypic genus of the Lily family (Liliaceae), and

pogon, &c. In colour there is some variation, though most are red, as in *Smilax*, *Asparagus*, and *Convallaria*, but now and then purple, or a lovely blue, as in the Turquoise Berry, *Ophiopogon japonicus*, and *O. Jaburan*. Some of the *Polygonatum*s have red fruits, but the common Solomon's Seal (*P. multiflorum*) has blue-black lustrous fruits not unlike black pearls. The berries of *Ruscus aculeatus*, or

through the gnarled old stems and branches of *Lentiscus* and other shrubs or small trees.

Although the Lily of the Valley in several of its best forms fruits year after year at Straffan, where it is very beautiful, I rarely see it elsewhere, nor do I remember ever seeing any record of its fruiting as growing wild in the woods of Westmoreland and Cumberland, though of course, it must often do so. The fact that several of the best varieties or forms of Lily of the Valley are growing side by side in beds at Straffan may account for its fruiting there so luxuriantly, but perhaps if artificial pollination were resorted to the pretty red berries might be obtained with tolerable certainty, as is the case with the exquisite blue Turquoise Berry when grown in pots in a dry cool greenhouse or frame. All the kinds of Lily of the Valley are so lovely that one can never have too much or too many of them, but when the spikes of snow-white cups or bells are succeeded by clusters of olive-green, orange, and crimson berries, an additional advantage is obtained.

F. W. BURBIDGE.

**Carnation Maggie Lawie or the Burn.**—"C.'s" note to the contrary notwithstanding, I maintain that my last communication was correct in every particular. I was quite aware that one who, perhaps, had some right to give it a name called it The Burn Pink, but the fact remains that it was called Maggie Lawie by the raiser, and that it was distributed by that name at his request. It is a matter of small consequence. My note was a protest against the too common practice of interested parties giving high-sounding new names to old subjects.—M.

**Viola pedata.**—This unique little species in the more sheltered parts of the rock garden still flowers more or less profusely, and is of value on that account alone. Where the plants are given a fair depth of peat and loam, with plenty of grit and a small quantity of very old manure, it is surprising how long even small examples will continue in flower. This is not the case when a position either too sunny or too dry is given. So pretty a plant is worth some care to make it a complete success, and where small groups can be formed in the rock garden it is well to give a mulching of small stones about the plants to retain a uniform condition of moisture. Heavy soils should be freely mixed with short leaf-soil to the extent of

Lily of the Valley in fruit. From specimens sent by Mr. F. Bedford, the Gardens, Straffan House, Co. Kildare.

produces comparatively large terra-cotta red or vermilion coloured fruits about the size of large Peas, on spikes 9 inches to 12 inches in length. This illustration, from specimens kindly sent from Straffan by Mr. Bedford, gives a good idea of the size, form, general contour and pose of the fruit. The berry-like fruits of Lily of the Valley are characteristic of many of the Liliaceae, such as *Asparagus*, *Smilax*, *Ruscus*, *Polygonatum*, *Ophi-*

*Butcher's Broom*, are rarely seen in England though common in S. Europe. They are of a bright crimson-red when ripe and contrast very effectively with the dark olive-green of the flattened branches. One but rarely sees the *Smilax* fruiting in our open-air gardens, but at Antibes and elsewhere in S. France and Italy it is wreathed with bright red fruit clusters, as it scrambles along with the prickly *Asparagus*

how long even small examples will continue in flower. This is not the case when a position either too sunny or too dry is given. So pretty a plant is worth some care to make it a complete success, and where small groups can be formed in the rock garden it is well to give a mulching of small stones about the plants to retain a uniform condition of moisture. Heavy soils should be freely mixed with short leaf-soil to the extent of

one-half, and in such a mixture the plants usually thrive and flower abundantly.

**Double Violets in autumn.**—What lately surprised me was to find not only the well-known double Violet Marie Louise blooming profusely in the open border at Fulbeck Hall, Lincolnshire, but also that too little known paler variety Lady Anne Campbell just as full of flower, the blooms being large and the stems long. I have grown this excellent Violet for a number of years, but have never gathered a bloom from the plants, however well grown and healthy, until February, when it eclipses all others as a profuse bloomer. The plants at Fulbeck prove that soil and situation have a great influence on even the date at which Violets flower, and I may mention that at Gunton I have more than once seen the white Comte de Brazza blooming freely in September in open borders, a thing it would never do with me here in Notts till spring, even in frames. I have now (beginning of October) plenty of blooms of Marie Louise.—J. CRAWFORD.

### NARCISSUS CALATHINUS.

THE writer of the notes on *Narcissus calathinus* which appear on page 277 of THE GARDEN has earned the goodwill of all lovers of wild flowers by trying to save from extinction in its only native habitat—*Ile Dréneec*, off the coast of Brittany—that interesting variety of *Narcissus triandrus* which he describes as *N. calathinus* (Lin.). He truly says that writers about *Narcissus*, both English and French, are inconsistent not only with one another but with themselves in the names they give to the varieties of *N. triandrus*; but one thing is certain, that Linnaeus, in enumerating *N. calathinus* as a species, had not present, either to his eyes or to his mind, any variety of *N. triandrus*, still less the variety found in the *Ile Dréneec*. Linnaeus published his "Enumeration of Species" about the middle of last century, and the *triandrus* of the *Gleanans* was discovered by Bonnemaison of Quimper in the beginning of this century; it was communicated by him to Loiseleur, who described it in error as *N. calathinus* (Lin.) in his "History of Daffodils Indigenous to France," published about A.D. 1810, and the error was adopted by De Candolle in the letter-press of Redouté's "Liliaceae," published about the same time. Linnaeus in enumerating *N. calathinus* refers the species to Clusius' "Rariorum Plantarum Historia" (A.D. 1601), p. 158, "*Narcissus juncifolius* amplo calice," No. 9. Those who will turn to that delightful book will find that Clusius there figures and describes a form of *N. odoratus* which he saw flowering in the Botanic Garden at Leiden in A.D. 1595. Moreover, it is certain that in the Linnaean Herbarium the specimen of *N. calathinus* is a form of *N. odoratus*. These facts were recognised by botanists in England at the beginning of the century. In the volume of the *Botanical Magazine* for A.D. 1806 (t. 934), Sims, the editor, fully points out, in figuring *N. calathinus* as a form of *N. odoratus*, that it is the *N. calathinus* of Linnaeus enumerated in his "Species Plantarum," ed. 2. The same editor, in vol. xxxii., tab. 1300, published in A.D. 1810, in figuring *N. triandrus*, warns his readers against the error of De Candolle in "Redouté," in making *N. calathinus* of Linnaeus a form of *N. triandrus*. Nevertheless, in spite of these correct portraits and warnings, English writers—Haworth and others—subsequently adopted the error of Loiseleur and De Candolle. The writer of the notes in THE GARDEN rightly says that the variety found in the *Ile Dréneec* is unique. Many years ago I received more than once from M. Blanchard, of the Brest Botanic Gardens, bulbs which I cultivated in my greenhouse and compared with

the typical form of *N. triandrus* from Oporto and other varieties collected in other parts of the Spanish peninsula. Some collected by Mr. George Maw near Gijon, in the Asturias, were given to me by him as *N. calathinus*. These, as well as occasional individuals amongst those sent from Oporto, had the crown as long or longer than the perianth when turned down; still, I could easily distinguish them by other characters from the *Dréneec* variety.

The writer in THE GARDEN says that Willkomm and Lange in their Spanish Flora claim a place in Spain for this variety, which they call *N. calathinus* (Lin.), alleging that it is found near the town of Goditano, in Spain. I have referred to the passage, "Flora Hispanica," vol. i., page 152. The authority cited is Boutelou, a Spanish botanist, who compiled a famous herbarium, still preserved, about the beginning of this century. A specimen in it is labelled *N. calathinus* (Lin.), "in agro Gaditano," that is, "in the neighbourhood of Cadiz"—a very unlikely place for any of the *N. triandrus* tribe, of which none is known to have been found within 300 miles of Cadiz; but the authors add "perhaps the specimen belongs to *N. juncifolius*." This is likely enough, as that species is common near Cadiz. They conclude by saying that *N. calathinus* (Lin.) belongs properly to *Gallia Armorica* (? *Armorica*), the Roman name for that part of France which includes Brittany and the adjacent islands.

I would suggest in consideration of the above facts, which anyone may verify for himself, that the variety ought to be called *N. triandrus* (Lin.) var. *calathinus* (Loiseleur).

Edge Hall, Malpas.

C. WOLLEY-DOD.

**Eulalias in Surrey.**—I think it is to be regretted that one does not oftener meet with these in gardens, considering they are not quite so tender as some people think. Just now they are conspicuous ornaments in the pleasure ground. The variety *zebrina* is very telling just now with its many crimped plumes. I have this variety in three positions, viz., on the lawn and in the herbaceous border, also in a dell in deep, open soil in rather a shady position. It flowers in all the positions named, but it flourishes the best in the same position as *Tropaeolum speciosum* does so well in. Here it throws up its grass and plumes 8 feet or 9 feet high by the dozen. I protect my plants in winter by placing round them some short sticks about a foot out of the ground and stuffing inside these some Fern.—J. R. HALL, *Foxwarren Gardens, Cobham*.

**Bulbs for cut flowers.**—If not already done no time should be lost in getting bulbs planted. During the past few years the demand for fresh cut flowers has increased enormously, and in spite of the enormous importations and the low rates at which they are sold, there is still room for growers in the neighbourhood of towns. No position I have yet tried for the beds suits them so well as the spaces between rows of bush and pyramid fruit trees, for when these are set out at from 12 feet to 18 feet apart there is ample room for a good bed of bulbs. The trees form an excellent wind-break, and the bulbs grow up, flower, and go to rest before there is much need to tread on the beds, while by the time fruit-picking comes on they have mostly gone quite to rest. I find Daffodils of all kinds the best of all bulbs for cutting, and they do not require lifting every year. Hyacinths and Tulips, Irises, Lilies of many kinds all do well on the permanent bed plan, and *Gladiolus The Bride* is very beautiful in the south of England, but as it pushes up its growth before the severe weather comes on we have to cover the beds with litter during frost. I need hardly say that Lily of the Valley is indispensable where cut flowers are grown, and the beds should occupy both sunny and fully shaded spots,

so as to prolong the season as much as possible for a very late supply is in many cases fully profitable as a very early one.—J. GROOM, *Goport*.

**American Carnations.**—In reply to Mr. Herrington's remarks in your issue of October 1 dated from Madison, N.J., I beg to say that what I wrote on this subject was intended for English and not American readers of your journal. There is no doubt whatever that these Carnations specially treated for the purpose, are excellent winter bloomers, but having imported a number of the best, or what are considered the best American Carnations direct, I find that they will not please in this country. What I meant by "papery petals" was that they had an absence of quality, were thin, and had not that substance that is here considered essential in a good Carnation. The saw-edged petal which is present in nearly all American Carnations is fatal to it being any matter of consideration over here. It is no "ground of offence" to me whatever. I look at the question simply as a matter of business. As an exhibition variety a saw-edged Carnation is absolutely valueless. The American Carnations, from the fact that the two countries England and America, look at the flower from two different points of view, are, commercially speaking, of no use whatever in England.—H. V. WEGUELLIN, *St. Mary Church, Torquay*.

### NOTES ON HARDY PLANTS.

**Aster spectabilis.**—I have only just had practical explanation respecting the garden qualities of this distinct species. For instance I have in these columns said repeatedly that the flowers are true to the name of Michaelmas Daisies by coming into bloom at the latter end of September, and further, that the flowers are fine blue, or rather a fine blue-purple, and my eye the nearest to a true dark or Oxford blue of any of the Michaelmas Daisies. I have heard from various correspondents that in these respects—timely flowering and deep blue colour—their experience of the plant was quite opposed to my statements, and I felt either someone's material must be wrong or someone must be colour-blind, and I tried to get over the difficulty by procuring plants from several sources which they seemed to contradict my plant. Looking round at the first real show of the Starworts, September 27, I saw a medley of form and colour in one group, where I at once recognised my favourite form of *spectabilis*. It would seem from this that at least three vars. under the same name, from three sources, flowered Michaelmas, but the colours were as different as could be, and the deep blue I have always known and which I procured from the Edinburgh gardens at least ten years ago, was not only vastly superior, but the only variety worth a place in the garden. From these facts I do not wonder that correspondents had such a poor opinion of *spectabilis*; to say the least, if their plants are true to name, they must be inferior varieties of the species.

**Alpine Strawberries** fruiting in October are to near the end of the year are among the most pleasing of all rock garden plants. This long season of fruiting is due to a peculiarly persistent habit and also to the great variety of kind, including European and Himalayan species. In its turn the variety, as regards the fruits, the size, colour and shape, is one of the most charming features where the varieties are grown and kept separate. The deep, rich, fresh colours of the fruits are refreshing to sight as well as taste. I find these to fruit nowhere so well as on a part of the sunny rock garden, and though it may seem questionable whether such a position is not too costly quarters for such rampant growers, we may come to present facts, and ask, What prettier in the autumn?

**Euphorbia pilosa** is equally attractive in the autumn as in early summer. The young growth is of a rich and conspicuous yellow, practical

whole plant, so that the yellow flowers can be distinguished close to. Later the plant becomes more like other plants, but to change in the autumn. Now the leaf tints are rich to the extreme—yellow, brown and bronzy scarlet, and a group of half a dozen plants 1½ feet high and 4 feet or 5 feet through makes an effective show. I have lately met with a variety called *P. grandiflora*. This is a name one never likes to use without good authority, but in this case there is certainly a larger and nobler type of plant to warrant the name, and, what is better, I find it more vigorous under culture.

**Pyrethrum uliginosum.**—The uncertainty of this doing well year by year is pretty well known. There is a way of dealing with it on which you may depend for a crop of fine flowers every autumn. It is to divide a number of the thickly matted roots every year in April. At the second year these are at their best, but generally the first autumn there will be a good show of the white heads if the summer has been favourable. By this plan you get a succession of strong plants and a longer season of bloom.

Yoodville, Kirkstall.

J. Wood.

### MIXED FLOWER BORDERS.

The accompanying illustration shows the pleasing effect produced by the informal introduction of fine-foliaged plants into the flower border. In this wide, wall-backed border there is no attempt at monotonous regularity; the Yuccas stand boldly, at different heights, from the flowers, while, further down, the thick foliage of an evergreen, spreading out to the box-edged verge of the path, makes an artistic break in the continuity of the view, temporarily shutting out the arrangement of the border, which becomes visible again in the distance.

This mingling of flowers with fine-foliaged plants, and here and there with shrubs, is often most effective, the courses of the former being set off to the best advantage by the noble or graceful forms of the latter, while they, in their turn, derive additional charm from such environment, their contour and striking outlines being most clearly defined when rising from a floral base. A clump or two of the Giant Reed (*Arundo donax*), a hardy Palm, or a few plants of one of the Yuccas or Dracenas at once give a character to an informal flower border, which may, with good effect, be broken at intervals by Pampas Grass (*Glycerium*), New Zealand Reed (*Arundo conspicua*), clumps of the Plume Poppy (*Aconita cordata*), which grows to a height of 7 feet, some of the larger shrubby Spiraeas, such as *S. Lindleyana* and *S. arifolia*, the Venetian Sumach (*Rhus cotinus*), or some of the more graceful of the Bamboos. These subjects, when given ample space, such as is available in a border similar to that seen in the engraving, assume their characteristic forms in a manner impossible to them when relegated, as we so often see them, to the crowded shrubbery, while with their varied heights they improve the appearance of the border, as a whole, by preventing any idea of stiffness and forming an admirable foil for the flowering plants with which they are associated.

S. W. F.

ties showing much diversity: they are useful for cutting, and last in a cut state. If anyone will take the trouble to save a little seed from one or two of the best types, and sow it, the result is sure to be quite satisfactory.—R. D.

### ROOTED CARNATION LAYERS.

THESE should be potted off without delay, especially from plants layered in the open air, because they are exposed to the danger of having the soil washed away from their shallow roots by the heavy autumn rains. Some growers who cultivate only in the open ground may contemplate planting out in beds at once, in which case the soil should be deeply dug and made as fine as possible, and, unless there is reason to think it is poor, there is no need to add manure, especially any of a rank character, as it may lead to canker and other evils. With care the rooted layers can be lifted with some soil adhering to their roots, and if some fine compost, made up of good loam finely sifted, leaf-mould, and rough sand, be placed about the roots, they will get to work much more quickly. Any fresh loam which may be employed should be carefully looked over for wireworm, and in digging the ground any found in the soil should be at once destroyed. A light soil can be made heavier by the addition of some strong loam of a clayey character to give it substance, as Carnations do better in a fairly

part of the spring they were planted out rather later than is desirable. The recent rains and cold nights were marrying the purity of the flowers, and this fact makes early planting out all the more desirable.—R. D.

**Cactus Dahlia Fire King.**—This is one of the most useful scarlet Cactus Dahlias I know. The plant is a very vigorous grower, and has done well with me in this not one of the best of seasons and in light, warm soil. Many of the otherwise good Cactus Dahlias have their blooms partially hidden by the foliage, which is a great drawback, at any rate where they are allowed to remain on the plants. Fire King is one which shows its flowers off to advantage, and so is good for either purpose. It is very easy to over-water Dahlias, this having the effect of making them run up tall and show few blooms. Mulching is most useful, and the neglect of it incurs more labour with the watering-pot, with in the end less satisfactory results. Old Mushroom manure, leafy refuse, or even lawn mowings answer the purpose, the two first being preferable.—C. C. H.

**Lilium Wallacei.**—Some Lilies increase rapidly by division of the bulbs, while others make but very slow progress in this way. One of the most prolific of all in this respect is *Lilium Wallacei*, a small-growing Lily, bearing a great general resemblance to some members of the *elegans* section. The bulbs, however, divide

A mixed flower border.

heavy soil than in a light one. If the soil is of an adhesive, clayey character, then it is well to lighten it. Old mortar rubbish, wood ashes and finely-sifted cinder ashes, long straw manure, cocoa-fibre refuse, half-decayed leaves and such-like will all help to lighten it, and to some extent act as fertilisers. When a bed is formed in the open at this season of the year it is well to raise it 6 inches or so above the level of the surrounding land, as water from autumn and winter rains will not so readily gather about the roots. The plants should be from 15 inches to 18 inches apart, according to their vigour, and if any of them—and this applies more to old plants than to young rooted layers—have long, loose shoots, they should be pegged down to prevent injury from rough winds.

R. D.

**The Tuberose in the open air.**—I saw a few days ago quite a large patch of Tuberoses which had grown freely and flowered finely in most cases; it was in the flower garden at Fanham Hall, Ware. They were in the open, but sheltered all round and at no great distance. The gardener said that owing to the dry weather in the early

naturally with great freedom, being quite unlike those of *L. elegans* or any of its varieties, but *L. concolor* behaves much in the same way. *L. Wallacei* is a very pretty Lily with orange-red flowers, borne about the end of July. It is not at all a common Lily, and is not sufficiently vigorous to hold its own with some of the more robust members of the genus. A coloured plate was given in THE GARDEN for January 30 of the present year, but the flowers are not drooping as therein depicted. The general appearance of a flower is, however, well shown. *L. Wallacei* is a native of Japan, and has been known in this country for about twenty years.—H. P.

**Dahlias.**—The fact that a frost of 8° was experienced on the morning of October 7, and completely settled all Dahlias in the open ground it was not possible to protect, just at a time when they are in great request, leads to the suggestion that another season a certain number should be planted in a position where they may be easily and effectually protected at any sign of frost, and so prolong for two or three weeks the season of flowers that cannot be replaced by hardier things. Good forms of the Cactus and decorative types,

**Single garden Marigolds.**—A bed of these is now a pleasant sight. The double and single types both are delightful autumn flowers, because they bloom freely all through the late summer and autumn months. I have some pretty single varie-

always the most acceptable for cutting, cannot well be protected on the open border. They throw the flowers well above the foliage, and grow under good culture to a very considerable height, so that anything raised above them in the shape of tiffany is very liable, should the weather change suddenly in the night, to be found at a distance from the plants in a rather mutilated condition. I have decided to reserve for some of them in future seasons a portion of a south-east border under a wall in a sheltered slip garden. A few upright poles will be placed along the outside of the border nearest the walk, and cross pieces nailed respectively to these and to the wall, so that any shelter afforded can be secured to the same and rolled up during the day under the wall; plenty of head room will be allowed, as the majority of varieties under consideration go up with good cultivation quite a foot higher than the height given against their names.—E. BURRELL.

#### WINTER VIOLETS.

I do not remember a finer lot of plants than those lifted this year for winter work, alike in size, in flower already developed and yet to come, and in immunity from red spider. This is in a great measure owing to the fact that we have had a summer with a rainfall rather over the average, and especially that the plants had the benefit of one or two thorough natural soakings soon after they were placed in summer quarters. So far as the preparation is concerned, I find with our light, dry soil that two things are indispensable—viz., good plants to start with, and a west or north-west border for planting. For several seasons the runners, with the tiny rootlets just showing, were dibbled into the open border where they were to remain, but the better plan is to insert them in a frame for a few weeks, and then to transfer to the summer border. Here they are planted 1 foot apart each way, the only preparation being to fork in a fairly good dressing of well-decomposed manure. A mulching of peat Moss or spent Mushroom manure is put on at once, and an occasional soaking given if the weather is hot and dry for a time after planting. Summer culture is simply to keep the bed clean, to nip off runners and to keep a sharp look-out for red spider. This pest has not been troublesome this year, but in hot, dry summers it is strongly in evidence, and with plants close to the surface of the ground remedial measures in the shape of insecticides are hardly practicable. The best preventive of future attacks is to mulch well with fresh horse droppings, breaking them small and packing well under the foliage, following the same with (in the evening) a thorough soaking of water. Why the fumes of ammonia that rise with the moisture that settles on the foliage should be so objectionable to the insect I cannot say, but I can recommend the remedy to all who are similarly troubled. The agency of the ammonia fumes being answerable for the clearance is testified by the fact that soakings of water without the mulching are not effective. When a considerable number of flowers is open, and buds in an advanced stage are plentiful, great care is necessary in the lifting. Cutting round should be practised at a fortnight and a week previous, and the plants taken up with a good ball. I house the winter Violets in pits where Primulas and similar plants have been standing through the summer months, and the soil from which has not been removed for years. Trenches are taken out slightly wider and deeper than the plants require, and they are placed in these at a sufficient distance to allow a very little space between the outside leaves. For a filling-in compost I mix three parts stiff roadsidings and one of horse droppings, and this is tightly packed both at the base and sides; a heavy watering follows, and the plants are shaded with a bit of tiffany for a few days if a spell of sunshine follows the planting. Plenty of air and the exclusion of frost are the secrets of successful winter treatment. If the pits are not heated, mats or dressed covers should be placed over them

in sharp weather; a little air both at back and front is, however, always necessary. If no special sorts are required in size or colour, the two best and most reliable Violets respectively as double and single are Marie Louise and Wellsiana. If there are any better I shall be glad to hear of them. E. BURRELL.

Claremont.

#### SEPTEMBER IN SOUTH DEVON.

DURING the past month 3.09 inches of rain fell on 15 days against 5.45 inches on 28 days in September, 1896, the average for the month being 2.39 inches. Three years ago we had a phenomenally dry September, for in that year the rainfall amounted to only 0.01 of an inch. The total fall for the nine months of the year amounts to 26.93 inches. During the same period of 1896 not much over half this quantity fell, the record being 14.62 inches. At the present, indeed, we are over 4 inches above the average for the first three quarters of the year, which stands at 22.63 inches, the total rainfall up to the present having been 26.93 inches. The month has been tolerably bright, the sun having shone for 156 hours 35 minutes, against an average of 157 hours 50 minutes, while in rainy September, 1896, only 105 sunny hours occurred. For the nine months already elapsed the sun has shone for 1495 hours 35 minutes, the average being 1478 hours 45 minutes, and the record for the preceding year 1469 hours 25 minutes. The year, up to the present, has therefore been rather above the average in sunshine, while 1896 was below the average. The mean temperature for the month (56.1°) is nearly 2° below that for September, 1896, viz., 57.9°, and the average for the month, 58.0°. The highest sun reading for the month was 115.2°, and the highest screen reading 66.5°, while the lowest reading in the screen was 42.0°, and the thermometer on the grass never fell below 31.0°, which it registered on the 19th. The total horizontal movement of the wind was 6291 miles compared with a record of 8689 miles in September, 1895, which was a particularly boisterous month and very different from September, 1895, the calmest month for two years, when the wind movement only amounted to 3175 miles. The greatest daily movement in the past month was 553 miles on the 5th, while the highest hourly speed occurred between 4 and 5 p.m. on the same date, when a rate of 33 miles per hour was registered. In September, 1896, the speeds were as high as 784 miles in 24 hours and 46 in the hour.

We have been fortunate this year in escaping the gale which wrought such havoc in the gardens on September 25, 1896, when almost all of the tall herbaceous plants were levelled to the ground. Now the garden is bright with perennial Sunflowers, Michaelmas Daisies, Dahlias, Japanese Anemones, and scarlet Lobelias, while the Virginian Creeper is fast assuming a crimson tint, and here and there the topmost boughs of the tall Elms show a tinge of yellow. With the latter days of August the swifts left us, the swallows following suit in mid-September, while by the end of the month most of the house martins had taken flight, bearing with them the last reminder of summer hours. An autumnal air pervades garden, field and hedgerow. The Old Man's Beard hangs in grey festoons from the branch and garlands the red rock, and on every side are indications that the year is settling to its rest. In

#### THE WILD GARDEN

the Acanthi have produced their lofty spires of bloom, the strongest grower being *A. mollis*, some of whose flower-stems have attained a height of 8 feet, while the spikes of *A. spinosus*, with its deeply-cut leaves, rarely exceed a height of 3 feet. *Achillea ptarmica* fl.-pl. The Pearl is still in flower, and its long-enduring blossoms will last in beauty through a portion of October, while the light blue of *Agathea cœlestis* is still in evidence. Of the perennial Asters or Starworts, a number are now beautiful, of which *A. Amellus bessarabicus*, with its large lilac-purple blooms, is

one of the best. This variety is not such a rampant grower as many of the others, which, with difficulty kept within bounds, and is, therefore, well adapted for situations where a kind of increase rapidly from the root-stock would be out of place. Three good whites, *A. Novi-Bel Harpur-Crewe*, *nivens*, and *polyphyllus*, have been in bloom, the first-named variety being trifle the earliest, but all three will be far past their best before the later, darker-colour kinds are in full beauty. Of these, *A. N. Archer-Hind*, with purple-blue flowers, is but just expanding its blooms, while *Pluto* and *Flora*, two good dark-flowered varieties, have but just commenced to flower. The handsome *Robert Park* also one of the *Novi-Belgii* section, is in flower and very beautiful it is, growing as does to a height of 6 feet and more, its grace shoots studded with large pale lilac blossoms. The well-known variety *A. diffusus horizontalis* so common of old in cottage gardens, is also in bloom, but, in comparison with the more attractive sorts now in commerce, is of little value for a decorative point of view. Another variety of merit with in the gardens of the poor, *A. linoxy* sometimes known as *Chrysocoma linoxyris*, is still more generally as *Goldlocks*, is a September bloomer, its flower-heads forming a mass of bright yellow during that month. The dwarf *A. diffusus* has been in profuse bloom during the month and has considerably exceeded its usual stature. This variety is seemingly more appreciated by the lepidoptera than are others of the *Starwort* family, as often many butterfly, red admiral, peacock, and tortoise-shell, as well as a good quantity of the brown gamma moths may be seen settled on its blooms, when but few are to be found on other varieties. With the honey-bee is also an especial favourite. The charming *A. ericoides*, with its numberless minute white stars, is fast approaching the zenith of its beauty, as is *A. cordifolius elegans*, which is much still in habit of growth, though varying in the colour of its blossoms. *A. puniceus pulcherrimus* very handsome *Michaelmas Daisy*, growing to 5 feet high and being of vigorous habit, its flowers when first produced are of a faint tint, but soon assume a white colour. They are borne in the greatest profusion, the shoots being literally smothered in blossom. *Aster Novæ-Angliæ ruber* and *Melpomene*, the former a dark red, the latter deep purple, have also commenced to display, and the late-flowering *Aster grandiflorus* has already expanded some of its large purple golden-centred blossoms. This is a superb variety, but is usually so late in blooming that it runs considerable risk of being cut by the frost before reaching perfection. In warm, sheltered situations in the south-west, however, unless exceptionally cold weather occurs in October, it usually matures its flower-crop unharmed.

The white *Anemone japonica Honorine Jobert* has been beautiful throughout the month, and grows very strongly, reaching a height of nearly 6 feet in moist situations. The flesh-coloured variety is also pretty and much preferable to the darker-tinted magenta-red. *Belladonna* does well in the south-west, and many a long list to be seen in full bloom in front of the glasshous on a September day, their light pink flower-seeds arising aloft on the dark chocolate stems—a pretty colour contrast. The tuberous *Begonias* are not so lovely than ever, and leave not an inch of ground visible between their leaves, their vivid colours and those of the new race of *Cannas* rendering the autumn garden brilliant on sunny days. Although recognising to the full the beauty of these large-flowered *Cannas*, one has a strong liking for an old favourite, *Canna Elmendorfii*, whose drooping rose-pink flower-seeds is now very charming, and whose broad, M-like leaves are most effective in sub-tropical gardening. *Campanula carpatica* and *C. turbinata* have both been blooming sparsely, while *Cybele* and *Herberti* blossomed well into the month. Dahlias have made a great show, there being many new *Cactus* varieties of fine form and colour, in some of which, however, the flower

ough beautiful when cut, fail to show above the foliage when in growth, a bad fault, which renders them useless for garden decoration. The second coming of the light blue Delphiniums has proved a welcome tint, and flowers are still to be met from *Erigeron speciosus*, which has been in bloom since early June. The little Mexican Daisy (*Erigeron mucronatus*) is as long-suffering as the former and is still producing its simple flowers. The Marguerite Carnations are pretty at this season of the year, the tone of their abundant leafage contrasting well with the green of the grass and with the pinks, scarlets, and whites of their own blossoms. A few bright crimson blossoms mark a bed of *Dianthus Napoleon III.*, as do some large golden stars, the spot where *Doronicum plangeum excelsum* was a sheet of bright yellow early in the year. These *Doronicums*, if lifted and placed under glass, are very useful for the production of bloom in the early spring. The *Millardias* still make a brave show in their scarlet and gold, and *Geum coccineum* has here and there a few open blooms, while a near relative, the *Waterlens*, is producing quite a quantity of autumnal wens. The Cape Hyacinth (*Galtonia caudicans*) has been a charming sight through the early part of the month, but is, unfortunately, not so lasting as we could wish, its white bells, though opening in succession, fading rapidly. The grey-white pom-spikes of *Funkia ovata* possess a suave aroma of their own, in striking contrast to the brilliant great flower-heads of *Erythrina cristallina*, some almost 2 feet in length, and reaching a height of over 5 feet from the ground. These are handsome when arranged in a tall jar, but care must be taken in handling them, as they are armed with sharp, sickle-shaped thorns that are capable of inflicting a deep score, especially upon male hands. *Hedychium Gardnerianum* has been in bloom in the garden, but a sunny position requisite to ensure its flowering. It is generally stored under glass during the winter, and planted out in well-prepared soil in the month of May. The perennial Sunflowers have been, as usual, among the brightest of September flowers, *Helianthus multiflorus* and *H. rigidus* Miss Mellish being the most effective; whilst a line of *H. giganteus* that tops a fence at the garden end is, with its (I) fringe of light yellow, a striking sight. *H. multiflorus* and its varieties, as well as *H. rigidus* (the type), were at their best in August, when the fallows loved to hawk over the broad bank on which they grew, for the golden glow was ever armoured with insect life. The *Hydrangeas* have been masses of bloom, but the tints are now rapidly becoming sere, and only the remembrance remains of the heyday of their beauty. The *Hippophaes*, however, are still brilliant here and there, while the last of the *Lilies*, *L. tigrinum* (the type), while preserving its character as a September bloomer, shed its last blossom ere the second week of the month. *Lobelia fulgens*, though having been in flower since the end of July, is still brilliant, and will continue to make a spot of vivid colour in the garden for some time to come. *L. rosea* is also still in bloom, as is the (I)-tinted *L. sylvatica*. A few *Montbretia* blossoms show out at long intervals in the borders, their bright orange-scarlet serving as a reminder of the brilliant display the thick sheaves of flower-spikes made not many weeks since. The *Fennel-leaved Matricarias* are still in bloom, and self-sown seedlings of *Nicotiana affinis* have taken the place of earlier matured plants, and, with the ever-strengthening daylight, open their blossoms as soon as the sun is off the border. A bed of *Oxalis flabunda rosea* remains bright, and the *Paris Lilies*, yellow and white, now grown to huge bushes, are studded with their star-like flowers.

*Plumbago Larpenae* has covered a large expanse of rock and has invaded much of the surrounding ground, but, seeing its beauty in the latter part of the year, one is loth to disturb it. A few *Poppies* have perfected infrequent blossoms, notably the Iceland and Welsh *Poppies*, which now and again a pale apricot bloom of *Papaver pilosum*, whilst one splendid blossom of *P. bracteatum*, a relic of the lost summer, has ex-

panded perfect petals of vermilion. The Ivy-leaved *Pelargonium* *Alme. Crousse* and *Souvenir de Charles Turner* still mask the rough stone edgings with salmon and cerise, and the spikes of *Phygelius capensis* bear at wide intervals their crimson blooms, while *Polygonum capitatum* has not yet ceased its flowering and the *Pentstemons* are still gay. Of the *St. John's Worts*, *Hypericum Moserianum* and *H. nepalense* are in bloom, and a scarlet *Helianthemum* has a fair amount of blossoms. The *Everlasting Flowers* (*Helichrysum*), though stiff in form, are bright in colour, and appear to advantage when the autumnal days have obliterated so much that is beautiful in the garden. (*Oenothera Lamarekiana* has been in flower through a great portion of the month, while the herbaceous *Phloxes*, though not emulating their summer display, have perfected many heads of bloom. The *Winter Cherry* (*Physalis Alkekengi*) is now approaching the zenith of its beauty, and its vivid orange calyces glow brightly among its leafage. This is very useful for indoor decoration, the calyces remaining in perfection for many months. The graceful *Pyrethrum uliginosum* is now in full flower, its wide-rayed white stars, borne on tall, slender branching stems, being most acceptable for arranging with the darker coloured *Starworts*, for by the time this *Pyrethrum* is in bloom the majority of the white *Asters* are past their best. *Rudbeckia Newmani* is a breadth of gold, and is at its best early in September, by which time *R. purpurea* is declining in effectiveness. The scarlet *Salvia* and *Salvia patens* have both been lovely during the month. The former usually endures the winters here without harm, and I have known *S. patens* to pass two winters in the open without protection. The latter is, however, so valuable for its colour, that it is always well to lift and store it rather than risk its loss. *Scabiosa caucasica* has produced a few of its beautiful light blue flowers, and *Sedum Sieboldi* is fast approaching perfection. At the commencement of the month the *Golden Rod* (*Solidago ambigua*) was in bloom, and *Stokesia carynea* has now unfolded its large purple blossoms, while *Tradescantia virginica* and *Zauschneria californica* are both in flower.

#### THE TEA ROSES

have been very lovely throughout the month, and many a charming bouquet of these fair flowers has been gathered. Two especially beautiful new introductions are *Queen Mab* and *Souvenir de L. Guillot*. Both are much similar to *Irene Watts*, of which I made mention in an earlier note, and have in their petals salmon, apricot, orange, yellow and rose delicately blended. Like the beautiful *Ma Capucine*, they are only valuable in the bud or half-opened bud form, as when fully expanded they are too single to appear at their best. The single white *Macartney Rose* has been in bloom since the end of June, and will continue until the weather becomes too cold for the chaste white blossoms to expand.

Of shrubs, *Choisya ternata* and *Cytisus fragrans* have come into second bloom, while in the early part of the month *Escallonia montevidensis* had its blossoms thronged with butterflies. *Hibiscus syriacus* has been covered with multitudinous flowers, and the shrubby *Veronicas* are in bloom. The *Sea Buckthorn*, with its grey-green foliage and orange berries, has been very ornamental, and the *Pampas Grass* has reared its tall plumes aloft on slender shafts, while *Aralia spinosa* has flowered well. The large standard *Magnolia* still bears its fresh, ivory-white chalice daily, and, from the number of buds still swelling, will bloom throughout October if not checked by frost.

Of climbers, I saw lately a large plant of *Abutilon vexillarium* in good bloom, and a fine *Plumbago capensis* growing against a cliff in a sunny, sheltered position is a mass of light blue flower-heads. Near to the latter is a large expanse of *Physianthus albens*, whose flowers are now fading, but which has produced a quantity of great seed-pods. *Solanum jasminoides* has been more lovely of late than earlier in the year, as the *Ampelopsis*

*Veitchi*, which surrounds and intermingles with it, has turned a deep crimson, which colour contrasts with the white flower-clusters, creating a most charming effect. Of *Tropaeolums*, the *Canary Creeper* (*Tropaeolum canariense*) has spread a golden trail over old walls and amongst the Ivy and evergreens, and the scarlet *Tropaeolum Lobbianum* has painted rock and trellis with vivid colour, while *T. tuberosum* is just commencing to flower, fully a month later than in Dorsetshire. I find it impossible to get early blooms from this *Tropaeolum* in my garden, even when the tubers are started in heat and planted out after good growth has been made.

Many annuals have added to the brightness of the garden during the month, the chief being blue *Cornflowers*, *Coreopsis lanceolata* and *C. sanguinea*, *Eschscholtzias*, *Marigolds*, *Prince's Feather*, *Salpiglossis*, *Scabious*, scarlet *Zinnias* and *Sweet Sultans*. S. W. F.

## TREES AND SHRUBS.

### THE VERY LARGE-FLOWERED HYDRANGEAS.

It is more particularly concerning *Hydrangea Otaksa* var. *monstrosa* that I wish to say a few words. *Hydrangea Otaksa* was introduced from Japan by Siebold about the year 1868, and was considered remarkable for the size of its clusters of flowers, but the variety *H. O. monstrosa*, which was put into commerce a few years since by M. Lemoine, of Nancy, is much superior to it, its large pink flowers, produced in terminal globular cymes, sometimes forming clusters of huge dimensions. The leaves are opposite, broad, and deeply serrated.

Like the common *Hortensias*, this plant cannot exist permanently in the open air without shelter, in the climate of Paris, at least during severe winters, but in the west of France the finest *Hortensias* are grown entirely unprotected in the open air. I have had the opportunity of seeing in the garden of an amateur at Viry, near Paris, a dozen clumps of *Hydrangea Otaksa monstrosa* which were most remarkable for size and general vigour of growth, and bore flower-clusters of extraordinary size, some of them which I measured being more than a foot in diameter, on branches which were over 3 feet high and nearly an inch in diameter. Some of these clumps, each of which was composed of two plants, were showing at the same time from five to eight flower-clusters of the same dimensions, while on other branches they bore clusters in a less forward stage of development.

These *Hydrangeas* were growing in tubs 2 feet in diameter and 1½ feet high, formed of barrels cut in two and placed on an open terrace in the full sunshine. Each tub contained two plants in a clump set in good heath soil. The bottoms of the tubs, being pierced with holes and well drained, permitted water to escape easily. These plants are stood in the *Orange house* at the approach of winter. In spring (May or June) they are put out of doors in the full sunshine and are then watered regularly and copiously, each tub receiving on an average about two gallons daily. No manure is used in the soil. When growth is commencing the branches which have borne flowers are cut back to one or two strong buds next the base, and not more than five or six branches should be retained on each plant, so that the clump of two may have ten or twelve branches which will bear flowers at their extremities. All other branches are to be suppressed, and all lateral shoots that may push are to be pinched out as they make their appearance. Every two or three years it is necessary to re-tub the plants

in order to renew the soil, and at the same time to divide the clumps and trim up the individual plants to improve their appearance if needful. From the foregoing it is evident that, contrary to what is generally supposed, *Hydrangeas* can be grown in a condition of vigorous health in the full sunshine, and that their flower-clusters may attain unusually large dimensions without the application of any special manures. All that they require is suitable soil, a sufficient supply of water, and judicious attention in the matters of pruning and disbudding. *Hydrangea Otaksa monstrosa* is easily increased from cuttings taken from the flowering branches; these cuttings will produce low-sized or dwarf plants which at blooming-time will be crowned with flowers, presenting the appearance of an immense roundish cyme.

Another species of *Hydrangea* (*H. paniculata grandiflora*) introduced from Japan in 1864, and also put into commerce by M. Lemoine, produces very large flower-clusters which might be termed prodigious, as they take the form of great, elongated panicles at the extremities of vigorous-growing branches. This variety of *H. paniculata* has, like the typical species, the advantage of being very hardy in the open air, and forms a shrub which may attain a height of 4 feet 10 inches or more. Its leaves are opposite or, more frequently, arranged in whorls of three. It is one of the most noteworthy subjects, and yet up to the present it is but little grown. The flower-panicles which it produces are large in proportion to the vigour of the plant and the favourable conditions under which it is grown. It requires a soil that is free from lime, light, moist, and largely composed of vegetable mould. It is also necessary that, by pruning and pinching, according to the strength and vigour of a plant, not more than from two to six flowering branches should be allowed to grow upon it. These will then produce panicles of flowers 1 foot 8 inches long or more and 10 inches or more in diameter at the base.

The regular flowering time of these *Hydrangeas* in the open air is from July to the end of September. They are, therefore, especially to be recommended for the autumnal floral display in gardens. They are also very easily forced in hothouses, so as to flower through the winter and early in spring. What is commonly called the flower in *Hydrangeas* is in reality the calyx, the sepals of which assume a petaloid character, growing to a great size at the expense of the other floral organs, the corolla and stamens, which sometimes even disappear entirely.—A. CHARGUERAUD, in *Revue Horticole*.

#### THE MAIDEN-HAIR TREE.

The Ginkgo was first made known by the German botanist Kaempfer, who discovered it in Japan in 1690, and in 1712 published a description, with an excellent figure of the foliage and fruit, in his work on that empire. He had found the tree in temple gardens, and believed that it was Japanese, for early European botanists in Japan had to do most of their botanising in gardens, and did not realise that many of the most popular Japanese garden plants had been brought from China with the Buddhist religion. Among these introductions was the Ginkgo, which grows nowhere indigenously in Japan, although it is now found in most temple gardens both in China and Japan, and it is possible that this once widely-distributed type has only been preserved by cultivation; for if we are not mistaken, the Ginkgo is nowhere known in a wild state. The unusual power of this tree to bear cold and

drought would indicate that it has long inhabited some region with a severe continental climate, and if it exists now at all outside of gardens it is probably in some of the elevated districts of Western China or of Mongolia, or on the still unexplored mountains of Northern Corea.

In old Japanese temple gardens the Ginkgo is frequently 120 feet high, with a tall massive trunk 6 feet or 7 feet in diameter and large drooping limbs sweeping out in wide-spreading graceful curves. Such trees are impressive objects, especially in autumn, when the leaves which flutter on their long stems assume the colour of gold. Ginkgo biloba, which is also sometimes called *Salisburia*, and by English-speaking people the Maiden-hair Tree, was introduced into the Botanic Garden at Utrecht about 1730. A male tree flowered in England as early as 1795, but it was nearly twenty years later before female flowers were seen, De Candolle discovering them in 1814 on a tree at Bourdigny, near Geneva. Scions from this tree grafted on a staminate plant produced in 1835 perfect fruits in the Botanic Garden at Mont-

in height from 2 feet to 3 feet in a year. Nurserymen propagate a variety with leaves which are larger and more deeply divided than in the type, and others with slightly pendulous branches and with leaves striped or blotched with yellow but none of these varieties have much to recommend them.

The yellow flesh of the Ginkgo fruit has most disagreeable, rancid flavour, but the seed kernel, which resembles the kernel of the Almond, is sweet and palatable. In China the trees are cultivated for the fruit, which is sold in great quantities in all markets, but in Japan where the fruit is also gathered and sold, the trees are cultivated for ornament only, and usually only in temple gardens. The wood is bright yellow with a close compact grain, and is capable of taking a beautiful polish; it is however, soft and easily broken, and is not considered particularly valuable.—*Garden and Forest*.

**Tamarix chinensis.**—This is admitted to be the best of the genus, and is found in some localities as *T. japonica* and also *T. plumosa*; the latter

A bowl of single-flowered Tree Peonies.

pelier, and fruit-bearing trees are now common in Europe; in the United States they exist in Central Park, New York, in Germantown, Pennsylvania, near Louisville, Kentucky, and probably in many other localities. In the United States the Ginkgo is perfectly hardy as far north as Massachusetts, and thrives as well in the south as it does in the north. There are not, however, any very large or fine specimens in this country, although the tree planted nearly a century ago in the garden at Hyde Park, on the Hudson River, has begun to assume mature habit and shows that later generations may hope to see Eastern America rival Eastern Asia in its Ginkgo trees.

The Ginkgo is very easily raised from seeds, which can now often be purchased from dealers and which retain their vitality for several months, and female plants, which are less common than males, may be obtained by grafting; it is easily transplanted and thrives in deep, rich drained soil, in which it will often increase

name is suggested by the dense, plume-like habit of growth and panicles of flowers, which are bright pink in the buds and turn to paler pink when expanded. I have found this genus extremely easy of propagation. It is an easy matter to prune time to cut the smaller twiggy growth into lengths of a foot and put them into the ground at the border the greater part of their length. Most of these will grow if the season is favourable. In a greenhouse is available the cuttings may be inserted in pots earlier in spring, and the plants thus started will be much stronger at the end of the first season and should flower the second year. In the year 1893 M. Lemoine sent out a new species called *Tamarix kasegharica*, which was raised from seeds collected in Central Asia. This flowers in September and has proved to be a good and distinct plant. It was afterwards found to be but a form of *T. hispida*, which has a very wide range geographically. Indeed, the genus has a very wide distribution. *T. gallica* is found all along the Atlantic shore of France; *T. indica* is a native of the East Indies; *T. tetrandra* comes from the Crimea, and *T. g-*

...nica is distributed over a great portion of the ... rope, among the mountains and along the river ... ks.—E. O. ORPET, in *Garden and Forest*.

GARDEN FLORA.

PLATE 1141.

TREE PEONIES.

WITH A COLOURED PLATE OF A SINGLE TREE PEONY.\*

Among the beautiful flowers of early spring are the Tree Peonies, as the sub-shrubby *P. Moutan* with its host of gorgeous and inimitable varieties is called. Beautiful as these Tree Peonies

back in this direction, a good depth of loam answering all their requirements. Perhaps the most important item in their successful cultivation in the open garden in Britain is that of

POSITION,

which is even more important in southern countries than in the north. This is due to the occasionally severe as also late frosts in spring, which injure the young growths and disfigure the flowers. The position for these plants should be decided upon with care for two reasons, viz., on account of the spring frost nipping the young shoots, and, secondly, because of their impatience at being disturbed when once planted. To attempt to grow Tree Peonies

affecting the plants. As the plants were nicely established, each year saw a beautiful display. In much the same way may choice shrubs be utilised in private gardens where these *Moutan* Peonies are grown. The gentle slope suggested above is not in any degree essential to success, yet it is in such a position, provided also a good depth of prepared soil is given, that the plants are generally more quickly established. In the more favoured parts of the British Isles these Peonies may be planted in almost any position where a good depth of soil is obtainable, and in these places it is not easy to predict the size to which the plants will attain in the course of years. Coming into flower so early in the year, it is impossible to over-estimate their value, for

A double-flowered Tree Peony.

undoubtedly are, it is only rarely we see a collection or even a selection of them in any garden. There are no other flowers in the early spring that can in any degree compare with them. Nor can it be urged that they are unknown, seeing that quite large collections have been grown in some of the leading nurseries during the last twenty years. Flowering, too, here all else in this noble family of hardy plants, a few groups would make a goodly show in any garden in the early spring-time. These plants, moreover, in common with the group to which they belong, present but few difficulties to the cultivator, none of which are insurmountable. Being perfectly hardy, there is no draw-

in positions where much shelter exists naturally is a step in the wrong direction, and should be avoided, as it is fraught with as much danger as is any attempt to cover for protection. The too sheltered position is not that in which the best matured growth is secured, while covering the plants in case of frost is liable to render the growths tender, and therefore more susceptible to injury. Where such exists there is no better position in the garden than a gentle slope with a western or even a north-western aspect. In the latter the growth and bloom are somewhat later, and if only a few days, lateness is important when these trying seasons occur. Many years ago I planted the whole of a very large and choice collection in this way, and with a bank of *Rhododendrons* on the sunny side protection of a suitable kind was afforded without in any way

even in the year or two of the growth and before their flowering is a certainty year by year, there is more than a passing beauty in the many and varied tints of the young and beautiful leaves.

In the matter of soil these shrubby kinds differ in no wise from the herbaceous section; indeed, the whole race of Peonies may be put down not only as gross-feeding plants, but as plants requiring a greater depth of rich soil for their successful cultivation than perhaps any other group of hardy perennials. At the same time it should be remembered that, once planted, they are safe for a dozen or even a score of years, with no other care than an annual mulching of rich material. In common with the herbaceous kinds, the *Moutan* Peonies prefer a rather strong loamy soil, though not retentive or too heavy. In the positions

Drawn for THE GARDEN by H. G. Moon at Gwyte Manor. Lithographed and printed by J. L. Gart.

selected, whether for beds or irregular groups or masses, the original soil should be excavated to fully 3 feet deep, and if the top spit is of good material, this should be set aside and returned. In most gardens there is a heap of old potting soil, together with peat siftings and the like, and this, incorporated with some good fibrous loam and plenty of manure, would make an excellent mixture. Very sandy soils should have a proportion of clay or heavy loam added.

The plants usually obtained in nurseries are about two years old, and grafted on the roots of the herbaceous kinds. Such plants should always be planted with great care, and be buried at least 2 inches or 3 inches below the union. It is also a good plan to thrust a stout piece of wire through the ball of the plant to extend 6 inches above ground, and bound somewhat firmly to the stem to prevent snapping off. A good season for planting is the early autumn, September and October preferred, unless the plants are established in pots, when they may be planted in spring when the flowering is past. In this case a thorough soaking of water will be needed at planting time. But whether planted in spring or autumn, the young plants during the first two years will be greatly benefited by occasional waterings in dry weather, liberal soakings of liquid manure in the heat of summer or twice or thrice during winter not being thrown away. Such a course of treatment may appear elaborate, and to some unnecessary, though it is scarcely possible to err on the side of supplying the richest of soils to these gross-feeding plants. Those who have not space in the garden, or from other reasons cannot grow them in this way, may attempt their culture in pots or even tubs: indeed, as pot plants for the conservatory they are not unknown, though it is to be feared that too often methods foreign to their well-being are adopted to bring the plants into flower, with little or no regard for their future. Where these plants are grown in this way, large pots will be necessary and strong plants to make a successful start, as also the most liberal culture. Artificial heat beyond what is needed for keeping away frost only should be given, taking care that the plants are removed as soon as flowering is past into quarters congenial to the proper maturing of the growth, which is the most important item so far as another season's bloom is concerned. Frequent, that is annual, repotting should not be indulged in, as the plants are impatient of disturbance. That these lovely Peonies are amenable to a generous treatment when grown in pots may be gathered from the fact that in my experience three-year-old plants in pots 14 inches across have produced splendid blossoms nearly 12 inches across in some instances, others of 8 inches and 10 inches diameter being quite usual in the more recent novelties. Equally remarkable with size is the range of colour to be found among these plants; every conceivable shade of colour and many exquisite combinations, together with double, semi-double, and single varieties. These single kinds, one of which appears in the accompanying plate, as well as the semi-double varieties, are largely of Japanese origin. Many of the kinds, while exceedingly beautiful, are also delightfully fragrant.

The propagation of this unique race is largely carried out by grafting on the roots of the herbaceous kinds, usually *P. edulis*, an operation best done during August, and in a cold frame where a close atmosphere may be maintained.

E. J.

**Narrowwater Park, near Newry, co. Down.**—This domain is just now very beautiful, rich in autumn colour, and the visitor is charmed

with the view of Warrenpoint and Carlingford by the fleeting light and shade on the mountains and by the glints of light on the sunlit sea. The crimson *Agaricus muscari* jewels the grass under the trees, and a fine group of *Lobelia cardinalis* Firefly near one of the largest known examples of *Gunnera manicata* is most brilliant and dazzling in its effect. *Tropeolum speciosum* is rampant here with its vivid crimson scarlet flowers and turquoise-blue berries draping bushes and dangling from the Lily stems. One special feature at Narrowwater near the gay flower garden is an Oak tree, up which a plant of common Traveller's Joy has scrambled like a tropical liane, and its glossy fruits now shine like burnished silver in the sun. There is a very large specimen of the richly coloured *Vitis Cœnœtia* in the garden wall just now most effective, as its leafage is changing from rich olive-green to yellow, orange, and crimson, or russet and brown.—F. W. B.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**ASPARAGUS BEDS.**—The tops having become quite matured nothing would be gained by allowing them to remain uncut after this; indeed, their early removal would prove an advantage to allow what sun we may yet have to reach the crowns. The stems should not be cut down close to the surface of the bed, as by leaving them a few inches high they mark the position of the crowns and prevent them being injured by treading or wheeling over them. Having removed the stems, hand weeding is better than hoeing if the beds have become foul, as this does not disturb the surface roots. The question of mulching depends in a great measure on the nature of the soil and the position of the beds. On light and well-drained land, or that of a sandy nature, a dressing of seaweed or well decayed manure may be given with advantage, as there is no danger of the soil becoming waterlogged before spring. A cold and badly drained soil is more often the cause of the roots perishing during the winter than severe frost, therefore it is only increasing the evil on such ground to add a thickness of manure on the surface, as this prevents both wind and sun acting freely on the ground, and excess of moisture cannot pass off. It is usual with such soil to form raised beds to ensure drainage, and where these are a foot or more above the natural level a slight dressing of seaweed or manure may be given, and if some is packed round the sides of the beds it prevents to a great extent severe frost striking to any great depth into the ground. For heavy land, compost of a light and porous nature, such as the edgings from roads which contain plenty of grit, burnt wood and other vegetable ashes are also beneficial.

**FORCED ASPARAGUS.**—With a good plantation of roots to draw upon, this delicious vegetable is obtained far more easily and at less cost than French Beans during the winter if only a warm greenhouse or pit is available. A certain portion of the oldest beds should be marked off now for lifting, but it is better to allow the crowns to remain in the ground as long as possible before they are taken up, to ensure a season of rest, when they will force all the more readily. Not less than three-year-old crowns should be lifted, or the produce will be light. In many large gardens it is Christmas before forced Asparagus is put on the table, though it can be obtained much earlier if necessary. The great thing to guard against, however, is not to unduly hasten it by affording a high temperature either by top or bottom heat. The more slowly it is grown the stronger will be the grass; therefore those who are anxious to produce a few early dishes, say by the beginning of December, should place the crowns in the forcing pit quite a month or five weeks before that time. A good bed of leaves which will give a bottom-heat of from 65° to 70° will be sufficient to start growth, while the top-heat need not ex-

ceed 60°. It is when this is allowed to exceed 70° during the short, sunless days that the grass comes weak and is unfit for use. It is better even to allow the night temperature to fall 55° than to raise it much above 60°. If the pits are not furnished with hot-water pip covering must be employed at night, while may be necessary, as the season advances and the nights become colder, to afford a good thickness of lining round the pit of long stable litter. Blanched Asparagus, which is easily obtained by obscuring light, finds favour in some establishments. Before placing the roots in the frame, that the leaves below are affording a steady warmth. These should be made quite firm by treading, adding more if necessary, so that will be ready to receive the crowns they will not be more than a foot from the glass. A few inches of loam soil or spent Mushroom manure should be placed over the leaves on which to arrange the roots. In lifting these, trim the longest roots off, and place the crowns quite close together, afterwards covering them with fine soil or sand. The steam arising from the leaves will afford plenty of moisture, and watering by any other means will be unnecessary. If a succession has to be maintained, other frames must be prepared in the same way, in readiness to receive another batch in the course of a fortnight or three weeks.

**SEAKALE.**—This probably is the most common of all forced vegetables, but its quality and pearance greatly depend on the treatment afforded, and it is appreciated accordingly. Until it is tender and well blanched it finds little favour and when not sent to table in a fresh condition becomes bitter and almost offensive. The earliest batch of plants which has occupied a sunny position during the summer will be found much further advanced as regards shedding the foliage than that grown on cool, moist borders. An outside supply of Beans is cut off by frost, and Seakale is about the first thing we turn to to assist in affording variety, but it is a mistake to lift the roots directly the leaves part from the crown. These with weeds, &c., should be removed so that the plants are fully exposed to a few frosts, which cause an enforced rest, which, though it may be for less than a fortnight's duration, is sufficient to make growth start more quickly when subjected to artificial heat. There are various methods employed for forcing this vegetable which vary according to the quantity required and the convenience at disposal. Small quantities, such as a few dozen crowns, may be packed rather closely in a deep box, such as bulbs generally arrive in, standing this beneath the stage of a warm greenhouse. Every particle of light must be carefully obscured, and if the outside of the box can be packed round with damp leaves of Moss so much the better, as this maintains an even temperature and prevents the escape of moisture. Some cover the crowns with 6 inches or more of sifted leaf-mould. Growth pushed through this and the shoots come beautiful white and crisp, and may be cut as soon as they push through the surface. Larger quantities should have a corner in the Mushroom house devoted to them, as in this position it can be easily examined and cut as required. Growth is rather too slow at this season, but good results to come from crowns placed in an ordinary cellar without some artificial warmth, though such a position is most suitable later when growth is more easily excited. It is very important that sufficient crowns be put in at regular intervals to meet the requirements, as the quality is quickly impaired if kept for several days after it is cut before being used. Seakale always of better quality when brought gradually under a good body of leaves, hence there is much to recommend the old-fashioned plan of covering the crowns with pots or boxes, but as this plan is hardly suitable for the early supplies, lifting the roots is the only alternative until the turn of the year, when the permanent stools may be covered as described above.

**GENERAL WORK.**—The autumn so far has been most genial, and the growth of winter crops is

ceived no check. The condition of the soil, has caused the seed of weeds to germinate freely, and if advantage is only taken to get these cleared down during dry weather, it would tend greatly towards securing a clean garden next spring. Exhausted crops, especially Peas and runner Beans, should be cleared off the ground as soon as the treading caused by their removal will do heavy soil a lot of harm later on when saturated with moisture. Continue to sprinkle with lime or wood-ashes between the rows of winter Spinach if slugs prove troublesome. Edishes, too, which have been sown at the foot of a south wall, should also be dusted over, and the clean, dry straw should be shaken over them at the approach of frost. In warm localities sowing of Black Spanish and China Rose Edishes may be made in a sheltered corner, and if they have the protection of a temporary frame, useful gatherings may be obtained most of the winter. Dig up and remove to a cool shed or dark Autumn Giant Cauliflowers when they have attained a serviceable size, as they would last in a better condition under cover than when exposed to frost. Also remove the stems of decayed leaves of those that have been cut over, as they not only look untidy, but also give an unpleasant odour when decaying.

RICHARD PARKER.

### FRUIT HOUSES.

**EARLY VINERY.**—The time for starting will of course vary according to the time ripe Grapes are required in the ensuing year, but should they be wanted in April next, the Vines should be started no later than November. This will allow none too much time if the forcing is conducted, as it should be, in a gradual manner, and it is always best to err on the safe side and to allow a margin in the shape of an extra week or two than to have hurried the Vines, particularly at the outset, when they are naturally slow in starting into growth. If the necessary heat is to be obtained from a fermenting bed of leaves and manure for the first few weeks, the materials should be collected and thrown together to ferment. After being turned once or twice to liberate rank steam and gases, it may be taken in and made up into a long ridge-shaped bed in the body of the house. The border occupies the body of the house, except a temporary stage of boards laid upon blocks to keep the materials off the soil, as they would do more harm than good if placed directly upon the latter. This heap should be added to as often as required, for which a heap should always be held in reserve outside. When replenishment is needed, take the opportunity for turning the whole mass, and if much vapour is given off, slightly open the top ventilators to allow it to pass away. The genial heat given off by the fermenting bed answers all requirements for the first few weeks, and is to be preferred to fire-heat, while it economises the latter. However, it is only those living in country districts who can avail themselves of this method, and those less fortunately situated must perforce make use of artificial heat from start to finish. At starting, the daily routine will be to syringe the rods once or twice a day with tepid water, according to the weather, but always have the wood dry by nightfall. The temperature should be 55° by day, with a rise of 10° more with sun-heat, and when air has been admitted, shut it off not later than 1 p.m. Keep the vapour troughs filled with water and do not let the night temperature exceed 50°. Until the Vines break regularly the rods should be bent round, or otherwise lowered from the trellis, so that the points or extremities should be below the level of the wall plate, which will ensure a more regular break by equalising the flow of sap.

**POT VINES.**—These are used in many places in the garden, and when skilfully cultivated give most excellent results. Should ripe fruit be wanted from them by April, they had best be sown early in November, and prepare the house for their reception forthwith. This should, if

possible, occupy a south or south-eastern position, and the roof should have a fairly steep pitch in order that every ray of sun may be utilised. With regard to the interior, a good bed should exist or be constructed to hold a bed of leaves if the plunging system is favoured, not but that equally as good results can be obtained if the pots are merely stood on a stage erected over the hot-water pipes running round the sides or front of the house. Plunging is the most economical if plenty of tree leaves can be obtained, as this both economises fire-heat and means less labour in the shape of watering when the pots are surrounded with the moist materials forming the bed. When the pots are to be plunged they must be stood on a good firm base, and for this purpose use either inverted flower-pots or build piers of loose bricks to the required height. Enlarge the crock holes before placing the plants in position, and a mound of rich compost, largely consisting of fibrous loam, may be built up round these piers and level with the base of the pots for the roots to work in. The bed may then be filled with Beech or Oak leaves, which have lain in a heap outside sufficiently long enough to have fermented, but do not compact them too much at the outset or until it has been found, by means of the dipping thermometer, the amount of heat that is being given off. The bottom-heat must not exceed 75°, and if the mercury indicates a higher figure than this, the leaves must be loosened and partially pulled away from round the pots until it is found that the heat is subsiding, when they may be replaced. The canes should be bent down to ensure their breaking properly, and in all other matters of detail as regards temperature, &c., observe the directions given above for permanent Vine-foreing. With regard to watering, the soil, after being moistened at the start, should be kept neither wet nor dry until the roots become active. When the Vines break freely, more water will be required, which, it is hardly necessary to state, must always be applied in a tepid state. If the pots are to be stood on side stages it is a good plan to stand each pot in another two or three sizes larger, wherein may be placed compost for the roots to feed in after a time. If this is objected to on the score of expense in purchasing pots for the purpose, should there be none available, compost may be placed under and round the pots, only the precaution should be taken to leave a clear space immediately under the crock hole at the bottom for water to pass away quickly. The roots, in search of food and moisture, will quickly find this compost, and it will prove of the utmost service in enabling the Vines to perfect the crop.

**POT FIGS.**—If ripe fruits are likely to be in demand at the same time as the Grapes, a house of bush trees should be started early next month. The trees as well as the house should be in a perfectly clean state, and the former should have been undergoing a thorough rest for some time past. Much, if not all, that has been said about the preparations for the forcing of pot Vines applies to pot Figs, and whichever method is approved of, steps for carrying out the same should be adopted. Top-dressing may be applied now, or it may stand over until the trees start growing, but in any case the balls of soil should be thoroughly soaked with tepid water as soon as the house is closed for starting. The temperatures given above for Vines will suit Figs admirably at the starting.

**EARLY PEACH HOUSE.**—Very often ripe Peaches and Nectarines are required in the months of April and May in addition to the other fruits named, and when this is the case it is imperative that the trees should be started not later than the middle of November. This will just give them sufficient time without having to resort to hard forcing, of which the subjects under consideration are very impatient. The necessary pruning, cleaning, and training of the trees should therefore be taken in hand at once, not neglecting to give the structure a thorough cleansing at the same time, and top-dress borders if this matter has not already had attention.

**POT STRAWBERRIES.**—Those intended for early forcing should be moved into cold pits and frames, where they should have free exposure, wet weather excepted, when the lights should be put on and tilted. Keep the soil in a medium state of moisture, neither too wet nor too dry, so that the crowns may experience a season of rest before being started. Successional batches of plants may be moved under cover as opportunity offers, placing them in orchard or Peach houses if pits and frames are not available. Plants for late forcing may be kept outdoors a short time longer. Keep all runners suppressed, and if more crowns than one have developed, reduce them to one, leaving, as a matter of course, that which is the strongest. Where plunging or staking of these late pot plants is practised, the same should be done about the middle of November or a little earlier, according to locality.

A. W.

## KITCHEN GARDEN.

### MARKET CUCUMBERS.

IN the course of the very comprehensive and admirable paper on "Progress in Vegetables and their Culture during the Queen's Reign," read by Mr. Arthur H. Sutton at the recent Crystal Palace fruit show, he said with respect to Cucumbers:—

Notwithstanding the almost endless varieties now procurable, it is generally admitted that none of them supply the ideal type required for cultivation on a large scale. For productiveness no sort equals the best strain of Telegraph, but the somewhat pale colour, especially when the plants are bearing a heavy crop, lessens its value for market. If the council of the Royal Horticultural Society should see their way to undertake a series of trials at Chiswick I would gladly offer a prize of £5 5s. for the seedling Cucumber, raised since 1896, which shall combine the productiveness and excellent form of Telegraph with the dark colour of Rochford's Cucumber.

Doubtless many persons will read these remarks, coming from the source they do, with surprise, for during the past ten years there have been put into commerce numerous varieties of Cucumbers generally regarded as of high merit; yet it seems as if not one were so good a cropper as the old and excellent Telegraph. But, as is remarked, that variety is not usually of good colour, dark and pale or yellowish green fruits alternating, and the outline is somewhat fluted. Probably one of the best coloured of modern Cucumbers is Lockie's Perfection, and it is remarkably smooth and handsome, yet it seems not to have as a market variety in any way displaced Telegraph. Rochford's Cucumber, a dark green form, is somewhat spiny, and here is presented an element in Cucumbers that would, in awarding such a prize as Mr. Sutton offers, have to be taken into consideration, because market growers generally agree that a spiny fruit, if of good length and colour and handsome, is more in demand than is a smooth one. Of course, such a point would have to be determined. Any trial of Cucumbers conducted at Chiswick would, to be efficient, have to be on a comprehensive scale. Possibly fifty diverse varieties might be sent in, and it would be useless to trust to any trial that comprised one plant only. Certainly not less than three should be grown, and the best results would be found in a long, low, broad span house, the soil being in wooden troughs about 16 inches wide and 6 inches to 8 inches deep. This is a far better method of growing the plants than in pots or on mounds of soil. Of course a large house would be needed, and there is none such at Chiswick. The money spent in build-

ing the useless entrance glasshouse might have been turned to far better account in erecting houses for the trial of such as Cucumbers, Melons, &c. GROWER.

**Drumhead Cabbage.**—Drumhead Cabbage is a capital variety for present cutting where there is a large demand. An impression prevails that it is strong and coarse, and certainly firm solid heads some 15 inches or 16 inches in diameter would tend to convey that idea; but, as a matter of fact, it is as mild as the best type of Savoy.—E. B. C.

**Vegetable Marrow as a climber.**—I have been in the habit of growing this delicious vegetable for many years in the usual way by planting it in a sunny spot, and allowing it to grow along the ground, but have invariably lost many fruits by damp and moulding off. This year I got a hint that such would be entirely avoided by planting it under a bare tree or any old trunk, and training the marrow up the stem—which hint I followed with entire success, not losing a single fruit; besides, the effect was most picturesque, the foliage of the marrow being most vigorous and of a beautiful deep green. I can thoroughly recommend this plan; besides, it saves much ground space.—A. G., in *Field*.

**Early Brussels Sprouts.**—I do not think that any vegetable crop repays extra care in the matter of getting the plants started early in the season, so as to give them a long season of growth, better than Brussels Sprouts. For several seasons past I have made it a rule to sow seed in a cold frame in February. The seedlings will be fit for pricking out on a sheltered border in April, and by the middle of May will be fine sturdy plants ready to go out in the open ground, and, once established, it must be a very exceptional season if they do not grow away vigorously, and make not only large stems but good hard ones, crowned with a head of foliage enough to ward off a sharp frost. When severe winters cut up the outdoor vegetable crop, it will be found that the early-sown and early-planted Brussels Sprouts put out on soil that has had no fresh manure applied will survive the ordeal far better than later planted crops put out on richer soil.—J. G., Gosport.

**Lettuces failing.**—A correspondent asks for a remedy against mould attacking Lettuce plants. I have frequently met with the same thing, the evil being more common with the Bath or Brown Cos than other sorts. Moreover, it is more often met with in gardens where Lettuce and other small green vegetables and salads have been raised for many years, the ground having become as it were Lettuce-sick. This fact points to the necessity of occasionally changing the ground for such things. This is sometimes difficult in gardens of small size, and in such cases the best way to prevent such attacks is to incorporate with the staple soil of the border a good dressing of gas-lime and wood ashes, and if a little fresh loamy compost can be procured as well, so much the better, mixing them all previous to digging the ground, this being best done in winter. Sometimes the fault lies in sowing old or poor seed improperly ripened, the evil being further encouraged by allowing the young plants to remain in the seed-beds too long in a crowded state.—C. C. H.

**Celery growing for market.**—Celery, it would appear, is, like other things, affected in various ways by different soils and localities, some varieties succeeding so much better in one district than another. Almost every Celery grower has his own favourite variety. At Gainsborough, in Lincolnshire, for instance, where scores of acres of Celery are grown for market, Clayworth Prize Pink is the favourite strain, and right well it grows too; while at Retford, some twenty miles distant, and where also very large acres are planted with Celery, Grove White and Grove Red are the favourite sorts. In market gardens in Norfolk and East Anglia generally, much is thought of that good old variety Ivery's Non-such. This in good ground grows taller than the

majority of Celeries, but it comes very firm and eats crisp. In many districts preference is given to Leicester Red, and my experience is, after having tried many varieties, that, while being all that can be wished for from a quality point of view, it has no equal for standing a wet winter.—J. CRAWFORD.

## ROSE GARDEN.

### ROSE MME. GABRIEL LUIZET.

THIS splendid Rose was introduced as far back as 1877, and since that time many excellent Hybrid Perpetuals have appeared, but yet for exhibitors it still retains the proud position of being the second best pink Rose in this class, the premier place being generally accorded to Mrs. John Laing. The colour of Mme. G. Luizet is a clear and delicate silvery pink with white edged petals, globular in form, and pointed centre. It is also sweet-scented, a quality that enables this Rose to take precedence over the lovely Baroness Rothschild, whilst its extra vigorous growth is all that one could desire. Perhaps some growers may com-

Rose Mme. Gabriel Luizet.

plain that they cannot obtain any autumnal flowers. Although I grant that it is anything but a free autumnal flowering Rose, it may, nevertheless, by careful pruning be induced to yield a fair supply. But with the wealth of Hybrid Teas and Teas that we now have we are far less dependent at the present day upon the so-called Perpetuals for our autumnal display than we were hitherto, and we may well rest content if such a Rose as Mme. Gabriel Luizet provide us with a glorious feast of blossom in June and July. PHILOMEL.

**Rose Ella Gordon.**—To say that this Rose is vigorous conveys but a slight idea of its luxuriant growth. It is not at all an uncommon occurrence for it to produce shoots 5 feet to 6 feet long in a season. This fact should be remembered by all who desire Roses of this nature, for their uses are manifold, be it to form hedges, training on pillars, or growing as single specimens on lawns. I know of no better crimson Hybrid Perpetual Rose for autumnal blooming than this. The globular-shaped flowers are large, but not coarse. They generally come good and have beautifully smooth petals of a brilliant cherry-crimson colour. I should take it to be a seedling from Mme. Victor Verdier.

We find just the same peculiar purplish wood the end of the shoots, but it is far more vigorous even than this grand Rose. I can commend also for pot culture. Under cool treatment it is formidable rival to Ulrich Brunner.—P.

**Rose Cecile Brunner.**—The popularity of this pretty Rose is increasing. The flowers are exceedingly tiny, and yet so perfect in form as to give one the impression that they are moulded in porcelain. The comely little buds, of a warm carmine and flesh tint, would be found very use by florists. It is one of the most vigorous varieties of the dwarf section of these beautiful Po-antha Roses, and an excellent kind to plant where a low hedge is wanted. Although not decorative as Gloire des Polyantha on account of its more branching habit, it is, nevertheless, highly attractive when grown in a mass.

**Fortune's Yellow Rose.**—No one seems to grow this superb climber more successfully than does Mr. Fyfe at Lockinge Park. It is there several houses, so as to have early and late bloom. No sooner are the flowers over in the spring than the flowering shoots are hard cut back to the main stems, and new growths breaking from the base are carried up. These run in the season great length, and being shortened back in winter to the hard wood, carry clusters of flowers from every leaf-bud. They are of a rich apricot-yellow and of exquisite beauty. A variety should make a capital market Rose.—A. D.

**Rose Perle de Feu** is remarkably coloured variety of the Tea-scented section. It may perhaps be best described as reddish or heavily shaded with gold-russet. It really is more fine in hue than Beauté Instantane. But having said much in its favour, I must point out that the flowers are very poor in size. The colour I can see for it is a basis for hybridists to work upon. I feel sure some excellent results would follow if this Rose were used as a pollen parent in hybridising some of our free-seeding Teas with orange shadings, such as Beauté Instantane, Grill, Mme. Chauvry, and venir de Mme. Sablayrol &c. One peculiar feature of some of these very rich dish-orange Roses is the lilac shading seen on some of the petals. Perle de Feu is a very good grower, the wood and foliage being of a rich russet-brown.—P.

**Rose Irene Watts.**—This Rose must speedily become popular, and perhaps in time entirely eclipse its parent, Mme. Laurette Messimy. The flowers are quite different in form from those of Laurette Messimy. As is well known, Mme. Messimy has very loose, informal blossoms, whereas those of Irene Watts are quite compact and certainly more double. It is difficult to distinguish the difference between some of the so-called Chinas and Tea-scented. I do not know that it matters much so long as we obtain fine-flowering Roses. Irene Watts has almost the requisite formation of a medium-sized Catherine Mermet, but of course not nearly so full. The colour is a clear China rose, merging to silvery-pink, the base of petals canary-yellow. Its beautiful bronze foliage serves to accentuate the fresh colour of the flowers. It will make a good contrast to Mme. Eugène Resal.—E.

**Mildew on Roses.**—The advice given in Dole's book, and quoted by "An Amateur" on p. 216, is quite sound, for soot is one of the best preventives of mildew there is. But it is not to be used in a fresh state, or the result will

An Amateur" describes. For years I have it for Chrysanthemums, and never had a leaf until two years ago, when I used some from the flue of ainery that had been pulled. The flue had not been used for several years. I thought I was safe in using the soot, but a few days after that all the tips of the plants were burnt. This led to an examination of the flue, and I found that the smoke from a boiler had been fixed in the place of the old flue for heating other houses had been leaking through into it. If "An Amateur" will save his for a couple of seasons and then use it, he will find he has a most valuable fertiliser and a natural fungicide as well. If well diluted and clear it is excellent for syringing Chrysanthemums, Pelargoniums, and other plants on morn'g evenings, while dusted over the foliage of many plants while this is damp it forms an excellent stimulant, and makes the leaves distasteful to insects of all kinds.—R.

**Sowing Brier and Rose seed.**—All heaps of Briers and Roses should be gathered as soon as possible now, or the birds will pick out the best and plumpest seeds. Store the heaps in sand for a week, taking care they are safe from mice. Break up the heaps and thoroughly mix sand and earth early in February. Then sow very thinly in shallow drills upon a warm border and protect with straw, birds and mice. The advantage of drills over broadcast sowing is in being able to use the soil between. Rose heaps may be sown in pans or boxes or in a cold frame, and where one has a choice heaps only, this may be the safest plan. Pick out the spring following, giving the seedlings good loam, and placing them a foot apart each way. Do not be too hasty in discarding any that do not flower or which seem inferior, as the first trials are not a fair test.—R.

#### AUTUMNAL ROSES.

The rich feast of Roses that has delighted the lovers to the recent Drill Hall and Crystal Palace exhibitions must have been a matter for regret to many who had the pleasure of inspecting them. Although for many autumns we have had the Bourbons, Chinas and Teas to beautify our gardens at this period of the year, only during the last eight or ten years that such varieties recently shown have been put into commerce, and a comparison of the plants now to be had with those available ten or twenty years ago must call forth our gratitude to those who have been instrumental in providing us with these delightful novelties. Because these varieties are so good in autumn, it must not be inferred that they are only good in this season; on the contrary, many of them were the first to expand their blossoms in the month of June, and they continue to open more or less the whole of the summer. Possibly the rather unusual display of Roses that has brightened our gardens this autumn is attributable to the drought we experienced in the summer months, which, as it were, stopped vegetation for a time, and then the copious autumnal rains that we had started the plants into new growth, resulting in the glorious display that we have lately witnessed. But, granted that this is so, we are, nevertheless, mainly indebted for this display to the recent introductions. I think it is a matter well worth considering whether some means could not be taken in a wet summer to ensure a gorgeous autumnal feast such as we have had this year. The main point to consider would be to take some measures after the first flowering to give the plants a rest by keeping the rain off, and this could be secured, I think, by placing over the beds of Teas and Hybrid Teas temporary covers with glass coverings. If this were done for three or four weeks to give the plants

a thorough rest, we should, as it were, produce the same conditions that the Rose growers of the Riviera obtain naturally, and thus secure a good autumnal and even early winter display in this fickle climate of ours. At any rate, it would be worth a trial, especially by market growers and gardeners who have large demands for autumnal Roses. P.

**Rose Queen Mab.**—This is a charming dwarf Rose, being one of a section to which a good deal of attention is now being paid. It is a China or Bengal, and the colour is apricot, shaded with orange and rose. Frequenters of the Drill Hall must have noticed it, as it has been admirably exhibited as a pot Rose, and it struck everybody who has seen it by its distinctness and free-flowering character. We have already had *Laurette Messimy* and *Duke of York*, both of which are highly thought of. There has appeared, too, a climbing variety of that very beautiful old China, *Cramoisi Supérieur*, which for brilliancy of colour is hardly surpassed by any Rose in this or any other section. It has been a grand season for autumn blooming. Hybrid Perpetuals, Hybrid Teas, and more especially pure Teas have given us many beautiful flowers, and, should the present weather continue, will do so for some weeks to come.—D.

**Hybrid Sweet Briers.**—My plants, each 10 feet to 12 feet high, exceedingly bushy and strong, had been fastened to stout stakes; but the growth was so heavy, that the recent gale snapped the stakes and completely mixed up the wood. I may say they are planted in the form of a semi-circle, intended to be brought over at top and thus make a pleasant arbour. All who have handled these Sweet Briers are aware of the immense strength and fierceness of their prickles, and will sympathise with me in the task of disentangling such a mass as these formed. It was simply impossible under ordinary conditions, so I procured several hop-poles, sawed some off to a length of 12 feet and drove them into the ground upon the outside of the arbour, fixing two rows of the poles lengthwise from these uprights. A second upright was fastened as far inside as possible, and another pole used to lever the growth up to the cross pieces first fixed. As I got the growths up they were fastened with rope yarn and the cross pole secured to the uprights on the outside with some strong wire taken from bales of peat moss litter. By following this plan right round the arbour I eventually got them into place, and so firmly secured that no gale will move them again. To have cut away some of the growth would have been a great sacrifice of bloom; besides, I could not have drawn out the severed wood without entangling the remainder even more than it was. As a hedge I do not think any plant can be more effectual in keeping out trespassers than the Sweet Briers. They are simply impregnable after the first year's growth. Nor could we have a more pleasing hedge. They root remarkably well as ripened cuttings and make capital stocks for strong-growing Teas or Hybrid Perpetuals. My own are now perfectly scarlet with hedges, and if these are gathered and sown, a large number may be raised for next autumn's planting. How very easy it would be to beautify our hedgerows and borders of woods with seedlings of these.—R.

#### SHORT NOTES—ROSES.

**Rose Rev. Alan Cheales.**—By those who are fond of large Roses, this new variety of Messrs. Paul and Son, of Cheshunt, will be much valued. It is somewhat of the Ulrich Brunner type of flower. The colour is very peculiar, being almost a pure lake. It is vigorous and free-flowering.

**Rose Bladud.**—This I believe to have been one of the late Mr. Bennet's seedlings, which passed into the hands of Messrs. Cooling and Sons, Bath. It is a very large Rose, full, outside petals silvery-white, with

pale blush centre. It promises to be a good garden Rose, but will also be found in many an exhibition stand.—D.

**Rose Paul's Single Scarlet.**—This promises to be a valuable addition to our single Roses. The colour is very brilliant, almost pure scarlet. As it is stated to be a H.P., we may fully expect that it will follow the example of Paul's Single White and give us a crop of its brilliant flowers in autumn as well as in summer; it is very vigorous in habit.

**Rose Cannes la Coquette.**—This is one of Nabonand's raising, and, although twenty years old, is not nearly so much appreciated as I think it ought to be. It is very vigorous, and the flowers are of a pleasing shade of very delicate fawn, marked with flesh, especially towards the edges of the petals, sometimes making it appear like *Homère*, and borne well into the autumn.—H. H. D.

**Rose Paul's Single White.**—Most of the single Roses are only summer bloomers, but as far as my experience of this Rose goes it has the advantage of giving a double crop of flowers. For the last two years I have had my plant of it quite as full in September as it was in June. The variety is well known and is very similar to *macrantha*; the stamens, however, do not retain their brilliant yellow colour so long as in that flower.—D.

**Rose Mme. Pierre Cochet.**—This is one of those charming Roses whose colour is most difficult to describe, in which, however, orange-yellow most predominates. The buds are long and pointed; in fact, it is in this state alone that it is valuable, for when it expands, the flower is loose and its brilliancy has departed. It is a profuse and continuous bloomer, and flowers may always be relied upon in the autumn months. It was raised by Cochet in 1892.

**Rose Mrs. Sharman Crawford.**—This beautiful pink Rose, which was sent out by Messrs. Dickson and Sons, Newtownards, in 1891, has now become established as a general favourite owing to its beautiful colour, good habit, and freedom of flowering, and to these recommendations must be added, I think, that it is one of the freest of autumnal bloomers, as the few plants that I have of it have afforded a plentiful supply of good flowers this autumn.—D.

**Rose Safrano a fleur rouge.**—As with many of the semi-double Roses, this variety is most lovely in autumn. It has fine deep petals, reflexed at the edges, the outer ones of a clear rosy red colour, and the centre a beautiful blending of salmon, orange and pink. I have generally found the petals to be a little firmer in texture than those of the old Safrano, but with this exception and in the colour it is identical with this popular variety. Just now it is one of the showiest in the collection.

**Rose Medea.**—This beautiful Rose, which was sent out by Wm Paul and Son in 1891, has been the subject of a good deal of controversy, owing to someone having compared it to *Maréchal Niel* and given it the preference—clearly a mistake. In the first place, *Medea* is a Tea and *Maréchal Niel* a *Noisette*, while in growth and habit they are both distinct. In colour, too, *Maréchal Niel* has not been approached by any other Rose. *Medea* is a very beautiful Rose, of a lemon shade of yellow, of good form and substance, while the growth is vigorous.

**Rose Sunset.**—It is surprising that many Rose sports do better outdoors than the varieties from which they emanated. This Rose has been grand with me this autumn, but I cannot say the same of *Perle des Jardins*. The flowers of this appear to open rather hard, but this is not so with *Sunset*. The colour of the blossoms is rich tawny saffron or apricot. This variety is far superior to *Mme. Falcot* in substance, but, of course, it will not surpass this old variety as a button-hole flower. *Sunset* is a superb variety under glass, and I can highly commend it.—PHILOMEL.

**Rose Muriel Grahame.**—There is a general consensus of opinion that this is a most valuable addition to our Tea Roses. It is a sport, not from *The Bride*, but from *Catherine Mermet*, and was obtained by Mr. Browne, of Reigate, gardener to Mrs. Waterlow, at Great Doods. It passed from him into the hands of Messrs. Alex. Dickson and Sons, of Newtownards, by whom it has been distributed. No greater testimony to its value can be given than the fact that it has obtained the silver medal of the National Rose Society for the best Tea in the amateurs' division both at the metropolitan show at the Crystal Palace and also at the northern provincial show at Norwich.

## ORCHIDS.

## ONCIDIUM JONESIANUM.

THIS is a very distinct and beautiful *Oncidium*. The pseudo-bulbs are so small as to be hardly noticed, and at a first glance one would say the plant consisted only of the leaves and roots. The foliage is often 1 foot and upwards in length, and its natural habit appears to be to grow with the points downward. The growths are very closely clustered together, and the spike appears at the base of those last formed. These grow erect at first, their weight gradually bringing them to an arching position, that shows off the blossoms very prettily. Individually these are about 2 inches across, and on strong spikes nearly a score of these are produced, making a fine and showy inflorescence. The

noticed on several occasions beginners in *Orchid* growing find a difficulty in firming plants of this description. If there are no roots or but very few, it is safest to wire the plants to small blocks of wood, placing these in the pans and wedging a few bits of crocks around them to hold them firm. Then as little compost as may be needed can be easily pointed in over them with the dibber. Rafts, as hinted above, are suitable, and on these the plants may easily be fixed with a little Moss under the roots in the usual manner. I am not much in favour of dressed blocks of any kind, but in wiring plants of this class on to small pieces of wood a little Moss may be placed underneath with advantage. The compost and receptacle for these strictly epiphytal kinds are in fact more in the nature of a mechanical support than a manurial one, for they derive nearly all the susten-

them well by exposure to sunlight when full grown. Then it is possible to keep them rest for a time without drying the roots sufficiently to cause the least shrivelling. Plants that have been for a season or two inured to this treatment are always more free blooming than those that make, perhaps, two distinct sets of growth in one season. Propagation is best effected in early spring by cutting with a sharp knife between the bulbs, allowing several leads, if possible, to each divided portion and setting each going on its account. R.

**Cattleya throwing up a flower-spike**  
I have a piece of *Cattleya* which I do not know the name of. It made three growths this summer, two with sheaths and one without sheath. The growth without a sheath is throwing up a flower-spike. not this very unusual W. D.

\* \* \* This is not a very common occurrence, it happens occasionally with *Cattleyas*, and *Epidendrums* with *Cattleya*-like habit. Ed.

**Calanthe vera folia.**—The pure white blossoms of this elegant Orchid are always welcome, and large healthy specimens have a fine appearance just now. The flowers last long, provided they are kept dry, but the least amount of water spots and blights figures them. The culture of this plant consists simply in potting in a good substantial compost in well-drained pots, giving abundance of water while growth is active and a little liquid manure occasionally.

**Angræcum fastidiosum.**—This is not, I think, the usual flowering season of this pretty plant, but I noted it in bloom a day or two since. The flowers are pure white with a little curving spur. The plant is dwarf, the leaves about 3 inches long, deep shining green, the spike curving near the upper part of the plant. It is a native of Madagascar and thrives well in suspended baskets or

pans well drained, and in a thin compost of Moss and charcoal. Plenty of heat and a brisk, moist atmosphere are required, the roots liking plenty of moisture as long as it drains away freely. It was introduced by Messrs. Sander and Co. in 1831.—H.

**Cattleya aurea.**—Among several plants of this lovely *Cattleya* now in flower there is a considerable variety, one having a very deeply tinted lip of that beautiful velvety appearance so much admired by everyone who sees it, especially in the first time. The outer segments are of a cranke-yellow, nicely undulated and broader than usual. *Cattleyas* of all kinds appear to be done remarkably well this season, and I never saw the autumn blooming kinds so free and full of promise. *C. aurea* is not a whit behind the rest, and owing to its attractiveness and the silky character of the blossoms, seems to lead the way

A single-flowered Tree Pwony. (See p. 325.)

sepals and petals are wavy on the edges, pale yellow, with deep reddish brown blotches in the type, though varieties exist with orange spots. The lip is large and showy, kidney-shaped, with a wavy edge, the crest being dotted with red. The flowers are very lasting, but unless the plants are strong and well established they must not be left on until they fade. Bare block treatment is often recommended for this species, and it does well grown thus if well attended to as regards moisture, but if I can get a plant to take hold of a little compost, if only on a raft, I usually treat it so. The roots of this species cannot, however, take hold of much material, especially if this is in the least degree close or apt to decay. Small pans nearly filled with crocks and a mere surfacing of *Sphagnum Moss* will grow it well, but I have

ance they need from a properly moistened atmosphere. The best position to grow *O. Jonesianum* in is an almost unshaded one in the warmest house at command, and, if convenient, the plants may with advantage be suspended over a water tank or in any part of the house where moisture is most abundant. On bright summer afternoons the syringe may be somewhat freely plied about the leaves, a gentle, fine spray being very helpful in keeping down insects. Growth is rapid when once the leaves emerge from the sheaths, and with the stimulating temperature caused by the sun and moisture, the little pseudo-bulbs soon swell up. With regard to its seasons of rest and growth, but little can be said, for the plant is very inconstant in this way. Endeavour in all cases where possible to bring the growths along rapidly, and ripen

along the labiate kinds. It delights in ample light and a full Cattleya temperature, and I find it better in baskets or pans suspended from the roof than in pots upon the stage. After the growths are fully developed and the flowers appear, the plants must be kept a little on the shade side at the roots, as they are apt to start in the summer. When they get over the first months of winter there is not so much danger, for if they do start the young shoots will by the time they need it get abundance of light. *C. Lippia* is a native of Colombia and was discovered by one of M. Linden's collectors, who first sent it home in 1868.—R.

**Laxillaria grandiflora.**—A plant or two of this beautiful old species should be in every collection if only for the sake of its delicious fragrance, which fills the house where it is flowering. The outer segments of the blooms are pure white and have a glistening, frosted appearance, the centre of the lip being yellow. Few Orchids are so troublesome to grow than *M. grandiflora*, provided the plants are kept clear of insects, and this is best done by growing them in a cool, shady and moist house all the year round, a minimum temperature of 50° suiting them well. Equal parts of peat, loam fibre and Sphagnum Moss suit it well, and it must be planted in medium-sized, well-lined pots. It is a native of Peru, and was introduced in 1850.

**Arkeria Lindleyana.**—The long many-flowered spikes produced by this species are among the most striking of any at this time of year. The plant grows erect, the stems being very slender and about a foot high, the spikes appearing at the apex of these just as growth is finishing for the season. The flowers vary a good deal both in colour and width of the segments, the usually recognised as the typical form being a very bright purple with a white centre to the lip. *B. Lindleyana* thrives best in a light and airy part of the Cattleya house during the summer and autumn, in fact until the growth is finished and the flowers past, and during the whole of the winter it must not be allowed to get dry. Owing to the peculiar nature of the roots these will not thrive in a large body of compost, and for this reason more frequent moistenings are necessary. A syringe, too, may with advantage be freely used about the growths. During the winter and early spring months the plants do with much less moisture and in a cooler house. Small shallow baskets or rafts kept flat suit the plants well, and the plants may be replanted after the growths have made considerable headway and are beginning to emit young roots from the base.

#### CYPRIPEDIUM SPICERIANUM.

This distinct and handsome *Cypridium* is now in flower, and popular as it has become, there is little fear of getting over-stocked with it. In fact it is not unlike *C. insigne*, but the foliage is usually shorter, of a deeper green and spotted on the under-side with dark purple. It commences to bloom the first week in October, and one often sees it as late as the end of January, so that its value in keeping up a display is obvious. In a good typical form the flowers are each about 4 inches across, the distinct white dorsal sepal hanging a line of deep blackish-purple running through it. The wavy sepals are light green, the petals shining brown. It is not a difficult plant to grow when the right position is found for it, a good deal depending upon the atmospheric condition of the house. I have seen it thriving well in an intermediate house and again some very successful growers give it quite tropical treatment during the growing season, but in any case a risk moist heat and a broken light rather than a very heavy shade suit it well. The compost for it may consist of good peat fibre, loam with most of the finer soil shaken out and clean Sphagnum Moss. If this compost is firmly placed about the roots *C. Spicerianum* will grow in it well. During the growing season healthy plants with their roots running freely

in the compost require plenty of water; indeed, the roots ought never to be dry. Badly-rooted specimens should be shaken clear of the old material if this is in bad condition, well washed, and repotted into small pots in a very light description of compost over good drainage. They soon recover if not too far gone, and make nice healthy little plants if carefully treated. Old plants with their roots much entwined about the pots require careful treatment when repotting becomes necessary. They are as easily tided over a bad check as most plants, but that is no reason for damaging them more than is necessary. The safest time to repot is the spring, as the plants may then be placed at once in a quick, moist temperature and soon get over the check to the roots. The flower-buds appear in late summer and autumn, when, if a large number of plants are grown, some should be taken to a cooler house to retard them and keep up a succession. The flowers last a long time in good condition if kept quite dry. R.

#### LAELIA PUMILA.

The pretty brightly-tinted blossoms of this species are very welcome just now, well flowered plants having a very fine appearance. The habit is dwarf, seldom exceeding 6 inches in height, and the blossoms are produced singly upon the scapes. Each one is about 4 inches across, the outer segments bright purplish-rose, the front of the lip having a fine broad purple blotch with a wavy margin. *L. pumila* cannot be described as a difficult plant to cultivate, yet many growers fail to do it well, and this as often as not is the result of using too much compost. To treat it the same in this respect as a vigorous rooting *Cattleya* or *Laelia* is to court disaster, for the plant has not the power to take hold of a large body of material. The roots issue from the growths and push out freely enough for an inch or so into the compost, but beyond this they cannot go, unless indeed it is an extra strong or vigorous one. The consequence is they decay at the tips and soon become of no further use to the plant. Had the same one been planted in a small and shallow pan, so that the roots could have reached the drainage or the sides, they would have been healthy and carried out their proper functions. Anyone having plants of this species, then, or *L. Dayana*, *L. prestans*, and other nearly related kinds in a close compost or one too thick for their needs, would do well to get them out of it and repot into the class of receptacle mentioned. About an inch of peat and Moss is ample for small and medium-sized plants, and even this will be better for the addition of a few crocks or pieces of charcoal. Air enters freely into a compost of this description, and in consequence it soon dries, needing water almost daily when the plants are growing freely. At this time they should be hung in a very light, sunny position not far from the roof-glass, and it will seldom be necessary to shade except for an hour or two in the middle of the day. A full *Cattleya* temperature may be maintained as long as growth is active, reducing this and the root moisture while at rest. The atmosphere should be kept fairly moist the whole year round, and the minimum temperature at night in the winter must not be less than 50°. *L. pumila* has long been known, but Messrs. Loddiges, of Hackney, appear to have been the first English firm to have imported it in quantity. This they did in 1843, and it has often been sent home by collectors since then. It is a native of Southern Brazil, where in the neighbourhood of Rio de Janeiro it is a fairly common Orchid, growing at various elevations on the sides of the mountains. It first flowered under cultivation in a French collection.

**Dendrobium chrysanthum.**—One of the finest Orchids I have seen for a long time was a grand old plant of this growing in a basket, this being placed in the pocket of a Fern-lined wall. The beautiful deep yellow of the blossoms with dense maroon eye showed up grandly against the

deep green of the Ferns, and as the flowers had opened more than usual the plant was all the more attractive. The longest bulbs were 4 feet 6 inches and clothed with blossoms from end to end. When well grown the foliage of this Orchid is fresh at the same time as the flowers.—H. R.

**Pleione humilis.**—I noted this pretty plant in bloom this week, though it has usually flowered with me in early spring. It is a variable kind, the typical form having nearly pure white sepals and petals, a slight tinge of rose sometimes appearing on them. The lip is pale rosy lilac, with orange-yellow and brown in a pretty combination; in fact, there are few more beautiful things in the whole Orchid family than the lip of *P. humilis*. Its culture does not differ materially from that of *P. lagenaria* and others, except that as it usually flowers later repotting takes place also later. It is a native of Nepal and was introduced in 1850.—R.

**Cattleya Gaskelliana.**—One of the prettiest forms I have seen of this species is now in flower with me. The plant is only a small one, the spike bearing three flowers of medium size. The sepals and petals are almost white when first open, a slight tinge of rose suffusing them when the blossoms are fully expanded. This paleness of the outer segments helps to show off the colour on the front of the lip, which is a deep crimson-purple, occurring in a narrow band down the centre. The side lobes are light crimson and prettily crisped, radiating lines of yellow taking the place of the usual orange tint seen in the throat.—H.

**The durability of Orchids.**—Of late there has been considerable discussion on this subject in the garden press. Very few instances are related where the examples mentioned are in as vigorous a condition as when they were originally introduced, and where an exception occurs it is worthy of notice. An instance of this may be seen at Gunnersbury House. In 1862 Mr. Hudson's father purchased a plant of *Laelia purpurata*, which has been in his son's charge ever since. Last season it bore thirty-five flowers. It has at the present time ten new growths, and fills an 18-inch pan. There are also two fine examples of *Vanda tricolor* that were procured on the same day. These are from 6 feet to 7 feet in height, and are clothed with foliage to the pots, truly remarkable instances of the longevity of plants. There are also several plants of *Cyrtopodium villosum* that were purchased at the same time. The whole three species do credit to Mr. Hudson's care.—H. J. CHAPMAN.

**Sophranitis violacea.**—Many people have found it difficult to get this species to succeed for many years together, but really it is not a difficult plant if reasonable care be bestowed upon it. Like all small-growing kinds, rapid changes in the atmosphere are very injurious to it. A dry or draughty house, let the temperature be as suitable as it may, will never do for it. Fresh air in abundance is good for it, and so is atmospheric moisture, but the elements require proper balancing, and the air should, if possible, be kept moving without opening the ventilators too wide. It likes a temperature rather higher than that of the *Odontoglossum* house, but the *Cattleya* house is too warm. The foliage is tender and easily damaged by direct sunlight. At the same time a very heavy, dense shade must be avoided, even in summer. It is the weakest grower in the genus, the pseudo-bulbs only about 1 inch in length, the narrow leaves being a little longer. The flowers are soft rosy magenta in colour. It grows most freely on soft pieces of Tree Fern stems, or, failing these, rafts lightly dressed with Sphagnum Moss or in very small pans. No resting season is needed, the roots being kept gently moving as long as possible and just moist when the growing season is over. It is a native of the Organ Mountains and was introduced in 1838.

**Dendrobium formosum giganteum.**—This is one of the finest of the white *Dendrobiums* and flowers during the present season. A recent visit to the gardens of Gunnersbury House revealed a

remarkable example of the successful cultivation of this lovely species. There were some fourteen plants in all. One was grown in a 12-inch basket. The longest bulb measured 22 inches and carried ten fully expanded flowers, each measuring  $4\frac{1}{2}$  inches across the petals by  $2\frac{1}{2}$  inches broad. There were some half-dozen other leading growths on the plant, with equally fine flowers, making altogether the total of thirty-five flowers. The flowers on this particular plant varied considerably from those of the other plants in the house, in that the yellow down the centre of the lip was of a deep bright orange, instead of the usual light lemon colour characteristic of this species. Another plant had a bulb 25 inches long and carried ten flowers. The plants were imported early last spring and placed in the baskets; they were then taken to the Fig house, where they were suspended close to the glass, and where they were fully exposed to the full power of the sun. Naturally under these conditions a highly humid state of the atmosphere had been maintained throughout their growing season, with plenty of moisture at the roots. They are certainly the finest examples of this Orchid it has been my lot to see.—HY. J. CHAPMAN.

## CHRYSANTHEMUMS.

### EARLY-FLOWERING CHRYSANTHEMUMS AT CHISWICK.

THE trial of early-flowering Chrysanthemums which is this year being conducted in the gardens of the Royal Horticultural Society at Chiswick will in all probability prove one of the most valuable of recent years. It is, indeed, not possible to fully estimate its worth, for even now, though the plants have been flowering for weeks in succession, the interest they are creating is quite remarkable. All the plants have been grown naturally, having no regard to the fact that some are pompons or hybrids of this set, and others—and these happily in a large majority—of the Japanese decorative class. Those having a special fondness for the late summer flowers will welcome the news that, even with the collapse of Dahlias and other tender subjects from the effects of the first frosts, there is still some hope of keeping the garden gay and beautiful for some weeks longer. For, after all, their greatest use and greatest value in the future must ever be as garden plants, and such of these as are perfectly hardy, vigorous, and free-flowering will not be wanting admirers. It is worthy of remark that Mme. Castex Desgrange and its several sports are not beaten to-day either for early flowering, freedom, or vigour. During the last two decades progress has been made, though somewhat slowly. During the last five years some good things have been brought to light, varieties, moreover, that will be valued for their effective colouring in the garden at this time. At page 312 of THE GARDEN the varieties considered worthy of the "three marks" are enumerated. This, however, is by no means an inclusive list of all that is good or useful for the embellishment of the garden generally, and, in fact, some striking things have in reality been passed over—so far, at least, as this trial is concerned.

Having made several visits to the collection at Chiswick, both before and after the recent severe frosts, it is possible the notes made on the spot may be of service to those having less opportunity for inspecting them, and while passing over without comment the ever-indispensable Mme. C. Desgrange, G. Wernig, and Mrs. Hawkins, I will briefly refer to what appeared the most worthy, at the time of my visit, from a garden or decorative stand-

point. The first visit of which I have note was in the last days of September, when the plants were extremely bright with the rich masses of colour, in many instances huge sheaves of blossom appearing in perfection and as the result of one short season's growth. In the white-flowered kinds, Lady Fitzvygram, 2 feet high and as much through, and Mrs. Cullingford, nearly  $2\frac{1}{2}$  feet, were excellent. Mytchett White is also a fine addition to the very early and dwarf sorts, though its rusty leaves do not improve its appearance. In yellow and orange shades, very fine masses of colour are Orange Child and Ivy Stark; both, however, are not wanted in one garden, so near do they approach each other in effect. The two kinds are about equal in height, i.e.,  $2\frac{1}{2}$  feet, and produce a mass of blossom at one time. The former I regard as the finer of these two excellent kinds. Bronze Prince, a salmony bronze, and Mme. Zephir Lionnet, a gold-bronze, are both grand and free at 3 feet high. Vice-President Hardy and Ambroise Thomas, shades of bronze, each distinct in itself, being excellent and of similar height. In shades of pink, Mme. Louis Lionnet, Mlle. Guindudeau, and Baronne de Briailles are very fine, Strathmeath, a lilac-pink, being very early, 20 inches high, and of the hybrid pompon class. Mme. Marie Masse, rose-mauve shade, is perhaps one of the most exquisite and charming in the whole of this lovely collection.

When the second visit was made, some days after the severe frost, I was surprised to find a large number little or none the worse, probably because of the dryness existing at the time, though the very earliest had passed their best, while on October 16 the following were in capital condition—indeed, making the only floral display in the open garden worthy the name. Of these, Orange Child and Mme. M. Masse, which have been in bloom for at least three weeks, were still good, and of course durability at such a time is a great point. Of others, Chevalier Ange de Bandeira, 2 feet, rose-magenta, was charming; Mme. F. de Cariel, a bronze-yellow,  $2\frac{1}{2}$  feet high, was at its best, flower of medium size and free; Ryceroft Glory, 3 feet high, was only just opening, but a mass of buds; Edith Owen, 3 feet high, has yellow flowers; Mme. Gajac, a rosy-lilac,  $2\frac{1}{2}$  feet high, was a fine mass of telling colour, and Mlle. Guindudeau was still in excellent condition. Crimson Queen and Ruby King appear identical, though only just opening; the colour is very fine, the plants less than 2 feet high, but it will need fine weather to the end of October to get even in southern gardens the beauty of this, the richest kind I saw. The free, compact habit is perfect.

These are the best to my mind from a free-flowering standpoint, and such as would, carefully disposed, make a lasting and beautiful display of warm, effective colouring in the garden as late as this is possible each year, with little or no staking or undue trouble. Many of the kinds noted here, if hardy enough to winter in the open garden—an all-important point—should flower earlier another year. This would bring some of the now later kinds into perfection in the first week in October. E. J.

**Chrysanthemum Klondyke**, referred to in last week's GARDEN, is destined to become a very popular market variety. Mr. Norman Davis, the raiser, says the habit and foliage are very similar to those of Elaine, well known to all growers as a first-class market sort. The flowers of the variety under notice are rich golden-yellow in colour with neat recurring florets, and build up a blossom of a useful size. For the decoration of large vases this variety would be valuable, especially

if autumn tinted foliage be used in association with the blooms. A good yellow of refined appearance is badly wanted during October.—C.

**Chrysanthemum Edith Tabor**.—The only fault of this lovely variety is its ungainly habit, this quite unfitting it for growing into a nice shaped plant. I have tried several plants in pots and cut them back hard, also single plants, and pinched them, but the result in both cases is the same—long shoots with leaves a long distance apart. It appears to belong to the same race as the old Thumbberg and one or two other yellow with graceful flowers but bad habit. What is needed is a really prettily shaped and coloured yellow with the habit and constitution of W. Lincoln.—R.

**Chrysanthemum Calvat's Boule d'Or**. This must not be confounded with the old kind of the same name. In the first place it is a much better grower, judging by plants I noted flower to-day (October 8), and it is also earlier. The blooms are large and handsome, of good build, and very distinct in colour. The low florets droop a little; the inner ones are nice and not too stiffly incurved, and although they are pointed, are yet of good substance. It appears to be a fairly dwarf kind, as plants very little over a yard high were carrying full-sized flowers.—H.

**Chrysanthemum Francois Vuillemet**. This variety, introduced in 1895, after a second season's trial in my own garden, I have every confidence in recommending as a valuable sort to the hardy border. The natural break is usually made when the plant attains a height of about 10 inches and a regular sequence of branches continues until the terminal buds form. Ultimately the plant measures quite 3 feet through and carries a profusion of blossoms each from 2 inches to 3 inches in diameter. The flowers reflex prettily in the early stages of opening, thus causing the rain to run off—a distinct advantage with early sorts in the open. The height rarely exceeds  $2\frac{1}{2}$  feet, and the colour of the flower is best described as deep rose-pink.—D.

**Chrysanthemums and frost**.—We have been visited by several rather severe early frosts in the neighbourhood, and I am told that one rather large Chrysanthemum grower has had many bloom buds frozen right through, and, of course, spoiled. In midland localities I find it unsafe to leave the plants out unprotected after October, but when the bloom is wanted for cutting and late as possible it is not necessary, except with extra large numbers of plants are grown, to take them under glass to be drawn up beneath, perhaps, Peach trees with green foliage on them. A rough framework erected over and around the plants, these being stood fairly close together, and a few coarse Hessian covers rolled over the top, ordinary garden mats being hung up round the ends and sides, will keep 9° or 10° of frost away and preserve the plants, removing them from doors at the end of the month.—NOTES.

**Chrysanthemum Emily Silsbury**.—This is a very beautiful white variety, and one that is worthy of extended culture. In habit it is that which can be desired, and I have large, well-developed blooms on plants less than a yard high. In several seasons I have been trying to make a selection of varieties that keep their foliage well and that one may pinch once or twice and yet get good blooms. Treated in this way, they make plants useful in a variety of ways, but especially when, as in my case, there are large entrance halls or reception rooms to furnish. The kind mentioned is an excellent one for the purpose, the only fault being its earliness. The flowers have a tinge of rose at first, but this they lose with age, becoming pure white. The petals are very prettily twisted in the centre, broad, and of good substance. The build of the flower is good. Many varieties fail to do well the second year, but this does finely. Last season my plants were small and stock rather short, so they were divided and potted up, and though the flowers are,

to be so good on these as from the young plants, they are decidedly useful for cutting just now.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL CHRYSANTHEMUM SOCIETY.

OCTOBER 12, 13, AND 14.

THE early autumn exhibition held at the Royal Aquarium on October 12 and two following days may be regarded as in every way a success. Although there were only sixteen classes, an excellent exhibition was got together. With the exception of a small portion of the ground floor space, the whole of this large area was utilised for the display of the cut flowers and miscellaneous exhibits, the greater portion of the south-west gallery being used for the table decorations. The competition in the leading classes was in every way satisfactory. In the principal classes of cut flowers were in most instances of a high order of merit, the quality in the leading stands being generally characterised as distinctly good. As regards form and size, while the colour in some of the flowers was quite remarkable so early in the season. Hardy border Chrysanthemums were well shown, in no small measure contributing to the success of the exhibition. Novelties were staged in goodly numbers, several promising growers being among them, and of which more will probably be heard later. Some excellent market varieties were seen in the exhibits of the specialists, good colour, pretty form, and flowering properties generally distinguishing them. Hardy fruits were freely staged, vegetables, too, being well shown. Hardy flowers were also represented in fairly good condition, thus assisting to make a very interesting and pleasing display.

#### PLANTS.

FOR a group of Chrysanthemums and fine-leaved plants arranged for effect there were twelve competitors, the leading position being secured by Mr. Norman Davis, The Vineries, Tunfield, Sussex, with a nicely-arranged group of bold and handsome flowers on plants, retaining their foliage very well. The blooms gave evidence of high culture, and included several of the best of the leading novelties. Conspicuous among them were George Seward, Emily Silsbury, John Mylly, Simplicity (pure white) and Elthorne Beauty (a large deep flower of bright rose, with a very reverse). The group was edged with dwarf plants of pompon and decorative sorts, relieved by a margin of Maiden-hair Ferns, a few fine plants of Cocos Weddelliana, Crotons and Nicanas being effectively used. The second prize was secured by Mr. W. Howe (gardener to J. Henry Tate, Park Hill, Streatham Common) with a very handsome group, with which some fine-leaved plants were pleasingly associated. This group was backed by some useful pieces of Imbos.

#### CUT FLOWERS.

THE principal class for cut flowers was for twenty-four blooms of Japanese in not less than fifteen varieties and not more than two blooms of each variety. This was well contested, no less than seven entries being forthcoming. The leading position was ultimately given to Mr. C. Penfold (gardener to Sir F. Fitzwygram, Leigh Park, Hyant), whose front and back rows were finely even, the middle row of flowers rather weak. The best blooms in this exhibit were Beauty of Teignmouth (a variety synonymous with Pride of Madford), Phebus, Mrs. C. H. Payne (large and coarse), Modesto, Edith Tabor, Surprise, Line d'Angleterre, rather coarse; Mme. Gustave Perry, a useful October white sort; Emily Silsbury, Mutual Friend, and M. Chénon de Léché. The second prize was won by Mr. James Agate, nurseryman, Ilavant, for a much more even lot of flowers, the quality being generally considered better than that in the premier stand. Mrs. J. Lewis, large white; Milano, rich bronze and

cherry carmine; Australie, Dorothy Seward, M. Chénon de Léché, E. Molyneux, and Philippe Rivoire, a grand new pure white flower, were the best. There were six competitors in the class for twelve blooms Japanese distinct, the first prize being won by Mr. F. G. Foster, Brockhampton Nurseries, Hants, the quality in this instance being rather poor. His best flowers were Edith Tabor, E. Molyneux and Phœbus, the latter one of the most useful October yellows. Second honours fell to Mr. R. Jones, gardener to Mr. C. A. Smith-Rylands, Barford Hill, Warwick, with a splendid lot of flowers, John Applin, long pointed florets, colour creamy-white, with a yellowish centre, Mme. Edouard Rey and Mutual Friend calling for special notice. Pompons were very poorly represented, Mr. Eric F. Such, nurseryman, Maidenhead, securing first prize in each instance for twelve bunches, not less than six varieties, and three in a bunch, and six bunches distinct with the same number of flowers in each bunch. A far prettier exhibit of these pompons would be obtained if larger bunches were asked for, the present number appearing somewhat insignificant. In the amateurs' A division for twelve blooms Japanese distinct there were only two entries, the first place being taken with an interesting lot of flowers from Mr. R. Gladwell, gardener to Mr. Sydney Smith, The Gardens, Wernden Hill, South Norwood. Oceana, Mme. Therese Rey, Mutual Friend, and Perle Dauphinoise, a golden-yellow, previously shown as an incurved variety, were among his best blooms. Mr. J. Knapp, gardener to Mr. F. W. Amsden, 22, Chichester Road, Croydon, was second. Mr. Gladwell was again first for six Japanese distinct with exceptionally fine flowers of E. Molyneux, Phœbus, and a fairly good flower of G. C. Schwabe. Second prize went to Mr. W. Perrin, gardener to Mr. C. W. Richardson, Sawbridgeworth, Herts, Boule d'Or (Calvat) and M. Pankoncke deserving recognition. For similar classes in amateurs' B division, Mr. Martin Silsbury, Providence, Shanklin, Isle of Wight, and Mr. H. Love, 1, Melville Terrace, Sandown, Isle of Wight, were placed first and second respectively, the latter exhibitor showing a rich reddish-bronze flower cut from the variety Matthew Hodgson, and which looks very much like a sport from that excellent sort.

#### TABLE DECORATIONS, &c.

THE chief class in this section was one for a table of bouquets, wreaths, sprays, button-holes, &c., to illustrate the decorative value of the Chrysanthemum. There were two competitors, the highest honours falling to Miss Nellie Erlbach, "Chards," the Florist, Stoke Newington. Numerous devices were well illustrated, including four handsome bouquets, a grand lyre, anchor, and an enormous vase in the centre of the table, finishing off with sprays, button-holes, and hand-baskets. Yellow, orange, and crimson flowers were mostly used. Mr. E. F. Such was a somewhat poor second. There was a splendid competition in the open class for three epergnes suitable for table decoration. The premier prize was won by Mr. D. B. Crane, 4, Woodview Terrace, Archway Road, Highgate, N., who had three elegant arrangements. The centre epergne, a new design of his own, and a portable one, was very light and pleasing, flowers of bright crimson, bronze, orange, and yellow colours being associated with Ampelopsis Veitchi, Scarlet Oak, Braeken, and other foliage having autumnal tints, and Maiden-hair Fern, Croton foliage, and Asparagus. Second prize was awarded to Miss C. B. Cole, The Vineyard, Feltham, Middlesex, also with a pretty trio of epergnes, each lightly arranged with fresh and clean blooms of good colour and daintily finished. For two large vases, each to contain twelve blooms of large flowering varieties, there were five competitors. Each exhibitor used Japanese blooms exclusively, and they made a bold and noble display. Foliage, &c., was allowed for their embellishment. First prize was secured by Mr. J. Brookes, gardener to Mr. W. T. Newman, Totteridge Park, Totteridge, with a pair of even vases carefully and tastefully set up. The blooms were of high quality and foliage was

pleasingly associated. Mr. Norman Davis was a good second, and had he spent more time in setting up his flowers, the chances are the result would have been reversed. This is a class that might with advantage be extended. The remaining class was one for a vase of Chrysanthemums suitable for table decoration, vase not to exceed 18 inches in height. There were five competitors in this. First place was given to Mr. T. Tullett, gardener to Mr. G. Alexander, Warley Lodge, Brentwood. This was rather a formal arrangement, with a great mixing of the colours and consequent lack of beauty. Mr. Crane was second, using white and bright crimson flowers, with suitable foliage and grasses.

#### MISCELLANEOUS EXHIBITS.

THESE at the early shows usually make a fine display, and on this occasion were no exception to the rule. The gold medal of the society was awarded to Mr. W. Wells, Earlswood Nurseries, Redhill, for a very good display of flowers. The exhibit was arranged in the form of a large circular group, with a twelve-board of exhibition Japanese blooms arranged at four points, equi-distant. The colours of the blossoms and their finish were all that could be wished for. The flowers of M. Hoete, Pride of Madford, M. Chénon de Léché, and other novelties were excellent. Mr. W. J. Godfrey, Exmouth, Devon, had his flowers arranged on twelve boards besides two dozen bunches of Carnations. The Chrysanthemums were very good for so early in the season. Vicomtesse Roger de Chezelles, Baronne A. de Rothschild, Mme. Philippe Rivoire, W. Prince, Mrs. Laycock, C. B. Haywood, and other new and promising sorts were good. This exhibit well deserved the silver-gilt medal awarded to it. Mr. H. J. Jones, Rycroft Nursery, Lewisham, S.E., had a very large table of Chrysanthemums in huge oriental vases, with fifty bunches hardy border sorts and seventy-two bunches zonal Pelargoniums, all set off with Ferns and other fine-leaved plants. A silver medal seemed a scant recognition of this display. Mr. Norman Davis staged a nice collection of Chrysanthemums, including a grand market variety named Klondyke, a rich golden-yellow Japanese of good form with recurring florets. The growth is very similar to that of the well-known Elaine. Mr. E. F. Such also had a nice table of hardy border Chrysanthemums, including capital bunches of Roi des Preoces, Mme. Zephir Lionnet, and Coral Queen. Messrs. H. Cannell and Sons put up a nice group of Cannas, including most of the best sorts, and in addition a fine lot of their new yellow Chrysanthemum Soleil d'Octobre, Milano, and others. A pretty little flambiated pompon, Golden Gem, was much admired. For these together with a very fine collection of vegetables, a silver-gilt medal was awarded. Messrs. J. Laing and Sons received a similar award for a collection of hardy plants and a grand collection of Apples and Pears. The Iethemic Guano Company again decorated the southern fountain and received a similar award. Messrs. Spooner and Sons, Hounslow, and Mr. H. Berwick, Sidmouth Nurseries, Sidmouth, Devon, for Apples and Pears, &c., each received an award of a silver-gilt medal; silver medals falling to the lot of Messrs. John Peed and Sons, West Norwood, for Apples and Pears, and Mr. T. Ware, Hale Farm Nurseries, Tottenham, for Asters and other hardy flowers.

IN other years the Dahlias have very materially assisted to make a bright display, but probably, owing to recent severe frosts, these were not in evidence, but this misfortune was amply compensated for by the interesting and fine display the miscellaneous exhibits made.

A meeting of the floral committee of this society was held on Tuesday last at the Royal Aquarium, Mr. T. Bevan in the chair. Some very good flowers were staged, and first-class certificates were awarded to the following:—

CHRYSANTHEMUM M. GEO. BRUNT.—An immense Japanese with great length of floret, colour pale rosy purple, darker towards the tips, centre white. Shown by Messrs. Pearson and Sons.

**CHRYSANTHEMUM VICOMTE ROGER DE CIEZELLES.**—Very large Japanese; centre florets incurving at the tips, golden yellow, shaded bronze, reverse silvery yellow. From Mr. W. J. Godfrey.

**CHRYSANTHEMUM AMBROISE THOMAS.**—A decorative Japanese; deep reddish crimson, pointed thin florets. From Mr. W. Wells.

A variety called *Soleil d'Octobre*, a compact, large Japanese of a pretty shade of pale yellow, was commended. Mme. Philippe Rivoire and Mrs. Barclay were also promising.

**Royal Horticultural Society.**—We learn that Her Majesty has been graciously pleased to confer the Diamond Jubilee medal upon Sir Trevor Lawrence, Bart., President of the Royal Horticultural Society, Her Majesty being herself patron of the Society. The next meeting of the committees will be held on Tuesday, October 26, at the Drill Hall. At 1.30 punctually the president and council entertain at luncheon the sixty recipients of the Victoria Medal of Honour. The lecture announced for the 26th will be postponed, and instead thereof, at 3 o'clock the sixty medals will be distributed to the recipients by the president in the Drill Hall.

The dates fixed for next year's meetings are as follows: 1898, January 11, February 8, March 8 and 22, April 12 and 26, May 10; Temple show, May 25, 26, 27, June 14 and 28, July 12 and 26, August 9 and 23, September 6 and 20; Fruit show, Crystal Palace, September 29, 30, and October 1, 11 and 25, November 8 and 22, December 13. Any gentleman willing to deliver a lecture on any of these dates would greatly oblige by communicating at once with the Secretary, 117, Victoria Street, S.W.

## NOTES OF THE WEEK.

**Hollyhocks.**—It is pleasing to note the tall spikes of these showy plants quite uninjured by the severe frost recently, and though the flowers are by no means so numerous as in the heyday of their beauty, yet the few that remain are welcome for their brightness now so many of the showy plants are cut down.

**Tufted Pansy Bullion.**—Among the many Tufted Pansies that we have, this one may be said to be always in flower. Week after week and month after month the plants continue to give an ever-increasing supply of golden-yellow flowers, and even now the glossy little tufts are rich in colour and still contain as many buds as do many kinds in the height of their flowering season.

**Chrysanthemum Rycroft Glory.**—Though one of the most free among yellow-flowered kinds, the above is not early enough for outside use, which, from this point of view, lessens its value. Could it be induced to open its flowers so as to be at its best at the end of September, it would prove of considerable value in the open. A day or two since, however, this variety was only opening the earliest flowers.

**Chrysanthemum Mm<sup>s</sup>. M. Masse.**—For producing masses of colour from the middle of September to the present time this lovely kind surpasses all else. Apart from the rich store of blossom, the variety also possesses great lasting properties, which, as a garden flower at this time, cannot well be over-estimated. The flowers are of a rose-mauve shade with silvery margin, the heads of blossoms being borne on well-disposed branches, which are not more than 2½ feet high at the most.

**The Choke Berry (Pyrus arbutifolia).**—I send a few sprays of this to show how fine it is, large breadths of it in damp soil, in which it runs about freely, are most brilliant. It is most at home near the water-side.—T. SMITH, *Newry*.

\*\* The leaves on the shoots of this are of an intense scarlet hue. It is one of the most valuable of the many shrubs that take on a rich colour in autumn, and like many of these, it is a native of North America.—Ed.

**Rudbeckia subtomentosa.**—Late as is the season now, it is pleasant to see how bright is this pretty Coneflower. It is known I believe as the "Hay-scented Coneflower," and the plant appears to possess in some degree the odour of

new-mown hay. It grows about 3 feet high in the light soil here, and is usually much admired, the dull grey-green of its leaves looking well among other plants when surmounted by its yellow flowers with dark centres. Like the others of the genus it is a native of North America.—S. ARNOTT, *Carsethorn, Dumfries, N.B.*

**Aster Ariadne** is probably one of the finest of the *Novi-Belgii* group. It is for small borders perhaps a trifle tall, as in good soil it attains to 5½ feet or thereabouts. But the pleasing and graceful habit, which is not at all dense, is sufficiently strong that no staking is needed, and the result, when planted with a free hand, is charming. The flowers are large and of a pleasing dark blue shade. It is among the finest in the Royal Gardens at Kew, where a lovely group 10 feet across may be seen in perfection.

**Campanula Hendersoni Tymonsi.**—In the flowers individually there is a good deal of *C. Hendersoni*, apparently one of its parents. In other respects the plant differs considerably, being taller and producing an almost pyramidal panicle of blossoms. The woolly and distinct foliage partakes somewhat of the downy character of that of *C. sarmatica*, though the leaf character is distinct even from this. But whatever its parentage it is certainly a most useful and beautiful plant, and after producing its quota of summer flowers on stems some 18 inches high or more, the plant is now bearing quite a number of flower spikes at this season, when most *Campanulas* are practically at rest. The plant is evidently a better grower than *Hendersoni* in many instances.—E. J.

**Early-flowering Chrysanthemums.**—Now that the dull October days are with us and the beauty of the garden is on the wane, it is pleasing to turn to the early-flowering *Chrysanthemums* now in their full beauty in the open. After the severe frosts of the past few days which have cut down all the Dahlias, the early-flowering *Chrysanthemums* are still uninjured and continue to open freely. In order to see these at their best, let them grow naturally with no disbudding. In this way huge bunches containing five and six blooms may be had for the decoration of the house. Another valuable characteristic of these early-flowering varieties is their lasting properties when cut. Messrs. Dobbie send us from their seed grounds at Rothesay a great number of varieties in splendid condition.

**Naming hardy plants.**—Much as this is to be desired when rightly applied, it is, on the other hand, to be deplored when names are given to varieties that do not possess as much merit as the species from which they came. There is this tendency at the present time in multiplying an already numerous family, viz., the *Starworts*, and in more than one direction. Last week we noted it at the Drill Hall, where a variety, to all intents and purposes identical with *A. N.-B. lævigatus*, had received a distinct name. Singularly enough, the attempts appear more generally with the *Novi-Belgii* section, or the Italian kind, *A. Amellus*; the former very numerous and the latter difficult to equal, much less surpass. But bearing seed freely is a possible temptation to some, and the true *Aster Amellus* and *A. A. bessarabicus* are so good in themselves that it seems a pity to attempt to circulate more or less inferior forms, while the best may be had in equal quantity from cuttings or division.—E. J.

**Pyrethrum uliginosum.**—This plant has been more than usually gay this year, the great masses of pure white bloom at 6 feet high being seen at a great distance. It is occasionally referred to as being too tall, and stopping the shoots is recommended. Those who want to make a dwarf plant of this should let it grow naturally till early in June, and then cut it down to within 9 inches of the soil. When this is done the plant flowers at less than 3 feet high, and with perhaps only three days' difference in the opening of the blooms. Too frequently, in place of this cutting down, the points of the shoots are removed as in the *Chrysanthemum*, this, how-

ever, only producing a greater number of smaller flowers. By cutting the plants down, several shoots quickly appear on each stem, and if half of these are removed at once, the result will be a fine mass of pure white at nearly 3 feet high. In this way the plant may be used even in quite small gardens, from which it is now excluded owing to its great height.

## OBITUARY.

MR. W. A. STILES.

WE have to record with much regret the death of Mr. W. A. Stiles, the editor of *Garden and Forest*. The esteem of his fellows is fully shown in the notices of his death in the New York papers, among them the following in the *Evening Post*:—

The death of Mr. William A. Stiles, the Park Commissioner, is a distinct loss to the city. He was one of those rare men in official life upon whom you could always depend for wise and just action. During the brief time that he was in the Park Board he made his influence felt in all directions of park control and development. He was an enthusiastic student of the work which he had in charge, and, in spite of constant ill-health he was untiring in his efforts to bring about good results and thwart all others. Nobody who has not kept close track of park matters in this city knows how incessant and insidious are the efforts of the vicious and the ignorant to despoil and deface the parks in one way or another. A park commissioner who has both the expert knowledge and the disposition to fight these attempts successfully is a very rare possession, and his leaves a vacancy which it is difficult to fill.

He was selected as editor of *Garden and Forest* when it started, and very ably occupied the post. He was a graduate of Yale College and the Rev. J. H. Twitchell writes of him as a classmate:—

During all the years since his graduation the presence of no man at Yale gatherings has been more desired or more welcome. To the friends of his youth, his classmates in particular, his memo is dear, and he was distinguished among them for his shining and various talents. He was at the same time a sprightly, merry soul, overflowing with wit and humour, the very genius of good fellowship. He was sensitive, sympathetic, and true-hearted, and drew to himself a rare quality of affection, which more intimate acquaintance with him never failed to deepen. Moreover everyone who knew him well soon discovered the underneath his vivacity were a thoughtful mind and temper of moral earnestness, by which respect was added to affection. The world held no more delightful, choice, and beloved spirit; not that leaves a sweeter memory.

When wanting a rest through illness two years ago he made a very short visit to England—flying visit it was, but sufficient to impress with his sympathetic and bright nature. He was in the time of wild Rose bloom, and as he rambled among them together his pleasure being among our English wild Roses was given to see. He will be much missed.

## ORCHIDS.

### NOTES ON PHALÆNOPSISIDS.

Orchids have puzzled cultivators more in instances, while in others their culture is very simple. In the same place and with the same grower one plant grows well and another fails to do so, while in some houses apparently well suited to them and where other Orchids from the same country thrive the *Moth* Orchids refuse to grow. The reason is not far to seek, but it is very difficult to give any directions that will enable amateurs to grow their satisfactorily. So little stands between success and failure, that everyone must to a certain extent experiment for himself, and when the most suitable place for the plant is found, leave it there, and endeavour by careful attention to small cultural details to keep it in health. Phalænopsids are naturally very free-rooting plants, as seen by the disposition of the roots to run in long straight lines rather than curve about the side of a basket, and this doubtless accounts for a great many failures. It needs no great stretch of imagination to picture a plant in its native home pushing for yards in length up or down a tree trunk and the foraging capabilities of such roots may be very greatly in excess of any that can possibly be produced under cultivation. Some may say, fasten the plants to long poles, and thus as been tried, but the difference between a living tree and a pole is much the same as between the climate of the habitat and that of our orchid houses. This being the case, it is obviously impossible to follow Nature with regard to the rooting medium, and although it is seen at first sight bad practice, I am of opinion it is much better, instead of using long cylindrical baskets, and so encouraging the long roots, to induce them, on the other hand, to ramify as rich as possible by presenting a rough, broken surface to them. This is most easily effected by using pots or baskets of ordinary material almost filling these with rough crocks and

charcoal and allowing a thin layer only of clean Sphagnum Moss. The size of these receptacles will, of course, vary with that of the individual plants and also the different species, for no one would think of treating the vigorous *P. Schilleriana* or *P. amabilis* on similar lines to *P. Lowi*. Atmospheric moisture is very necessary to the cultivation of Phalænopsids; not only must it be plentiful during the growing season, but it must be used to soften the dry atmosphere in winter caused by the sharp application of fire-heat required to keep up the temperature. Ventilation, fire-heat and moisture must, in fact, go hand in hand, so to speak. A house kept close and moist is quite as unsuitable to these Orchids as one kept draughty and cold. When it becomes necessary to use fire-heat, keep a little air on as well and damp freely so as to cause a nice evenly-balanced temperature. In late autumn, especially when every bright day is anxiously looked for by careful cultivators, the sunlight may be made the most of by these means, not by shutting the house up close, as some advise. A few degrees of warmth are of course saved by the latter proceeding, but it is at the expense of the consolidating influence of the sun's rays, and this is a very important consideration. The leaves by this time will be getting fairly hard, and no shading will be required if this has been systematically reduced. From the end of August onwards a gradual diminution is required, while after the first bright days in March it will not be safe to leave the blinds up entirely. When growth recommences the condition of the foliage is soft and tender, and it is just then that the most shading is required. During the heat of summer the blinds must be kept off the roof as long as possible in the morning, the foliage meanwhile having been kept cool and dry by early morning ventilation; then by taking off a certain amount of the air and lowering the blinds, a calm, moist state of the atmosphere is easily maintained without an approach to stuffiness. Watering at the root needs care and judgment. Few Orchids like more moisture when root action is

really brisk, but they are easily injured by over-watering when at rest. All the year round a certain amount must be given, but with a cold wind perhaps blowing outside and a rather lower temperature in early morning than is desirable, one always feels easier if the roots are a little on the dry side. The details must, as mentioned above, be largely left to the individual grower, and will vary according to circumstances, such as the position of the house and its aspect, but it is well to keep in mind the few more cardinal points above noted. R.

**Oncidium divaricatum.**—This is a pretty species when well grown, the long branching scapes having a light, elegant appearance, although the blossoms are small individually. It has clear yellow flowers, these being spotted about the base of each segment with bright crimson. It requires a good long season of growth, and after this a decided period of rest, and during the latter the roots may with advantage be kept well on the dry side. During summer a full supply of moisture is necessary, and for this reason a rough open compost must be allowed.

**Oncidium aurosum.**—Flowers of this species come from a correspondent for a name. It is one of the long-branching flowered kinds having pseudo-bulbs about 4 inches high, bright green leaves, and blossoms of a bright golden yellow, lightly spotted with reddish brown. It is a native of Peru and Guatemala. It is not a difficult plant to grow, and thrives in a cool, light house. The compost may consist chiefly of peat and Moss, with plenty of crocks and charcoal added. Pot in medium-sized pots, and give plenty of water at the roots during the growing season and abundance of air all the year round.

**Cypripedium amandum.**—This is a pretty hybrid of the easiest culture, and quite as hardy and free as the good old *C. insigne* or *C. venustum*, from which it was raised. Plants here have been growing in a greenhouse all the season with the usual occupants of such structures and no special care, and they are now flowering finely. The foliage is more like that of *C. insigne*, but with a few dark markings. The flowers are of medium size, the dorsal sepal light green, with

deeper stripes and large spots, the pouch prettily venated, not unlike that of *C. venustum*. It first flowered with and was raised by Mr. Bowring, of Windsor.

**Epidendrum purum.**—Although not a showy plant, this has many good points, not the least of these being its delicious fragrance and long-lasting qualities. The habit of the plant is tufted, the stems rising about a foot high, and from the top of these occur the branching racemes of pale yellow blossoms. The plant is not difficult to grow, thriving and flowering freely at the cool end of the Cattleya house. It should be potted in rough peat and Moss over good drainage, and requires plenty of moisture. It is a native of Colombia, and was first introduced in 1844.

**Dendrobium album.**—The blossoms of this species are not exactly pure white, but some of them have very little colour in them. They are usually of a creamy tinge, the centre of the lip being yellow and produced towards the end of the growths in racemes of two or three. The stems grow horizontally or pendent, not unlike those of *D. chrysanthum* in appearance, and, like this species, it may be grown in a warm, moist house not far from the roof-glass. Fairly large wooden baskets and a rough open compost suit it well. *D. album* is a native of the Nilghiri Hills.

**Zygopetalum Gautieri.**—This handsome species is now blooming freely, the fine showy blossoms showing well upon the deep green foliage. In habit it differs from *Z. maxillare* and similar kinds, being almost intermediate between these and *Z. Mackayi*, but the blossoms are among the showiest in the genus. The sepals and petals are yellowish-green with heavy chocolate markings, the lip varying in colour, but usually of a bluish-purple, fading to white. Like the species noted above, *Z. Gautieri* likes a piece of Tree Fern stem, and, failing this, a basket made wide rather than deep, and a thin compost. It does well in the Cattleya house and is a native of Brazil, whence it was introduced in 1868.

#### CATTELEYA LABIATA.

THE earlier blossoms of this species are now in perfection, and each season its splendid constitution and free-flowering characteristics are more apparent. As is well known, the flowers are among the best, both for size and colour, and this, combined with the fact of their filling up a break of a couple of months at least, which before its re-introduction were not remarkable for wealth of bloom on Cattleyas, makes it a favourite plant everywhere. The latter point is in fact a great recommendation, for though there are kinds blooming between *C. Gaskelliana* and the earliest forms of *C. Trianae* and *C. Percivaliana*, these are by no means remarkable for their free-flowering qualities. It comes nearest the former useful kind in habit and general characteristics, but a noticeable point is the double sheath, though this is not always present. In colour the flowers range over a great variety of tints, from the lovely albino form to others of a very deep rose on the outer segments. Its culture presents no special difficulty, and anyone who is successful with the *C. Mossiae* or *C. Mendeli* groups may with every confidence take up its culture. It is a fairly vigorous rooting plant, and well-established specimens should be given fairly large pots, though for the first year or two the rooting medium need only be thin. Good peat and Moss in equal proportions and plenty of rough nodules of charcoal will grow it perfectly provided the drainage is in good order and the plants are carefully watered. During the time growth is most active a light sprinkling with tepid water from the syringe does good on very hot days, but during dull weather and while the leaf is issuing it must be discontinued, otherwise it is apt to collect in the cup that is formed thereby and to damage the plant by damping. *C. labiata* is a species that keeps well to its annual routine of growth and rest, and possibly this in a measure accounts for its satisfactory condition in collections.

The plants like plenty of water at the root as long as the compost is in good order, but naturally much less is needed during the winter than in the growing season. Its culture, in short, is of the simplest possible description, and it will doubtless long continue to be a popular Orchid. It has been known since 1818, in which year Mr. Swainson sent it home from Brazil, but until very recently it was very rare, dozens of collectors having searched in vain for its habitat.

**Gongora atropurpurea.**—This Orchid seems nearly always in flower, one spike being hardly over before another appears. The flowers are not large individually, but very interesting in structure, and their deep reddish or port-wine colour is rather unusual. The pseudo-bulbs are large, pale green, very deeply ribbed, and each bears a pair of leaves of hard texture, about 4 inches wide. The roots are very freely produced in a suitable compost, often pushing in an upright direction like those of a *Grammatophyllum*. I like it best in teak baskets suspended not far from the roof glass in the Cattleya house, as here the pendent or arching spikes show nicely. The compost may be of a fairly sound description, a little loam fibre doing no harm if mixed with twice its bulk of peat and Moss for strong plants. Crocks or charcoal must be freely mixed with these materials, and drainage is a very important item. Few Orchids require more water than this during the growing season, and in a warm, moist house the plants may with advantage be somewhat heavily syringed overhead. In the genial temperature thus produced growth is very rapid, and red spider, thrips, and other insects sometimes affecting the plants are by this means easily kept away.—R.

**Oncidium Forbesi.**—This beautiful plant is now in good condition, the fine branching spikes carrying a large number of flowers. These are large individually, bright shining brown, with a golden yellow margin, prettily undulated. It is one of the most beautiful of *Oncidiums*, and a plant well worthy of the utmost care. But this, unfortunately, will not make *O. Forbesi* a success under cultivation. I have tried it in various temperatures and under different modes of potting and basketing, but the result is not satisfactory over many years. It is true that this Orchid is more often than not killed by the thoughtless plan of leaving the flower-spikes on until they fade, this weakening the strongest plants and often killing weaker ones outright. Still, with the best of care it is a difficult plant to grow, and I have known plants that one season plumped up immense bulbs the next year refuse to grow at all. The likeliest place for it is a light, airy position not far from the roof glass and near a ventilator in the Cattleya house. It must have a diminished supply of water at the roots during winter, but must not be entirely dried off. It dislikes much material about the roots or frequent disturbance; consequently when repotting is done the drainage should have especial attention and only lasting material used.—R.

**Dendrobium bigibbum.**—Although this fine Dendrobe has been in cultivation since 1824, when it is said to have flowered at Kew, it was not much known until 1855, when it was discovered by Dr. Thomson in one of the islands in the Torres Straits. It is one of the finest of the Australasian kinds, the spikes of rich magenta blossoms appearing during this month from the apex of the young pseudo-bulbs and occasionally from the older ones as well. *D. bigibbum*, like many others of the same section, often begins to grow in late autumn, and for this reason should be kept fairly warm during the winter months. Keep the plants on the move when once they have started, but endeavour, by allowing plenty of light and air, to consolidate the growth a little as it is produced. A short resting season is of great advantage in summer if it can be arranged, not by drying the roots, but by taking the plants out of the warmest house to one a few degrees

cooler during the time growth is inactive. The plants should be allowed a light, sunny position not far from the roof glass, and are best potted in small baskets or pans. The root must not care for a great thickness of material about them, and about an inch is ample for all but large specimens. The best time to repot is in early spring, when the young bulb is about formed and is commencing to root freely on its own account.

## STOVE AND GREENHOUSE

### AZALEAS GRAFTED ON RHODODENDRONS.

IN the year 1884 M. Seidel, senior, first suggested to his son (M. Rudolph Seidel) the idea of grafting the Indian Azalea on a Rhododendron stock, and, as an experiment, they were gentlemen, with the assistance of their friend, M. Lauterbach, made a dozen grafts of the description. At that time M. Seidel had the doubt that this operation was the first step towards a thorough revolution in the culture of Azaleas, and that it would come into general practice. It was certain that it would not be adopted anywhere at once, and the greatest difficulty was that of securing for it a favourable reception in the horticultural world. So indeed, it had to encounter criticism, when, in the year 1894, M. Seidel showed for the first time, at the exhibition at Gand, the specimens which had been grafted in 1884. For vigorous growth, fine appearance, and unusually flowering qualities these received a certificate of merit for advancement in the culture of Indian Azaleas. Notwithstanding this, M. Seidel returned home to Saxony under a cloud of adverse criticisms. The Belgians, and other people as well—nearly everyone in fact—asserted that these plants could not live, and that many varieties of Azaleas would unite imperfectly with the Rhododendron stock, so that they would be easily broken off in packing and in transit. Numbers of objections were made which had no foundation, the matter was merely in the initial stage of development, and criticism could only suggest assumed possibilities. In spite, however, of all the hostile criticisms, Azaleas grafted on Rhododendrons made their way into favour. In the year 1894 M. Seidel offered some specimens for sale, which, on account of their vigorous habit of growth and the fineness of their flowers, which surpassed that of the ordinary Azaleas in beauty and regularity, were so much preferred by purchasers, that every year since M. Seidel has received more orders for plants than they have been able to supply, and to meet these daily increasing orders they have this year grafted 40,000 plants.

I do not know whether the critics still think that Azaleas grafted on Rhododendrons are of no value, but in any case I think they will not lay down their arms and join with those who have adopted this system, considering that the last autumn plants grafted in this manner, their way into the forcing houses at Berlin (where Azaleas grown in the ordinary way had previously held the field without a rival) gave great satisfaction there. Of course this does not imply that no other kind of Azaleas will be forced there, but the numerous specimens which will be given this year by these Berlin forcers will show at least the advantage, if not the superiority, which is attached to this system.

The objections which were made against this system have been proved entirely unfounded, for up to the present Azaleas grafted

we have done quite as well as those grafted on the Azalea stock, and always grow more vigorously. One cannot, of course, be certain that they will live as long as the old-fashioned kinds, one of which are now sixty years of age, while one of the plants grafted on the Rhododendron stock are as yet more than thirteen years old. But even if they should not live for more than twenty years, the high reputation which they are gaining will suffer nothing in consequence, since Azaleas of that age are of very little use in a commercial point of view. It is quite true that certain kinds which, like *Souvenir du Prince Albert*, unite very badly when grafted on Azalea concinna or other Azalea stocks may not take well when grafted on the Rhododendron stock; but the number of such kinds is so small, that no difficulty will be thereby raised in carrying out this system of grafting, and the circumstance cannot be considered a drawback. We may then come to the conclusion that this new method of grafting has a great future before it, and it would not be surprising if, in the course of time, it entirely superseded the other methods which are at present in use. Up to the present no attempt, at least so far as I am aware, at this method of grafting Azaleas has been made in France, but the florists of Paris may take heart, for undoubtedly they will soon be able to furnish their shops with these superb plants. M. Duval, the well-known nurseryman at Versailles, was this year to have commenced his first essays in this method of culture, which, with such a skillful operator will no doubt be crowned with success.

I will now describe the means which are employed in MM. Seidel's nursery for obtaining the plants as speedily as possible by this method. The only variety of Rhododendron which is thus used as a stock is *R. Cunningham's White*, because, rooting well and growing vigorously, it yields excellent stocks on which the Azaleas take very well. The Rhododendron cuttings are taken in November and December, and, as far as possible, from wood a year old and in a good healthy condition. If cuttings are plentiful, the upper part of the stock only is used, for this part produces the best stocks, growing more rapidly and regularly than those obtained from any other part of the shoot. The cuttings are planted in a warm house on shelves covered with a layer of sand 4 inches deep, topped with about a quarter of an inch deep of peat very finely crushed. These shelves are naturally closed in, and are warmed underneath by pipes or otherwise, so as to have a bottom-heat of from 69° to 76° Fahr. The atmospheric heat of the house should be kept under 69° as much as possible. It is necessary to shade when the sun is shining, even in February and March, in order to keep the temperature down to this, as a high temperature induces thrips. The cuttings take root in about 6 months, but usually they are not potted off until the following April, when they are potted in 4-inch or 3½-inch pots. The newly-potted plants are then placed in a house with some bottom-heat under them to expedite their taking root. After on they may be placed close together in frames, where they will be able to increase in length as they grow, as they must be grafted in the winter following, when they should have a stem as slender as possible and at least 6 inches or 8 inches long. Grafting may be done from January to April. For this purpose the cuttings are placed in a house with a temperature of 69° Fahr., where in a few days they will be growing vigorously, with an abundance of sap flowing in their tissues. This is the right time to graft so as to ensure that the Azalea

scion will speedily unite with the Rhododendron stock. The mode of grafting employed is plain whip-grafting, such as is practised, in July and August, when *A. concinna* and *A. Hexe* are used as stocks. The treatment after the graft has taken is precisely the same as that described at p. 47 of *Le Jardin* for 1896, except that these small plants are planted out in the open ground in May or June, and instead of being potted in the autumn before they are sold, they are not potted until spring, so that they will have been only six months in pot instead of a year. Another difference worth mentioning is that these plants sell for nearly double the price of plants of the same age grafted on *A. concinna* or other stocks, because they are more vigorous growing and of larger size, and exhibit a regular and robust appearance which recommends them to all good judges of plants.—E. TREILLAUD, in *Le Jardin*.

**Cineraria eruenta.**—Though hybridising has done great things in improving the flowers of this plant, none of the present-day kinds have the pretty elegant habit of the old species. I saw it a day or two since flowering very freely, and I think that even now its beauty and continuous flowering should ensure it a greater amount of care. The foliage is roughly heart-shaped, pale green above, purple beneath, the flowers occurring on loose heads nearly the whole year round. It is very easily grown, as it thrives in a cool greenhouse, if not starved at the roots, and kept free of insects.—H.

**Fuchsia Dr. Shaw.**—This is a very fine variety raised at the Clifton Zoological Gardens, Bristol, by Mr. G. Harris, the superintendent of the gardens. The tube and sepals are blush, with a pink reverse to them; the corolla, which is large, well expanded and of the finest form, is of a pale purple colour, with a distinct carmine heading. It is an excellent grower and blooms very freely. I was much struck with it when I recently saw it in one of the plant houses in the gardens. Mr. Harris has other seedlings, good growers and very free blooming, and of decided value for his purpose. The gardens form a delightful lounge, and there is a large, varied and valuable collection of hardy Ferns to interest such as are attracted by them.—R. D.

**Salvia splendens grandiflora.**—The brilliantly coloured *Salvia splendens* and its varieties flower at a time when they are particularly valuable, that is just before the bulk of the Chrysanthemums come in, and when many subjects that have bloomed throughout the summer are on the wane. The variety *grandiflora* was shown in grand condition at the meeting of the Royal Horticultural Society on September 21. It is altogether superior to the ordinary form, as not only are the flowers larger, but the calyces as well, and also the spikes of blossoms. In the case of these *Salvias* the flowers are not of long duration, but the calyces, which are of the same colour, remain fresh and bright for a long time. They are all of easy culture, and by some are planted out during the summer months, and potted just before the flowering season.—H. P.

**Lachenalias in autumn and winter.**—Many gardeners who grow *Lachenalias* well stand their plants in the open for a time after repotting the bulbs in September. This is a good plan, but they should be removed to frames early in October, as cold and wet together do not suit the roots. When in frames, however, full exposure by day should be given in fine weather, drawing the lights on at night. The less codding *Lachenalias* have the better, and when put into the greenhouse at the end of October, they should have a very light position near the roof-glass. I have seen them subjected to slight heat in spring to induce an earlier expansion of the bloom-spikes, but to have them in the best form and the foliage stout and dark coloured, a cool atmosphere from first to last is necessary. *Lachenalia*

*Nelsoni* is a beautiful variety for pot culture, its tall well-furnished flower-stems of pure yellow having a fine effect in spring. The old tri-color, however, is still one of the best for growing in pots, also for growing in baskets for the conservatory.—J. CRAWFORD.

**Costus igneus.**—It is really surprising that this beautiful Gingerwort is not more often met with in gardens, as it is of the easiest culture and maintains a succession of blossoms for a lengthened period, while the colour—a rich orange—is pleasing and decidedly uncommon. For some years now it has been grown at Kew, where in one of the stoves it was recently flowering very freely. It is a native of Bahia and was introduced by M. Linden in 1882. This *Costus* forms a stout root-stock from whence sturdy stems are pushed up. When confined in pots it will flower freely when not more than 18 inches high, but planted out in a warm house it will attain a considerably greater height. Like many of its allies, the blooms of this *Costus*, which are each about 2 inches across, are thin and do not last long, but a succession is kept up from one head for a considerable period. It grows freely in a light open compost and requires copious supplies of water during the summer months.—H. P.

**Early pot bulbs.**—In many gardens both Roman Hyacinths and Paper-white Narcissi are brought forward as soon as possible, the blooms being wanted to take the place of the general run of outdoor flowers. Both these subjects when potted early in September will now have grown considerably, and will need removing from the covering of leaf-mould or ashes. It is a mistake to take them straight from such quarters into light and much heat. My plan is to stand the pots on a brick kerb in a cool house, and to cover them with another pot inverted. A little light can then penetrate through the hole of the pot, and in about ten days the plants may be fully exposed. A fortnight in this temperature, previous to placing in the forcing house, will secure stout, well-developed blooms with few blind growths. Some place the pots in a frame on an ash bottom, fastening a couple of garden nets over the light to secure partial darkness. This plan answers very well.—GROWER.

#### PANCRATIUM SPECIOSUM.

Will you please say what treatment I should give *Paneratium speciosum* to get it to flower about the end of July next year? It has just now finished growth. There are twelve bulbs in a 12-inch pot and well established.—W. DAVIS.

\*\* To get your plants to flower next July will be an easy matter if the growth made this year is well ripened. By the term well ripened, we mean this new growth must be well developed before you attempt to rest or keep the plants quiet. On the other hand, twelve bulbs in a 12-inch pot are too many, as the bulbs must be small for that sized pot to contain them. You give us no idea as to size of bulbs or age, and we can only surmise that they are young. The usual plan is one bulb in an 8-inch pot, or three in a 12-inch. This is the size of flowering bulbs, but it does not follow your plants will fail to flower in the pot named, as they often bloom much better if the roots are restricted. On the other hand, there must be a fair-sized bulb before the flowering stage is reached. You say your plants are well established, but in a young state they grow freely, and by this we fancy the pot is quite full, and under the circumstances named you will be unable to get very good bulbs in so restricted a space. There is not room for the bulbs, and there will be too much crowding. We should be inclined to make at least three pots of the plants another season, repotting just before new growth begins. Failing this you may shift on into a larger pot, but we fear unless you thoroughly understand their culture you will not find it so successful as three or four bulbs in a smaller pot. You see it is impossible for the bulbs to attain size with so many in a pot, and you cannot get fine spikes till they are of a good

size. On the other hand, the pots must be full of roots, and your plants will have exhausted all the goodness from the soil. The bulbs, we fear, are not now able to get more sustenance, and in such a condition are not likely to improve. You must get strength before you can get flowers. You may possibly get a weak flower or two from such bulbs, but we fear even this chance is remote, and in the end you will find it best to give more room. It is not necessary to rest young plants that are not strong enough to flower. We have seen them kept growing quietly all the winter. By this means a larger bulb is obtained. Of course you could not do this now, neither is it wise to repot or divide your plants now, growth is nearly finished. If your plants do not show flower in the spring we would certainly divide, not wait till July, as then you will get a longer season of growth for the plants next year. After the plants are in the pots named the less shifting or repotting the better. You can then feed freely to keep the plants vigorous. You must get a strong plant to begin with, and we fear yours are not. When strong there is no difficulty in flowering at a certain season, and with several pots you may have a succession of bloom from June, or earlier. You may say, Why not feed the plants in the pot named? Certainly; but you cannot get a fine bulb growth under such conditions. The plants are not at all free-flowering unless a good growth is made yearly. The winter treatment for flowering plants is to keep them in a temperature of 55° or 60° during winter, giving just enough water to keep the leaves green, giving more warmth in spring, and then thoroughly damping the plants twice daily. Red spider is troublesome in dry houses or if the plants are grown near hot-water pipes. After flowering, feed freely to build up new growth and give ample supplies of water till growth is finished.—Ed.

#### SHORT NOTES.—STOVE & GREENHOUSE.

**Nerine Meadowbanki.**—If not the most striking of this beautiful genus, this is indeed a very attractive one for the brilliant colour. A most brilliant shade of scarlet is quite unique even among the many good things in this family. In a setting of Maiden-hair Fern a mass of its flowers may be tolerated, otherwise when alone it is too dazzling.

**Pancretium canariense.**—This very neat and elegant species is now in flower at Kew, and is represented by a scape 1½ feet high, with the leaves just issuing from the bulb. The blossoms are very compact, the segments scarcely more than 2 inches in width, these with the short, well-expanded cup, which is about 1½ inches across, being pure white. The umbel contained some six or eight buds, which will keep up a succession of blossoms for some time.

**Propagating Gardenias.**—The following plan of propagating Gardenias I have found to answer: I take some twenty cuttings of half-ripened shoots and put them into a large pickle bottle filled with water, and stand them in the stove house. In about a fortnight they begin to make roots. When the bottle is filled by the small roots I then pot them up and repot as necessary. I find that I get better and stronger blooming plants than by making cuttings and putting them into a propagating case.—M.

**Funkia subcordata grandiflora.**—It is not in the open-air garden alone that this is useful or even desirable. Indeed, as a pot plant it has many claims, though more especially where fragrant flowers are admired and where little heat is at command. A fine tuft in a 10-inch pot that has become established will produce several flower-stems and a large number of blossoms. These latter are pure white, fragrant and of considerable length. In quite a cool greenhouse the plant will remain in flower for weeks in succession.

**Rhipsalis Houletii.**—This distinct and curious Brazilian species is now flowering in the large succulent house at Kew. The plants are

about 2 feet high with flattish pendulous branches, the latter deeply serrated. The curious part is that the small yellowish blossoms are produced in considerable quantity along the sides of the toothed divisions. Though not showy, the plant is interesting for the reason noted. The plant may be grown in the same way as Epiphyllums and the like.

## FLOWER GARDEN.

### SOME LATE MICHAELMAS DAISIES.

SOME Michaelmas Daisies are habitually so late that they hardly reach flowering here in ordinary seasons, and others are destroyed by wet and severe frost alternating before they are half over. I heard to-day that there have been 10° of frost in the Lowlands of Scotland, and that the varieties of *Aster cordifolius* have been destroyed past hope before a flower had opened. We are not so badly off as that, for *A. turbidellus* is in flower, and this is my test plant of a Michaelmas Daisy season, being the latest to which I give a place in my borders with any hope of its becoming ornamental. Many other species of *Aster* have early flowering and late flowering varieties, as well as good and bad; for example, the type of *Aster puniceus* is not only coarse and unmeritable, but very early, being over by the end of August, but it has a variety of less spreading and taller habit, which, I think, was called *pulcherrimus* at the Chiswick conference, and seems to be the same as that described on page 313 as *A. p. grandiflorus*—a better name for it, as these superlative surnames leave no room for improvement, a quality which ought to be the object of all gardeners. It is, however, distinct and showy and worth its room, but it seldom begins to flower here till the middle of September.

There are few classes of hardy plants which depend more on the conditions under which they are grown than Michaelmas Daisies. In favourable soils and surroundings a second or third-rate kind will attract more admiration than the best, if badly managed, and there are two common causes of mismanagement: either the stalks are tied together in a close bundle, or the roots have become so unhealthy by the collection of a woolly mass of dead stalks at the base of the plants that they wither up prematurely from starvation. Some kinds are especially liable to this failure. *Arcturus*, *Archer-Hind*, *cordifolius* all grow from a small base without spreading their shoots, and if left alone for more than two or three years become shabby. But running kinds of *Aster* are hateful. I had one (an early kind) with white flowers, commonly known as *niveus*, but I believe it belonged to *Tradescanti*, which ran about so wildly that it has given me some trouble to get rid of. Perhaps the best habit is to spread closely and moderately, so that the stems have room to ascend without great crowding, and that the clumps can be conveniently lessened. *A. Novæ-Angliæ* is one of this kind, so is *Robert Parker*, and varieties known as *Ariadne* and *Purity*.

The colour of *Asters* should be judged in full daylight, or by candle-light if wanted for candle-light ornament. I say this because nearly all of them look so beautiful on a clear evening for about half an hour before sunset that we are apt to be misled with regard to their merits. *Arcturus* and *densus* and two or three unnamed seedlings which I have look tolerably blue by daylight, but towards dusk, on a fine evening, *Archer-Hind*, which is by no means the bluest in sunshine, shows quite a brilliant sky-blue.

Whites are most of them early. There are a few better than *Harpur-Crewe* and *J. N. Wood*, though I have some twenty seedlings which have been under probation for three or four years. Some of these have the versicolour habit of turning purple when they have been out for a few days, and others keep their whiteness to the last. Preference in selecting will be given to those which flower after *Michaelmas*; two or three old kinds, one, I think, of the type of *A. paniculatus*, another the type of *ericoides*, and a very late dwarf, *versicolour nanus*, are all worth keeping. I have a very choice late seedling called *May Crun*, which comes out pure white and passes into pale pink, somewhat in the same manner as the late Mexican Daisy; it is of excellent habit, and I consider it one of the best seedlings I have raised, and as I have distributed it for two or three years it is probably in commerce, but I am afraid it will not do for Scotland. Two other late seedlings, both to be found in catalogues and both raised here, are *Ella*, an improvement in flower on its parent, *Robert Parker*, and *Edith*, a very free, semi-double, large-disked form, with flowers of a pearly lilac. One from a Devonshire garden known as *Coombe-hishacre* has great merits from its excellent habit; it has white flowers with a purple centre, double the size of those of *horizontalis*, which it somewhat resembles, keeping it company in its season of flowering. The *cordifolius* section is now well known; it seeds about very freely, and now and then an improvement comes. I have one of the purest white. The delicate plume-like racemes of some of the best forms of this species are most beautiful, and as it shades where it may escape frost, and has a good blooming season, it supplies flowers often to the end of November. C. WOLLEY-DO

*Edge Hall, Malpas.*

**Campanula patula.**—If "A. D. G." has a friend in Shropshire he ought to be able to obtain seeds of this beautiful annual. I have found it abundantly near Haughmond Abbey at Albrighton, in the neighbourhood of Shrewsbury, and unless, like many other choice flowers, it has fallen a victim to the pernicious system of giving prizes to children "for the best bouquet of daisies" (meaning in effect the extirpation of annuals), it is probably still to be found in the soil and other parts of Shropshire, a county producing, I believe, a greater variety of wild flowers than any other county in England. The "A. D. G." I have never met with any offer of seed, but any nurseryman in Shrewsbury or Lichfield could have little difficulty in procuring it. T. H. ARCHER-HIND, *South Devon.*

**Hemerocallis minor.**—The introduction of the beautiful *Hemerocallis aurantiaca* major led to a good deal of attention being directed towards the Day Lilies of late, and various names thereon have at one time or other appeared in THE GARDEN. Very little, however, has been said concerning *H. minor*, and I have not seen any reference to its most prominent characteristic, viz., the late season of blooming compared with the other members of the genus, for at least a clump of it was bearing a number of blossoms on October 4, and I also saw it about the same time in a similar state in other gardens. The general appearance of the flower is very like that of *H. flava*, which is, however, about the earliest member of the genus to unfold its blossoms, while *H. minor* is much the latest. This last form consists of narrow grass-like leaves, and the branching flower-stem, which reaches a height of about 18 inches, bears several of its comparatively large blossoms of a beautiful clear yellow, tinged slightly on the exterior with green. *H. minor* is also known by the specific name of *graminis*, which well expresses the general appearance of its foliage.—H. P.

## LIGULARIA MACROPHYLLA.

THIS is a very bold hardy perennial, well suited for a position in the border or in the wild garden, where plants with large leaves and of striking appearance may be desirable. The plant here illustrated was photographed in the series of Messrs. R. Veitch and Son, Exeter, where it is flourishing in an ordinary border. Seen from a distance the plant looks as if it belonged to the Cruciferae, but closer inspection reveals the fact that it is a very quaint member of the composite family.

The plant represented in the illustration has flower-spikes each  $4\frac{1}{2}$  feet in height, bearing an elongated panicle of golden yellow flowers. The appearance of the individual flowers is most peculiar and unlike that of most composites, as in this case there are only two or three ray-florets with narrow, ligulate petals, each quite three-quarters of an inch to 1 inch in length and of a bright golden yellow. The disc florets are campanulate and also bright yellow. The leaves which spring from the base are very large, oval in shape, and quite 18 inches long and 10 inches to 12 inches broad, with a slightly undulated, dentate margin. They are smooth and glaucous, with a very broad midrib, most resembling a Cabbage leaf.

Altogether, *Ligularia macrophylla* is a striking plant and well worth a place in the garden.

Elmside, Exeter.

F. W. MEYER.

## THE AUTUMN SNOWFLAKE.

ONE of the most exquisite of our autumn-flowering alpine plants is the autumn Snowflake. Growing in the rock garden it excites almost universal admiration, and elicits many expressions of praise for its beauty. But few seem well acquainted with it, and many who see it appear to think its beauty too fragile to be possessed by a sturdy flower. It has been called a fairy-like flower, and few can question the use of such a term, so ethereal seem its little satin-like drooping bells depending from such slender and unsubstantial-looking stems. Very delicate-looking it is, but its hardiness in many gardens has been amply proved, and one can only hope that a few orders in its favour may draw some attention to this chaste little flower. Although grown also in the border, it is in the rock garden, among the choicest alpine flowers, that *Leucojum autumnale* would find a home. With a carpet of some dwarf creeping plant above its roots it will spear through, its flowers being all the purer from the protection against the splashes caused by heavy rains afforded by the carpeting plant. On an elevated spot among these choice flowers the autumn snowflake is in perfect keeping with its surroundings. It has no showy colours to recommend it to those who love the garish colouring of many flowers. Its beauty consists in its elegance and in the charms of its white flowers, prettily fringed and with a lustrous interior, their beauty heightened by the rosy tinge at the base of the segments and by the chocolate-coloured stems, about 6 inches long, which elevate the flowers above the soil. One of the merits of *L. autumnale* is its lengthened period of bloom. Here this year it came into flower in the beginning of August, and now (just the middle of October), although some of its seeds are nearly ripe, there are yet open flowers on the same clump. It is grown here in sandy soil with good proportion of peat, and thrives well in such a compost, although not increasing rapidly by means of offsets. It ripens seed annually, and by sowing this as soon as ripe, flowering bulbs are soon produced. Self-sown plants are sometimes seen, and one hopes that some day a distinct break may be found which may originate some well-marked varieties. *L. autumnale* is its autumnalis of Salisbury, and is found from Portugal and Morocco to the Ionian Islands. It was introduced in 1629. I prefer planting in pots, but with care it may be removed when in

flower. It is usually after the flowering period that the slender grassy leaves are produced. The variety *pulchellum*, mentioned by Mr. J. G. Baker in the "Handbook of the Amaryllidaceae," I have never seen. The flowers of this are larger and the leaves are produced with the flowers.

Cursethorn, Dumfries.

S. ARNOTT.

**Lilium candidum variegatum.**—Variegated varieties of many plants are by no means improvements on the typical forms in any way, but the leaf markings in this case are very pretty during the autumn and winter. The foliage is of the same shape as that of *L. candidum*, the margin of the leaves having a broad band of yellow running the entire length. At first sight it looks a good deal like the yellow variegated Funkia. The flowers are not quite so good as those of the type, but are produced abundantly enough to make it worth growing on this account, while the foliage serves to brighten up the border in winter.

The mixing craze is carried to great lengths and often with very bad effect in present-day

*Ligularia macrophylla* in Messrs. Veitch's nursery at Exeter. From a photograph sent by Mr. F. W. Meyer.

bedding. A charming collection of the old-fashioned scented-leaved Geraniums to be seen recently in one of the beds in Hyde Park had, planted among it, a few weedy Gaillardias and Celosias that were anything but helpful. Certainly there were no flowers to speak of on the Geraniums, and neither were any wanted, as the variety of form and colour in the leafage was sufficiently attractive in itself, and would have been restful to the eye had there been no attempt to brighten it by mixing with it flowers of garish colours and incongruous forms.—J. C. T.

**Calceolaria amplexicaulis.**—This fine *Calceolaria* is so commonly grown as an annual from cuttings and employed in masses or mixed with other plants, that its capacity to bloom freely when grown as a bush is hardly understood. Mr. Price, of Egham, grows it as such in pots, wintering the plants in a cool house, cutting back

in the spring, and obtaining free growth again and then plunging the plants in beds outdoors in the summer, where, standing individually and flowering profusely at from 3 feet to 4 feet in height, they are very attractive. It is one of the admirable properties of this excellent variety that old plants bloom very freely.—A. D.

## NEW DAHLIAS.

THE note in THE GARDEN (p. 302) by J. Burrell does not prove to me that my comments as to awarding certificates were wrong. Last year nine varieties gained the coveted stamp of merit, but out of that number I have failed to observe five in the exhibition stands of this season. I should not, perhaps, say failed, because here and there I observed three of them exhibited. This on one occasion, however, is not enough. Improved sorts are noted generally—to wit, Charles Woodbridge and Starfish. Having grown at least eight of last year's certificated varieties, I fail to see in what way, for instance, Mrs. Leopold

Seymour is an improvement upon an older kind named Mrs. Barnes, and what there is in Iona and Mrs. Kingsley Foster to prefer to sorts of similar tints, Frances Humphries and Harmony. Mrs. Gordon Sloane, again, is voted by most people a dull and poor class flower. Now this season the number of certificated kinds in the Cactus type has reached nineteen; there may have been more, but these I have seen. Whilst admitting that wonderful strides have been made with this popular class of Dahlia, it is a little too much for one to think that these are all improvements, considering the excellent sorts we already have. If the number of certificates is doubled every year, where shall we stop?

One could also desire a better system of granting certificates than that which obtains at present. The blossoms are judged, but there is no means of knowing the habit of the plant; whether it throws up its flowers well, a matter quite as important to most people as the flower itself, because, after all, it is but a limited number who cultivate Cactus Dahlias for exhibition. I know, in the case of several varieties which will not throw out their blooms from the leaves, that they

may be made to do so by manipulating the growths. The general cultivator, however, does not want to bother about such a matter, and those (by far the greater number) who esteem the Dahlia in the garden rightly consider such sorts worthless.

The trials of varieties of popular flowers like that lately carried out at Chiswick with early Chrysanthemums are most useful and instructive. If Cactus Dahlias could be included in the list, much good would follow and a number of disappointments prevented. S.

**Campanula isophylla and Convolvulus Sabatius** are two plants peculiar to the Capo di Noli (the Vada Sabatia of the Romans) and its immediate neighbourhood. I remember observing plants of the *Campanula* when collecting the

Convolvulus at the end of April. The Campanula, of course, does not flower till much later in the summer. In its wild state the lilac-coloured form is, I believe, much the commoner. A correspondent also asks about Campanula patula. I have found this growing wild on the banks of the Wye, between Monmouth and Chepstow, and presumably it seeds there.—SHERBORNE.

— This handsome trailing plant is inquired about in the last issue of THE GARDEN. The true plant, though existing, is certainly extremely rare. Many hardy plant growers say they have the true plant, but I find invariably that the most they have is the name. What appear to be in circulation are but seedling forms of this fine species, that vary considerably and are generally greatly inferior to the original plant. I have during the present year twice seen the true *C. isophylla*, which I thought I possessed myself, only to find my mistake as the plant developed its leaves and flowers. Frequently *C. fragilis* is substituted for it, but this is not a trailing Campanula in the same sense as *C. isophylla*, and, indeed, from a decorative point of view it is much inferior. The plant does exist no doubt in many old gardens, and it is possible that inquiries concerning it may bring it more generally into cultivation.—E. J.

#### THE YELLOW-FLOWERED PEONY.

THE genus *Peonia*, rich in herbaceous species, did not until lately exhibit either in gardens or in herbariums a single woody species except the Montan Peony, a remarkably fine kind, it is true, and better known under its obviously exaggerated specific title of *P. arborea*, or Tree Peony. Ten years ago a second woody species was introduced by the Museum of Natural History at Paris, to which seeds of it had been sent by M. l'Abbé Delavay, missionary at Yunnan, well known for the great number of fine plants which he has contributed to horticulture in France. The seed-packet was labelled "Seed of an alpine plant gathered on the Ché-Té-Hotzé above Ta-pin-tzé, October 15, 1886." It contained twenty-six seeds of mediocre appearance, which were sown immediately after they arrived, in the early part of the year 1887, and produced only three plants, which made their appearance on May 28, 1888. These plants commenced to flower in the beginning of June, 1891, which, it is needless to say, interested us very much. In the following year they flowered again, and on this occasion the plant was exhibited by Professor Max Cornu at the meeting of the Société Nationale d'Horticulture, held on June 9, 1892, and it was again exhibited at the meeting of the same society held on May 25, 1893. At that time the plants produced only very few flowers, and continued to do so up to the present year, when a specimen which had been grafted and grown in a pot bore eleven flowers all at the same time. This specimen was very handsome, and its abundant bloom appeared to us to be the result of the grafting, as the other plants on their own roots, although vigorous in growth and of fine appearance, produced only one or two flower-buds each this year, and even these did not come into bloom. This new species has been named *Peonia lutea* by Franchet, and is not to be confounded with the Caucasian species (*P. Wittmanniana*), which also has (pale) yellow flowers, but is an herbaceous kind.

The prominent characteristics which at first sight clearly distinguish *P. lutea* from *P. Moutan* are (besides the yellow colour of the flowers of the first-named species) an appreciably dwarfer habit of growth, leaves light green instead of dark green, larger, and with more numerous and much more pointed lobes; secondary petioles winged instead of being

channelled, and the plants come into bloom from ten to fifteen days later, at the same time as *P. albiflora* commences to flower. The plant, which we had under notice this year, showed its first flower on May 28. It was in full bloom on June 1 and had gone out of flower on June 12.

We have not yet sufficiently ascertained the constitution of this plant so as to enable us to state whether it is hardy or not in the climate of Paris. Up to the present, on account of the small number of specimens which we possess and the doubt which we entertain of its hardiness, we have not ventured to risk any of them unprotected in the open air in winter. One plant which we put out in the open ground last year passed the winter in safety under a bell-glass, and has sent up several suckers.

This question of hardiness, however, seems to us rather of secondary importance. However interesting and handsome the typical plant may be, it is especially valuable (as Professor Cornu pointed out when exhibiting it) for the sake of the hybrid varieties which may be raised from it. As it flowers later than *P. Moutan*, it will be necessary, in order to obtain pollen at the proper time, to force the flowers into bloom a fortnight earlier, and our skilful hybridisers will have no difficulty in doing this.

The few shoots of *P. lutea* which, up to the present, we have been able to utilise for grafting have done well on *P. corallina* (Retz) as a stock, and it does not appear doubtful that other stocks which are commonly employed in the propagation of Peonies will answer equally well. We are convinced that grafted specimens of this plant flower far more freely than those raised directly from seed. A siliceous soil appears to suit this plant especially well.—L. HENRY, in *Le Jardin*.

#### FLOWER GARDEN NOTES.

THIS is a busy time in all those gardens where the dual system of bedding is still carried out. The frosts in the early part of the week commencing October 3 made a clean sweep of all tender plants entailing the work of removal, preparation of beds and replanting as soon as possible. Besides plants raised from seed, as Wallflowers, *Alyssotis*, *Silene*, &c., Daffodils, Tufted Pansies, and Polyanthuses are largely included in what is commonly known as spring bedding, a planting of Daffodil bulbs in beds previously filled with dwarfer things being an arrangement held in considerable favour and somewhat largely adopted. I think it is rather a patchy style of gardening, although there can be no doubt as to the fine display of colour secured or the pleasing contrast afforded. Personally, in all cases, where additions are made to the stock of Daffodils, they are planted on grass in the pleasure grounds as a foreground to clumps of evergreens by the sides of walks, or places of a similar nature. They may, however, be also utilised to great advantage for filling in large beds that are mainly planted with herbaceous things of large size. This is specially applicable in the case of Peonies, especially those varieties whose foliage in a young state is very brilliant. The contrast between this and the yellow Daffodils is very fine. Beds too, that are made up for the benefit of Peonies will grow Daffodils to perfection. The above is alike a contrast that is effective and a combination that is natural. It is something that might be employed in any part of the garden, or that would look quite at home in the centre of a wood. The note on this association leads to the suggestion that planting at this season of the year might well take a more permanent form than the insertion of things that have to be uprooted in spring. The flower gardener of to-day is likely to have a stock of hardy plants on hand that would cover the beds through the winter, come into flower in succession, and last, in

the majority of cases, well through the summer. In cases where the plants are not already to hand provision can be made to furnish them by another spring, by the various means of propagating most calculated to give the best results. I have just finished planting up beds with Carnations, Pinks, Tufted Pansies and Pyrethrums. The herbaceous *Lobelia*s will be divided as soon as they are ready, and later, Phloxes, Pentstemon and Antirrhinums, that have been obtained from cuttings or seed, will go into positions reserved for them. Reverting back to the Peonies, I should be glad to know if the young foliage can claim immunity from the attack of rabbits. Mr Barr tells me the occasional rabbits that get into the Long Ditton nurseries have not been known to touch it. An occasional visitor, however, different from where they are to be found in quantity, and I should like to be fairly certain at the point before attempting to naturalise. The few things rabbits will not touch. I can across a batch of seedling Foxgloves the other day that had been closely nibbled. I have never known them touch Daffodils.

STARWORTS.—Two of the older Starworts, just now about at their best and holding their own well among the newer sorts as very charming in cut state, are Robert Parker and Tradescant. It is almost impossible to find anything better than the former in the matter of colour—a beautiful soft lavender-blue—that shows to great advantage against dark or gilded vases. I noticed a mass of it the other day inside a window in a large vase: the sun was shining brightly upon it and the colour struck me as exceptionally fine. The individual flowers of Tradescanti are very small, but the manner and profusion in which they are produced make the variety very useful. Shoo cut the entire length and tastefully arranged in pots of damp sand last a long time in the house and are very nice for church decoration arranged with feathery Palms, Bamboos, or things of a similar nature. The value of the Starworts, at any rate, the majority of them in a cut state is considerably enhanced, from the fact that they require no foliage. A stem or two of Asparagus well loaded with berries is very well as a change, occasionally with the different shades of blue at lavender, but they look equally well alone. Naturally the varieties of dense habit—of which *A. Amellus* and its forms, *A. acris* and *A. dumosus* may be taken as types—are not so acceptable in a cut state.

CARNATIONS.—I have decided to defer the planting of these until early spring. They are going out on the same border, which means that the work once commenced should be carried through, and an examination of the layers has shown that whilst some are splendidly rooted others are not so good, and would be all the better if allowed to remain longer on the parent plant. The border destined for their receipt will get a heavy dressing of peat moss manure and be turned up deeply, leaving it in the rough so that given a visitation of frost it will be a grand trim for planting in February, or early March, as the weather will permit. I have picked out some of the strongest looking layers this week, and potted up batches of Haye's Scarlet Ketton Rose, Lady Nina Balfour, White Clove, The Pasha, Miss Audrey Campbell, and Uria Pike. These all do well in pots, and are sufficiently varied in colour alike to give a display in the greenhouse and to cut for button-holes. Lady Nina Balfour takes the place of Countess of Paris; the latter for the last three seasons seemed to have lost its vigour, its roots slowly and differently, and will not come away kindly.

CARPET PLANTS.—Plants of very dwarf habit enter largely into many flower garden arrangements, and no one can deny that things of tall growth show to the best advantage when there is a little space between the clumps, and that space is clothed with greenery instead of showing only the bare earth. It is always advisable, however, before carpeting in this way, to make sure that the necessary time can be spared for keeping the same clean and tidy. Such things as the alpine

## SHORT NOTES.—FLOWER.

**Gynerium argenteum.**—The greenish tinge of youth as seen in the lofty plumes of the Pampas Grass is now being replaced by the silvery hue from which the plant derives its specific name. The largest tufts are very pleasing where both shades are to be seen at the same time. On the grass in the Royal Gardens, Kew, are many fine tufts in full beauty at the present time.

**Canna Paul Bert.**—This fine deep scarlet-flowered *Canna* has stood out prominently among others at Kew this autumn. It is handsome alike in foliage and flower, the leaves being large and of a deep bronze colour. Well-grown *Cannas* are a great boon in the flower garden if only from their imposing habit of growth, and when to this is added a profusion of handsome flowers the effect is very fine.—J. C. T.

**Kniphofia nobilis.**—This handsome Torch Lily is still pushing forth its fine heads of bloom, so large indeed and so massive in general appearance as to be almost suggestive of its distinctive name. But the true character of such plants does not appear until

distubbing are required to produce large, symmetrical, deep blooms with perfect centres. Were this not done all the flowers would come open-eyed. If I wanted a good supply of white Dahlias in my garden, I should depend upon pompon *George Brinckmann*, a variety which is rather large as a pompon, but produces charming flowers in great abundance.—R. D.

## KITCHEN GARDEN.

## OUTDOOR TOMATOES.

To grow Tomatoes successfully out of doors the seed must be sown by the middle of January and placed in a nice warm propagating pit or frame. As soon as the plants are fit to handle they should be potted off singly into 3-inch pots and put into a close frame for a few days. The compost should not be rich, but consist of good fresh leaf-mould one part, fibrous loam two parts, and a little sharp sand. I find the plants grow much better when planted out and potted in this way than when a richer compost is used. The chief thing to aim at is to keep the plants as sturdy as possible, short-jointed plants fruiting much quicker when planted out than those that have been allowed to become drawn. By the first week in April they should be nice plants and need more air on bright days, as this will assist very much in hardening them ready for planting outside, which should be done about the end of April or the first week in May, taking care to cover them at night till they are safe from frosts. The sorts which I find do best out of doors are *Chiswick Red*, *Polegate*, *Carter's Early*, *Viceroy*, and a seedling the result of a cross between the *Old Red* and *Polegate*. *Chiswick Red* is a splendid cropper outside.

There is still one more feature in outside culture, and that is getting the fruit to ripen after it is grown. How often do we hear people say they can grow plenty of Tomatoes outside, but they cannot get them to ripen. If they will cover the fruit at night from about the middle of September and keep off the rain and dews, they will find that the greater part of the fruit will ripen well outside. Not only is the fruit

much better when ripened on the plants, but a good portion of the crop is often lost through being picked green.

The enclosed photograph was taken on September 27, and most of the fruit has now (October 12) ripened well outside.—W. J. EMERSON, *The Gardens, Amphil Hill House, Beds.*

— This has been one of the best years for outdoor Tomatoes that I remember, and if it had not been marred by cold, wet, stormy weather during August and the early part of September, I should have ripened the largest percentage of a heavy crop. Owing to the latter part of September and the early days of October proving fine and dry, a deal of fruit has been forwarded sufficiently to get it into a condition when a few days under glass will ripen it off, and certainly good wall-grown Tomatoes are far superior to anything in the way of imported fruit. Anyone growing this crop in the

boxes, Sedums in variety, Camomile, *Ajuga reptans*, *Aubrietias*, and the like, are planted to and for several seasons rather than to be treated as annuals, and such undisturbed ground will produce weeds in considerable profusion in positions where it is not possible to use the hoe, but hand-weeding is the only means to be employed to secure eradication. Given, however, the necessary amount of labour the above can be used both in large herbaceous beds and borders, and also on beds sparingly planted with bulbs, and is present is a good time to set about the work; it is much better than letting it stay over until the spring, when, as a rule, there is little time to do more than is absolutely necessary. Tufted *Lisias* can also be largely used, and may be planted now if well rooted; if not they are better left until spring.

E. BURRELL.

Claremont.

**Hardiness of Carnations.**—Mr. Burrell writes undoubtedly in good faith when he asserts that the hardiness of Carnations is but a matter of well-rooted plants. It may surprise your correspondent to know that, although I live within ten miles of Claremont, I cannot keep Carnations in health through the year in the open ground, no matter how much care I may take in preparing the ground and planting strong, well-rooted layers early in autumn. Carnations are hardy or otherwise according to local conditions, and every would-be grower of them must adopt a local system that will assure him against the effects of damp and disease. Left in the open ground all the winter, Carnations with me in seven years out of ten fall victims to the fog demon. Those who have hitherto failed should follow the hints given by Mr. Crawford and "E. J.," and they may rely on securing satisfactory results. Last season I was late in layering and many of the plants were indifferently rooted. At the end of October I planted them all in frames in light, rather sandy soil, giving one good watering to settle the soil round the roots, but not a drop afterwards. The lights were put on to keep off rain and snow; in foggy weather they were tilted at the sides to allow of a current of air passing through, and were kept off in a time of sharp frost. During the winter they made a quantity of white roots, were planted out in March, and I never saw Carnations make finer growth.—J. C. B.

**Good bedding Fuchsias.**—The use of Fuchsias for flower garden decoration continues to increase, and few plants give more pleasure when well placed. All varieties do not succeed equally well for the purpose, and though there are some notable exceptions, the majority of those which do best belong to the section with red sepals and plum coloured corollas, these being hardier generally than most of the lighter coloured forms. I noted a week or two back in Hyde Park some excellent varieties, old and new, mostly of the form of big pyramid-shaped plants, and flowering freely. One of the most noteworthy was the old Tower of London, which was planted in combination with *Coreopsis lanceolata*, this being so in good condition, tall, and finely flowered. Scarcely was it blooming freely, the flowers being of globular form, suggesting the old and very pretty *F. Riccartoni* as one of its parents. Another good variety of globular shape was *F. Prinka*, the colour of this being almost self red. *Mrs. Rundell* is a very distinct and charming Fuchsia with flesh-coloured sepals and vermilion corolla, the flowers long, and much like those of the better-known *Mrs. Marshall* in form and size. *F. Mme. Cornelissen* was also exceptionally good, and it remains still the best of all Fuchsias with white corollas. The fine plants of this were badly carpeted with mixed colors, the various colours of which spoiled the effect of what should have been an attractive white. A green carpet would have been far more effective than this indiscriminate mixture of Asters in many colours and shades, some of them very pretty indeed. To the above good outdoor varieties may be added the fine old *F. fulgens*, a bed of which seen at Kew was uncommon.—J. C. T.

Tomatoes in the open air at Amphil Hill House, Beds. From a photograph sent by Mr. W. J. Emerson.

they are some three or four years old, when the towering spikes will reach 8 feet high. For this reason it is well to anticipate its maximum height when planting it.

**Crocus speciosus.**—The flowers of this lovely species have been more than usually abundant this year, particularly when growing in the more grassy spots on banks and the like. Very often the flowers of this and allied subjects that appear in advance of the foliage suffer greatly from pelting rains. The flowers are more durable in the grass than in places fully exposed. Few things are more beautiful in the grass than these, particularly on banks or slopes.

**Dahlia Mont Blanc.**—The proper name of this variety is *Gloire de Lyon*, under which it was sent out from France some years ago, and by which also it is known in Dahlia catalogues and exhibited at Dahlia shows. When caught in its best character it is a fine white self, but not so constant or so fine in quality for exhibition as *John Walker*. Those who grow *Gloire de Lyon* for exhibition allow the plants to carry all the buds until they get one or two or more which are likely to produce fine blossoms, and then thinning out and

open air must, even on the south coast, get the plants as far advanced as possible under glass, and plant out as early in May as possible. I generally plant at the end of April, and cover the plants when frost threatens, for even half the area of early plants will finish off more ripe fruit than double the quantity put out at the end of May, and that they repay good deep culture and rich soil I am quite convinced by the crop. In deeply trenched borders the plants have gone to the top of a 10-foot wall, and are loaded with green fruit to the tips. As regards varieties suited for outdoor culture, I think a sort called Brookes' Freedom has surpassed all others in freedom of cropping, and the fruit is of about the size and shape that find most favour with purchasers. A bright red, round Tomato weighing a quarter of a pound is far more saleable than one double the size.—J. G., Gosport.

**Cabbage sprouts.**—"S. M." (p. 283) is hardly fair to me in saying that I think Cabbage sprouts superior to young Cabbage, as in my note on this subject I simply said that I saw no falling off in the quality of these sprouting hearts. I have not the least hesitation in sending such to table, and, more than that, I get no complaints for so doing; neither are they necessary. Of course, this would not be the case if the land was not well prepared and in good heart to withstand the strain of prolonged cropping, but, given this and a good variety for the purpose, I see no advantage in the destruction of useful beds before their time, and, from the point of garden economy, I consider the advice to do so is wrong. At the same time I have nothing whatever to say against the practice of planting a few rows of spring-sown plants as a supplementary measure or from motives of tidiness.—J. C. T.

**Broccoli Michaelmas White.**—Wherever grown this variety is sure to please owing to its size, colour, and flavour, and coming in nicely between ordinary sowings of Veitch's Autumn Giant and Self-protecting Broccoli. Even if it be sown at the same time as the September batch of the former, it being a somewhat slower grower, will follow it, and as the weather is then cooler it comes on gradually and lasts over a considerable time. One of its characteristics is the pure white heads, in this respect surpassing all other autumn sorts. Market growers would do well to turn their attention to this Broccoli. Hundreds of acres of Autumn Giant and Self-protecting are grown, but good though these be the fine delicate appearance of Michaelmas White would catch the eye of buyers, and secure for it a ready sale.—C.

**The Rochford as a market Cucumber.**—Many Cucumbers will do well enough grown in the summer months, but are useless for producing profitable crops during the trying period of December and January. The good old Syon House is still one of the best, its somewhat short fruit being produced on healthy plants even more freely than the much-grown-for-winter sort Telegraph. Lord Kenyon's Favourite is another good winter Cucumber if it can be obtained true, but few nurserymen now catalogue it. A variety, however, that when well grown by gardeners for winter fruiting will be always valued is the Rochford. This is a selection made by the great fruit-growers of that name; it cannot be beaten where profit is a consideration. I was recently talking to a grower for market, who informed me that he grew the Rochford exclusively. He also said many failures in winter Cucumber-growing occur from the plants having too much soil to grow in. Deep beds, or even bulky hillocks of soil get sour before the roots can permeate them, and the plants at once go back. His opinion was fully justified by the grand crops he grew last winter in very small mounds of manure-free soil, half an inch more being added when the roots appeared on the surface.—J. CRAWFORD.

**Notes from Baden-Baden.**—Of the typical *Scabiosa caucasica* a white variety has been

raised. It is a beautiful plant, but lacks robustness, being of rather delicate constitution and also particular as to soil and situation. We have, moreover, a variety of the type which is called elegans or conata, which is a very robust grower, with larger flowers and more imbricated ray petals. This variety I have used for many years in order to obtain new varieties. This year I have been so far successful, and have obtained different forms and a break in colour. A bright deep ultramarine form and a snow-white variety have been raised, the latter a far superior plant to the now common *S. caucasica* alba. *Liatris graminifolia* alba is quite a little gem, the pure white flowers look very cheerful. After great trouble I have succeeded in getting a small supply of *Ramondia Nathalia*, now nearly extinct in its wild habitat. It has larger and deeper coloured flowers than *R. serbica*. *Crocus Cartwrightianus* albus and *C. marathonsis* are very showy pure white autumnal blossoms. Another *Crocus* is very beautiful just now. It is a species new to cultivation, flowers snow-white, with a few faint black stripes, the leaves are glaucous grey, and have no points, but angles.—MAX LECHTLIN, *Baden-Baden*.

#### NOTES ON STRAWBERRIES.

WE have to thank our readers all over the country for so kindly replying to the following questions, and we hope that the notes will prove valuable:

*Will you kindly aid us in throwing some light on Strawberries of best quality for the use of private growers, as market growers have a different standard from that which applies to the private gardener, and favour those kinds that bear carriage, rather than those that are remarkable for flavour and quality? For those who use their own fruit we think that a different standard should be in use.*

1. *What kinds do you consider the best for flavour in your district, i.e., as grown in gardens, not taking into account those grown in the open field for market?*

2. *The best early and late kinds for the open air in your district?*

3. *Which of the newer sorts do you find most worthy of cultivation from a garden point of view?*

4. *The best time to plant so as to secure the best and most regular crops?*

—Royal Sovereign, Vicomtesse Héricart de Thury and President I consider the best either for forcing, cropping or flavour. These are hardy, free bearing and of good quality. Auguste Nicaise and La Grosse Sucrée are both early kinds, of good flavour, good for forcing and free bearing, but they suffer very much in severe winters, not being so hardy as the first-mentioned. A variety called Louis Gauthier gave a few fruits, but the colour I should imagine will be very detrimental to it ever becoming very popular in England. Louis Gauthier with me is a kind of cream and pink, or magenta, as a person once remarked to me. At the time of writing (August 17) I have plenty of the alpine variety, which is most prolific, good in colour and of robust constitution. Though small, it is well worth growing for mixing with other fruits for tarts or jam, or even dessert where variety is required; another advantage is that birds do not trouble it much. There are some kinds I cannot succeed with. They make plenty of growth, but fail to fruit, so have been discarded. Among these are Keens' Seedling, Dr. Hogg, Sir J. Paxton, British Queen and Elton Pine. Several have been discarded owing to poor flavour—Noble, for instance. I give Royal Sovereign the premier place for all purposes as a Strawberry of recent introduction, while older kinds, as President and Vicomtesse Héricart de Thury, still retain their position. The ground

is a strong clay and with deep cultivation suit the Strawberry well. As a rule I plant on ground that has been cropped with early Peas or Potatoes, and give a dressing of burnt ashes on decomposed soil from the rubbish heap, with a addition of lime if they follow Peas. The ground is dug over, but not after Potatoes. I then plant in rows 2 feet apart and 1 foot 9 inches from plant to plant, except alpine varieties, these are a foot each way. They usually stand three and sometimes four years if they remain in good condition. I plant on permanent ground as soon as I can obtain good runners, and generally get a nice crop of fine fruit the first season. In the following spring—April or May—according to weather, give them a good mulching of half rotten manure which keeps the moisture in the ground and also keeps the fruit clean when ripe, as most of the substance is washed out of the manure by the time. When the fruit is gathered, I clear off the runners except those required for planting. Never dig or fork between the plants, only use the Dutch hoe occasionally to loosen the surface. I have had heavy crops for years with this treatment. This is a cold, late district, the atmosphere charged with sulphur, which is most disastrous at times to vegetation.—T. BONNAL *Blom Hall, Leeds*.

—The best Strawberries for flavour in the garden are Lord Suffield and Gunton Park. The best early kinds are Royal Sovereign and Vicomtesse H. de Thury; the best late sorts, Latest All and Elton Pine. The newer sorts most worthy of cultivation in this garden are Gunton Park, Monarch, and Latest of All. The best time to plant so as to secure the best results is early in August from early layered runners from plant grown especially for producing them, these never being allowed to bear fruit.—JOHN CRAWFORD *Coldington Hall, Newark*.

—The best flavoured Strawberry grown here is Sir Joseph Paxton. It is one of the best to be cultivated. Noble is the best early variety I grow. Some of my friends say it is wanting in flavour. I agree with them it is not one of the best, but when grown 3 feet from row to row, well exposed to the sun and gathered before it is too ripe never have any complaints. James Veitch's Waterloo succeed well here as later varieties. The best time to plant Strawberries is as early in August as possible, so as to get the plants well established before winter sets in. At the first signs of frost I give a good dressing of manure but see that the crowns of the plants are not covered. This annual mulching should be given each year as long as the plants are required to bear. I think close planting and digging between the plants are the greatest errors in Strawberry culture. I never plant nearer than 3 feet from row to row and 18 inches in the row. I never dig the ground from the time of planting until the plantation is done away with, which is always soon as the third crop has been gathered. I have adopted the above system now for over twenty years, and, wet and dry seasons alike, never fail to have a crop.—THOS. CANNING, *Aldenhall Park, Bridgworth, Salop*.

—The best flavoured Strawberries here are Keens' Seedling, Sir Joseph Paxton, Royal Sovereign, President, Laxton's Commander, The Countess, and Latest of All. The best early sorts are Keens' Seedling, La Grosse Sucrée, Royal Sovereign, Sir Joseph Paxton; the best late Latest of All and Elton Pine. Of the newer sorts that have done well are Royal Sovereign, Laxton's Commander, and Gunton Park. For planting consider the best time about the first or second week in August if you have good rooted plants ready and the ground has been well sweetened and manured.—T. RANDALL, *Holme Lucy, Hereford*.

—The Strawberries that are most in favour here are Royal Sovereign, Sir Joseph Paxton, and Sir Charles Napier. For an early variety I like Royal Sovereign. Grown side by side with Noble it was quite as early and much better in every way. Latest of All is preferred for a late crop. Of newer varieties tried Royal Sovereign and Latest of All are the best. Competitor crop

all, but the fruit is too soft. I like to plant as on as strong plants can be got at the end of July or beginning of August. Plants layered on all squares of turf are liked much better than those in small pots. I make a new plantation annually, and do not keep the beds more than three years. — Wm. ANDREWS, *Trigothuan, Cornwall*.

— The following Strawberries succeed well here, viz., Royal Sovereign, President, Sir Joseph Paxton, James Veitch, Sir Chas. Napier, Waterloo, Dr. Hogg, Oxonian, Elton Pine, and Latest of All. The following three varieties I have discarded, British Queen, La Grosse Sucrée and Noble. They were not satisfactory. The kinds giving the best flavour are Dr. Hogg, President, Sir Joseph Paxton, Royal Sovereign, and Latest of All. Waterloo by some is greatly admired. The earliest kind I grow is Royal Sovereign; by the time its latest fruits are ripe the earliest fruits of President and Sir Joseph Paxton are ready for use, followed by others. The best late kinds I grow are Latest of All, Oxonian, and Elton Pine. The only new kinds grown here are Royal Sovereign, Latest of All, and Waterloo, which are very satisfactory. The best time to plant for securing a good crop the following season is the latter end of July or as early in August as possible, but in such seasons as the present it was very difficult to secure young plants for July planting. To prolong the Strawberry supply I find it a good plan to plant a south border for the earliest. The second principal beds are planted in the open. The best are planted on a north border. From such planting as I have named the results have been most satisfactory. — W. GLASSEY, *The Gardens, Howbery Park, Hately-on-Thames*.

— The varieties I consider the best for flavour are Vicomtesse Héricart de Thury, Royal Sovereign, President, Gunton Park, and Dr. Hogg. The only other kinds I grow are Laxton's No. 1, Anguste Nicaise, and Oxonian. The best early beds are Laxton's No. 1, Vicomtesse Héricart de Thury, and Royal Sovereign, which ripen in the order named. The best late kinds are Gunton Park and Oxonian, the latter continuing the supply so long as I have found it possible to gather Strawberries of good flavour out of doors. Of the newer kinds the only ones I have found thoroughly satisfactory on this soil are Laxton's No. 1, Royal Sovereign, and Gunton Park. Lord Suffield and Waterloo I found to be of excellent quality, but they did not crop sufficiently well to be retained. I plant the layers about the middle of August, in well-manured and deeply trenched ground. Part of the annual plantings is composed of forced plants. These are put out in June and always afford heavy crops the following season. Forced plants of Vicomtesse planted out in May in most seasons afford a late autumn crop, but my experience is that outdoor Strawberries give no flavour after August, in the north at any rate. — J. TENNINGTON, *Ripley Castle Gardens, Yorks*.

— The Strawberries I find to do best with me on this soil, which is a stiff clay, are Vicomtesse Héricart de Thury, Sir Joseph Paxton, Gunton Park, Royal Sovereign, Sir Charles Napier, and Lord Napier. The best early kinds are Vicomtesse Héricart de Thury and Sir Joseph Paxton; the best late, Sir Charles and Lord Napier. Of the new kinds, Royal Sovereign is the best, Noble lacking flavour. The best time to plant greatly depends on the condition of plant and soil. If the plants have been layered early to pots, and the soil well prepared and in good condition, planting may be done in August with very good results. I prefer to delay planting till March. I take the layers off in August and plant them thickly on a good piece of ground, forming a kind of nursery bed. Then in March I pick out the strongest and best and transplant to the permanent bed. I agree with destroying the beds after three years' fruiting. — A. CANNON, *Abouley, Edinburgh*.

— For earliest kinds I find Vicomtesse Héricart de Thury still good. Although not a large kind, it is reliable in every way. Royal

Sovereign is a most useful Strawberry, of large size, good flavour, an abundant bearer, and of good colour when well exposed to the sun. It is rather soft for travelling long distances, but for home consumption first rate. This is the best of the new kinds I have grown. Of the second earlies, Sir J. Paxton is a reliable kind and will travel well. John Ruskin is a most abundant bearer and of fair quality. Of late kinds, Frogmore Late Pine is well known. Jubilee is a first-rate kind, most abundant cropper, and of good quality. It is a valuable kind and everyone should give it a trial. Latest of All is a good variety. Countess is the finest flavoured Strawberry I know; the fruit, handsome, of cockscomb shape, and splendid colour, is freely produced. The following I have found wanting in various respects, although some of them I still retain for further trial: King of the Earlies is richly flavoured, but too small; Pauline worthless; Noble large, but of poor flavour and soft; La Grosse Sucrée of poor flavour; Anguste Nicaise large, poor flavour and very soft; Lord Suffield and Gunton Park have very large, soft fruit of poor flavour; Sensation very large fruit of the poorest quality; Waterloo too delicate in constitution; Loxford Hall Seedling is of first-rate flavour, but too uncertain for general use. The best of the newer kinds grown here are Royal Sovereign, Latest of All, and Jubilee. The best time for forming new plantations is, in my opinion, August, provided the weather is suitable. — THOMAS ARNOLD, *Cirencester House, Gloucester*.

— No hard and fast rule can be laid down, so far as my soil is concerned, on the best way of growing Strawberries. It is simply a matter of so treating each variety that it is grown in such a manner as will lead to the best results, for whilst one will do well as an annual and degenerates after the first year, another gives altogether better crops, greater in bulk and equally good in quality, in the second and third years. I am rather chary of trying new varieties, several that were strongly recommended having signally failed. The following are very reliable: Of Black Prince, a few grown on a south border connect the season between indoor and outdoor fruit; trusses are thinned and bloom receives protection; annual treatment from early runners layered in turf. Vicomtesse H. de Thury is my heaviest cropper. It is grown on the three years' system, trusses and bloom are thinned for dessert; for general kitchen use, however, and preserving, for which latter purpose it is one of the best, no thinning is required. La Grosse Sucrée is still one of the most reliable varieties, of close and compact habit, and may be planted thickly. Annual treatment being indispensable, the plant is worthless after the first year. Royal Sovereign grows very strongly and throws good fruit, but there is a tendency to mildew. President is the best mid-season variety, and is grown on the three years' system either from rooted layers or old forced stuff, the latter preferably; the same latter cultural note should have been made of V. H. de Thury. Of late sorts I have tried Unser Fritz, Frogmore and Filbert Pines, Hélène Gloede, Loxford Hall, and Waterloo, and the last-named is decidedly the best; annual treatment giving the best results. Filbert Pine is a good late variety, requiring good soil and liberal treatment. Noble and Sir J. Paxton were formerly grown and proved exceptionally heavy croppers, doing well under the three years' treatment, but I have discarded them, the first-named being useless for dessert, and Paxton not so good as President, that is if one gets the latter true. There are two Presidents in the field, the one a high-class Strawberry, the other very poor indeed. Neither British Queen nor Dr. Hogg are at all satisfactory. — E. BURKELL, *Claremont, Esher, Surrey*.

— The best flavoured early Strawberry is without doubt Héricart de Thury, and besides giving good crops the fruits are usually of nice table size. This is hard run for earliness by Royal Sovereign, a variety that has become very popular and is now universally grown. Following this come The

Countess and Edouard Lefort, both giving high flavour and neat, excellent fruits. Gunton Park and Lord Suffield are both fine flavoured mid-season varieties, and for late use the best are Latest of All and Veitch's Perfection, a variety that furnishes the flavour of British Queen with the deep colour and lateness of Waterloo. Here are eight varieties that apart from other qualities give flavour in the highest degree as found in Strawberries, and all are on the average good growers. Too many persons associate acidity with flavour; that is a mistake. British Queen, the best flavoured of all the old varieties, is but slightly acid, whilst its aromatic flavour is pre-eminent. All who would test flavour in any new variety should have British Queen as a test fruit. So far are answered the three first queries found in the circular issued from the office. Possibly from other quarters will come other results, but the conditions imposed on replies to these queries necessarily limit the range of selection of varieties, and so far that is a good thing, as by excluding the large, soft, or flavourless varieties more than two-thirds of the commonly known ones are avoided. With respect to question four, there can be no doubt whatever that Strawberry plants cannot be put out where to fruit too soon after they have become well-rooted runners. If that work can be done in August, either from pots or hand-layered plants, lifted with balls of soil, and replanted in deeply-worked and well-manured ground at once, then not only does rooting follow rapidly and the soil be widely gripped, but strong crowns also are produced; as only from stout, firm crowns can such bloom be produced in the spring as shall evolve fine and abundant fruits. Where ground cannot be spared in August, the plants lifted from the old beds should be put into a nursery ground for a month and be transplanted where to fruit later, but the sooner thus planted the more stout and firm is the leafage, the earlier does it mature, and the more solid the crowns. For first early uses the plan of putting out the young plants on to warm borders in August at 12 inches apart is a good one, as double the crop on a given area is thus obtained the first year, and then some other crop may follow so soon as the plants are cleared off. In that way the border can produce two crops in the year instead of one only if Strawberries stand for three years. — A. DEAN, *Kingston-on-Thames*.

— The crop this season has been very poor with me. My favourite sorts for flavour and cropping are John Ruskin, Noble, Royal Sovereign, President, Sir Charles Napier and Latest of All. Noble is a grand fruit, but rather deficient in flavour. Napier is my favourite, both for general crop and forcing, it also being one of the best for travelling. I have not tried many of the new varieties, but Royal Sovereign and Latest of All are my favourites amongst those I have tried. In making new plantations, I like to get the runners rooted in small pots for planting in their permanent quarters as early as possible to insure good returns the following season. After fruiting three years I destroy the plants. — Wm. SANGWIN, *Trelissick, Truro*.

— The varieties I consider best in flavour are British Queen, Royal Sovereign, King of the Earlies, Gunton Park, President, and Vicomtesse Héricart de Thury. I find the following varieties best for early use: King of the Earlies, Noble, President and Vicomtesse Héricart de Thury; and for late use: Latest of All, Veitch's Perfection and Elton Pine. I find the following new varieties best worth growing: Royal Sovereign, Gunton Park, Sensation and Monarch. The best time to plant Strawberries here is from September 20 to 30—I mean runners that were taken off and potted in August, and put close together in a shady place till rooted. — Wm. MOORE, *Albion Hall, Leeds*.

— I find the best kinds here are Vicomtesse and Keens' Seedling for early work and preserving, while for dessert I find Royal Sovereign, Sir Joseph Paxton, Dr. Hogg, and British Queen the best, coming in the order named, with Oxonian for very late. Vicomtesse, Keens' Seedling, La

Grosse Sucrée, and Royal Sovereign are the best early kinds, with Dr. Hogg, British Queen, Oxonian, and Latest of All for late use. Royal Sovereign is the best new variety. I plant good strong-rooted plants at the end of August and get a fair crop of extra-sized fruit the following season.—F. HARRIS, *Eastnor Castle*.

—The Strawberries grown here are principally old kinds, and I have never known them fail to produce a good crop. The kinds I find bear carriage best are Noble, James Veitch, President, Gunton Park, Royal Sovereign, and Dr. Hogg. The following are the kinds I consider best for flavour in this district: Royal Sovereign, Scarlet Queen, Gunton Park, Vicomtesse H. de Thury, and Dr. Hogg. The best early and late kinds that I find do best here are Royal Sovereign, Scarlet Queen, Noble, Vicomtesse H. de Thury, James Veitch, Auguste Nicaise, La Grosse Sucrée, President, Sir J. Paxton, and Dr. Hogg. Of the few new kinds I have grown I find Royal Sovereign is one of the best. Scarlet Queen and Gunton Park also do well here. The best time to plant so as to secure the best and most regular crops is, I consider, as early as possible. I always get the runners into the pots as soon as they are large enough, and as soon as they are well rooted I have them planted out into well-manured ground. By planting early the plants have time to make good crowns before the cold weather sets in, and in the spring are ready to make a good strong start. I only allow a bed to remain two years, as I find the plants do no good after that time.—WILLIAM CONWAY, *The Gardens, Abberley Hall, Stourport*.

—The Strawberries I find do best in this garden are Royal Sovereign, Waterloo, Vicomtesse Héricart de Thury, James Veitch and Latest of All. Royal Sovereign is by far the best Strawberry grown for all purposes: it is splendid for forcing and does well in the open. James Veitch is a capital Strawberry as a second early, and it withstands the drought well. Vicomtesse is a grand old sort always to be depended on, and where Strawberries are in demand for preserving there is nothing better. I always layer my Strawberries into small pots, get them on early and plant out after early Peas or Potatoes: I thus get a good crop the following year. Another good plan which I have adopted for years, and which never fails to give good results, is to put out the best of the plants that have been forced. Stand the plants in a cool frame after they leave the forcing-house and look after them well, and when the ground is cleared of other crops plant them out and well water. The result will be a full crop the next year.—T. B. FIELD, *Ashwellthorpe Hall, Norfolk*.

—I have been trying Royal Sovereign this year, and am very well satisfied with it. It is a good bearer, fruit of good colour, large, and earlier than President. I am planting a larger bed of it this year. I have thrown away Noble, the flavour not being good enough. President I still find the best Strawberry for all requirements when in season, and follow up with Elton Pine when there is only room for three sorts. I consider these the best. Dr. Hogg I like very much. Black Prince, Hélène Gloede, James Veitch, Sir Harry, Sir Jos. Paxton and Vicomtesse Héricart de Thury I have discarded.—F. OLDFIELD, *Broomfield Hall, Derby*.

—Of the many Strawberries that I grow I prefer Royal Sovereign. I layered it into small pots last autumn and planted it out in the spring of the year, when it yielded a fine crop of large, fine-coloured fruit. Vicomtesse Héricart de Thury is one of our best flavoured and always carries a good crop. Keens' Seedling does well with me and is a great favourite. President also does well and is much liked. I consider Royal Sovereign the best early and the best new variety on our soil.—J. HUNTER, *Lambton Castle*.

—I am no believer in a number of kinds of Strawberries any more than I am in a number of sorts of Potatoes. About three kinds of either I find sufficient for all purposes. Without being over hasty in putting Sir Joseph Paxton in the

background for general purposes, I think I must give the place of honour to Royal Sovereign, as it has done exceedingly well with me these two seasons and is in every way good. Sir Joseph Paxton I grow largely for main crop as the fruit travels well and is of good shape and colour, the plant being prolific and of good constitution. Vicomtesse H. de Thury I still grow largely, it being a good early variety and very prolific. Frogmore late Pine is a good late kind, and where the season needs extending will always repay the attention bestowed upon it.—C. WARDEN, *Clarendon Park, Salisbury*.

—I regard Sir J. Paxton as one of the very best flavoured Strawberries suitable for garden culture. It is also a grand cropper, and for appearance very hard to beat. Royal Sovereign, La Grosse Sucrée, Countess, Waterloo, and Leader, added to the first-named, are six varieties not easily beaten when flavour, appearance, and cropping qualities are taken into account. As a very early variety we cannot yet do without Laxton's No. 1, for, although the flavour is not quite first-rate, gardeners must produce early Strawberries in the open air. Royal Sovereign is a fine variety to succeed it. Frogmore Pine, Latest of All, and Waterloo are the best late kinds for this district. The best of the newer sorts are Veitch's Perfection and Laxton's Monarch. I consider that early in August is the best time to plant, so that the plants may get thoroughly established before severe weather sets in, and thus be able to produce a fair crop of fruit the following season. If the soil is dry and the weather bright at planting time it is, however, necessary to water and mulch. Extra attention of this description is well repaid, because it enables the cultivator to secure a crop in less than a year from the time of planting, when, without such attention, but little if any fruit would be obtained till the second year.—H. DUNKIN, *Castle Gardens, Warwick*.

—The best flavoured kinds of Strawberries grown here I consider to be Vicomtesse H. de Thury, President, Sir J. Paxton, and Royal Sovereign, in order of names. The best early kinds, as far as I have grown here, are Royal Sovereign and Vicomtesse H. de Thury. Elton Pine is relied upon for a late supply. Royal Sovereign I consider a very useful variety both for earliness and general cropping. For earliest crop I always plant out rooted runners in August at 1 foot apart each way on a south border, and treat them as annuals, destroying them as soon as fruiting is over. These produce ripe fruits from a week to ten days earlier than old-established beds. General planting is also done at this time or earlier.—C. HERRIN, *Dropmore*.

—Up to the present time I have found none to supersede Keens' Seedling in point of flavour, but, unfortunately, the stock, unless frequently changed, has a habit of growing out and becoming valueless. In spite of this drawback, I retain it on account of its high flavour, which is very rich indeed, and it always meets with appreciation. The next kind is Sir J. Paxton, which with me is always richly flavoured, and it is a variety eminently suited to this soil. It is now some thirty years since this kind was first introduced here, and the stock has never been changed: in fact, the necessity for doing so has never arisen, as it is as vigorous as ever, and exhibits not the slightest sign of being worn out. Whether I have a superior strain or not I am unable to say, but certain it is that for size, colour, and, above all, flavour I have not yet found anything to beat it. Next come Gunton Park and Lord Suffield, both of which possess very high flavour. These and the two varieties previously mentioned form a quartette of the best flavoured kinds most suited to this soil. Royal Sovereign has proved to be the best early Strawberry yet introduced for this district, and as such it will be largely grown for many years to come. It is a vigorous and a hardy grower, and produces very heavy crops of fruit. The individual berries are large, and well coloured, and the flavour is also very good indeed. So very satisfactory has Royal Sovereign proved to be here that several hundred more

plants have been set out just lately. Regarding late kinds, I find nothing to equal Oxonian for late use, and this after repeated trials. Here the fruits attain a richness of flavour which is lacking in many places, and it will continue to be grown until a better is found. Royal Sovereign and Oxonian are the best early and late kinds in this district. I am not in a position to give an opinion as to the merits of Leader and Monarch as I prefer to give them another season's trial before doing so; but with regard to other varieties my choice falls upon Gunton Park, Royal Sovereign, Lord Suffield, and Empress of India. The best time for planting is as early in August as circumstances will allow, as an excellent crop of fruit, and that of a superior quality, is secured the first season. My method is to layer the requisite number of runners as soon as enough have been secured for pots, and to plant these out as soon as they are well rooted and before they become pot-bound. With one exception the plantations are broken up after fruiting the third season, so that one-third of the number of plants grown is replaced annually with young stock. The exception mentioned is the case of Oxonian, which is best treated as biennial, as the crop produced the third season is very poor. This is the system that I find answer best, and by its adoption heavy and continuous crops are secured.—A. WARD, *St. Edith Gardens, Hereford*.

## GARDEN FLORA.

### PLATE 1142.

#### THE IRISH HEATH.

(WITH A COLOURED PLATE OF DABECIA POLIFOLIA.\*)

THE charm, both in habit and flower, which is characteristic of almost all the dwarf members of the Heath family, is well shown by the Irish Heath. Of neat and graceful habit, flowering with great freedom and over long season, of exquisite beauty of blossom, is, besides, very hardy and of easier cultivation than many of its allies. It is a native of Western Europe and has been found in Ireland, Western France, Northern Spain, and in the Azores. In Ireland it is most abundant in Connemara, but has also been gathered near the lakes of Killarney. On the mountains of Mayo it has been collected at elevations of over 2600 feet above sea level. The common name for it in the west of Ireland is St. Dabeoc's Heath, from which the present generic name was derived. The genus is nearly allied to *Menziesia*, to which it belonged till 1834, when was separated by David Don. It is a shrub from 1 foot to 2 feet high and forms a dwarf evergreen bush with erect branches. The drooping flowers are borne in erect racemes, each 3 inch to 6 inches long. In the commonest form (as the one which may be regarded as the type) the flowers are of a bright purple. The white variety was discovered in Connemara in 1827. These two forms are here figured, but there is also a third known as var. bicolor, which bears both purple and white flowers, both colours occasionally appearing on even the same flower. It blooms from early June to October.

The Irish Heath thrives under the conditions which suit the great bulk of the Ericaceae. It should have a peaty soil or, if that is not available, a good loam devoid of lime and with plenty of leaf-soil. It ripens seeds in plenty, and their means can be raised in abundance. The seeds should be sown at any time after they are ripe in well-drained pans of peaty soil and stored.

\* Drawn for THE GARDEN by H. G. Moon, Gravetye Manor. Lithographed and printed by J. Gouffart.

IRISH HEATH *VERBENA POLIUM* L.

a cool, moist pit or frame. When large enough the seedlings should be pricked off into pans or boxes and eventually planted out to the nursery border, where they flower the second season. When grown from seed the plants show a tendency to vary. At Kew there are now some curious specimens raised from seed of the typical form which are as dwarf and close in habit as some of the Stonecrops. Ordinary seasons it is perfectly hardy, but, like several other native shrubs, it suffered during the severe frosts of January and February, 1855. Contrary to most of the shrubs that were affected by that terrible spell of cold, it was the young plants that were least injured; both old and young were killed to the ground, but the latter broke into growth again much the more freely. But such a season may come only once in a generation. Of its value as an ornamental shrub there can be no question. It may be grown as an edging to other taller peat-loving shrubs, or as a sort of undergrowth where they are not too thickly planted. It is also pretty and effective when grown in groups.—  
W. J. BEAN.

— Among the reasons which we have given in THE GARDEN—and strong ones we think—why English names to garden plants there is one which perhaps has not had enough consideration, namely, the fact of the frequent alteration of Latin names inevitable perhaps owing to the growth of knowledge breaking down the barriers between the genera. Recently, for instance, one may look in vain for the long-known name of the beautiful Irish Heath in the London catalogue of British plants; it has got a new Latin name—*Boretta*. With a good English name these changes are of less consequence.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**CELERY.**—Nothing could be more favourable than the weather and soil for moulding up this crop; the only thing that one has to fear is that if the work is pushed on too rapidly on light and porous soils the roots will lack sufficient moisture to ensure the produce being of the highest quality. Indeed, I have proved this already, as for the last week the Celery which I have been digging is taken from soil almost dust-dry, and it is somewhat tough in consequence. As it is hardly expected that there will be sufficient rain now to penetrate to the roots of that which has been moulded up for some weeks, I shall lift what is required quite a day in advance. A good portion of soil will be retained on the roots, the outer foliage will be tied round loosely with a strip of matting, and the heads will be stood in a few tubs of water in a cool, dark cellar. I find this improves it greatly, and it is decidedly more crisp than when used direct from the dry soil. It may appear strange to water this crop in October, but it would certainly be a wise plan on dry soils with later batches. By giving the trenches a good soaking advantage could be taken of the dry weather to draw soil round the plants, as when rain does come a favourable opportunity may not occur. There is one advantage with the present dry weather, viz., less danger of worms and slugs eating into the centres, and the crops should turn out clean. It is later, however, in the soils that this has to be contended with, and before recommended, a good dusting of lime should be given about the plants before the soil is drawn round them. A sharp look out should be kept for diseased leaves, which should be picked off at once and burnt. It is surprising how quickly this disease spreads when not checked.

**BROCCOLI.**—Long before Autumn Giant Cauliflowers will be over the earliest of the Broccoli will be turning in. In my case the varieties will be Snow's Winter White and Veitch's Self-pro-

teeting Autumn. The absence of rain, together with more than the usual amount of sun at this season, has caused the plants to remain much dwarfer than we generally see them at this date. This is a great advantage, as they are less liable to be damaged by frost, owing to the leaves being of a firmer texture, and they are more easily retarded by either lifting or removing them to a north border, or by simply heeling them over than is the case when they have made large sappy growth. The plantations should be looked over frequently, and the plants should be so regulated that not more than what is required to meet the demand allowed to turn in. Where no attention is given in this way the heads come on too quickly, and many of them become too large before they can be used, and as a result are wasted. This is more to be regretted where there is not a large quantity of later varieties coming on to succeed them. Broccoli when they have attained the size of a cricket ball are in the best condition for retarding, as this is the most serviceable size for the dining room, and the check they receive by being lifted and laid in a cool position preserves them in this state over a much longer period than when they are left undisturbed. Smaller quantities may be lifted with a good ball of earth and stood in a cool shed, but the foliage soon turns yellow, and this plan is not nearly so satisfactory as keeping them in the open. While on the subject of Broccoli I may add that fewer kinds are really required to maintain a long supply than is supposed. For instance, I have Snow's Winter White in three stages of development by sowing in March, April, and May. Those sown first are now turning in, and the later batches promise to give a long season from this one variety.

**CAULIFLOWERS.**—Autumn-sown plants will have become quite sturdy, and they should be still fully exposed as long as possible. It only requires the protection of glass for a very short period to alter their appearance and cause them to draw up weakly. It is almost better to run the risk of a little frost at this season than commence to coddle them, as the more hardy they can be made, the better able are they to stand severe weather later on. The surface soil should be slightly stirred between the plants and a dusting of soot or lime applied, but as a firm root-hold tends to the formation of sturdy growth, it may prove an advantage, after treating the plants as described, to make the soil firm about them by treading. Later sowings made in frames for spring planting should have the lights kept off them as long as possible. See that the seedlings are not too crowded. A one-light frame will protect a large number of small plants during the winter, and when it is not desirable to prick these off now to allow them more room, all the smallest should be drawn out to allow each plant to stand clear of its neighbour. Press the soil firmly round the roots of those which remain after thinning and work a little fresh loam between them if they have become rather leggy.

**LETTUCE AND ENDIVE** which have been planted on old hot-beds will probably require watering after the present spell of dry weather. The leaves, &c., which were used to make up the beds will act as drainage, and the small depth of soil above them is apt to become dry. There should be no lack of salad this winter, as it has been a most favourable time for getting the plants forward. In spite of this, however, accidents do happen, and where there is likely to be a scarcity of Lettuce later on I would recommend sowing seed now in shallow boxes. Veitch's Golden Queen and Early Paris Market are the best for this purpose, as they naturally turn in quickly, and being of very compact habit, they are more suitable for box culture than the larger-growing kinds. Boxes about 3 inches deep should be filled with light rich soil and the seed sown rather thickly, covering it afterwards with sandy soil. Water through a fine rose, and stand the boxes on a shelf near the glass in a warm greenhouse. If desirable, the seedlings may be allowed to grow thickly and simply cut over like Cress when about 3 inches or 4 inches high.

**FRENCH BEANS** growing in unbeated pits should have the protection of double mats at night, as, though there may be an absence of frost, a low temperature checks the quick growth of the pods. It would be better not to ventilate too freely, and what air is allowed during mid-day should be taken off again while the sun strikes the lights, so as to conserve as much solar warmth as possible. Later batches in pots should be placed near the glass in a nice growing temperature. A high night temperature is not desirable, and great care should be used not to overheat the pipes, this leading to weak growth as well as attacks from red spider.

RICHARD PARKER.

### FRUIT HOUSES.

**LATE VINERY.**—Lady Downe's and other late varieties usually grown with them will now be quite ripe, when a dry atmosphere and a free circulation of air on every favourable occasion, or when the temperature exceeds 50°, will be needed. A little artificial warmth will be required to keep the air of the house dry. When the weather clears up after a spell of foggy weather, take advantage of the first fine day to give the house a thorough airing, well heating the pipes at the same time for a few hours, when all moisture, should there be any, will be quickly dispelled. All leaves should be gathered up daily as they fall from the Vines, and the washing of the floors should now cease, as occasional sweeping with a soft hair-broom will suffice to keep them clean until the Grapes are bottled. Should any of the inside borders require water, afford it on fine days only, and well cover the surface afterwards with a good thickness of dry litter to keep back damp. Outside borders, if not covered as advised, should be done forthwith. Look the Grapes over once or twice a week and cut out any berries found to be decaying, and with a camel's-hair brush carefully remove webs if spiders have taken up their abode in the interior of the bunches. All corners and any places likely to afford these pests congenial quarters should also be brushed out weekly. Where these late Grapes are not yet finished sufficient artificial heat must be given to keep the temperature up to the mark, and this must be persisted in until every berry is properly coloured and finished. Air also must be admitted on every favourable opportunity. See that inside borders do not suffer from want of water, and continue to apply it at a temperature of 85° until the Grapes are ripe, well mulching the surface with some dry non-conducting material to prevent moisture rising and condensing on the berries and roof glass.

**MUSCATS.**—These, if occupying a house to themselves, may be treated a little differently, a few degrees more warmth being beneficial. On the other hand they must not be kept too warm, otherwise the berries will shrivel. A safe rule is to keep a night temperature of 50° with an addition of 5° more for the day. Above these figures air may be admitted on every fine day, but avoid cold cutting draughts, as these will soon rust the berries, and shut it off early in the day in low-lying, damp situations. If the above figures are objected to as being too high, care must be taken to see that the temperature does not get too low, or so that moisture is deposited on the berries. If there are any bunches still hanging on any of the earlier started Muscats they should be cut and bottled, which will enable the house to be freely aired, borders attended to if necessary, and the Vines themselves subjected to a more perfect season of rest.

**LATE HAMBROS.**—These having such thin skins will require careful treatment during the ensuing month, when we are liable to so much foggy weather, and when the Vines will be shedding their leaves. The air must be kept in motion by keeping the hot water pipes slightly warmed both by day and night. If there is an inside border it should not be watered unless absolutely necessary, because the roots will find sufficient moisture for

their needs in the outer border should they have the run of both. Look the grapes over frequently, gather up the falling leaves every day, and spare no effort towards keeping them in sound condition. These Grapes, with care, can be kept until the end of the year, when, as far as my experience goes, they are highly appreciated.

**OTHER VINERIES.**—If the remains of any of the crops are still hanging in any of these houses they will keep much better in bottles than on the Vines. The Vines may then be partially pruned, cutting away all sub-lateral growths and shortening back the laterals themselves to a greater or less extent, according to their age and condition. Should the wood on any of the Vines be still unripened, shortening back must be deferred until, by the application of a little fire-heat and plenty of air, the bark assumes a brown appearance. This, however, is not likely to occur with healthy, established Vines, and is a condition generally to be found in young and extra strong rods, or in those whose roots have found their way into the cold subsoil and have got beyond control. Proceed with the pruning of Vines in earlier houses as soon as the leaves are off them, and after washing both them and the structures in a thorough manner, dress them with an insecticide. The rods after the cleaning is effected should be slung loosely from the trellis until starting time arrives. All outside borders still unprotected may be covered at once with Bracken or long dry stable litter, which if so placed that it slopes from the front of the house to the outer edge of border will shed off a considerable amount of water and snow, while it will tend to conserve the little warmth still remaining in the soil.

**LATE MELONS.**—These will require plenty of top and bottom-heat to ensure good flavour. Heat must not be lessened in any degree until the fruits are ready for cutting. The plants as a rule make but little growth at this late season, but the roots require a good deal of water, especially if the compost they are growing in is in proximity to the hot-water pipes. Stimulants may be given, but with caution, as an overdose, particularly towards the finish, would spoil the flavour. Watering is best done early on bright mornings, so that the superabundant moisture may pass away while the ventilators are slightly open. Closing should be done early, and what little damping down is required should be done with a fine rose-pot, syringing being entirely dispensed with. When the fruits begin to colour cease watering and damping, and keep a chink of air on the house night and day if well heated, if not, by day only, to improve the flavour. Late Melons will keep in a sound condition for ten days or a fortnight. A. W.

**The use of autumn-tinted foliage.**—The recent exhibition of the National Chrysanthemum Society at the Royal Aquarium was specially noticeable for the large and varied character which the decorative exhibits partook. Each season it is noticed that a fine variety of foliage with rich autumnal tints is used, and by its adoption flowers of warm and rich colours in particular are made to appear far more effective than they otherwise would. On this occasion lovely growths of the richly-coloured *Ampelopsis Veitchi* were seen in most of the exhibits, and their association with blooms of bronze, yellow, and crimson, both under artificial as well as during daylight, further intensified the richness of the colouring. Other subjects, such as the Beech with lovely tints of a golden hue, the rich crimson of the Scarlet Oak, and the long trailing sprays of the Japanese Honey-suckle, were largely used. Occasionally some exceptionally clean and pretty species of Bracken were brought into use, sometimes as the base of an epergne, and at others in the embellishment of a vase of large Japanese blooms. Grasses which had been carefully picked in the early summer and dried were invaluable in light artistic work. Asparagus in long sprays was always seen, this in most instances giving considerable grace and finish to the picture. The use of foliage of a hardy kind should be more frequently used than

is now the case. The National Chrysanthemum Society has done much during recent years in encouraging the display of floral arrangements of all kinds, and there is still room for additional classes. The large vases, each filled with twelve blooms showing cultural excellence, is the beginning of reform in the methods of exhibiting this popular autumn flower, and if classes of this kind could be extended, using autumn foliage certainly at the September and October shows, an object lesson would be given to the flower-loving public, in arranging huge blooms in a different way from that which is generally considered the orthodox one, viz., on boards.—C. A. H.

## CHRYSANTHEMUMS.

### CHRYSANTHEMUMS AT CHELSEA.

ALTHOUGH the Chrysanthemum is justly regarded as pre-eminently a town flower, yet growers in the vicinity of large towns labour under difficulties and disadvantages that are little appreciated by those whose good fortune it is to live in the purer atmosphere of the country. Outside the London radius Chrysanthemums are almost always brighter in tone and richer in the shades of crimson, purple and bronze than within, but cultural difficulties can to a large extent be got over even in town, in proof of which the excellent collection at Messrs. J. Veitch and Sons' Royal Exotic Nursery is a striking object-lesson.

Entering the nursery from the Fulham Road, the visitor passes through a glass structure, the central path of which is lined on both sides with freely-flowered bush plants bearing a multitude of showy blossoms, not so much distinguished for their being new as for their value for the purpose for which they are intended, viz., decoration. In a large greenhouse, containing about 1000 plants that make a brilliant and effective show of colour, we find almost everything that is newest and best in the various types. The collection is not a miscellaneous one, but seems to have been the result of careful selection, and the culture is of a high order of merit. Almost every plant is a proved variety and worthy of the fullest recommendation, unlike some collections, where at times the novelties are a matter of speculation.

Continental varieties here, as elsewhere, show themselves to be very formidable opponents to American and home-grown novelties. *Leocadie Gentils*, a pale lemon-yellow hairy sport from Louis Boelmer, is large and effective. *Louise*, a well-known seedling of M. Ernest Calvat's, is, as usual, massive and good. The same raiser is also represented by *Reine d'Angleterre*, *Le Mouche-rotte*, *Australian Gold* (very large), *M. Chenon de Léché*, *Amiral Avellan*, *President Borel*, *M. G. Montigny*, *Souvenir de Petite Amie*, *l'Emindra*, *M. Geo. Biron*, *President Armand*, *Boule d'Or*, *Commandant Blusset*, all of which are too well known to the average lover of Chrysanthemums to need anything like verbal description. Good yellow Japanese of various types are to be found in *Phebus*, a well-known variety; *Lady Oporto* *Tait*, globular in build, and having long grooved, intermingling florets; *A. H. Fewkes*, *Charles Davis*, *Modesto*, very rich, and *Marjorie Kinder*, large and very fine in colour.

One of the most delicate shades of colour is that found in *Lady Hanham*, whose creamy rose and salmon tint will enable it to find a place with *Charles Davis* and *Vivand Morel*, with both of which it is closely related. *Elthorne Beauty* is large, but the colour is not pleasing to our taste, being of an undecided rosy mauve. *Eda Prass*, pale pink, is good in form and colour. *Sunflower*, *Col. W. B. Smith* and *H. L. Sunderbruch* need only be mentioned by name, and such white varieties as *Pride of Exmouth*, *C. B. Haywood*, *Mrs. C. Blick*, *Simplicity*, *Mutual Friend*, and *Miss Elsie Teichmann* are no new-comers this season.

*Mrs. Hermann Kloss* is very rich even for a Japanese: it is of a deep warm golden terra-cotta, tipped gold. *Pride of Madford*, deep vel-

vety plum-coloured amaranth, with silvery reverse, is large and seems likely to remain. The crimson *William Seward* and *John Shrimpton* still maintain their reputation for richness and distinctness of colour, but close at hand is a very large rival called *Octoroon*, with incurving florets of deep blood-red and reverse of golden bronze. *Mrs. G. W. Palmer* is a golden-bronze sport from *Mrs. C. Harman-Payne*. *Lady Byron*, lar solid, and good, proves to be quite as fine when first introduced.

The Chelsea collection does not count among its varieties a large proportion of the old incurving type, but *Baron Hirsch* was large and good of capital colour. *Prince of Wales*, *Gold Beverley*, *Mr. J. Kearns*, *Mr. James Murray*, *R. Bahuant*, and *Mme. Darrier* were the principal representatives in their class.

Some *Anemone*-flowered varieties in good form are on view, *Descartes* being one of the largest and best; and *Junon*, very perfect in build and of a pretty soft lavender shade, is worthy of mention. *Mrs. Hugh Gardiner*, of recent introduction, also appears in excellent condition, but this section does not now-a-days seem to attract anything like the attention it used some years ago, and in the trade displays not many of the standard sorts are now-a-days seen in any number.

### OCTOBER CHRYSANTHEMUMS.

THERE were some very fine blooms at the Aquarium show. Many, however, exhibited signs of having been grown in heat, and were not fully open. Such flowers, therefore, gave no criteria as to the merits of the sorts for blossoming in October. *Edith Tabor* and *Mutual Friend* were in good condition, and *Phabus* was represented by several excellent blooms. *Emily Silsbury* could be seen in many instances in first form. This is a capital October variety, and makes a nice pot plant not disbudbed. It is fine and the habit dwarf. *Louise*, as a bushy large incurving flower, was good thus early in the year, and *M. Hoste* comes fully open at this time. It is a large, flat-petalled bloom of a pleasing bluish-white shade. The flowers of *Mme. Gustave Henry* were barely open. They were very large, the long florets slightly incurving at the point. This kind is of easy culture and of short growth. *John Neville* and *Geo. Seward*, welcome kinds, gave nice colour to one or two stands. *Chenon de Léché*, too, although so early in the season, was seen in very good condition. Its tinct colouring is especially bright under a light. *Pride of Madford* stood out among other blooms as one of the largest. This is the first-rate Chrysanthemum for any purpose that was named in some instances *Beauty of Te-mouth*. In the first-prize group *Elthorne Beauty* appeared most distinct and showy; it is a variety of a pleasing pink colour and a bloom of nice form. *Mme. G. Bruant* is a fine addition regards size, the flowers are very large, the florets being handsomely drooping. It is white with rose-coloured points to the florets. These are of unusual length. It should be noted as the novelty of the season likely to be of great value for show. Although *Miss Elsie Teichmann* was not seen at the Aquarium, it is a splendid variety, at its best in October. It reminds of *Mlle. Thérèse Rey*, and has a similar richness in its petals. Being of easy culture, it should place the latter, which disappoints one too often in its habit of forming flower-buds that refuse to develop. *Lady Byron* is another good white now at its best. It is a lovely blossom.

But, apart from exhibition flowers, there are excellent varieties to supply cut bloom early in the autumn in quantity, which are of pretty shape and colour. *Klondyke*, a new yellow of a capital shade, should be noted as very fine. *Sunflower d'Octobre* (another new yellow of a light shade) especially free and likely to become a most useful kind. *Yellow Lady Selborne* and the *White* are very free and valuable. *Rycroft Glory* is a good bush plant; it is very dwarf in growth, the bronzy yellow flowers are of medium size,

ly last well when cut. Source d'Or (a late October sort) is well known; its shade of bronzo is most valuable for all kinds of floral decorations. A first-class early white is Lady Esther Smith; the blooms have substance and a pearly ture; it is exceedingly free-flowering and dwarf. Of somewhat similar shape is Queen of the Earlies. This, too is a first-rate white. Souvenir de Petite Amie is a white sort that reflexes florets instead of being incurved in form, as the last named two are. This is a most useful October kind; the habit is particularly dwarf and free. The old Elaine has white blooms of great purity, hence it is freely grown, although the habit is rather tall. Another tall grower—Mrs. E. G. Hill, bears pretty blush-white flowers in October. Margot is a free salmon-pink sort best useful for cutting; so is Sam Barlow. It produces flowers of that shade in great profusion in this early season. L'He des Plaisirs is a red kind which has been in cultivation some years; it is yet an excellent one. Wm. Holmes (crimson, painted gold) has a first-rate habit and flowers best freely. This is a well-known sort which has been surpassed in its way. O. J. Quintus is really an October variety. This has pleasing light pink blooms of medium size. Sunshine (a dull, very bright yellow blossom) strikes one as likely to be good for early flowering. H. S.

#### CHRYSANTHEMUM MRS. HAWKINS.

The golden sport to which "J. C." (p. 296) refers doubtless the above, and has been eight or nine years in cultivation. It originated in at least two places at about the same time, and gained a good deal of notoriety. The same sport occurred in my own case, the flowers of a large plant of Mrs. Wormig coming wholly golden, and from which my stock of Mrs. Hawkins has been raised. I took the precaution, however, of verifying my stock by comparing it with the certificated plants in Covent Garden Market. In the varying stocks of Mrs. Hawkins in cultivation to-day some are much more free of growth than others, and, apart from this, the deepest coloured form I have seen has rather smaller blooms. In my own district there are several large growers who have never bought their present stock of yellow or golden Desgrange, this having sported either wholly or partly from the then existing stock of white. The stock is a particularly free-branching variety and appears intermediate in tone. I believe there are in cultivation to-day several slightly varying shades of yellow in this group that are quite distinct, when seen side by side, from the named varieties that are mostly grown. These latter, four in number, are given in the order in which they originated. One, Castex Desgrange (white, yellow centre), Mrs. G. Wormig (clear canary-yellow), Mrs. Drell (a very pale sulphur or straw-yellow), and Mrs. Hawkins (the deep, almost golden yellow, the best of all the yellows, and still without a rival in the very early kinds). And then, apart from the differing shades of colour, those who grow the plants naturally and in quantity will not fail to note the sportive character of the blooms. To years ago I selected a large spray of a very pale white sport in which the flowers were pure white, but though I layered the branch and rooted cuttings and grew the old plant again, I never saw any more of what I imagined promised to be an acquisition. My most recent sport was noted before the scientific committee of the Royal Horticultural Society a year ago. In this case all the usual ray florets were suppressed, and the active greenish florets, scarcely 1 inch long, appeared instead. At first sight the incident appeared to be want of good or proper nourishment, but the sportive plant was one of two growing in the same pot, and, of course, receiving sport identical with another that developed the usual flowers. E. JENKINS.  
Hampton Hill.

Fungus on Chrysanthemum leaves.—I found some leaves of Chrysanthemums with fungus

on the underside. The disease was first noticed on some new sorts of this year's growing, but it has spread on many more, and syringing with insecticides does not stop it. Since the plants have been housed this disease has increased. I should be obliged if some reader could tell me what is the cause of it and a probable cure.—M. S. P.

\*.\* The leaves are covered with a disease known as leaf rust, most destructive, but not often seen. Sulphide of potassium at the strength of a quarter of an ounce to a gallon of water has been effectual in such cases. This should be syringed on the undersides of the affected leaves. I would take off the leaves and destroy them if not within about 18 inches of the blooms. They would serve no useful purpose at this season in developing the flowers.—H. S.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Soleil d'Octobre.**—As its name implies, this is an early variety, but very pretty and of good size. The colour is a pure chaste pale yellow.

**Chrysanthemum White Swan.**—Admirers of the hairy section will find in this a large Japanese variety in which the hairiness is very marked. The petals are long, tubular, very pure white, just faintly tinted in the centre.

**Chrysanthemum Lady Hanham.**—Like Charles Davis, this is a sport from the well-known variety Vivand Morel, which it very closely resembles in form. The difference, however, is chiefly in colour, a delicate shade of cream and salmon-rose.

**Chrysanthemum Mr. Hurley.**—A promising market variety of pretty Japanese form and rather larger than these flowers usually are. The colour is golden terra-cotta and should be very effective under artificial light. Mr. Godfrey says the plant is free flowering.

**Chrysanthemum Leocadie Gentils** is a hairy variety, a sport from *Enfant des deux Mondes*. It was shown last year in Paris in very good form, but under English cultivation it seems far superior this year. The colour is pale clear lemon-yellow, very pure and effective.

**Chrysanthemum Buff Globe.**—Good Gracious, an American variety with curiously twisted florets, is already known, as also is its white sport. Buff Globe is another sport from the same parent, but in colour of a very decided cinnamon-buff. It is large and of good substance.

**Chrysanthemum Mme. Ed. Roger.**—This is one of the most curious and, at the same time, one of the most distinct novelties we have ever yet met with. In build it is Japanese incurved with medium-sized grooved florets. It is large, solid, and compact, and the colour pure pale sea green. The raiser is M. Ernest Calvat.

**Chrysanthemum Yellow Gem.**—This is a charming little pompon flower, and invaluable for cutting. Messrs. H. Cammell and Sons had a capital bunch of this variety in their stand at the recent show at the Royal Aquarium. When grown in a free manner, the blossoms, each about 1½ inches in diameter, develop pretty little full heads. The fimbriated florets also add to their attractiveness. The plant is dwarf and the colour a bright citron-yellow.—B. C.

**Chrysanthemum Mme. la Comtesse Foucher de Cariel.**—At the time of writing (Oct. 18) this variety is at its best. It is of dwarf, branching habit of growth, not exceeding 2½ feet in height, most profuse blossoming, and in colour a bright orange-terra-cotta. This variety does not take kindly to disbudding, and is never seen better than when grown in the freest manner possible. The sprays of blossoms are extremely useful for decoration at this season.—C.

**Chrysanthemum Mrs. Geo. Hill.**—This pretty little decorative Japanese sort is said to be a seedling from Lady Selborne. A plant was recently shown by Mr. M. Russell at the National Chrysanthemum Society's floral committee meeting, and appeared to possess a fair habit of growth, height not exceeding 3 feet. The blossoms are each from 3 inches to 4 inches in diameter, creamy white, the centre being sulphur-yellow, deepening at the base.—C. A. H.

**Chrysanthemum Notaire Groz.**—A few plants of this variety in the border last year were so pretty and free flowering that it was determined to

grow it more extensively this year. The wisdom of doing so is seen in the delightful display the plants are now making. They are rather taller than most of the others, being quite 4 feet in height, yet making fine bushes, with elegant sprays of dainty little blossoms of delicate lilac-mauve. For cutting, this pretty little Japanese flower should be largely grown.—C.

**Chrysanthemum Philippe Rivoire.**—This promising Japanese variety was exhibited before the floral committee of the National Chrysanthemum Society on October 12 by two different growers, one set of blooms under the above name, and another with the prefix Madame. The flower is very large, with long and broad florets, possessing much substance. The florets are also slightly twisted and curled. Some of the flowers, evidently those from early buds, were somewhat coarse, but others, no doubt from later buds, were very neat and promised to be of considerable value for exhibition.—C. A. H.

## ORCHARD AND FRUIT GARDEN.

### LIFTING ROOTS OF APRICOT TREES.

ONE of the most common causes of failure in Apricot culture is planting the trees in a too rich compost at the outset, which mistaken kindness leads to nothing but quantities of gross, unfruitful wood being made. This growth is also continued late in the autumn, and the natural consequence is that the wood, by reason of its soft, sappy nature, cannot possibly ripen. These gross-habited trees sooner or later fall a prey to gumming, branch dying follows close in its wake, and they ultimately die. Very often in such cases the climate or soil is blamed as being unsuitable, while in reality the fault lies in the border having been constructed of far too rich materials. Another cause of Apricot trees making gross wood may be traced to the digging in of heavy doses of manure when the borders in front of the trees have to be utilised for vegetable growing, particularly if they are cropped up to within 3 feet of the wall. The remedy for this is only too apparent, but when kitchen gardens are small and the utmost use has to be made of every foot of ground, it cannot very well be avoided. There is a remedy both in this and the foregoing case as far as the Apricot trees are concerned, and that consists in root lifting now and again, or when necessary. When the unfruitfulness of the trees arises from the cause mentioned at the commencement of this note, the proper course to pursue is not only to lift partially or entirely, but also to remove the rich compost which has been the cause of the mischief and replace it with that of a poorer and more calcareous nature. In the other case, when close cropping and manuring of the borders cannot be obviated, the trees should be subjected to a periodical root-lifting in precisely the same manner as are Peach trees when well managed. This will cause the trees to make short-jointed wood of medium strength, which will be clothed from base to tip with fruit-buds. No greater mistake can be made than giving Apricots a too rich rooting medium, and my experience teaches me that the less rich the soil is within reason the better the results. I gather my finest fruits of Moor Park, from trees which are planted in a compost consisting of quite one-third of broken bricks, lime rubble, and a little wood ashes, the remaining two-thirds being the loam of the locality, which is inclined to be heavy and contains a rather high percentage of lime. In this the trees make medium growth, are extremely fruitful, and enjoy almost complete immunity from sudden loss of branches. Other trees planted in compost into which calcareous matter does not enter so largely in its composition are quite as fruitful, but they are more subject to branch

dying, and since discovering the beneficial effect of the employment of a larger percentage of the materials named, they are freely used when planting new trees.

Animal manure I avoid altogether, and always employ it simply as a mulch, when it does a deal of good by attracting and keeping the roots near the surface. Should manure be deemed necessary through the loam being considered at any time to be of poor quality, it is supplied in the shape of half-inch bones and bone-meal, both of which encourage the formation of wood of the right description. Although the season is far advanced for lifting the roots, it is not yet too late to undertake it, and I would strongly urge those possessing trees which make a great deal of growth and bear but little or no fruit, to deal with them in the manner indicated. Trees that are too far gone should be grubbed out and fresh ones planted in new compost, taking care at the same time to mix plenty of calcareous matter with it. Those having light sandy loam to deal with would find the addition of marl or clay beneficial, and half-inch bones or bone-meal should also be added. The amount of lifting required will depend entirely on the condition of the tree. Partial lifting may suffice in some cases where strong growth merely requires a check, but when the trees are altogether unfruitful, it is then necessary to lift, if not quite entirely, certainly to remove all the soil about the roots with the exception of that immediately surrounding the main roots close up to the stem. This would leave a fair-sized ball of old soil, and the new soil can be placed and made firm all round it as the filling in proceeds. The new soil should be made firm and watered home to

possible, so that the roots, particularly the fibrous ones, do not become dry, and it may be necessary in cases where the trees still have

form. From trees on a south wall grandly colour fruits are obtained, but they mature too early. This may not happen in a good holding soil or

*Pear Fondante d'Automne.*

green leaves upon them to syringe them for a few days to prevent them flagging. A. W.

#### APPLE LEMON PIPPIN.

MANY growers favour the larger Apples, and do not think such small kinds as Lemon Pippin desirable. They lose sight of the free-cropping character of many of the smaller or medium-sized Apples and do not take quality into consideration, which is a great point. This variety may be termed medium-sized when well grown, the fruits oval, the skin green, turning to a yellow or lemon colour when ripe, eye small and stalk short, with a peculiar fleshy knob in which the stalk is inserted. When gathered from trees with full exposure the fruits are streaked with russet on the sunny side, and at the turn of the year much resemble a medium-sized Lemon in appearance. This variety does not possess many synonyms, like many other Apples, possibly owing to its distinct appearance. It is pleasantly acid, flesh firm, and when gathered late and stored in a cool place it does not shrivel like many late fruits, retaining its good flavour till the last. This variety on the Paradise stock is one of the best Apples an amateur can grow for late use, as it may be had as late as April.

**Pear Magnate.**—I have this seedling Pear in cordon form, and have on previous occasions referred to its good cropping qualities. This year on a south wall I had grand fruits and of excellent quality. At p. 309 "A. W." writes of the cropping powers of this variety and inquires as to its quality. This shows that in his district the fruit must be later. I endeavoured to keep fruits for September 30, but failed

in older districts. I notice it is a favourite for exhibition, but I think Marguerite Marrilat, a very fine showy new variety, is superior as regards flavour. Does "A. W." grow this variety? With me it is a grand fruit, but I only have in cordon form, and from a bush it may not be so large, but it will, I think, be profitable on Quince if grown for early use. It bears fruit when young.—G. WYTHES.

#### GOOD AUTUMN PEARS.

OF good autumn Pears there is no lack, scarcity being felt later on. New kinds such as Le Lectier, Baron Leroy, Beurré Dumont, Duchesse de Bordeaux will be most valuable they succeed in our climate, in lengthening the Pear season. One of the best autumn fruit is Fondante d'Automne, here illustrated. Varieties are superior in quality when in sea. Unfortunately, it decays quickly, so that it is scarce in storing. The fruits of this variety are medium-sized, though on cordon trees this variety with a light crop they have exceeded the named and have been of superior quality, the white, melting, very juicy, and rich, roundish fruits covered with brown russet, especially in heavy soils. Its season is generally as October, but this year some of my fruit were ripe at the end of September. It is not so common as it deserves, as it is not so showy a fruit. On the other hand, its usefulness should commend it to all Pear lovers. The growth of this variety is very distinct, the leaves rather small, and the growth vigor. It rarely fails to crop. I have seen grand crops of this variety in the southern counties on standard trees, but I prefer it grown in bush or pyramid form on the Quince, as thus one gets a better flavour and it is an easy matter to pick the fruits, also to feed the trees when cropped freely. In cordon form the fruits are large and useful for special purposes. Grown thus it is a sure fruiter if the roots are not too deep in the wood allowed to get too gross. It is an excellent variety grown as an espalier, as it fruits so quickly in a young state, and in the northern parts of the kingdom, grown in various ways it is much valued, as it gives later fruit, rarely fails.

*Apple Lemon Pippin.*

settle it about the roots, applying a mulch to the surface as soon as the work is completed. The work must be done as expeditiously as

some of the largest going soft. It must be classed as a valuable addition to the early Pears, but in my opinion it will be of better quality grown in bush

Whilst referring to the qualities of this my note would not be complete with-mention of Thompson's, another variety grown so much as it deserves. Where good quality Pears are valued, Thompson's is excellent to follow Fondante d'Automne. Of late the Doyenné du Comice has been more largely grown on account of its good qualities, and it mainly deserves extended culture. We have a large number of poor Pears; indeed, catalogues need much weeding out if quality is to be considered. In the useful catalogue of Pears shown at the Chiswick conference in 1881, Mr. Barron describes over 600 varieties, and I wish he would give us further information on the best kinds. He having had them under close observation for many years, his long experience would be a splendid guide. Of the autumn Pears, the newer Dr. Jules Goussier will, I think, prove a valuable addition to the earlier kinds. This precedes the one named above, and though inferior to it in quality is useful as an early Pear. It closely resembles Williams' Bon Chrétien without the juicy flavour, and appears to be a constant cropper. For quality, I think the new Director Hardy will prove a valuable October fruit, as I have only seen cordon trees fruiting, but it promises well. In a brief note on autumn Pears I do not think it advisable to name older well-known kinds.

G. WYTHES.

**Japanese Plums.**—Have any of your readers made trials in England of the various Japanese Plums which I see alluded to, and sometimes praised for their vigour, fertility, and hardness, in the case of the Satsuma, Botan, and Masu. I ought to give a very good account of themselves in our country if what is said about the hardness be true.—H. L.

**Apple Red Hawthornden.**—Among the notable dishes of Apples at the Crystal Palace that exhibited by Mr. Hartland under the name of Red Hawthornden. This was perfect in every way, the fruits solid, heavy, and clean, with bright red cheeks and very shapely. A clean specimen of the old Hawthornden is very rarely met with as the fruits have a great tendency to be spotted, and a substitute of equal quality as the new Apple and as clean as that here noted would be very acceptable.—J. C. T.

**Apple Autumn Pearmain.**—This was one of the most striking-looking Apples among the new varieties shown at the Crystal Palace. It came from the Sidmouth Nurseries and was presented by a fine dish of large, deep russet, glossy-cheeked fruits, of which one would have to learn more as regards quality and keep-also the section to which they belong. I do not find it under the above name in any fruit list I have by me, and should be glad of any information that can be given about it. It struck me as being the appearance of a good and fairly long-keeping Apple.—J. C. T.

**Pear Duchesse de Bordeaux.**—I noticed at the recent fruit show that the above variety was staged by two exhibitors from Kent. I had hoped to show it, but my fruits dropped owing to frost. It is a fine variety and of excellent flavour. The fruits are large, yellow, covered with pale russet flesh, juicy and melting. It is in season at Christmas, and grown on a cool soil may be kept till February. Last season this variety was also good. It is one of those which are suitable for warm soils. I do not use it for wet soils or exposed positions, and find ample supplies of food whilst perfecting the fruit. My trees are on the Quince stock.—S. B.

**Apple Gravenstein.**—For use during the autumn this variety is much liked. With care rarely fails to crop, my trees being mostly

in bush form. Though grown in this way the growth must not be crowded, as it is of spreading habit in good soil. Gravenstein is so distinct as regards flavour that it is worth room in all gardens. I notice the Royal Horticultural Society in their classification of dessert and cooking Apples place Gravenstein in the dessert class, and rightly so. I have been in places where this variety was preferred to all others for dessert, and was obliged to keep up as long a supply as possible. It is well worth growing on account of its free cropping qualities.—S. M.

**Pear Gansel's Bergamot.**—"J. C." (page 259) notes how seldom this handsome and good Pear is seen. Probably the cause of this is that it is a very slow grower, and not a Pear for every soil and district. Be that as it may, a few magnificent dishes were shown at the recent fruit show at the Crystal Palace, and as seen there it was most attractive, highly coloured, and would prove very valuable for dessert, though ripening at a season when there are many other good Pears to be had. It requires a wall to finish the fruits properly in northern gardens. Some nurserymen send this Pear out only in double grafted form, and probably this is the better way most so as to positions.—J. C. T.

**Pear Durondeau.** It is unfortunate such a splendid looking Pear as Durondeau is not of better quality. I am aware in fruit catalogues it is classed as a large, handsome Pear with rich, delicious flavour, but I fear in a flavour competition it would stand a poor chance. I am aware as an exhibition fruit it has long been a favorite. I would like to see classes at the next great fruit show, under the auspices of the Royal Horticultural Society, for Pears or Apples noted for their flavour. Of course at the season named several varieties would not be in condition to test quality, but the various kinds are so well known that competent judges could with little difficulty give awards when they had good specimens of the best kinds before them. For years I have grown Durondeau in various ways and have endeavoured to get fruits of first quality, but have failed. For size, appearance, and crop it well deserves front rank.—S. M.

**Apple Allington Pippin.**—This new Apple promises to be a standard dessert variety, and its cropping is all one may desire. This year young trees are laden and the fruits are of first-rate quality. I thought highly of this variety when it was certificated a few years ago under the name of South Lincoln Beauty. One must expect great things from such parents, as, if I mistake not, Cox's Orange and King of the Pippins are the parents. This variety more resembles Cox's Orange in quality, but the King in colour. It is in season from November to February, a season good dessert kinds are rather scarce. I saw excellent fruits in May of this variety from bush trees. The tree is a vigorous grower and bears very freely in a young state. I do not know if it will succeed in standard form like King of the Pippins. Its free cropping, in addition to its first-class quality will make it a valuable addition to the late dessert Apples.—G. WYTHES.

**Pear Thompson's.**—This is usually classed as a November Pear, and doubtless in the northern parts of the country its season would be early November, but I have never been able to keep it after the middle of October. This failing is not only the case with Thompson's, as unfortunately many of our best Pears are ripe weeks in advance of the season given in catalogues. Those who value good flavour in fruit cannot do better than add Thompson's to their collection. It was the best at the meeting of the Royal Horticultural Society on the 12th inst., although Doyenné du Comice was pitted against it. I was pleased to see Thompson's take so high a position at the meeting alluded to, as it shows that this Pear, though old, is worthy of first place in any collection for quality alone. This is a point worth more consideration in judging, as huge Pears often only fit for cooking receive favourable notice. In fruit

catalogues Thompson's is recommended as a good kind for standards. I cannot advise it as it has never done well with me. I admit it grows freely, but the trees do much better in a sheltered position; indeed, it is well worth a wall or grown as a bush or pyramid in a sheltered garden. My best trees are those on the Pear stock or double-grafted, the fruit large, and the flesh melting. It may be classed as a fair cropper grown as advised. In my light soil the fruits mature very early, and cannot be kept. It cannot be called a handsome fruit, and I notice only five lots were staged at the Crystal Palace, Mr. Powell having the best dish. I noticed when I lived in Devonshire this variety did well in dwarf bush form. Of late years this Pear has not been seen so much at exhibitions, larger fruits often taking its place. I have had trees on various aspects, but the best flavoured fruit I always get from trees in bush form on a south border.—G. WYTHES.

**Apple White Nonpareil.**—This excellent late-keeping dessert Apple succeeds well when grown as a standard, and it is also a most constant cropper. I have a tree of this description which seldom misses bearing heavy crops of fruit. The tree is more than thirty years old, and it looks likely to continue bearing for many years to come. It also does well grown in bush form, but its habit of growth is rather against it being cultivated as a pyramid, as the branches have a tendency to spread rather than to grow upright. Of the three forms of tree mentioned, I think this Apple is more prolific when grown as a standard, and it may safely be planted as such without any fear as to the results. As regards its habit of growth, it partakes more of the character of Scarlet Nonpareil than of others of this useful class of Apple, the young shoots being slender and only of moderate growth. Like all the Nonpareils, the tree when established produces a profusion of flower-buds, so much so, that growth is then very slow. In shape the fruits resemble those of Scarlet Nonpareil, but instead of being red the skin is a pale straw colour, sometimes strewn with a few russet patches. It is, therefore, not so handsome, but it loses nothing when comparisons are made as far as flavour is concerned, as its greenish flesh is both crisp and juicy and richly-flavoured. It comes into use in January, and when kept in a cool and rather moist place to prevent the skin shrivelling, it may be had in excellent condition for quite three months.—A. W.

**Apples on iron soils.**—When lately in the lower part of Surrey, I was surprised to learn that Apple trees could not be induced to thrive in that district. That seemed odd, seeing that generally these fruits grow well in the county. It was stated that iron permeated the soil of the district very largely. On the other hand, most descriptions of trees seem to do well, there being a great wealth of fine timber, and it is usually held that where ordinary trees grow well Apple trees do well also. I suggested trying the plan I recently mentioned as adopted by Mr. Fyfe, on the ragstone at Lockinge, planting in mounds on the surface and gradually furnishing root space by means of decomposed vegetable matter and garden refuse. Very probably the surface soil of several inches depth is not so highly impregnated with iron as is the lower stratum. For that reason trees may do very well for a few years until the roots get into the iron stratum. It is a somewhat unusual case and may have its parallels elsewhere. If any reader of THE GARDEN has experienced similar difficulty, perhaps he will detail his procedure to overcome such a trouble. The locality in question is high, and in every other respect seems to be as fertile as the surroundings are beautiful. Of course in this case very little may have been done in a practical way to counteract the evil. At Lockinge, because of the presence of chalk so largely in the soil, the Pear trees there have leafage almost yellow, yet seem to be very healthy. So far no application seems to have been able to impart the ordinary green hue to the leafage. This is again another instance of the presence of something noxious in the soil.—A. D.

## FERNS.

## NEPHROLEPISES.

From a gardener's point of view, and on account of their habit and of their mode of growth, the Nephrolepises form a totally distinct group of plants. All the species known to the present

day, and with very few exceptions their varieties, have their fronds simply pinnate, that is to say, once only divided to the midrib, and their leaflets, instead of being fastened to it, are articulated at the base. This character, which is most conspicuously shown in dried specimens, is also very noticeable in living plants when it so happens that through want of sufficient moisture at the roots their leaflets drop off; but even when such is the case the plants, after a few weeks of attentive nursing, soon recover and produce another crop of fresh foliage, which usually takes the place of the fronds previously destroyed. The fronds, which in some kinds attain 4 feet in length, are in most, if not in all, cases produced from crowns disposed on long, thin, rapid-growing stolons or rhizomes of a wiry nature and of almost indefinite length. In some species the fronds themselves have the power of adding annually to their length. This peculiarity was first observed, or at least was first made known, by Mettericus, who, in his "Filices Horti Botanici Lipsiensis," published at Leipzig in 1856, states (p. 99) that there is no necessary limit to the apical development of the fronds in mature plants. In that interesting work on the subject he gives the result of his observations by saying that "the fronds are characterised by the perennial, indefinite growth of the rachis or leaf-stalk, and the consequent unlimited periodical production of the pinnae of the uninjured apex long after the older pinnae have fruited or fallen off. In *N. exaltata* the oldest fronds continue to develop at the apex, and the growth of the frond is limited only by some injury happening to the apex; the limit of the yearly increase of the frond being usually indicated by the smaller size of the pinnae." The production, just below the points where the fronds are inserted on the rhizome, of the slender stolons previously mentioned, is a feature peculiar to the plants contained in this genus, and by this means most of them are

rapidly increased, especially the reputed barren forms, such as *N. Duffii*, *davallioides furcans*, *multiceps* and *plumosa*, *rufescens*, *tripinnatifida*, and also the fertile but very variable *N. davallioides furcans*, the seedlings of which show their crested character in a more or less marked degree. On account of the naturally elegant drooping character of most species, these are par-

ing baskets and growing all around them, thus making perfect balls of gracefully pendulous foliage, which, provided the plants are supplied with water at the roots all the year round, remains a long time in excellent condition.

Most Nephrolepises are of an evergreen nature, *N. Bausei*, *pluma* and *undulata* be-

*Nephrolepis exaltata* as a basket plant.

particularly well adapted for basket culture as also for planting on rockwork, a position in which they soon form ornamental masses of a striking and very attractive nature. They also possess a singular propensity for taking possession of the outer surface of rockwork boulders or of hang-

the only kinds known to be entirely deciduous. These, as also several of the evergreen species, are provided at the end of their rhizomes with small tubers of a succulent nature which serve to reproduce the plants after a period of rest; but it frequently happens that

the only kinds known to be entirely deciduous. These, as also several of the evergreen species, are provided at the end of their rhizomes with small tubers of a succulent nature which serve to reproduce the plants after a period of rest; but it frequently happens that

For a want of knowledge these deciduous kinds should be kept so dry during their resting season, when they should start into growth again, these rains have ceased to live. The soil which contains them must, all through the winter, be in a moderately moist condition, so as to prevent them from shrivelling up and to secure healthy strong growth in the spring. Whether in pots, in baskets, or planted out, the soil used for them should be of an open nature composed of coarsely-broken peat, chopped sphagnum, and silver sand in about equal parts. Such a compost the roots and also the stolons will run freely, and the latter will soon produce young plants, which, if required, may safely be detached from the parent when they have produced three or four fronds.

Epiphytes may also be used with great advantage for covering walls and pillars, as they require but very little soil and can almost be kept thriving on moisture alone. In such positions many of them may also be found to protect themselves from spores, which germinate freely and make nice young plants in a remarkably short time. Although they have no objection to strong light, they succeed best when out of the action of the direct rays of the sun, and, notwithstanding the permanent want of moisture in which their roots require to be kept, it has been amply proved that they are better and that their foliage lasts much longer when the latter is not frequently watered over.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

OCTOBER 26.

It would appear as if the exhibitors on this occasion had determined to make the very best display possible, for no finer meeting has ever been held at the end of October. All the table space was occupied, and even the floor as well for groups, so much so, in fact, that it would have been a difficult matter to have found room for any more exhibits.

On every side there were objects of the greatest interest. Chrysanthemums were, of course, strikingly in evidence both in groups of plants and in cut flowers. The Japanese forms were present in far the greater quantity, and of these there were several decided novelties. If the present decision may be taken as any criterion of what will be produced at the coming November exhibition, the standard will be a remarkably high one indeed. The weather during the present month has without doubt had a most beneficial effect, in connection with good culture, in developing big class flowers. The plants on this occasion bore flowers of the best possible quality, colour, substance, and size combined. The same good results were also apparent in the cut blooms, which were again staged in nearly every instance with long stems and plenty of foliage, which is infinitely better than the old method, wherein no foliage whatever is to be seen, save upon an occasional flower in the front row. With small Ferns and other plants of convenient size the effect is very greatly enhanced. A grand group of *Ignonia Gloire de Lorraine* was again exhibited in its most marvellous condition and profusion of flower, coming from the same source as at the recent meeting. Roses, too, were staged in excellent condition, considering the lateness of the season. Of *Nerines* there was a most remarkable exhibit, several new and most uncommon varieties being staged, the setting up being very commendable indeed. A group of fine-foliaged plants likewise added to the interest of the meeting.

Orchids on this occasion made a most distinct advance both in quantity and effect. Cattleyas of

the labiata section were present in quantity, and *Vanda carulea* was well represented also. The style of setting up the several groups of Orchids is decidedly improving. Effect is not enhanced by overcrowding, but it is most certainly so by the addition of a few small Ferns, &c.

Fruit was shown in considerable quantity again, some first-class examples of both Apples and Pears being staged. Grapes were represented by one fine collection of autumn kinds in well-finished bunches. Vegetables were shown also, and exceedingly well, the selections being typical of the best varieties in each class.

The attendance was remarkable, and the keenest interest was evinced in the meeting.

Orchid Committee.

Awards of merit were adjudged to—

**CATLEYA HARDYANA MAGNIFICA.**—A lovely form, with delicate rose sepals and petals mottled with white, lip deep crimson-purple in front, shading to bright yellow in the opening of the throat. The side lobes are purple, shading to yellow, striped with brown at the base. From Mr. F. Hardy.

**C. BOWRINGIANA** (Pallant's var.).—A remarkable form, the sepals, petals, and lip being nearly twice the size of those of the typical form, the colour also being deeper. It carried a spike of twenty flowers. The growth of the plant was very distinct, and nearly 3 feet long. From Mr. R. Pallant, Weybridge.

**LÆLIA PRESTANS ALBENS.**—A distinct form, the sepals and petals white, slightly tinted with rose, lip white, with a band of purple running round the centre, and bright yellow in the throat. From Mr. F. Hardy.

**CYPRIPEDIUM HAYNALDO-CHAMBERLAINIANUM.** A distinct and pretty hybrid, raised from the species from which the name is derived, the dorsal sepal white, lined and suffused with rose, spotted with brown at the base. The petals have the characters of those of *C. Chamberlainianum*, green-spotted, and suffused with brown, the lip deep rose, shading to pale green at the base, margined with yellow at the opening of the pouch. From Mr. E. Ashworth.

**CATLEYA OLIVIA** (*C. Trianae* × *C. intermedia*).—A distinct and delicate form, with pale rose-tinted sepals and petals; lip pale rose in front shading to white, suffused with yellow at the base; the side lobes white, shaded with rose. From Messrs. J. Veitch and Sons.

**CATLEYA MELPOMENE** (*C. Mendeli* × *C. Forbesi*).—A pretty form with deep rose sepals and petals, the lip rose, heavily fringed at the margin, shading to yellow at the base, the side lobes rose, shading to white, and suffused with brown at the base. From Messrs. J. Veitch and Sons.

**ODONTOGLOSSUM CRISPUM SUNLIGHT.**—A lovely form with white sepals and petals, the sepals suffused with rose in the centre and heavily spotted with bright brown. The petals have numerous small spots of the same colour, the lip white, shading to yellow, and spotted with brown in the centre. A cut spike of eleven flowers came from Mr. R. B. White.

**LÆLIA PUMILA MAGNIFICA.**—A remarkable form with extra broad sepals and petals, deep rose in colour, the lip deep crimson-purple, shading to yellow in the throat. It has a prominent white blotch in the centre. The plant carried two flowers. From Messrs. W. L. Lewis and Co.

**LÆLIA PURPURATA** (var. *Mrs. R. I. Measures*).—A lovely form, the sepals white, slightly suffused with rose; the petals white, heavily veined and suffused with purple, the lip crimson-purple in front; the side lobes also deep purple shading to yellow, lined with purple at the base. The plant carried three racemes of flowers, two with three and one with four flowers each. It is one of the most distinct we have seen. From Mr. R. I. Measures, Cambridge Lodge.

A botanical certificate was awarded to *Lælia longipes*, a well-known species, with deep rose sepals and petals and bright yellow lip. From Messrs. W. L. Lewis and Co.

Messrs. J. Veitch and Sons sent a large and interesting group. In this were finely-flowered *Oncidium*s, *Dendrobium stratiotes*, and *D. taurinum* var. *amboinense*. Amongst the many forms of *Cypripedium*s were large made-up specimens of *C. insigne* in fine varieties, *C. Lecanum*, *C. Arthurianum*, and *C. T. B. Haywood*. Among the *Cattleyas* were good forms of *C. Mantini* (*C. Bowringiana* × *C. Dowiana*), *C. Wendlandiana* (*C. Warscewiczii* × *C. Bowringiana*) and *Lælio-Cattleya Tiresias* (*L. elegans* × *C. Bowringiana*), having very dark segments. A grand form of *L. C. Pallas*, good varieties of *L. C. Lady Rothschild* (*L. Perrini* × *C. Warscewiczii*) and *L. C. Decia* were also shown (silver-gilt medal). Messrs. H. Low and Co. sent a large group consisting principally of finely-flowered *Vanda carulea*, good forms of *Cypripedium Arthurianum*, *C. Lecanum* and the rare *C. Fascinator* (*C. Spicerianum magnificum* × *C. hirsutissimum*), in which the dorsal sepal is white, heavily suffused with rose, shading to green and spotted with brown at the base. The petals and other segments show the intermediate characters of the parents in a remarkable degree. Messrs. F. Sander and Co. sent a group consisting principally of finely-flowered *Cattleya labiata*, varying from deep rose to white in the sepals and petals, a good form of *C. aurea*, a fine plant of the lovely *Cypripedium insigne* *Sanderi*, and other mountain forms of *C. insigne*. *Miltonia vexillaria superba* and *Habenaria carnea* were also well represented. Messrs. B. S. Williams and Son sent a large group consisting of good forms of *Cattleya Bowringiana*, *C. labiata*, *Lælia Perrini*, *Dendrobium Phalenopsis*, *Vanda tricolor*, *Oncidium Phalenopsis*, and numerous *Cypripedium*s, both species and hybrids. Messrs. W. L. Lewis and Co., Southgate, sent several good forms of *Lælia pumila*.

Mr. R. I. Measures, Cambridge Lodge, Flodden Road, Camberwell, was awarded a silver Flora medal for a large group consisting principally of good forms of *Cattleya labiata*, the most distinct being a variety named *C. l. lilacina*, in which the flowers were wholly of a lilac colour. A large specimen plant of *Oncidium ornithorhynchum album* with seventeen spikes of flower, several of the spikes being upwards of 2 feet in length, was also noteworthy. Amongst the many *Cypripedium*s were *C. Allanianum superbum*, *C. Arthurianum*, and several forms of *C. insigne*, including a yellow form, *Vanda tricolor*, *Oncidium Marshallianum*, *Phalenopsis violacea*, and *Dendrobium aureum* were also well represented. Mr. P. C. Walker, Percy Lodge, Winchmore Hill, sent a nice group consisting of finely-flowered *Oncidium Forbesi*, *Cattleya labiata* in great variety, *C. Bowringiana*, *Dendrobium Phalenopsis*, good forms of *Odontoglossum crispum*, *O. madrense*, and a plant with two flowers of *Scuticaria Hadweni*. A silver Banksian medal was awarded. Mrs. Wingfield, Amphill House, Beds (Mr. Empson, gardener), sent a group of finely-flowered *Oncidium*s, numerous forms of *Cattleya labiata*, *C. aurea*, *C. Bowringiana*, very fine in colour, *Dendrobium formosum*, and *Cypripedium*s in variety. A silver Banksian medal was awarded. Mr. F. Hardy sent three fine forms of *Cattleya aurea* and *L. C. Tydea* (*C. Trianae* × *L. Dayana*). Mr. T. Statter sent the original plant of *Cattleya Hardyana* with three flowers on the spike, the most remarkable feature of the plant being the roots, which had extended through the bottom of the cylinder to the length of 4 feet. *C. aurea Johnsoni*, *C. Wendlandiana*, and a fine spike of *Dendrobium Phalenopsis Schroederi* were also sent. Mr. G. Law-Schofield sent *Lælia purpurata* var. *Annie Louise*, a form very much in the way of the variety *Mrs. R. I. Measures*. Mr. C. J. Ingram sent *Lælio-Cattleya Homère* (*L. Perrini* × *C. Percivaliana*), *L. C. Lady Rothschild*, *L. Diarmid* (*L. Perrini* × *C. elegans Turneri*), and a good form of *C. Bowringiana*. Mr. J. Bradshaw, Southgate, sent a choice collection of *Cattleya labiata*, which included *C. l. R. I. Measures*, *C. l. glauca*, with a slate coloured lip; *C. l. Etoma*, sepals and petals white with a crimson-purple lip; a dark form named *Ruby*, and

*Cypripedium parpuratum*. Mrs. Briggs, Bury Bank House, Accrington, sent two distinct forms of *Cattleya gigas*, *Cypripedium Arthurianum pulchellum* and *C. insigne* Ballie, a yellow form in the way of but inferior to *C. Ernesti*. Mr. Hockliff sent *Cattleya Hardyana*, a pretty form with delicate rose sepals and petals; and Mr. E. Ashworth sent *Cypripedium Arthurianum pulchellum*. Sir T. Lawrence sent a distinct form of *Lalia Perrini*, the sepals and petals white, the ground colour of the lip also white with a distinct band of rose on the front lobe. The plant carried three spikes of flower.

#### Floral Committee.

A first-class certificate was voted to:—

**MARATTIA BURKEL**.—A distinct species, and one, too, which promises to be a decided acquisition. In its parts it is much smaller than most kinds, the growth being compact and the much-divided fronds well clothed with quite small pinnae, thereby giving the plant a most effective appearance. From Messrs. Veitch and Sons, Chelsea.

Awards of merit were awarded to—

**CHRYSANTHEMUM MME. PHILIPPE RIVOIRE** (Japanese large flowered).—A distinct white variety with long drooping florets of unusual breadth. From Mr. J. Godfrey, Exmouth.

**CHRYSANTHEMUM ELLA CURTIS** (Japanese large flowered).—Of a pleasing shade of yellow, the florets drooping and of considerable length. From Mr. Godfrey.

**CHRYSANTHEMUM LADY RIDGEWAY** (Japanese incurved).—A variety with broad petals of a bronzy shade, the reverse much lighter. From Messrs. Cannell and Sons, Swanley.

**CHRYSANTHEMUM SIMPLICITY** (Japanese large flowered).—A pure white kind with gracefully drooping florets, an acquisition and quite distinct. From Messrs. Cannell and Sons.

**CHRYSANTHEMUM MODESTO** (Japanese reflexed).—A deep golden yellow, very full, of extra quality and substance. From Messrs. Cannell and Sons.

**CHRYSANTHEMUM LADY BYRON** (Japanese incurved).—Another white variety, but not remarkably pure. The petals are short and of considerable breadth. From Messrs. Cannell and Sons and Mr. Wells, Earlswood, Redhill.

**CHRYSANTHEMUM SUNSTONE** (Japanese large flowered).—A lovely variety, in colour a pale primrose-yellow, very full and of excellent form. From Mr. Wells.

**CHRYSANTHEMUM ROBERT POWELL** (Japanese large flowered).—A variety of pleasing shades of colour, golden bronze and yellow predominating. From Mr. Wells and Messrs. Cannell and Sons.

**CHRYSANTHEMUM N.C.S. JUBILEE** (Japanese incurved).—A ridiculous name, to say the least, to give to a flower. In colour this is a distinct shade of mauve, large and full. From Messrs. Cannell and Sons and Mr. Wells.

**CHRYSANTHEMUM LADY HANHAM** (Japanese large flowered).—A pleasing variety in which the prevailing tints are golden, with a suffusion of rosy shades. From Messrs. J. Veitch and Sons and Mr. Wells.

**CHRYSANTHEMUM G. F. WARREN** (Japanese large flowered).—A sport from Mme. Carnot of a pleasing shade of pale lemon-yellow. From Mr. W. Wells.

**GESNERA AMABILIS**.—A profuse flowering species, each plant bearing a dense head of bloom, the colour, a pale lemon-yellow, contrasting well with the dark bronzy-green leafage. (In "Dictionary of Gardening" this plant will be found under the name of *Negelia multiflora*). From the Duke of Sutherland, Trentham (gardener, Mr. P. Blair).

**NERINE LADY LAWRENCE**.—A charming variety, which under the light at the committee table appeared to be of a clear orange shade, but upon closer inspection a salmon tint prevailed. It is a very distinct colour in any case and a decided acquisition (as are all those kinds which follow). From Mr. Elwes, Colesborne, Andoversford, Gloucester.

**NERINE LADY MARY SHELLEY**.—A clear flesh colour, singularly handsome and distinct, the truss large. From Mr. Elwes.

**NERINE LADY BROMLEY**, in which the colour is carmine-rose, with a lilac-purple stripe up each segment, a most remarkable and unique variety. From Mr. Elwes.

**NERINE LADY LLEWELLYN**.—A dark carmine, suffused with cerise, the truss large and the segments broad. From Mr. Elwes.

**NERINE LADY MARY HICKS-BEACH**.—A vinous-crimson, rich in colour and the truss large. From Mr. Elwes.

**NERINE DONNINGTON**.—A pale blush, with a pale pink and a deep pink line up each segment, a charming mixture of soft colours. From Mr. Elwes.

**NERINE COUNTESS BATHURST**.—A pale blush-pink, with soft rosy lines, very distinct and handsome. From Mr. Elwes.

Numerous large groups of *Chrysanthemums* were staged, and collections of cut blooms were also very plentiful. Of the groups, perhaps the finest and largest came from Messrs. Veitch and Sons, Chelsea. It consisted of remarkably sturdy plants, with large, finely-developed flowers and rich clean foliage. The colours, too, were exceedingly well marked and bright, considering that the season is yet very young. The arrangement was in the orthodox style, semi-circular in form, and well calculated to display the blooms to the greatest advantage. Many popular and standard varieties were well represented, the following being among the best: Vivian Morel, well coloured and of good form; its lovely sport, Chas. Davis, which is almost without a rival among the bronze-yellows; William Fyfe, large and graceful blooms; Pride of Madford, a lovely combination of purple and mauve; Mutual Friend, a graceful white of excellent substance; and William Seward, the richest of dark reds. This excellent group was awarded a silver Banksian medal. A somewhat similar exhibit, and containing specimens of the pompon and incurved sections, was staged by Mr. W. Wells, Redhill, Surrey. The Japanese varieties were, however, the most striking. Three magnificent blooms of Thomas Wilkins, the fine and shapely dull yellow variety sent out by Mr. Owen three years ago, attracted considerable attention by reason of their size. Mrs. J. Lewis, one of the grandest whites, was equally well shown. Other notable things were Piedmont, a well-formed variety of a charming shade of pink, and raised by the King of Italy's gardener; Edith Tabor, a very bright clear yellow, with thick curled petals; Mrs. G. W. Palmer, a curious and very striking flower of great size, the colour shading from bronze to dull red, the centre petals being almost straight and the outer ones tightly curled. Lady Hanham, a very pleasing creamy flesh-tinted bloom, and Nellie Brown, an effective and free-blooming *Chrysanthemum*, bronze-yellow in colour, a sport from Rycroft Glory, were also shown (silver-gilt Banksian medal). A smaller group of *Chrysanthemums* in pots was shown by Mr. T. S. Ware, Tottenham. It was a pretty group, but the blooms were imperfectly developed (silver Banksian medal). A superb collection of cut *Chrysanthemum* flowers came from Mr. W. J. Godfrey, Exmouth, Devon, containing upwards of 150 huge Japanese blooms of remarkably even quality, and equally striking for their excellence of form and colour. A few of the best were Royal Standard, brilliant crimson; Simplicity, a graceful and very pure white; Mons. Delamotte, one of the brightest of golden yellows; Lady Ridgway, a very substantial bloom of a ruddy bronze hue; Maggie Shea, a pretty bright lemon-yellow, with the reverse of its petals of a lighter tint; Pride of Madford, Modesto, a dazzling yellow; Ethel Tabor and Ella Curtis. A pleasing and tastefully arranged collection of cut *Chrysanthemum* blooms came from Mr. Wythes, gardener to Earl Percy, Syon House, Brentford. The flowers were generally arranged in bunches of three, each variety separate, the groundwork being Maiden-hair

Fern. The following were among the best: M. Ch. Molin, Amos Perry, G. C. Schwab, Reine d'Angleterre, Etoile de Lyon, Edw. Molyneux, W. H. Fowler, and Stanstead Whit, all varieties of good standing and too well known to need detailed description (silver Banksian). Another good collection of cut *Chrysanthemum* came from Messrs. Cannell and Sons, Swanley. The best were William Seward, Lady Byron, particularly good form, M. C. Andre, well-coloured blooms of Mme. G. Bruant, Dorothy Seward, shapely and handsome bronze; charming flower of Chas. Davis, and exceptionally fine one of Robert Powell and Lady Hanham. From the same exhibitors came a collection of very delightful single *Chrysanthemums*, containing good examples of Mrs. Glyn, a pretty deep rose; Blanc Chapman, a large light pink, and Rose Pink, very beautiful sort. These single forms can be too highly recommended for decorative purposes. Nothing could be more graceful for vases, with their lasting properties are admirable (silver Banksian medal). Mr. W. Fyfe, gardener, Lord Wantage, Lockinge Park, exhibited a collection of seedling Sunflowers of good form a substance, admirably arranged in large bunch and making a fine show. An artistically arranged group of miscellaneous plants was staged by Messrs. Cutbush and Son, Highgate. The floral element was supplied by Begonia Gloire de Lorraine, Carnations and some very pretty Heat with a few Japanese *Chrysanthemums* (silver Banksian medal). Messrs. John Laing and Sons were represented by a group of decorative a fine-foliaged plants, with a few *Chrysanthemums*. *Dracena Goldianna*, a collection of richly-coloured *Bertolonias*, *Saxifraga sarmentosa* tricolor superba, and some brightly-coloured *Crocus* were notable (silver Flora medal). An exhibit of great beauty, consisting of Begonia Gloire de Lorraine and *Adiantums*, was staged by Mr. H. B. May, of Upper Edmonton. The Begonia were all superbly grown plants, bushy and symmetrical, the contrast between their bright blossoms and the vivid green of their foliage being delightful. The softening effect of the *Adiantums* was most pleasing (silver Flora medal).

Of exceptional merit was a collection of cut seedling *Nerines* from Mr. H. J. Elwes, Colesborne, Andoversford, Gloucestershire. Their range of colour was remarkably varied, and the tints were throughout of great brilliance and purity. The named varieties included five specimens: *N. amabilis*, *N. excellens*, *N. rosea crispata*, *N. dulata*, *N. Fothergilli*, *N. Novelty* and *N. flexa* (silver Flora medal). Messrs. J. Veitch and Sons had a collection of plants of their beautiful javanico-jasminiflorum hybrid *Rhododendron* and a box of small plants of Begonia Gloire de Lorraine; also a plant of Begonia Mrs. Heath garden hybrid of excellent habit, and bearing a large quantity of pleasing flowers. Messrs. W. Paul and Son, Watlington Cross, staged an extensive exhibit of cut Roses admirable for the season. Marie van Houtte, La France, Marquise Salisbury, Mrs. John Laing, Gloire de Dijon and Enchantress were among the best varieties shown (silver-gilt Banksian). Bushy and free-flowing plants of a lovely creamy white Gesnera were shown by Mr. Blair, gardener to the Duke of Sutherland, Trentham, Staffordshire. A silver Banksian medal went to Miss Emmet for some marvellously clever models of flowers. Orchids and Virginia Creeper leaves were among the specimens shown, and they could hardly be distinguished from natural examples.

#### Fruit Committee.

This was one of the best meetings of the year. Not only were the exhibits greater in number, but the quality was excellent. There were some very fine collections of hardy fruit and excellent vegetables.

Awards of merit were given to:—

**MELON EXCELSIOR**, a very handsome medium-sized fruit, skin golden, much netted, with scanty flesh of great depth and richly flavoured. It is a seedling between Beauty of Syon and Syon House

om Mr. G. Wythes, Syon House Gardens, Kentford.

**GRAPE MARCHIONESS OF DOWNSHIRE** a large white berry, not unlike Muscat of Alexandria in force, but when grown in a cool house the berries and bunch are much larger and of a duller tinge; skin thick, flesh sweet and refreshing. It is a seedling between Muscat of Alexandria and white Gros Colman. From Mr. Thos. Bradshaw, gardener to the Marquis of Downshire, Hillsborough Castle, co. Down, Ireland.

**TURNIP GOLDEN BALL**, a beautifully shaped Turnip, with very small tap-root, colour light golden. It is an excellent winter variety, the quality being first-rate. From Messrs. Dobbie and Co., Rothburgh, and Orpington, Kent.

**TURNIP WHITE MODEL**, a white variety of a beautiful shape. From Messrs. Dobbie.

One of the best collections of Grapes seen of late years at these meetings was that sent by Mr. C. A. Meyer, Forest Hill (gardener, Mr. W. Taylor). Thirteen varieties were staged, and most of them first-rate finish. Muscat of Alexandria and white Pincee were exceptionally good; Alicante was large and beautifully coloured; Lady Downe's, Gros Maroc, Gros Colman, Gros Guillaume and other kinds were also excellent, well meriting the ever-gilt Knightian medal awarded. Messrs. J. King & Sons, Forest Hill, S.E., staged 100 dishes Apples and Pears. Of the Apples, Sandringham, Alexander, Loddington, Peasgood's Nonsuch, Reinheim, Hollandbury and Lane's Prince Albert were good. We have seen larger Pears, but the quality was good. There were excellent Doyenné du Comice, Nouvelle Fulvie, Beurré Baltet père, and other Beurré and large stewing kinds, the whole collection being nicely arranged with small plants (ever-gilt Knightian medal). A collection equal in quality to the last-named, also 100 dishes, was sent from Messrs. Cheal and Sons, Crawley. The dishes were splendidly coloured. Mère de Ménage, Peasgood's Nonsuch, Bismarck, Alexander, Cox's Pomona, Lord Derby, Bess Pool, and Warner's King were noticeable for size. The best Pears were Duchesse d'Angoulême, General Tottleben, Nouvelle Fulvie, Hôu Moreceau, Pitmaston, Grandpère and Doyenné du Comice (silver-gilt Knightian medal). Messrs. Cannell and Sons sent a collection of vegetables, mostly onions. Most noticeable were The Reading, Red Glands, and the Scotch. Anglo-Spanish, Ailsa Craig, Wroxton Improved, and Cannell's Mammoth. Leeks, Autumn Giant Cauliflowers, Carrots, Beetroots, and Potatoes were also sent (silver Knightian medal). Messrs. Carter and Co., High Holborn, sent a collection in variety, both Turnip and long-topped. The Crimson Ball Turnip-rooted was excellent. A few of the others were a trifle large. There were also very fine Carrots (bronze Knightian medal). Messrs. Dobbie and Co., Rothburgh, N.B., had some splendid stocks of Turnips, very large Turnips, and Kales in variety. An Apple from Mr. G. Dyke, Stubton Hall Gardens, Newark-on-Trent, was asked to be sent to March to test its keeping properties. Mr. B. Wright, Lyndon, Oakham, sent an Apple, a seedling from Wellington. These the committee reserved for a later meeting. Mr. Ross, Newbury, sent a Pear named Popham. The Pear was good, but at this season we have many Pears of equal merit. A seedling Apple, recommended as a market fruit, came from Mr. Beale, Shoreham, but it lacked quality. From Messrs. Gareia and Co., Covent Garden, W.C., came three cases of fruit, mostly Pears, from California; the fruits were in excellent condition and of large size. The flavour of Doyenné du Comice, Beurré Clairgeau, Winter Nelis and others was first-rate; one or two varieties were not ripe. Mr. Cook, Forde Abbey Gardens, Chard, sent Golden Drop and Late Red Plums, also a dish of Tomatoes. Messrs. Barr, King Street, Covent Garden, sent the Persian Melon. Mr. Outram, Oakham, sent a fine dish of Medlars, and Mr. Hart, Audley End Gardens, Saffron Walden, exhibited Potato Diamond Jubilee. This has been tried at Chiswick, and was an excellent cropper. It was decided to test its cooking properties.

The Veitch prizes for flavour brought forth seven dishes of Apples and eight of Pears, the premier award for Pears going to Mr. Powell, Hsington Gardens, Dorchester, for a grand dish of Doyenné du Comice—Emile d'Heyst, from Mr. Woodward, Barham Court, Maidstone, being a good second. Marie Louise and Beurré Superfin were likewise staged. For Apples, Mr. Herrin was first with Cox's Orange, nice fruits and just ripe, Mr. Woodward being second with American Mother. Other kinds shown were Ribston and King of the Pippins.

**Victoria Medals of Honour.**—The Victoria Medals of Honour granted by the Royal Horticultural Society in honour of the Queen's Jubilee reign were distributed by Sir Trevor Lawrence the afternoon of the meeting. Previous to the distribution the recipients of the honour (whose names will be found in our issue of July 10, p. 32) as well as some friends were entertained at luncheon in the Windsor Hotel, Victoria Street, Westminster, Sir Trevor Lawrence in the chair.

## NOTES OF THE WEEK.

**Rose La France** is still very fine in some gardens, a fact amply illustrated at the Drill Hall this week, when Messrs. W. Paul and Son, Waltham Cross, brought a lovely gathering of its handsome blossoms.

**Helianthus orgyalis.**—The tall slender plums of this fine perennial are among the most graceful things in the border at the present moment, and on the grass, where plants have stood for years, it is distinct and beautiful.

**Chrysanthemum Crimson Queen.**—We have in this fine variety a medium or perhaps small Japanese kind with flowers of a dark crimson hue and very freely produced. It is a gem in its way, being bushy and scarcely 2 feet high.

**Violet Princess of Wales** is undoubtedly a very fine acquisition to this family, the flowers being of the largest size, rich in colour, and delightfully fragrant. The ample leafage and long stems that obtain in this variety render it all the more valuable.

**Helenium nudiflorum** is still flowering with some freedom. The warm tone of colouring in this plant and the free-branching character generally are of especial value in the garden, while its long-continued season of flowering cannot well be over-estimated.

**Nerine flexuosa excellens.**—A very striking and beautiful variety, with heads of blossoms of a bright rosy-pink shade and a dark carmine rib in the middle of the reflexing segments. It is rather dwarf when compared with some kinds, and noteworthy for its free-flowering.

**A note from Dublin.**—Autumn tints are lovely just now. Acer colchicum, A. japonicum, Quercus coccinea, Liquidambar, Euonymus europæus and Berberis Thunbergii are amongst the most attractive at present. Vitis Coignetiae is lovely.—F. W. Moore, Glasnevin.

**Chrysanthemum Modesto.**—For richness of colouring, as well as for its size and fine petal, this handsome kind is, perhaps, unique. Many kinds have flowers of a deep yellow shade, but in the intense rich gold and glistening petals there is a richness of tone that is very rare.

**Rose Enchantress.**—This valuable and ever-flowering Rose was shown at the Drill Hall on Tuesday last by Messrs. W. Paul and Son. Judging by the delicate and lovely shade of the blossoms and the number of prominent buds, it is an ideal Rose for decoration or for cutting.

**Carnation Mme. d'Albertina.**—While possessing a fine constitution and the shade that is usually so eagerly sought after among winter Carnations, this kind appears to be wanting in general beauty and refinement. The pink shade, moreover, is somewhat cloudy in tone.

**Arnebia echioides.**—This interesting rock plant is still producing its spikes of yellow dark-spotted flowers; and in some large clumps noted quite recently this is the third crop of flower-spikes this year, the first appearing quite early in spring, and the last in the closing days of October.

**Nerine crispa.**—Among a large number of beautiful and showy forms this frail kind is interest-

ing and pretty where several bulbs are grown in one pot. Less showy it may be than most, yet it is not without its attractive side when the more highly-coloured varieties are not so much in evidence.

**Chrysanthemum Amos Perry.**—At the Royal Horticultural Society's meeting on Tuesday last Mr. Geo. Wythes, Syon House Gardens, set up a splendid lot of well-grown flowers of the above. It is a fine yellow flower, occupying a very conspicuous place by reason of the richness of the blossoms.

**Chrysanthemum Nellie Brown.**—This is said to be a sport from the well-known Ryecroft Glory, and the flowers, which are of a bronze shade, are very effective. On Tuesday last Mr. Wells exhibited its blooms cut from the open. It is of a pleasing shade, each blossom about 3 inches across.

**Phyllocactus anguliger.**—A very distinct Mexican species with satiny-white flowers and yellowish sepals that expand in the daytime, when the blossoms emit a powerful fragrance. The deeply-angled stems are very distinct, as are also the blunt triangular divisions that form the lobes. This species is now in flower at Kew.

**Chrysanthemum Queen of the Earlies.**—A variety of considerable promise among October-flowering Chrysanthemums, though scarcely early enough in an ordinary season. Quite recently at Long Ditton, however, it was doing well in the open ground, and at the Drill Hall this week it was also shown well. The colour is creamy white, with pale green centre.

**Delphinium in autumn.**—While we have many shades of blue and lilac in the perennial Aester family, the late spikes of these showy plants are still welcome now flowers are scarce in the open borders. These late spikes being but the product of a second flowering are of course smaller, but where the large clumps flowered in June a fair percentage has been producing good spikes for some weeks, and still a few remain.

**Heterocentron roseum.**—A pretty free-flowering sub-shrubby plant, well suited for the greenhouse when well grown in pots. The pretty rose-coloured blossoms are produced in considerable numbers in large terminal panicles, that keep up a succession of flowers for a long time. In the greenhouse in autumn and winter it is very attractive. Equally so are older bushes when planted in the open ground for summer flowering.

**Lithospermum tinctorium.**—This rare, and in some gardens fastidious, species was beautifully in flower a day or two since at Winchmore Hill, the intense blue flowers attracting immediate attention. The plant is growing here with more than ordinary vigour, a fact we are pleased to note, while the prolonged flowering of this lovely species will assuredly arouse interest among the lovers of hardy plants. We never before remember this species flowering so long and so profusely.

**Rose Souvenir de la Malmaison.**—Some old bushes of this grand autumn favourite are providing splendid blossoms, and during the past few weeks it has been one of the gayest of Roses in the garden. Large, full, and handsome, as well as free-flowering and beautiful in its shade of colour, it is little wonder so fine a variety is so generally appreciated. It is certainly not a good summer Rose, but few Roses can compare with this one so late in the year when the majority are past and gone.

**Ixora macrothyrsa.**—This is, perhaps, one of the most stately and vivid of this lovely genus of stove flowering shrubs. Some large examples that are now flowering in the Victoria house at Kew display the fine heads to advantage. The plants are naturally grown, and as a result produce immense heads of the richly-coloured blossoms. The flowers are brilliant reddish scarlet, verging to crimson in the oldest flowers. The foliage, too, is abundant and of large size, and, all in all, it is one of the most valuable of the Ixoras.

**Hardy Crinum.**—Mr. Moore, of the Royal Botanic Gardens, Glasnevin, writing to us regarding the Crinum that he finds hardy, says: "I have tried a great many Crinums with varying results, but in the end those that flower well each year reduce themselves to C. capense, C. e. album, C. Powellii, C. P. album, C. Moorei, C. M. album,

C. scabrum, C. amabile, C. lineare, C. pratense, and C. yennense. With these you have a first-rate selection. The last three I am delighted with. C. pratense was especially fine; flowers pure white, very numerous, and with great substance."

**Flowers from Weybridge.**—I bring you up a few late flowers, half a dozen of Marliac's Water Lilies, some Primroses and Gentians. These have flowered well with me owing to the absence of hard frosts. The Liquidambar has coloured so well this season, that I think it worth bringing you a few sprigs.—GEORGE F. WILSON.

\*.\* A rich gathering of these beautiful flowers, the shades of colour in the Primroses being very varied and bright. The Liquidambar leaves were exceedingly rich in colour, and a large specimen with the sun shining full on the leaves is a beautiful object in the landscape now that the flowering plants are on the wane. The autumn tints this year seem to be very bright.—Ed.

**Hybrid Nerines.**—From Andoversford Mr. Elwes brought a remarkable series of these plants to the Royal Horticultural Society this week, when seven out of eight varieties sent up for certificate received this distinction. Brilliance of colour in the self kinds was remarkable, particularly the clear salmony orange of Lady Lawrence and the intense carmine-scarlet hue of Lady Llewellyn. Other noteworthy kinds are Lady Dorrington (pale pink and white segments somewhat widely separated, and with rich carmine rib), and Lady Mary Shelley (delicate pink, tips of the sepals recurving). Countess of Bathurst is white flushed pink, and having a line of deep pink 1 inch long from the base of the segments. Lady Lucy Hicks-Beach, a crimson-scarlet, is very compact, and Lady Bromley a curious mixture of carmine and purple.

**Begonia gracilis Martiana.**—This very distinct variety is very useful for autumn flowering. I lately saw some nice plants of it in the Oxford Botanic Gardens, and most effective they were among other flowering plants in the conservatory. The plants were in 6-inch pots, and had several erect-growing shoots about 18 inches high, covered with bright rosy-pink flowers. This variety may be propagated from the small bulbils which are formed in the axils of the leaves. These may be kept in a cool, dry place and started early in January, treating them in the same way as seeds. They may be grown in a moderate stove temperature, and should be fully exposed to the light. During the summer they may be grown in the cool conservatory, and with good treatment will keep up a bright display for a long time. Young plants will be more effective if several are grown together in the same pot or pan. A good rich loamy compost should be used for potting, and after the plants begin to flower liquid or artificial manure may be used freely.—A. H.

**Begonia Gloire de Lorraine.**—This was introduced about eight years ago, and a first-class certificate was awarded by the Royal Horticultural Society five years ago. Yet it was not until last autumn that it became generally known. It was raised by V. Lemoine, of Nancy, and is a hybrid between B. Martiana and B. Dregei. A remarkable feature of this variety is that it rarely produces seed vessels. Among some thousands of plants I have found only three perfect female flowers, and I am afraid these will prove abortive. The absence of these may account for its free flowering. I know of no other variety that will produce so much bloom and continue flowering so long. Grown in a temperature of 60° to 70° F. with good treatment, the same plants will continue to flower from now until February. It is of dwarf habit and the soft pale green foliage shows off the bright pink flowers to great advantage. Few flowering plants are more suitable for table decoration than this Begonia. It may be grown under the same treatment as other winter flowering varieties, but requires rather more warmth. The greatest difficulty is to procure good cuttings, the plants becoming exhausted by continual flowering. By care-

ful treatment, however, it is possible to get good cuttings about February; old plants will usually break back from the base, and the short jointed shoots must be taken before they begin to show flower. These will root freely if put into light sandy soil and placed in the stove propagating pit. The plants recently exhibited should fully prove its value as a plant for decoration, yet, I understand, on the Continent where it was raised growers have so far failed with it that it is now almost out of cultivation.—A.

**The weather in West Herts.**—A very warm period, in fact, what is termed a "St. Luke's Summer." On the warmest day, the 17th, the temperature in shade rose to 67°, which is the highest reading recorded here as late in October during the thirteen years over which my observations extend. The previous night also proved singularly warm; indeed, the nights, as a rule, have during the past week been even more unseasonably warm than the days. The temperature of the ground is at the present time about 2° higher than the October average at 2 feet deep, and about 3° higher at 1 foot deep. Rain has fallen on only one day as yet during the present month, but on seven nights. The total measurement, however, amounts to little more than half an inch. For the time of year the ground is remarkably dry: in fact, no measurable quantity of rain-water has come through the heavy soil percolation gauge for eight days. On the 18th, the sun shone brightly for altogether seven hours.—E. M., *Berkhamsted*, October 22.

—Another warm week, but not nearly so warm as the previous one. On the 26th the shade temperature rose to 61°, which is high for the time of year. Both at 1 foot and 2 feet deep the soil is now about a degree warmer than is seasonable. Rain fell during the early morning hours of the 26th, but to the depth of little more than a tenth of an inch. The ground is still very dry for October, no measurable quantity of rain-water having come through either percolation gauge for two days. The wind has been recently very light, the average rate of movement at 30 feet above the ground during the last nine days amounting only to about 3 miles an hour. The record of clear sunshine has been very variable, but taking the week as a whole the mean duration was rather more than three hours a day.—E. M., *Berkhamsted*.

## OBITUARY.

MR. E. J. BAILLIE.

WE regret to announce the death, at the age of forty six, of Mr. E. J. Baillie, F.L.S., at his residence, Woodbine, Upton, shortly after ten o'clock on Monday morning, Oct. 18. Though Mr. Baillie had been ailing for some time, his end has come with tragic suddenness. From a notice of his death in the *Cheshire Courier* we take the following: Deceased was educated at Tarvin, and on leaving school he spent a few years on his father's farm. Rather more than thirty years ago he entered the firm of Messrs. F. and A. Dickson and Sons, seed merchants and nurserymen, Eastgate Street, Chester. He commenced as a junior in the correspondence department, the charge of the department eventually falling to his care and supervision. He was next appointed cashier and confidential adviser of the firm, and afterwards became a partner, and subsequently managing partner of the business. When the two firms of Dicksons were amalgamated, Mr. Baillie became deputy chairman and a managing director of Dicksons Limited.

By Mr. Baillie's death Chester is much the poorer, and his labours on behalf of the Grosvenor Museum will not soon be forgotten. For some years he had acted as honorary secretary and treasurer of that institution.

Cut down in the prime of life and usefulness a blank has been created which it will be difficult to fill. Every work having for its object the raising of the intellectual and social condition of the people found in Mr. Baillie a warm supporter. The cause of temperance has long had in him a consistent advocate. He was Fellow of the Linnean Society, and published some years ago a flora of the district. He was awarded the Kingsley Memorial Medal, and was one of the prime movers in the formation of the Chester Paxton Society, and he initiated the Chester Guild of Arts and Crafts. The citizen have him very largely to thank for the excellent displays of pictures from time to time at the museum, and also for the exhibition opened some months ago by the Duke of Westminster. A Fellow of the Royal Horticultural Society, Mr. Baillie on several occasions lectured before this body, while articles on fruit culture frequently appeared from his pen in various publications, and he was an enthusiastic vegetable grower. Mr. Baillie was a clever artist, having a remarkable facility for transferring facts and striking bits of scenery to paper, which he was also a good shorthand writer. Articles from his pen on subjects connected with agriculture and horticulture often appeared in music he took a keen delight, and was a performer of no mean order. A willing and a liberal helper of every good cause, a true friend and a delightful companion, faithful to his friends, marked his walk and conversation, and won for him the affection and respect of all with whom he came into contact.

MR. ISAAC DAVIES.

WE regret to announce the death, at the age of 85, of Mr. Isaac Davies, which took place at the Brook Lane Nursery, Ormskirk, on the 10th in the morning. Up to within two months of his death he conducted his business in every detail. Mr. Davies raised many good Pelargoniums and Calceolarias, as also Azaleas and Rhododendrons, Rhododendron *præcox* being one of his earliest attainments. Azalea *Daviesi* and A. *Avalanche* were also raised by him. He also turned his attention to sweet-scented Rhododendrons, and gave us Countess Derby, Countess of Sefton, Lady Skelmersdale, Duchess of Sutherland, Miss Davies, and Miss Jas. Shawe. The hardy Rhododendrons were also taken in hand, and to this class many fine varieties were added. He has no doubt left the world richer by his enterprise, and has contributed in no small degree to the pleasure of those who take an interest in their gardens.

The business, which was first started at Wavertree, near Liverpool, and removed to Ormskirk thirty-one years ago, now comes to an end, the stock having been disposed of at a sale by auction the end of September last.

## PUBLIC GARDENS.

**The Churchyard Bottom Wood, Highgate.**—At a recent meeting the Islington Vestry decided to subscribe £2000 towards the purchase of the Churchyard Bottom Wood, Highgate, provided that the balance of the purchase-money £23,000—is otherwise subscribed. It was decided to apply to the London County Council for a loan of the sum named being obtained on loan.

**Names of plants.**—*F. Tomlin.*—*Eriobotrya japonica* (the Loquat).—*Richard Butler.*—Not all uncommon.—*Arthur P. Nix.*—*Cestrum aurantiacum.*—*W. G.*—1, *Woodwardia radicans*; 2, *Asplenium viviparum*; 3, *Paulinia* sp.; 4, *Sedum* sp.; 5, *Sedum japonicum*; 6, *Tradescantia zebrina*; 6, *Solidago ambigua*; 8, *Veronica salicifolia.*—*Spring Hill.*—1, the colour you speak of is not unusual; 2, *Mitella cuneata*; 3, impossible to name from such a scrap.

## ORCHARD AND FRUIT GARDEN.

### SCARCE APPLES AT THE CRYSTAL PALACE SHOW.

BECAUSE a few classes did not fill well it must be taken for granted that the Apples are worthless kinds. I admit they may lack the popularity of some kinds for exhibition, but I think, in judging, more points may with advantage be given to quality. If we take that soft Apple Lord Suffield, a fairly popular show kind, it cannot be termed a good all-round variety, as in some places it soon spots and is useless for keeping. Golden Spire, which finds its favour as an exhibition fruit, is a better keeper, less tender, and a more regular cropper. I am aware Lord Suffield is a great favourite in my gardens, but in damp, heavy soil the tree is tender. It succeeds in light, warm soil, but Golden Spire is not fastidious as to soil, bears freely every year, and, though fit for use in September, keeps good till December. I have never known it to fail even in the worst of seasons. The dish of this variety shown by Mr. Woodward at the Palace show was very fine. One object to its shape. I do not think it so valuable as Lord Derby and many others. Another Apple I was surprised to see only one of which was Royal Jubilee. Why this excellent Apple is not more grown I cannot imagine. I noticed it was prominent in collections. It is a very distinct fruit, large, and of a clear lemon colour. It always crops. What makes it more valuable is its late flowering. Seaton House, another kitchen variety, was none too plentiful. It is a handsome fruit, late, and valuable for small gardens. This crops so well in bush form, that I was surprised to see it so poorly shown. I have seen grand crops of this variety in the southern parts of the country, and in a few places it is used for dessert, though, of course, late in the year. Another variety, Horstead's Pearmain, a very handsome Apple, was only shown by two exhibitors. It is an excellent

variety, and in the west of England was much valued for its regular cropping and good keeping. Spencer's Favourite, a pretty Apple of the Golden Noble type, was poorly shown as regards numbers. It is an Apple of great merit on account of its close growth and cropping so abundantly as an orchard tree. This is well suited for small gardens. Bramley's Seedling was only poorly staged as regards numbers, four competing. This excellent cooking Apple is a great favourite in the north on account of its vigorous growth, late keeping, size, and free bearing. I think Grenadier may with advantage be left out, as though an early and free bearer, this and Lord Grosvenor are so much alike that one of the two would suffice. I would like to see classes for Lady Henniker, an excellent Apple; Mrs. Barron, a fine variety for autumn use and a compact grower, and Waltham Abbey Seedling, a grand cropper on old trees. There are others which could be named as none too plentiful, but I will now briefly refer to the

### DESSERT KINDS.

First comes Allen's Everlasting. Of this only three dishes were staged. In the Thames valley I have seen grand crops of this variety, and I should regret seeing its place taken by other kinds. Such kinds as this which keep till May are of great value to the private grower. I admit it is not a showy fruit, but the Royal Horticultural Society will do well to include varieties which keep well. The quality of this is superior to that of many during the spring months, and it is a good cropper in most seasons. I notice this is not a good Russet year. Though Egremont Russet was only shown by two exhibitors from the Maidstone district, it is one of the best of its class, and I think anyone who objects to it will not do so if he compares its quality next December with that of other Russets. It usually bears freely. Mabbot's Pearmain appears to be scarce this year, but it is a handsome Apple and a great bearer in many parts of the country and of first quality. I was

surprised to see only two dishes staged. This is not a taking fruit, and unless its quality is known its appearance does not tell when placed alongside larger and more highly coloured fruits. Much the same remarks may be made concerning Mannington Pearmain in season with Mabbot's. This was more plentiful certainly, but with me it is less reliable. The quality is first-rate. Scarlet Nonpareil was fairly well shown. It is a most useful dessert variety. I am pleased to see these classes for late fruits recognised by the society, as though they may not make much show they have their value for dessert when softer and brighter-coloured fruits are past. A variety less shown than any was Williams' Favourite, an American variety, a handsome conical fruit of a rich red colour and a pleasant flavour. This is not so well known as it deserves, and doubtless will become a favourite. At the first show four years ago several kinds like those named above were not shown, but they have now come to the front and are largely staged.

G. WYTHES.

**Pear Comte de Lamy.**—This deliciously-flavoured, though small Pear has been in perfection during the past ten days, the fruits having been grown on upright cordon trees on the Quince stock. The fruits produced by such trees are perhaps a trifle smaller when compared with those gathered from bush trees, but in my opinion they are more highly flavoured. Pears of good quality being plentiful during October and November, two or three cordon trees of this variety would yield as many fruits as would be required for ordinary private consumption, or as many as could be consumed while in good condition. If wanted in bulk the best way would be to grow the trees either as bushes or standards, as it is a vigorous-growing, hardy, free-bearing variety.—A. W.

**Apple James Grieve.**—Those who are anxious to make a selection of the best dessert Apples would not be disappointed if they added this variety to their collection. "G. W." drew attention to it on page 316. I have recently seen it fruiting very freely in the north of

Scotland. The trees were small, but each was carrying a heavy crop of large clean fruit, and though there were many other varieties in the same plantation, none equalled this one for free cropping. I predict there is a good future for this Apple, but good as its qualities are I can hardly follow "G. W." in saying it resembles Cox's Orange Pippin either in appearance or flavour. I should say it is at its best during October, and fruit eaten direct from the trees was most refreshing.—RICHARD PARKER.

**Plum Reine Claude de Bavay.**—This excellent late Gage Plum deserves wall culture, when the fruits produced amply repay the grower for the extra trouble taken in the training by their extra large size. In addition to this, as they will hang late, they can then be the more easily protected from flies and wasps when grown against a wall. The skins should be slightly shrivelled before the fruits are gathered, when they are perfect sweetmeats and highly prized for dessert. It is also much valued for cooking and but little sugar is required. In colour the fruits resemble the ordinary Green Gage, but are much larger, while the tree is also a more vigorous grower. Regarding its cropping qualities, it is about on a par with the variety just quoted, and is a consistent bearer. On account of its being inclined to be a strong grower, a little root-lifting is necessary to induce fruitfulness, but once it commences to bear no further trouble need be apprehended.—A. W.

**Pear Beurre Baltet pere.**—This useful Pear is not grown so much as it deserves, as when grown in various positions it will give good fruits up to the end of the year. There are few Pears of better quality, the flesh being melting, juicy, and richly flavoured. I have this variety in bush form and as a cordon, and only in the latter form as fruiting trees. Anyone who does not know this variety and sees it growing would at first sight take it for a stewing Pear of the Bellissime d'Hiver type. Though a large fruit, it is a free bearer and its large turbinate fruits are handsome. They should be left as long on the trees as possible. On the Quince this Pear does not make a strong growth, and this is important in gardens limited in size. It produces fruiting spurs abundantly and promises to make a compact pyramid. This, with its free bearing and late keeping, should commend it to Pear growers. I find it does well on an east wall.—G. WYTHES.

#### OCTOBER WEATHER AND FRUIT TREES.

If a fine autumn has anything to do with the ripening of the wood on fruit trees, after the present one it should be thoroughly matured, as we have an exceptional one this season. Often these fine autumns are the forerunners of hard winters. Let us look back to 1879, which was the nearest approach to the present, that being the driest October on record, there having during that month fallen only .77 of an inch of rain. Most of us remember the winter of 1879-80 and the injury that was done to trees and shrubs. The year 1879 was wet throughout, for up to the end of October there had fallen 30.70 inches of rain, while during this year there have only fallen 24.04 inches, or a difference of more than 4½ inches. Never do I remember the colouring of the Pear leaves being so beautiful. It is not one variety alone that has assumed these glorious tints, but many of them, more especially those on south-east walls. The foliage of Napoleon is almost a vermilion-crimson, and that of Marie Louise and Duchesse de Mouchy is almost as bright. Plums on most walls have ripened well, the leaves being of a beautiful golden colour, while Cherries have assumed tints that I have never before seen, some of the leaves being almost scarlet. This no doubt is owing to there being no frost to check the flow of sap and the bright sunshine we have experienced during the greater part of the month. So far—and we have reached the 25th of October—there has only been .27 of an inch of rainfall, and were it not that we

had a very wet day at the end of September, there would not have been half an inch for the last six weeks. While there is time it will be well to make some provision in case severe weather should suddenly set in. There are many things that, though fairly hardy, would be all the better with a little protection. Those who contemplate planting ought to get the work done as soon as possible that the soil may settle round the roots. The ground should also be mulched to keep out the frost, and so assist the trees to resist the cold. Figs in the open are almost sure to suffer unless removed from the walls and covered, and the same applies to the more tender plants. H. C. P.

#### THE GRAPE ROOM.

As the time is near at hand when this most useful adjunct to gardens, where Grape growing is carried on to any extent, will be required, steps should at once be taken to put it in order. Washing of all woodwork and the lime-whiting of ceilings, when lath and plaster take the place of match-boarding, will be the first to claim attention. If by chance any repairs should be necessary, these must be done, but these, when possible, are best seen to during the summer months, particularly if bricks and mortar or new plaster have to be made use of, as the materials then have several months in which to dry. The cleaning and refilling of bottles should be done while the room is being cleaned, and after placing a few small pieces of charcoal in each, they may be placed in position in the racks. The outside of each bottle should be wiped perfectly dry before taking it into the room, and if filled nearly full of water, which will allow for a slight waste by evaporation, they will then be in readiness when the Grapes are cut and brought in later on to be bottled. When all this has been done, the room should be dried as thoroughly as possible by opening the windows or ventilators, as the case may be, also by drawing the valve, if heated by hot-water pipes, so that a current of warm, dry air may be continually passing through the building. It is essential that all moisture be dried out beforehand, for the Grapes keep badly in a damp, stagnant atmosphere, and if this is not done and fire-heat be used to counteract it after bottling the Grapes, there is a danger of going to the extreme by the employment of too much heat, which causes shrivelling of the berries. Once the bunches of Grapes with the portions of laterals attached are severed from the Vines and inserted in the bottles, they keep best when subjected to a cool, but dry atmosphere, or when the temperature does not fall below 45° nor rise higher than 50°. By this it will be seen that if all damp has been dispelled, and the building is in a thoroughly dry state when the Grapes are taken in, but little artificial warmth is required, and then in a general way only sufficient to keep the temperature from falling to too low a point when the mercury is at or below freezing point outdoors. Grapes, unlike Apples and Pears, do not throw off moisture, there is therefore no danger of the atmosphere becoming charged with it; consequently the room if in a dry condition at the outset will remain so with the aid of but little artificial warmth. Some gardeners fill up what little space remains in the necks of the bottles after the pieces of wood are inserted with plugs of cotton wool or dry Moss, acting under the assumption that this prevents evaporation and the escape of moisture. After a trial spread over several seasons, I found neither good nor harm result from the practice, and have discontinued it. In the cool, steady temperature mentioned above the water wastes but very slowly. For

the refilling of the bottles with water, nothing better can be used than a can with a long curved spout, such as is sold for filling petroleum lamps with. This holds about a quart of water, and the end of the spout being small, can be easily inserted in the neck of the bottle, and the necessary quantity of water run in without a drop being spilt on the floor or by having to withdraw the bunch. A fine bright day should if possible be selected for bottling, and it is best done in the forenoon when the outside air is comparatively dry. The bunches should be cut with as much wood attached as can safely be spared. A. W.

**Pear Beurre Bachelier.**—I was interested "J. C.'s" note upon this Pear on page 315. My friend had a large crop of this variety last year and gave me two to eat. One was very good and buttery, something like a Glou Morceau; but the other, which ripened a week or so later, was little better than a Turnip. I was so pleased with the first one that I ordered two trees of it, but a doubtful after eating the second fruit if it were wise to plant it. Can "J. C." explain this, has he experienced the same difference?—B. ADAM Birkdale, Southport.

**Apple King of the Pippins.**—This Apple is very variable, many seedling varieties being sent out from nurseries under the name of King of the Pippins. Not only do they vary in size and shape and colour, but also in flavour. Some are really useless, while the true kind is a pleasant though not richly flavoured Apple. It has cropped well in several gardens this year, and will be useful in this scarce season. Some very fine fruit of it I noted recently at Boxted Hall from espalier trees, under which system it thrives better than most kinds.—R.

**Pear Gansel's Bergamot.**—This Pear is very free bearer and of fair quality, the flavour being much liked by some. It is usually a little gritty, but the flesh has a buttery, rich taste and is very deep. In shape the fruits are short and much flattened, yellowish, rough brownish on the side nearest the sun. I recently noted a nice lot of fruit of this variety at Ickworth, where it does well and crops so freely that it is necessary to thin somewhat heavily in order to get good fruits. It seems to thrive under almost any description of training, and should be grafted on the Quince.—R.

**Pear Passe Colmar.**—In most places this Pear is of good quality, but the best fruit, as a rule, comes from a warm soil where the tree is grown on an east aspect. The fruits are of medium size, true Pear shape, green at first dotted with brown, changing afterwards to a deep lemon-yellow. Its season is from now onwards until the middle of December, and where there are trees on different aspects this succession may easily be kept up. The flesh is of a deep yellowish tint, very juicy and melting. On dwarf bushes or pyramids in the open it is a fine variety, bearing very freely, and the tree is very vigorous.

**Pear Van Mons Leon Leclerc.**—I have been in several places where complaints of the character of this fine Pear were common, and possibly it can hardly be recommended to anyone having a very heavy cold soil. But on medium soils if the roots are kept up and the branches properly thinned, it will usually be satisfactory. Where room can be found on a wall for it the fruit will be of very fine quality, large and handsome, while if judiciously managed, it will be abundantly produced. The flavour is quite distinct from that of any other Pear, and its handsome appearance is always noticed.—B. S.

**Apple Tower of Glamis.**—There are few more profitable Apples to grow than this when it is obtained true to name and well cultivated. Unfortunately, it is not always supplied true, and some nice young trees I met with recently

had been supplied from a well-known nursery we bearing a full crop of a large, flattish red Ale, quite different from Tower of Glamis, which at no time is very highly coloured. It is a local, angular-looking fruit, lightly streaked with red on a pale green skin, the flesh as white as snow, and of that firm, juicy texture that is met in September, and yet will keep well into the new year.—GROWER.

**Apple Cox's Orange.**—The crop of this fine dessert kind is very thin in most places this season, but this has had the effect of improving the size of the fruit. In several gardens recently visited I have been struck with the unusually fine colour and appearance of the fruit, and in my own case Cox's Orange was never better as regards size or quality. What a pity it is this fine Apple is so often seen on starved espalier-trained trees, every young wood being spurred back annually. The result is usually a few fruits on the end of the branches and in the centre a thicket of unfruitful wood. Free pyramids or bushes take up more room and are infinitely superior in every way.—GROWER.

THINNING FRUIT CROPS.

Many advantages to be derived from a judicious thinning of most kinds of hardy fruits, when they set too freely, ought to be more generally understood, for if this were so, and growers practised thinning in time, we should see fewer inferior samples on the market. It would seem that in some places most kinds of fruit were scarce this season, yet, owing to so many inferior samples prices have ranged rather low, unless those of superior quality. Black Currants at the time were fetching from 16s. to 20s. per bushel, but many Apples have been sold in this district at as low as 2s. the bushel. This was for small, badly-grown specimens, but for first-class samples as much as 12s. and 15s. have been paid. Now which would be best, may I ask, four bushels of small fruit at 2s., or one bushel of good fruit at 8s. or 10s.? All gardeners pay special attention to thinning Grapes and Peaches in the houses, while those crops outside are left to take their chance. Suppose, for example, all the bunches that showed themselves on a well-ripened Vine were allowed to remain, and none of the berries were removed, all the feeding and attention that could be given them would never produce fine Grapes. If this holds good with Grapes, why not with Apples, Pears, Plums, Peaches, and Nectarines? It is, however, more to the first that I wish to draw attention, because, if trees are allowed to be over-cropped one season they seldom produce a crop the next, as they are so exhausted as not to be able to make fruit buds, and if formed they do not become thoroughly developed, so that it is impossible for the flowers to produce any fruit. It may seem out of place to write about thinning fruit just now, but my object in doing so is to draw a comparison between the price obtained for good samples and those of inferior quality. We cannot expect, neither is it advisable, to have extra large fruit for general use, but an even average specimen is of far more value than a lot of small ones, unless it be for making cider. If we look over the dishes at shops, it is astonishing how few varieties are popular, and many of these are only grown for show, and by thinning the fruit, together with feeding, these are made to grow to an enormous size. Such fruit is not economical, as it will not keep for any length of time; therefore the practice of over-thinning and undue feeding is not to be recommended. What is required for general use are even, fair-sized samples, and such crops as do not weaken the trees. Most of my neighbours in this district are complaining of a scarcity of fruit; in fact, some of them

have quite a failure and are astonished to find that I have so much, but the explanation is not difficult, as my trees have been duly thinned of their crop each season, so that they are healthy and vigorous, having the flower-buds well developed, and at the time of flowering they are able to withstand the extra strain put upon them. We are apt to forget that at this period there are many things to contend with. If the weather be too wet the pollen seldom dries, while if dry and the flowers are deformed, the petals drop off before fertilisation has taken place, and when this is so the fruit never swells. Badly developed flowers, too, will not withstand the frost so well as those that are well formed; therefore, if there are only a few flowers, and these of the finest quality, there is far more prospect of having good fruit than when the trees are over-laden. Thinning, too, is seldom done early enough, as many are afraid to remove a portion of the crop, thinking that if more were to drop off it would be a short one, forgetting that though the number was less the bulk would be quite as great. I am no advocate of growing simply for exhibition, as such fruit is of but little value for any other purpose; but if trees are healthy and the crop evenly distributed over them far finer results would be obtained. Pears and Peaches on walls are usually thinned to advantage, then why not Apples and Plums? If this were more generally adopted I doubt if there would be a glut of fruit one season, and little or none the next, as the trees would be in a better condition to resist the inclement weather experienced in spring at the time they are in bloom. Fruit growing, if for profit, should be thoroughly understood before attempted, and the same applies when grown for private consumption, otherwise failures are sure to follow. Many gardeners not only fail to thin sufficiently, but neglect to do it in time, hence the reason the fruit is so small. Some varieties we know are more productive than others, and for this reason require to be attended to before the fruit has grown very large, otherwise much mischief will be done to the trees. H. C. P.

**Apple Ribston Pippin.**—In a season when good dessert Apples are none too plentiful, it is a welcome surprise to many to have a good lot of the old but valued Ribston Pippin. Some very fine fruit was staged at the recent Crystal Palace fruit show; indeed, in a few cases the fruit was equal in size to ordinary cooking Apples. With a revived interest in fruit culture the Ribston has had a full share of attention, and though formerly many only grew this variety in standard form, now by having it as a bush on the Paradise stock there is less canker, which ruined so many fine trees, and I notice the trees grown thus rarely fail to crop. This variety delights in a warm summer, and in good soils finishes a grand crop. My fruit from cordons near the soil this year is very fine, but it lacks the quality of that grown on bush trees.—G. W.

— In this season of scarcity of good Apples it is pleasant to find a really fine lot of such a good dessert kind as this, and this I did at Eekworth recently. Not only was there a heavy crop of fruit, but it was large and of excellent quality. The trees, too, on examination proved to be full of likely-looking fruit spurs, and therefore the promise for next season is good. Mr. Coster says that these trees were rather severely root-pruned some few years since, and doubtless this has something to do with their great fertility.—R.

**Strawberry Scarlet Queen.**—In the numerous answers of your correspondents I have only noticed one who mentions Scarlet Queen. It ripens after Royal Sovereign, and if I were limited to two va-

rieties, these two would be my selection. Scarlet Queen is of a good colour, fair size, very fruitful, sweet, and much superior to Royal Sovereign. My three-year-old plants carried heavy crops this year. The other varieties that have done well here are President and Marshal McMahon. Latest of All is delicious, but I get very few fruits from it. With the varieties named, grown in different aspects, I had a good supply of fruit for eight weeks this year and seven weeks last year. The soil is sandy, but good loam and rich manurial dressings, hot-bed and artificial, the latter applied in spring, have been added. The plants are watered, and about 2 feet below the surface what is called here "ream-water" is always found, so they do not dry up in summer. The runners are rooted in pots and planted out as early as possible.—B. ADY, Birkdale, Southport.

NOTES ON STRAWBERRIES.

We have to thank our readers all over the country for so kindly replying to the following questions, and we hope that the notes will prove valuable:—

*Will you kindly aid us in throwing some light on Strawberries of best quality for the use of private growers, as market growers have a different standard from that which applies to the private gardener, and favour those kinds that bear carriage, rather than those that are remarkable for flavour and quality? For those who use their own fruit we think that a different standard should be in use.*

1. *What kinds do you consider the best for flavour in your district, i.e., as grown in gardens, not taking into account those grown in the open field for market?*

2. *The best early and late kinds for the open air in your district?*

3. *Which of the newer sorts do you find most worthy of cultivation from a garden point of view?*

4. *The best time to plant so as to secure the best and most regular crops?*

— I grow on a south border for earliest sorts Black Prince and Laxton's Noble. The former is the better flavoured, but Noble is early and handsome, although soft for packing. It will be supplanted here by Royal Sovereign, which is almost or quite as early, and very fine, also better flavoured and firmer for packing. Black Prince is an enormous bearer but small. Sir Joseph Paxton is my best all-round Strawberry. I grow it in the open quarters for general crop and under a north wall for late supply; the fruit is large and handsome, firm, and well flavoured. Newton's Seedling is a fine cropper and fairly late, and good for preserving. I also grow a local sort—Colleton Pine—which is a strong grower, good cropper, fruit well flavoured, and firm. Sir Charles Napier with me is a great cropper, but acid. I have lately tried John Ruskin, Sensation, and La France, but they have not given me satisfaction when compared with other sorts. I plant out in July the plants that have been forced, into a piece of well-prepared ground, which ensures a good crop the following year. Other sorts for new beds which I do not force I layer into pots the same as those for forcing, and plant out in August.—JOHN GARLAND, Killerton, Exeter.

— Regarding flavour in Strawberries, I find that soil, situation, and seasons have a wonderful influence on varieties. One variety I grow, Marshal McMahon, which has usually been fairly sweet with me, has had a strong metallic flavour this year, so much so that it was quite unfit for dessert. For flavour, I consider Sir Harry, British Queen, President, and Royal Sovereign best, and Vicomtesse Héricart de Thury fairly good. Noble is the earliest variety, earlier than Royal Sove-

reign, and Latest of All and Jubilee the latest sorts. Jubilee, however, although a firm Strawberry, is of rather inferior flavour, except in sunny summers. To secure the best and most regular crops, I like to plant at the end of July, putting three in a clump, 3 inches apart, and 2 feet from centre of clump to centre of clump, with a space of 2½ feet between the rows. Under favourable conditions, such plants will yield a good crop the four following years, at the end of which time they may be destroyed.—J. RIDDELL, *Castle Howard*.

Referring to Strawberries, they were about our best crop this year, and had some of the early flowers not been injured by the frost, we should have had a fine crop. From the results of the last few seasons, I do not think it wise to grow very early Strawberries, as there is such great risk of the early flowers being spoilt by frost; better a little later, and safe. The best flowers of Royal Sovereign, Scarlet Queen, and Noble were spoilt, as they were advanced enough to get a touch of frost. In reference to late kinds, the last I tried were Latest of All and Frogmore Late Pine, but they have not proved satisfactory with me. A neighbouring gardener grows very fine fruit of Latest of All, which shows that the adaptability of certain kinds to different places (soils) is very apparent. After trying a lot of kinds, I have not yet found a better one than President for its good qualities, that is, bearing good crops of fine fruit and of fair flavour. Royal Sovereign is certainly a good variety of recent introduction. John Ruskin, where it will grow well, should prove a very useful kind, but it will require to be well established in good strong plants, as it is not such a strong grower as many sorts. The best time to plant is, no doubt, as soon as young, strong plants can be obtained. I find they do very well after early Potatoes, as the ground is in good condition, requiring little preparation. After the ground has been pointed over I place some old Mushroom manure along where the plants are to be, and this, when planting is done, gets worked in round the roots, which helps them greatly to get strong before winter, and the almost certainty of a good crop of fruit the succeeding year if frost keeps off when in bloom. There is nothing like planting a young lot every year about the first week in August, then a corresponding old lot can be dug down every winter. My batch for this year comprised President, Royal Sovereign, Sir Harry, and John Ruskin, and they were planted on August 6.—R. MCKELLAR, *Abney Hall, Cheddle*.

I find the best results are obtained by making a fresh plantation each season, on well prepared ground, as early in August as possible. I prefer young plants in 3-inch pots, which can easily be obtained by taking the best runners and layering as early as possible in the season. I am this season giving Royal Sovereign more space, as it grows very vigorously with me. On the other hand, such sorts as Gunton Park and Latest of All may be planted considerably closer together. I also find that by putting out strong, well-rooted plants about the second or third week in August, they will, if well cared for, carry a splendid crop of fruit the next season; it must also be noted that these young plants ripen their fruits in advance of the older plants, which is of considerable importance, and from results obtained I feel convinced that the finest fruits are produced by these yearling plants. A full and heavy crop is generally obtained the second season, after which I find the plants begin to show signs of exhaustion and are better destroyed. If kept and fruited the third season, the fruit is considerably smaller, consequently not so profitable. After a trial of a number of varieties, those that find most favour here are Royal Sovereign, Gunton Park, Leader, Monarch, President, and Latest of All. The last I consider a very valuable addition to the late varieties, it crops well, and is of excellent flavour. I shall grow more of it in future. I gathered the first dish of Strawberries in the open on June 14 (being ten days later than last year), off Royal Sovereign; the last being gathered off

Latest of All July 24, and this in spite of the heat and drought. A constant supply was maintained for upwards of six weeks. Of the new varieties of Strawberries here, Laxton's Monarch and Leader have produced the best fruits, they are both fine mid-season varieties coming in after Royal Sovereign. Of the two, I should give the preference to Leader, the fruits are very large, the flavour also is very good. For flavour, colour, and size combined, the palm must certainly be awarded to Gunton Park. This is a great favourite here, and from young plants very fine fruits are obtained.—JAMES HAWKE, *Osterley Park Gardens, Isleworth*.

The Strawberry crop suffered from the May frost, which destroyed the early blooms, otherwise there was every prospect of a good full crop, and then towards the finishing of the crop the hot, dry weather prevented the proper maturity of the fruit, which was, on the whole, under the average. The varieties most favoured here are Royal Sovereign, Sir Joseph Paxton, Auguste Boisselot, Keens' Seedling, and Vicomtesse Héricart de Thury, the last for preserving, the fruit coming out whole after being cooked. For forcing I like Stevens' Wonder, which has done well with me, also Royal Sovereign, Keens' Seedling, and Noble. Keens' Seedling is much appreciated for its flavour, although of late years there has been the cry for large fruit, and for this reason Noble was, and is still, tolerated, although lacking in flavour and firmness. Vicomtesse H. de Thury by many is considered too small. I am a strong advocate for yearly planting, making a new plantation every autumn, layering into small pots, and planting on well-prepared ground as early as possible in August; by so doing a good crop of first-class fruit is obtained the following year. I have of necessity planted in September and the following spring, but have never obtained such good results from the practice, and as far as this neighbourhood goes, early planting is recommended. I am no advocate for retaining the plantations after the third year, when much better results can be obtained from younger plants.—J. LEE, *Gopsall Hall, Warwick*.

The best kinds for flavour in this district are Vicomtesse Héricart de Thury, La Grosse Sucrée, and British Queen. The best for early use are John Ruskin, Vicomtesse Héricart de Thury, Noble, and La Grosse Sucrée; for late use, Elton Pine and British Queen. Of the newer sorts, Royal Sovereign is the best. The best time to plant is about the last week in August.—W. CHESTER, *Chatsworth*.

For flavour I must give preference to Royal Sovereign, Latest of All, and British Queen. The two former are the best I have tried. I have had perfect fruits of Royal Sovereign over 2 ozs. each. Keens' Seedling, closely followed by Royal Sovereign, British Queen, and Latest of All, which carry us well on to the latter end of July, I consider the best for open air in this district. The newer kinds I find do best here are Royal Sovereign and Latest of All, and what I have seen and heard of Veitch's Perfection I think it will make a grand midseason variety. Strong runners layered early in July into 3-inch pots may be severed from the plant and placed on ashes, and given plenty of room between each plant so that they do not become drawn. In about two weeks they will be fit to plant out in ground that has been trenched and liberally manured, taking care to well firm the soil round the plants. I have three large plantations, and do away with one each year and plant one; by so doing the plants are young and healthy.—H. W. BLAKE, *Clendon Park, Guildford*.

Noble is a wonderful cropper and as early as any here. In hot seasons it is acceptable for dessert, but in wet seasons it is only fit for jam. Royal Sovereign is only four or five days later; I have grown it two seasons, but the crops so far have not been heavy, hardly an average crop, and flavour not first-rate. Monarch, about a week later, is a very fine fruit, rather shy bearer so far, flavour fairly good. Leader is very large, of good flavour, but I will try it again before recommend-

ing it. President is by far the best Strawberry here, a good heavy cropper, of the finest flavour any season, and keeps a long while before decaying. Auguste Nicaise is a heavy cropper, and a fine flavour, but wants gathering the same as it ripens or it goes dead, and it does not stand hot, dry weather. It forces well as a second early. Sir Joseph Paxton is not a good cropper here, the soil perhaps is too rich, as it runs very much to leaf; flavour good, but the fruit is hard and not so nice as that of President. Latest of All I have only grown this year, but I think will be the best late, fruit large, of good flavour but rather woolly and hollow in centre. Grosse Sucrée should have been placed before President in the order of ripening. It is of very fine flavour, nearly equal to President, but is not a very heavy cropper. I always get the runners as early as possible, so as to plant by the week in July on land that was trenched the previous winter and cropped with early Peas. I do two years, then destroy the plants.—J. LANSDOWN, *Barkby Hall, Leicester*.

The best for flavour are Vicomtesse Héricart de Thury, President, Lord Suffield, Gunton Park and British Queen. The best early and those mentioned, with the addition of Royal Sovereign. The best new variety is undoubtedly Royal Sovereign. Monarch and Leader produce well, but it is yet too early to give a definite opinion. The best time to plant, I find, is early in August, on deeply cultivated ground, with runners taken from young plants layered into pots.—J. BLACKBURN, *Elmstead Grange, Chislehurst*.

Strawberries on the whole have yielded abundantly. Both early and mid-season varieties were good, but owing to the hot, dry weather later varieties were prevented from maturing their fruits. While dealing with Strawberries, there are several varieties which I would point out as being most suitable for private use only, and in this flavour is the first consideration; secondly, the prolongation of the season's fruiting. Both here and the surrounding district, Royal Sovereign can be equalled by any other variety of its season either when forced or grown in the open border. Vicomtesse H. de Thury and Scarlet Queen two excellent varieties, and either may be planted to come in quick succession to Royal Sovereign followed by a selection of very choice mid-season kinds, namely: Sir Charles Napier, Sir Joseph Paxton, President, Dr. Hogg, Gunton Park and British Queen, the richest-flavoured Strawberry yet introduced. It must have high culture, otherwise the results will prove most satisfactory. Waterloo, a very distinct, dark coloured variety is, I may say, one of the best most sought for late kinds. Laxton's Latest of All is a grand Strawberry, and no collection complete without it. This season I have tried several varieties of recent introduction, but from my knowledge of their quality so far, I fear they will not be appreciated by the private grower.—A. METCALFE, *The Gardens, Burghley House, Stamford*.

Of Strawberries I only grow seven varieties—Royal Sovereign, Vicomtesse Héricart de Thury, Sir Charles Napier, Sir Joseph Paxton, President, Waterloo, and Aromatic. I find the above varieties of fairly good flavour in an ordinary season. President is a favourite here and is the best of the lot for flavour. If planted too close the fruit is rather inclined to be of a light colour. Royal Sovereign is the best early, Noble, John Ruskin, and La Grosse Sucrée have been discarded. Waterloo on a north border is the latest, and very much esteemed here for dessert. Royal Sovereign is the only new variety that I have tried. I must say it is a capital cropper, carrying heavy crops of fine fruit. It does well outside. I always layer runners as early as possible, and plant out of pots when well rooted as soon after July 20 as possible, and usually a nice crop the first year. Vicomtesse H. de Thury is grown chiefly for jam, but when not allowed to stand over three years on the same ground it crops of a good size and a nice flavour.—F. W. BEEVEY, *The Gardens, Stoke Court, Slough*.

STOVE AND GREENHOUSE.

HELICONIAS.

OME of the Heliconias are very ornamental plants for the stove by reason of their lustrous foliage. They are nearly allied to the Ananas, and some of them bear a general resemblance to the dwarf-growing members of that genus. They are not much known, and are but rarely met with in gardens, by far the

and the entire plant is altogether more graceful than *H. aureo-striata*. *H. illustris* is in the way of *H. aureo-striata*, but the colouring is altogether different. In this the ground colour of the leaf is green, with the prominent mid-rib of a beautiful shade of deep pink, while the veins are also marked in a similar manner. The leaf-stalks, too, are bright pink. In the variety *H. illustris rubricaulis* (here illustrated) the leaf-stalks are of a bright vermilion-red, the leaf-blades rosy red, the venation being a combina-

tion of stagnant moisture, yet need plenty of water during the growing season. In the winter the soil should be kept moderately moist, but nothing more. They must be shaded from bright sunshine throughout the summer months, otherwise the leaves lose a good deal of their bright colouring. These plants are readily increased by division, and when it is intended to propagate them in this way, the early spring is a very suitable time for the purpose. In carrying this out, as much of the soil should be shaken off as is necessary for tracing the course of the suckers, which must be separated with a sharp knife, with as many roots as possible attached to each. They must then be potted into suitable sized pots, and if plunged into gentle bottom-heat in a close case till root action recommences, so much the better. Instead of shaking off the soil, there is less liability to injure the roots if it is removed by holding the ball of earth underneath a tap, provided the water is warm.

Mr. T. Ryan, Castlewellan Gardens, sends us the following note:—

The plant grows rapidly in a moist stove temperature, doing well in rich loamy soil. When growing freely plenty of water should be given. It requires to be shaded from bright sunshine and is propagated freely by division of the root-stalk. The illustration represents a specimen growing in a pot 12 inches in diameter in the Water Lily house in the Earl of Annesley's garden at Castlewellan. The plant is 5 feet in height and has over twenty leaves, each leaf being 9 inches across.

**Fuchsia triphylla.**—This is valuable for its distinct colour, and would doubtless, in the hands of a careful hybridiser, be turned to good account. But while possessing a very distinct and beautiful colour, a shade by no means common, the species is not usually seen in good condition in gardens. This may in some degree be due to the fact that in a wild state the plant is found in much warmer regions than most species, and for this reason is not likely to submit to the same treatment as the hardier species or their varieties. *F. triphylla* is found in the West Indies, and requires a warm greenhouse to grow it well. The flowers are glowing cinnabar red, and as grown by Mr. Latham, in the Birmingham Botanic Gardens, it constitutes a most showy and attractive plant.

**Carnation Winter Cheer.**—This old kind is still useful, and, where the old plants have been taken care of, will produce good blooms for some time to come. Possessing less of the tree character than most perpetual flowering Carnations this does not run away to growth as do many kinds, and thus even two-year-old plants are under 2 feet high when grown in pots the whole time. As a scarlet it is a more desirable plant than the old *A. Alegatiere*, which appears to have lost much of its early vigour as also its fine colour. This is so in certain districts near London, and, as a result, the larger growers are discarding it wholesale. During the past two years many flowers have become streaked with white, and, while receiving the same culture as formerly, diminished in size also. The variety seems to be nearly worn out.—J.

**Pelargonium Duke of Fife.**—This Pelargonium (which, by the way, is not the only variety bearing the above name), belongs to the semi-double zonal section, a class which, for cutting at least, is very popular, owing to the fact that the petals do not drop so readily as those of the single kinds. It has been grown for some time by Messrs. Hawkins and Bennett of Twickenham, so well known in connection with market Pelargoniums, but as cut blooms only were disposed of it was not cultivated elsewhere. It is, however, now to be sent out, and in order to show its freedom of flowering and the fine, bold trusses of blossoms borne on long, stout stems, numerous examples in bloom were shown both at

*Heliconia illustris rubricaulis* in the Water Lily house at Castlewellan. From a photograph by Lord Annesley.

most commonly cultivated being *Heliconia aureo-striata*, which was introduced about a dozen years ago. In this the leaves are of a deep green, the veins running from the mid-rib to the margin, marked out by yellow lines, thus forming when in good condition a really striking plant. A species, very distinct from the preceding, is *H. metallica*, which suggests a fine, bold, yet somewhat dwarf-growing form of *Can.* The leaves are of a bronzy-green tint edged with red. They are slightly drooping,

and the entire plant is altogether more graceful than *H. aureo-striata*. *H. illustris* is in the way of *H. aureo-striata*, but the colouring is altogether different. In this the ground colour of the leaf is green, with the prominent mid-rib of a beautiful shade of deep pink, while the veins are also marked in a similar manner. The leaf-stalks, too, are bright pink. In the variety *H. illustris rubricaulis* (here illustrated) the leaf-stalks are of a bright vermilion-red, the leaf-blades rosy red, the venation being a combina-

tion of crimson-lake, vermilion, rose and yellow evenly distributed. These Heliconias are by no means difficult to cultivate, succeeding best in a mixture of loam and well-decayed leaf-mould, with a liberal dash of sand. They dislike soil of too heavy a nature, and though the quality of loam varies a good deal, yet, generally speaking, equal parts of loam and leaf-mould will form a suitable compost. The pots should be well drained, for the plants, while

the Royal Horticultural Society's meeting and at the Aquarium on October 12. As a winter-flowering variety for providing cut blooms in quantity it promises to take high rank.—H. P.

**Nertera depressa.**—This is met with much less frequently than it was a few years since, but it is such a charming little plant that it is matter for surprise that it does not increase in popularity. It is of a dense cushion-like growth, and is fresh and cheerful at all seasons. Its beauty is considerably enhanced by its brightly-coloured little berries, which, nesting as they do on the green Moss-like cushion, have a wonderfully pretty effect. This *Nertera* is a very shallow-rooting subject, and may, therefore, be grown in pans if required, while for carpeting the surface of an indoor fernery it is extremely useful. Where needed for edging groups or for similar purposes, it may be grown in pots 4 inches or 5 inches in diameter, in which case it should be borne in mind that no great depth of soil is required; hence the pots should be given ample drainage. This *Nertera* is readily increased by division, which should, however, be carried out quite early in the spring, as there is then ample time for the plants to become established before the flowering season. The blossoms are greenish, and play no part in the embellishment of the plant. It succeeds well in loam and leaf-mould, with a fair sprinkling of sand and broken brick rubble. Do not pot too deeply. Ample overhead watering is very essential during the growing season. This *Nertera*, which is nearly hardy in this country, is a native of the southern part of South America, and it also occurs in New Zealand.—H. P.

#### CANNAS IN FLOWER.

APART from *Chrysanthemums*, one of the most attractive exhibits at the Aquarium on October 12 was a fine group of *Cannas* in flower sent by Mr. Cannell from Swanley. Such a collection well illustrated the great strides that have been made in this now popular class of plants within the last few years, and it also showed the diverse forms that are to be found amongst them. Particularly noticeable in the group were *Aurore*, salmon-red; *Aurea*, bright clear yellow; *Incendie*, orange-red, edged gold; *Progrès*, bright scarlet; *Doyen J. Liaband*, light yellow, with large red spots; *Paul Lorenz*, rich crimson flowers, dark foliage, one of the very best; *Duchess of York*, yellow, thickly spotted red, unsurpassed in its class; *Antoine Crozy*, rich crimson; *Alphonse Bouvier*, deep purplish crimson; *Martin Cabuzac*, vermilion; *Queen Charlotte*, bright red, with a broad margin of gold; *Italia*, scarlet and yellow; and a very beautiful variety bearing the inordinately long name of *Reichskanzler Fürst Hohenlohe*. The flower of this is large and well shaped, the colour uniform bright yellow, except the small segments in the centre, which are slightly marked red. This class of *Cannas* is valuable for so many purposes, and is now so generally grown that one scarcely regards them as of such recent introduction, for it was only in 1888 that the earliest forms received certificates from the Royal Horticultural Society. Since that time immense numbers have been propagated in this country, still larger quantities sent here from some of the continental nurserymen—notably from M. Crozy, with whom this section originated; while at least one dealer in Algiers disposes of large quantities, apparently grown in the open ground. Bermuda, too, has taken the variety *Mme. Crozy* in hand. Last spring several boxes of this *Canna* were sold in the London auction rooms, but they were cheaply disposed of. The raising of new varieties still continues, though not much carried out in this country. M. Crozy himself generally issues a few novelties each year, while the two large-growing forms (*Austria* and *Italia*), which have attracted so much attention within the last year or two, are of Italian origin. These two are, however, for general purposes scarcely so useful as the dwarfier forms known as *Crozy*

*Cannas*. All these are of very easy culture, and many of them will continue to flower for a long time. A proof of their varied season of blooming is shown in the fact that *Cannas* of this section always form a particularly bright feature at the Temple show in May, and now the same may be said of them at the Aquarium in October. Planted out in the summer, too, they are very beautiful, but there is one disadvantage in treating them in this way, for at the commencement of autumn they push up far more flower-spikes than at any other season, and the cold nights prevent the blooms from opening properly. When grown in pots a little heat can be given them during this trying period, and the results then are highly satisfactory. These *Cannas* are all liberal feeders, and should be potted in a compost consisting principally of good loam and well-decayed manure with a dash of sand. If they are obtained during the winter in the shape of dormant rhizomes they should be potted as soon as possible and placed in a greenhouse temperature, the soil being kept slightly moist. Just about the time that the young leaves are pushed up the roots are very active, when if required they may be put into larger pots, using the same compost as before. If the rhizomes are of sufficient vigour, many of the plants will soon flower, after which secondary shoots are pushed up, which in their turn produce spikes of blossoms. These *Gladiolus*-flowered *Cannas*, as they are sometimes called, are of little use for cutting, otherwise they would be more grown than they are now. There is a great deal of difference in the hardiness and vigour of the several varieties, and in a general way it will be found that those with yellow blossoms, dotted more or less with red, require more care than the scarlet or crimson-coloured varieties. During the winter the soil should be kept slightly moist, as if too dry the rhizomes, especially of the more delicate kinds, will suffer. H. P.

**Rust on Malmaison Carnations.**—Every late autumn I am much perplexed at the appearance of rust on my Malmaison Carnations. I have tried all ways and means to prevent its appearance and subsequent spreading, but all to no purpose. Uriah Pike and Miss Jolliffe grown side by side never take it. What seems the most singular thing is that it entirely disappears in early spring, and the plants get quite vigorous and healthy, though of course with loss of lower leaves. When layers were potted up in August scarcely a trace was visible. Now it spreads very rapidly, the layers being much worse than two-year-old plants. I notice a long spell of damp, sunless weather favours the rapid spread of the disease. The roots of all are in excellent condition. The plants are potted in the best yellow fibrous loam, grit, and half-inch bones. They were taken from the frames early in September to a dry, airy house with a minimum temperature of 50°, and have had nothing but clear water with the exception of weak soot water a few times. They have only been watered when quite dry. Any enlightenment as to the cause and prevention would, I am sure, be read with interest by many of the readers of THE GARDEN.—I. R.

**Zonal Pelargonium Adolphe Brisson.**—This *Pelargonium*, which received the award of three crosses at a meeting of the floral committee of the Royal Horticultural Society, held at Chiswick on October 4, is one of M. Lemoine's seedlings, and is a very distinct and beautiful variety. It shows traces of *Souvenir de Mirande*, which when first sent out attracted a good deal of attention owing to its distinct character. This proved to be the commencement of quite a new race of zonal *Pelargoniums*, and several varieties were in turn put into commerce by different nurserymen. One of the most richly coloured was *Mme. Jules Chrétien*, which soon became and is still popular, but the above-named variety, *Adolphe Brisson*, greatly surpasses it in this respect. It is of medium vigour and good habit, while it flowers profusely. The colour is extremely difficult to describe, but it is a kind of earmine-

scarlet, lit up with violet towards the centre while it has a light coloured eye. This variety was put into commerce by M. Lemoine in 1878. A second variety from the same raiser also received an equal award—viz., *Jules Lemaître*, which is very large, well-formed, crimson-scarlet flower. This was sent out a year before the preceding. There are certainly many very distinct zonal *Pelargoniums*, especially from the Continent, as there are double forms of this *Mme. Jules Chrétien* section as well as single, white spot flowers, perhaps more of a curiosity than anything else, but decidedly distinct, are among the latest novelties.—H. P.

#### CRINUM MOOREI.

ALTHOUGH such a handsome plant and so useful for conservatory decoration or cutting, this *Crinum* is not often seen in good condition. In nine cases out of ten where this is grown the plants have taken their own way, and are left lying about some odd corner while they should be making their growth. It is one of the very easiest plants to grow, and possibly this is why it is so often ill-treated. The bulbs are quite safe in any lished during the winter if house room cannot be spared for them, provided only frost is excluded. They may be kept quite dry until February or March, when they may be taken to a vinery or Peach house just starting. Thoroughly soak the soil once, then let it get fairly on the side again before watering. After this increase the supply as the leaves form; growth will be very rapid and the spikes appear the sides of the bulbs. Large old plants I have been in flower since June, and there are several flowers to open. If the plants are in least pot-bound, some artificial manure should be used as a top-dressing, as it is important, if proper habit of the plants is to show, that they not checked in any way. *C. Moorei* is a very strong-rooting plant, and the roots, if confined soon burst the strongest-made pots. For reason they should be repotted when they are well-filled their pots with roots, and when they get above a manageable size split them up and repot into smaller pots. The best time to do this is in spring, and the most suitable compost, rough, open one consisting of sandy loam, 1 part mould and manure. The foliage has a neat appearance when well grown. The leaves are not easily injured by sunlight, still, it is safer not to expose them to the full sun in summer. The plants are sometimes grown in a vinery until the flower-spikes are nearly fully grown, and then taken to the conservatory, where they miss the shade of the vines and become spotted. If they been grown in the full light right through no harm would have been done, as the leaves would have become firmer and harder in texture. They may remain in the conservatory as long as they are ornamental, but in most cases have come out to make room for *Chrysanthemum*. The lightest and sunniest position available should then be allowed until the leaves fall, when they may go again into their winter quarters. B.

**Celsia cretica.**—This plant is very pretty just now, the spikes of yellow blossoms making a capital subject for grouping in the greenhouse conservatory. It is best grown as a biennial, sowing the seed in a cool house or frame about midsummer and keeping the seedlings general on the move through the autumn. During the winter they may be kept just secure from frost in small pots, allowing them the lightest position available. Place them in their flowering pots in spring—early or late as they are required to bloom—and keep them growing freely in a cold frame until the flower-spikes show, when they may be taken to the conservatory.

**Christmas Roses in pots.**—It is now high time, if not already done, that these should be moved under glass, as growth having some time practically ceased harm will occur if they become repeatedly saturated by cold rains.

fectly cool house and a light position suit best. In such the useful white blooms will usually be ready for cutting in January. I have several times moved a few plants into a gentle pit, say 60°, in order to secure earlier flowers, and they force fairly well, but the plants do not do for the ordeal, those forced being considerably weaker in growth at the end of the following summer. Since the cultivation of Christmas trees in pots has become better understood many blooms are produced, equal both in size and value to wreath-making to the Eucharis, the plants being grown without one half the trouble. The large white Bath variety is still the best as regards size and whiteness.—J. CRAWFORD.

**American Carnations.**—On page 320 Mr. Vaguelin informs your readers that the American varieties of Carnations have saw-edged petals, which are papery and thin and have no substance. I quite agree with the remark in respect to the serrated edges, but the Americans prefer the serrated edges to be regular. I am afraid in water-blooming Carnations it is difficult to find, even among the English productions, any other than rough-edged blooms. I do not assert that there are none, but the majority have rough edges to the petals. I know of no American variety which has such fringed edges as Mrs. Gardner Muir, certificated by the Royal Horticultural Society some two years ago, thereby proving that the saw-edged petal is not fatal to its consideration. I must take exception to Mr. Vaguelin's assertion that the American Carnations lack substance. It is a strong point in their favour when properly grown, this and a long, strong stem being essential with the judges in that country. When we consider the great distance that many of the American-grown flowers travel, it will be conceded that substance is a matter that should not be overlooked.—W. J. GODFREY.

**NERINE FOTHERGILLI.**

These plants are more showy or beautiful than this year, the strong spikes, each with an umbel of brilliant scarlet flowers, being very freely produced when the plants are properly grown. Not the least of the merits of this fine species is its extreme hardiness, for specimens in flower will stand in draughty passages or conservatories without taking any harm. The culture of this Nerine is not difficult, yet in many places where it is attempted the plants are not satisfactory. It is important that the plants make a good growth after the flowers are past, a good position for them being a light sunny greenhouse or slightly heated frame. If old pot-bound specimens they should be assisted by a little manure water, this being materially to swell up the bulbs, thus causing the production of finer spikes of bloom. Newly-potted plants should not be too highly watered, for it is not a gross feeding plant by any means. The growths fully made up, the plants should be taken to a cool and rather dry house, placing them on a shelf not far from the roof lights. The foliage having fallen no water should be given, but the plants be kept quite cool and dry until the flower spikes appear when they may again be watered. It is too often the custom to stand the plants about under greenhouse stages after the flowers are past, the result of this treatment being weak, badly-ripened growths that never bloom properly because they never rest. Drip from the other plants upon the steps gets into the centre of the growths and rots them. They would be far better outside during the summer than in such positions, but the best of all places is a dry, light house or frame. The plants do not often require repotting unless it is for the sake of propagation. In this case they may be divided frequently and kept in the same pot for a couple of seasons only. But for producing a quantity of flower old pot-bound plants are best. The best compost for them is a rather light loam, if this can be procured, or, if not, the ordinary loam mixed with leaf mould, a little peat, and crushed charcoal. Good drainage is absolutely essential, and this should be kept in good

order by using a little rough peat or similar material before putting in the soil. Pot very firmly, and use pots of medium size, so that the roots soon get a good hold. They always seem more free flowering when the bulbs are crowding each other and growing out over the sides of the pots. Insects seldom trouble them if kept cool and with a good circulation of air all the year round. H. R.

**Gardenias.**—At page 267 "H. P." gives some most useful hints on the cultivation of Gardenias. He, however, deals with pot culture only, which, of course, in many gardens is the only method that can be followed. The best results that have come under my notice have been achieved under the planting-out system, heated pits being even better than small ordinary span-roofed or lean-to houses. In the former a uniform temperature can be maintained and a moist atmosphere, which Gardenias delight in when making new growth. Some time ago I saw a grand batch of plants at Ossington Hall, near Newark, these having been planted out in a bed of loam, peat, leaf-mould and sand when they had well filled a 4½-inch pot with roots. They made wonderful progress,

*Galanthus Icaria at Gravetye Manor. From an original drawing by H. G. Moon.*

growing into really dense bushes in one season, the foliage being of a dark green hue, and the flowers and buds when I saw them in October numerous. A little clarified soot water and weak liquid manure were given occasionally, and when making their growth the foliage was sometimes syringed, when the pit was closed, with water, into which a little of the latter had been poured, this aiding to keep insects off. In summer the heat was maintained by closing early and airing judiciously, the temperature during winter by fire-heat being kept as near 60° as possible.—J. C.

**SHORT NOTES.—STOVE & GREENHOUSE.**

**Salvia Bethelli** is a very pleasing and useful greenhouse plant, now well suited for effective groupings, where this is extensively adopted, by reason of the bushy character of the plants and their freedom of blooming.

**Zonal Pelargonium Hermione.**—This semi-double variety is a great advance both for summer and winter flowering. The blooms open well and are pure in colour. It is very free-flowering, whilst the habit is unusually dwarf.—H. S.

**FLOWER GARDEN.**

**SNOWDROPS IN SCOTLAND.**

The Snowdrop appeals to all. It brings with it the promise of spring, and on its appearance the flower lover rejoices. The Snowdrop is never more beautiful than when seen in snowy sheets in the meadows or woodland glades or scattered by the streamlet, but even in the more limited garden quarters it finds a welcome place. There, indeed, should be grown the choicer and rarer species and varieties which are as yet not plentiful enough to naturalise. Galanthus Elwesi is now cheap enough to plant in quantity, and is strikingly effective in great masses, but it is to *G. nivalis*, our common Snowdrop, that we have principally to look for giving these sheets of snow we delight to see in the park and woodland. The lover of the Snowdrop is not, however, content to limit himself to these well-known species. He seeks variety in form and in marking, and, besides, desires to prolong his season of pleasure by growing Snowdrops which come early into flower or bloom long after the others have lost their attractions. A good collection gives much to interest, and in a flowerless time helps to make the garden what it ought to be—a place into which one may go in any day of the year with the certainty of finding some gem to admire. In my garden these rarer species and many of Mr. Allen's choice seedlings are well represented, and a few notes of personal experience, supplemented by that of others, in the south-west of Scotland may appropriately accompany the engraving of one of the finest and most distinct of our newer Snowdrops.

The mild and moist climate of these almost sea-girt counties is not the most favourable for the welfare of the Galanthus. Moisture it does not object to, but when accompanied by a mild atmosphere, the dreaded Snowdrop fungus, once it gets a hold in the garden, spreads with great rapidity. To this pest I have to attribute the loss of a number of Snowdrops during the two last winters, which were both exceedingly mild. It has not as yet attacked the so-called autumn-flowering Snowdrops, but *G. Icaria*, a good sturdy grower in most places, has not been exempt, though some distance from parts of the garden where the fungus had previously made its appearance. One finds that the more elevated and airy the position, the less liable are the Snowdrops to the attacks of this disease, and that if it finds its way into a clump it is better to lift the affected roots and burn them with a little of the soil, well dusting the earth round about with sulphur.

**VARIETIES.**

There are too many Snowdrop names, and for practical garden purposes the autumn-flowering forms of *G. nivalis* may be said not to be recognisable under their names of coreyrensis, octobrensis, Regine Olga, &c. Collected roots of any of these do not flower together, and plants received as *G. coreyrensis* cannot be distinguished from those obtained as *G. octobrensis*. These varieties are mostly weak

growers, the best being *G. Elsee* and some received by way of Holland under the name of "species, probably *octobrensis*." It may be said that they are in this district not true autumn bloomers, the earliest generally coming into bloom in November. This year the first to appear above the soil is *G. Elsee*, which to-day (October 27) is only peeping through. This species—or rather variety—is a good doer here, and in this respect is a marked contrast to *G. Rachelæ*, a sister plant, which is a weak grower.

With the first days of the year we have a large number of Snowdrops either in flower or on the way. For all of these deep planting seems beneficial so far as producing stronger growth and larger flowers. *Galanthus Elwesi* in its several forms is among the first to come into bloom after the new year begins, coming occasionally, indeed, before it is entered upon. It is very variable, as may be expected in a species so widely distributed, and there are some charming forms to be found among the varieties of this Snowdrop. There is also a great difference in the blooming time, some varieties being a month or more after others. These varieties and selections from them would take up too much space to detail at the present time, but unsurpassed are *G. E. ochroscipilus* and *G. E. Cassaba*, although these vary much in themselves, the best being exceedingly fine. *G. E. unguiculatus* is a distinct variety, better in some seasons than in others, but valuable in most years by reason of its brave and sturdy-looking habit. Among the plants of *G. Cassaba* there will be found some which greatly surpass in beauty the much-praised *G. E. robustus*, which beside these best forms looks lumpy and ungraceful.

The really fine *G. plicatus* is very unsatisfactory from its habit of dying off without apparent cause and without showing any trace of the fungus. I have several hybrids here which are much more robust and have much finer flowers than the ordinary *plicatus*. *G. Imperati* from imported Italian bulbs appears difficult to establish, and no flowers I have yet had have nearly equalled those of its variety *Atkinsi*, a capital Snowdrop from every point of view, as is *G. Melvillei*. *G. latifolius* is not a satisfactory plant here. Frost injures its foliage, and it never recovers from the damage due to this, and eventually dwindles away. *G. Ikarie*, the subject of the woodcut, is much hardier, and from its superior flowers is more worthy of being grown, possessing, as it does, even more distinct leaves than those of *latifolius*. These long, bright, yet deep green arching leaves are very beautiful, and when grown in fairly good soil the flowers are also large and beautifully pure in colour. For most of the bulbs of this Snowdrop in my garden I was indebted to Mr. Edward Whittall, whose kindness has also given me an opportunity of growing several of the forms of *G. Elwesi*. The fungus, as already mentioned, has made me lose some of the Icarian Snowdrops. *G. caucasicus* does well in the rock garden here, but its principal merit is its broad, handsome leaves, the flowers being small in proportion. *G. Alleni* is a much finer plant in every way, but, like most of the strong-growing Snowdrops, it prefers a rather heavy soil. Among plants of *G. byzantinus*—a hybrid between *G. plicatus* and *G. Elwesi*—there is much variety, some being exceedingly poor, while a few are at least superior to *G. plicatus*. Garden hybrids of similar parentage are finer still, and a set of these gives many flowers of great beauty. From Mr. James Allen some of very superior excellence have come. On the light soil of my garden *G. Fosteri* thrives and in-

creases well. Our common Snowdrop has merits of its own which will make it hold its place in popular favour. Its many varieties are plants for the connoisseur, and not for the ordinary gardener. The so-called

#### YELLOW SNOWDROPS,

which have the markings and ovaries yellow instead of green, are really prettier than those who have not seen them would imagine. *G. lutescens*, which is the more delicate of the two known varieties, did very well for several years, but, to my disappointment, did not appear last season. The more robust *G. flavescens*, with brighter markings, is, however, in existence and receives many a look when in flower. *G. Sharlocki* is a peculiar little Snowdrop, whose long divided spathes and flowers, spotted with green outside, are always watched for on their appearing. It is a good grower, and superior in this respect to the delicately beautiful *G. poeciliformis*, whose inner segments are unmarked with the green streaks so familiar to those who examine the common Snowdrop. *G. virescens* does very well, and though dull-looking through the green which flushes its outer segments, grows strangely on one's liking. There are a good many of Mr. James Allen's seedlings here, and one might say much about these, as well as about selected plants from some wild Snowdrops, were it not that this note is already too long. I may be allowed, however, to remark that no attempt has been made to write of them from a botanist's, but from a gardener's point of view. To him—amateur or professional—the greater the interest taken in the "early herald of the infant year," the greater the pleasure he will derive from the study of its purity, its grace and its variety.

S. ARNOTT.

#### Carsethorn, by Dumfries, N.B.

**Fibrous-rooted Begonias.**—When looking at the splendid plants of *Begonia Gloire de Lorraine*, shown at the recent Drill Hall meeting by Mr. H. B. May, I could not help wishing that raisers and cross-breeders would endeavour to create just such a section for garden decoration. How beautiful were the heads of bloom, and how effective. For one bloom obtained from a big and very often an ungainly plant of the large-flowered tuberous section, now so much grown in the flower garden, these plants had twenty, though of course relatively small, but how much more pleasing. We have some charming things for summer work in the now varied *semperflorens* section of fibrous-rooted kinds, but the best of these are for decoration still far behind the beautiful heads of *Gloire de Lorraine*. The field thus opened for hybridisation should tempt experts to try and produce a new and, if possible, quite an effective strain for the flower garden. Certainly the large-flowered forms are already somewhat tiring their admirers.—A. D.

**Artistically-grown Carnations.**—In Mr. E. H. Woodall's note on "Border Carnations" (p. 258) allusion is made to the method of growing Carnations in such a manner that the plants may hang over a wall or bank and cover its surface with foliage and flower. The beauty of Carnations grown in such a way cannot be surpassed, and I can well imagine the appearance of the great breadths he refers to as growing in the stable-yard at Tarifa. I have often been delighted, when passing through some little Spanish town, at the sight of wrought-iron balconies of the quaint houses literally ablaze with Carnations, brilliant vermilion, bright rose, yellow, pink and white. Large plants are these, growing, for the most part, in deep boxes, from which the vigorous foliage threading the ironwork forms a mat of glaucous green, that spreads over a space of the balcony and droops below thickly starred with blossom. To the artistic eye the effect of these

freely-growing flower masses is charming, a possesses a grace of form that is lacking when plants are grown in flat beds.—S. W. F.

**Early planting of frame Violets.**—Mr. Crawford on page 280 draws attention to the necessity of planting Violets, in the frames a pits in which they are to flower through the winter, not later than the last week in September. All Violet growers should follow this wise advice for by so doing they will ensure their plants getting a good hold of the soil before the first frost, which checks root-action and entails putting on and closing of the lights. Some advocate delaying the planting till the middle or end of October, but even in the south-west such protraction is inadvisable, as a sharp frost at the end of October or beginning of November is not unheard-of occurrence in that most favoured region, while further north the likelihood of frost arriving before the plants are established is greater. I was looking lately at a 200-foot pit that was filled with well-grown Violet plants towards the end of September. The clumps were taken up well studded with buds, and, he rains falling immediately after their planting they were well settled into the soil and not flagged for an instant. By the commencement of October they were in bloom, and since the first of the month have produced about 1000 large bunches of fragrant blossoms.—S. W. F., Torquay.

**Herbaceous Lobelias.**—I am glad to find from his note (p. 299) that "R." finds these beautiful Lobelias hardy with him. Both the green-leaved variety, which, I believe, is the proper *cardinalis*, and those whose leaves hold more red in them and are smoother in texture, which belong to the *L. fulgens* strain, are hardy with me. Since their first planting in 1892 they have increased year by year, and although they have had not the slightest protection in the form of a mulch and are growing in damp ground close to water, have never suffered from the frost which in their low-lying situation has sent the mercury down to 11°. Three times the clumps have been divided during October, one occasion being in 1894, just prior to the prolonged frost of 1895, but not a plant succumbed. "A. D." on page 280 says that in cold or wet soils it is safer to lift the roots rather than let them remain *in situ* during the winter. It, of course, appears reasonable that the roots should winter more safely in a warm, dry soil than in a cold and damp one, but in practice I have found that just the opposite was the case. These Lobelias live through the winter after winter without a glance being bestowed upon them in this heavy loam; whereas, some years ago I was unable to keep them alive in light, dry soil and in a remarkably sheltered position, although I took every precaution to preserve them unharmed. The finest spikes are fully 4 feet in height, and lasting as they are through almost two months, a mass of these brilliant flowers is a most striking feature in the autumn garden.—S. W. F., Torquay.

**Winter treatment of Cannas.**—I have several dwarf Cannas in the garden in bloom. Should they be potted now, and can they be kept through the winter in a cool greenhouse? Any information as to their treatment will be acceptable.—E. O.

\*.\* The dwarf-flowering Cannas are less robust in constitution than the strong growing kinds, and in order to winter those successfully that are now in the open garden they should be taken up as soon as possible and potted at once, using for the purpose pots just large enough to get the roots into without injury. They may be wintered safely in a cool greenhouse, that is to say, a structure from which frost is excluded, but they should not be dried up by placing them too near the water pipes. The soil throughout the winter must be kept slightly moist, that is, just sufficient to prevent it becoming dust-dry, but nothing further. These dwarf Cannas would have been better if lifted and potted a week or two ago. Instead of using pots the roots may be safely stored during the winter in shallow

kes, a few holes being made in the bottom and a layer of broken crocks placed thereon for drainage. They must then be covered with soil exactly as in pots, and tho after treatment is just the same. The advantage of potting these Cannas instead of planting them in boxes is that in the spring they get into growth without any check, and when the danger from frost is over they can then be planted in the open garden; whereas if wintered in boxes they must be potted separately when growth recommences in the spring. As a partial offset, however, may be mentioned the fact that a number of roots in a box occupy less space during the winter than when they are all potted separately.—H. P.

ANDROSACE LANUGINOSA.

WHAT may be accomplished by doing things well is shown in THE GARDEN at page 257 by an illustration of the above plant. As a lover of alpine plants, the example appealed to me as quite unique in a British garden, and to my request for some further particulars concerning it, Mr. Milner has responded freely and fully. This lovely patch of one of the best alpine plants, it appears, is growing on a slightly elevated rockwork some 3 feet above the ground. The soil, which is about 2 feet deep, is made up of loam, leaf-mould, peat, yellow sand and half-inch limestone chippings freely mixed together. The aspect in which the plant is grown is full south. I have very carefully counted the trusses of bloom at the moment the picture was taken, and find at least 130. This was on the 29th of the present year. Writing on October 21st Mr. Milner kindly informs me the plant is "fairly well covered with its beautiful flowers now and began to flower in the end of May." Such information is of the greatest value. Too often the lovely species is seen with a dozen or so of flower-heads and a few extended and somewhat woody stems that do not bear evidence of much vigour. The unequalled success with this pretty species at Totley Hall is obviously due to the deep bed of prepared soil in which the plant is growing. This having ensued, the flowers come in profusion. But because an alpine is dwarf of stature or of low trailing habit or small proportions generally, the merest handful of soil is given at planting time; hence many of the most beautiful gems of the true alpine flora are but short-lived and poorly flowered in our gardens. The *Androsace* in question is by no means noteworthy as a great rooter or even so difficult to grow as some species; yet, with the illustration of its success at Totley Hall, none can gainsay the innumerable benefits that accrue from giving abundance of soil, and this of good quality, so that the roots may descend and find moisture in the heart of summer. In these deep-rooting mediums alpine plants never feel the heat and drought. At were a much larger number of choice alpine plants in a liberal depth of soil, we should see, as at Totley, lovely patches of colour, bearing a far greater profusion of blossoms than is frequently the case at present. E. J.

**Ornamental The Burn Pink.**—Referring to your note on above in your issue of 23rd ult. (p. 19), I beg to say, once for all, that the above name was never distributed as *Maggie Lawie* by the raiser or by any authorised person, and I am perfectly certain that it never was known by that name until after the raiser's death. If "*M.*" is a better authority on the subject than my gardener—a son of the raiser—let him give his name. At the same time I must say that *Duchess of Fife* is still more improper name for this variety, as it is raised about fifteen years before there existed a *Duchess of Fife* at all, and its advertisement as a new seedling under that name was very misleading. I therefore fully agree with "*M.*"'s protest.—CHAS. McINROY (Col.), *The Beech Edzell, N. B.*

**Tree Peonies.**—Among a number of Tree Peonies imported from Japan I flowered one

exactly like that depicted on the coloured plate in THE GARDEN October 23, and a charming variety it was, the contrast between the deep-coloured markings at the base of the petals and the rest of the flower being very pronounced. There was also from the same source a smaller flower of much the same colour, while the most admired of any was a huge semi-double bloom of an intense silvery whiteness, a variety which seems to crop up pretty frequently among these Japanese importations, for I seldom flower a few without one or more plants of this particular form making their appearance. A considerable number of Tree Peonies sent direct from Japan are to be met with during the winter months in the London auction rooms, and, as far as my experience of them extends, the selection of varieties is generally very good. It is only within the last few years that they have been sent in quantity. Previous to this I have seen them fetch comparatively high prices when sold by auction; thus I have a note of lots consisting of seven or eight plants realising as much as twenty-eight shillings in the early part of 1890. Now, however, they may at times be picked up much more cheaply. These Japanese Peonies are all grafted on to roots of the herbaceous section, which push up suckers continuously, so that constant attention is necessary, otherwise the graft will soon be completely choked. The thick, fleshy roots on which they are grafted no doubt enable them to withstand the journey better than they would on their own roots, which are less stout than the others. In potting or planting, however, especial care must be taken to prevent the scion being broken off, as the point of union is generally a weak spot.—H. P.

THE LEAF-BROWNING DISEASE.

In a previous article I directed the attention of the Horticultural Society of France to the leaf-browning disease and the parasite which is the real cause of it. I pointed out the *Pseudococcis Vitis* (Debray), one of the gelatinous or slimy fungi, as the source to which should be assigned those premature mortifications of leaf-tissues which were supposed to be the result of scorching from sunstroke, while the brown colour of these dead tissues, so disfiguring to ornamental plants, was actually produced by the ravages of the parasitic *Pseudococcis*. Since then I have made fresh observations, which appear to me to be sufficiently interesting to warrant my laying them before the society, and of which the particulars will be found in the following paragraphs:—

(1) **THE CURL, A DISEASE OF THE POTATO LEAF CONNECTED WITH THE LEAF-BROWNING DISEASE.**—In the course of my cultural experience I have discovered the explanation of an old disease of the Potato (the true cause of which was previously unknown) in the fact that it is the work of this same parasite. It may be remembered that I stated that some Potatoes which were more or less blackened by the *Pseudococcis* had produced in spring rather short shoots, the blackened and withered extremities of which contained plasmodia of this slimy fungus. I planted several of these tubers to see what they would come to. Five of them produced no stems, and I thought they had entirely decayed, but on taking them up, six weeks after they were planted, I found that the shoots, of which the ends only were dead, had produced some stolons on which small tubers were growing. Some Potatoes, however, with shoots attacked in the same manner, which had been kept in boxes had also produced some of these small tubers, but had no visible stolons. It is usual, I think, for all Potatoes which, from some cause or other, do not produce overground stems to act in this way, following the direction of their vital force manifesting itself in an off-hand production of tubers which grow at the expense of the other parts. Other tubers, however, the shoots of which were not so seriously attacked, did not fail to produce leafy stems, but in the case of a certain number of these the stems were

short and stunted and the leaves curled and marked with reddish or blackish spots. Others, again, had more vigorous and almost normal stems and pretty broad leaves, which, however, were mostly turning yellow or were similarly spotted. The produce of these tubers was almost nothing in some cases and very trifling or indifferent in others. For a long time this disease of the Potato, when it is only slightly developed, has been termed "*rouille*" or "*rust*," and when more fully developed it is known by the name of "*frisolee*" or "*curl*." It has been noted in France, Germany and England, in which last-named country it is called "*curl*." The description of its characteristics by old writers agrees in every respect with what I have stated about it. At the present day less attention is given to it because people are apt to confound it with the Potato disease, which is produced by *Phytophthora infestans*, and which it resembles in its effect of turning the leaves brown. In reality this "*curl*" disease is only one of the many forms of the leaf-browning disease. I think that, in order to escape this form of disease in kitchen gardens, the best way is to plant only sound Potato sets with an unbroken skin and without any brownish spots on either the skin or the shoots. Sprouted Potato sets have been recommended as the best for planting. This, in my opinion, is worthy of attention, as one can then, by examining the sprouts or shoots, ascertain whether or not the tuber has been attacked by the parasite. Another condition, however, will be necessary, namely, not to have in these kitchen gardens any fruit trees which usually harbour *Pseudococcis*, and of which the diseased leaves might infest the Potato crop. I may add that the Beetroot disease described by Payen in 1833 appears to me to have been also produced by this same parasite choking up the sap vessels of the root.

(2) **ORNAMENTAL PLANTS ATTACKED BY THE LEAF-BROWNING DISEASE.**—With M. Debray as my authority, I have already mentioned a certain number of garden plants which are more or less liable to be affected with this disease. I have myself observed some others suffering from it in various degrees, and these it may be serviceable to point out, as it must be remembered that the diseased leaves of these plants, strewn the soil as they fall, may be the means of spreading the infection of the parasite. The plants in question are *Hepatica triloba*, *Cynoglossum Omphalodes*, *Papaver bracteatum*, *Tradescantia virginica*, the Holly, Mahonia, Ivy, Begonia, Cannas, *Petunias*, *Epimedium alpinum*, *Helianthus*, *Aneuba japonica* (leaves and berries), *Tropaeolum majus* and *T. canariense*, the Lily of the Valley, *Stocks*, *Phytolacca decandra*, *Mirabilis longiflora*, *Echinochloa*, Spanish Sainfoin (*Onobrychis*), *Fuchsias*, *Anemone Pulsatilla*, *Salvia Sclarea* (stem or leaves), *Digitalis*, *Paony*, perennial *Lupin*, *Lycnis chalcidonica*, *Phloxes*, *Funkias*, *Asters*, *Cyclonia japonica*, *Deutzias*, *Astrantia major*, *Malope trifida*, *Montbretia*, and *Gladioli*. I have also noticed the parasite on the leaves of the Currant and some trees, such as the Oak, Beech, Hornbeam, Horse Chestnut, Sycamore, Elm, *Acer Negundo variegata*, and *Paulownia*, as well as on various kitchen garden plants, as the Artichoke, Cardoon, Sorrel, Melons (in frames), and Strawberries. Moreover, I have observed it on the seeds of Kidney Beans (various kinds), *Lupinus*, Broad Beans, and *Ricinus communis*. These spotted seeds often produced plants which were more or less affected with the disease. Lastly, the Vine, on which this leaf-browning disease was first noticed in the south of France, has not escaped its attacks in our own part of the country. I have noticed it in the discoloured leaves of Vines which, however, were only slightly attacked by it, and I cannot anticipate whether or not the disease may reappear this summer and with greater severity. Since the last sentence was written I have seen young bunches of Grapes which were suffering from the attacks of the *Pseudococcis*. In these, some of the berries were covered with small brownish specks, and the stalk was either similarly marked or else with

short brownish lines. I intend to watch the further action of the parasite on these bunches. In general, this parasite appears to act in such a restricted manner as not to completely destroy the growth of the plant which it attacks. On certain plants it is often seen only on the lower leaves which are in contact with the soil, the moisture of which may have rendered them more susceptible of being infected with the disease. It also depends on the fact that the ascending movement of the parasite is very slow either on the stems or on the leaves, and that it requires favourable conditions before it can keep pace with the growth of the plant on which it is preying.

(3) FRUIT TREES.—All the stone fruit trees are liable to be attacked by the Pseudocommis, and Plums are so in a less degree than Almonds, Peaches, Apricots, and especially less than Cherries. This slimy fungus can live on the branches of these trees, usually attacking the extremities of the young branches and causing them to decay sooner or later. When the sap-vessels of these branches are choked up by the plasmodes of the parasite, gumming ensues, and the upper part of the branch dries up and dies away. When the leaves are attacked they first show spots of a reddish or blackish brown colour. These spots are surrounded by a narrow ring of a darker colour, and as the diseased tissue shrinks or contracts they become detached and fall out, leaving holes in the leaves. These fragments of plasmodium-infected tissue, I am convinced, when washed into the soil by rain, serve to spread the infection of the Pseudocommis. The leaves of Apricot and Cherry trees in our part of the country were this year all more or less riddled with holes in this way. Even the fruit of the Cherry trees is attacked by the parasite, and when the symptomatic spots are large, the fruit makes little or no progress in growth, and the spots become covered with mould fungi. When the spots are small, the Cherry ripens, and the only effect of the spots is to leave very slight blackish depressions in the skin of the fruit. The fruit of Apricot trees attacked by the Pseudocommis suffers from it in another way. On such trees the Apricots are, unhappily, few in number, and fall from the tree before their time, one after another. Inquiring into the cause of the premature dropping and examining the lower part of the very short stalk which is detached from the tree along with the fruit, one may observe the orange-yellow or brownish tinge of the tissue at that part, and also that the ruptured sap-vessels there have the same tinge. Here I have detected the presence of the Pseudocommis, which causes the tissue to decay, so that the fruit cannot hold on firmly to the branch and is easily blown off by the wind. Moreover, if one of the wind-fallen Apricots is cut through, the stone or shell of the kernel will be found to be diseased, and the kernel itself to be usually wasted away. Pear trees and Apple trees have their leaves and sometimes their fruit also attacked by this Pseudocommis. In the case of the Pear tree the symptomatic spots are of a blackish colour, while they are of an orange-yellow or brownish tinge on diseased Apple trees. On the leaves of Apple trees I have observed that the disease was conveyed in a deposit of fine dust impregnated with plasmodes or microscopic cysts which had been formed on the surface of the soil by plasmodium-infected fallen leaves, and thence disseminated by the wind over neighbouring plants. The wood also of the Apple tree may be attacked, for I have seen the stem of a small tree the central part and bark of which had been the prey of the parasite. I may add that the young Apples which fall from the tree prematurely exhibit the same morbid features as the Apricots, except that in their case the entire fruit-stalk is attacked by the brown discoloration, which also shows itself on the bottom part of the young fruit, the flesh of which, although remaining firm to the touch, takes on a characteristic yellowish or reddish colour. The leaves of the Walnut tree are not exempt from the attacks of the Pseudocommis, and I have had an opportunity of verifying the

observations made by M. Debray on the leaves of this tree in Algeria. In our part of the country the disease exhibits the same effects in even disfiguring the leaflets sometimes. I have not seen any instance of the fruit or nuts being attacked by it. The Hazel nut tree is very liable to be attacked by the Pseudocommis, when the leaves turn brown at the margin or here and there on the blade, where sometimes it shows itself in very numerous and very small spots, and on other occasions in fewer and larger ones. The leaf-tissue thus attacked by the plasmodes of the parasite rapidly dries up, is broken away by the contraction which accompanies the desiccation, and falls to the ground, leaving behind it a hole in the leaf. This condition of the leaves being, as it were, quite riddled with holes, has been attributed to very different causes. The Pseudocommis also shows itself in broad spots of an orange-yellow colour on the involucre or husk of the nut, and the nut itself is finally attacked by it. What should be especially noted, however, is the dispersion and dissemination of the particles of the plasmodium-infected tissue of the spots which are carried about by the wind and infect the neighbouring vegetation. Cultivators, therefore, should be careful about planting near certain crops Hazel nut, Cherry or Apricot trees, or in general any kind of tree which is liable to be attacked by this parasite and would help to propagate it.

(4) CUTTINGS AND SEEDLINGS IN FRAMES.—From my experience in raising seedlings under damp bell-glasses, which has taught me that very few germinating seeds are proof against the attacks of the Pseudocommis. I was led to establish the fact that culture under frames is very favourable to the development of this parasite. While visiting the establishment of M. Foucard at Chatou, where the propagation of Pelargoniums or Geraniums is successfully carried on, I had an opportunity of ascertaining that the multiplication of these plants from cuttings is no longer as satisfactory as it used to be. Cuttings which at first appear to be doing well soon show signs of suffering from some malady. The leaves become spotted, the spots become covered with mould fungus, and the plants produce hardly any flowers. This is a special disease, well known to cultivators, and appears to be characterised by the presence of a brownish filament in the stem of the cutting.

M. Foucard kindly permitted me to examine some of the diseased plants, which I found to be affected in the following manner. The tissue of the lower part of the stem of the cuttings was entirely pervaded by the Pseudocommis, which had found an entrance at the cut surface, and which had also spread to several of the roots. I likewise found the parasite in some of the sap-vessels of the stem, and it is certainly from these that it spreads to the leaves and the flowers, in which I have also met with it. I did not come across any plants so badly diseased as to show the characteristic brownish filament in the stem, but I think I am able to say that this must mean a bundle of sap-vessels discoloured by the plasmodes of the parasite. Free and frequent ventilation, being unfavourable to the growth of the Pseudocommis, arrests the development of the disease, but the plants will still remain in an ailing condition and flower badly.

I will now mention some difficulties which attend the process of multiplication. In raising seedlings and striking cuttings under frames, it is necessary to be careful that the soil is free from contamination, for if the seed and cuttings are in a sound condition, the fault, if any, must rest with the soil. This amounts to saying that it should be sterilised before it is used. M. Opoix employed boiling water for this purpose, but cultivators find that this is not a very practicable method when a large number of frames has to be gone over. If the frames were made of iron or of wood lined with sheet iron, could not wood be burnt on the surface of the soil, and sufficient heat be thereby obtained to destroy any parasites it might contain? Or, could not gratings covered with burning charcoal be slowly moved over the sur-

face of the soil until it was sufficiently heated when the soil underneath could be turned up and exposed to heat in the same manner? I throw out these suggestions as they occur to me, but someone, perhaps, may devise other more efficacious plans for heating the soil in a frame such a degree as will destroy all the infective germs that it may contain. This being accomplished, all that would then remain to be done would be to prevent infection from being conveyed through the air by placing the frames at distance from any plant or tree attacked by the leaf-browning disease and likely to disseminate.

The foregoing are the fresh observations which I wished to lay before the society. The true cause of a disease being known, it may, perhaps be difficult, but not impossible, to discover an effective remedy for it. What we want in the present case is to make ourselves acquainted with the conditions which are favourable to the action and propagation of the parasite, and then employ the means which are necessary to minimise the risk if not to get rid of them entirely.—M. E. ROZE, *Journal de la Société Nationale d'Horticulture France.*

## GARDEN FLORA.

### PLATE 1143.

#### IRISES AND IRIS GARDENS.

(WITH A COLOURED PLATE OF—1, IRIS GEORGE THORBECK; 2, I. VARIEGATA AUREA.\*)

HERE are figures of two blossoms from an Iris border made about one year from the time of blooming, and although so short a time after the formation of the border, the general result is very pretty, but naturally one would expect a much better result in another year or two. The border was planted—as it ought to be perhaps soon after midsummer and throughout the early autumn, when Irises take pretty well.

The Iris is typical of various plants that most beautiful when grown in any good way arranged, above all things, with some kind of harmony and emphasis of grouping. One can anywhere about London see the poor Garden Iris struggling with tree roots in all sorts of conditions, and often half buried in the rubbish of which all the London gardens are full, and which has only one charm, namely, vigour, many of the things used being those that never produce a flower or a fruit worth looking at, like the Privet. Notwithstanding this very bad treatment, one may often see a plant in beautiful bloom about London in many little private gardens.

It is hardly necessary to say how much better in a country place and in good soils it can be done not only with the common Irises of the garden, but many varieties, or so-called hybrids raised between this and the allied species, which are among the most beautiful hardy flowers known to us. One object of making a border or garden is to get these together and to be able to treat them and enjoy them as a whole. The Iris appeared to us to have unusual merits for a border or garden of its own because of its graceful and almost evergreen leaves and of its good colour. In making such a garden border, one, of course, escapes the common error of letting things be choked by the common bushes we spoke of, as you are able to pay more attention and they have a fair chance of developing themselves.

Then comes the question of effect. To many people this may seem a matter of taste merely, but really there is much more in it, because of grouping or massing Irises the effect is very

THE WEEK'S WORK.

HARDY FRUIT GARDEN.

ROOT-LIFTING AND ROOT-PRUNING.—Work of this description should be in a forward condition generally, but if through a scarcity of labour, or through other pressing matters, it has up to the present time been neglected, advantage should be taken of the open weather to make a start and press on with it. The advantages to be gained by the performance of either of these operations when necessary, having been stated in previous notes, it is unnecessary to again repeat them here. The great thing is to carry out the work with all due despatch, and while there is still a certain amount of warmth remaining in the soil, which will cause new rootlets to be made all the more speedily, or before any severe weather is likely to set in.

PLANTING.—For planting home-grown fruit trees and bushes the weather of late has been all that could be desired, as with one or two exceptions there has been an absence of dry, parching winds, while there has not been any very great amount of bright sunshine to cause the foliage either

readiness by the side of each if requisite, and then no delay will occur when the trees arrive. If the roots are found to be dry when they are unpacked, immerse them in water long enough to moisten every portion, and in no case should the trees be planted with their roots in a dry state. Should it not be convenient to plant them upon their arrival, lay them in by the heels and well cover the roots with fine damp soil, putting some long straw or the packing material on the surface, should sharp frosts set in, as a further protection. Trees which arrive during very severe weather are best placed in a cellar or potting shed, and the unpacking deferred until the weather breaks.

PRUNING.—I have in a previous calendar advised that fruit bushes be pruned and steps taken to clean the ground underneath, especially Gooseberries, where caterpillars have been rampant, and to do the manning of the plantations afterwards. Some growers are averse to pruning thus early, but there can be no objection to its being carried out now as the leaves are off the trees, unless it should be in localities where birds dislaid them very severely. Even in this case the difficulty is not insurmountable, as the bushes may be netted over so soon as the pruning is completed and the birds set at defiance. Where Gooseberry and Currant plantations are protected or covered with a framework of wire netting, or where birds give but little trouble, the pruning may be done at once. In pruning Gooseberry bushes, those from which the fruit will be gathered for preserving or cooking may have the wood left somewhat thicker than in those on which the berries will ripen and hang for dessert. Cut away all wood having a tendency to droop downwards, leave a young shoot here and there to provide for future contingencies in the shape of the loss of branches, and spur to two or three buds all surplus wood. The young wood at the extremities of the branches may be cut close, or left one-third or two-thirds its length, according to the age and size of the bushes. Cordon trees should have all side growths pruned in close, merely tipping the leader or cutting it back to a sound bud if required for future extension. Red and White Currants succeed best spur-pruned, and the centre of the bushes should be kept open for the free admission of light and air. In their case leave young growths to supply possible losses in the near future. Cut away all pendant branches and encourage the bushes to grow more in an upright than in a spreading manner. Both Gooseberry and Red and White Currant bushes should be grown with clean stems, quite a foot high before they are allowed to branch out, and all growths emanating from the base in the shape of suckers should either be pulled or cut clean out. This should be borne in mind when pruning young trees, and leave the shoots for the formation of future branches at regular intervals, giving those the preference which point upwards, so that cup-shaped bushes will eventually be the result. Cordon trees should be treated the same as cordon Gooseberries. Black Currants must be thinned out instead of being spurred, and the oldest of the wood cut out at the same time. If this is done annually they will be kept in a fruitful state with but little trouble. Where the Currant mite has been troublesome, and for which the only remedy appears to be the rooting up and burning of the bushes, new plantations should be formed on a piece of ground as far removed as possible from the infested plantation. New bushes should be obtained from a clean source, and pains taken to see that nothing is likely to occur which may convey the insects, either in the shape of soil or portions of infested wood, to them. As a further precaution, the ground, after the old bushes are grubbed up, may be dressed with gaslime, which, if spread on the surface and allowed to remain there all the winter, may be dug in in the spring. As the leaves are nearly all off Morello Cherries, with the sweet varieties, Pears, Plums, and Apricots following suit, the pruning, dressing, and training of these may be undertaken in the order named. The few leaves there may be remaining on the trees may be brushed off without the

natural; we have to plan with some deliberation. We study the conditions that suit them and we get a picture which cannot be got by the common dotting way. It is not merely a matter of taste, therefore, but a returning to more artistic and natural ways, both of culture and effect. The variety of Irises is very great and finds itself very well to the making of a bed or border. The times of blooming vary. The variety of the hardy rhizomatous Iris in particular is very great, whilst other and rarer distinct species may be introduced among them. In sandy, peaty, and warm soils the various dwarf Irises form pretty and good edgings, some flowering very early.

No one need fear monotony from such an arrangement, the variety and grace of the plants exclude it, and we are not obliged to confine the border or bed to Irises alone. Some other hardy bulbs, such as the Gladioli, may be associated and grouped with the Iris, and the sult will be good, open spaces being left for its purpose in case we wish to put any half-hardy bulbs in in spring. It is needless here, as

Spanish Irises in an American garden. From a photograph sent by Mr. Hicks Arnold, 7, East 83rd Street, New York.

we have done it so often, to enumerate the various kinds of German Irises that are beautiful; they are mentioned in so many catalogues, and we have often dealt with the question before as a whole. The two kinds we figure are, it need hardly be said, very pretty ones.

**Aster sericeus.**—This distinct and beautiful species is somewhat rare in cultivation, though on the singular beauty of its downy silken leaves it is worth a place in all gardens. The other thin and wiry habit, as well as the leaves, covered on both surfaces with a pronounced very pubescence, render it unique. The blossoms, of a pale violet hue, are likewise very distinct, and, being a late-flowering species, it should be more encouraged. Hitherto the plant has been somewhat rare. The plant should be grown in a warm position in a light, open mixture of sand and leaf-mould. In some text-books this species is described as half-hardy, which is scarcely correct, the plant being quite hardy in the majority of soils, though not a success on a soil of a clayey and retentive nature.—J.

to flag severely or to shrivel and drop prematurely. Consequently both trees and bushes have been but little distressed, and they will shortly be shedding their leaves, but not before these have been of great service in assisting and promoting the formation of fibre at the extremities of the majority of the roots. Where, through force of circumstances, a start has not yet been made with planting of home-grown trees, I would urge that it be taken in hand at once, for although a week or so of valuable time has already been lost as far as the speedy re-establishment of the trees is concerned, fruit trees planted during November always succeed better than when planted either in the dead of winter or in early spring. As fast as the trees are planted, stake and tie all that require it, and above all do not omit to mulch, as this both conserves warmth and excludes cold in the shape of frost. Judging by the ripening of the foliage on fruit trees, nurserymen should be in a position to commence lifting somewhat earlier than usual this season, which will be an advantage to both grower and purchaser. Have stakes, haybands, tying material, and other accessories to hand, in addition to having the holes dug and a modicum of good soil placed in

slightest harm resulting, and the performance of the necessary operations named above can then be done much more expeditiously, and with greater comfort to all concerned than if deferred until mid-winter.

**OUTDOOR FIGS.**—In those parts of the country where it is necessary to afford the trees protection during the winter, the matter better have attention as soon as the trees have shed their leaves. The best material I have found for this purpose is dry Bracken, held in position with mats. The branches should be unfastened and tied into convenient-sized bundles, and the latter lowered and brought to as near the ground-level as possible, when the Bracken can be worked between and around them, covering afterwards with mats, which should be fastened to the wall. This is an effective and economical method of preserving both the embryo fruits and wood from the frost.

**PROPAGATING.**—After the Currant and Gooseberry bushes are pruned, collect the desired number of cuttings of each particular variety, tie them in bundles and correctly label them. On a wet day these may be prepared, heeling them in under a north wall afterwards, so that the wood does not get dried, and plant them on a piece of ground or a border prepared purposely for them the first opportunity. Cuttings made and planted during the present and succeeding month root more quickly, and there is a smaller percentage of losses than when the matter is left over until the spring. A. W.

#### KITCHEN GARDEN.

**VACANT GROUND.**—The importance of getting all vacant ground dug or trenched early in the autumn is not always recognised. It is not in all gardens, however, that ground required for most of next summer's main crops can be allowed to remain vacant during the winter, as the space available may be barely sufficient to produce enough vegetables to meet the demand, and close cropping has to be resorted to. There are two good reasons why the soil, especially that of a heavy nature, should have early attention in the autumn, namely, not having become saturated by heavy rains, it allows digging to be done with a less amount of labour, while, being exposed for a long season to the weather, it becomes thoroughly pulverised and sweetened. To this may be added the further advantage that less labour is required in spring to bring it into a suitable condition to receive seeds and plants when many other matters claim attention. It too often follows that the old rule of tillage is never departed from, such as an annual dressing of light strawy manure, which is barely buried by the shallow practice of digging. Under such treatment it is little to be wondered at that such crops as Peas quickly collapse after a short spell of hot, dry weather. The manure employed possesses little or no feeding properties, while on light sandy soils it only causes them to become more porous and facilitates the escape of moisture. A change from shallow to deep cultivation often proves of greater benefit to future crops than an extra application of manure. The top spit may, and often does, become manure-sick, and lacks those holding properties necessary to support growth during a trying season. Double-digging in such cases proves a great gain, especially when the work is done in such a way that the soil from the second spit becomes thoroughly incorporated with the top. On some soils this is much preferable to trenching, as in this case the subsoil which is made to form the surface is of an ungenial nature, becoming hard when exposed to the sun and unworkable after rain. This shows that the cultivation must depend on the nature of the subsoil. Light and porous soil requires deep cultivation and more feeding than that of a heavier nature, as the manurial properties are more quickly exhausted. Those who have cold, retentive soils to deal with know the value of liberal dressings of road grit, burnt garden refuse, or even fine ashes. These form a natural drainage,

and when porosity is once attained warmth follows. Until such ground has been brought into this condition it may prove a disadvantage, rather than the opposite, to be heavily charged with rank manure. Ridging is a practice strongly recommended, especially with heavy land, as in no other way is it exposed more to the influence of the weather. Spits that are turned over roughly now, though they may cling to the spade, will invariably crumble to pieces when March winds follow severe frost. Many have to resort to this method when preparing for Potatoes. The ridges are formed of sufficient width to allow of the sets being placed between them in April. In this way large breadths are soon planted, and the soil having been brought into a friable condition is easily levelled, and growth pushes through freely.

**DRESSINGS FOR LAND.**—Really well-decayed farmyard manure is anything but plentiful in many gardens, but there is generally to be found a large heap of weeds and rubbish, the accumulation, probably, of twelve months. This, after being turned over perhaps a few times, forms the chief dressing available. When properly prepared it proves of great assistance to most crops, but unless sufficient time has elapsed to destroy the seeds of innumerable weeds, it should be strictly avoided, or a foul garden will be the result. A cartload of lime to every six of refuse, and the whole turned over several times for a couple of years at least, will bring it into a suitable condition for use, the finer portions of which are invaluable for seed beds, &c. Unless it can be treated in this way, the only thing to be done is to burn it. This will reduce the bulk considerably, but there are no evil results likely to follow when used sparingly. The same care should be exercised in preparing stable manure before it is used in the garden. This does not consist wholly of straw and droppings, but waste hay and the sweepings of lofts are generally mixed with it, these proving a fruitful source for the introduction of dock and other rank weeds, which would take years to eradicate when the seed is once allowed to germinate. Nothing but fermentation will destroy these, which should be brought about by turning the heap several times, to prevent dry rot and cause the whole to decay before being used. Now is the best time to apply gas-lime where it is deemed desirable for the destruction of slugs, wireworm and other vermin. It is too powerful to be used just previous to seed sowing, hence ground that has to carry a crop of Onions next year should be dressed with this now. It should not be dug in for several weeks, full exposure causing the lumpy portions to fall to pieces. Used with care this is a great purifier of the soil, but when employed too freely and just before the ground is cropped it may lead to loss and disappointment. RICHARD PARKER.

## ORCHIDS.

### MILTONIAS.

This genus consists of a large variety of plants, some of the species having scores of named varieties, though the number of actually distinct species is small. They are epiphytal plants, natives of South America, some of them being of close tufted habit, others having the pseudo-bulbs occurring at varying distances on short creeping rhizomes. Their culture varies a little in the different species, the candida, Clowesi, cuneata, and Regnelli varieties being, perhaps, the easiest to grow and flower well. These like a good sound description of compost, consisting of peat fibre cleared of every bit of sand and earth with sphagnum in about equal proportions. Mix with this plenty of very finely broken crocks and charcoal, but not large lumps. The roots are small, and though liking a compost that air can enter freely, they are not so satisfactory if it is too loose. In choosing the pots let them have a medium margin of compost, and let this be pressed very

firmly, first filling the lower two-thirds at least with drainage material. For a little while after repotting it is not advisable to keep the compost very moist, though it needs frequent watering, owing to its running dry so quickly, but after this the roots must be kept very moist until the young pseudo-bulbs are quite finished. Even in winter they must be kept moist, requiring even then as much moisture as some Orchids do in summer. The best position for this class of Miltonia is a light one in the Cattleya house, but not where direct sunlight can reach the plants. The plants vary considerably in their time of flowering and resting, *M. Clowesi*, for instance, flowering sometimes in July and August, at others in December, and this will of course be kept in mind in all cultural operations.

Quite a distinct section is that comprised by *M. spectabilis*, *M. Moreliana* and *M. anceps*. The pseudo-bulbs occur on stout creeping rhizomes and the roots are small, though very persistent in most cases. One and all in this class abhor anything like closeness in the compost and also dislike much material about the roots. On trellised rafts or in shallow baskets they are usually satisfactory, and they may with care be grown in well-drained pots. About an inch of material is ample for small and medium-sized plants, and this may consist of a similar kind to that mentioned for the *Clowesi* section. Where roots are fairly plentiful they may easily be fixed in pots or baskets, but badly-rooted ones are more easily accommodated on rafts, as wire may be used for fixing them. Very little difference is needed in the summer and winter temperature for these Orchids, and they thrive well in the cooler part of the Cattleya house. Plenty of water is needed while growth is active, and while at rest the compost must be kept just moist. Nearly all the kinds mentioned above have a pale yellow tint in the foliage, but this is quite natural to most of them and not a sign of ill-health. *M. cuneata* is greener—in fact, it should be of quite a deep green if perfectly healthy—but the others, and especially *spectabilis*, will always be poor in colour. *M. vexillaria*, *M. Roezli* and *M. Phalenopsis* used to be included in *Odontoglossum* by botanists, but they are now usually called *Miltonia*. The first-named is one of the grandes of Orchids, and so well known that no description is needed, and its culture may be said to present no great difficulty. It does best in medium-sized pots, in a clean, well-divided medium, not heavy enough to get close or to hold moisture unduly, yet fairly substantial. I should be repotted some time after growth commences, just as the roots are forming, and until this occurs they may be kept well on the dry side after blooming. When the young pseudo-bulb are finishing and the bloom-spikes forming, the plants require plenty of moisture. An intermediate or Cattleya house temperature suits it best, the growth and flower being much finer than if grown in a cool house. Much the same treatment is needed by the other two kinds named in this class, but both of these do with more heat all the year round than *M. vexillaria*. A short description of the leading kinds is given:—

*M. ANCEPS* is a dwarf and pretty kind, the pseudo-bulbs a couple of inches in length and leaves of a pale yellowish green. It produces its blossoms singly on the scapes, and these are olive green and brown of varying shades, with purple markings on the outer segments, the lip being white, spotted and barred with red. It comes from Brazil, whence it was introduced in 1851, and is by no means a common species.

*M. CANDIDA* is a useful, free-flowering and easily grown kind, and in its best forms one of the hand-

most of autumn-flowering Orchids. It bears spikes of blossoms, eight or nine on each, these being large individually. The sepals and petals are yellowish, barred with reddish brown, the lip pure white in the typical form, but having many variations. It is a native of Brazil, and was introduced in 1830.

*M. CLOWESI* is not unlike the last named in habit and general appearance, and thrives under similar cultural conditions. The blooms are large, the scape many-flowered, the outer segments chocolate-brown with spots of yellow. The lip is almost heart-shaped, pure white in the front, the base a deep vinous purple. This is not so variable as some other kinds, yet there are many which have received varietal names. This also comes from Brazil, and was introduced in 1843.

*M. CUNEATA* is one of the best known kinds from the same country. The spikes bear about half a dozen flowers, these being prettily undulated on the sepals and petals, brown and green in colour; the lip white, spotted with rosy purple. Its proper flowering season is in early spring, but sometimes blooms again in autumn.

*M. MORELIANA* is a beautiful species, usually classed as a variety of *M. spectabilis*, but there are so many sub-varieties that it seems quite entitled to be kept apart. The spikes bear single flowers in late autumn, these being large, deep purple on the sepals and petals, the lip lighter, often with radiating lines of a deeper hue. The varieties differ considerably in colour and size, the flowers of the best forms being each over an inch across.

*M. PHALENOPSIS* is a charming Orchid, not exactly easy to grow, yet often seen in a thriving condition where care is taken in its culture. It is a dwarf tufted plant, with pale green arrow leaves and pseudo-bulbs, the scapes rising from these and carrying a few flowers on each. These are white, with lines of purple in the centre of the lip. It occurs naturally at considerable elevations in New Grenada, whence it was introduced in 1850.

*M. ROEZLI* and *M. VEXILLARIA* are very nearly related kinds, both lovely in bloom and well worth very care to bring them to perfection. The former bears pure white flowers with a purple centre, and there are several named varieties.

*M. SPECTABILIS*, the type of the genus, was introduced in 1837 from Brazil, and is still one of the most useful Orchids grown. The single-flowered scapes rise about 8 inches high, the outer segments are white at first, afterwards becoming a pale yellow, the lip varying considerably in the different varieties, but usually being of some tint of purple.

*Lælia autumnalis venusta*.—This is a pretty variety of the large-flowered, pale-tinted section. The bloom-spikes are stronger and stouter than those of the typical form, producing more flowers on each, these being individually large and of great substance. The segments are broad, of a pretty rosy mauve, the base of each being nearly pure white. The lip is broad and handsome, but not so deeply tinted as in the type. It thrives well under the treatment usually recommended for the type.

*Masdevallia tovarensis*.—The earlier flowers of this Orchid are now open, and as it keeps up a succession of the snowy white blossoms for about three months it is of great value either as a pot plant or for cutting. It is not good policy to cut the spikes entire unless they are wanted with long stems, but no great harm is done by taking off a few in this case. It is quite as easily grown as any in the genus, though it undoubtedly likes rather more warmth in winter than the *M. Barryana* varieties. It is a native of Caraccas, and first flowered in England in 1864.

*Masdevallia corniculata*.—I have noted this pretty species in bloom in several collections around London during the week. It is a free-flowering and very bright and effective, the base of the flower consisting of the ovary, and part of the tube is enveloped in a green bract.

The base of the segments is brownish-erimson suffused with yellow and some deeper-coloured spots; the tails of the sepals are narrow, clear orange-yellow. There is considerable variety among the flowers, some being much smaller and paler in colour than others.—R.

*Masdevallia Veitchiano-Estradæ*.—This is probably one of the most free-flowering *Masdevallias* in cultivation, small plants of it being covered with bloom. The name signifies the parentage, the latter being the seed-bearer, and it was raised in Captain Hinek's collection at Richmond. In habit it most resembles *M. Estradæ*, but the influence of the other parent may be seen. The blossoms are larger than those of *Estradæ*, the perianth bright orange, suffused with scarlet, the elongated tail bright orange-yellow, the lip purple. This bright and pretty hybrid first flowered in 1893.

*Masdevallia muscosa*.—This very singular *Masdevallia* was first imported by Mr. Bull, one of whose collectors found it in New Grenada, and there are now several plants of it in flower in his Chelsea nursery. It is the only known species having a sensitive lip, and is very interesting on this account. Directly the lip is touched it begins to move upward, and at last closes up under the column. It is also peculiar in its very hairy stems, these being covered with a soft white down. The whole of the flower, with the exception of a chestnut-brown blotch on the lip, is clouded white.

*Mesospinidium vulcanicum*.—This bright and pretty plant is in flower at Mr. Bull's. It is of dwarf habit, each pseudo-bulb about 3 inches high, and the spikes producing about a couple of dozen of the charming little rosy-red blossoms. These vary in size considerably, and to a certain extent in colour and the number produced on a spike. Coming as it does from Peru, it thrives with the cool section of *Odontoglossums* in a moist, shady, and well-ventilated house, kept as cool as possible during the summer months and at a minimum of about 50° in winter. Peat and moss suit it well for compost, and small pots are preferable to large ones.

*Cymbidium elegans*.—The flowers of this species occur on elegant racemes, and are individually very pretty. The plant is strong and of vigorous habit, producing long sword-shaped leaves that in themselves are very ornamental. The flowers are rather crowded on the spike, and seldom open quite fully. They vary from nearly pure white to a tawny orange colour, and are spotted about the lip with bright crimson. It does well in pots in a good substantial compost, and is best suited in an intermediate temperature. A fine plant of the giganteum variety I recently noted in bloom.—R.

*Cattleya aurea*.—This does very well at Camberwell, and Mr. Chapman considers it one of the easiest of *Cattleyas* to grow. The specimens are small, but the bulbs in every case are improving in size, one nice growth carrying a three-flowered spike, the blossoms large and fine in colour. Few things are more beautiful than the labellum of this species, the rich purple, with golden overlying blotches and pencillings, being remarkably handsome. Doubtless the cardinal points in its culture are a good light position and comfortable quarters while growing, care being taken that the basal buds do not start after flowering, but remain dormant during the winter, when they start and grow rapidly in spring.

*Cycnoches maculatum*.—This pretty species, although known since 1839, has always been somewhat scarce in cultivation. Mr. W. Bull has imported it, I believe, and a fine spike of it was recently in flower at his nursery. The plant has rather short pseudo-bulbs for a *Cycnoches*, these tapering upwards. The plant had one spike of eleven flowers, these being rather thickly set and making a full and pretty arching inflorescence. The sepals and petals, which reflex, are narrow, buff-yellow with crimson spots. The labellum is very singular, being greenish, the

disc cut up into many small white filaments, each having a distinct black dot on the top. It is a native of Mexico, and requires the same treatment as *C. chlorochilon*.

*Cattleya Miss Williams*.—This is a distinct and pretty hybrid raised in Mr. Temple's garden at Leyswood, Tunbridge Wells, where it has recently been flowering. The petals are broad, the colour being a distinct tint of rose. The sepals also are fine in substance, similar in colour to the petals. The front lobe of the lip is rich purple, shading to white at the base; the side lobes white, slightly tinted with rose, with some yellow at the base. The parentage is unknown, but there is no doubt *C. Loddigesii* was the seed-bearing parent, the other, one of the *C. labiata* group. It is a desirable variety, and when stronger promises to be a useful addition to the *Cattleya* hybrids.—H. J. CHAPMAN.

#### NOTES ON ORCHIDS.

THE dullest season for Orchids—thanks to the fine weather, that has brought many autumn flowering kinds in very quickly—is now past, and the flowering house is very gay. Of the splendid *Cattleya labiata* little need be said, as its characteristics are now so well known. Then the earlier plants of *Dendrobium Phalenopsis* are making a fine show, as well as *D. aureum*, *D. chrysanthum*, and one or two others. *Cattleya Gaskelliana* has held out much longer than usual, while *C. bicolor* and a few of the *C. Loddigesii* section have this season joined hands with *C. Bowringiana* and its varieties. Several plants of *Cypripedium Charlesworthii* are still in good order, also of course *C. Spicerianum*, and the number of hybrids just now flowering is very large. In the cooler houses there is a wealth of bloom, *Oncidium tigrinum* with its charming violet-scented blossoms being one of the finest in the genus, and I have seen several plants of *O. Marshallianum* already in flower. *Odontoglossums* are not yet numerous, but a few *O. crispum* are out, also the useful *O. tripudians*, not a large, but a very showy plant. *Masdevallias* of the *Chimera* section include the type, *M. Wallisi*, *M. nycterina*, and one or two more, while the white *M. tovarensis* and many quaint botanical kinds help with the already numerous hybrids to form a pretty picture.

It is not perhaps the best time to be pulling *Cattleyas* about at the roots; still where it is necessary that such as *C. Mossiae*, *C. Bowringiana*, or even *C. labiata* are about producing a fresh set of roots, they may with advantage be seen to, especially in districts where fog is apt to destroy the flowers. *Dendrobiums* are finishing up this season in a manner very pleasing to those growers who have had experience of dull, sunless autumns. All the crassinode, *Wardianum*, and similar varieties that have been hanging in a cool, light house are rapidly losing their foliage, while *D. nobile* is quite finished and the nodes swelling for flower. Small bits of the latter and any fine forms that have been propagated by being laid on Moss or similar material may still be potted up. A recent visit to a very skilful propagator was instructive. Cocoa-nut fibre had been used in place of Moss, and apparently almost every node had produced a plant. As those operated on were of such fine varieties as *D. n. Ballianum*, *D. n. nobilium*, and the like, the value of this mode of propagation may be imagined. Later *Dendrobies* will need a little more time, and must be kept in company with such of the Australian kinds as are making their growth in a warm, moist house. *Thunias* should by now have lost their foliage, and may be turned out of their pots and placed in any out-of-the-way corner in a warm house. All or nearly all the warm-

house *Cypripediums* are in active growth and must be treated accordingly, giving plenty of water at the roots and a genial, moist atmosphere. *Catasetums* and *Cyanoches* as they go out of flower should have the bulbs well ripened up and be kept dry for a time, but any that are still in active growth must be pushed along as quickly as possible. In the *Cattleya* house many of the *Oncidium*s are throwing up their spikes, the useful *O. Cavendishianum* being among the number. A good light and a fair quantity of moisture must be allowed them, and where there is an opportunity the plants may be fumigated, as otherwise green fly is almost sure to put in an appearance during the winter season.

Shading may now be entirely dispensed with, as it is imperative that all the light possible enter the houses. For this reason the glass should be frequently washed down outside, especially after foggy weather, and the inside of all the houses should be thoroughly sponged, both woodwork and glass coming in for attention. Whenever time can be spared, sponging should be followed up in the *Cattleya* house, as the small white scale insect soon spreads at this time of year. Especial care is needed where newly-imported plants are introduced among well-established ones, as these are often covered with insects, that increase directly they are brought into heat. In the cool house, too, much more time will need to be spent in cleaning both the house and its occupants, a soft brownish scale and also the black scale with a white marking around the outside edge making a lot of progress just now. It is, perhaps, not generally known that fumigation will nearly exterminate this latter pest, greatly reducing its numbers, if not actually ridding the house of it. Keep the growth moving on *Odontoglossum crispum* and any similar kinds that have not yet finished up their bulbs, and as *Masdevallias* and others root out into the new material increase the water supply. Repot *Pleiones* as they go out of flower, keeping them absolutely dry at the roots after the first soaking to settle the new soil. Keep *Sophronis* and other dwarf *Orchids* advancing for flower in a nice equable state as regards root moisture, and while allowing as much air as possible to this house keep it free from draughts. The minimum night temperature will now be in the East India house 60°, in the *Cattleya* house 55°, and in the intermediate, Mexican, and cool houses from 50 to 55°. R.

#### SHORT NOTES.—ORCHIDS.

*Lælia pumila albens*.—In this the sepals and petals are pure white, of fine form and substance. The lip has a rich band of purple around the front lobe, the side lobes white, shading to yellow at the base.—H. J. C.

*Lælia Perrini* var. *leucophæa*.—This is a distinct and pretty variety of this well-known species. It differs principally in the colour of the flowers, the sepals and petals being white, slightly tinted with delicate blue; the lip white with the exception of the front lobe, which is of a distinct slate colour. It is similar in colour to *Cattleya Mossie* E. Ashworth and *L. præstans* (Gatton Park variety). The above plant was recently in flower in Sir F. Wigan's collection, Clare Lawn, East Sheen.—H. J. C.

*Masdevallia Measuresiana*.—This is in fine condition just now at Camberwell in Mr. Measures' collection. It is a hybrid between *M. amabilis* and *M. tovarensis*, and while retaining the habit of producing flowers successively like the latter, only one is open at a time. In habit and general characteristics it is about intermediate between its parents. The blossoms are white at the base of the perianth tube, the lower part of the sepals being suffused with lilac, becoming much deeper towards the margin and in the middle veins.

*Catasetum Chrietyanum*.—A small plant of this extraordinary species at Mr. Bull's is carrying

three of the largest flowers I have seen. It would appear that, like *Cyanoches*, the *Catasetums* when they produce a few flowers only on a spike have them larger individually. The blossoms are marvellous in their structure, the green sensitive horns to the column having a curious likeness to a diminutive pair of legs, one pointing forward, the other back, as if in the act of walking. Both sepals and petals are brown with darker spots, the lip being green shaded with purple.

*Cypripedium Reginae*.—This is an extremely pretty hybrid, raised by crossing *C. Lecanum* and *C. Fairrieanum*, and it combines in a marked degree the good qualities of both parents. A very fine plant now in flower at Cambridge Lodge has six growths. The foliage is deep green with very light tessellations. The drooping petals are pale in ground colour, with lines of an almost transparent brownish red. The dorsal sepal is bright green at the base, white above, and covered nearly to the apex with small spots. The

broad purple band down the centre, which is a characteristic of all the *C. Spicerianum* hybrids. The ground colour of the petals is greenish yellow suffused with purple, heavily spotted and lined with brown, the lip green heavily suffused with chocolate-brown. It is the result of crossing *C. Spicerianum* and *C. Curtisi*, and was raised in the collection of Sir F. Wigan, Clare Lawn, East Sheen.—C.

## CHRYSANTHEMUMS.

### TYPES OF JAPANESE CHRYSANTHEMUMS.

The varied shapes of this class, in addition to the rich colouring, have been the means of making them so popular. In beauty as well as ease of culture the Japanese are the finest of *Chrysanthemums*; they appear, indeed, to be gradually ousting every other class out of cultivation. Among the predominating types, perhaps the drooping or tasselled form is that esteemed more generally, and I think, too, sorts of this type are the least difficult to grow. *Mlle. Lacroix* was, perhaps, the first of this charming form. Ten years or so ago this variety was exhibited in splendid condition. New ones, however, eventually superseded it, being larger, and we now rarely note it in first-class selection. The *Belle Paule* became the highest form of the type.

Beautiful blooms of the white and rose-edged kind were for several seasons the fore. *Triomphe de la Rue des Châlets* was another extra fine type of the drooping-petalled bloom; the colour of this a brick-red or terra-cotta was most distinct. It is a pity such a kind has gone out of cultivation. But somehow, after a few seasons' culture for the purpose of obtaining huge exhibition blooms, grand varieties develop some undesirable characteristics and are therefore cast aside for some new-comer that can be more easily grown. *Mme. Carnot* is the present-day ideal of the droop-

Japanese *Chrysanthemum* *Mme. Octavie Mirbeau*.

pouch, light yellowish brown, is like that of *C. Lecanum* in shape.

*Lælia purpurata* var. *Annie Louise*.—This beautiful variety has recently flowered in the collection of Mr. G. W. Law-Schofield, Newhall Hey, Rawtenstall. The sepals are white in the centre, becoming slightly suffused with rose towards the edges. The ground colour of the petals is white, suffused with rose and heavily veined from the apex to two-thirds its length with a deeper shade of rose. The large lip has a broad band of deep crimson purple from the front. This colour is also extended well over the side lobes, shading to bright yellow, lined with the purple of the front lobe at the base and through the throat. It is a distinct and desirable form.—H. J. C.

*Cypripedium Allanianum* (Clare Lawn variety).—This is one of the most attractive forms of this lovely hybrid I have seen. The dorsal sepal is white, suffused with deep rose at the top, and green suffused with brown at the base. It has an unusually

ing type. This is undoubtedly a very handsome *Chrysanthemum*. It may easily be overgrown; hence by being too kind in the matter of manures many fail with it. *Vivian Morel* and its sport, *Charles Davis*, are well known examples of the tasselled form. *Mme. Octavie Mirbeau* is after the style of the old *Belle Paule* both in colour and form. This variety, too, is an exceptionally good one to last. It is charming with an edge of rose colour to the florets on a white ground. *Edith Tabor* has a bloom of most distinct formation. The long florets droop, only the tips pointing in an upward direction. This characteristic, with the clear yellow colour and substance, made it to my mind as a show flower the most finished and handsome *Chrysanthemum* in existence.

neeb perfects blooms of a drooping habit, at the florets are shorter than in many of the po. Mme. Marius Ricoud is somewhat similar form. Sunflower is a perfect form in the scelled flowers, but is a trifle small for growers to-day. Miss Dorothea Shea is another pital example; so is Wm. Seward. Simplicity long the newer kinds will please lovers of ooping-petalled Chrysanthemums.

A form scarcely less beautiful is the broad reading bloom. Mutual Friend and Golden ate are first-rate types. Another is M. Chenon Léché. Australie and Col. W. B. Smith ve a formation quite their own, and most ndsome, too. They build up into a ball-aped, loosely-formed mass of petals, but the ints, curiously, turn in a downward direction. hese appear to me perfect examples in the y of Japanese Chrysanthemums. The real in-eriving type in this class is also a very beautiful e. Take a good bloom of Mme. Ad. Chatin; is noble in formation. Oceana, although not se close in build, is grand; its petals also e thick and massive. Modesto is a grand rving flower, apart from the richness of its ide of yellow. Pride of Madford is a fine oe, the petals being extra broad and rich. ost handsome forms are M. Panckouke and hat's Australian Gold, characteristic flowers ring long florets which weave in an upward ection, and finally produce an irregular ball-aped mass of soft, dainty colour. Thunberg in old variety not beaten in this form when ll grown.

The above are the more striking types. ers of intermediate shapes are not wanting— e reflexed, in which one petal is laid upon other in a somewhat formal way. These, if nly coloured, are desirable. The hirsute or rry-petalled kinds, again, are curious, and rners are striving to obtain other forms as rse as those mentioned. There is one type e the Japanese flower I cannot see any beauty i that is the quill-petalled bloom. The florets i such are closed, as it were, and exhibit t outward colour only, which is usually dull. ese long petals remind one of the porcupine or hgehog, and have as much grace in forma- t. H. S.

**Chrysanthemum N.C.S. Jubilee.**—This is an especially pleasing new variety. The oms are full, deep and well formed. Its t of colour may be described as heliotrope, soft d charming. The florets are broad and long, u much substance. Add to these merits a erf, sturdy habit. It is one of M. Calvat's sts of the present year, and will be highly prized w better known.—H.

**Chrysanthemum Vicomte Roger de Che-** zes.—This recently certificated variety is an usually tall grower, and on that account will e disappointing to many. Nor are the flowers of e-rate merit. Probably the blooms, which e exhibited in a mass of a dozen, looked more ings than three would have done—the number el National Chrysanthemum Society requires; at hence the committee may have been carried ay by bulk. But even as seen, we have many ber yellows. This is not really the natural e of the flowers of the variety. It is quite bzy, with a spreading form. When the early k bud is secured, it develops the yellow shade d becomes somewhat incurving in shape. H.

**Chrysanthemums at Fawkham.**—Mr. P. Waterer, whose handsome vase of twelve ms of Mlle. Marie Hoste won the gold medal ed by the National Chrysanthemum Society merica on the occasion of the National Chry- anthemum Society's jubilee show last year, has y nice lot of blooms almost fully developed. Majority of the blooms are of good size, even for, and in many instances bright and rich in

colour. The collection numbers between 250 and 300 plants, and contains a goodly number of the most promising novelties of last season. Hand- some blooms of Emily Silsbury, the beautiful white Japanese somewhat resembling Mlle. Thérèse Rey, and here distinctly superior to that variety; Matthew Hodgson, a brilliant crimson- red, not by any means large, but valuable for its colour on the exhibition board; Miss Elsie Teichmann, pearly white and very graceful in form; Modesto, undoubtedly one of the best deep rich yellow sorts of recent introduction; Mme. Carnot, and Australie, the largest of the Japanese incurved, rosy amaranth, with white reverse, were good. Queen of the Buffs was as fine as we have seen it, the blooms being very deep, yet distinctly fresh and clean. A. H. Wood, the beautiful yellow sport from Primrose League, was seen in all stages, some of the later flowers giving promise of making blooms of exceptional grace and beauty. Pride of Exmouth, on both late and early buds, was striking, the later buds giving a pretty tint of rosy pink on the long, broad petals. Many of the older standard sorts were represented in excellent condition.—C.

CHRYSANTHEMUMS AT SWANLEY.

MESSRS. H. CANNEL AND SONS have in their large show-house, 160 feet x 25 feet, an extensive and thoroughly representative collection from all sources of the popular autumn flower. The quality of the blooms is of a high order of merit. The plants are arranged with considerable taste, there being a group of low dwarf varieties round the sides of the house, with a wide, sloping central bank of plants having two faces. A large proportion of the varieties are unnamed seedlings on trial, then a number of quite recent introduc- tions, with a fair sprinkling of old-established, well-proved varieties.

Continental novelties were strongly represented, by far the best and finest in every sense of the word being those sent out by M. Ernest Calvat, whose numerous successes on the Continent last year led us to hope, and not apparently in vain, for many varieties worthy of upholding his repu- tation. Very curious and distinct is the green incurved Japanese Mme. Ed. Roger, which has florets of medium width, good foliage, and dwarf habit. Werther, a large purple Japanese, big and solid, already shown in good form at the October show of the National Chrysanthemum Society, is worthy of note. Baronne Ad. Rothschild, a large, white, spreading flower, is quite as good as last year, and N.C.S. Jubilee, a capital globular in- curving Japanese—colour pale silvery lavender, reverse silvery pink—is even better at Swanley than it was either at the Ghent or Paris shows last autumn when first exhibited by M. Calvat. M. B. Verlot, a Japanese incurved with narrow grooved florets, colour rosy mauve, with silvery pink reverse; Capt. L. Chauré, of the same type, but deep golden yellow, shaded bronze outside; M. G. Chabanne, a pretty golden bronze Japanese incurved with curly tips; and Souvenir de Me- lines, bright brick-red, reverse gold, are all among recent novelties sent out by M. Calvat. So, too, are M. Massange de Louvrex, a fine canary- yellow Japanese; Mme. R. Grenier, very pure white; Secrétaire Fierens, golden yellow and crimson-bronze; Directeur Liebert, a long- petalled Japanese, colour purple-rose; Princesse de Galles, a big bloom, colour pale pink, tinted purple; Mme. Lawrence Z de, pale purple; Soleil d'Octobre, a fine new yellow; Topaze Orientale, yellow; Mlle. Lucie Faure, white; Isérette, golden bronze; Souvenir de Mme. F. Rosette, velvety purple; M. Ed. André; Mme. Ferlat, pure white, slightly tinted; Congrès de Bourges, purple-amaranth, and Mme. X. Rey Jouvin are all novelties of either this year or last of M. Calvat's raising; while most of those already well known, such as Mme. Carnot, Australian Gold, Mme. Gustave Henry, Ma Perfection, Le Moncherotte, &c., show what a large contributor to our present-day exhibition flowers this raiser has become. It is worthy of

note that several of M. Calvat's newest flowers show signs of hirsute origin. Whether this peculiarity is accidental or designed we do not know, but the chief characteristic of these is the same as in his others, the large size and massive build of the flowers being always the leading feature.

Among the Japanese kinds from various sources, Mrs. C. Probin, pale silvery pink, incurving in form and having pointed florets, is distinctly promising, and Lady Hanham, a fine sport from Vivian Morel, creamy rose and salmon, will soon find a place on the show boards. Robert Powell, a big, solid Japanese incurved, golden reverse and inside reddish bronze, was also in good form. Some well-known whites, such as Lady Byron, Mutual Friend, C. B. Hayward, Western King, Mrs. C. Bick, Kentish White, of which there was a very effective group, Mrs. H. Weeks, and Emily Silsbury, all found worthy representa- tives. Yellows of known merit were well and substantially shown in examples of Edith Tabor, Modesto, Buff Globe, a distinct sport from Good Gracious; Lady Oporto Tait, Swanley Yellow, &c. Here and there throughout the collection it was interesting to observe several first-class ad- ditions from Great Britain over the sea. Australie, Oceana, and Pride of Madford are well known, but to these varieties of colonial origin must now be added H. Cheeseman, a Japanese of reddish carmine on a deep golden ground, with narrow florets; Miss Mary Underbay, a Japanese in- curved with deeply grooved florets of a very pretty shade of pale golden yellow; Mrs. Ernest Carter, a large Japanese with medium-sized florets, colour pale yellow, reverse silvery; and a fine sport from Pride of Madford called Mabel Kerslake, which is similar in build to its parent, but of a deep rich velvety bright red-crimson, the reverse golden yellow.

In the incurved section no novelties of extra- ordinary merit were noticeable, but standard varieties such as Mrs. R. C. Kingston, Violet Tomlin, Lord Wolsley, Lucy Kendal, Baron Hirsch, Golden Empress, Prince Alfred, Princess of Wales, Mrs. Heale, Globe d'Or, and many more show that this old type is not neglected. The Anemone section is also represented at Swanley, but not to a large extent, and in the hairy type we noticed Hairy Wonder, still one of the best; Mrs. C. B. Freeman, a dull purple and gold sport from Louis Boehmer; Belle des Gordes, a very delicate pale pink, and large in size; White Swan, a fine addition, with long tubular florets; Leocadie Gentils, the new pale yellow French variety, and a few others.

Standard of quality in Chrysanthemums.

—In the report of the council of the Royal Horticultural Society for the year 1896 a wish was expressed that the various committees would be somewhat less generous in the recommendation of awards during the ensuing year. In past years Chrysanthemums with very little claim to distinction have been given awards of merit, but a change for the better appears to have set in, and only those sorts possessing high quality have so far this season been recognised. For some years the floral committees of the Royal Horticultural Society and the National Chrysanthemum Society have certificated blooms possessing size only. It seems to be an easy task to raise seedlings of Japanese sorts with coarse and irregular form and pale washy colours. However, there is evidence that ideas are changing, and no better proof of this can be obtained than that of an inspection of the rejected varieties at the floral committees of the two bodies previously alluded to. The public taste will not be satisfied with coarse and dowdy flowers, and interest must necessarily be lessened if no regard be paid to colour and form. Flowers of medium size, but of bright and clear colour, together with neat and pretty form, have over and over again been passed because they have not come up to the standard as regards size. Let flowers of medium size and proper form, together with bright and lasting colours, be the

basis of a standard of quality. The dowdy and washy colours often seen in exhibition blooms would not be tolerated in flowers grown for decoration, and more attention should be paid to raising sorts of the character advocated, as by their use a better display might easily be made.—GROWER.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Werther.**—The colour of this may be described as deep purple-red. Growers on the look-out for novelty in colour would find this variety worth growing, as the blooms are of good size with fairly long florets of medium width, slightly incurving at the tips, and showing the silvery reverse.—D.

**Chrysanthemum Geo. Gover.**—A flower somewhat after the style of Reine d'Angleterre, with long, broad, and pointed petals slightly curling and showing the reverse. The colour is mauve-pink, with a silvery reverse. The floral committees of the National Chrysanthemum Society wished to see the variety again when placed before them at a recent meeting.—H.

**Chrysanthemum Rayonnante.**—This is one of the newest of the continental sorts, and is after the Lillian Bird type, but superior to that variety. Many growers have little regard for flowers with tubular florets, but although this variety possesses this character they are sufficiently long and possess plenty of substance. The colour is a lovely shade of flesh-pink; the habit dwarf.—C.

**Chrysanthemum Pride of the Market.**—As a market variety, this should be in demand. The colour is a deep golden-yellow, freely suffused with crimson. The plant attains a height of from 5 feet to 5½ feet, and as it develops its flowers quite freely, and these are also of a goodly size for cutting, it should be very serviceable. There is another variety of the same name, but different in colour.—C. A. H.

**Chrysanthemum Nellie Brown.**—This is a sport from the well-known variety Ryecroft Glory, and has been exhibited before the floral committees of the Royal Horticultural Society and National Chrysanthemum Society quite recently. It is best described as crimson-bronze, and makes a pretty and bright display when freely flowered. The flowers of the parent variety on late buds often assume a crimson colour, this being more noticeable in the case of plants grown in the country.—C.

**Chrysanthemum Ella Curtis.**—Growers familiar with the character of the flowers of Boule d'Or and the difficulty experienced in getting really good blooms of it suitable for exhibition, should appreciate the variety under notice. This is a very large Japanese flower with long and broad florets, gracefully curling and twisting. As recently exhibited it compares favourably with the old sort alluded to, and if only a little more substance can be had with the bloom it should become a standard sort for exhibition. Evidently it is a much easier sort to grow.—D.

**Chrysanthemum Lady Hanham.**—This is the second sport that Vivian Morel has given us, and judging from blooms which have been exhibited it promises to exceed in beauty both Chas. Davis and the parent variety. The catalogues describe the colour as golden rosy cerise, but a more accurate description would perhaps be a pleasing shade of rosy-fawn. Flowers from early buds have yellowish centres with an edging of rose, but the later buds are now developing blossoms of a very lovely colour. A fine batch of this variety, with flowers of a most desirable shade of colour, is now fast opening at Ryecroft Nursery. The plants were propagated quite late in the season.

**Apera arundinacea.**—This graceful and beautiful plant, when brought before the floral committee of the Royal Horticultural Society recently by the Messrs. Veitch, was granted a first-class certificate, which, judging by the admiration the example called forth, was well merited. This singularly beautiful plant should be of considerable use in the higher portions of the rock garden, particularly in raised positions, so that its gracefully pendent plumes may be seen to advantage. The rush-like habit of the plant is quite erect and about 2 feet high, but the plumes issue therefrom, and, arching over, descend, when opportunity permits, to 4 feet in length. Given an elevated position, this elegant New Zealand Grass would produce unique results.

## ROSE GARDEN.

### WHITE TEA ROSES.

AMONG white Roses, the old and well-tried Niphetos must take front rank. Its name was very aptly selected by Bongère more than fifty years ago, and up to the present time this variety has had no equal. For outdoor culture, especially as standards, I prefer the climbing form, as it yields much larger blossoms than the dwarf form, but under glass the latter will grow and flower most profusely if a nice warm sunny spot be selected for it. In The Bride the form and texture of the flower are superb, a fact that has enabled it to secure almost the highest number of medals of the National Rose Society of any Tea Rose in existence. But the colour is not pure, and florists prefer Niphetos for this reason. If we could obtain a Rose as pure white as Niphetos

Rose Purity. From a photograph sent by Messrs. Geo. Cooling and Sons, Bath.

and as exquisite in form as The Bride, we should have a real gem. Hopes were raised that we had secured this in the White Maréchal Niel, but I think we shall find this Rose to be of very little value. Under certain conditions the old form of Maréchal Niel may be obtained of this sickly yellow shade. Souvenir de S. A. Prince is a very fine Rose, and perhaps the best white Tea for outdoors. Some do not care for the globular form, but it is nevertheless a very serviceable variety. The Hon. Edith Gifford is also a splendid Rose, useful alike at all seasons. It is creamy white with a flesh-coloured shading. This variety appears to have partly eclipsed the old Devoniensis, but it certainly has not its sweet perfume. The dwarf form of Devoniensis is a very poor grower, otherwise it is still one of the best whites. Where space is no object, I would recommend the climbing

form. If planted under glass and treated similar to Maréchal Niel, by cutting back hard after flowering, some grand shoots will be produced, and, provided they are well ripened, a plentiful crop of flowers may be secured the following spring. Mme. Bravy is one of the best former Teas, and although old, it is still worth retaining in our collections. Etendard de Jeanne d'Arc must not be despised. It is a very firm flower and very hardy. In Sombreuil we have a splendid late flowering kind of semi-climbing habit. Of Hybrid Teas, mention should be made of Kaiserin Augusta Victoria. Why it is classed with these Hybrid Teas I cannot imagine. It is a magnificent Rose of a creamy white colour, and produced abundantly on good stiff stems. White Lady is probably one of the finest large-flowered Hybrid Teas. Its immense flowers are really magnificent, and it is a better grower than Lady Mary Fitzwilliam. The Noisette Lamarque is a beautiful Rose, but rather tender.

The fine new hybrid Rose Purity (here illustrated), raised by Messrs. Geo. Cooling and Sons, Bath, has pure white flowers with a faintly flushed centre, the petals stiff and of great substance. When shown at the National Rose Society's show at Portsmouth on July 1 of the present year it was much admired. E.

**Rose Baronne de Maynard.**—With such a fine Rose as Boule de Neige in the collection one would imagine that another white variety was unnecessary; but the above Rose, not being so vigorous in growth as Boule de Neige, appears more suitable for decoration. Its flowers, freely produced, are very pure in colour and wanting in the rosy margined and often imperfect blossoms of Boule de Neige. It is true the flowers of the Rose under notice are not so perfect in form as those of the old favourite, but perhaps they are none the less valuable if the petals are irregular and sometimes pettled and crumpled. In some seasons I have found Baronne de Maynard most serviceable for cutting than Boule de Neige.—P.

**Roses with extra vigorous growth.**—There is a widespread impression among amateur gardeners that the so-called climbing Roses can only be properly cultivated upon walls or fences or supports of some kind. This is a mistake, and I would recommend anyone this season to try a few of the climbing Teas and Noisettes as bushes. Let them be planted in a sheltered spot affording plenty of room, say 4 feet to 5 feet apart each way. If severe weather threatens, tie the long shoots to a stake and protect with bracken or hair bands; then when all danger from frost is past allow these shoots to spread out in their own way. If the growths are well ripened we may expect a quantity of blossom to appear almost their entire length. When they have borne their crop of flowers some of these shoots may be removed so as to encourage the younger growths which are so freely produced by this method of cultivation and thus lay the foundation for next year's supply.—E.

#### SHORT NOTES—ROSES.

**Rose Albertine Borquet.**—This is a very perfect shaped Rose that reminds one of the favourite M. Furtado, but the flowers are large

The colour is a beautiful pale primrose, and the petals, particularly arranged in an exquisite circular form, are prettily reflexed at the edges.—P.

**Autumn pruning of Roses.**—This is often neglected, perhaps owing to its importance being under-estimated. Good Roses can only be produced from well-ripened wood, and by removing at this season soft late growths, together with thin and weakly ones, the remaining shoots will be considerably benefited by the freer admission of sunlight and air. Four or five well-ripened shoots upon each plant will yield the best blossoms, and more of them, than can ever be obtained from several weakly unripened ones.

**Roses seeding.**—This year many of the Hybrid Teas, such as Belle Siebrecht, Marquise Litta, Mc. Abel Chat-nay, La Fraicheur, Caroline Testet, Josephine Marot, Lady Mary Fitzwilliam, White Lily, Souvenir de Wootton, Germaine Traehen, and others are seeding very freely. I would advise amateurs who have nice snug little gardens to encourage the cross-fertilising of these varieties and to sow the seed in a cold frame as soon as it is ripe. They may reasonably expect in a year or two some good varieties, [excepting, perhaps, many existing kinds.—Ed.]

## KITCHEN GARDEN.

### ASPARAGUS BEDS IN WINTER.

I THINK the old, but still common plan of making Asparagus beds in winter will be less observed as time goes on, as it is about the worst system possible, and the loss of many plants and want of vigour in others in a great measure may be attributed to the winter manuring. I have seen it advised for light gravelly soils, but even on such I think it does more harm than good, and certainly is a waste of material. I am aware in some gardens there is a deficiency of labour to apply food during the growth of the plant, viz., from May to the end of August or even early September, as then the plant is building up the growth for next year's supply. Summer feeding does not take long if the weather is favourable. In rainy weather a surface dressing of fish manure, or, failing this, guano, soot, or other fertilisers is quickly applied. For summer feeding I have found no food equal to liquid manure from stables, and if a system of irrigation can be carried out, the plants delight in such treatment. Do not advise salt as food, and certainly there is no worse time to apply it than at this season. Salt given say in October, when the tops are cleared, has killed many roots at weakened others; in fact, it has done greater injury than hard cutting or years of neglect. Salt applied to light soils at the time mentioned above may be beneficial with other foods, but given now in large quantities (at any season) it destroys instead of feeds the plants. Much better results may be obtained by feeding in spring with nitrate of soda in the form of a top-dressing; not one heavy dressing, but, say, two or three during growth. I fail to see the utility of making Asparagus beds 3 feet deep, giving huge quantities of manure when forming the beds, and heaping on large quantities in the autumn. Plants treated thus cannot absorb the food given. I have often examined roots from such beds, and found most of the lower ones decayed or dying. A few new surface roots are made annually, to be killed later on by large quantities of manure, keeping the soil in a wet state, and certainly not assisting the formation of new roots. The best Asparagus I ever had was grown in soil, given an ordinary dressing of manure and double dug; sowing the seed in lines 3 feet apart, and thinning the seedlings to half that distance in the autumn. This mode of culture was adopted to all of forcing, but the plants grew so strongly that they were retained for permanent use. I fail

to see why young plants should have such large quantities of manure. Far better feed from the surface than sicken the plants before they are sufficiently strong to absorb the food.

Another great mistake in winter dressing is that it prevents the weather acting on the soil. The manure sours the soil and in many cases prevents surface roots spreading freely. Asparagus is not tender; the roots are never killed by frost if they have a covering of soil, no matter how severe the weather. If covered with manure, growth is later and not so vigorous. The beds may be made neat on the surface and tidy at the edges. By the latter I do not mean cutting down with the spade a portion of the tender roots. I am not in favour of the cutting-down process at all. I find much better results are obtained by merely having the beds defined by a slight depression. In light soils avoid deep alleys, as these cause the beds to be drained, and the side roots suffer. Beds made on the flat, or, what is better, rows of plants with a wider space at certain distances for wheeling or working between, are the best. A lot of expense is often incurred in making beds. Many think their land not suitable for the plant, but there is no difficulty in making it so. A few cartloads of fine mortar rubble, burnt garden refuse, road scrapings, or any material which makes a heavy soil porous, and for light soils a few loads of heavier material will grow good plants. Asparagus will do in most places if given sufficient depth of soil not drained to excess. G. WYTHES.

**Cauliflower Autumn Giant.**—This fine Cauliflower is often found fault with on the score of coarseness, but this in nine cases out of ten is the fault of the grower. Plants are raised early, pricked out and planted in rich, loose soil, where they grow very quickly and form large, unshapely heads. I have been cutting it during the past fortnight from a piece of ground cleared of early Peas, but not dug or manured, and the quality is excellent, nice, firm white curds, about 6 inches across, well protected by ample foliage from rain or light frosts.—R.

**Pea Autocrat.**—Too much praise can hardly be given this fine Pea. It has done splendidly with me this season, and looking round the kitchen garden at Ickworth, Bury St. Edmunds, to-day (October 25) I found that it is still being gathered almost daily, though the frost has destroyed Runner Beans and the haulm of nearly every other Pea is quite dried off. Nor is it only a late variety that Autocrat may be recommended; the quality is good enough to pass muster in July, while its deep colour and the handsome appearance of the pods make it a fine kind for late summer use.—R.

**Sutton's Drumhead Kale.**—I find this Kale of great service just at this season, and although the early winter greens have not, owing to the open weather, been so much run on as usual, the close heads are much appreciated in the kitchen. It has a very distinct appearance, the leaf-stalks broad and succulent and of a mild and agreeable flavour when cooked. After the heads are cut a plentiful supply of young shoots may be relied on all through the winter, these being much preferred here to either the Asparagus Kales or the curled varieties. If sown in March, and put out early at a good distance apart on firm ground, it is sure to be satisfactory.—S.

**A new Parsnip.**—This year I have grown Tender and True Parsnip for the first time. It is well worth growing by those who study quality. Tender and True is quite different from The Student, and may not be so much liked by those who regard size, as the new variety is much smaller than the older kind. What I so much value is the fine quality of the new kind. The roots are perfect in shape, with a clear white skin, free of irregularities, and being smaller

are very solid, and should keep well. The Parsnip has fewer varieties than most vegetables, and there was ample room for the new introduction. Many do not like coarse vegetables, and in Tender and True they will find a valuable addition to the list of useful vegetables.—G. WYTHES.

**Tomato Eclipse.**—This is a grand cropper, and what pleased me was the uniformity of the crop, there being an absence of very large, coarse fruits and very few small ones. Having noticed this variety in 1894 when grown at Chiswick and then given three marks, I determined to give it a trial when in commerce. It has done grandly, and in the open it produced excellent crops of highly-coloured fruits. I have no knowledge of its parentage, but I should think Conference was one of the parents, owing to its free-cropping and handsome medium-sized fruits; doubtless it will become a market favourite on this account. I notice there is no cracking at the stalk with fruit grown in cool houses. I have not forced this variety, but should say it would answer well grown thus.—G. W.

### KEEPING PARSNIPS.

Most growers are aware that the quality of Parsnips lifted and stored in dry sheds cannot be compared with that of those left in the soil and dug as needed. The roots stored grow out badly, shrivel, and lose flavour. Another point often lost sight of in sowing for winter supplies is that coarse vegetables keep badly; in fact, they are not worth keeping. Many, I am aware, make it a rule to sow Parsnips as early in the spring as possible; in fact, February is advised, and for exhibition roots a yard long it may be advisable, but these are not the best keepers. I usually make two sowings, my last being made early in May. These roots are left in the soil till the following spring and lifted as required. The roots are not large, but they are large enough for any purpose if quality is considered, and the flavour of roots grown in a short time is so marked that anyone who likes the Parsnip as a winter vegetable will get superior quality by this mode of culture. It is surprising what excellent roots may be grown in the shorter period named. This year I had a difficulty at the later date owing to the drought. The roots made but slow progress till August was well advanced, but now they are excellent and quite up to the usual standard. Doubtless owing to their quick growth they will be of first-rate quality. As regards keeping, many object to leaving the roots in the soil on account of the difficulty of lifting in frosty weather. A few roots may be lifted and laid in; these covered with litter are always ready for use; indeed, I have seen large breadths lifted, laid in in a north border thickly, and the land turned up roughly if needed for early crops. Plants left in their growing quarters till March can be kept sound much later if lifted then, placed under a north wall, and well covered to prevent shrivelling. The lifting at the time named causes a check and assists keeping. In severe winters Parsnips are welcomed, as there is often a scarcity of other vegetables, and frost does not affect the flavour. For late spring supplies I advise the smaller kinds. The Student and Tender and True are specially good. These are medium growers. S. H.

**Globe Artichokes in winter.**—Many can grow good Artichokes during the summer, but, owing to soil and locality, cannot with safety winter their plants. If they have a good variety it is well to take care of it, as in purchasing new stock it is not always possible to get it good. Now is a good time to pot up a few suckers for next spring, detaching the suckers from the parent plant with a small portion of root, potting up into 6-inch pots and using somewhat coarse, gritty soil. These will make nice plants for next spring, and should the old plants winter well the above work is not lost, as the young plants give later supplies and a new plantation occasionally is

advantageous. I lost all my stock a few years ago, and was unable to get home-grown plants. Many were introduced from the Continent, with the result in my case they produced prickly heads of inferior quality and were valueless. I am aware stock is easily obtained from seed, but I fear there is not sufficient care in saving seed, as many seedlings prove worthless. I find suckers treated as advised winter well in cold frames if the pots are plunged in ashes or at the foot of a south wall, and covered in severe weather with Bracken or light litter.—G. W.

**Forcing Seakale.**—In many gardens this useful vegetable has to be grown for forcing, and the first lot forces none too readily unless well-ripened crowns are selected. Frost is of great assistance in shedding the leafage, but it often happens we do not get sufficient frost in time to assist early maturing, and other measures have to be adopted. For very early supplies it is a good plan at the end of October to take up sufficient of the best crowns, those most exposed to the light and sun being preferred. The lifting causes the roots to cast any green foliage, and the check given prepares the roots for forcing. It is surprising how much more easily plants treated thus force over those lifted and placed direct into heat. For supplies, say, two months hence this may not be necessary, but at the time named I have seen strong unripened roots given much heat at the start make a very poor growth. By lifting as advised there is no waste, as the strong roots may be cut into lengths for future planting. If these are plunged in soil they will make the best material for early planting next spring.—G. W. S.

—Leafage on Seakale is now rapidly ripening, and where tidiness specially prevails may be cleared off and placed where it will decay. The roots being ready for lifting, it is practicable to get the whole, even if running into thousands, carefully lifted, well preserving the side roots in doing so; indeed, the best method is to open a good trench at one end of the breadth, and thus trench it out thoroughly. The advantage of that method is that not only are the roots so much more completely removed, but the ground is left well broken for a succeeding crop. When the stems have been trimmed of their side roots they may be laid in thickly in soil, where, should hard weather come, some litter will exclude frost, and they may be got up as needed at any time. The root-cuttings, when made, may be either planted in fresh ground at once, or be laid in thickly also.—A. D.

## BOOKS.

### MANUAL OF PRACTICAL ROOM-GARDENING.\*

This most excellent German work has been published only quite recently. The author, Herr Max Hesdörffer, who is also the editor of several German horticultural journals, has spared no trouble or expense to compile a most useful guide and reference book for amateurs. Though many professional gardeners might profit by a perusal of its pages, the book is not intended (as the author explains) for the professional, but rather for the amateur who is compelled to grow the flowers he loves in rooms, on flower-stands, in window-boxes, or on a balcony, and who may have no previous knowledge of gardening. This kind of gardening the author describes most minutely and in full detail in a book of some 500 pages, illustrated by sixteen large plates and 328 original engravings of excellent quality.

The first 117 pages deal in a general way with the various contrivances and tools required for

cultivating plants, the best arrangement of a room garden, and the various modes of propagation, watering, heating, giving air, and general treatment of room plants. This part of the book also contains directions for getting rid of the various enemies to plant life, the treatment of such plants as can be turned out into the garden during summer, the storing of plants in sheds or cellars during winter, and some most artistic arrangements for balconies, flower-stands, window boxes, glass cases, tables for flowers, various forms of hanging baskets, &c. The various stands, &c., illustrated are artistic in design, and above all intensely practical. The methods of potting, pruning, grafting (as in the case of Cactus), &c., are so clearly illustrated by good engravings, that the merest novice could not fail to grasp the meaning at a glance. Directions are also given for restoring to health plants that look sickly from some cause or other.

In the second part of the book nearly 300 pages are devoted to the description and cultivation of such plants as can, in the author's opinion, be safely recommended for cultivation in rooms. The various temperatures required by the plants are given, and will be an excellent guide for the amateur. Elaborate directions are also given for the artistic grouping of plants requiring the same kind of treatment. The illustrations throughout are faithful reproductions of the plants they represent and whose treatment is discussed in detail. Considerably over 200 capital pictures of such suitable plants appear in this part alone. Very handsomely illustrated is also the part devoted to aquariums of all kinds and sizes, most of the pictures being of a very high order of artistic merit, showing the elegant forms of plants that may be grown in a large or small aquarium in rooms. The chapters dealing with the aquarium extend to nearly fifty pages, and contain not only engravings of graceful water plants, but also illustrations of very ingenious contrivances for heating the water and methods of working a small fountain from electric and other motors. Another shorter chapter is devoted to the terrarium, showing how plants may be grown in glass cases of ornamental design. The author distinguishes between the moist and the dry terrarium. The former is intended for all kinds of Ferns, fine-foliaged plants, &c., while the latter is to be the home of various Cacti and other plants of the succulent type. Hints are also given—for those who like such things—how the terrarium may be further enlivened by lizards, small frogs, and other reptiles.

The third and last part of the book is also richly illustrated, and deals with the forcing of all kinds of flowers, and especially bulbous plants and their treatment.

Altogether Herr Hesdörffer's work deserves to be fully appreciated, and if translated into English would doubtless be a great boon to those English amateurs who are not sufficiently conversant with the German language to read this valuable book in its original form.

Elmside, Exeter.

F. W. MEYER.

**Clearing off mealy bug.**—C. Edwards can at little expense very easily keep mealy bug down by cleanliness and pure methylated spirit. My viney is about 200 feet long and 16 feet high. I generally have about 1000 bunches of Grapes yearly. The house has not been painted inside since it was built—about twenty-five years since. Therein are all sorts of Vines, Loquat, Acacia, &c. I seldom syringe, perhaps once or twice yearly, but give all roots plenty of water every week. All roots are inside the house. It is warmed by

three large stoves. About April I syringe the glass outside with a mixture of new milk and whitening, and add half water. About January I lime-white, mixed with plenty of methylated spirit and soft soap, all the walls, and also wash all the glass and woodwork inside with hot water mixed with plenty of methylated spirit and soap; then I take all the surface earth away from the borders and cover all roots with bone manure and then over that spread some 3 inches of coco nut fibre refuse. I then dress the Vines as usual and just dab a small camel's hair brush full of pure methylated spirit into all the joints where any mealy bug can be seen or expected. I have a jar of methylated spirit always in the house and at any time of year if any mealy bug is seen I at once give it a dab of pure methylated spirit. AMATEUR.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the general committee of the society was held on Monday evening, October 25, at Anderton's Hotel, when Mr. T. W. Sanders occupied the chair. The reading of the minutes and correspondence occupied some considerable attention, and after these preliminaries had been disposed of, Mr. Harman-Payne called attention to a letter received from the president of the French National Chrysanthemum Society, M. Maximé de la Rocherie, offering an invitation to the members of the English society to attend the Orleans conference on November 6, expressing a wish to see some blooms there, English cultivation. No proposal, however, was made, there being apparently nobody desirous of making the journey.

It was announced that the annual dinner of the society was fixed for Wednesday, the 24th proximo at Anderton's Hotel, and that Mr. T. W. Sanders was the chairman of the general committee, who preside on that occasion. It was also announced that the society's annual outing for 1898 had been fixed, and arrangements made with the G. E. Co. to undertake entire charge of the party. The event is fixed for July 18. Stewards for the November exhibition were elected, the following gentlemen being chosen, viz., Messrs. Langd Simpson, Taylor, Willis, Ingamels and Ree. Following an old-established precedent, the committee have invited members of the floral committee to dine together on the evening of the day on which they meet, namely, December 13, in consideration of their services to the society.

The dates of the society's shows for 1898 are proposed as follows: September 6, 7 and 8, October 11, 12 and 13, November 8, 9 and 10, December 6, 7 and 8. The secretary then presented a rough financial statement concerning the cost of sale of the society's Jubilee edition of the catalogue, which was, considering everything, regarded as satisfactory; the demand is steady, and it is expected that there will be a good demand for this work during the present season. Mr. Bevan called attention to the fact that at present there was no catalogue committee in existence, and having been elected early in the year, and thought this was a matter that should be settled without delay.

Thirty-one new members were elected and following societies were admitted in affiliation: Wolverhampton Chrysanthemum Society and Romford Society.

A meeting of the floral committee of this society was held on Monday afternoon, October 25, at T. Bevan in the chair. There was a good display of novelties. First-class certificates were awarded to the following:—

CHRYSANTHEMUM LADY HANHAM. — A lovely rosy-fawn sport from Vivand Morel, and partaking of all the excellent qualities of the parent. The blooms from late buds were very pretty, and it promises to be the most interesting of

\* "Handbuch der Praktischen Zimmergärtnerei." Von Max Hesdörffer. Published by Robert Oppenheim, Berlin.

Exhibited by Messrs. H. Cannell and Swanley.

**CHRYSANTHEMUM MRS. PROBYN.**—A pale flesh-Japanese incurved flower, with paler reverse; petals of great breadth and substance, pointed, and evenly incurving to the centre. This is a form of lovely form and elegant and delicate coloring. From Mr. Norman Davis, Framfield.

**CHRYSANTHEMUM PRIDE OF THE MARKET.**—This was exhibited as a market variety, and should be valuable for that purpose. It is a form of medium size with rather broad florets. The colour is golden-yellow, freely suffused with a dash of crimson at the base. Several vases, each filled with about a dozen blossoms, made a most effective exhibit. Shown by Mr. N. Davis.

**CHRYSANTHEMUM MME. PHILIPPE RIVOIRE.**—A large pure white flower, with broad florets of splendid substance, slightly twisted and curling, making a promising bloom. Those from early buds are inclined to be coarse, later flowers being somewhat free from this only blemish. From Mr. W. J. Godfrey, Exmouth.

**CHRYSANTHEMUM ELLA CURTIS.**—An immense flower, very much resembling in form the old *Bois d'Or*, but a distinct improvement upon that variety; florets broad and strap-like and intermingling in a pretty manner; colour rich yellow, with reverse of a lighter shade. Exhibited by Mr. W. J. Godfrey.

**CHRYSANTHEMUM LADY RIDGWAY.**—An enormous flower of Japanese incurved form, with broad and massive florets; colour rosy red inside, with light bronze reverse. Shown by Mr. W. J. Godfrey.

**N.C.S. Jubilee**, a Japanese incurved, colour pale-pink with paler reverse; Gladys Roul, a chin white reflexed Japanese with narrow florets; Geo. Gover, a large mauve-pink Japanese with long broad petals, in the way of *Reine d'Arleterre*; King of Yellows, a deep rich yellow incurved flower; Werther, a reddish purple flower, with florets of medium width; Nellie Brown, a crimson and golden yellow sport from *White Glory*; Mrs. G. W. Palmer, a rosy white sport from Mrs. C. H. Payne, and distinctly better than the parent variety; G. J. Warren, a self pale yellow sports from the popular *Mme. Carnot*, and Mme. Desblanc, a Japanese flower, with long narrow florets, colour pale mauve-pink with a white reverse, were other good varieties shown.

The floral committee of this society met at the Royal Aquarium, Westminster, S.W., on November 1st. Mr. Thos. Bevan in the chair.

A great many novelties were submitted, and a large number of certificates were awarded to—

**CHRYSANTHEMUM G. J. WARREN.**—This is a pale white sport from *Mme. Carnot*, and late flowers appear in colour in the centre. The flowers partake of all the other characteristics of the parent variety. From Mr. W. Wells, Earlswood.

**CHRYSANTHEMUM MRS. G. W. PALMER.**—A rich rosy white sport from Mrs. C. H. Payne, with a white reverse to the broad florets. It is a distinct advance upon the parent variety, late flowers being very rich in colour. From Mr. W. J. Godfrey.

**CHRYSANTHEMUM LADY ISABEL.**—An immense flower with broad florets of good substance; colour pale blush, with white centre, late flowers being of a beautiful pale flesh-pink. From Mr. W. J. Godfrey.

**CHRYSANTHEMUM LENA WEE.**—A distinct flower of spreading form, with long semi-fluted florets of good substance and incurving at the tips; colour intermediately edged with pale violet-rose. From Mr. Gerbeard, gardener to Sir Henry Peek, Bart., London Common.

**CHRYSANTHEMUM MRS. F. A. BEVAN.**—An immense Japanese with long florets of medium drooping and incurving at the ends; a pleasing shade of flesh-pink, with paler reverse. Sent by Mr. W. J. Godfrey, Exmouth.

**CHRYSANTHEMUM GEORGE FOSTER.**—Massive incurved Japanese of pleasing form, with broad-

tightly incurved and twisted florets; colour rich yellow. From Mr. Godfrey.

**CHRYSANTHEMUM MRS. CHAS. BIRCH.**—Another deep, compact, incurved Japanese, with florets of medium width and tightly incurving. The florets also are hirsute; colour white, slightly edged pale rose. Mr. Godfrey.

**CHRYSANTHEMUM MARY MOLYNEUX.**—A large spreading flower, with long, broad, incurved and curled florets of good substance; colour inside deep rosy pink with a pretty reverse of silvery rose-pink. From Mr. N. Molyneux, Rookesbury Park, Fareham.

**CHRYSANTHEMUM MRS. N. MOLYNEUX.**—Massive incurved flower, of globular build, with fairly broad florets, somewhat irregularly arranged; colour creamy white. Also from Mr. N. Molyneux.

The committee commended N.C.S. Jubilee, a large flower, with florets too short for the quantity there are to develop; colour silvery mauve. From Mr. Wells. They wished to see again Mrs. P. R. Dunn, a pretty Japanese Anemone, with well-formed disc, slightly tinted yellow, and ray florets of the purest white, and Thos. Singleton, an incurved of very fair form, colour pearly white, edged rose-pink.

Other varieties deserving notice were Mrs. C. S. Bates, a bright nankeen-yellow incurved; Mrs. Coombes, long florets, curling at tips, colour pale flesh-pink, deep rose centre; Admiral Ito, a very large Japanese, colour straw-yellow, with slightly twisted and curling florets, making a bloom of much substance; and Beauty of Adelaide, large spreading flower with long fluted florets, incurving at the ends, colour pale rosy pink.

**Royal Horticultural Society.**—The next fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, November 9, in the Drill Hall, James Street, Westminster, 1 to 4 p. m. At 3 o'clock a lecture on "Roots" will be given by Professor F. W. Oliver, D.Sc.

**Royal Gardeners' Orphan Fund.**—At a meeting of the committee of the Royal Gardeners' Orphan Fund on the 29th ult., the secretary announced the receipt of a bequest of £457 2s. 11d. from J. W. Thomson, late nurseryman at Haywards Heath; also the following donations, for which the special thanks of the committee were accorded: Rev. A. Lowe, Rangemore, Burton-on-Trent, proceeds of a collection at harvest festival, £6 1s. 6d.; Sandringham Estate Cottage Garden Society, £5 5s.; Wimbledon Horticultural Society (sale of flowers), £5; Uckfield Chrysanthemum Society (sale of flowers), £3 3s.; J. Selway, Betteshanger, £3; per F. Roberts, local secretary, Ramsgate, £2 1s.; Forest Hill Horticultural Society, £1 10s.; Hesse and District Horticultural Society, £1 4s. 3d.; Bradford Paxton Society, £1 2s. 6d.; C. Herrin, Maidenhead, £1; G. Carpenter, Byfleet, 10s.; J. Dunkin, Warwick, 10s.; M. Kneller, Basingstoke, 8s. It was decided to hold the annual meeting at Anderson's Hotel, Fleet Street, early in February, when the election of children to the benefits of the fund will take place. The necessary nomination forms may be had on application to the secretary.

**The weather in West Herts.**—The weather remained warm until the 2nd inst., but since then the day temperatures have fallen considerably. On October 29 and 30 the temperature in shade rose to 63°, a very high reading for so late in the month. The daily range in temperature has also been very remarkable for the end of October, the difference between the highest and lowest temperatures in the thermometer screen amounting on two days to respectively 29° and 30°. The temperature of the soil both at 1 foot and 2 feet deep remains about a degree warmer than is seasonable. No rain fell during the week, but on several mornings there was a measurable quantity of water in the rain-gauge yielded by fog. On two days the mean rate of movement of the air fell short of a mile an hour. There has been lately a splendid record of bright sunshine for the time of year, the

average duration for the last six days reaching nearly five hours a day. October proved very warm, particularly the latter half of it. Taking the month as a whole, it was the warmest October since 1893. That month is usually the wettest of the twelve, but this year less rain fell than in any October during the last forty-two years, with the exception of 1879, when the total rainfall was very nearly the same. The sun shone on an average for three and three-quarter hours a day, which is the best record for the month since 1893. During the twelve years over which my wind observations extend there has not occurred any other October so calm.—E. M., *Berkhamsted*.

NOTES OF THE WEEK.

**Erica ciliaris purpurea.**—Broad patches of this in the upper portions of the rock garden at Kew are now very showy. It is certainly a fine plant for such positions, or again for a belt to a bank of *Rhododendrons*.

**Stobæa purpurea.**—This striking plant is still giving its picturesque blossoms, and though not showy when compared with many flowering plants, possesses an individuality of its own as much in the flower-heads as in the distinct Thistle-like habit of the whole plant.

**Sidalcea malvæflora atro-purpurea.**—The late spikes of blossom of this plant are now very showy, and since so little of colour remains in the garden, the tall spikes 3 feet high are readily seen. Like the other members of this race, the above is free-flowering and suitable for rock garden or border.

**The Gentiella (Gentiana acaulis).**—This autumn in certain localities this is making quite a pleasing display. The past few days, however, in the London district with its dense fogs have not assisted the flowers, but in more favoured spots the autumn buds open in a very charming manner and are always welcome.

**Polygonum sphærostachyum.**—One very surprising characteristic of this striking plant is the great length of time the spikes of flowers retain their brilliant colouring. Even a few spikes make quite a display. This species, however, does not spread with the freedom of many kinds, so that it will not be a common plant as yet.

**Chrysanthemum Souce d'Or.**—Though one of the oldest of *Chrysanthemums*, this is still a most beautiful one, if not indeed unique, by reason of its colour. The blossoms, of medium size, are produced in large sprays on stiff stems, that render them particularly useful for vases. It grows freely, and amateurs will find this variety still of sterling worth.

**Gazania splendens.**—Possessing a hard constitution, or at least in a greater degree than most summer flowers, some large patches still in the open have been crowded with their brilliant flowers during the past few days. Particularly fine is a large group near the entrance to No. 7 house at Kew. The plants had quantities of fully expanded flowers on them a few days since.

**Rhododendron Princess Alexandra.**—Among the greenhouse species, particularly such as flower during autumn and winter, very few can equal this in point of freedom. Once it begins to flower it is pretty sure to continue for at least three or four months in succession. The blossoms are white, flushed with rose-pink, and are produced rather freely in terminal bunches.

**Primula japonica**, in several shades of colour, and *Primula capitata* are still flowering at Kew. The latter species is by no means uncommon as an early autumn flower, especially where the plants have not grown freely during the heat of the summer. Both species are welcome at any time of the year, though the Himalayan kind is not the most reliable of the species in all soils or gardens.

**Crocus cancellatus var. cilicicus.**—The type here mentioned with its beautiful variety are among the most charming of the autumn-flowering Croci. The Cilician form is now flowering in the rock garden at Kew, and very effective it is in the pretty patches of colour here and there. The blossoms are large and of a pleasing pale blue shade when fully expanded, the orange anthers very conspicuous.

**Achillea Trautmanni** is a neat and pretty species, with deeply cut and long linear leaves after

the manner of the taller *A. serrata*, which, however, attains nearly or quite 3 feet high. The above species, a native of Austria, is scarcely more than 6 inches or 8 inches high, having umbels of pure white flowers above the very dark green tuft of leaves. It is now bearing a few delicate sprays of its pure white flowers.

**A mild season.**—At the Exmouth Chrysanthemum show held last week (October 28 and 29) *Nasturtiums* formed a portion of the flowers used in the table decorations, whilst single and Cactus Dahlias and Sweet Peas were exhibited by Mr. W. J. Godfrey. French Beans and green Peas, as well as cut-door Tomatoes, were exhibited in collections of vegetables grown by cottagers.

**Polygonum affine.**—Though the actual flowering of this attractive species is past, there is still an equally good effect from the well-coloured spikes of flowers and the richly as well as variously coloured leaves. Any plant serving a two-fold purpose in such a way as this certainly merits general cultivation. Those who trim the flower-spikes from this plant the moment the blooms have lost their first beauty should in future wait to see its effect in autumn.

**November flowers.**—We send you herewith a few blooms of French Marigolds and single Cactus Dahlias to show the extreme mildness of the season at this date. These were all grown in an open and exposed situation, the Dahlias on a low and the Marigolds on a higher level. Of Marigolds we have about 15,000 in full bloom still.—DOBBIE & Co., Orpington, Kent.

\* \* Very bright and pretty.—Ed.

**Calceolaria amplexicaulis.**—After thirty years' experience of the value of *Calceolaria amplexicaulis* in a west of Ireland garden, where it flowers freely, irrespective of weather, from the time of planting out—beginning of May—until now—beginning of November—I can fully confirm all that "A. D." (p. 316) says. The bed is still a lovely mass of primrose colour, as in early summer. No golden *Calceolaria* can at all rival it in growth and beauty.—E. F. G.

**Polygonum vaccinifolium.**—Now that November has come, garden flowers become scarce. I do not think *Polygonum vaccinifolium* is grown enough. The pale pink flowers are very pretty in a large bed, which the plant being so free a grower soon covers. A group in our rootwork here, of about 4 feet across, trailing down to some large early Hellebores in flower, with a background of large Holly Ferns as green, has a very good effect.—GEORGE F. WILSON.

**Aster diplostaphioides.**—Though one of the very largest so far as the flower-heads are concerned, this very desirable species does not appear to be generally cultivated. In the manner it springs from the soil the plant more resembles some of the varieties of *Erigeron speciosus*, yet not producing the free tuft of leaves. It is a native of the Himalayas and attains 2½ feet high, the blossoms usually solitary, each fully 3 inches across, the ray florets of a purplish-blue shade, the disc purple.

**Chrysanthemum Miss Rose.**—Though little more than 15 inches high from the pot, this is among the showiest of all its race. The blossoms, each not more than 2 inches across, are of a lilac hue and produced in great numbers, the little bushes being completely hidden by the flowers. The shade of colour is pleasing, and rendered more attractive by the lighter centre that prevails in so large a number of the blooms. A large number of plants is now in bloom in the greenhouse at Kew.

**Rose Marie van Houtte.**—This lovely variety is flowering abundantly this autumn, and this in spite of the October frosts that were severe in some localities. Owing to a fine dry time since as much as during the attack of frost, a large array of beautiful flowers has resulted. Good sorts such as this are most valuable for carrying on the season and cannot be too well known. The combined pale yellow and rosy-blush tint at this season is charming.

**Leucojum (Acis) autumnale.**—All who have grown this chaste little autumn flower will agree with what Mr. Arnott has said concerning it recently in THE GARDEN. At times the hardy bulb specialist grows this pretty plant in pots. With several bulbs together and established in this way it is quite easy to transplant bodily. Let it be so planted in good soil that it may remain three or four years, and in the meantime, by saving the seeds that are usually produced each

year, a nice stock will result. It is a charming little plant and one scarcely known.

**Gesnera amabilis.**—The value of this beautiful autumn and winter-flowering species was amply illustrated at the Drill Hall quite recently by some well-flowered examples from Trentham. Though grown in moderately-sized pots, the plants were freely flowered, the blossoms borne in a large pyramidal panicle of a cream-yellow shade, the throat of the drooping flowers almost golden. Quite as attractive in this as in many others of the genus is the beautiful and handsome foliage, in this instance of a dark bronzy hue. Such well-grown plants are valuable at this season and are worth every attention.

**Tricyrtis pilosa.**—An appropriately named species with large ovate acuminate leaves, decidedly downy on both surfaces. Not only is this species distinct in its rather woolly leaves, but equally so in the prettily-marked blossoms, the latter white and freely covered with blue-mauve spots, a yellow blotch appearing at the base of the segments. The species is, perhaps, the most elegant of this small genus and one of the most freely flowered, the blossoms appearing freely in terminal heads and likewise in the upper axils of the leaves. It comes from the Himalayas and is now flowering in the Royal Gardens, Kew.

**Saxifraga Fortunei.**—Though fairly hardy in certain aspects, this valuable species is not sufficiently so in all positions and soils to make it a reliable plant. Very frequently the roots will manage to survive a spell of cold weather, but as a rule the plants are so weakened thereby that their flowering is uncertain. It is better to face the facts and not expose all the stock of a valuable and by no means common species in the open garden. At Kew the plant is grown largely in pots for the embellishment of the greenhouse, for which it is well suited. It is now in flower, the large panicles of white blossoms being very attractive.

**Good Peas in November.**—I send you a box of Sutton's Late Queen Pea to show its excellent quality as a late autumn Pea. I have at the present time (November 2) a good crop, and the haulm is still in full bloom, which you will see by the enclosed. I shall continue gathering if the weather is favourable for another month.—A. G. HOOKINGS, *The Gardens, Olddown House, Almondsbury, Glos.*

\* \* Excellent Peas for any season, and very welcome in November. Why we should not sow more late Peas is a question should be asked in every garden, as the best of the Pea season may in some years be the autumn. Several sowings should be made in July.—Ed.

**Aster grandiflorus.**—Only very rarely is it that one sees this lovely perennial Aster in good condition in the open garden. In certain warm seasons a few blooms expand, sufficient indeed to make one crave for more of such beautiful late flowers. It may be—and indeed is—grown in pots in the greenhouse, as at Kew and elsewhere, but under glass the flowers quickly lose the fine depth and richness of colouring that are seen when naturally grown. The plant has a singularly neat, elegant habit, and when well flowered is one of the finest of the late hardy plants to bloom. Deep and good soil is needed for full development, though more important still is a warm position that will forward the growth in summer.

**Cosmos from Ireland.**—We have had no frost yet to cut down Dahlias; hence the varieties of *Cosmos* are very beautiful. Supposing the *Cosmos* never flowered, the foliage is very beautiful. For table decoration, blended with the leaves of *Prunus Pissardi*, *Liquidambar*, *Parrotia persica*, &c., the effect is very unique. The single Cactus Dahlias are equally useful in small glasses. I also send a few blooms of Mary Anderson Chrysanthemum from two-year-old plants grown naturally.—W. BAYLOR HAETLAND, *Ardeairn, Cork.*

\* \* Very pretty, graceful plants. Some buds we cut and put into water a week ago have

opened, and now are as fresh as on the plan—Ed.

**Flowers in the Isle of Man.**—I send you with two boxes of flowers cut this day from the open. The list includes *Gladioli*, *Dalys*, *Kniphofias* (space permits small spikes only, *Leichtlin's Triumph* is included), *Fuchsias*, *Cerise*, *Veronicas*, *Lilies*, *Begonias*, *Sweet Peas*, *Spiraea Anthony Waterer*, *Etealea palmata*, *Mignonette*, *Nasturtium*, *Hydrangea*, *Ceanothus* and *Chrysanthemums*.—R. OKELL.

— I herewith send you a box of flowers cut at random from the open on November 1. We have a good display all round yet, which is some at exceptional. The gathering includes *Sweet Peas*, *Chrysanthemums*, *Nasturtiums*, *Dahlias*, *Roses*, *Salpiglossis*, *Pentstemons*, *Corndrops*, *Caffre Lily*, *Anemones*, *Begonias*, *Leopard's-bane*, &c.—JAMES INGLIS, *The Gardens, The Nursery, Isle of Man.*

\* \* Numerous and beautiful flowers in the state for November.—Ed.

**The Jasmine Nightshade (Solanum jasminoides).**—I am glad to hear this plant so highly spoken of. It may not be generally known, but it does well and flowers freely in a north house. One is often asked to recommend a plant suit for the roof or back wall of a north house fernery. *Solanum jasminoides* will be found useful for this purpose. Some time ago I tried a house facing north into a cool fernery, planting this *Solanum* against the back wall. Here it most luxuriantly. It very soon covered the roof and I trained it down the rafters, and now the entire roof is covered with it, and at the present time (November 1) it is carrying a large number of pure white blossoms, which are useful for bouquets or for house decoration. It does well in a mixture of leaf-mould and loam, likes plenty of water in the growing season, if kept rather dry in the winter will stand several degrees of frost with impunity.—T. B. F. *Ashwellthorpe Hall, Norfolk.*

**Outdoor Chrysanthemums.**—There is a remnant left who will not fall down and woe the giant *Chrysanthemum*—charming as a mop upon its handle or as a Cauliflower on its stalk. To these belated lovers of Nature as opposed to the monstrosities of the growers the outdoor *Chrysanthemum* appeals, and we have in wonderful late autumn had an unusual character admiring it. The outdoor trials at Chiswick must be hailed with delight by all lovers of door flowers, for the bedding rage of twenty to thirty-five years ago drove the outdoor *Chrysanthemum* practically out of cultivation. It was when there was an outdoor show of it in the Temple Gardens, and bright and gay the pot plants and the reflexed shone among their smoky roundings. Happily, a taste for more natural things is again among us, and the Chiswick trials are a sign of it. One thing is wanted—a race of single outdoor *Chrysanthemum* to flower, in fairly good years, between September 15 and November 9. They would be our usual deluges of rain, interspersed with fogs and frosts, much better than the deluges of flowers. The colours, too, would form a delightful contrast to the blues, whites and purples of the Starworts, while single flowers would mix better with the latter than double ones. If florists, as seems probable, are raising many outdoor *Chrysanthemums*, let them refrain from throwing away early singles. They will assume their reward if they keep them.—J. I.

**Names of plants.**—*Geo. Smith.*—1, *Isoetes macrospora*; 2, *Pteris longifolia*; 3, *Selaginella selaginoides* probably *caesia* if of a peacock blue colour, but cannot say for certain from such poor specimen; 4, *Alisma plantago-foliosa*; 5, *Lastrea dilatata*; 6, in the absence of fruitification cannot identify. Send better specimen or portion of frond with spores or fruits on. *J. H. W. Thomas.*—The common Bryony.—A. 1, *Picea Nordmanniana*; 2, *Abies Menziesii*; 3, *Rubus androgynus*; 4, *Lycocystis formosa*. We cannot undertake to name four specimens in one week.

## ORCHIDS.

### PHALÆNOPSIS LOWI.

Orchids have a worse character as garden plants than this, and I was rather pleasantly surprised to come across several fine plants of it in bloom recently. Doubtless this species is almost strictly deciduous in a state of nature, and although I have always had an idea that the plants were best kept slightly on the move, the specimens in question had been differently treated. No water was allowed after the last of the blossoms were past, which was usually in the early part of December, but the plants were kept in a warm, moist house during the winter. Most of the plants lose the whole of the foliage, one or two would retain, perhaps, a single leaf. All were treated alike, however, and as soon as the first signs of activity appeared in February, the temperature was increased and the plants were given a thorough soaking of water. No more was given until the plants were getting on the dry side again, but as the season advanced and root action with it, the moisture was more freely applied. The majority of the plants put on about five leaves during the summer months, and all of them flowered at various times in October and September. This is the routine that has led in this country to success, but one or two points may be considered before one allows that this treatment is correct, or should be followed. The plants have not, I believe, been very long under cultivation; consequently they still retain a good deal of the latent vigour of their native habitat. This would enable them to stand with impunity a check that plants long acclimated could not. The house, too, where they were grown doubtless suited them well; it obtained many choice *Cypripediums* and a collection of Australian and New Guinea *Dendrobiums*, and was, therefore, kept much warmer than the usual *Phalænopsis* house. This would of course prevent the compost from

drying so rapidly or thoroughly as would be the case under different circumstances, and all these points need consideration. Certainly the plants, after a decided resting period, come away very vigorously. The same thing is seen in many other genera and species, and wherever the rest is thorough, and spread over a season of at least two months, I am quite sure the plants are more likely to bloom freely. But the rest must not be so prolonged as to weaken the plants, and if after trying it one season and finding the plants start in spring with decreased vigour, I should certainly not repeat the experiment. The rooting medium for *P. Lowi* should be carefully arranged. I used to grow it on wood blocks without a particle of Moss, these being sunk into pots filled with water. Enough moisture found its way up the blocks to keep the foliage green during winter, and these plants were the most satisfactory I ever had under my care. I have lately seen it thriving in small wooden baskets, about three or four plants in each, and these when in flower were very bright and effective. But in any case the thinnest possible compost should be given and a few lumps of limestone used in place of the crocks for drainage, and also mixed with the Sphagnum Moss, will be found of benefit. While growing freely a very brisk moist heat is necessary, and although the plants like a clear light the rays of the sun must be well broken up by the use of suitable blinds. Insects are not usually troublesome, and are easily kept under by the usual means. *P. Lowi* is a very dwarf species, almost stemless, with leaves about 4 inches in length on strong plants. The spikes of flower rise in autumn to the height of 15 inches or 18 inches, and the individual blossoms are about 2 inches across. The sepals are very narrow, the petals much broader, rosy white, with a suffusion of purple at the base. The lip and column are purple, the latter much elongated, and arching over the former. It is a native of Moulmein, where it was discovered by the Rev. C. S. Parish—recently deceased—and sent by him to Messrs. Low in 1862. R.

### MASDEVALLIAS.

THERE are few species of Orchids that make a finer display or are more admired than *Masdevallias*. Yet how seldom do we meet with them well grown. They are either found huddled together at one end of a house as if of no consequence, or maybe they have become so disfigured with the black spot, that they do not present a respectable appearance. I am sorry to say the latter cause is often put forward as an excuse for failure. This is to be regretted, as with a little forethought and attention, the spot, if not totally destroyed, can be considerably diminished. My experience in this matter is, that the spot is usually caused by the combination of two things, viz., subjecting the plants to too low a temperature and keeping them too wet at the roots. I think the temperatures usually accepted for *Masdevallias* during the dull and cold winter months are far too low. The temperature I have found most suitable to their requirements is about 50°. This is for *M. Harryana*, *M. Veitchi*, and others, both species and hybrids belonging to this section. If the temperature falls much below this for any length of time, the dreaded spot usually makes its appearance. It is better to maintain a few degrees over 50° than under, as it affords opportunities of bringing the ventilators into use, thereby helping to maintain the desired condition of the atmosphere. I usually pot the plants in the month of September, as they at that time commence growing. They soon get hold of the new material and quickly become established, which it is desirable they should do before it becomes necessary to resort to the use of fire-heat. If the plants are kept in a fairly dry condition through the dull winter months, the young growths do not make their appearance to any large extent until there is a prospect of brighter weather and the return of spring. The plants, having then the benefit of good material in which they have become established, grow away freely. I have only dealt with the cool and most attractive section. There are many more interesting species, such as *M. tovarensis*, *M. Schroederiana*, *M. macrura*, *M. Ehippium*, *M. gargantua*, *M. leontoglossa*, *M. Shuttleworthi*, and the many members of the *M. Chimæna* section, that require an intermediate house temperature during the cold months of the year. These are

always attractive when in flower. I usually leave the potting of this section until the spring.

HY. J. CHAPMAN.

**Vanda Sanderiana.**—The remarkable plant of this species which was exhibited at the Royal Horticultural Society's meeting at the Drill Hall on October 13 last year, on which occasion it was awarded a gold medal, is now again flowering in Mr. Gurney Fowler's collection at South Woodford. It has at the present time nine spikes of bloom, which are in fine condition. The colour, no doubt owing to the bright season, is finer than last year. The flowers, on the whole, are larger, and the plant is in good condition.—H.

**Cattleya labiata glauca.**—This is a desirable variety, and was recently noted in flower in the collection of Mr. J. Bradshaw, The Grange, Southgate. The sepals and petals, of fine form and substance, are delicate rose, the front lobe of the lip of a distinct deep mauve shade of colour. The side lobes are pale rose, shading to yellow, lined with purple at the base. It is a recently-imported plant, and one of the most pleasing and beautiful varieties we have seen.—H. J. C.

**Mormodes pardinum.**—This lovely and interesting species is a native of Mexico, and first flowered in Mr. Bateman's collection in 1838. The flowers have a faint perfume. The ground colour of the twisted flowers is light yellow, heavily spotted with chocolate-red. They are produced on dense spikes, each upwards of 1 foot in length. A considerable number of this species and its variety unicolor was recently in flower in the nurseries of Messrs. W. L. Lewis and Co., Southgate.—C.

**Lælia purpurata var. Mrs. R. I. Measures.**—This lovely form has flowered in the Cambridge Lodge collection. The sepals are white, slightly suffused with rose, the petals white, suffused with deep rose and heavily veined from the tip to the base with the deep crimson-purple of the lip, the front lobe of the lip being deep purple, heavily veined with velvety crimson. The plant bore three spikes, with an aggregate of ten flowers. It is one of the most distinct and beautiful forms we have seen.

**Cattleya Bowringiana lilacina.**—Though not so showy as the typical form, this variety is very delicate and pretty. A nice plant of it at Camberwell is now in flower, the blossoms being of medium size, the sepals, petals, and ground colour of the lip being of a uniform lilac-rose tint, the blotch on the front of the lip replaced by a purplish suffusion and the centre creamy yellow. It is unfortunate for metropolitan growers that this fine plant flowers so late in the season, as the blossoms are among the first to show the evil effects of the fogs now so prevalent.

**Dendrobium Phalænopsis.**—This popular Orchid is flowering freely this season, and I have noticed many fine forms of it in several collections around London. Mr. W. Bull has a fine stock of it in many charming varieties, these including both the deeply tinted purple-lipped forms and the more delicate pale tinted ones, such as *D. P. bellum* and *D. P. delicatum*. All are very useful at this season when such a demand for choice cut flowers for all purposes exists. It is no use attempting to grow this plant without plenty of heat and moisture, but given these and due attention its culture is not difficult.

**Angræcum bilobum.**—A nice lot of plants of this chaste and pretty species was recently flowering in Mr. Bull's nursery where it is well cultivated. The species seldom exceeds half a foot in height, the leaves are short, deep green, and the scapes droop prettily from between these. About a dozen flowers occur on each, these being pure white on the sepals and petals, the elongated spur sometimes tinged with red. *A. bilobum* is a native of Sierra Leone and other parts of Africa and thrives well in strong heat while making its growth. Small baskets or pans are the best re-

ceptacles for it, the compost consisting of clean Sphagnum and charcoal.

**Restrepia Lansbergi.**—This plant has become rare in Orchid collections, not being a large or very showy species. It is, however, very beautiful, and, as I noted recently at Cambridge Lodge, very free flowering. It is a dwarf growing plant, the flower-stems being thrown only a little above the leaves, and the blossoms are bright orange-erimson, spotted with a deeper tint. The sepals are very delicate in texture, so much so as to appear semi-transparent. It is a native of Caracac, and delights in a mild and moist climate the whole year round. It was discovered and sent home by M. Wagener in 1850.—R.

**Cattleya labiata autumnalis var. lilacina.**—This very distinct variety has recently flowered in the Cambridge Lodge collection from a batch of imported plants. The sepals and petals are of the average size, but of a distinct pale lilac colour. The lip is the most distinguishing feature, the front lobe being of the same colour as the sepals and petals, with two distinct white blotches at the base. The rich purple of the front lobe characteristic of the type is entirely dispensed with. The side lobes are a shade darker at the top than the front lobe, becoming suffused with yellow and brown at the base.—C.

**Cypripedium Allenianum superbum.**—The best form of this rare hybrid I have ever seen was recently in bloom at Cambridge Lodge, where it was raised by Mr. Chapman. It is far before the typical *C. Allenianum*, the dorsal sepal being nearly 3 inches wide, white at the apex with the median line as in *C. Spicerianum*, and a rosy suffusion at the base. The petals are light green, the pouch deeper, and all are heavily suffused with brown. It makes a most beautiful and refined flower, one of the finest of hybrids in existence, and is the result of crossing *C. Spicerianum* and *C. Curtisi*.—R.

#### DENDROBIUM AUREUM.

The presence of this pretty species in flower is at once apparent in a house, the delicate fragrance being quite distinct from that of any other *Dendrobie*. It is flowering now in many collections, and where plenty of plants are grown will continue in bloom over several months. *D. aureum*, although not a very showy species, is noteworthy from the fact of its being one of the parents of several of the finest hybrid *Dendrobie*s in existence. It is too well known to need any description, but a line on its culture might be interesting to beginners. Not being a very large grower, the receptacles used for the roots should be of medium size only, and I have found nothing better than the ordinary make of pot or small hanging pans. The compost may consist of the usual peat and Moss mixture, about an inch of this over good drainage sufficing for ordinary sized plants with two or three leading bulbs. Frequent disturbance is unnecessary and harmful; in fact, the plants may be in the same pots for a dozen years provided the old material could be got away and new substituted. But in the ordinary course once in three years is quite often enough to renew the compost, and considerable care is needed in removing the plants from the old pots, the roots, if they have done well, usually having a firm hold upon them. Remove all dead roots and sour or decayed compost without damaging those that are fresh and alive more than can be helped. Bed the new material firmly about these, and fix the plant with the base of the last formed pseudo-bulb just resting on the top of the compost, this being trimmed off neatly in the form of a rather flat cone. The best time to repot is after the flowers are over and the young growth is forming, but before this commences to root independently. The young roots then give the plants a good hold upon the new material. After repotting, place the plants in a warm, moist house and give only a very little water until the roots are taking a good hold of the soil. A light, sunny position and abundance

of atmospheric moisture is now required, supply to the roots being increased by dew until the young pseudo-bulbs are fully developed when the plants should be taken to a light, sunny, and rather dry house, there to ripen rest until the flower buds appear. *D. aureum* is one of the most widely distributed *Orchids* occurring over an immense area in Asia. It has been collected by scores of different Orchid seekers, but first of all by Gibson, who found it growing in the Khasia Hills, and sent it home in 1837.

#### SHORT NOTES.—ORCHIDS.

**Masdevallia glaphyrantha.**—This hybrid was recently in fine flower at Cambridge Lodge, where Mr. Chapman grows it well in company with the *M. Harryana* and similar kinds. The tube of the flower is brownish-erimson, the sepal yellowish with a purple border, the lower purple beneath with golden-yellow tails.

**Catasetum colosum.**—This species is seldom seen, but I noticed last week a fine spike bearing ten flowers in Mr. Bull's nursery. The sepal petals are a light sepia-brown, the lip broadly shaped at the base, the front lobe elongated, narrow, bright green—a very peculiar combination of colour. It is a native of La Guayra, whence it was introduced in 1840.—H.

**Cypripedium Arthurianum.**—In this hybrid we have a striking example of the potency of the old *C. usigne* as a parent. The sepals, petals, and pouch come very near in colour to some of the *usigne* varieties, but the drooping recurved petals remind one of *C. Fairricanum*, its pollen parent. The plant was raised in Messrs. Veitch's nursery Chelsea, only one plant, it is said, resulting from first sowing.

**Oncidium crispum grandiflorum.**—A plant of this with eighty-three fully expanded flowers on one spike. There would have been about 100 more, but they got rubbed off. Is that good? A *Dendrobium formosum giganteum* has ten flowers on a spike.—H. KRUSE.

\*\* Yes, very good indeed. We do not remember ever having seen a larger number of flowers on one spike, and a note on your method of culture would be interesting. The *Dendrobium* is good, but not unusual.—Ed.

#### AMERICAN NOTES.

[From *Garden and Forest*.]

**THE NEWTOWN PIPPIN APPLE.**—The first of this season's fruit, from Virginia, were offered here last week and sold mainly for export at from 5 dols. to 8 dols. a barrel. Owing to the weather during the past month there is second-grade fruit in this crop than was expected. This means smaller Apples, lower prices, according to experience in other years, and keeping qualities.

**FILBERTS.**—Cultivated Cob Nuts, or English Filberts, have been imported within the week from Kent, England. These fresh nuts are sold in their husks, and fifty cents a pound is willingly paid by those who esteem delicate meat. Chestnuts, from cultivated trees in New Jersey, sell for forty cents a quart. Eighteen of these immense Nuts weigh a pound and two dozen fill a quart measure. Some of the largest weigh 2 ozs. each.

**LYCORIS SQUAMIGERA.**—This noble flowered Chinese *Amaryllis* grows in California with surprising luxuriance. It is freely used at Golden Gate Park, at San Francisco, where it grows without irrigation, increasing rapidly and produces in September abundant flowers 3 feet or 4 feet high. It is more vigorous and beautiful, and apparently much more hardy here than in the Eastern States, where, however, it is perfectly hardy.

**THE CANADIAN YEW** (*Taxus canadensis*) is a low shrub, with nearly prostrate, wide-spreading

branches, and is a common inhabitant of northern woods, often covering large areas of moist soil in their dense shade, and is distributed from Newfoundland to Lake Winnipeg and southward to Virginia and Iowa. This course, a perfectly hardy plant, although it thrives in moist, shaded soil, and it can be used more frequently than it is to be the grounds in parks and gardens.

*YEW CUSPIDATA* inhabits Manchuria, Corea and the island of Yezo, where it is widely scattered through the forests of deciduous trees, and where it often rises to the height of 50 feet with a tall, straight stem freely 2 feet in diameter. In Japan this Yew favourite garden ornament, being one of the plants most generally cut into fanciful shapes, for, like the other species, it can bear shears. It was introduced into the eastern United States in 1862, and has proved to be perfectly hardy as far north at least as Boston; grows rapidly in cultivation and promises to become here a large, long-lived tree, and a very important and valuable addition to the list of evergreens which can be successfully cultivated in the Northern States.

THE PACIFIC COAST YEW, which under favourable conditions becomes a tree 80 feet in height, with a trunk occasionally 4 feet in diameter, has not been fairly tested yet in the east. It grows not only on the coast as far north as the Queen Charlotte Islands, but it spreads eastward to the western slopes of the northern Rocky Mountains in the United States and to the Selkirk Mountains in British Columbia, where the winter cold is much more severe than in New England. The snowfall, however, is lighter, and small plants are protected all winter and until late in the spring by a deep covering of snow, while in summer the ground, shaded by the dense coniferous forest, never becomes very dry in the situations which this species selects.

THE DEAN HOLE.—A few specimens of this Rose have been on exhibition in the show window of W. H. Brower, on Broadway, within the past week. These partly opened, firm buds suggest flowers of large size when fully grown. The Dean Hole Rose differs from the cream-tinted President Carnot, which pales under gas-light, in that its rich shell-pink petals are particularly beautiful in artificial light. For this reason it is likely to be in special demand for winter decorations, and it is expected that the supply will be large enough this winter to provide some of the smaller flowers for this use. The stems are strong and the foliage is luxuriant and pleasing. This Rose was first shown two years ago at the dinner given in honour of Dean Hole in this city.

THE GERMINATION OF CONIFER SEEDS.—A great difference exists in the germination of conifer seeds from different localities. I have never seen this fact stated in print and give my experience in the hope that others may do likewise. The seeds of all the conifers hardy in the east come up at the same time or nearly so. Norway Spruce, White Spruce, Scotch, Austrian and Mountain Pines, the Colorado conifer, *Picea pungens* and *P. Engelmanni*, Douglas Spruce, *Abies concolor*, and other common conifers can all be uncovered at one time. But the seedlings come up ten days after the first one appears, while conifer seeds from a warmer climate are very irregular in germinating. I raised a large quantity in California in 1889 and 1890. The kinds already named were sown in beds adjacent to the more tender kinds, *Pinus boreyi*, *P. ponderosa*, and *P. tuberculata* started from two to four weeks before the others came up. *Abies magnifica*, *A. grandis*,

and *A. amabilis* came at long intervals; the first of these appeared in April and the last in September, and they required careful attention. The various kinds of *Cupressus* varied as much as those of the *Abies*. Douglas Spruce, *Abies concolor*, and *Pinus ponderosa*, from Colorado, came up much more regularly than the same species from seed collected in California, but the seedlings from California seed made much larger plants at the end of two years. Most of the seed from the Orient acted as those of our native and European species do, being very regular in germinating. The exceptions are *Picea Morinda* and *P. ajanensis*, but as I had very little seed of the latter, and that apparently two or more years old, I may be mistaken in this particular. The seeds of *Sciadopitys verticillata*, *Cedrus Deodara*, and *C. Libani* are also irregular in time of germinating. *Cedrus atlantica* may also be added to the list, but it comes up more evenly than the seeds of other Cedars. The seeds of our native White Pine are the most uneven in germinating of those of the hardy conifers; but although they sometimes come irregularly, this tree can hardly be classed with the species which are irregular in germinating. *Thuja gigantea* and *Libocedrus decurrens* are irregular.—R. DOUGLAS.

THE SWAMP MAGNOLIA (*M. glauca*) varies from a deciduous shrub at its most northern limit to an evergreen tree in the extreme south. Its most common form is that of a shrub from 6 feet to 20 feet high, having extreme beauty of foliage and flower and delicious fragrance. The growth is very rapid, ranging in one season from 6 inches to 5 feet, and the flowering branches develop normally three growing points, of which one usually far outgrows the others. The flowers, the smallest of our native Magnolia blossoms, are of an exquisite ivory-white from 2 inches to 3 inches in diameter; they are borne on short stalks with outspread leaves that fall and flutter about the flowers, so that, except for their perfume, one might easily pass a blossoming shrub without seeing any of the flowers. The small fruit-cones, about 2 inches long, have scarlet seeds.

The written records of this Magnolia begin with that first voyage to Virginia in 1584, where on the islands of Pamlico Sound its beauty and fragrance were noted by those keen-eyed old sea-dogs, whose conciseness of description is unequalled. A century later that careful observer and judicious collector, the Rev. John Bannister, took plants of *M. glauca* from Virginia to England, where they were planted in the Episcopal garden, at Fulham, by Henry Compton, Bishop of London. Here the Magnolia found an old swamp friend in the fine large tree of Red Maple, taken over some thirty years earlier. About this time the Rev. Cotton Mather, also busy with observations and collections of a less pacific nature, as he was journeying from Salem to Gloucester, paused in his pursuit of witches in order to discover the source of an unknown fragrance, and made known that farthest north colony of *M. glauca* that has since given its name to the town of Magnolia. Exportations of Magnolia to England were continued early in the eighteenth century, for Collinson in 1735 wrote to Bartram "not to send any more cones of your Swamp Laurel," but the demand must have increased, for two years later he wrote for more cones, saying "it is a fine plant, and when the wind turns up the silken side of its leaves it has a pretty effect." It is figured and described in Catesby's "Hortus Britanno-Americanus" as *Magnolia laurifolia* (edition of 1763) and mentioned as one of the American plants with which "England should be enriched."

NOTES ON STRAWBERRIES.

WE have to thank our readers all over the country for so kindly replying to the following questions, and we hope that the notes will prove valuable :-

*Will you kindly aid us in throwing some light on Strawberries of best quality for the use of private growers, as market growers have a different standard from that which applies to the private gardener, and favour those kinds that bear carriage, rather than those that are remarkable for flavour and quality? For those who use their own fruit we think that a different standard should be in use.*

1. *What kinds do you consider the best for flavour in your district, i.e., as grown in gardens, not taking into account those grown in the open field for market?*

2. *The best early and late kinds for the open air in your district?*

3. *Which of the newer sorts do you find most worthy of cultivation from a garden point of view?*

4. *The best time to plant so as to secure the best and most regular crops?*

— Strawberries have been an excellent crop and the quality has been good all through the season. The varieties I find best here for private use are Royal Sovereign (the best variety yet raised), British Queen, Sir Joseph Paxton, Gunton Park, Elton Pine, Latest of All, Sir C. Napier, and Monarch. The best fruits are obtained from one year old runners, layered into pots and planted out the first week in August. The ground is prepared as follows: A very heavy dressing of manure is dug in 2 feet deep and mixed with the soil in digging. Then the ground is made firm, a good dressing of old Mushroom dung is spread on the surface, lightly forked in and trod down again before planting. I plant at 3 feet between the rows and 18 inches in the rows, pressing the soil firmly round the plants. The result is a grand crop of fruit the following year.—J. SMITH, *Mentmore, Bucks.*

— The kinds that are most in favour here are Noble, La Grosse Suerée, Dr. Hogg, Keens' Seedling, President, Royal Sovereign, and McMahon. I consider Noble the best for early use. Certainly it lacks flavour, but it has an excellent constitution, is a heavy cropper, and comes in a week before other kinds. To follow I find the other kinds named do well. Royal Sovereign is a very strong grower and crops freely, but the fruit is of a very dull colour and has an acid taste. In my opinion the best flavoured Strawberry is the old Keens' Seedling, a kind that is fast being pushed out of cultivation by the newer kinds that are constantly being introduced. For late use I grow McMahon, a fine fruit, plant robust, and good doer, but unfortunately it does not colour well at the point. For pots I grow three kinds, viz., Noble, Keens' Seedling, and Royal Sovereign. I find Noble an excellent one to come in about the middle of March. To follow about the middle of April, I like the old Keens' Seedling on account of its flavour, and Royal Sovereign for its heavy cropping qualities. I consider the best time to plant Strawberries is about the middle of July. It is not advisable to allow the plants to remain long in one place. The plan I adopt is to start on one side of a plot of ground and destroy a portion of the plants every year. From the ground that I intend to plant this year I take off a crop of early Potatoes, then manure well, dig deep, plant firm, and water well. By so doing I can secure a moderate crop of very fine fruit the following year.—B. MARKS, *Hardwick Gardens, Bury St. Edmunds.*

— The best kinds of Strawberries in this neighbourhood are President, Auguste Nicaise, Wizard of the North, and Vicomtesse Hélicart de Thury. The best early Strawberries are Vicomtesse H. de Thury and La Grosse Suerée. I grow

a few Noble for the first gathering, but the quality is not good. The best late kinds are Wizard of the North and Loxford Hall Seedling. The only new sort that I know of grown in this district is Royal Sovereign, and all that grow it speak very highly of it. The best time for planting is early in August. I usually plant out as soon as the forcing plants are potted up, which is from the end of July to the first week in August.—A. G. HOOKINGS, *Olddown House, Almondsbury.*

— Strawberries, taken on the whole, do very well in this and immediate neighbourhood. I find President, Vicomtesse Héricart de Thury, Sir Joseph Paxton, and Noble do well here. The above kinds I consider the best for this district. I find Noble the earliest of the above sorts, and Sir Joseph Paxton the latest. Royal Sovereign I find the most worthy of cultivation of the newer varieties. The beginning of September is a very good time to plant out the general crop of Strawberries, the ground having previously been prepared for them, also the runners layered into 3-inch pots.—W. STANTON, *Cuddington Hall, Dunstable.*

— The best kinds of Strawberries for flavour I find are for early use, Royal Sovereign, Paxton, and President. British Queen I have failed with, but I have seen some very good samples grown in the district. The best early kind is Royal Sovereign. Oxonian is a good late kind, but not very sweet, so probably Waterloo is the better flavoured. Among the newer varieties I grow, Royal Sovereign is the best for all purposes. The best time to plant is early in August. These will bear well the following year. Destroy after two years if possible.—J. HILL, *Babraham Gardens, Cambridge.*

— The site on which the Strawberries are grown here seems well adapted for their requirements. The ground, on a sharp slope towards the south, is a heavy loam in which a quantity of shale had been mixed during the formation of the gardens. The variety that finds most favour here is British Queen, which I consider the best for general use when it does well. Here I gather fine-coloured fruit well ripened to the point, not very large, but of excellent flavour. The best earlies are Royal Sovereign and John Ruskin, and for late work I prefer Dr. Hogg. Of the newer sorts tried in these gardens, Royal Sovereign is by far the best, and as a forcing variety is in great demand. The best time for planting is as early in the season as plants are procurable, which in this late district is in the latter part of August or early in September.—FREDERICK HARBON, *Eastwood Grange, Ashover, Chesterfield.*

— The best Strawberries grown here, on a light warm loam highly manured, are John Ruskin, Vicomtesse Héricart de Thury (better known locally as Garibaldi) and James Veitch, in their order of ripening. Nearly every popular Strawberry has been tried within the past quarter of a century, but the three named succeed the best, and these I grow in quantity. John Ruskin is best when treated as an annual. I have abundance of forced plants, and these I plant out in May or June and obtain a heavy crop from them the following year. After bearing once they may be trenched down, planting a fresh lot every season. Garibaldi is easily grown under all ordinary circumstances, and never fails to bear except when cut off by late frost; but after the first picking it is apt to run small in warm weather. James Veitch gives more than double the bulk of a crop of any other Strawberry that is worth growing on the hot, dry soil, and in such a soil it is firm, highly coloured and excellent in flavour, not at all like the same variety when grown under different conditions on a stiff, cool soil, where the Elton and other Pine Strawberries flourish so well. In this district, within a radius say of ten miles, the soil, exposure and altitude vary so greatly that no variety can be safely trusted to do equally well all over it, either for early, main or late crops. Generally speaking, Garibaldi is the favourite in private and market gardens for an early crop, but Royal Sovereign is

doing well generally, and as it is a fine showy fruit and of tolerable flavour, it may come into use as the earliest market Strawberry. Moffat's Duke of Edinburgh and President are grown to some extent on good Strawberry soils, where they succeed well as the main crop; and Elton Pine, where it does well in high-lying and cool districts, is by far the best late Strawberry, remaining in fine condition in good seasons till the month of October. Some very promising varieties of Strawberries have appeared in recent years, but none of them have been sufficiently tested to warrant a definite opinion as to their merits.—M. DUNN, *The Gardens, Dalkeith, Midlothian.*

— The undermentioned varieties of Strawberries I consider the best for this district, viz., King of the Earlies, Royal Sovereign, Sir Joseph Paxton, Keens' Seedling, Monarch, Eclipse, Waterloo, and Latest of All. I find Royal Sovereign and Monarch the most worthy of cultivation of the newer sorts in this district. I always try to get strong plants in pots by the middle of August, and then I commence planting, and at once mulch with decayed manure. By so doing I never fail to get good crops of fine fruit. Some gardeners plant late in September and October, but I have never seen good results from late planting.—C. E. MARTIN, *The Hoo Gardens, Welwyn, Herts.*

— Vicomtesse grows to a good size here, and gives general satisfaction. Royal Sovereign, President, and Sir J. Paxton are the ones generally relied upon. Vicomtesse, Royal Sovereign and Leader are the best early kinds, with President, Sir J. Paxton, Latest of All, and Waterloo for late work. Of the newer sorts, Royal Sovereign, Laxton's Leader, Gunton Park, and Monarch are the best I have grown. The plan I adopt, and which is very successful here, is, as soon as the second crop of Peas can be cleared off the ground, to plant those that have been forced, which is generally towards the middle of July, the ground having been prepared for their reception in the autumn. Here they fruit twice before being destroyed. A new plantation is made each year, the plants are put out 2 feet 6 inches from plant to plant, and 3 feet between the rows.—GEO. H. MAXCOCK, *Luton Hoo Gardens, Beds.*

— The best kinds with me, taking flavour and cropping qualities into account, are Royal Sovereign, President, and Paxton; the best early sorts, Noble and Royal Sovereign; the best late, Waterloo. Of the newer sorts, Gunton Park I think a good useful sort. I find the best time to plant is the last week in July or the first week in August, so as to get the runners well established before winter.—CHAS. DEANE, *Cassibury Gardens, Watford, Herts.*

— Pauline, Royal Sovereign, La Grosse Suerée, Auguste Nicaise, Waterloo and Oxonian are my favourites. I tried for several years to grow President and Sir J. Paxton, both grand in some places, but with me very subject to mildew, so I have done away with them. I can send fruit of good quality to table from early in June to the last week in July from the above list, all of which are good travellers. I have tried Frogmore Late Pine, Elton and one or two other late varieties, but nothing does so well with me as Oxonian. Planted in open quarters it succeeds Waterloo, and on a north border it is grand for several weeks after all others are over. My practice here for close on twenty years has been to let well alone, not disturbing my permanent beds under six or seven years, and scarcely ever digging between them. Hoeing and top-dressing lead up to the greatest success in our light sand and gravelly soil. When I do make new beds I like spring planting from runners pricked into nursery beds the previous autumn, giving them 2 feet apart each way upon ground trenched two spits deep, and a foot below that turned over, but not brought to the surface, the whole very liberally treated with good farmyard manure.—C. DEAVIN, *Harewood Lodge, Sunninghill, Berks.*

— I only grow a very few sorts here which I find to serve me best. The soil is very gravelly and light, and therefore not very suitable to

Strawberries. The best kinds for flavour Pauline, John Ruskin, Royal Sovereign, President, Sir Joseph Paxton and British Queen. The early and late kinds in this district are Noble, Royal Sovereign, Sir Charles Napier and Waterloo. I find Royal Sovereign succeed well in this district. The best time for planting is early in August, or the middle or end of July, for plants which were forced in the spring.—COOMBES, *Englefield, Reading.*

— I have found the following to be the best flavoured Strawberries after trying a great number of varieties: Dr. Hogg, Veitch's Pétion, La France, Lord Suffield, Latest of All, President. The best early varieties are Laxton's No. 1, Royal Sovereign, and La Grosse Suerée. The first two ripened their fruit at the same time, growing under the same conditions under a south wall. The three best late varieties in my order of ripening are Frogmore Late Pine, Waterloo and Loxford Hall Seedling. The best time to plant is the end of July or the first week in August.—W. DAVIES, *Nidd Hall Gardens, Rye, Yorks.*

— The best varieties for private use here are Royal Sovereign, Auguste Nicaise, President, Dr. Hogg, Frogmore Late Pine, Latest of All. These three best varieties to depend on in our dry soil are Royal Sovereign, Auguste Nicaise and President. For preserving I still grow End Scarlet in preference to any other variety as it retains its colour, shape and flavour after being boiled. I obtain the best results from planting young plants in July every third year in a deep dug or trenched, unmanured ground, made perfectly firm and hard, mulching heavily in the spring just as the plants commence growth with fresh horse manure. By digging and preparing the ground some weeks before required for planting a distinct advantage is gained.—T. CURRIE, *Wilton House, Salisbury.*

— I should place Vicomtesse Héricart de Thury first for flavour in this district; indeed for any purpose it is hard to beat, the first three gatherings are usually of a good size for table use, and the smaller fruits make excellent preserves. It has also the merit of being a grower and free cropper in almost any soil. Sir J. Paxton, President, Aberdeen Favorite, &c., are also of very good flavour here. The best very early and late sorts, irrespective of quality, are Noble and Myatt's Improved. The former only satisfactory from one-year-old plants. The best time to plant is early in September, the plants get a good hold of the ground in winter, and may either be allowed to bear fruit the following season, or by pinching the flowers and runners they give a very heavy crop of fine fruit the second year.—J. IRONSIDE, *Edrom.*

— The best flavoured Strawberries grown in this neighbourhood are British Queen, Dr. Albert, King of the Earlies, Royal Sovereign, Gilbert Pine, Gunton Park, Sir Harry, Victoria, and Vicomtesse H. de Thury. The best early is King of the Earlies, Royal Sovereign, Noble, and Vicomtesse H. de Thury; the best late: Elton and Waterloo (very late, shy bearer).—F. J. BOURNE, *Boughton House, Kettering.*

— The best for flavour as grown here are Royal Sovereign, General MacMahon and President. The best earlies are Royal Sovereign, Noble; the best late, Elton Pine, Elton Pine Improved, and Latest of All. Of the newer sorts most worthy of cultivation is Royal Sovereign. The best time to plant so as to secure the best most regular crop is in August or September. If set out then the plants are well rooted and established before the winter sets in.—D. HULL, *Tulloch, N.B.*

— I find Royal Sovereign a good all-round variety. It is the earliest I grow, very prolific of good colour, size, and flavour, firm and it will travel well for mid-season. Lord Suffield and Gunton Park are of good flavour and firm. For late work Latest of All is the best. British Queen does wonderfully well on our light sandy soil.—G. R. ALLIS, *Old Warden Park, Biggleswade.*

STOVE AND GREENHOUSE.

CHRYSANTHEMUMS FOR THE CONSERVATORY.

produce a pleasing and graceful effect, and to show up the relative merits of the Chrysanthemum for inside decoration, different ways of growing the plants must be carried out. Happily, in my case the objects are cut bloom for conservatory decoration; hence there can be grown bush plants, plants on single stems, and down plants and a good percentage for large blooms, which, as shown in the annexed engraving, tell well in the background amongst overhanging Palms, Dracenas and the long sprays of Fuchsias drooping from the pillars. A mixed arrangement of this kind with an ample background of Palms and fine-foliaged plants, and a judicious mixture of other plants has a very telling effect. Poinsettias, Euphorbia and Calanthe Veitchi add wonderfully to

3 inches long and an inch wide. Though heart shaped at the base, they taper off to a point. A variegated-leaved variety of this was awarded a first-class certificate by the Royal Horticultural Society during the present year, and when sent out will no doubt be a good deal sought after. The curious manner in which the upper portion of *F. stipulata* will thicken out and produce large leathery leaves and occasionally fruits is now pretty well known, and doubtless these other kinds will sooner or later show the same character. —T.

**Eranthemum tuberculatum.**—Though differing widely from each other in general appearance, many of the Eranthemums are very beautiful flowering plants, and, in nearly every instance, of easy culture. The various species flower at different times of the year, some of them being very attractive during the autumn and winter months. One now in bloom is *Eranthemum tuberculatum*, which was introduced from New Caledonia in 1863. It forms quite a little bush, composed of slender branches, clothed with small ovate leaves. The flowers, which are freely borne on the shoots,

winter. The process of propagation, which usually begins in January, is first to remove some of the outer leafage, then to notch slightly the bases of the crowns in layer fashion, then to drop the plants into pots a good size larger, and to place round the tops an inch of fine sandy soil. If stood in gentle warmth, rooting soon follows, and when each plant is lifted from the pots and the newly-rooted parts are severed from the old, then got into small pots and returned to gentle warmth, very quickly are sturdy plants obtained. When shifted into 4½-inch pots and warmer weather has come, the best place is a cool span-frame, where standing on a firm ash bed good growth is continued, and later they are got into 6-inch, or if very strong into 7-inch pots, and in these well established, soon begin to carry bloom. When I saw these plants very recently there were amongst them heads from 12 inches to 15 inches over of Marchioness of Exeter, White Lady, Lucy Hillier, Mrs. Barron, and others. What a quantity of pure white flowers such a variety as White Lady produces, and how admirable are these to gather and wire for bouquets or button-holes. The old double white may be free-flowering, but the blooms are much smaller. The layering seems not only to ensure the production of roots more readily, but also helps to create finer plants. The work needs to be done with care, but the results well repay the trouble taken.—A. D.

TUBEROSES IN WINTER.

As the Chrysanthemum season gets past, the Tuberose, though less showy, fills up a void, and is grown so easily, that anyone with a temperature of 55° may have blooms from October to Christmas, or even later. In a note a few seasons ago I advised growing the Tuberose with less heat, thus getting stronger spikes, but I did not touch upon its culture for mid-winter supplies of cut bloom. Since then I have seen Tuberoses planted out and lifted like other autumn plants with great success. Of course, planting out is not advised in any soil or position, and even under the most favourable conditions a good season is essential to success. Plants grown thus are remarkable for their sturdy habit and strong spikes of bloom. I follow a midway course, using pots, thus saving the potting up. At the same time the plants are grown as hardy as possible, never giving any heat till October, or even November, just as the blooms are opening. To get bulbs to flower at this season it is essential to pot up later than is often practised, but there must be no forcing of any kind. I always secure the best ripened bulbs. The Pearl is the best variety for the purpose; indeed, in my opinion, African bulbs are so inferior that they are not worth growing for the purpose named. The bulbs when received are spread out thinly on shelves in a cool, dry fruit-room and occasionally moved about, any side growths which show being removed. The potting up is done during April and May, one large bulb in a 4-inch pot or three in a 6 inch or 7-inch pot will suffice. Firm potting is essential. When potted the bulbs are well watered, placed in a cold frame, covered with fine ashes and left till the roots are running round the sides of the pot. It may be asked, why place in frames if the bulbs need no protection? This is done to throw off heavy rains, as excess of moisture at this stage is fatal. The sashes are only used in rainy weather. Failing cold frame room the plants may be plunged in the open and anything which throws off the moisture placed over them. When top-growth is a few inches long the plunging material is removed and the plants are fully exposed all through the summer. Towards the end of August they will be strongly rooted, very dwarf, and take occasional supplies of liquid manure, care being taken not to pour the latter into the

kind of decoration, giving effect and brilliancy, and also varying the arrangement. Unquestionably such an arrangement is far superior to where large blooms only are used.

**Ficus falcata.**—Of the small creeping kinds of Ficus that we have now in our gardens, and which are particularly valuable for clothing damp walls and for similar purposes, by far the best known is *F. stipulata*, or repens as it is frequently called, and the still smaller variety of it—*minima*, which is exceedingly neat in growth. To these may be added *F. falcata*, which is well adapted for the same purposes as the others, the style of growth being similar; but the leaves are totally different in shape, being peculiarly curved, hence the specific name of *falcata*. The leaves are about 5, about an inch in length, and of a deep green colour. It grows very freely under favourable conditions when it is once established, and its roots just as *F. stipulata*. Besides these there is the larger and looser growing *Ficus* species, whose leaves are each from 2 inches to

are pure white, each nearly 1½ inches across, and in appearance somewhat suggesting *Bouvardia Humboldtii corymbiflora*. As it will flower freely when little more than a foot high, and in a pot only 5 inches in diameter, it is particularly adapted for small structures. This *Eranthemum*, in common with most other members of the genus, requires the temperature of a stove. Another species now in bloom is the upright-growing *E. Andersoni*, whose white flowers, marked with purplish lake, vie with some of the Orchids in their colouring. *E. albiflorum* is a rather uncommon kind, whose upright panicles of blossoms are very like sprays of white Lilae. Those grown for the sake of their foliage—notably *E. reticulatum*, whose bright green leaves are heavily veined with gold, *E. albo-marginatum*, *E. tricolor*, and *E. atropurpureum*—are bright and attractive at all seasons.—H. P.

**Double Chinese Primroses.**—The huge plants of these which are now in quantity at Woodside, Leatherhead, demonstrate in a forcible way the ease with which not only the finest varieties may be grown, but their exceeding value for supplying beautiful double flowers during the
