hearts of the plants. Early in October or at the end of September it will be necessary to shelter them, as a few of the strongest will be throwing up spikes, and these may if required be given more warmth. The bulk of the plants, however, is left in the frames, not being given heat till November. Grown thus the plants give a winter supply of bloom and last a long time. There is less fear of the bulbs failing to flower, and by this mode of culture they may be had in bloom all the year, as it is an easy matter to pot up batches of plants from November till June. G. WYTHES.

#### BOUvardias FOR CUTTING.

The great popularity of the Chrysanthemum has, doubtless, to a certain extent led to the neglect of these beautiful plants. This is a pity, as the flowers of no greenhouse plants are so valuable for cutting. The section represented by Hogarth, Priory Beauty, Dazzler, and the double forms like Alfred Neuner, President Garfield and others is by far the most useful, and greatly to be preferred for cutting to Humboldt corymbiflora or jasminoides. Florists are quite alive to the value of these flowers, and, in consequence, they are grown in very large quantities by the market men, but private gardeners in many cases do not take up their culture with any spirit. The cuttings should be taken as early in spring as possible, and should consist of small, fresh green points produced by cutting back an old plant or two after resting and placing in a slightly warm house. It is important that the cuttings be kept quite fresh and moist from the first. As soon as the cuttings are rooted lift them out of the plunging material for a day or two, and then place the pots where they may be lightly shaded for a little while and in a genial temperature. Top them almost at once, and when growth recommences pot them singly into the smallest-sized pots. By the end of May these should be nice little bushy, hard stuff ready for planting out either in a frame or on prepared borders outside. In the light sandy soil in the west of England I have frequently planted them in the ordinary soil and had capital results, but in most soils and situations it is safest to plant in prepared frames in light, peaty soil, made very firm by ramming both before and after planting. In loose soil the plants make a lot of growth, but give trouble later when they are lifted; but the fine balls of soil that come up with the roots when made firm enable the plants to get over their disturbance almost without a check. After planting give one good watering to settle the soil, but only close the frames on cold nights. All through the summer let the plants have thorough exposure to sun and air, keep them moist at the roots, and anticipate the production of flower-buds by topping frequently. Several times daily the syringe may be lightly plied about the plants, as the abundance of fresh air and light does away with any possibility of softness in the growth. About the middle of September the plants may be lifted and potted into fairly large pots, soaking every part of the soil well a day or so previously. Pot firmly and stand the plants in a sheltered shady spot for a few days before housing. Any light sunny house or frame, where a little fire-heat may be turned on at night so as to allow of ventilation by night and day will suit them. It is the greatest mistake to coddle them by allowing fire-heat except as indicated. Still keep the syringe going among them and around the pots; there need be no fear of soft growth provided plenty of air and an unbroken light are afforded. The result of this treatment will be plants absolutely covered with flowers, and they keep going for months. When the best of the blossoms are past, they may be cut back and kept slightly drier at the roots, the treatment the second season being the same as for young plants except that they will naturally require more room in the frames and subsequently larger pots. The specimens, as a matter of fact, may be kept going for an almost indefinite number of years, but it is

not advisable to keep them too long. Any old ones not required again may be planted out in the flower garden, for they are naturally summer-blooming, and only induced to flower in winter by the frequent pinching advised above. Bouvardias differ from many greenhouse shrubby plants in that they cannot be forced, but the retarding system may be easily carried out, and of course serves the same purpose. R.

**Bouvardias Pride of Brooklyn and Pride of Rochester.**—I have several times heard the above varieties mentioned. By their names they would appear to be of American origin, but I do not know either of them. I shall be glad to know if any of your readers have grown them, and if they are distinct from other varieties now grown in this country. I have already met with what I first knew as Vreelandi under three other names, viz., The Bride, Alba elegantissima and Davisoni, and it is probable that those referred to above are old sorts re-christened.—A.

**Raising Lotus seed.**—Having had some Lotus seeds sent me from India, I shall be glad if you will tell me how to grow them.—DORA L. WADHAM.

\*\*\* Seed of the Lotus should be sown in well-drained pots filled with sandy loam. The seeds may be covered with about their own depth of the same soil, when the pot or pots should be stood up to the rim in a tub of water. A stove temperature is necessary—that is, a structure which in the winter does not go down below 60°. When large enough the seedlings may be potted off, using the same compost, but as they get older a little well-decayed cow manure is of service. The Lotus may be grown moderately well in a large pot stood in a tank of water which is heated by hot-water pipes passing through, but it is seen at its best when planted out in a bed of mud, under which conditions it succeeds remarkably well at Kew in a corner of the tropical Water Lily house.—H. P.

#### RUST ON MALMAISON CARNATIONS.

IF by "rust" on these plants "J. R." (see p. 360 of THE GARDEN) refers to that terrible pest *Helminthosporium echinulatum*, I can only say that so far no remedy is known to exist. I take it by the way it affects his plants that this so-called rust is the same that troubles large growers here, and which has in its day ruined thousands of well-grown plants. Some years ago I read in a contemporary that "picking and burning" was the only cure, but, of course, such a method if followed up would be just as disastrous in its results as any disease possibly could be. What makes the above disease so utterly beyond the reach of any remedial measures is the fact that the fungus vegetates within the cuticle of the leaf, and having reached a certain stage of maturity eats its way through the upper and under surfaces of the leaves, and, bursting, casts its minute grains in all directions. Indeed, so fatal is it to the whole of the Malmaison group in this district, that large growers who hitherto had several houses 108 feet by 24 feet occupied by these plants have quite given up their cultivation. For some years I tried to combat this disease myself, and spent a lot of time in the endeavour to rid the plants of such a pestilence. The fungus appears to revel mostly in low districts, particularly those in the vicinity of some large river, and once the disease takes possession of a large-leaved variety, like the Malmaison, it is almost a hopeless case. A few at a time I burned the worst of my plants, till at length the whole of my stock, close upon 3000, went to the fire-heap. I have still traces of the fungus remaining, and as soon as I notice it upon the plants I get a little sulphur mixed to the consistency of thin mustard and paint

lightly over the place, taking care always to leave a goodly amount of the sulphur when I think the mature fungus will cast its spores. By this application I notice a distinct change in the colour of the fungus, and a certain inability to spread by reason of the added weight of sulphur. The latter in no wise prevents the fungus vegetating at the time, yet I hope it will arrest its vital powers for the future. Of course even this is tedious, and does not add to the beauty of the plants, though it is better than picking off the entire blade. The fungus gets in low-lying districts would appear ever present and simply awaiting a resting-place for its spore. So long as a leaf remains perfect fear need be entertained, but the slightest abrasion of the skin is sufficient to account for its presence, and once located on any part of the leaf is easily transmitted to other portions of the same leaf, and in due time vegetates and spreads again. Unfortunately, it is an unspeakable foe, and its presence is not felt till the fungus is about half developed, when it may be detected by a slightly uplifted portion the size of a pinhead and of an ash-grey tint. To the large-leaved kinds it is deadly, while the smaller leaf sorts appear proof against its attacks. Very curious, too, is the fact that in certain localities at higher altitudes these very plants can be grown with perfect ease and immunity from attacks. E. JENKINS

Hampton Hill.

#### OUR GLASSHOUSES IN FLOWER GARDENS AND ON LAWNS.

To many, a good big glasshouse is a near approach to an earthly paradise, and to such, to those who never take notice of the beautiful things about them in the home views of a country place, little need be said. No do they will go on covering the land with glass just as Guernsey has been covered of late years. But to those who think of beauty in our home landscapes, the position of the glasshouse in flower garden or pleasure ground is a serious matter, and some of the most interesting places in the country are defaced by glasshouses out of place. In the various dividing lines about a country house there can be no difficulty in finding a site for the glasshouse where it will be out of the way of doing harm to the views. There is no reason for placing a glasshouse in front of a beautiful old house where its colour mars the prospect. Very often, in looking across the land towards a country house, we see first the glare of an ugly glass shed. If this only happened in the garden of people lately emerged from the towns of the suburbs of our great cities, it would not be so remarkable; but when some of our finest country places like Knole, West Dean, and Goodwood are disfigured in this way, it is time to say something about it. For, apart from the fine old houses and the landscape being defaced by the hard lines and colour of the glasshouse, there is the result on the garden itself, or our efforts to get any harmony or refinement of colour in the flower garden. Our troubles in the effort to get plants into harmonious and beautiful relations we can testify from long experience are very much increased if we have a horror in the way of a glass shed staring us. It may be; indeed, in two places I have lately seen it placed in the middle of the lawn, with the smoke from the early fires arising, and perhaps a load of coal on its way to the stokehole! Is it any wonder in face of such things to find the artist driven from the garden though we may discover him near the horse farm or the cottage?—Field.

## CHRYSANTHEMUMS.

## CHRYSANTHEMUMS OUTDOORS.

ALTHOUGH Chrysanthemums are imported in immense numbers annually from the Continent and America, in addition to the hundreds of home-raised seedlings yearly grown, with a few to the discovery of new and improved kinds, we do not make much headway in raising for the outdoor garden varieties which may be called really hardy sorts, such as will live through the winter for some years, and make their growth and develop a crop of blooms without any protection. If we had such varieties which would meet the requirements named above, many otherwise dull gardens would be made bright during the winter months, but we must fall back on the old-established kinds.

At the present time a good selection of varieties can be had which in reasonable seasons

Plants which have been growing in the same place for several years get worn out and exhausted. They should be dug up and divided, discarding the centre of the roots if plenty of stock is obtainable from the outer parts of the clump, where sucker-like growths will be found much more vigorous than those in the centre. Pieces of roots 3 inches square make nice bushes the first year if a little fresh soil is placed about them, just digging over the ground deeply, at the same time adding some half-rotten manure. If the plants are put out on a new piece of the garden it will not be necessary to add new soil, but where they are simply dug up and replanted again, it will be essential to give fresh soil to promote a free growth, without which a full crop of blossoms cannot be had. Care must be taken that the soil is not made too rich, or the growth will be immature. In that condition the plants will suffer much more from frost during the winter, very likely to the

aspect which faces either north or west and is overshadowed by tall trees, the growth of the plants in such a position as either of those named being immature. The best position that can be obtained is a border facing south, backed up at the north and east sides with shrubs or other protection. If the plants are carefully cultivated during the summer season, it will not be time ill-spent to provide some means of protection from early or sudden frosts.

The variety illustrated, *M. Gustave Grunerwald*, blooms well in the border in September, and must be classed amongst the best sorts for the open ground. Both in form and colour the blooms are similar to those of *Vivand Morel*, the colour bright pink-lilac, fading to almost white with age. The habit of growth is good, an average of 2 feet being attained.

*Early Chrysanthemum M. Gustave Grunerwald.*

**Chrysanthemums in vases.**—A delightful contrast to the orthodox way of showing the Chrysanthemum has now become the rule at the Highgate and District Chrysanthemum show. Blooms showing high culture are exhibited both on boards and in vases, and in the latter they have made a most effective display. In this exhibition, by an extension this season of exhibits arranged in vases, the whole aspect of the show has been altered. Each exhibitor had studied his own particular fancy, with the result a most diverse method of arrangement was the outcome. This is the most forcible way of illustrating the practical uses to which large Chrysanthemum blooms can be put.—D. B. C.

**Chrysanthemum Souvenir de Petite Amie.**—This is one of Calvat's varieties of 1893, and is well described as having graceful flowers, pure white, first-rate habit, very dwarf, and vigorous. In height it is from 2½ feet to 3 feet, the stems stout and erect, bearing blooms of large size, full, handsome in shape, and very pure in tint. Mr. B. Dockerill, gardener to Mr. G. W. Walker, Elmfield, Reading, grows this variety largely. A fine development of bloom is one of the objects sought by Mr. Dockerill, and he secures plants with five or six stems on the average, each being surmounted by a flower of large size and highly attractive. It is a peculiarity in the growth of this variety that it forms something in the way of a broad flat head, and the flowers being on a level, it is of great value for forming a front line to a batch of plants in a conservatory.—R. D.

**Pompon Chrysanthemums.**—These charming little flowers are very fine this season, the display made in the competitive classes at the Highgate show—always noted for its pompons—being excellent. The flowers were set up in threes, and these, with their deep rich green foliage, called for special praise. The exhibits gave evidence of high culture. The most striking sorts among them were Mlle. Elise Dordan, rose-pink, of unique form; Comte de Morny, bright purple; William Westlake, bright golden yellow; Black Douglas, dark crimson; President, rosy carmine, still one of the best when well grown; Pygmalion, deep rose; Prince of Orange, light orange-amber, a good bright flower; Maid of Kent, white; Rubrum perfectum, deep rich crimson, golden reverse, very fine; La Vogue, bright golden yellow; Frémy, light brick-red, shaded yellow, large, early, limbrated; and Magenta King, bright magenta, very fine.—D. B.

**White and yellow Chrysanthemums.**—These the past year or two have been very fine and also numerous. There are probably no other colours that have received such substantial additions, and in good crimsons and purples it may be said that the novelties of the past two years comprise none at all. For beautiful pure clear whites of very recent introduction we have had from America, Snowdon, Simplicity (a grand flower), Mrs. M. A. Ryerson, and Western King (fine everywhere this season). Ernest Calvat supplies Baronne Ad. Rothschild, Mme. Gustave Henry (early), Princesse de Galles, Mrs. J. Lewis

produce a good crop of blooms, although, of course, much depends upon the weather experienced at the time they are in beauty. Where blossoms are required for cutting, some of the best kinds might be planted in batches in the kitchen garden, choosing a warm border. In cottage gardens one often sees plants fully in flower of sorts that are hardly met with now-days out of such gardens, as the old Emperor of China or Cottage Pink. Many are pompons, a section well adapted for out-of-door culture. The petals, being reflexed and generally imbricated, do not hold the water from heavy dews or rain, as in the case of incurved sorts, for instance, which are really quite useless for outdoor use.

extent of losing the whole crop of flowers. The soil about the roots should be made firm to induce a stocky growth, which produces the best blooms and withstands cold weather. The foregoing note on the culture of hardy Chrysanthemums applies to established plants only. Directly the flowering season is past is a suitable time to replant any that require it. When growth starts in the spring, if the shoots promise to crowd each other they should be thinned, which induces sturdiness—a desirable point in the after success.

Those who now contemplate growing hardy Chrysanthemums for the first time should make a proper selection of kinds and choose a suitable site, which is very important. Avoid an

(an exceptionally fine one this season), Mme. Deis, Mme. Ferlat, and the grand acquisition Mlle. Lucie Faure, while miscellaneous ones of equal merit may be found in Mrs. C. Bliok, Mrs. H. Weeks, Mme. Ph. Rivoire, Emily Silsbury, Lady Byron, Mrs. Rd. Jones, and many more besides. Some of the new yellows are grand in richness of tone, Modesto, Marjory Kinder, Oceana, and Royal Sovereign being perhaps the most noteworthy in this respect. Paler, but not less beautiful, are G. J. Warren (the yellow sport from Mme. Carnot), Australian Gold, M. Massange de Louvrex, Topaze Orientale, and Mrs. C. Orchard. Others such as Edith Tabor, Sunstone, Georgiana Pitcher, and Soleil d'Octobre leave little to desire in their own shades.—C. H. P.

#### CONTINENTAL VARIETIES OF 1897.

Those who visited the leading shows on the Continent last year must have been looking forward with some degree of interest to see how the novelties shown abroad would behave when submitted to English cultivation. It was only reasonable to expect to see some variation in the seedlings that were exhibited for the first time at the French shows last year, and the same when grown here a year afterwards. With very few exceptions almost everything that was considered promising, either at Ghent or at Paris, this time last year has been imported into our own trade collections and in the course of my usual autumn visits, I have naturally looked out for the novelties that impressed me and my fellow visitors the most during our visit to Belgium and France this time last year. Those that appeared to be the best there verify the good opinion that was then formed of them by being the best here, and referring to the original descriptions they seem to be much about the same, although it must be confessed in several cases the colouring under our English sky does not in a few instances appear to be so bright and pure.

From an exhibitor's standpoint, I should say that the following selection comprises all the best of the French varieties that have been distributed this year. Novelties from other sources are lacking in substance and build, although there are a few in which fine colouring is observable.

**DIRECTEUR LIÉBERT (Calvat).**—Japanese; of very large size and compact build; the florets are of medium size, grooved and curly; colour deep lilac-mauve.

**LUCELLE MATHIEU DE LA DRÔME (Reydellet).**—This promises to be a useful addition to the old florists' type of incurved varieties. It is large and deeply built, the florets narrow and regularly incurving; colour pale golden yellow.

**MME. FERLAT (Calvat).**—A grand massive Japanese incurved; the florets are heavily grooved, the colour pure white.

**MME. LAURENCE ZÉDE (Calvat).**—Another big globular Japanese incurved, with grooved, pointed florets of medium width; inside colour violet-amaranth, reverse silvery pink.

**WERTHER (Calvat).**—Globular Japanese of large size, having grooved incurving florets; colour rich deep rosy amaranth, reverse silvery. A fine effective novelty.

**VICOMTE ROGER DE CHEZELLES (Calvat).**—Wrongly described in most reports as Vicomtesse. A very large Japanese, the centre florets incurving and closely resembling Mr. Briseoe-Ironside's seedling Arona; colour golden yellow bronze, reverse silvery yellow.

**MME. PH. RIVOIRE.**—This is a Japanese, also of great size; florets very broad and ribbed on the reverse; colour pure white.

**MILLE. LUCIE FAURE (Calvat).**—A fine novelty of the Japanese incurved type, the florets of great length, good substance, and deeply grooved; colour pure white. It will probably rank as one of Calvat's best.

**PRINCESSE DE GALLES (Calvat).**—Japanese, with very long florets, which are grooved and of medium width; colour pale pink shaded yellow, tinted purple.

**TOPAZE ORIENTALE (Calvat).**—A solid, compact incurving Japanese, very globular and regular in form; florets grooved and broad; colour pale lemon yellow.

**M. G. CHARANNE (Calvat).**—A closely built Japanese incurved, with rather broad florets; colour rich golden yellow.

**SOUVENIR DE MOLINES (Calvat).**—Japanese, close and compact in build; golden carmine bronze, reverse golden.

**LECADIE GENTILS (Quétier).**—A sport from *Enfant des deux Mondes* raised in France last year; it has narrow grooved florets, the blooms are of large size, and the colour pale pure lemon yellow. Very hairy.

**SOUVENIR DE MME. F. ROSETTE (Calvat).**—A big solid Japanese incurved, with good florets pointed at the tips; colour plum coloured amaranth, with silvery amaranth reverse.

**M. HUGUIER (Reydellet).**—A very large Japanese, but rather flat in build; florets incurving, of good substance, and grooved; colour pale rosy mauve, reverse silvery pink.

**PAPA VILLARD (Nonin).**—Japanese, of good size, but not overlarge; the florets are rather broad, curling at the tips; colour very deep rosy mauve with silvery reverse.

**MME. DESBLANC (Reydellet).**—An incurved Japanese, with twisted intermingling grooved florets of medium width. A pretty shade of bright rosy pink.

**MILLE. LOUISE BROSSILLON.**—This, too, is a Japanese incurved of very large size; it has medium-sized grooved florets that are twisted. It is said to be a seedling from Mme. Carnot, and its colour is a pure white, very slightly tinted.

**DON PIETRO BARAGIOLA (Reydellet).**—Japanese, with narrow, flat, reflexing florets, not large, but very striking and distinct; the colour is deep golden yellow, shaded rosy carmine.

**MME. G. BRUANT (Calvat).**—A monster Japanese, with very long, drooping florets; colour pale rose shaded purple towards the tips, centre almost white.

**SOLEIL D'OCTOBRE (Calvat).**—A rather early blooming Japanese, with medium-sized drooping florets, curling at the tips; colour a pretty shade of pale lemon yellow, reverse silvery.

**MME. ED. ROGER (Calvat).**—Japanese incurved; florets of medium width and grooved, large solid globular-shaped blooms. This is a most distinct novelty, being of a pale but decided sea-green colour, which in its early stages is very effective.

**N.C.S. JUBILEE (Calvat).**—Another very fine globular Japanese incurved variety; the florets are broad and grooved; colour pale lavender pink, with silvery pink reverse. A noteworthy acquisition in its section.

**M. MASSANGE DE LOUVREX (Calvat).**—Also of the Japanese incurved type; florets of medium width; colour a very fine clear shade of pale yellow.

C. HARMAN-PAYNE.

**New incurved varieties.**—The 1897 novelties do not appear to contain a large percentage of this old type, and, indeed, after recent decisions it appears somewhat difficult to decide what an incurved Chrysanthemum really is. But, following the example set by the National Chrysanthemum Society's classification committee and using the term in its fullest possible sense, the following seem to me to be the most promising of recent novelties in the incurved section: *Rena Dula*, small in size, florets sharply pointed, colour deep rose, tipped white; *Chrysanthémiste Bruant*, very massive and compact, very regular florets, colour deep golden bronze; *M. Desblanc*, deep reddish rosy bronze, reverse golden bronze; *Général Mauric*, small, but very regular, colour deep yellow in the centre, outer florets pink; *Emile Nonin*, deep rich golden chestnut, very regular; *Lady Isabel*, a fine bold, deeply-built flower of great promise, the florets substantial and the colour a charming shade of silvery blush;

*Triomphe d'Eve*, narrow white florets; *Lady Gormanston*, white; and *Lucille Mathieu de la Drôme*, large, globular, pale golden yellow, with narrow florets.

**New Chrysanthemums.**—We are now getting such an overwhelming number of new varieties, all of which are supposed to possess some merit, that it is very difficult to make a selection and keep within reasonable bounds with regard to numbers. I find last season there were upwards of fifty varieties which received either first-class certificates or awards of merit, and this season already there are a number which have received the same distinctions. Now, although this has been going on for years, yet many of the old varieties will still be found in the best stands of exhibition blooms. I think *Modesto* is likely to become a general favourite, being of free growth, and the large, full, deep golden-yellow blooms may be distinguished at a distance among all other yellows. *Western King* is another which will require something good to beat it; the large pure white flowers are of remarkable substance and it appears to be one of the best to manage—H.

#### SOME NEW CHRYSANTHEMUMS.

FOLLOWING the precedent of previous years, append a list of the best of the novelties of the season seen up to the date of writing these notes with the exception of Continental novelties, which form the subject of a separate paper. A large proportion of novelties of somewhat older date are in good form everywhere, and of these, *Edit Tabor*, *Mrs. C. Bliok*, *Australie*, *Pride of Macford*, *Oceana*, *Emily Silsbury*, *Mutual Friend*, *Mrs. H. Weeks*, and many others referred to in former notes justify the good opinion that we then formed of them. The most interesting of the English and American varieties for the present season from the exhibition standpoint appear to be:—

**MRS. P. R. DUNN.**—A very fine large Japanese Anemone variety with flat guard florets and distinctly tinted yellow.

**MABEL MILLER.**—Of the same type as the preceding, guard florets creamy white and flat form, blooms large, with large yellow disc.

**MRS. CATERER.**—Also a Japanese Anemone with long drooping guard florets; colour pure white.

**LADY HANHAM.**—A really fine and attractive sport from *Vivian Morel*, which it resembles very closely in build. In colour it varies, but may be described as of a pale creamy salmon shaded rosy bronze. A very fine addition.

**MRS. HERMANN KLOSS.**—A large-sized Japanese with long spreading florets; colour a very rich shade of warm golden terra-cotta, tipped gold.

**MRS. G. W. PALMER.**—A sport from the well known exhibition variety *Mrs. C. Harman-Payne* and probably identical with the French novel *Mme. Eugene Testout*, which had the same origin and closely resembles *Mrs. G. W. Palmer*. The colour is a deep rosy bronze, but in other respects it does not differ from its parent.

**WHITE SWAN.**—A very large Japanese with long tubulated florets; colour pure white, faintly tinted in the centre, very hairy.

**MABEL KERSLAKE.**—A fine sport from the Australian novelty *Pride of Madford*. The inside colour is a deep rich velvety crimson, reverse golden.

**MRS. S. C. PROBIN.**—Japanese incurved; florets grooved and pointed; colour pure white shading off to pale rose.

**LADY RIDGWAY.**—An immense Japanese incurved with deeply grooved florets of good width; colour reddish-bronze, reverse salmon-buff tipped gold.

**LADY ISABEL** will probably be classed with the old type of incurved although its great size seems to indicate Japanese parentage. It is deep build, the florets very regularly arranged and fine form; colour silvery blush.

**GEORGINA PITCHER.**—Japanese incurved; very large and globular, florets deeply grooved and

ory broad. A fine massive-looking variety; colour pale canary-yellow, reverse silvery yellow.

**MARJORY KINDER.**—An incurving Japanese of large size and evidently a Londoner's variety, being exhibited in fine form at Southwark Park; colour rich dazzling golden-yellow, solid, compact forms.

**PRIDE OF RYEHOFF.**—Niveum, from which this a sport, was justly held in high esteem. Pride of Ryeoff is pale sulphur-yellow, deepening towards the centre. In form and build it resembles its parent.

**MRS. COTESWORTH BOND.**—Japanese, with long drooping florets, curly at the tips; colour a very delicate shade of pale pink.

**WESTERN KING.**—This American novelty was seen last year. It is a fine compact Japanese curved with a splendid grooved floret, and the colour, a pure waxy white, is very fine. This is the variety is good wherever it has been seen.

**G. J. WARREN.**—A grand sport from the famous Mme. Carnot and worthy of its parent, which it closely resembles in form, but varies in colour, which is a very pure pale shade of yellow. It will be certain to become a favourite with the exhibitors.

**SUNSTONE.**—A fine globular and incurving panicle; colour a fine shade of apricot-yellow.

**SIMPLICITY.**—This, like the preceding one, is of American origin. It belongs to the Japanese section, and has very long drooping florets; colour beautiful clear snowy white.

C. HARMAN-PAYNE.

#### PROSPECTS OF THE SEASON.

As far as the Chrysanthemum is concerned there has not been much to grumble about in regard to the weather during the past season, although in a few districts the frosts of late May did some damage. The young plants, which were then standing in the open air, were tender, and consequently the tips of the growths became weakened, which, of course, gave so severe a check that in those cases the effects are visible now, at flowering time. The Chrysanthemum does not require a forced growth, but progress must be steady and unchecked from the beginning to obtain the best results in the way of blooms. I am sure that too many coddle the young plants induly, and in that way lay a poor foundation to their growth. This coddling is perhaps a secondary mistake to over-growing the popular tumbling flower. Among all collections I inspect, whether an amateur's with a few dozen plants or where the champion blooms usually come from, it is curious to note the difference of treatment that exists. In some instances feeding the plants with strong liquid and other manures, it is easy to see, has been a leading feature, and when the sired crop of splendid, highly-developed flowers would be seasonable, such cultivators are disappointed to find they are not forthcoming. Several examples of over-growth have been noted this autumn. Securing early buds, again, is a fruitful source of failure. This mistake, in the same way as over-feeding, only exhibits its bad effects in a collapse at flowering time. The buds push out of the foliage on long peduncles; they appear to be swelling so kindly that the growers may well expect a rich harvest. All goes well until the florets begin to show colour, then perhaps a row or two will run out at great length, but the buds absolutely refuse to go further. There are many, dear, who have been delighted with their huge buds of Mme. Carnot, Australian Gold, Reine Angletterre, to mention a few, who are not over-anguine now. Early buds, too, produce in so many varieties blossoms of bad colour. The Vivand Morel, Charles Davis, and such monster flowers as Mrs. C. H. Payne, develop shades of washed-out tints, and are anything but pleasing. The weather has been favourable to good results. This is especially so now, as the blooms are opening. Except for an occasional visit of frogs the elements have for the past few weeks been fine. We have had but little rain since the Chrysanthe-

mum plants were placed under glass, nor has the air been cold. It has, therefore, required quite a small amount of fire-heat to assist the opening blooms, and, where growth of a medium strength obtains, flowers are developing exceptional substance. I fully expect to find the exhibitions quite up to the average of other years. Of course the finer displays are made with the Japanese flowers. Incurved Chrysanthemums do not seem particularly fine. One rarely meets, for instance, with nice blooms of the Queen type, which a few years back were the ideal flowers in that class. A new type is springing up in such varieties as Chas. H. Curtis, Mrs. R. C. Kingston and Duchess of Fife. These are, indeed, noble examples when well grown, neither are they difficult to grow. I should say the only way of keeping the incurved class from falling out of cultivation is the introduction of sorts as good as those named, in other colours.

The hairy-petalled kinds do not appear to gain in favour, as, with the exception of one called Hairy Wonder, they are not frequently seen. Single-flowered kinds are exceptionally pretty and useful for cutting, but the still way of exhibiting them, tied to wires, does not enhance their beauty. The type of which Framfield Beauty is an example appears likely to be esteemed. This produces long petals of a rich colour, that hang down in an informal manner. New varieties of Chrysanthemums are as numerous this year as ever, but it is rather early to judge of them. So far Ella Curtis and Robert Powell are very fine. They both partake of a bronzy yellow character and are of English origin. Those obtained from a plant "sporting" are in two instances very fine. I mean G. J. Warren (a lemon-yellow facsimile of that grand white Mme. Carnot) and Lady Hanham (a charming shade of salmon-rose, in shape similar to Vivand Morel, the parent plant). It is certain, too, that among the new kinds of M. Calvat's noted strain several most beautiful sorts will be seen before the season is past. At present N.C.S. Jubilee, Mlle. Lucie Faure, Mme. Edmond Roger and Mme. G. Bruant appear to be novelties of the first order. In a new Australian variety called Master H. Tucker there appears to be something exceptionally good as regards colour—a dark crimson; and as the growth is also sturdy, I note this as one of the best of the year.

H. S.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Mrs. Caterer** is a Japanese variety with pretty pure white flowers of good build, the guard florets long and drooping.

**Chrysanthemum Pride of Ryeoff.**—Those who know the very chaste American variety Niveum will welcome this novelty, which is a very pale primrose or sulphur-yellow sport from it.

**Chrysanthemum Trafalgar.**—A charming little Japanese pompon, if the term is permissible. For cutting it will be very useful where a deep rich velvety crimson-maroon shade is required.

**Chrysanthemum Georgiana Pitcher.**—This is a very large and compact Japanese, with deeply grooved florets of good width. The colour is rather pale canary-yellow, the reverse a silvery shining yellow.

**Chrysanthemum J. B. Yvon.**—A sport from Vivand Morel and fixed in France. Although duller in tone and different from Lady Hanham, it seems likely when aged to be scarcely wise to stage it in the same collection.

**Chrysanthemum Maurice Boissard.**—A fine hairy novelty of the Japanese incurved form. The florets are medium in width and deeply grooved, pointed at the tips. The blooms are of good size, the colour pale golden yellow.

**Chrysanthemum Mrs. C. Harman-Payne** has given several sports, but two of them appear to be identical. Mrs. G. W. Palmer and Mme. Eugène Testout are both rosy bronze, but the third, called Mme. Louis Rémy, is a pure white counterpart.

**Chrysanthemum Lady Ridgway.**—This sort bears very large blooms, which are of incurved form. The petals are of great substance. Its buff-tinted flowers are very distinct, and either for exhibition or

for conservatory decoration it can be recommended.—H.

**Chrysanthemum Mrs. S. C. Probin** is an American variety of very great beauty. The shade of flesh-pink is delicate and pleasing. It has large blooms that are inclined to be round in shape and of extra substance. The habit of the plant is dwarf and sturdy.—S.

**Chrysanthemum Lady Isabel.**—This is a charming variety belonging to the old incurved type although somewhat larger and deeper in build than many of that section. The form is excellent. The florets are rather broad and incurve very perfectly; colour, pale silvery bluish.

**Chrysanthemum Ella Curtis.**—Some fine flowers of this new variety are opening. It is not unlike the old Boule d'Or in its long and wide drooping florets. It may be called an improvement on that uncertain kind in every way. As an exhibition bloom it is quite one of the best of the season.—H.

**Chrysanthemum Don Pietro Baragiola.**—This novelty was raised by M. de Keydellet. It is a Japanese with narrow, flat, reflexing florets. The colour is deep golden yellow, shaded rosy carmine. Although not over-large, it is a very striking and effective novelty, and quite free from coarseness.

**Chrysanthemum Mme. Ferlat.**—One of Calvat's 1897 novelties. It is a very large, globular Japanese, solid and compact in build, florets grooved and incurving, pure white in colour. It was staged in good form at the Paris show last year, but appears to even greater advantage in England this season.

**Chrysanthemum Dorothy Seward.**—I am not at all pleased with this variety. The colour, a deep terra cotta shade, is nice, but the florets are short, and this gives the bloom a close appearance the reverse of graceful. It is uncertain, too, and late-formed buds are giving quite single blossoms.—S.

**Chrysanthemum Mme. Philippe Rivoire.**—This variety obtained a certificate recently, but, considering that it has been in cultivation several years, that honour is somewhat late. It is, however, a very good white flower and especially easy to grow. The blooms are full and deep, the florets have first-rate substance, and it is altogether a desirable kind.—H.

## TREES AND SHRUBS.

### NOTES ON TREE LIFE.

THE difference in the vitality of trees, especially in the characteristics in connection with their decay, is very marked. This would seem to be considerably influenced by different soils. Any observations on such subjects are always the more interesting when one can settle within a few years the date of the planting of such trees, and so form a tolerably correct estimate as to their longevity under different conditions, or, in the case of healthy trees, determine the annual progress made both in matter of height and bulk. The knowledge, for instance, that the pleasure grounds here were planted by Lord Clive in or about the year 1760 enables one to say with certainty that the limit of life of the Silver Fir on this soil is 130 years. Not one of the trees is in good health, and many have already been removed. They die hard, grand old specimens nearly 120 feet high, the majority of the branches dead or dying, and yet the tree as a whole fine in its decay. It seems almost a pity to anticipate their fall, were it not that if allowed to come down naturally they are apt to smash into and destroy young trees that have been planted to replace them. Surrey is famous for the number of its Beeches and the lovely autumnal tints they assume. The tree does well here and assumes large proportions; it grows quickly, but is not long-lived, and once it begins to go the decay is very rapid. The first symptoms of decay are an early leaf shedding, some three weeks before the healthy trees. The next season's foliage is small and scanty, and by the end of that season the tree is dead. The Elder goes even more quickly; after showing

a deterioration in the foliage early in the year, it is bare and dead before that year is out. *Apropos* of this tree, there is an instance of reproduction in a colony of young trees produced from seed that must have blown across the lake. From the age standpoint, not the least interesting is the contemplation of the various clumps of Yews that are scattered here and there, and a comparison between their size after 140 years' growth and that of the monarchs one meets with in old churchyards gives a better idea as to the wonderful age of the last-named. It is possibly the knowledge of the slow growth of the Yew, and that several generations must come and go before the tree is seen at its best, that are accountable for the few that are planted. It should, however, be remembered that in certain situations it is one of the finest trees we have, and where those situations exist and there is a probability of their continuance, no one should hesitate to plant, sparingly of course, the sombre character of the tree not warranting grouping on a large scale. I watch with each succeeding year the appearance of our only specimen of the Sugar Maple. It is a large tree and well furnished, but Mistletoe has obtained a firm and ever-increasing hold upon it, and if the theory is true that the longevity of trees is considerably shortened by the parasite, then the days of the Maple are numbered. Starting at the top with pieces doubtless at first unnoticed, but which have now attained large dimensions, it is spreading all over the trees. In connection with the destructive influence of the Mistletoe it would seem that it applies to some species and not to others. Of respectively Lombardy Poplars and Thorns, for instance, that were carrying fifteen years ago quantities of Mistletoe, and all apparently in the best of health, the Poplars are dead, but the Thorns none the worse. It may be the parasite had nothing to do with the death of the former, I simply give the result of observation. Can any cause be assigned for early collapse of the greater part of the foliage of the common Plane? The trees are apparently in the best of health, they break well, and the leaves up to the time of attaining their full size are fresh and vigorous; then there is a shrivelling of the leaf-stalk, a premature browning of the leaf, and down they come in shoals. This applies solely to the large-leaved or common Plane; I have never noticed it in the cut-leaved variety. Reverting again briefly to evergreen trees, I noticed a paragraph lately on *Taxodium semper-virens*, so far as its value as a timber tree is concerned. Given sites and soil where it does well, would it not be advisable to plant it rather largely in this country? I am aware that in some pinetums it is not at all ornamental, presenting a ragged, rusty appearance, and as though its leader had received one or two very severe checks; but on the other hand there are places where it is close on 100 feet high, and bearing in mind the fact that the tree was introduced so late as 1843, it is certain that these last have done their work very quickly, and would not in this respect suffer in comparison with the most rapid growers of the coniferæ. The comparatively new *Abies brachyphylla* is another fast-growing tree; one, some 4 feet in height when planted here thirteen years ago, is now 24 feet high. I think it is one of the handsomest of its class. E. BURRELL.

Claremont.

**Vitis Coignetæ.**—At the recent meeting of the Royal Horticultural Society at the Drill Hall the Messrs. Veitch had some capital examples of this distinct looking Vine. The plants were grown to a single stem and nearly 10 feet high,

the large, handsome foliage, somewhat woolly in character, being very showy. Of quite another character was the smaller kind, *V. vinifera purpurea*, of which there were also several plants with finely-coloured and beautiful, though much smaller, leaves, and both are welcome if rightly placed in the garden and quite distinct.

**Leycesteria formosa.**—This shrub does not always flower so freely as desirable, but when it does the effect of the nearly pure white flowers, the dark crimson bracts and seed vessels, and the deep green foliage is very pretty. It usually produces a few flowers in any position, but to flower it freely, a nice warm sunny position and fairly good soil are necessary. It is an easily-propagated plant, growing freely from cuttings in a hand-light. They may be dibbled into pots or a bed made up for them, and when they are rooted and planted out in light, rich soil, progress is very rapid.

**Ulex nanus.**—The dwarf Furze must certainly have a place in any selection of autumn-flowering shrubs, as its bright golden blossoms are very freely borne at this season of the year,

*Rosa rugosa calocarpa.*

and a group of it is just now particularly striking. Later on the common Furze and its double-flowered variety will commence to bloom, but at present the field is held by the dwarf variety alone. It is readily increased by cuttings, or shoots may be layered, which, from the habit of the plant, is an easy matter. When planted in a bed the branches may be layered and allowed to remain so, and the shoots then pushed up will form quite a mass, and when in flower make a goodly show.—T.

#### SHORT NOTES.—TREES AND SHRUBS.

**Blue Hydrangeas.**—In "A. D.'s" note on the above (p. 310), he remarks that the blue colour is usually found in the flowers of plants growing in boggy or black soils. This is not invariably the case, as the hue is often present on plants growing in the red soil of South Devon.—S. W. F.

**Cotoneaster horizontalis.**—This well-known plant, with its neat, almost dense habit of growth, is

well suited for covering a large piece of rock, and with a sunny aspect so much the better. A good depth of soil for its roots will not be without its ward in the season of growth. At the Drill Hall recently Messrs. Paul and Son had some fine plants of this freely covered with bright berries.

## GARDEN FLORA.

### PLATE 1144.

#### WILD ROSES.

(WITH A COLOURED PLATE OF *ROSA CALOCARPA* AND *R. HUMILIS RUGOSA*.)

SOME of our Rose-growing nurserymen have awakened to the fact that some wild Roses are worth growing, and even at flower show a number of them have been seen; they do not, however, appear to advantage in show. But on cool grass in the hot summer days

there is nothing that is more delightful whether they be those of our own count like the Sweet Brier, Dog and field Roses or those of other countries, such as the beautiful Altai, the American swan Rose, gallica and many others. Soon we hope to be able to get many of them easily in nurseries as any other Roses, and if our trade Rose growers would only get out of their narrow way of offering plants singly at needlessly high prices we might yet see effective groups of wild Roses. But they should be sold by dozens, and Sweet Brier and Dog Rose which could be used as covert, should be offered by the thousand. As to growing wild Roses, the best way is not to plant them in the garden itself, but rather on grass walks or rough banks, or in new-made hedgerows. One of the prettiest ways we have seen was a border of them in a grass orchard of young trees, with groups of wild Roses on either side of a grass walk between; and beyond meowing once or twice, no other care was given, as wild Roses are able to look after themselves. If their beautiful bloom does not last long, the fruit is pretty, and though they are not of the things that please us well for garden cultivation, as the best garden Roses, the wild Roses may often be used with fine effect.

Among the wild Roses that give us most pleasure there may be named the Needle Rose of Japan (*R. acicularis*); the field Rose or the Dog Rose, which generally represent themselves in our hedgerows pretty freely, and therefore generally need no planting; the Carolina Rose, charming for its distinctive way of blooming and very late flowers, excellent also for the house for cutting; the alpine Rose and its Pyrenean variety, excellent for rocky banks; the Cherokee or the Indian Rose, tender away from protection, as all single Roses should be hardy; the glossy Rose (*R. lucida*), one of the most excellent and free we have, blooming, like the Carolina, late in the year, and growing

\* Drawn for THE GARDEN by H. G. Moore, Gravetye Manor. Lithographed and printed by J. Goffart.

ROSA CALOCARPA 2 R. HUMILIS RUBOSA

marshy or almost any ground, pretty in flower too in winter; the Austrian Brier, a native of Central Europe, and hardly even among wild Roses, although we are accustomed to treat it as a garden plant; the Musk Rose and its forms, all handsome Roses, and also the many-flowered Rose (*R. multi-loba*), and, second to none, our own sweet briar and the Japanese Roses (*R. rugosa*). The Scotch Rose also is pretty, and has long been represented in many gardens by its noble forms. One of the most beautiful of its single forms is the Altai Rose, a large, soft lemon-coloured flower. The creeping Rose of China and Japan (*R. Wichuriana*) is quite distinct from any, and excellent for running about rocky banks and as a climber. These probably are but a small number of the Roses with which the northern and mountain

colours are, we think, in a mass as beautiful as any, as, for instance, the Oak woods of Sussex and Beech in Surrey and Bucks. At present there is scarcely a hardy summer-leaving tree of Europe or America that is not beautiful in colour, though that colour varies much according to the soil and other conditions. For instance, the Aspens, so pale in colour in Sussex and in Ireland, on the limestone have sometimes the most brilliant of fine colours. One tree we have noticed lately is very handsome—namely, the Tupelo tree (*Nyssa*), which is not a European tree, however.—Ed.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**PEAS.**—In favoured localities and sheltered gardens a sowing of some dwarf early Pea may be made during the present month with a view to having a few gatherings somewhat earlier than is obtained by sowing at the latter end of January.

**BROAD BEANS.**—These being somewhat hardier than the Peas, there is less risk in autumn sowing, and a few rows should certainly be put in now on a warm border. If such ground is scarce just now the rows may be made closer together, and if all goes well with them the plants in every other row may be transplanted in the spring. A few dishes of these early in June are considered a delicacy, and well repay for any trouble incurred during the winter in affording a slight protection. Early Mazagan is recommended for present sowing, as it possesses a hardy constitution, is of dwarf habit, and turns in early. Beck's Dwarf Green Gem is of recent introduction compared with the former, and is recommended as being prolific, early, of dwarf and compact habit, and worthy of a trial for present planting. Beans do not require the same attention as Peas, as birds do not attack them, but it would be wise to coat the seed in the same way as recommended above to secure even rows of plants.

**TURNSIPS.**—If by chance some of the more tender varieties have been sown and any doubt exists as to their hardiness, it would be wise probably to get them off the ground before we get any severe frost. The roots will keep for a long time in good condition if not exposed. They may be stacked against a north wall and covered with bracken or straw. This entails very little trouble, and it is convenient to get the roots as they are required. The main late sowings of Chirk Castle are sufficiently hardy to stand the most severe winter; therefore they should be allowed to remain undisturbed, as their quality is never better than when used direct from the ground.

**LEEKS.**—These will be in greater demand now the summer vegetables are over. If the plants have not been moulded up as recommended, it is not too late to draw some soil round the stems 6 inches or more in depth. Where they were not planted in trenches the same as Celery it will be necessary to loosen the soil on either side of the rows, but not too close to the roots, to get the soil in a suitable condition for the purpose. Before doing so, however, a good soaking of liquid manure will prove of great assistance, as perhaps no other crop absorbs more moisture and nutriment out of the ground than this one, and after such a dry autumn the soil about the roots will contain very little moisture.

**TOMATOES.**—The past month has been very favourable for these plants, bright sun with abundance of air causing them to make short-jointed, firm growth, while the flowers have opened strongly and set freely. The earliest fruit will be changing colour, and though it is necessary, to obtain these of the best flavour, to allow them to remain on the plants until they become well coloured, they should be gathered directly they reach that stage to encourage later fruit to develop. Continue to surface-dress the roots piecemeal, using rich loam and some plant food, which is more lasting and of greater benefit to the plant during the winter than soaking the soil with liquid manure, or top-dressing the plants with several inches of decayed manure. Keep the plants free of superfluous growth by pinching out crowded shoots; when these are allowed to develop the knife has to be used, and the sudden removal of a large quantity of foliage gives the plants a check. Give fresh air on all favourable occasions, and keep sufficient warmth in the pipes to expel moisture. On no account should the plants be syringed, neither should the floors, &c., be damped, as moisture in this way is often the forerunner of disease.

**BRUSSELS SPROUTS.**—Like other winter crops this season, these have done remarkably well, and promise to give a good supply over a long season. Care is necessary in gathering these to see that the right sprouts are used if the plants are to remain productive as long as possible. It is not uncommon for the daily supply to be obtained from one or two plants which happen to come first, resulting in some being

*Rosa rugosa.*

world is clothed, and of which many have yet come to our gardens.

**Autumn tints.**—I am constantly hoping to see an article in your columns on autumn-tinted trees and shrubs. Of course, if one lives near the water the matter is simple. You can go there week after week and note the tints you like best. But if you do not live near an arboretum you have not so good a chance. The trees in a nursery are generally too young to show their real effect. I have about 50 acres available for planting. I propose to use them principally with a view to autumn tints. I am, unfortunately, on a hillside facing west, near the sea, so I shall not be able to attract as well as the lucky people in the midlands; but with adequate shelter belts something may be done. I should, therefore, greatly appreciate an article by some specialist on hardy trees and shrubs which take beautiful autumn tints.—K.

No doubt it is interesting to find out the names of trees and shrubs that have brilliantly coloured leaves in autumn, but it is to a lover of autumn tints almost an academical inquiry. Of late, in this country around London the difficulty is to find a tree that has not beauty of colour. Even the most common trees that are never noted for their

For this purpose either of the following varieties may be selected, as they are of good constitution and naturally dwarf and early: Chelsea Gem, Early Sunrise, William Hurst, and Ringleader. A warm, well-drained soil is necessary, such as a south border, where they can get all the sun possible during the winter with the protection from cutting winds which the wall affords. The seed should be put in at once while the ground is still warm. This will cause it to germinate quickly, which is very essential, as when it remains in a dormant state for any length of time at this season, many of the seeds decay, and thin rows result. As a further protection against this the seed should be coated with red lead, which also preserves it to a great extent from birds and mice. Constant attention will be necessary to protect the plants during the winter. Wire guards are best to ward off birds, and frequent dustings of fine dry ashes to preserve them from slugs. Broad shallow drills should be formed and the seed sown evenly, it being better to draw a little soil round the plants as they push through than to bury the seed too deeply at first. Should, however, the plants fail to stand through the winter, the loss of seed and labour are not great, and the ground is available for sowing again towards spring.

quite small and barely fit for table, while others are past their best and are loose and open. These are not satisfactory when sent to table, and lead to a certain amount of waste. Looking the plantation over carefully and gathering the sprouts when they have reached the desired size will save this, and their season will be prolonged. The heads of the plants should be retained as long as possible; the early removal of these causes the sprouts to develop more quickly and thus shortens their season.

**BEEFROOT.**—Owing to the absence of frost the roots in most gardens are still in the ground, which is an advantage, as the quality is not likely to suffer as when early lifting and storing are resorted to. The roots are not so tender as many suppose, and I would advise those who have always made a practice of lifting the crop to leave a portion at least in the ground. If every other row was carefully lifted and some soil drawn well round these roots that are left, I do not think many will be found decayed in spring unless the winter proves exceptionally severe.

**RHUBARB.**—Those who can afford to lift a few roots of Royal Albert or some other early variety and can command a gentle warmth, either from a bed of leaves or a warm greenhouse, will find little trouble in having Rhubarb ready for use within a few weeks. The simplest plan is to lift a few clumps with soil about them and pack them in a deep box. They can be easily placed under the stage in a warm house, but not too near the hot-water pipes. It is better to exclude light, which is done by covering the box with old sacks. Clumps may also be placed in the Mushroom house or a warm cellar, or, failing either of these, a hot-bed of leaves and manure about a yard deep should be formed, the clumps placed on this and covered with cement barrels or boxes. A gentle warmth excites growth so long as plenty of litter is placed round and over the covering. The old stools should not be destroyed when they are done with, but split up in the spring to form new plantations.

RICHARD PARKER.

#### FRUIT HOUSES.

**PINES.**—With the exception of fruiters, Pines will now be resting, especially successional plants required for starting in the ensuing and two following months. Most growers defer starting these until the turn of the year, but when fruits of the Queen variety are required in the early spring months, there is no alternative but to start a batch of plants early in December. It is essential that the plants have as long a period of rest as it is possible to afford them. With this end in view, the bottom-heat should not exceed 70°, while a temperature of 60° and 65° will suffice for night and by day. If growing in pits, damping down should be entirely dispensed with, but if in lean-to or span-roofed houses, a slight sprinkling of the paths will be beneficial on bright days, and a little air may be admitted during the forenoon to prevent the temperature rising too high. If the plants are plunged in a bed of tan or leaves they will require but little water, but at the same time they must not be allowed to become dusty, as this will mean loss of roots. It sometimes happens that a few of these plants start to throw up fruit just when they are being got to rest. This in some instances is far from being an evil, as these fruits will ripen at a time when variety for the dessert is very limited. Such plants should be removed to the fruiting house at once. The next batch of plants intended to form a succession to the above need not be kept quite so dry at the roots, but the soil should never approach more than a medium state of moisture at the most. If these are in a separate pit or division, treat them as regards temperature, &c., as recommended above. Suckers potted up as advised in the latter part of September will be sufficiently rooted for the temperatures to be lowered to the above figures, but if those which were shifted at that time into 7-inch and 8-inch

pots are not yet sufficiently rooted to be got to rest, continue former treatment for a week or two longer. Fruiters must have a brisk day temperature of 80°, and from 70° to 75° at night, according to outside conditions. See that they get sufficient root moisture with accompanying stimulants, especially those plants carrying fruits which are rapidly approaching maturity. Sprinkle the floors and the surface of the beds with a fine-rosed water-pot several times a day, but for the next few weeks dispense with the use of the syringe. As a set-off against this, keep the vapour troughs constantly charged, and strew a little guano in them every few days. To economise fire-heat, cover at night with blinds, dressed covers, or mats. There are disadvantages attending the use of covers unless the precaution is taken to shut off part of the heat when these blinds are let down or mats put on. Between now and the end of the year a good supply of Oak leaves should when possible be collected and put by in some out-of-the-way place for future use. Failing Oak leaves, Beech or Spanish Chestnut are the next best, but if these are not obtainable, it is better to use tan for Pine growing. The latter is best bought in some little time before it is wanted, so that rank gases may be dispelled in the process of fermentation previous to placing it in the plunging beds. If there is a likelihood of the house in which the first lot of Queens is to be started being at liberty, give the structure a thorough cleaning.

**CHERRIES.**—In many places where very early Cherries are in demand it is the practice to house the trees early in November and to bring them on gradually by the aid of fermenting material alone until the buds are in a forward state. When leaves are not obtainable, fire-heat has to be relied on to give the necessary warmth, but of this little or none will be required in the initial stages so long as the weather remains fine and open. In the event of frosty weather setting in, a day temperature of 45° will suffice and 5° less than this will be quite high enough for the night. When the buds begin to show signs of moving, a rise of 3° more both by day and night may then be allowed. If the soil about the roots is in a dry condition, give it a soaking of tepid water, but do not water it if in a medium state of moisture, as it should be if the trees have been standing outside. If the trees are planted out in an inside border, test the latter and afford water in sufficient quantity to moisten it throughout if found necessary. In this case I am assuming that such matters as house cleaning, lime-washing of walls, and dressing of the trees with an insecticide afterwards, also the training and tying of the trees to the trellis, have had attention. If the border has not yet been top-dressed, get it done when closing the house for starting. Remove as much of the inert surface soil as can be done with safety and replace it with fibrous loam with which has been mixed a little lime rubble or old plaster and some bone-meal. This should be spread evenly and be firmly trodden afterwards. Houses containing planted-out trees which will be started early in the new year must in the meantime be kept fully ventilated, and see that the borders do not become too dry. As opportunity offers, get the trees pruned and retied to the trellis and the houses put in proper order. Trees in pots or tubs may, of course, remain outdoors until actual starting time arrives, but see that the litter, Braeken, or old hot-bed material is well mounded over and around them should frost succeed the present mild open weather.

**PEACH HOUSES.**—All the inside borders of houses in which the trees are now resting should be frequently tested to guard against their becoming over-dry. Alertness in this particular will in a great measure prevent the trees shedding their buds, as over-dryness of the border is more often than not the cause of this complaint. Proceed with the pruning, dressing, and tying of the trees as circumstances will permit, keeping a fair amount of work of this description in reserve should a change of weather cause a suspension of outdoor operations.

A. W.

## FERNS.

### HARDY EXOTIC FERNS FOR GROUPING.

SOME Ferns are much more suitable, because more effective, than others for the purpose under consideration. Among those most desirable are a number of exotic kinds as hardy, as in some instances hardier, than our native Ferns possessing characteristics and variety of foliage quite distinct from those of the British varieties. They should therefore be planted in the hard fernery along with our native kinds, and thus a more varied and interesting, as well as distinct, effect will be produced. North America furnishes us with a very handsome hard Maidenhair in

**ADIANTUM PEDATUM.**—This species is so hard that 30° of frost have failed to injure it in dormant condition. Owing probably to its being so hardy it commences to grow early in the spring and is then liable to injury from late frosts also from the cold east winds. If planted where it is protected from these injurious influences, and in the shade where it will not be burnt by hot sun there is no reason why as lovely a clump of this Fern should not be secured as any in its native wilds. It grows 2 feet in height, the stems being long and bearing spreading pale green beautiful foliage. If half-a-dozen or so plants are put in a clump they will be sufficient to produce a very pleasing effect.

**LASTREA GOLDIEANA** is another North American species, very pretty, bold and effective. Its fronds are each 2 feet to 2½ feet in length, the pinnae occupying about one-third of the frond in length, wavy, and of a striking metallic green of the shades, which give a peculiarly pleasing appearance thereto. It is of erect habit and is a good kind for the background.

**LASTREA MARGINALIS** is spreading in habit, the colour pale green, the fronds each 15 inches to 20 inches long, triangular in outline and quite distinct from those of any other hardy kind.

**ONOCLEA SENSIBILIS** requires a sheltered a shady position rather inclined to be damp, and forms one of the most beautiful objects in the hardy fernery. Each frond attains to a height of 2 feet to 2½ feet, the leafy portion is a lovely pale green, each pinna being almost exactly like an Oak leaf, the frond having the appearance of a number of these fastened by their bases to the stem. In America it is called "the sensitive Fern" owing to its susceptibility to injury by wind and sun, but, when protected from these, will form a mass of lovely foliage. It is extremely hardy and free in growth. The fertile fronds are very remarkable, as they grow about a foot or 15 inches high, the upper portion, 2 inch or 3 inches of the top of the frond, looking like a number of dark green beads secured to the stem. These are the receptacles of the spore cases, and remain standing erect on the plant long after the barren fronds have perished in the autumn. There are three very ornamental North American ferns, two of them totally distinct from the British Royal Fern, but equally hardy.

**OSMUNDA CINNAMOMEA** produces large barren fronds not unlike a male Fern, but more pointed at the apex and thicker in texture. The remarkable feature of this Fern, however, is its fertile fronds, which are produced in the centre of the plant, and stand perfectly erect. These fronds are very woolly and destitute of foliage, the upper portion consisting entirely of the spore cases and their receptacles. As these mature they take on a beautiful cinnamon colour. This characteristic has given rise to its specific name as well as its common name, the Cinnamon Fern. A clump of this very distinct and ornamental species forms a most attractive object in the outdoor fernery.

**O. CLAYTONIANA** is quite distinct from the preceding. Its fronds are much more blunt, as are the pinnae; the colour is a lovely pale green

quite a velvety appearance. The fertile are similar to the barren ones, only that of the pinna midway of the frond on each the stem, instead of being like the others, inverted into the spore-bearing portions, being contracted, and eventually becoming give an appearance to the frond which has the characteristic name of O. inter-

It is a very handsome Fern, and should be very hardy fernery.

*PYCNIDIUM GRACILE* resembles the British O. but the fronds are much lighter in texture and more graceful in habit. The young fronds often come up nicely tinted. This is another which should not be omitted from a collection of hardy Ferns.

*PHYSICUM MUNITUM* is a handsome dark species, bearing along the stem closely set, divided pinnae, serrated at the margins. The fronds are often 2½ feet to 3 feet long and 4 inches wide. It is a remarkably effective species and very hardy.

*SCITHOPTERIS PENNSYLVANICA* and *S. GERMANICA* are both commonly called the Ostrich-tail Fern and the Shuttlescock Fern, the former because of the very decided curl of the pinnae in process of development, and the latter because of the strikingly symmetrical habit of growth and the shuttlecock arrangement of the fronds. These ferns come, the first from North America and the other from many parts of Europe. They are very many considered to be the same species, differing slightly as the result of climate or position. They are, however, sufficiently distinct to constitute it desirable to have both in cultivation.

*Pennsylvanica* grows much larger, is of a darker green in colour, and appears to be hardier than the other. *S. germanica* is, however, the prettier in colour is a greyish green, the fronds numerous and more graceful. The fertile fronds of both are produced in the centre of the plant and are devoid of foliage, being solely spore-bearing, very peculiar in appearance. These last come to the plant months after the barren fronds have been away.

*STRÆA ATRATA* is a very hardy Japanese Fern, standing erect in habit, dark green, evergreen and effective.

*SREBOLDI*, another Japanese species, has broad, leathery fronds, distinct and desirable for contrast with the lighter foliaged kinds.

*LOMARIA ALPINA* is a perfectly hardy New Zealand species which grows in dense clumps, dwarf; fronds 4 inches or so in length, not unlike the British *Blechnum Spicant* in appearance. It spreads quickly, creeping over stones and rock-work, and forming quite a carpet of green foliage.

*LOMARIA* is a variety of *L. alpina*, with narrower fronds, which are more slender and prettily veined. The fertile fronds of both these *Lomarias* are totally distinct from the barren ones, being erect and the leafy portion rolled back to form a covering to the spore cases on the back of the frond.

*PHYSICUM ACROSTICHOIDES* is a North American species. It is evergreen, has fronds each 18 inches to 24 inches long; the upper fertile portion is contracted. This species is very distinct and forms a nice contrast when surrounded by other clumps of lighter coloured and more careful kinds.

Besides the preceding there are other exotic kinds which may be cultivated successfully in many parts of the country, but which are not sufficiently hardy for cultivation in some of the cooler and more exposed parts. The foregoing, however, are so hardy, that they may be planted with full reliance in their hardiness in any part of the kingdom. B.

**Shade and sun-loving Ferns.**—It is a mistake to consider all Ferns as plants requiring shade and moisture. There are, on the contrary, many which like full sunshine and bright light. With our outstanding *Cystopteris alpina* and *fragilis*, which grow in our walls as well in sun as in shade, there is the class of Ferns which actually requires sunshine. *Cheilanthes* from the Old World, as well

as those from the New, only do well in a sunny aspect. I have had experience of this for some years. I could not succeed at Geneva in cultivating *Cheilanthes odora*, *lanuginosa* and *vestita*. In spite of every care given to them, they suffered from general weakness, ending in decay. At last I one day saw *Woodsia hyperborea*, that delicate and fragile plant, in full sun along an alpine road in Italy, and an idea occurred to me; and on returning I planted all my *Cheilanthes* in sunshine on a south wall. The result was good, and I recommend the plan to Fern growers. But it was necessary also to change the soil in which these plants were cultivated, and I set them in soft porous mould composed of Sphagnum Moss, peat and sand; good drainage and frequent watering ensured an immediate and excellent result. That which proved satisfactory for *Cheilanthes* I then tried for *Woodsia hyperborea* and *ilvensis* (the treatment did not do for *W. obtusa*); then for *Scelopendrium hemionitis*, that pretty and curious Fern from the south so rarely met with in gardens, where it is considered difficult to grow. Then I subjected to the same treatment *Nothochlena Marantæ*; and this lovely Fern, which formerly did not do successfully with me, turned out marvellously well. It is, then, absolutely certain that many species of Ferns—examples could be multiplied—require sun and plenty of air—H. COREYON, in *Gardener's Chronicle*.

ROSE GARDEN.

STANDARD ROSE STOCKS.

THE traveller by road may now see men grubbing up Dog Rose sticks to use to graft fine and often delicate Roses on, the sticks in heaps beside the roads, rootless, and looking like crutches for cripples, which they are to be in another sense in a year or two, when dying Roses are to be seen supported by them in our gardens. Nurserymen buy them from the men who cull them in the hedgerows and copses and think them good enough to put Roses on. Everybody who has tried to get a Dog Rose out of the ground will know how deep running the roots are, and how difficult it is to get them up, and in their rootless state the wonder is that any of the plants live at all. Many die, but how can we expect such dried sticks to become living founts of energy for the Rose? Most wild Roses, unlike trees, do not send all their life through the same stem for years, but throw up fresh stems as the old ones wear out and die. It is by the merest chance that we get a healthy Rose from such a stock, and so we may see more than one reason why the Rose should die often when it is quite hardy. A great improvement on this way is grafting Roses low on the seedling Brier, which means young clean roots and vigour. When Roses are worked low on this stock they sometimes throw out roots above the union, and liberate themselves, so to say. Besides, the stock is young, and far more certain to endure some years than the dried, and often half dead, sticks of the wild Rose, on which not one in fifty Roses will ever attain to the size and dignity of a real Rose bush. It is as if we were foolish enough to put an acorn on the top of an old stub Oak and expect it to become a tree. And it is not only that we put our Roses on worn-out crutches, but we put them high in the air, so that the Rose, often of somewhat tender origin, is set in the best place for the frost to kill it, while Roses grafted on the root or on the collar of the seedling Brier will be quite safe with 2 inches of earth above them; so that if the frost kills the tops, as it often does even in Southern England and Ireland, it will not hurt the root, and the most delicate Tea Roses will spring up again vigorously after the hardest

winters and bloom as well as before. Vigorous Tea and Bengal Roses on their own roots are none the worse for being cut down in this way, though they are often thrown away by mistake because the tops are dead.—Field.

**Rose Gloire des Polyantha.**—Want a lovely gem this is for massing or for pots. Its pretty miniature deep pink flowers are produced in immense pyramids—really wonderful for such a diminutive plant. A hundred or more of this beautiful Rose would provide a fine mass of colour the best part of the summer and autumn. It should also be valuable for pots for conservatory embellishment. Nothing is more telling than this and kindred Roses when well grown and interspersed among fine-foliaged plants in the conservatory. They also come in very useful for room decoration. This Rose has been one of the most attractive in this unusual autumn, and there are only three or four others among the Hybrid Teas, such as *Camoens* and *Marquise de Salisbury*, that can really compete with this fine Polyantha variety for garden or park decoration.

**Colour in Mme. Falcot Rose.**—Herewith I send you some buds showing their very rich colour, running W. A. Richardson very close. The fact that from April to December flowers can be had every day places Mme. Falcot far ahead of W. A. Richardson. The plants are grown in a cool, airy, span-roofed house running north and south. About a dozen varieties of Teas are grown; amongst them are four large very old plants of Mme. Falcot, and from these I gather the richest coloured Roses. Young plants on their own roots or budded from these fail to give anything like the rich colouring of those sent. The plants have been budded on standards, and I know them to be above twenty years old. The border was entirely re-made two years ago, and this year the result has been beyond all expectations. These four plants have given us thousands of Roses in May and June, over 100 were taken every morning, and now I can gather on an average two dozen every morning with hundreds of buds to open. I have been trying for several years past to get the same colour into flowers on young plants, but have never been able. Is it the age that does it?—J. R.

**Chinese, Bengal or Monthly Roses.**—These old-fashioned Roses do not appear to have been in much demand of late, but now that we have such good additions as Duke of York, Irene Watts, Madame Eugène Resal, and Queen Mab, they may once more come to the fore. Probably we have no more certain autumnal bloomers than these. They commence to flower as early as any, are continuous, and seldom fail to carry a few presentable blossoms as late as the middle or end of November. The old Common Blush China has been introduced for a little more than a century, and is still a favourite in many cottage gardens. The Chinas have a close affinity with our Teas and Noisettes, often exceeding these in freedom of flowering. As a hedge of 3 feet to 4 feet the stronger growers are charming, and may be pruned very roughly without fear of losing blossoms. I would select the Old Blush, Mrs. Bosanquet and Abbé Melan as hedge plants. But it is against a low wall that is well sheltered that we find these Monthly Roses most at home. Here they grow and flower in delightful profusion. When the dwarf growers, such as Queen Mab, Cramoisi Supérieur, Eugène Beaulainais, Little Pet and Red Pet are massed thickly, there are few better or more permanent subjects for bedding. They are far from expensive, being the very easiest of all Roses to increase, and doing much better when grown upon their own roots than upon foster roots. In a warm nook or corner, especially if the winter be fairly mild, one can cut Roses all the year round, and late flowers stand well. Nor does this continuous blooming harm the plants for the ensuing spring and summer. They are the most thoroughly perpetual Roses we have. No matter what the season they are charming, and deserve far more

attention than they have received of late. Being few-petalled, they open freely, and whether the season be wet or dry, hot or cold, the Chinas will not fail us.—R.

**Roses at Kew.**—We rarely see Roses in full growth covered with buds and open flowers, and with foliage looking beautifully fresh, in October. A few varieties were seen in this condition then at Kew, and among them all, the beautiful Tea Rose G. Nabonnand is the best, the dark bronzed leaves, without a blemish, forming a perfect setting for the clusters of flowers and handsomely shaped pointed buds. Very nearly akin to the above in leaves and flowers, but not, perhaps, quite so free-flowering, was Clement Nabonnand, and other fine Teas or H.T.'s were Hon. Edith Gifford, Augustine Guinoisseau, Grace Darling, Abricote and Mme. Lambard. Some of the China Roses too were full of flower, the best noted being Laurette Messimy, with pink and yellow flowers that had much of the Tea Rose form about them; Fellenberg, deep pink and immense clusters, especially on lateral branches of strong shoots which appeared to have been stopped; Sanguinea, very fine, and Cramoisi Supérieur. A group of White Fairy, with large clusters of flowers much resembling those of Félicité Perpetue, but on a dwarf plant, was full of bloom. These late-blooming Roses are a great boon, and further additions will be very welcome. A large mass of Rosa rugosa Blanche de Coubert is now well in flower at Kew. This is a fine Rose with pure white flowers, borne in big clusters and almost fully double. The growth is particularly fresh looking, and only rose some 2 feet at most above the soil, which was completely hidden beneath it. This new plant will probably supplant the other whites in the class, as the flowers are more enduring, though not sufficiently double to appear lumpy, and the buds are shapely and chaste-looking.—J. C. T.

## FLOWER GARDEN.

### LINARIA ANTIRRHINIFOLIA.

This elegant little rock plant here illustrated was photographed in the nurseries of Messrs. R. Veitch and Son, Exeter, where it forms a very neat spreading mass about 2 feet across and about 6 inches to 8 inches high. It has the advantage of not spreading so rapidly as some of its congeners. It has flowered incessantly throughout the summer, and at the time of writing (November 2) is still in bloom. The flowers are arranged in a raceme and of a bright purple colour. The three-lobed upper lip is yellow at the inflated base, while the lower lip is marked with dark maroon veins. The corolla, calyx and stems are covered with minute hairs. The leaves are alternate, rather fleshy, ovate in shape, scarcely more than a quarter of an inch in length, with margins entire. The lower leaves are glabrous, the upper ones slightly pubescent. The plant is of the easiest possible culture, and can be highly recommended for the rock garden.

Elmside, Exeter.

F. W. MEYER.

**Seeds lying dormant.**—Is it usual for the seed of Castor Oil plants to lie dormant? A seedling has sprung up which must have been in the pot some five months.—E. O.

\*.\* As a rule, Castor Oil seeds germinate quickly, though occasionally they will come up in a somewhat intermittent manner, but even then five months is an unusually long time for a seed to remain dormant. Many subjects, however, are very irregular in their germinating, and a good deal of this depends upon the length of time the seed has been kept before sowing. Some of the Primulas, for instance, will grow at once if sown directly the seed is ripe, while if the seed

is kept a few months it will sometimes lie in the ground for a year or nearly so, and grow fairly well after all. When a quick-growing subject like the Castor Oil lies in the ground for an unusually lengthened period, the probability is that it is caused by a low amount of vitality, and the young plant is at first generally a weakling. I have had seeds of one of the Coral trees (Erythrina) lie for nearly two years and then several of them grew, whereas they generally germinate very quickly.—H. P.

### PLANTING SMALL BULBS.

DURING some years of practical experience among bulbous plants, and generally with large and varied collections, the question has been frequently put as to the depth at which certain bulbs may be planted. The answer usually given is that ordinary bulbous plants may be planted at twice their own depth, and though this may appear a fair and reasonable depth for many classes of bulbs, I am convinced by continued observation that this rule-of-thumb method is not at all times the best. By planting on the above lines, the very smallest

rather deeply embedded in the earth, though they descended to these depths is quite clear. Some few years ago I had through my hands several hundred thousands of Tenby Daffodil collected in Wales, all be lifted with their foliage as complete as possible. In measuring I found many bulbs had upwards of 18 inches deep, while an equal distance remained from the ground level to tips of the leaves. Here was a length of 3 of growth as the output of one small bulb. Under cultivation, too, I have repeatedly witnessed the same thing where chance bulbs have been buried through trenching the soil. Frequently I have found such things as Chionodoxa, Starch Hyacinth, Crocus species, Icojum vernum, &c., at a depth varying from 12 inches to 18 inches, while all have small bulbs.

The curious part of the whole matter is that all such bulbs produce much stronger stems, leaves and flowers above ground than those planted at the usual depth. For example, the sprouts of Chionodoxa have contained as many as eighteen flowers, always larger than those

*Linaria antirrhinifolia* in Messrs. Veitch's nursery at Exeter. From a photograph sent by Mr. F. W. Meyer.

of bulbs, for instance, the Snowdrops, Chionodoxas, Scilla, Starch Hyacinth, Fritillaria pudica, and all such, are brought very near to the surface. This nearness to the surface, particularly in the case of bulbous plants requiring a longer season of rest than the majority, surely cannot be good, when one day incites perhaps to a rapid start, and the next, by some extreme change of wet or cold or both combined, is equally calculated to retard in the same degree. Much of this undue excitement may be modified by planting many things at greater depth. In doing this, however, we must be guided entirely by local influences, especially of soil, although it is not expected that the increase would be material. Doubtless many who have choice collections of hardy bulbs would hesitate before planting some of the smallest of them, say, at 6 inches deep, and yet I feel that for a permanency many things would be safer than at the orthodox depth of, say, 2 inches or 3 inches. The Narcissus family, for instance, is now planted shallow for the most part, and so grown produces bulbs of capital form and with little neck. In Nature, however, the bulbs are often found

planted in the ordinary way. The same mark applies with equal weight to Snowdrops and other things. And while there is this doubted increase of vigour in these small rooted plants, the question appears to arise: Are we not losing a good deal through planting the majority of small bulbs too shallow? Particularly does this strike one in regard to naturalising hardy bulbous things generally, because if Snowdrops and Snow Glory can with impunity be buried at these greater depths, and then the flowers greatly increased in quantity and large size, there is surely something to be said in favour of very deep planting of such things. The only point upon which I have no trustworthy evidence is whether these bulbs, deep turned in by accident, appear at all in the ensuing year or not. This, however, could be readily determined by turning in a few such bulbs, and noting the result the next season. Less than a year ago I was an eye-witness at Long Ditton of an endeavour to raise some particularly strong examples of Chionodoxa Luciliae. While every care was used and some patience the general result was the same, and a lot

ched stem 12 inches or 15 inches in length away without the bulb. Now in the ordinary way we plant such things at 2 inches or 3 inches deep at most, yet we never see the sprays of blossom or even the stouter and more vigorous leaves from this treatment, and which is so noticeable in the deeply buried examples. At the latter will come to the surface actually there is no doubt, and flower abundantly and well, and at the same time be out of the way of ordinary interference. In trade sections the trouble is to get the ground where such things as *Muscari* and *Chionodoxa* have once been established. And if such bulbs can thus take this firm hold of any spot themselves, there is little to prevent their being planted in this way if anything may be deduced thereby. So far it appears to be a gain of greatly increased vigour all round; and if this is so with those named, other things, *e.g.*, *Neissus triandrus* and such like, are worth a try in the same way. E. JENKINS.

Ampton Hill.

ACANTHOLIMON.

A SMALL genus of beautiful alpinines, flowering usually in July and August when many of the other alpine flowers are past. In *A. venustum* and *A. glumaceum* (the former more particularly) the tufts are composed of rigid, downward-pointed leaves that are very spiny. *A. glumaceum* is of the same tufted growth, but not so spiny. These pretty alpinines are not at all difficult to grow, and, if we except the plants just mentioned, prefer a light sandy loam about 1 foot deep and a partly shaded position in the rock garden. *A. glumaceum*, on the other hand, by reason of its free, vigorous growth and more profuse flowering, is better suited to soil that is deep and rich, at the same time not too heavy. This species is easily increased, and makes a capital edging to paths and beds in many parts of the garden. The other species are of decidedly slower growth and difficult to increase, unless seeds are obtainable, which is not always the case. As regards the general propagation, and where large plants of the rare kinds exist, it is a good plan to work some cocoa-nut fibre and sand in equal parts into the tufts in early autumn. Before working in this material some of the shoots should be gently torn, so as to half sever them at the heel or junction; then gently work in more material around and water to settle the soil. Many of the growths thus treated will root by spring. Cuttings made in the ordinary way are by no means certain, but when this method is adopted August or September is the best time. All cuttings so-called should be torn off with a scalpel and inserted without further ado. Cuttings made to a joint are only so much waste material. The following are the best kits:—

**ACANTHOLIMON GLUMACEUM** is the best known and so the most vigorous and free grower, producing compact cushions of narrow dark green leaves that are spiny at the point, and spikes of rose-coloured flowers from June to August. Given liberal treatment and a deep sandy soil, this free-growing plant is of the easiest culture. At least many years ago this species formed an edging a foot or more wide and about 150 feet long and when in flower was a pretty object. Such free-grown plants may be pulled to pieces readily, and if done in April, the losses will be very few. Firm planting is most essential. This species is about 6 inches or rather more high. Native of Armenia.

**A. VENUSTUM**.—This is the best of this little group, and a really delightful plant when seen in good condition. I lost the finest specimen I have ever seen during the great frost of 1895. The

plant, unfortunately, had been left fully exposed with other alpinines in pots. This lovely species in the summer of 1894 produced some forty spikes of its charming pink blossoms. The tufts are dark green with a slightly greyish or glaucous tint overlying the same. This species is of much slower growth than *A. glumaceum*, and requires some good sandy loam, with leaf soil and broken brick rubbish mixed freely with the soil. It produces its rose-pink flowers in July on one-sided, slightly arching spikes, and is certainly one of the most charming of midsummer alpinines. Very firm planting, a rather sheltered spot, and a deep soil, well drained, should be given. It is a native of Cilicia, and grows about 6 inches high. If seeds could be obtained freely this would make a most beautiful plant, but I have not yet been able to obtain a crop of seeds after many trials, and would gladly welcome any hint to bring this about from either home or continental growers of this fine species.

**A. ANDROSACEUM**.—This species is easily distinguished from all else by the more dense tufts which it forms when established, as also by the rosettes being less spiny. This is not so much due to the spines as to the pliant nature of the leaves. It is of easy culture, spreads somewhat freely over a ledge of rock, and produces pink blossoms on sprays 4 inches high.

**A. ACEROSUM**.—The very dense character of this species and the grey glaucous hue of the leaves at a short distance remind one of *Dianthus cæsius*. A closer inspection, or even an unwary placing of the hand upon the spines, will quickly dispel any such idea, since the short, greyish glaucous leaves are the most spiny of all. In growth it is much more compact than *A. venustum* or *A. glumaceum*. The flowers are pink, and produced freely on stems nearly 6 inches high. From Asia Minor.

These, I believe, are all the species at present in cultivation. The following information has been gathered from the dried specimens at Kew:—

**A. KOTSCHYI** is about 4 inches high, with distinctly broad leaves, being spiny and freely flowered, blossoms white.

**A. ARMENUM** has pink blossoms on sprays nearly 6 inches high.

**A. CEPHALOTES** has rosy pink flowers in globose heads, the latter resembling the *Armeria*, while the spiny leaves are less numerous in the rosettes than in most kinds. This comes from Kurdistan.

**A. LANCEOLATUM** is the tallest species, growing about 9 inches high, the leaves long and narrow.

**A. LIBANOTICUM** is exceedingly woody and dense in growth. It is a Syrian species, with flowers of pink blue.

**A. PINARDI** also has pink blossoms, the specimens varying in stature, possibly on account of age.

So far as could be determined by dried specimens, many of these not now in cultivation are very beautiful, and, from the general scarcity of good midsummer alpinines in the rock garden, would be greatly prized. If seed could be secured in the native habitats of the plants, this would constitute the best method of introducing them to cultivation. E. J.

**Panicum bulbosum**.—It would appear this plant inherits its specific name from its bulbous root, while the nearest approach to this character I have seen is an enlargement of the stems just below ground. As an isolated specimen, however, it is a most elegant species, and both its habit of growth and light, graceful bearing when in flower are sure to attract attention. Being only 3 feet high and quite compact, it is worth a place in the border or with a mixed arrangement of plants in groups.

**Carnations**.—My hearty sympathy is with all Carnation growers who fail with these as *bound fide* hardy plants, that is who are reduced to the necessity of potting up layers and keeping them under cover through the winter, and it certainly does surprise me to know that only ten miles

away "J. C. B." is compelled to resort to the practice. I think he will have to look further than fog to find the cause of failure; at least, we get fog badly here in some seasons, and I have found no ill effects from the same. Some four or five years ago a spell of very sharp weather was preceded by fog that was continuous for several days, leaving everything at its departure with a black coat and necessitating the washing of all glass. The sharp weather following close was fatal to a considerable quantity of saturated vegetation, and I remember fearing the Carnations had shared the same fate; but, as a matter of fact, the loss that year was only about 3 per cent. If failure has resulted from autumn planting, I should certainly advise leaving the layers as they are until the spring, planting then before resorting to potting up. Many theories have been advanced as to the cause of failure, and possibly we are not yet at the root of the matter. I still think, however, it is in a great measure the result of weakly, indifferently-rooted layers.—E. BURRILL.

A TRIP TO FAIRYLAND.

THERE are on occasion gardens not made intentionally by human hands which in the fulness of their beauty make all man's efforts vain. Such, at least, was our experience the other day when journeying southward from England. We had passed a day and a night crossing the plains of France, which lay bare to the chill autumn sky, shorn alike both of leaves and crops, waiting patiently for the winter's shroud of snow. After a night of fog and keen white frost we slowly climbed the northern slopes of the Alps while the rising mists obscured our sight. Cold and grey looked the fresh-fallen snow on the top when first we reached it; bleak and wintry was the outlook as we went steadily on; but as we descended again the sun broke out in southern splendour, and turned the grey powdery snow to dazzling diamonds. Then, suddenly in our descent we turned, and in an instant we were in fairyland! Surely those trees, those shrubs, those clambering Vines were not real, but fairy trees, fairy bushes, made of rubies, made of gold? Surely those slopes so rich and green were emerald, those spiry trees, that flamed in the nearer distance and paled as they mounted higher, were of chryso-prase, powdered with diamond dust as they neared those unapproachable peaks which glittered as no diamonds could shine save in fairyland? Higher and higher towered those brilliant peaks in our descent till we could gaze no more at their dazzling brightness, and turned our eyes to that sky which spread over us a celestial vision of purest turquoise. For two hours did this panorama of gorgeous colour, rich in beauty of form and radiant with light, defile before our eyes while we sat absorbed, lost, entirely void of any desire save to gaze and gaze again lest this fairy vision should fade from our eyes; nor till in our descent we came to a deep dark gorge which barred the upland from the plain did we lose this unspeakable glory; then in an instant the curtain fell and we were in the work-a-day world again! Such an enchanting experience is worth seeking, and I would advise all those who are in search of a new sensation to visit the higher slopes of the Southern Alps in October, when these glories are at their fullest. No words can give adequate expression to their beauty.

Once more down in the rich plains of Lombardy, reeking with autumn rains after summer heats, the rank growth and entire absence of rich colour are the more striking after the glowing threshold of the Alps, but in the gardens of Milan there is much to attract the eye of the wanderer, and if he be a gardener, to compel

his attention and admiration. Although November is near, the splendid specimens of *Musa Ensete* in the public gardens and squares are fresh and green, their solid leaves untouched by any autumn blast. Beds of tall crimson *Celosias* rejoice in the warm sun, while graceful scrolls of dwarf *Ageratum*, *Alternantheras* of varied dyes, and *Sedum carneum* (most happy foil to such bright hues) attract a northerner's eye. Scarlet *Hibiscus* bushes and tree-like specimens of *Erythrina Crista-galli* still show bravely, while tall white *Cactus Dahlias* in the most superb masses of bloom fill with envy the mind that recalls the black devastation wrought by frost weeks ago in northern lands. Perhaps, too, the tall standard plants owe their freedom of bloom to being kept to one single and tall stem, and suggest the thought that in suitable places it would be well worth trying its effect in England. Standard *Magnolias* are conspicuous by their coned heads of crimson seeds, which show brilliantly against the pale lemon of the *Ginkgo* (*Salisburia adiantifolia*) trees and the more cinnamon shades of deciduous *Cypress*, while the *Plane* and *Sophora* trees still keep their summer dress. E. H. W.

#### SHORT NOTES.—FLOWER.

**Violets.**—I had an opportunity of comparing four of the large-flowering Violets the other day, viz., *Victoria*, *Princess of Wales*, *Princess Beatrice* and *California*, and should decidedly give the palm to the first-named. The difficulty with all these in the majority of soils is that they are decidedly shy.—E. B. C.

***Sempervivum arachnoideum.***—It is surprising how very effective are the Cobweb Houseleeks when cultivated in large patches in the rock garden. To get the best results, prick out a group of the rosettes 2 feet across or more on an uneven surface, allowing an inch between each for development. With a season's growth many offsets will be produced, and, treated in this way, the rosettes generally will be much larger than usually seen.

### ORCHARD AND FRUIT GARDEN.

#### LATE PLUMS.

THE Plum is amongst the most useful fruits grown when it is taken into consideration the many purposes for which it can be used and the length of time good fruit may be had. The late kinds are the most useful, as at this season all other soft fruits are over. To grow late Plums profitably in the open, the trees must be given wall space. They succeed in almost any situation, but I prefer them on a west aspect, although I have a tree of *Coe's Golden Drop* on a north aspect, and often I get good fruit from this tree as late as November. It is very important to protect these late kinds in the open early with some kind of material, such as frigi domo, to keep insects from destroying them, as if they are the least damaged they will not hang. Another reason for protecting them is to keep the fruit dry. In damp seasons this is a serious drawback to fruit on the open walls. Having this evil to contend against (as this garden lies low), I resolved some years ago to grow some late Plums in a cold Peach case, and nothing could be more satisfactory. They may be grown either in the bush form or trained to a trellis. Many cultivators do not succeed with them under glass when planted out, either from not giving them enough air, or from allowing them to grow too strong and get coarse rooted. The best managed trees I ever have seen have been those that have been pinched during the growing period, so that no pruning was needed in the winter. Should they get too

strong, which young trees are prone to do, then I lift them, doing one side this year and the other side the following should it be needed, keeping the roots near the surface. When the trees commence bearing there is no danger of this under glass. I have a long Peach case with a trellis in front, the lights sliding open in front to give air. This trellis is within a foot of the glass, and in this position the Plums prove most satisfactory. In one house I have three trees, one of each of the following kinds: *Reine Claude de Bavay*, *Coe's Late Red*, and *Coe's Golden Drop*. This year the crop was grand, the first named kind coming in first and keeping up the supply well into October, this being followed by *Coe's Golden Drop*. The tree from which this illustration was taken gave me good fruit for dessert for eight weeks. I gathered the last fruits on November 2. The crop was heavy; on some shoots a foot long there were about three dozen fruits. These were thinned. By the side of this tree is grow-

*Plum Coe's Golden Drop.* From a photograph sent by Mr. J. Crook, Forde Abbey, Chard.

ing *Coe's Late Red*, and although not to be compared with the former for flavour, it is nevertheless a useful late kind, and I doubt if a later kind is to be found, as I often have good sound fruit from this tree at the end of November. These are most useful for kitchen use, seeing there is but little at this season for pies and tarts beside Apples. Other good kinds for growing under glass are *Ickworth Imperatrice*, *Archduke*, *Grand Duke*, *Monarch*, and *Wyedale*. Another recommendation for growing some trees under glass is the advantage of having a crop in seasons when there is no crop outside. When grown under glass they can be allowed to hang a very long time. The treatment the trees receive here is the same as that given to Peaches. I give the border an abundance of water at all seasons, more especially during the growing period, with manure

water when the fruit is swelling off. In many instances late Plums would pay far better to grow than Peaches, seeing they are much more hardy and a good price can be made of high class Plums when Peaches are over.

*Forde Abbey.*

JOHN CROOK.

**Strawberry Waterloo.**—A rather large grower for market in this neighbourhood think highly of this Strawberry, and a large break of it just recently was looking remarkably well from this year's runners. The fruits of course, as is well known, are good in flavour, and, coming late, it is very valuable. The grower mentioned has found that it is not reliable under ordinary culture, that is, renewing the beds about ever three years, but if left alone and fed from the surface it remains fruitful for a great many years. This reminds me of a garden in the west of England where several lines of this variety had been grown in a north border for many years, and every season fine crops were gathered over a long period. It is worth trying when this kind does

not thrive under the usual conditions, and I am having some plants to see if they will improve by being longer on the ground. If not, I shall have to discard it, though reluctantly. I should like to hear the opinion of other growers who may have tried leaving it on the ground for several years.—R., *Bury St. Edmund*

**Apple Sturmer Pippin.**—As a dessert Apple to succeed the *Nonpareil Sturmer Pippin* stands unrivalled, for not only is it an excellent keeper but it does not attain full flavour until late in the season, when late dessert Apples are becoming scarce. It is a seedling from *Ribston Pippin*, obtained by crossing this with the pollen of a variety of *Nonpareil*, and the flavour when in perfection is a combination of that of both the sort named. As a garden tree it is a capital cropper and although but a medium grower it is hardy, the wood partaking of the character of that of *Old Nonpareil*. It is also recommended for growing as a standard. The late Dr. Bull formed so high an opinion of this Apple that he was at great pains in distributing number

of scions of it some thirteen or fourteen years ago. He consigned a good bundle to me at the same time for distribution, but I am afraid that it has not led to such a large increase in its cultivation as it deserved, as it would be a valuable Apple from a market point of view if carefully gathered, properly stored and disposed of during the month of March. Like all other late kinds *Sturmer Pippin* should be allowed to hang as long as possible before being gathered. If this is not done the fruits lose much of their high flavour, and are apt to shrivel.—A. W.

**Pear Magnate.**—A few weeks ago I sent you a note about this Pear, as to its fine appearance, &c. Since then the fruits have ripened and have given the greatest satisfaction. Not only was the flavour most excellent, but the flesh was quite melting and entirely devoid of grittiness. I shall certainly give it a trial as a bush tree. I need only all that Mr. Wythes has to say with regard to it

behaviour with him, and there appears to be a difference of several weeks in the ripening in the two districts, for which I think the soil may be accountable, as my trees are growing on a northern aspect.—A. W.

**Apple Ross Nonpareil.**—Of the whole family of Nonpareil Apples, this variety I think could be considered the hardiest and most vigorous of them all. When grown as a standard in an orchard, and allowed to grow unrestricted, the tree soon attains to large proportions and bears enormous quantities of fruit. Even when grown in the more restricted forms it grows very freely, and leaves nothing to be desired from a cropping point of view. It is not, I think, generally cultivated, but none the less valuable as a dessert fruit on that account, and, although too small for market, it is a splendid little Apple to grow for private use, as it keeps in excellent condition until the end of February. The fruits are regularly formed, inclining to be conical, or not so flattened as many of the other varieties of this class of Apples are, and they are generally nicely coloured. The flesh is crisp, and possesses a rich, sugary, aromatic flavour.—A. W.

**Grape Lady Hutt.**—This new Grape I purchased last year sent out, and fruited it for the first time last year. I was not altogether satisfied with its appearance, but formed a high opinion of it as regards flavour and keeping. The fault I had to find with its appearance was that it failed to colour properly, for when perfectly ripe the berries were still of a greenish hue. As regards flavour it was exceedingly good for so early a variety, and that a white one: the flesh being very sweet and refreshing I resolved to give it a further trial. This season it has coloured much better, the greenish hue complained of having disappeared, and the berries have assumed a light amber tint. This I attribute to having tied the foliage on one side so that the bunches got an abundance of light. I am inclined to the belief that this, the only drawback to what I consider will eventually turn out to be a valuable late Grape, can be overcome by giving the bunches, when on the point of colouring, free exposure to the light. In all other points this variety is very satisfactory, the Vine being a vigorous grower, and it produces an abundance of healthy foliage, which is of a firm leathery texture.—S. E. P.

#### POT STRAWBERRIES.

Those who take special means to secure a supply of runners will have good reason to congratulate themselves this season. To depend entirely on plants that have fruited is to court disappointment and partial failure. The production of a crop of fruit is quite enough to expect from a Strawberry plant, and if it fulfils reasonable expectations in this respect the grower should be content and not exact from it. To plant the runners that are to give him his chief and perhaps most important crop. The immature badly rooted plants that one so frequently sees in private gardens are almost invariably obtained in this way. Runners made from old fruiting plants are generally later, and are rarely so free of growth as those produced by young plants that were set out either in the previous autumn or in spring. By planting expressly for a supply of good runners the Strawberry grower kills two birds with one stone. He makes use of securing a good lot of runners for early sowing, and also guards in the most effectual manner against a break in the outdoor supply. It is, I consider a mistake to employ runners from fruiting plants for making new plantations in the open. The check that is given to plants which are carrying a good crop is sure to communicate itself to the runners, and puts into them an element of weakness from which they never, even with the best of culture later on, quite recover.

To use runners of this description is a penny wise policy, the only place for them is the rubbish heap. In a very hot and dry season, when the fruit ripens off under a scorching sun, the runners are made so late that it is impossible to get the soil in 5-inch or 6-inch pots thoroughly filled with roots by the close of the growing season. I always plant out good strong runners in the early part of October, as I find that when the spring months are very dry they make a much stronger growth than those set out in spring. I set them out 15 inches apart on ground from which Potatoes have been lifted. I choose a time when the surface is dry, take up the young plants with a nice ball of earth, tread them in, and if the weather seems likely to remain dry, water them in. In the course of a few days they begin to take hold of the ground, and by winter they are well established and secure against frost-heaving. The hoe is used freely among them through spring and early summer, and in a general way runners are made very freely. If the first runners are used and layered when formed they will make very fine plants with about five crowns each, and the soil thoroughly matted from the drainage to the surface with roots. The secondary runners layered about the middle or end of August will make good plants with a couple of crowns, and if these are kept in 4½-inch pots they will in a general way bear hard forcing better than larger plants.

Many are too anxious to get their plants into what are called fruiting pots. It is a mistake to suppose that fine fruit cannot be produced in pots less than 6 inches across. I have grown plants side by side in pots ranging from 4½ inches to 8 inches in diameter, and could see no difference in the quality of the fruit they produced. When the runners are later, or not so strong as could be desired, it is wiser to keep them in rather smaller pots, unless they are only to be brought along gently for fruiting in May, when the roots are so much more active. Some prefer to layer the runners into small pots, but if runners of the proper quality can be had I see no advantage in doing so. The old-fashioned way of ramming the soil hard into 6-inch pots is the most economical as regards labour, and the results are equally good if a sufficiently early start is made. As soon as the roots begin to travel freely round the sides of the pots the plants can be removed to a more convenient place for watering, which, as with all things grown in pots, is a most important matter. In the case of plants that are rooted early in July, a lot of moisture will be needed in hot weather, especially during August, when they become root-bound. They will want looking to three times daily; in fact, they must never be allowed to get dry. There is an immense difference in the condition of plants that have been attended to in this way and those that have been managed without due recognition of the importance of this detail. The crowns will be stouter and the foliage will remain in good order until young leaves begin to form again. Just as growth is coming to a standstill and the crowns and leaves are maturing, frequent waterings with soot water are helpful. It frequently happens that the soil by that time is to a great extent exhausted, and this causes the foliage to lose in some measure its healthy green colour. Soot water is at all times beneficial, more especially in autumn and in the earlier stages of growth when the plants are forced. I am not at all in favour of using strong stimulants, even in a weak form, until the fruit is swelling, but soot can hardly be termed such, its action on plants being rather to impart colour to the

foliage than to promote actual growth. It is too drying to be of much use during periods of hot weather, when frequent and liberal supplies of moisture are needed, and I have never seen that it has any appreciable influence on the swelling of the fruit. J. C. B.

**White Raspberries.**—Although these fruits have flavour quite equal to the red kinds, are good croppers, and in every respect are as nice for eating, yet prejudice against colour prevents their culture generally. White Raspberries, it is feared, would have a very poor chance against reds in the market. But did persons having gardens but know how relatively sweet they are, no doubt more would be grown. The oldest is the White Antwerp, which has been with us probably for a century. The White Magnum Bonum is finer and extremely pleasant eating, but the finest of all is the new white Superlative, from the red form of which it is either a sport or a seedling. In any case the fruits when ripe are like pale yellow Superlative fruits, and the plants have that famous variety's habit and appearance. I saw this in Messrs. Bunyard's nursery at Maidstone last autumn, and could but realise that it presented a most valuable addition to our few white Raspberries.—A. D.

**The Quince as a decorative tree.**—There are few fruit trees that so well merit planting for decoration as the Quince. The habit of the tree is drooping, the growths coming quite to the ground. When in full bloom the heads are beautiful objects, and when the fruits are ripening they help then to make the tree very attractive. The fruits will also hang for a long time after colouring unharmed. There are several varieties, but the old favourite Pear-shaped seems to be the best. It is hardly needful to assert that the fruits may be put to useful domestic purposes—so much is very well known. With Quinces may be added Morello Cherries, Worcester Pearmain and Col. Vaughan Apples, Siberian and other Crabs, and even Farleigh Prolific Damson, for these trees bloom profusely, and the fruits, after colouring, will hang for a long time, whilst none are more pleasant eating than are those which fall on the grass. Many deciduous trees planted on lawns are not half so pretty as are these fruits.—A. D.

**Californian Pears.**—Although the samples of Pears sent to the Drill Hall the other day from the highly-favoured clime of California were excellent of their kind, and evidenced how admirably fruits of this nature properly packed can be sent safely into the English market, yet was there in the samples nothing to be highly enraptured over. Comparison of the best Doyenné du Comice, for instance, with the fine fruits shown in the flavour competition showed ours to be of firmer flesh, really less watery, and distinctly more highly flavoured. The fruits were also larger and richly coloured. Beurré Diel cut in half showed grit round the core most unmistakably, this feature being more marked than is seen on our wall fruits. Winter Nelis was, of course, early and fine, but it did not excel ours in flavour when ripe. The matter to deplore is that fruit culture does not more generally follow upon nursery and the best private garden lines, producing for us the most superb samples skill and the climate can produce. It is only in that way, and carried out on a very large scale, that we can hope to contend with what other countries send us. The care bestowed in packing is of course also of the very best; indeed it is almost perfect. If our best fruits were wrapped in tissue paper, set in shallow boxes, packed neatly with wool, and in that way sent to market, the returns would far more than compensate for the trouble taken to send the fruits for sale in the most perfect condition.—A. D.

**The fruit trees.**—Comparing the autumn of last year and that of the present—the former so wet, the latter so dry and warm—we see as a result that fruit trees have ripened leafage in perfect form, and often with beautiful colour, that

wood is very hard and that buds are plentiful and plump. That is a different state of things from what existed in so many directions last autumn, when the excessive rainfall so materially helped to excite root action and to promote leaf and bud activity after it was assumed that all wood and buds were perfectly matured. Now that leaves have fallen no amount of rain would unduly excite roots, even though the soil is generally unusually dry. The rain, whilst moistening ground, would also lower its temperature, and thus check activity. It will therefore be very interesting next spring to note the diverse effects (if any) on fruit production. Generally the operation of last year's wet autumn has been very adverse to fruit, the best crops being found on old or somewhat stunted trees little affected by too abundant root moisture. Possibly next year we may see, as a result of the present fine condition of the trees, a large fruit crop. So much I fully anticipate, but much rain will be needed to fit the roots and trees to withstand the stress of large crop-production. Very largely cold winds and frosts were credited with such harm to the bloom last spring, leading to its ultimate barrenness, but there has been no proof furnished yet that the fine bloom of that time was efficiently supplied with pollen to produce fertility; indeed, it was believed that the heavy rains of the previous autumn were inimical to its production. With the assurance of a fine bloom next spring, we shall then be able to see whether fertility results or otherwise.—A. D.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

NOVEMBER 9.

OWING no doubt in a great measure to the gloomy condition of the atmosphere, with a heavy fog hanging over the metropolis and extending far away into the country, the exhibitors who usually patronise these meetings hesitated somewhat, not caring to risk their productions under the circumstances. There were counter attractions of course amongst Chrysanthemum growers at the meeting of the National Chrysanthemum Society at the Aquarium and that of the Kingston Society, both of which open on the same date. Certainly the extent of this meeting from some cause or other fell far short of its usual character.

Orchids were shown in good numbers, notably so the newer hybrids, of which the Cattleyas and Lælio-Cattleyas were specially fine. A finely-grown lot of Dracaenas and Cordylines was staged in an informal group. The style of this arrangement should be noted by exhibitors; it was somewhat in the way of the letter S. Several good examples of Tree Ivies were an interesting feature, the foliage of the silver and golden varieties being in excellent character. Of Chrysanthemums, there were several of the newer kinds staged for certificates, and a splendid group of cut blooms of high-class quality came again from Syon House, which makes the third occasion in succession whereat Mr. Wythes has contributed to the display. On this occasion there were about 100 varieties or thereabouts, chiefly in triplets, arranged informally upon a carpeting of Maiden-hair Fern, making as an exhibit the finest display in the hall. Fruit was not shown in any great quantity, the best exhibit by far being four grand baskets of highly finished Gros Colman Grapes from Somerset. The condition of the atmosphere militated greatly against this meeting, it being impossible to examine anything under favourable conditions.

#### Orchid Committee.

First-class certificates were awarded to the following:—

**CATTELEYA FABIA.**—A hybrid between Cattleya labiata and *C. aurea*. The sepals and petals are of fine form and substance, deep rose in colour. The large lip, having the intermediate characters

of both parents, is deep rose-purple in front, shading to a deeper purple in the centre, the side lobes deep purple, lined with yellow towards the base, where it has also a shade of bright brown. From the Rt. Hon. J. Chamberlain, Highbury, Birmingham.

**CALANTHE VEITCHI ALBA.**—A lovely clear white form of this well-known Orchid, the only trace of colour being yellow in the centre of the lip. The plant bore a raceme of twenty-five flowers. From Messrs. H. Low and Co.

Awards of merit were given to—

**CATTELEYA LABIATA LEWISI.**—A lovely form with pure white sepals and petals: the lip rich purple, mottled and margined with pure white, the side lobes white, shading to yellow at the base. The plant carried a raceme of three flowers. From Messrs. W. L. Lewis and Co., Southgate.

**CYPRIPEDIUM LEEANUM MAGNIFICUM.**—Very similar to *C. L. giganteum* of Cypher. The dorsal sepal is upwards of 3 inches across, clear white, shading to green at the base, where it is slightly spotted with brown, the petals pale green, suffused and spotted with brown: the lip chocolate-brown, shading to deep green. From Mr. G. Shorland-Ball, Wilmslow.

Messrs. J. Veitch and Sons sent a choice collection of hybrid Cattleyas and Lælio-Cattleyas, the most prominent being a fine form of *L. C. Decia* (*L. Perrini* × *C. Dowiana aurea*). The *Dowiana* parent becomes more pronounced as the plants grow stronger. Lælio-Cattleya Novelty, a distinct form, with pale rose sepals and petals, lip deep crimson-purple, shading to yellow, lined with purple at the base, is the result of crossing *L. Dayana* and *L. C. elegans*. Cattleya Eurydice (*C. labiata* × *C. Aclandæ*), certificated last year; *Cypridium Tityus* (*C. Spicerianum* × *C. ænanthum superbum*), a lovely form, the dorsal sepal white, suffused with rose at the top, shading to green, spotted with purple at the base; a fine form of *C. Niobe*, and a large-flowered variety of *C. Euryades* were also included (silver Flora medal). Messrs. W. L. Lewis and Co., Southgate, sent about fifty plants of *Lælia pumila*, which were well flowered and showed remarkable form and substance. The group also contained *Mormodes pardinum*, good forms of *C. Loddigesi*, and fine forms of *O. Rossi majus* (silver Banksian medal). Messrs. F. Sander and Co. sent a small group, which contained fine forms of Cattleya labiata, *C. aurea*, *Lælia Eyerma niana*, a finely-flowered mass of *Sophranitis grandiflora*, *Dendrobium Johnsonæ*, *Lycaste Skinneri*, and a cut spike of *Renanthera Lowi* with thirty-two flowers (silver Banksian medal). Messrs. H. Low and Co. sent a small, but choice collection, consisting of good forms of *Vanda cœrulea*, grand forms of *Cypridium Leeannum*, *C. bellatulum album*, *C. Niobe*, a hybrid of the *C. concolor* class, and Cattleya labiata with a slate-coloured lip.

Mr. G. Shorland-Ball was awarded a silver Banksian medal for a grand collection of *Cypridium*s, which included two plants of *C. insigne Sanderæ*, one with six, the other with four flowers. *C. Memoria Moensi*, *C. Niobe*, *C. Leeannum*, and *C. ænanthum superbum* were well represented. The group also included good forms of *Masdevallia Veitchi* and *Dendrobium Phænopsis album* with three flowers expanded. Mr. C. J. Ingram sent Cattleya Comfrey (*C. Lawrenceana* × *C. Warscewiczii*). The Rt. Hon. J. Chamberlain was awarded a silver Banksian medal for a choice collection of hybrid Cattleyas, consisting of Lælio-Cattleya Sallieri (*L. purpurata* × *C. Loddigesi*), *L. C. Semiramis* (*L. Perrini* × *C. Gaskelliana*), the sepals and petals pale rose, lip purple, with some white in the throat; Cattleya marseillensis (*C. aurea* × *C. Trianae*), and *C. Mr. Endicott* (*C. maxima* × *C. Loddigesi*), in which the *maxima* parent was most prominent. Mr. W. Vanner sent a group of cut *Cypridium*s, prominent amongst which were good forms of *C. Spicerianum*, *C. Niobe*, *C. Schrœderæ*, *C. Eyermannianum*, a dark form of *C. ænanthum*, and *C. Vanneræ* (*C. Veitchi* × *C. selligerum*). *Odontoglossum Dormanianum*, a spotted form with seven flowers on the spike, was also shown. Mr. S. G. Lutwyche sent

*Cypridium Pavonianum* and another seedling in the way of *C. Indra*. Mr. J. T. Bennett-Po sent *Cypridium Phoenix*, a distinct hybrid, the dorsal sepal white, suffused with rose in the centre and spotted with brown at the base, the petals pale green, suffused and spotted with brown, and a good form of *Vanda Sanderiana*. Mr. H. Tate, Liverpool, sent two hybrid *Cypridium*s and a *C. insigne* with two dorsal sepals.

#### Floral Committee.

Awards of merit were given to—

**WALLFLOWER PARISIAN EARLY.**—This is a fine acquisition for autumn, being of sturdy habit, flowering most profusely, and having a very powerful scent. The colour is a rich golden yellow tinged with dull red. From Messrs. Veitch and Sons.

**BOUVARDIA HUMBOLDTI GRANDIFLORA.**—This a large variety, of handsome growth and splendid habit, the blooms very large, pure white and sweetly scented. From Messrs. Crane and Clark March.

**CHRYSANTHEMUM ADMIRAL ITO** (Japanese reflexed).—A beautiful bloom, very large and full rich sulphur-yellow in colour and very graceful growth. From Mr. Godfrey, Exmouth, Devon.

**DRACENA INDIVISA BURTONI.**—This is a handsome plant with dark bronze foliage, the leaves long and narrow. It is very distinct and beautiful. From Mr. R. Gülzow, Bexley.

**SONEHLA LADY BURTON.**—A large-leaved variety with an abundance of lilac-coloured flowers. The foliage is silvery, veined with light green. This is a very striking plant, and was shown by Sir Trevor Lawrence, of Burford, Dorking.

**DRACENA ALBO-LINEATA.**—A green and white variegated form of graceful habit, narrow-leaved and very effective. From Mr. R. Gülzow, Bexley Heath.

Of considerable interest was a group of seedling Dracaenas from Mr. R. Gülzow, Melbourn Nurseries, Bexley Heath, Kent. Every plant was in splendid condition, perfectly clean, and the picture of health. The foliage of the colour varieties was very brilliant, and the group was arranged with great taste (silver-gilt Flora medal). Cut Chrysanthemums were again admirably shown by Mr. Wythes, gardener to Earl Percy, Syon House, Brentford. The collection of the time consisted of seventy-two varieties and made a very brave show. Surely this magnificent group deserved a higher award, seeing that the previous meeting for only six dozen blooms the same award was given. What encouragement have private growers to bring their products to the Drill Hall if all are to be served in the way of a few of the best were Hairy Wood Oceana, W. H. Fowler, Pride of Madford, Moncherotte, Col. W. B. Smith, John Lightfoot Mlle. Thérèse Rey, Lord Brooke, Graphic, An Perry, Vivian Morel, Robert Owen, and Roy Sovereign (silver Banksian medal). A few very fine new varieties were shown by Mr. Godfrey, Exmouth, Devon. The most striking were Mrs. M. Grant, a bronze-yellow, with looser petals and Lady Northcote, a pretty pink. A small collection of late seedling Pentstemons came from Mr. C. F. Thompson, Llandaff. They were very good for the season of the year. Messrs. H. Low and Co. sent a group of Carnation Matthe Winter Red, a sweet-scented variety of compact habit, with shapely blooms, fairly full, and freely produced. Mr. Robert Owen, of Maidenhead, exhibited a few very good new incurved Chrysanthemums, among them Creole, a dark maroon good shape; Thomas Singleton, a charming pink white; J. Lockyer, a pleasing light pink; Arthur King, a rich bronze-yellow, very even the petals. Messrs. Veitch and Sons sent plants of *Aster grandiflorus*, a large and handsome variety. Messrs. W. Balchin and Sons, Hasso Nurseries, Sussex, sent *Diplacus Jubilee*, a charming pinkish terra-cotta variety, and *D. ruber*, a stronger-growing plant of dull red colour. John Russell, Richmond, Surrey, staged a group of Ivies in great variety, well-grown plants

ry strong, the foliage of good substance (silver Banksian medal).

#### Fruit Committee.

This was one of the smallest meetings of the year, but this committee had its share of exhibits. The Grapes from Frome were excellent, and there was a nice collection of Pears from Belvoir Castle. Mr. W. Iggulden, Fruit and Flower Nurseries, Frome, Somerset, sent four baskets of Gros Colman grapes weighing 48 lbs. These were excellent in such and berry, and we think deserved a higher yard than a silver Banksian medal. The way the fruit was packed was an object-lesson. Mr. Iggulden (gardener to the Duke of Rutland, Belvoir Castle) sent thirty-two varieties of Pears, of large, but of excellent quality. Emile Heyst was very good, as also were Glou Moreceau, Doyenné du Comice, Josephine de Malines, Brown Curré, Marie Louise and Durondeau. There were also some stewing varieties (silver Banksian medal). A new Apple named Munster Pippin came from Messrs. Hartland and Sons, Cork. It is a nice fruit, large, bright red, but not considered superior to those in commerce. A new Pear came from Mr. A. Knowles, Woking, but much past its best. Messrs. Harrison and Sons, Leicester, sent a large collection of Beetroot, shapely roots and of good colour. The best were Cheltenham Green Top, Ragnell's Exhibition, Covent Garden Black, Turnip-rooted in variety, and some large-leaved kinds not so much known, but of good quality (ronze Banksian medal). One of the most noticeable exhibits was the Cucumber from Mr. Thomas, the Royal Gardens, Frogmore. It is named All the Year Round, and is a cross between Richard's Market and Dickson's All the Year Round. It is a smooth, shapely fruit with small neck and good colour. It was asked to be seen again somewhat later in the season. Mr. Wythes sent new seedling Cabbage named St. Martin, an autumn variety, and of great merit as regards size, shape, and colour. It is quite distinct from the Colewort and Drumhead Autumn Cabbage. It will be tried at Chiswick.

The Veitch prizes for flavour brought forth nine dishes of Apples and the same number of pears. For Apples, Mr. Turton, Maiden Erleigh, Reading, was first with Cox's Orange; second, Mr. Woodward, Barham Court Gardens, Maidstone, with Ribston Pippin. For Pears, Mr. Woodward was a good first with Doyenné du Comice, the Rev. H. Palmer, Reading, being second with Glou Moreceau. The other Pears were Brown Beurré, Doyenné du Comice, and Beurré Diel; and of Apples, Cox's Orange and Ribston mostly.

A meeting of the above committee met at Chiswick on Nov. 5 and examined late Potatoes and cabbages. Of the former, two varieties received two marks. The Kales were given three marks in a few cases, but these were not confirmed at the meeting at the Drill Hall. We think such should be the case, as the varieties should be brought to the next meeting and the awards made public, as only a few members of the committee can see the Chiswick work. Formerly fruit and vegetables, especially the latter, were always shown at Westminster after a Chiswick committee. Kales in a few cases at Chiswick were very badly diseased, and should certainly have another trial in land of a different nature.

**The weather in West Herts.**—A week of changeable weather as regards temperature. For instance, the highest reading in shade on the 4th was 43°, whereas on the 9th it reached 54°. In the previous sunny week the difference between the lowest night and highest day temperatures varied on several occasions considerable, but in the dull week just past the range was small, and one day amounted to only 3°. At 2 feet deep the temperature of the soil is now nearly 3°, and at 1 foot deep nearly 5° higher than the November average. Rain fell on the 8th, but only sufficient to wet the surface of the ground. No

measurable quantity of rain water has come through either percolation gauge for a fortnight, which is very unusual indeed at this time of year. The last six days have been very calm and gloomy.—E. M., *Berkhamsted*.

## NOTES OF THE WEEK.

**1 Chrysanthemum Robert Owen.**—This is ever a striking and noticeable variety, and such as must be included in every group by reason of its colour, distinctness of form and the like. It is one of the best kinds raised by the late Robert Owen.

**Pentstemons.**—A capital lot of seedlings of these brilliant border flowers was at the Drill Hall this week, the collection coming from Mr. C. F. Thompson, Llandaff. As a whole they were a good assortment of this useful plant, which near London has finished flowering long ago.

**Vitis heterophylla humulifolia.**—Some sprays of this pretty plant, accompanied by many clusters of the nearly blue berries from Mr. A. Kingsmill, Harrow Weald, were among the most interesting exhibits at the Drill Hall this week, the plant rarely fruiting with such freedom.

**Wallflower Parisian Early.**—A basket of plants of this ever-welcome flower obtained an award of merit this week from the Royal Horticultural Society. The blossoms are nearly yellow and the fragrance remarkable. The exhibit, which came from Messrs. Veitch, attracted a good deal of attention.

**Begonia coccinea.**—This is a capital kind for growing in the large greenhouse or conservatory, where it may display itself to advantage, and being both free in growth and flower also, is most effective when well established. The medium-sized flowers are produced in large drooping bunches and are very showy.

**Diplacus ruber** and another kind, *D. Jubilee*, were exhibited before the Royal Horticultural Society on the 9th inst. Both came from Messrs. Balchin, Hassocks, Sussex, the former being of a reddish hue and the latter orange-coloured—an improvement on the old species, which unfortunately is not grown so much as its merits justify.

**Anthurium Andreanum atropurpureum.**—The varietal name here indicated appears a little out of place in a flower, or, more correctly, a spathe of blood-crimson hue. Apart from this, however, the variety is a very effective one, the colour striking and the spathe bold and conspicuous on its long, erect stem of 2 feet high.

**Ornithogalum thyrsoides.**—The white-flowered variety of this species may now be seen at Kew, the blossoms large and clustered somewhat closely on a dense raceme. The scape, which is about 12 inches high, is stout and vigorous, the bulb being of the size of an ordinary Hyacinth. If obtainable in quantity, it would make a useful plant at this time for the greenhouse.

**Protea cynaoides elliptica.**—Some plants of this distinct shrub are now producing their handsome blossoms in the greenhouse at Kew. Though only small plants in pots, the blossoms are at least some 6 inches or 8 inches across. The large spreading heads with the rosy-tipped scales are very striking. The plants require a rather warm greenhouse and are natives of tropical South Africa.

**Cypripedium insigne.**—A very fine display of this old favourite is now to be seen in the entrance to the Orchid house at Kew, where large specimens in pans are freely covered with the useful flowers. Not only are the flowers of considerable service, for the plants also when hardly grown are especially valuable when well-flowered in the sitting-room, and make an agreeable change to the ordinary room plants.

**Trollius europæus.**—Some idea may be formed of the exceptional character of the season by a really good display of the flowers of this early summer plant during the present week. Flowering usually in May and June, we were somewhat surprised to see quite a large gathering of this Globe Flower at the Aquarium during the present week. The whole of the plants are not blooming, but merely a few, and these it will be interesting to note at the usual flowering next spring.

**Primula Poissoni.**—If the term perpetual-flowering could be at all applied to any hardy species of Primula, this one should certainly prove worthy of the distinction, seeing that the plants

have flowered almost unceasingly for months in succession. It is possible that in the low and somewhat sheltered position the plants find a uniform condition of heat and moisture at once congenial to their well-being, and in such the flowering goes on continuously. A good deep soil with some shelter is clearly what the plant delights in.

**Heliophila scandens.**—There is an exceptional charm in this pretty climbing plant not usually seen among cool greenhouse subjects. The plant is not only neat in foliage, but very pretty in the dull days of winter with its abundance of pure white blossoms. It is a member of the Cruciferae, as may readily be seen, and among the most free-flowering of its race. The species is of quite easy culture in sandy loam and peat, and in positions where freedom at the root may be given it would make a very effective climber for the greenhouse.

**Carnation Matthews' Winter Red.**—A group of plants of this variety came before the Royal Horticultural Society on Tuesday last. The weather at the time was fatal to the Carnation, and many kinds shrivel completely under its poisoning influence. The flowers of this variety did not appear to suffer so much in this respect, and should they be proof against fog they would be useful. The reddish blossoms are of medium size, and in the plants referred to not numerous. Larger plants would in all probability be more freely flowered.

**Vanda cœrulea.**—I send you two or three blooms of *Vanda cœrulea*. I bought about eighteen months ago three small imported pieces, I wired them round a small block and inserted the block in a 10-inch basket, and they have done remarkably well. Last autumn I had two small spikes; this year I have had four splendid spikes, and should have had five, but one met with an accident.—J. D., *Fanfall Park Gardens, Broomsgrove, Worcester*.

\* \* The flowers are of good size, but too starry and lacking in colour.—Ed.

**Aster turbinellus.**—Though scarcely a showy kind, as this term is understood among the perennial Asters generally, it is, notwithstanding, a most graceful and pretty variety when seen in fair-sized clumps. But even here if we would have all its beauty it should be allowed a good deal of its own way, as any attempt to tie it up would most effectually stifle all the grace and beauty of the blossoms on their long, slender, almost delicate stems. It is, however, not a delicate plant. In the rock garden it is a capital plant allowed to have its way, and equally pleasing and effective when well grown in pots in the greenhouse.

**Chrysanthemum Silk Twist.**—So far as novelty is concerned in this extensive group of autumn flowers, the above variety is perhaps the most peculiar. This is so as much in the quaint thread-like florets, that doubtless suggested the name, as in the general form of the flowers. In the colour, which is of a creamy white, there is nothing to attract, but the general formation of the flower-heads is novel. The variety is of the small-flowered section, and, so far as size alone is concerned, partakes of the hybrid pompon class, with which, however, the erect bristle-like florets have nothing in common. In a cut state the effect is very distinct, the variety associating well with flowers in general.

**In South Devonshire on November 1** the following were in bloom: *Lonicera sempervirens*, *Escallonia rubra*, *Coronilla glauca*, yellow *Marguerite*, white *Marguerite*, *Nicotiana glauca*, *Geraniums* (various), *Abutilon vexillarium*, *Phlox* (perennial), *Jasminum nudiflorum*, *Montbretia crocosmiflora*, *M. aurea*, *Rosa rugiflora* in fruit, *Rose Mme. Berard*, *Rose Souvenir de la Malmaison*, *Violet The Czar*, *Neapolitan Violet*, double white *Violet*, *Michaelmas Daisies* (several), *Chrysanthemums* (various), *Delphiniums* (several), *Pyrethrums* (several), *Puehsias*, *Petunias*, *Carnations*, *Heliotropes*, wild *Strawberries* in flower and fruit, *Verbena venosa*, *Schizostylis coccinea*, *Pentstemon*

mons (several), Dahlias (various), Aloysia citriodora, Rose Gloire de Dijon, Abelia floribunda, and Lavatera trimestris. In a neighbour's garden were also Macartney Rose, Caryopteris mastacanthus, and Cyclamen europæum.—W. T., *Bishop's Teignton*.

**The Cosmos.**—In last week's GARDEN you mention that varieties of Cosmos are blooming at Cork. I may state that at Clevedon these plants are beautifully in flower, and had it not been for a heavy wind a short time back breaking the head of the tallest plant, it would have been fully 5 feet to 6 feet. As it is, the others are about 4 feet to 5 feet in height. Our climate is such that it is only in an exceptionally severe winter that Solanum jasminoides succumbs, whilst the white Vine-leaved Abutilon I have had in the open for nine or ten years, also the New Zealand Flax.—A. B. TRESTRAIL, *Southdale, Clevedon*.

**Peristrophe speciosa.**—To many readers this useful species will be better known as *Justicia speciosa*, though in more recent years the plant has not received so much attention as formerly. As a pot plant for the greenhouse in winter, it flowers over a lengthened period, and this, combined with a bushy, compact habit, makes it a useful subject in greenhouse decoration. For this latter small plants in 5-inch or 6-inch pots may be easily grown in a few months, and these commence flowering in the earliest days of autumn. The blossoms are of a distinct shade of mauve-purple, over which appears a reddish violet tint that is most effective.

**Physalis Franchetti.**—This handsome plant promises to surpass the old Winter Cherry *P. Alkekengi* not only for its vigour and the striking effect in beds or the border, but more particularly in its hardiness. The old kind, though perfectly hardy at the root does not retain its foliage very far into the autumn; indeed, the plant loses its leaves almost as soon as the calyces have attained their colour. With the new comer it is different as the plants which are now loaded with the large coloured calyces have the foliage nearly as good as was the case weeks ago. An instance of the striking effect of the new species may still be seen in the herbaceous ground at Kew where two large beds have been devoted to it this year. These plants are still in excellent condition, while the old form a little distance away shed its leaves soon after the early frost. The greater vigour of the new kind as also its hardy character should render it among the most popular of garden plants.

**Tibouchina macrantha** is, for the moment at least, the most recently adopted or revised generic name of an extremely popular and showy plant that in the past has been known as *Pleroma*, and formerly as *Lasiandra*. This frequent alteration of the names of the more popular plants is to the gardener most confusing, because once it begins, the alterations appear at frequent intervals. The value of the plant, however, is the same, and its beauty still on a par with the old days, when as *Lasiandra* this fine old Brazilian shrub was known to most gardeners. There is no need to call attention to its beauty or its worth as a greenhouse shrub. It is not a climber in any sense, but a shrub of free and quick growth that quickly covers an allotted space on the interior of the greenhouse roof, and, there enjoying the full light and sunshine, produces in great abundance its large, deep saucer-shaped blossoms for many weeks in succession. The flowers, often 5 inches across, are of a deep violet-purple and very handsome. This species is also well suited to covering pillars, or it may be grown in pots in bush form.

**Connemara Heaths.**—The picture issued with THE GARDEN of October 30 is very charming, but their great value as autumn bloomers was omitted from all mention in the letterpress. Large beds here containing many thousands, which have been stopped twice during the summer, are now in the first days of November masses of beautiful flowers. The principle involved is that if you prevent a plant flowering at one time it endeavours to do so at another, and it is quite worth a little sacri-

fice to have a show so late in the season.—T. SMITH, *Neeray*.

\* \* \* This plant has been flowering all through the summer and is in bloom now on a bank fully exposed to the sun. Mr. Moon's drawing was made from the same plants of the white variety on June 15 of the present year. The soil is not peat, but a coolish loam on a hill facing the sun. No water is ever given other than what falls from the clouds, and the plants have withstood the droughts of recent years. There are good spikes now (November 9). The fine autumn may have helped to prolong the bloom, but, on the other hand, the drought was against the plant. In any case it is a remarkable instance of length of flowering, and charming flowers, too.—Ed.

## PUBLIC GARDENS.

**Open spaces.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., the Earl of Meath, chairman, presiding, a communication was read from the City Parochial Foundation consenting to the allocation of their open space grant of £1000 to the cost of laying out Bethnal Green parish churchyard, and to the provision of a drinking fountain therein, in accordance with the proposal of the Association made some time previously, and it was resolved to seek permission to erect a tablet in the ground, with a suitable inscription, as a record. It was also agreed to offer trees for planting in thoroughfares at Kensington, Calvert Avenue, Shoreditch and Hoxton Market, and to grant seats for South Grove, Camberwell, and De Beauvoir Square. The chairman reported the opening on the 1st inst. of a playground in Benbow Street, Deptford, secured and laid out by the Greenwich Board of Works, and provided with ample gymnastic apparatus by the association. Letters were read respecting the proposed acquisition for the public of Churchyard Bottom Wood, N., Pymmes Park, Edmonton, N., a part of Golder's Hill Estate, N.W., a site at Bromley, Kent, a burial-ground at Barking, E., Camberwell Churchyard, a cleared area in Islington and a plot of land in Ratcliff. It was also decided to see whether any steps could be taken, and, if so, what the cost would be to improve the churchyards of St. Nicholas and St. Paul's, Deptford, in order to render them more available as public gardens than at present.

### The Commissioners of Woods and Forests.

—The 75th report of the Commissioners of Woods and Forests has just been issued as a Parliamentary paper. The income derived from sales of forest produce in the New Forest amounted in the year 1896-97 to £7355 4s. 11d., in addition to certain surface rents amounting to £3099 11s. 8d., the corresponding receipts in 1895-96 being £7060 12s. 7d. and £3014 13s. respectively. In the case of Dean Forest the same sources of income produced £5305 17s. 7d. and £1156 12s. 11d., as against £6539 3s. 10d. and £1959 6s. 1d. in 1895-96. The mineral royalties of Dean Forest for the year ending March 31 last reached a total of £13,906 19s. 7d., as against £12,332 10s. 8d. for the preceding year. The greater part of the Oak woods, the report says, have arrived at an age when the income derived from their thinning may be expected to be less than heretofore for some time to come, and the system of management which was best when the Oak was grown specially for the purposes of the Navy requires reconsideration now that it is no longer devoted to the building of ships. It is suggested, therefore, that it is desirable to produce other kinds of timber for which there is a market, and to utilise the Oak already planted according to present-day requirements. Turning to other parts of the United Kingdom, the report states that Crown property in Scotland produced during the year an income of £24,737 16s. 1d., in Ireland £37,954 8s. 4d., consisting mainly of quit rents, in Wales

£15,107 12s. 1d., and in the Isle of Man £5654 7s. 5d.

### Royal Horticultural Society's awards.

The awards of medals to exhibitors at the Drill Hall on November 9 were, to say the least, very singular and inconsistent with those of the late meetings. A notable case of this occurred in the award to the cut *Chrysanthemums* staged by Mr. G. Wytbes, from Syon, a report of which will not doubt be found in its proper place. At the last meeting, a fortnight previous, for an exhibit of sixteen blooms in triplets, the award was a silver Banksian medal. On the occasion in question a similar award was made, the exhibit being more than treble the size of the former, comprising 250 blooms in 100 varieties. The setting up was most commendable in every sense, and quite an object-lesson as contrasted with the formal and orthodox fashion followed by most exhibitors. The quality of the flowers was excellent, the incurved section being well represented. True, in faking up or doctoring of the flowers had been followed, they being simply shown as grown and as they should be. The very least award that could fairly have been made was a silver Flo medal to this extensive exhibit. The other case was that of the Gros Colman Grapes from Mr. Iggulden, which were simply perfect examples in every sense, fine in berry, bunch, colour, and even flavour. Here the award undoubtedly ought to have been a silver Knightian medal.—ALPHA.

—One of the finest exhibits of *Chrysanthemums* ever staged at the Drill Hall came from Earl Percy's garden, Syon House. The exhibit was in fact made up of over 200 blooms, nearly 100 varieties, and occupied about 60 feet or 70 feet of tabling. The blossoms were of all sizes, with stems from 18 inches to 24 inches long, arranged in threes, stood out boldly and well, supported by splendid foliage of their own; amid groundwork of Maiden-hair Fern; graceful Palm forming the background. The exhibit was among the very finest I have seen, as, apart from its representative character, the flowers bore ample evidence of excellent culture. On Tuesday last was one of the few things to admire at the Drill Hall. It seems impossible to believe that the society has done its part by the award of a silver Banksian medal that it has thought fit to give to so handsome and well grown a collection. I do not in the least know who is responsible for an award so ill-considered and unjust; at the very moment, too, when every grower of *Chrysanthemums* had forsaken the society to go elsewhere. Surely the Royal Horticultural Society can afford to treat so staunch a supporter in this way for however desirous the council may be of rectifying such mistakes, errors of judgment, or whatever they may be, the sting of the slight remain. Indeed, it is one of those glaring mistakes that never should have happened, and which the Royal Horticultural Society in the future should avoid.—A FELLOW.

**Pears under glass.**—Will any reader tell me the best kind of glass-house in which to grow, in the north of England, cordou Pears planted out a trained like Vines, say, Doyenné du Comice a Josephine de Malines, and the best way to destroy prevent caterpillars?—X. Y. Z.

**Names of fruit.**—A. B.—Impossible to name from such a poor fruit and only one specimen seen.—J. R. Elliot.—Pears: 1, too far gone; 2, Chamois; 3, B. Clairgeau; 4, Doyenné du Comice; rotten.—Denton Park.—1, W. Bon Chrétien, second crop; 2, Beurré Bosc; 3, Catillac; 4, Beurré Charmeuse; 5, Maréchal de la Cour; 6, Autant Bergamot; 7, Pitmaston Duchess; 8, Beurré Doyenné; 9, Beurré Diel; 10, Beurré d'Anjou; Josephine de Malines; 12, Orange Bergamot. I have named all you send; we, however, only undertake to name four kinds in one week.—H. R. 1, Hollandbury; 2, Gloria Mundi.—W. J. Burston.—1, Beurré Diel; 2, Brown Beurré; 3, Josephine de Malines; 4, not recognised; should like to see good specimens.—W. J. P.—1, not recognised; 2, Scarlet Nonpareil; 3, Northern Greening; 4, M. de Ménage; 5, Ribston; 6, not recognised.

## ORCHARD AND FRUIT GARDEN.

### DESTRUCTION OF INSECT PESTS.

THE autumn and the early part of winter offer a favourable opportunity for the destruction and prevention of future attacks of the various kinds of insects which infest fruit trees. The trees then being clear of foliage, every portion of wood can readily be reached, and much stronger solutions used than would be permissible when the trees are in a growing condition. When fruit trees are sprayed or washed at the season of the year indicated, it is astonishing the numbers of insects and their eggs which are destroyed. If persisted in year after year, spring and summer attacks are reduced to a minimum. Those who annually wash or spray their trees when dormant are rewarded for their pains by seeing them, if not altogether free from attack, certainly very much less infested than is the case where a let-alone policy is adopted. Spraying can now be done cheaply if the proper appliances are used, and any objection on the score of its being expensive will hardly hold good. The whole of the collection of fruit trees here, which is by means a small one, is sprayed in the winter by a comparatively small cost. The appliances are a force pump fixed in a galvanised cistern mounted on wheels, 20 feet of armoured hose, with a 6-foot branch pipe at the end on which is fitted a sprayer. A coarse or fine spray can be had simply by unscrewing or screwing the glass cap up tighter. An active intelligent man with a lad at the pump can spray a great number of trees in a day in a very efficient manner. The best time to perform this is directly after the trees are pruned, or as soon as the prunings and leaves are raked up and cleared away. Digging or pointing of borders and alleys should be deferred, on account of the person manipulating the sprayer having to walk round and to

pass backwards and forwards in front of the trees. Calm weather should be chosen, especially if insecticides of a caustic nature are used, so that the person applying them does not run the risk of having the spray blown into his face. Windy weather causes a waste, as the greater portion of the spray is carried away without ever touching the trees unless growing closely together.

Regarding insecticides, the following can be safely relied on as being the best for the purpose: Petroleum emulsion and a solution of caustic soda and crude potash. The petroleum emulsion is made in the following manner: Take from 4 lbs. to 6 lbs. soft soap, according to quality, 100 gallons of water, and bring it to boiling point. Then add 1 fluid oz. of petroleum for every gallon of water, boil for five minutes, and then draw or put out the fire. To prevent an accident occurring, the vessel in which the mixture is boiled must not be quite full, in case it should boil over and the petroleum catch fire. This may be used in a warm state and applied with a sprayer to ensure thorough diffusion of the petroleum, when it will injure neither wood nor buds. This is recommended when the trees have been badly infested during the previous season. The second is the more efficacious for winter use, as it cleanses the trees of all kinds of insects, it kills their eggs, and relieves the branches and stems of Moss and Lichen without injuring them in the slightest degree. This is made as follows: Take 1 lb. of caustic soda, 1 lb. crude potash, add 10 gallons of water, and boil until all is thoroughly dissolved. This should be used while warm; apply it with a sprayer, leather gloves being worn to prevent the mixture burning the hands.

Extra pains should be bestowed on trees infested with American blight, as spraying is not sufficient in itself to kill these insects, surrounded as they are with a cotton-like substance. A very strong solution well brushed into every affected part of the trees is an excellent remedy. To render this effective, every particle of loose bark should be cut away, so that the insects

can be more easily got at. The soil, too, under the trees should be removed down to the uppermost roots and burnt. If any of the insects are found on the roots, spray with petroleum emulsion and cover them with fresh soil from a non-infested source. Plum, Damson, and other fruit trees may also be washed over with a mixture of limewash, with enough soot added to tone it down and make it less conspicuous. This cleanses both stem and branch and renders the buds distasteful to birds, but I have never found it of any practical use for killing either insects or their eggs. This is also an excellent wash for Gooseberry and Currant bushes where birds are in the habit of disbudbing them. Freshly-slaked lime may be used instead of this wash for fruit trees, and it should be cast among the branches when moist either from rain or fog and on a calm day. For the destruction of the winter moth, grease banding, for which a special kind of grease and paper for wrapping round the stems can now be bought, is used. Cart-grease should be avoided, as it is apt to injure the stems of the trees. As the grease soon hardens from exposure to the air, it should be renewed or smeared over afresh every few days, or as often as is found necessary. This traps great numbers of the female winter moths when on the way up the stems for the purpose of laying their eggs, but it cannot be depended on for catching all of them, as the male oftentimes carries his mate with him at pairing time up to the branches.

All prunings, leaves and rubbish should be carefully raked up and charred at some spot remote from the trees, which will get rid of great numbers of these pests, also their eggs. The soil under the trees should also where possible be pointed over a few inches deep, and at once apply a dressing of freshly-slaked lime, which will kill any chrysalides or eggs there may be in it. In orchards the same kind of thing may be done for about a yard round the trees, and if poultry are kept and allowed to roam in them, the application of lime will be unne-

sary, as they soon make short work of both insects and chrysalides as they are turned up

A. W.

**Highly-coloured Apples.**—At Livermere Park recently I was much surprised at the very high colour of the dessert Apples just now. King of Pippins was very bright, the fruit large and symmetrical, evidently well grown. Court Pendu Plat, Cox's Orange Pippin, King of Tomkins County, and the good old Ribston were alike good in quality and handsome in appearance. The soil at Livermere is light and porous, and not apparently the best for Apple culture, but feeding from above and rational treatment of the growth conduce to the above result.—VISITOR.

**Pear Brown Beurre.**—This Pear can hardly be too much praised when gathered and stored in good condition. The tree grows vigorously and fruits freely on light soils, but in heavy, cold soils it is not so satisfactory. It appears to do well at Livermere, and I saw some very good fruits of it last week. It is large enough for all purposes, and the quality is excellent, the greenish, juicy flesh being good for weeks together. Another fine Pear that Mr. Tallack grows well and thinks very highly of is *Conseiller de la Cour*. This is ripe now, but keeps in good condition for a long time, the flesh being soft and good right to the core.—H. R.

**Stewing Pears.**—The best stewing Pears with me are *Catillac* and *Beurré Clairgeau*. The former never fails to produce a heavy and reliable crop, and is, moreover, the best flavoured stewing and keeping Pear I know of. Properly stewed it will keep for several years, and certainly improves the second year. *Beurré Clairgeau* is a good cropper, but its flavour is not equal to that of *Catillac*. *Black Worcester* is not very successful with me, and as to *Grosse Calvasse* I have two or three trees, but find them hardly worth growing even against a wall. *Uvedale's St. Germain* does fairly well, but is not to be compared in my garden with *Catillac*.—GWENT.

**Digging around fruit trees.**—The time is now at hand when the pruning of fruit trees and bushes having been done, digging amongst them will be proceeded with, and from a long and careful study of the matter I am convinced that digging with a spade is responsible for many of the ills that fruit trees suffer from, from the fact that the fibrous surface roots are cut off or broken, while the large, deep-rooting ones that promote a gross watery growth are left. Although I have long since discarded the spade, I am compelled to use in its place the steel fork, which is doubtless the most useful for loosening and pulverising the soil without mutilating the roots. At this time of year all the old mulching materials that can be spared for the fruit tree quarters are forked in and left in a rough state during the winter, and then in spring when the drying winds begin to rob the earth of its moisture, the soil is raked down fine again. Nothing I have yet tried for counteracting drought is so effective as frequent surface-stirring.—JAMES GROOM, *Gosport*.

**Liquid manure for fruit trees.**—The exceptionally dry spell, lasting for many weeks in succession, is in such direct contrast to the autumns of several preceding years that it makes even old practitioners alter their usual routine of work. Seldom do I remember having to use the water-pot so much at so late a period of the year. When one finds the soil around fruit trees dust-dry before the fruit-buds are fully plumped up, it is quite time to set about supplying the deficient moisture if full crops are looked for next year. The roots that supply the fruit-buds most directly with what they need are undoubtedly those that are near the surface, and it is, therefore, of the utmost importance that these should not lack moisture. This is the time when a good soaking of liquid manure of some kind can be supplied with the greatest advantage. Anyone having drainage of any kind that has manurial elements in it will do well to apply it without

delay to fruit trees of all kinds, wall trees in particular. Failing manure water, some kind of artificial manure should be spread over the roots and washed in with copious supplies of clear water.—J. G., *Gosport*.

**Strawberries.**—With, I know, many others I am much pleased at the great interest which THE GARDEN is taking in seeking information in regard to Strawberry cultivation. I have in Monmouthshire two large private gardens, and I somewhat extensively cultivate this fruit both under glass and in the open garden. Under glass with me the first on the list is *Royal Sovereign*, followed by *Vicomtesse Héricart de Thury*, *Stevens' Wonder*, and *Scarlet Queen*. Noble I have, after many trials, discarded, indoors and out. Early, prolific, and fine looking it certainly is, but tasteless and not worth growing for that reason. With regard to outdoor culture I give preference to *Royal Sovereign*, *Vicomtesse*, and *President* as the best early sorts, whilst among the late ones nothing equals *Latest of All*, *Waterloo*, and *British Queen*. I break up, as a rule, all my beds after four years, but am not sure that three years would not answer better, unless specially well attended to. September and October are the best months for this work. The forced plants I plant out in July on well-prepared ground, watching for a fall of rain when so doing, so as to establish the roots as quickly as possible, mulching them early in November.—GWENT.

**Pear Bishop's Thumb.**—This is a very useful Pear just now, and though possibly the flesh is not so rich and buttery as that of other kinds now ripe, there is a brisk and pleasant flavour not easily beaten. I had usually looked upon it as a somewhat dull-looking, but good-quality fruit—one of those kinds that improve on acquaintance, but looking through the fruit room at Livermere recently Mr. Tallack showed me fruit of a rich and bright colour, that could only be the produce of well-cultivated trees. So bright, in fact, were the fruits that, although I am sending the same variety to table, I did not recognise it. When pressed as to the cause of the high colour, Mr. Tallack somewhat laconically replied, gas-lime, but I am inclined to think that the free method of training practised at Livermere has a good deal to do with the satisfactory results. Where every bit of young wood is ruthlessly cut back every season how can the trees give good results. Several old trees in this garden that had for years been so treated I have allowed to grow freely since taking charge some three years ago, and this season for the first time I had a crop of large and good fruit from them. If more freedom of growth were allowed and this thinned early in the season, there would be far less need of root-pruning.—R.

#### A NEW WHITE GRAPE.

WERE there a distinct paucity of white Grapes in commerce, we might, perhaps, have some tangible reason for welcoming a new one, but on what grounds a majority of the fruit committee did at a recent meeting grant an award of merit to the new Grape *Marchioness of Downshire* it would be difficult to determine, especially when such an award was made in opposition to the judgment of the best authority on Grapes in the kingdom. The new variety may claim the merit of being a spoilt Muscat of Alexandria. The raiser crossed that variety with white *Gros Colman*, doubtless in the hope of throwing some Muscat flavour into the latter, which seems to have been so poor a Grape that no one has cared to grow it. Even the black *Gros Colman* is a tolerated Grape because of the size of its berries and the weight per rod it produces to the market grower. On the score of flavour it ranks amongst the lowest. Now with respect to the samples shown at the Drill Hall recently, either the Muscat flavour which it is professed has been imparted to the seedling is distinctly wanting or else the Irish climate has entirely failed to impart it. Certainly on the bunches sent for tasting the berries were of Muscat size and shape, wanting colour, and the

flavour or quality of the most moderate kind. What, then, has been gained to Grape culture by the introduction of such a variety? Amongst the white Grapes we have in commerce now are *White Nice*, *Foster's Seedling*, *Mrs. Pearson*, *Duke Buccleuch*, *Golden Champion*, *Chasselas Napoleon*, *Lady Hutt*, *White Gros Colman*, *Dr. Hogg* and others, yet how few of these are in general cultivation. What object is there in putting any more indifferent varieties into commerce? Why cannot we have a trial of new Grapes at Chiswick before granting any award? Realising the granting of such recommendations to standards of fruits of this description is a very serious matter and if another failure should ultimately be recorded, what becomes of the reputation of the fruit committee? Here is a Grape getting an award without any knowledge by the committee of its habit or its cropping. It is indeed a veritable leap in the dark, and remembrance of how many white Grapes had previously obtained awards, and yet have become almost general failures, might well make those empowered to grant certificates careful how they commit themselves. A most useful object-lesson in Grape values was furnished at the same meeting in the wonderfully fine and varied collection of Grapes shown by Mr. Bayer, of Forest Hill, in thirty varieties. There were but three white Grapes in the collection, and of these the best was *Muscata of Alexandria*. A. D.

**Watering fruit trees.**—The weather has been so exceptionally dry, that watering of wall fruit trees has been necessary much later than usual. Fine, dry autumn weather is usually looked upon as favourable to the ripening and developing of fruit-buds, and, unquestionably it is, so as long as the roots are kept moist, but when the rainfall is low and a much greater amount of sun than usual is recorded in October it is not altogether an unmixed blessing. During the past fortnight I have been busy planting spring flowers, and the dry state of the borders and beds led to an examination of the fruit borders, with the result that they have had thorough soaking of water. Fine weather is one factor in the well-being of trees just now, but moisture at the root is a much more important one. Without it the roots cannot carry out their functions, and that it is necessary is proved by the free emission of roots during September and October. Provided the branches and spurs of fruit trees are judiciously thinned so that air can play freely about them, the grower need not fear what the weather does, and though it seems strange, perhaps, to some, I have no doubt that trees allowed to take care of themselves will develop their buds in a wet, unless autumn moisture better than in a dry one, when the roots cannot find sufficient moisture.—H.

**Vine sports.**—The interesting Muscat of Alexandria sport at Chiswick exhibited its variation last year in producing on an outer rod of a Vine at the west end of the house and some 8 ft from the ground a weak lateral and a small bar of exceedingly large-berried Grapes. The wood, however, was too weak to give eyes. This spring the new break was stronger, and the result I believe a lateral just a little stouter than are the near lower laterals on the Vine, with leaflets deeply lacinated, more so than is the ordinary leafage. The bunch produced was rather larger than that of last year, but the berries again were very fine, oval, and clear as well as very firm. Really they presented all the well-known size and form as well as flesh and flavour of the Cannon Hall Muscat, but seem to have been presented here, in a comparatively cool house both last and the present years, very free-setting qualities. The present wood is stout enough to furnish several good eyes, and therefore we must not have to wait long ere seeing independent plants fruiting both in pots and planted out. Should then all the present sportive or divergent features be maintained, even if in the end it does not prove to be distinct from the Cannon Hall

There will be furnished absolute proof that Vines can and do sport. The Vine on which the sport appeared is probably one originally planted in 1857, when the great viney was first transferred to its present uses. That was forty years ago. It seems, therefore, all the more singular that so long a period should have elapsed ere this abnormal form was generated. It would be interesting to learn whether other *bond-fide* sports are within the knowledge of readers.—A. D.

**Apple Mabbot's Pearmain.**—I noticed this excellent variety at Chiswick Gardens, and at the Able Congress in 1883 it was well shown. My fruits this year lack size, as the soil was so dry though the summer months. In the west of England I used to get very good fruits from standard trees. I have grown it since in bush form only, and it is a good cropper, the fruits keeping firm well into the new year. It may rightly be classed as a midseason dessert Apple, the fruits medium sized, orange yellow, streaked with red.—G. W.

**Pear Beurre Baltet pere.**—I am glad to see this Pear receive favourable mention at the hands of Mr. Wythes, and I quite agree with all that he has to say in its favour. I have it in cordon form only, and it leaves nothing to be desired either in size of fruit, cropping qualities, or flavour. My trees are on the Quince stock, but they make excellent growth, and produce an abundance of fine buds. Mr. Wythes mentions that it succeeds well on an east wall with him, but I am afraid that it would lack flavour on our deep blinding loam if grown in such a position. Some magnificent fruits of this Pear were exhibited at the Hereford fruit show in 1896, but this year they were neither so plentiful nor quite so fine.—A. W.

**Pear Fondante de Thirriott.**—This is one of the best Pears this season, and deserving of a name. Probably the flavour may not suit all palates. It is distinct from that of many of our autumn Pears, but a flavour many like. The fruits are very juicy and very refreshing. I need there was an excellent dish of this variety at the Crystal Palace, Mr. Woodward having sent me some. It promises to make a valuable exhibition Pear, being a good cropper and of excellent quality. With me it does well as a cordoned. My trees are on the Quince, and I have found the best flavoured fruits are obtained from trees on this stock. Trees in bush form on the Pear free stock produce later fruits. This is a gain, as we have no lack of October Pears. I saw this variety good at Christmas grown in heavy loam in bush form on the free stock in the eastern part of the country, and it was thought much of, but rarely failed to crop.—G. W. S.

**Grapes at autumn shows.**—I have this season found Grapes lacking the usual good qualities to be seen. At a recent show only two competitors were entered for the prizes offered, and the Grapes were not worth second place, though the prizes were good. What can be the cause of the scarcity? The October weather should have been favourable, and there was no lack of sun to finish late Grapes. I also notice that more second-rate varieties are now staged than formerly. This is to be regretted, as although they have size and a nice look at, there is a lack of quality. The other day judging with one of our very best fruit growers I was pleased to see the standard made for quality; size had no charm for him. We have excellent Grapes which take up the show room as poorer ones. I admit they may need better culture, but this should not deter growers from growing those noted for quality in preference to mere size. For market, size may be valued, but even then quality commands the best price.—B. M.

**Apple Allen's Everlasting at Brighton.**—This above variety is not so much grown as it deserves, but it is meritorious on account of its excellent keeping properties. I admit it is not so striking in appearance as some, and in these days, to gain favour, those fruits with bright colour or good size have the preference. This variety

will be good next May, given cool storage, at a season there are very few Apples, at least scarcely any equal in flavour to this. I recently saw some very fine fruits of this variety at Brighton, and was told that it did grandly on the chalk. Its compact growth should make it a favourite. It did well with me when in Gloucestershire on limestone, but is less prolific in Middlesex. On the other hand, we cannot expect good results in pear, very shallow soil resting on gravel. It is a distinct fruit, somewhat flattened, and in places where it grows freely the fruits are quite medium-sized, of a bronzy green, very firm, and of a good shape.—G. WYTHES.

**Pear Lucy Grieve.**—A little-known Pear and one seldom met with owing, no doubt, to the tree being a shy bearer. I have a tree of it as a pyramid, and although it has been planted some ten years I have never been able to gather a good crop of fruit from it. This season the tree certainly bore more fruits than ever it has done before, but it could not be termed a full crop. The individual fruits were also finer than usual, and the quality was first-rate. Wasps, hornets, and tomatoes are exceedingly fond of this Pear while quite green and hard, and if left unprotected they soon spoil the fruit. The fruits ripen during October, and are very highly flavoured. The bark of the tree is conspicuous on account of its dark-looking, rugged appearance. It is but a medium grower with me, and produces an abundance of fruiting spurs. Perhaps it would do better on the free stock and allowed to grow unrestricted. Has any reader of THE GARDEN grown it in this way?—A. W.

**Apple Jas. Grieve.**—I am much obliged to Mr. Parker (p. 356) for his note on the above, and my note (p. 316) should have read, "The variety in question is not unlike Cox's Orange in size and in habit. It differs in growth and is a softer fruit." Mr. Parker's note coincides with my own respecting its good qualities. I am aware it is a much earlier fruit than Cox's, and I should not have been far wrong if I had described it as a good late September or October Cox's Orange. After October it is not so good. Fruits from the trees on the Paradise stock are of good quality, and there is more colour in my fruit than in Cox's Orange. Like the last-named, it fruits freely and is not a gross grower. I am pleased to note Mr. Parker speaks highly of its cropping; in this respect it is superior to many. I noticed this variety fruited so freely in a small state that I was induced to give it a trial. I have only small trees, but they carried a nice crop, of good quality and appearance.—G. WYTHES.

\* \* \* The fruits sent by Mr. Wythes were far more highly coloured than those sent by Mr. Parker, this, no doubt, owing to the locality in which they were grown (Middlesex), Mr. Parker's having been grown in Scotland.—Ed.

**Autumn Pears.**—I was very glad to notice that Thompson's had secured the "flavour prize" at a recent meeting because it is a Pear of excellent constitution and also a free cropper, although from a quality standpoint it would seem to vary considerably. I remember a few seasons ago a writer asserting that with him it was not even second-rate. That the quality of Pears will, however, vary with the season quite as much as from different soils is apparent. I noted recently that this year for the first time Marie Louise d'Uccle was very fair indeed, so also is Beurré Bachelier; on the other hand, two Pears that, as a rule, are thoroughly reliable, Beurré Superfin and Van Mons Leon le Clerc are nothing like up to their usual standard. These, however, it must be added, are from old trees. Beurré Diel, also from old trees, is useless, except for stewing, but the same variety from cordons is very good. Writing of this Pear in connection with dessert reminds me of a dish I saw a fortnight ago at a show in a collection of four dishes of fruit as green as a Leek, and, saving a withered appearance from premature gathering, as hard as a bullet. Surely fruit should at least be in fair form when shown in a collection available for dessert. Two useful Pears at the present

time are Gansel's Bergamot and Passe Colmar, the former from a very old tree, the latter from cordons. Passe Colmar is a great and consistent cropper and keeps well; it does not come so large as I remember it on the heavy Sussex loam, neither does it merit the description of "a highly flavoured Pear" given in some catalogues; it is, however, refreshing and probably one of the most juicy Pears in cultivation. Nouvelle Fulvie came in earlier than usual. This, too, is small with me, but a good little Pear that crops well. Perhaps some reader of THE GARDEN may be able to tell us something of Duc de Nemours, from a show standpoint one of the very finest November Pears. I have only seen it at one place (Pains Hill), and here it is said to crop well and to be in its season one of the best dessert Pears. Why is Winter Nelis so susceptible to American blight? Several cases have come under my notice of fine old trees that have to be annually treated for this when other Pears are quite exempt.—E. BURRELL, *Claremont.*

#### SHORT NOTES.—FRUIT.

**The Vierlander Strawberry.**—This Strawberry is peculiar to a marshy district in the immediate neighbourhood of Hamburg. The fruit is very aromatic and nearest to the wild Strawberry, and some prefer it to any other sort. Unfortunately, the fruit will not keep, and under some conditions it has lost its taste and appearance after twenty-four hours.—ROB. M. SLOMAN.

**Apple Wheeler's Russet.**—This Apple is very conspicuous at this time of year by its peculiar grey russet appearance, which, however, assumes a slightly yellowish tint when the fruits are ripe. Like most of the other varieties belonging to this section, it possesses good keeping qualities. This combined with its rich flavour renders it a valuable sort for late use. The tree is a medium grower, and therefore suitable for garden culture.—S. E. P.

**Apple Wormsley Grange Pippin.**—At the fruit and Chrysanthemum show recently held at Hereford a very fine dish of this Apple was included in the first prize collection of thirty dishes of Apples exhibited by Mr. Lee Campbell, of Glewston Court, Ross. These fruits were faultless both in form and colouring. It was the finest dish of this variety that I have ever seen. It is a pity that Wormsley Pippin is not more often met with, as it is an excellent November Apple, good alike for dessert and cooking. It is a good cropper and a hardy, free grower, succeeding equally well as a bush on the Paradise as when grown as a standard in the orchard.—A. W.

## STOVE AND GREENHOUSE.

### TREE CARNATIONS.

THE exceptionally mild weather we have experienced during the autumn has been favourable to these where plenty of air has been given. I find among those whose experience is limited there is a great tendency to give too much heat and not enough air. Carnations cannot be forced into flower at midwinter. They must have been previously grown on so that buds are well formed during the autumn. It is rather difficult with a limited number of plants to ensure having good blooms at any particular date, but it is easier to retard them than to force them on. When we are getting bright sunny weather, extra heat with plenty of air will do no harm, and in dull, heavy weather the cooler they are kept the better. There are now many varieties included under what are called "perpetuals," but none of these keep up a succession of flowers on the same plants, though good blooms may be had throughout the year by growing on a succession of young stock and stopping the plants at different intervals. Some sorts branch out and keep up a succession much longer than others. Winter Cheer is perhaps the nearest to what may be termed "perpetual." Planted out, [J

have seen the same plants continue to flower for months together. Uriah Pike has several times been in dispute with regard to its claim to being a perpetual. My experience is that plants propagated in the spring and grown on with others will flower from the main stem during the autumn, but under any conditions the side shoots cannot be induced to start away for bloom until the following spring, while with others I have had the same plants flower five times in one year. When I first saw Mrs. Leopold de Rothschild (or Mme. Thérèse Franco) I had my doubts about it keeping up its character, the growths being very thin. However, after growing it several seasons I can speak well in its favour; the growth and blooms have improved rather than deteriorated. We are badly in want of a really good white. Although we have such fine varieties for summer flowering, it is difficult to find one that will bloom really well in winter. Mrs. Moore was a favourite, but I have not seen it doing well during the last year or two. La Neige is very free, but the flowers are small and the growth thin.

Since the advent of Uriah Pike, crimsons have become numerous. The latest addition I have met with is Countess of Warwick; this is very dwarf in habit, with flowers of a bright claret-crimson, the broad, smooth petals of good substance. It is a seedling from Winter Cheer, and seems likely to make a good companion to that useful variety. Of yellows, Primrose Day has flowered better during the winter than any other variety I have tried, though it cannot be regarded as a perpetual, for, like Uriah Pike, the side shoots will not start until the spring. Two-year-old plants will flower best. I find the flowers are more inclined to burst than when I first grew it. Miss Audrey Campbell is a fine yellow for spring flowering. Grown in pots and kept in a cool pit during the winter and taken into a light, warm house early in the year, the plants soon throw up bloom. A.

*Salvia splendens grandiflora.*—I can quite agree with "H. P.'s" note on p. 337 respecting this bright and effective plant. I noted it a few days since in Mr. Bull's nursery, and was much attracted by the brilliant colour and large size of the spikes of blossoms. Many of these *Salvias* are of great value in keeping up a display of bright effective colour in greenhouses and conservatories during the autumn, but so ubiquitous is the *Chrysanthemum*, that many gardeners nowadays hardly know what a *Salvia* is. Such a bright and beautiful kind as this should ring the genus into greater favour.—H.

*The yellow Calla.*—I confess to a certain amount of disappointment when I see from time to time fine specimens of the yellow *Calla* exhibited. As I understood that the beautiful *R. Pentlandi* could be grown in a cool house, I was tempted to try it. Had I known what I do now, I might have saved myself the trouble, for, though very similar in appearance to the common white *Arum*, it comes from a different and warmer part of Africa, the Orange Free State, and so requires a higher temperature than I can give it. The brother of a gentleman who introduced it some time ago told me that in its native habitat it was to be obtained in quantity.—D.

*Drosera dichotoma.*—The Sundews are an interesting family of plants, and the larger section of the genus as represented by the species above-named may with advantage be grown by those having a warm, moist house at disposal. It is an easily grown species, thriving well in pots or baskets or on a bed of *Sphagnum Moss*. It is propagated in various ways, as by seed, division of the roots, and it may also be grown by cutting the roots into small pieces and laying these in pots or pans of peat and Moss. A moist atmo-

sphere is of more importance than much water at the roots, and fumigation must never be allowed in the house where Sundews are grown.

#### NEPENTHES AT KEW.

PROBABLY no other group of plants among the many of importance grown under glass in the Royal Gardens at Kew excites so much interest among the visitors as the rich collection of Pitcher Plants. Great as has been the interest displayed in these plants hitherto, this is now more likely to be increased. Formerly all the plants were suspended in the warm section of the No. 7 range adjoining the Victoria house. Here, however, these *Nepenthes* were associated with a rather full collection of flowering and fine-foliaged plants, where, by reason of the loftiness of the structure, a large number could not be properly seen. Happily, however, all this is changed and the *Nepenthes* have a new home. More than this, all who are interested may now view the plants with perfect ease, the majority being suspended within 5 feet or 6 feet of the ground. The present home of the plants adjoins the old one, a house entered from the stove, as also from the Victoria house. In the present structure no staging of any kind exists; the house is span-roofed, and perhaps not more than 12 feet wide inside walls. A kerbed pathway runs through the centre and abundance of light and heat is provided. The plants, growing in baskets, are suspended to the rafters in two long lines on either side the path, and the back row, alternating with the front, assists the uninterrupted view of all. The arrangement is simple, but withal so effectual both for observing the plants and for the latter receiving the fullest light and attention. On the floor, by way of relief, specimen fine-foliaged plants suited to the heat and moisture are arranged, the fine crop of pitchers hanging immediately above. No doubt the plants will derive benefit from the improved condition of their surroundings. In any case the fact must not be lost sight of by those gardeners who perforce must still grow them in mixed plant stoves, that these plants, many of them fine examples of their kind, have attained their present fine proportions in a mixed plant house in these gardens, which with the *Nepenthes* added was certainly unduly crowded. For it is not improbable that *Nepenthes* may in the near future be more largely employed in the decoration of the mansion or dwelling house. Their use within the dwelling could have no other than a unique effect, provided of course a good crop of well-coloured pitchers was upon the plants at the time. Take for instance one such as a central object on the dinner table or upon a marble pedestal or column, or, indeed, in any position where the pitchers may droop to advantage, these things would at once attract by their picturesque bearing. And then the remarkable variety of the plants themselves and their beautiful and richly-coloured pitchers are ever attractive when the plants are at their best. At Kew at the present time such fine kinds as *Northiana* have many splendid pitchers, so also *Morgana*, *Mastersiana*, *Stewarti*, *Hookeriana*, *mixta*, *Sedeni rubra*, and the handsome *Amesiana*. Others equally good are *Dicksoni*, *Williamsi*, *Curtisi*, *Lindleyana*, *Dominicana*, *edinesis*, *Rafflesiana*, *Wrigleyana*, *Kennedyana*, and many more. In some kinds the pitchers droop to a considerable length; in others they cluster just below the basket, or scarcely this, as in *N. phyllanthiflora*, a kind with small greenish pitchers. E. J.

*Rust on Malmaison Carnations.*—"J. R." on page 260 says he is much troubled with rust on his Malmaison Carnations. As I grow about 200 in pots and have had trouble with rust, I will give my treatment of them. I find they require the greatest care and attention possible in the matter of watering. The plants are potted in good sound fibrous loam, leaf-mould, and silver sand. No manure is necessary until they are

showing bloom, when a little weak liquid manure is beneficial. I give just sufficient fire-heat to keep out frost, plenty of air day and night, even in very severe weather or when cutting w prevails. After they have done flowering I set them out of doors until the middle of September when they are taken into the greenhouse. In three years long enough to keep them, as at the second year the plants begin to get leggy and the flowers from old plants are not so good as those from younger ones. The old plants planted out in a cold frame as soon as they have done blooming, and layered in the usual way some nice soil. When they are rooted sufficient for lifting they are put into well-drained pots, stood in a frame and kept close and shaded for a few days. When they are established they are treated like the older plants.—J. W. JACK *Rotherby Hall, Leicester.*

*Heliconia illustris rubricaulis.*—This *Heliconia*, which is illustrated on page 359, is an ornamental fine-foliaged subject when in flower, but at the same time it is particularly liable to lose a great deal of the bright-tinted veining which forms its most attractive feature if a rich potting compost is used or the plant is fed liberally with liquid manure, it will disappear, but much of the bright colouring will disappear. A mixture of loam, peat, and sand will suit it well, and overpotting should always be guarded against, for it colours better when somewhat pot-bound. It is essentially a stove plant and it should be shaded from bright sun during the summer months. This *Heliconia* readily increased by division, but at the same time I find that if this is carried out in the latter part of the summer or in autumn it is difficult to keep the plant in good health during the winter; therefore division is best performed in the spring or early summer. At this time of year the plant should be kept moderately dry in an atmosphere not too much saturated with moisture, otherwise the leaves are apt to become discoloured. This is particularly liable to happen if the temperature at any time is allowed to get rather low. The golden-veined *H. aureo-striata* which is a much older plant than the preceding forms a good companion to it and needs equal careful cultivation. Much the same treatment may be given it as recommended for the other.—H. P.

*Notes from Ireland.*—I went round the borders and beds to-day and made a note of the plants still in flower and those which are flowering prematurely. The thermometer to-day (November 8) in the shade registered 57°; in the open air exposed to a moderate breeze, 75°, which may account for many of the spring plants being in bloom. The following are in flower, many of them as gay as at any time during summer: *Achillea* in variety, *Acanthus Candelabrum*, *Aubrieta*, *Leichtlini*, *Antirrhinum* in variety, *Mirabilis*, *Jalapa*, *Carnations*, *Roses* in variety, *Pentstemon*, *Geraniums*, *Gladioli*, *Veronicas*, *Salvia patens*, *Kniphofias*, *Agapanthus umbellatus*, *Calceolarias*, *amplexicaulis*, *Commelina celestis*, *Asters*, *Lupinus*, *Violas*, *Anemone japonica*, *Mimulus*, *Pyrethrum*, *Aconite*, *Fuchsias*, *Marguerites*, *Lobelias*, *Gaildreas*, *Tradescantia virginica*, *Polyanthus*, *Veronica*, *Nicotiana glauca*, *Solanums*, *Campanula*, *Chrysanthemums*, *Cheiranthus*, *Senecio pulchellus*, *Sedum spectabile*, *Phloxes* in variety, *Heliotrope*, *Helianthus*, *Doronicums*, *Schizostemone*, *Polygonum Brunonis*, *Clematis*, *Chelidonium*, *Phygelius capensis*, *Hydrangea*, *Monarda*, *Viola*, *Rudbeckia Newmanii*, *Spiraea*, *Pampas*, *Grass*, *Hypericum*, *Jasminum nudiflorum*, *Tropeolums*, *Malva moschata* alba, *Eurotia speciosa*, *Passiflora edulis*, *Primula*, *The Lady*, *Heaths* in variety, *Myosotis*, *Oxalis*, *rosea*, and *Mignonette*. Many of the things here enumerated would have been long since over for the unusually wet and cold summer. As *Ericoides*, which should naturally flower early in October, is not yet fully expanded.—T. See *Ashford, Cong.*

ST. MARGARET'S.

The house of St. Margaret's is supposed to be from the fourteenth century, having originally been a convent in connection with "the ancienne Abbaye of Tichefelde." It formed part of the estate of the celebrated Thomas Wriothesley, first Earl of Southampton, and eventually passed into the hands of the Delmé family, whose descendants are the present owners. Many parts of the building attest to its antiquity, while a stone bench led into the wall of one of the rooms in the tower suggests ideas of the discipline which may have prevailed during the régime of the fair and sainted mother superior from whom the mansion takes its name.

The house is of red brick, very picturesque. It is completely covered with flowering plants, creepers, &c. An immense Magnolia

are always dry and far more pleasant and springy than is hard-rolled gravel. With an ordinary lawn mower grass walks are easily kept neat, indeed, they give much less trouble in sweeping and rolling than gravel walks do.—A. D.

FLOWER GARDEN.

POLYGONUM SPHEROSTACHYUM AND ASTER DIPLOSTICHOIDES.

SHORT notes on the plants bearing these long names appeared recently in THE GARDEN (pp. 373-374). I ask to be allowed to say a few words about each of them. First I find that the highest and most recent authorities are not agreed as to the correct name of the Polygonum. Hooker's "Flora of British India" gives *P. spherostachyum*, which is the name adopted in the "Kew Hand-List," but "Index Kewensis"

but even then the rearing is no easier. I have also tried covering them with peat soil where they fall round the parent plant, with no better success. The species seems to do best in rather shady places and moist peat, but it may be doubted whether as a garden ornament it repays the trouble of rearing. A good variety of *P. amplexicaule* if grown in dry and poor soil is as bright in colour, though less compact in growth. Another kindred species, *P. affine*, though the colour is not so conspicuous, is far more easy to manage, and has qualities which make it more desirable as a garden plant.

The Aster with the long name I raised from the same lot of Himalayan seeds as the Polygonum. The plants, which were few, flowered and died, and I set it down as a biennial, though I now know that it ought to be perennial. Up to this time I have heard of only one garden where it flourishes with real vigour, and that is high in the Peak of Derbyshire. I refrain from indicating the place more precisely for fear of subjecting the owner to undue requests for plants, but by his generosity I was supplied with a bountiful stock, which I tried in vain to make happy in my garden by planting in different situations and soils; at the end of two years none remained alive. As the note in THE GARDEN observes, at present it does not appear to be generally cultivated, but if it was more amenable to general cultivation it would not be offered in nurseries at the almost prohibitive price of 5s. or 7s. 6d. a root.

Edge Hall, Malpas. C. WOLLEY-DOD.

*Polygala paucifolia*.—I am extremely anxious to grow this. I asked Mr. Smith, of Newry, Mr. Thomson, of Ipswich, and Mr. Perry, of Winchmore Hill, to get it twelve months ago. They have all failed me. Mr. Smith sends me a dull-looking, soft, un-Polygala-like thing, which does not take me, or to me, at all and dies, the sender allowing that it is the plant that he has constantly failed with. Does any reader grow it—really grow it and flower it? Is it deciduous? I hope in time to have large masses of the three hardy *Polygalas*—*Chamaebuxus*, *Chamaebuxus purpurea*, and the three vars., red, white, and blue, of the native Milkwort; the last is a quite charming alpine when petted in a garden.—ROBERT BATEMAN, *Bentham Hall, Brosley*.

*Lobelia cardinalis*.—It is hardly fair for "S. W. F." to assume that, because roots of these assumed hardy plants winter safely outdoors in the locality of Torquay, therefore, they will do so anywhere. I never could safely winter them in Middlesex if the season was either very wet or very severe. It is so much better to be on the safe side, and either lift the plants in November and put them singly into sufficiently large pots, or plant them into boxes thickly, putting some fine soil about the roots and keeping them in a cool frame or greenhouse during the winter. Of course they should be near the light. If it be desired to propagate stock, that can be readily done by careful division in the spring before planting. Those who like these flowers should obtain stock of that lovely variety *Carmine Gem*.—A. D.

**Sweet Peas for cutting.**—The value of Sweet Peas for cutting cannot be over-rated, seeing the many good qualities they have. During the last nine or ten years I have been growing these in separate colours, as I need a continuous supply of flowers for table work, and have found Sweet Peas amongst the most useful, seeing the length of time they can be had in bloom, and they are always admired, let the season be what it may. For dinner-table work good self colours are far the best. Every effort should be used to arrange them as lightly as possible. Glasses with narrow necks should be avoided. Light foliage is the most effective to arrange with them, and as far as possible some sprays of their own foliage should

St. Margaret's, near Titchfield, Hants. From a photograph sent by Mrs. Deane, Fairfields, Farcham.

is the most prominent object, but Roses, Myrtle and Jasmine may all be found there. The house is surrounded by woods, and the lawn in front of the house is gay with many coloured flowers, bounded by a wall and herbaceous border separating it from the woods beyond. M. DEANE.

**Grass walks.**—Whenever I enter a garden the walks of which are of turf, I invariably feel as if there was added to even the loveliest surroundings a charm that similar gardens having gravel walks do not possess. If the soil be of the least retentive nature and becomes soft and wet in winter, a remedy can now be found in laying a pipe or rubble drain 2 feet beneath, and, at further, adding to the surface soil some ashes or grit, slightly rounding up the centre so that heavy rains either run off or quickly percolate away, and so that for walking on in winter they

gives the preference to the name *P. macrophyllum* for the same species. I first flowered this plant about fifteen years ago from seed collected in the Himalayas, and I agree with the remark that it will not yet be a common plant, even if it is destined ever to be so. Plants which have been growing in the same spot in my garden for at least ten years show no inclination to become divisible, continuing to be as one-rooted as a plant of *Fraxinella*. It is true that every one of the red flowers on a spike is a possible plant, and if collected when ready to fall nearly all of them develop growth, but for some unknown reason they are difficult to rear, and if I sow a thousand of them in a pan a foot square the produce at the end of three years is not more than a dozen flowering plants. In some seasons, as in the autumn of 1896, the spikes are as viviparous as those of *P. viviparum*, the seeds developing leaves whilst still on the stalk,

be mixed with them. During the summer I have used various kinds of greenery, but none produced so good an effect as *Gypsophila paniculata*. —DORSET.

### FLOWERS IN YORKS.

It is popularly thought that Yorkshire has an inclement climate. As a correction of this misconception I enclose you a list of the plants now (November 9) in flower in my garden here at an elevation of 400 feet above the sea.

<i>Anemone japonica</i>	<i>Hieracium aurantiacum</i>
<i>silvestris</i>	<i>Hypericum calycinum</i>
<i>Antirrhinum majus</i>	<i>Helianthus</i>
<i>Auriculas</i>	<i>Helenium grandicephalum</i>
<i>Aloysia citriodora</i>	<i>striatum</i>
<i>Aubrietia purpurea</i>	<i>Illecebrum bracteatum</i>
<i>Asters in variety</i>	<i>Jasminum nudiflorum</i>
<i>Achillea Ptarmica fl.-pl.</i>	<i>Lobelia cardinalis</i>
<i>Coreopsis</i>	<i>Milleri</i> and <i>syphilitica</i>
<i>Ceanothus azureus</i>	<i>Linaria Cymbalaria</i>
<i>Clematis</i>	<i>Menziesia polifolia</i>
<i>Crocus aurea imperialis</i>	<i>Mignonette</i>
<i>Calendula officinalis</i>	<i>Nigella damascena</i>
<i>Colchicum autumnale</i>	<i>Nicotiana affinis</i>
<i>Collinsia bicolor</i>	<i>Omphalodes verna</i>
<i>Chrysanthemum Burridge-</i>	<i>Primula denticulata</i>
<i>anum</i>	<i>Phlox (herbaceous)</i>
<i>maximum</i>	<i>amona</i>
<i>uliginosum</i>	<i>Pelargonium (bedding)</i>
<i>Campanula muralis</i>	<i>(scented-leaved)</i>
<i>hirsuta</i>	<i>Pentstemons</i>
<i>Crucianella stylosa</i>	<i>Physalis Franchetti</i>
<i>Coronilla glauca</i>	<i>Polygonum vacciniifolium</i>
<i>Choisya ternata</i>	<i>Physostegia speciosa</i>
<i>Dianthus</i>	<i>Roses in variety</i>
<i>Erodium Manescavi</i>	<i>Rudbeckia speciosa</i>
<i>Ecremocarpus scaber</i>	<i>Scabiosa atro-purpurea</i>
<i>Eucharidium grandiflorum</i>	<i>caucasica</i>
<i>Eschscholtzia californica</i>	<i>Salvia patens</i>
<i>Erica ciliaris</i>	<i>Spiraea Anthony Waterer</i>
<i>Erigeron mucronatus</i>	<i>Sedum stoloniferum</i>
<i>Escallonia Philippiana</i>	<i>Symphyantra Hofmanni</i>
<i>Fuchsia</i>	<i>Saxifraga Fortunei</i>
<i>Gentiana acaulis</i>	<i>Tritoma Uvaria</i>
<i>Geranium nodosum</i>	<i>corallina</i>
<i>pneum</i>	<i>Tropaeolum canariense</i>
<i>Hydrangea paniculata</i>	<i>majus</i>
<i>Hanamelis virginica</i>	<i>Vinca minor</i>
<i>Helleborus niger</i>	

R. MILNE-REDHEAD.

### BASAL ROT IN DAFFODILS.

THERE has more than once in THE GARDEN been a discussion respecting basal rot in Daffodil bulbs, without elucidating any knowledge as to the cause of the disease. Having bought a few dozen bulbs of Mary Anderson recently, and following the good custom of carefully examining the base of all bulbs before planting, I found an unusually hard, solid dead mass at the base of each bulb that would not separate. The healthy condition of any ripe bulb is that the dead base of previous year's growth should be able to come away freely and clear from the sound living bulb. Any attempt to remove the hard body in this case met with no success when dry. It was too hard to cut freely, and no separation could be effected otherwise. Moreover, the knife involved damaging living parts of the bulb, or, as there was no level line of cleavage, still leaving some of the hard dead substance bedded in the living portion. After soaking the bulbs in water for twenty-four hours or so, the dead matter could then only be separated by cutting and scraping, with very occasional stripping of small portions in a more natural manner. The condition of these bulbs conveyed clearly to my mind that fresh roots could not be produced except at the outer radius of the bulb, whereas in healthy Daffodil roots are produced in several rings within the outer one. A finer-grown sample of bulbs I never saw, but they satisfied me that planting with this hard dead mass attached is the secret and cause of basal rot. Basal rot had actually made progress in some half-dozen out of eight dozen bulbs; no doubt planted in this condition many more of the bulbs would have developed it next year.

Having, I believe, arrived at the cause of basal rot in the bulbs, the next thing was to seek the cause of the existence of this hard woody mass. It should evidently be cast by a natural process, and would in a state of nature be so cast and rapidly decomposed. These bulbs showed no natural line of cleavage from which the dead base could be cast. The bulbs had no doubt been taken up before natural cleavage was established, *i.e.*, while the base and roots were still alive. There was evidence of unripeness at top of the bulb to support this view. I think further investigation will prove that too early raising of bulbs is the cause of basal rot. If this is so, it can be dealt with by covering up in trenches for a short time any bulbs that prove to be taken up before the base is in a proper condition. We all know the mischief caused to Lilies by unseasonable lifting, but I think it has been overlooked in respect to Daffodils. DUDLEY DOCKER.

King's Norton, Worcestershire.

**Polygonum vacciniifolium.**—Mr. G. F. Wilson's note on this plant (p. 374) is a timely one. In mild seasons, such as the present, every additional flower helps to make the outdoor garden more attractive and lessens our dependence upon glass. A group such as that spoken of by Mr. Wilson is very bright, and its effect is greatly heightened by being associated with other plants, as he says. This rock Knotweed is at times difficult to establish in the garden, and a good many lose plants soon after planting, with the result that they come to the erroneous conclusion that it is not hardy. When once established it is hardy enough, and those who desire to make a trial of it would do well to procure young plants. *P. vacciniifolium* appears to prefer half shade, and although some say moisture is essential, I do not find this absolutely necessary if the roots are well under the stones of the rock garden.—S. ARNOTT, *Carsethorn, Dumfriesshire, N.B.*

**Pyrethrum uliginosum.**—I am surprised to see Mr. Wood class this among hardy flowers that are not thoroughly reliable. I have always considered it to be one of the coarsest habited things we have and hardly fit for association with the ordinary run of hardy perennials. With me it quickly takes up a lot of room, and I have frequently to prune with the spade and sometimes cast a barrowload on the rubbish heap. It is one of those things that, in spite of its undeniable value, there is but little demand for now. Those who once obtain it rarely have to do so again, and this kind of hardy flower is seldom asked for in the trade. I have a row of this *Pyrethrum* that was planted about five years ago, and without any care it every year produces thousands of blooms, which this season were as good as in the first year after planting. It was lately suggested in THE GARDEN that the plants should be cut down in June to make them dwarf, but I have but little sympathy with the efforts that are being constantly made to lower the stature of our taller growing hardy perennials. The height to which *Pyrethrum uliginosum* attains renders it useful for positions where things of quite moderate dimensions would be out of place. I lately saw it in large masses among neat bushes and low-growing shrubs apparently quite at home, and by reason of its height very effective. Anything less robust and of dwarfer growth would have been lost in such a position.—J. C. B.

**Tigridias.**—How very seldom one sees these beautiful and brilliant autumn-flowering bulbs in private gardens, and I have often asked myself why this is so. The experience of the last few years has rather solved the question for me, for I have been quite unable to harvest them properly. I have tried various plans; have lifted them at the same time that I have done my Gladioli, have placed them in dry sand out of the reach of frost, but they shrivelled up and have been of very little use at planting-time. Thinking, perhaps, that I might be wrong in this, I have lifted them with a considerable quantity of

earth, have left them in that, and allowed them dry off gradually, but here again the result has been the same. Some years ago, on visiting the garden of a lady friend, I saw a magnificent bed with hundreds of roots in it, with a multitude of blooms. I saw the owner of this garden the other day, and she told me she had lost every one of them, and in another garden where there was a goodly number the same doleful story had to be told. I have obtained imported bulbs which seemed to be plump and good, but by the time the planting season came round I found them very much diminished in size, which was, perhaps, natural, and when planted a number of them seemed to do no good. Have any of your readers had any experience with these remarkably striking flowers, and can they give any information as to the best way of wintering them? I see that the Dutch growers state that all these bulbs are easily grown, and recommend that they should be kept dry during the winter, a plan which, as I have said, has quite failed with me. If, then, a readers of THE GARDEN will give me any hint how I can better manage these delightful Mexican bulbs they will perhaps confer a favour on other beside myself.—D.

### FLOWER GARDEN NOTES.

A NEW departure that is very welcome has taken place within the last few years, both in public and private gardens, in the planting of beds of large size. I mean the selection of tall plants for filling the same and the gradual weeding out for the particular purpose of such things as Geraniums and others of similar height. This is all the more desirable when the surroundings are of a nature to suggest the use of tall plants, such, for example, as when the beds have a background of trees or when they are interspersed with other devoted to tall shrubs, both deciduous and evergreen. Under such circumstances the aim should be as far as possible to utilise the larger perennials, and if to many of them flowering rather than is objected to, a mixture could possibly be effected that would altogether give a long-sustained display. Planting should always depend on the surroundings. Where, for instance, foliage in great variety is naturally abundant, the employment of Palms and sub-tropical plants of all kinds or noticeable for their foliage is hardly to be recommended. This is simply adding to the mass of greenery, and somewhat on a par with the idea of pleasure-ground planting that formerly prevailed in covering every available space with common Rhododendron, Laurel, and things of similar character. Rather, if foliage is already abundant the aim in new planting should be the supply of colour that will best harmonise with existing beds, and where this has to be done, it is well this season of the year to go carefully through the well-prepared catalogue of herbaceous plants to ascertain the number of things that can be used with the view to present planting, or, failing this, to work up a stock for spring. In connection with several of the large families it should be remembered that many of the later introduction flower considerably earlier than the old type and are consequently contemporary with bedding plants; also that with a little attention in the way of the removal of dying flowers, nipping out first spikes, &c., in good time, to secure a more rapid development of the second show of flowers, and the complete furnishing of beds by the formation of bushy plants, nearly all of them can be depended on to furnish a long display. In all cases where a knowledge of the flowering season does not exist the plants should take care to acquire the same. A good system of planting can hardly be carried out without this. This applies to varieties as well as species, the variation in the case of the former being very considerable. Besides these large families, such, for instance, as Phloxes, Saxiflowers, Lilies, Starworts, &c., which may respectively be employed in variety in separate beds, there are other less known plants which will help to make very interesting mixtures, quite sufficient, I fancy, to plant the majority of garden

successfully with only a very little aid from other things. *Bocconia cordata* is an instance of a hardy plant splendidly adapted for bold dening. It is occasionally found in shrubberies, but I would also recommend it for bold beds in the open, where it should be planted fully, allowing plenty of room for development on all sides. The intervening spaces can be filled with *Aster Amellus grandiflorus*, *Chrysanthemum Anastasia* and *Little Bob*, dark-flowered *Antirrhinums* and *Antirrhinums*, or things of similar nature. Any of the above groundwork plants may act in a similar capacity to *Galtonia edicans*, which under favourable conditions will run up high enough to throw its graceful spikes well above them. I like to plant the bulbs in clumps of three or four, as a good mass of flower is hereby secured. The ground for their reception should be well broken up. Plant firmly at a depth of 6 inches, and give a winter mulching.

Returning to *Bocconias*, I have not seen the form *carnea*. If it bears out the description it should be a decided acquisition, and the deep-coloured spikes would afford an opportunity of contrasting lighter things beneath than those employed with the type. The tall *Sea Holly* (*Argemone superbum*) is another plant that may be used successfully in large beds only, as the foliage is somewhat peculiar. Anything on a smaller

should be well done, as both species will repay liberal treatment, the *Spiraea* especially, with its tendency to spread, being a decidedly hungry plant. *Hemerocallis* and *Funkia*—known respectively by the common names of Day and Plantain Lilies—may have one or more beds reserved for them, the former occupying the more central positions, although one of the family, *Sieboldii* or *Dumortieri*, as it is also called, is not taller than the *Funkias*.

Additional attraction will be given to beds so filled if a few of the variegated forms of each family are employed; indeed, some of the *Funkias* in this respect are on a par with the most pronounced variegation to be found among stove or greenhouse plants. The list of things available for large lawn beds might be considerably extended. I just offer the foregoing as instances of what can be effected in this direction, and if a start is once made the result will be satisfactory and lead to annual strengthening of the same. Naturally, the brilliant colouring of the best of the Dahlias, Sweet Peas, large-flowered Marigolds and the like is an inducement to include them if a preponderance of bright colour is desirable, and whether the mode of propagation is from seed or cuttings, the aim should be to secure healthy, sturdy plants in good time, so that, once planted, they go away quickly and come early into flower.

*Linum narbonnense* in Messrs. Veitch's nursery at Exeter. From a photograph sent by Mr. F. W. Meyer.

scale used in connection with it should be carefully selected. *Cimicifuga cordifolia* and *C. racemosa* are also worth a trial; the white feathery flowers show to great advantage against richly coloured, fine-foliaged shrubs, and should be equally effective in connection with other flowers. Beds that cannot fail to please are formed by an association of *Montbretia crocosmiæflora* and its varieties with *Gypsophila paniculata*. I hold because, given good cultivation, the tops of the spikes of the *Montbretias* will be quite 4 feet high. They start early into growth, and are consequently the better for early planting. Plant at a depth of 5 inches or 6 inches and mulch with short manure, not necessarily as a protection, but to prevent the soil drying out and to secure rust, sturdy growth. The number of corms in each clump will depend on the size of the bed, and they should be so arranged that some of the big-like foliage and flower-spikes will show up through the spreading panicles of the *Gypsophila*. To beds might be devoted to herbaceous *Lobelias* and *Spiraea filipendula* comparatively early in the season. When the *Spiraea* is in flower the foliage of the *Lobelia* will afford a pleasing contrast to the same, whilst later the relative positions would be completely changed. In all gardens where the *Lobelias* are found to be perfectly hardy such an arrangement might be planted at once. The beds

I never practise autumn-sowing of Sweet Peas, as birds are very troublesome, necessitating constant watching, even if the clumps are staked and otherwise protected by string, cotton or similar materials.

E. BURRELL.

Claremont.

**Cactus Dahlias.**—There is great confusion in this country as to what are really Cactus Dahlias and what are not, the tendency of exhibitors being to regard the decorative Dahlias as Cactus varieties. I and others are desirous of remedying this condition of things, and intend to have the names of the true Cactus varieties printed in the new schedules of the Massachusetts Horticultural Society, provided we can get the authentic list. Will any reader of THE GARDEN kindly give me the names of the true Cactus Dahlias.—W. E. ENDRICOTT, Canton, Mass., U.S.A.

**Kales and Beetroot in the flower garden.**

—We see, without much pleasure, a plate in the *Rural Horticult* of variegated Kales, which unhappily are used by some for the "decoration" of gardens. New, the form and colour may be as fine as in many other things, but for the decoration of our gardens such things are rubbish, if only from the fact of their evil odour after hard winters, and no waste of time could be worse than growing such things, which never can take a place

in any true flower garden. Of the same character are the purple Beets, used at Kew in the flower garden. Whatever we do in the flower garden, it is hardly necessary to use Kales and Beet in it when there are so many lovely things we neglect or forget, and things, too, like some of the wild species of Azalea and Lily, which may show their grateful faces to us for many years after planting them. If we wish to cool our eyes on esculents, the best way is to go to a good kitchen or market garden, either about London or Paris, where we willingly admit there are good forms of leaf and much better colour than in these variegated Kales and liver-coloured Beets.—Field.

#### LINUM NARBONNENSE.

The elegant plant here illustrated was photographed in the nurseries of Messrs. R. Veitch and Son, Exeter, where it is growing on the rockwork, and forms a spreading bush 2½ feet across and about 18 inches high. The flowers are arranged in a loose panicle with long pedicels. During dull or rainy weather the flowers are closed, but in bright weather they are expanded in their full glory, forming a most elegant object in rockwork or border. The individual flowers are fully 1½ inches across, bright azure blue, somewhat paler beneath, with white anthers and a white spot in the centre of each flower. *Linum narbonnense* flowers throughout the summer, and though we are now in November, quite twenty flowers are still open on the plant mentioned. The calyx is of a bright green colour; the leaves are linear, lanceolate, 1 inch to 2 inches in length and about an eighth of an inch broad. They are very pointed at the apex and are arranged alternately. The margins of the leaves are entire.

Altogether *Linum narbonnense* is a most desirable plant and of the easiest possible cultivation. When planting, a place at least slightly elevated should be given the preference in order to show the elegant drooping habit of the flowers to the best advantage.

Elmside, Exeter.

F. W. MEYER.

**Tufted Pansies.**—I saw in a garden in Midlothian during the past summer a simple, but very efficient arrangement with these Pansies. They were planted in a border running east and west, in the centre of which was a row of dwarf fruit trees and on the south side a row of Sweet Peas supported by galvanised wire Pea trainers. The Pansies were planted along the north side of the border in the form of squares, each square being 3 feet, with 15 inches of clear space between each square, in front of which was a grass edging. I here give the names of the Pansies. Lord Elcho formed its own square, as also did Archie Grant, Countess of Hopetoun, Blue Gown, J. B. Riding, Sylvia, William Niel, Ardwell Gem, Favourite and *Rosea pallida*. Each grew vigorously and bloomed profusely, aided by the kindly shade and the abundance of Moss litter at the roots.—W. L. M.

**Bulb planting.**—In October, 1896, I planted a large bed on the lawn with some 1200 poeticus *Narcissus*, and as the bed during the summer is filled with *Fuchsias*, I tried the following plan. The soil to a depth of 1 foot was taken out and the bulbs placed firmly in and re-covered with the 12 inches of soil. I was looked upon by gardeners in the neighbourhood as a lunatic, throwing away or rather burying money never to be seen again. In due course the leaves came up very strongly, and I began to fear that my experiment would fail, and I should have nothing but foliage and no bloom. However, I was delighted when the flowers began to show, and in the end I had a waving mass of bloom, much to my delight and somewhat to the disappointment of my neighbours. I see no reason why I should not have

this next year as fine a show as last. Out of curiosity, I dug down to see how the bulbs were looking. I found them in excellent condition. The advantage of this deep planting is that it does not interfere with the bedding-out in the summer. This last summer the bed referred to was filled with Fuchsias varying from 5 inches to 2 feet 6 inches high. The soil here is light, and all Daffodils, I find, increase rapidly. I am so satisfied with my last year's experiment, that I have tried it again in a basket, which is now filled with some 600 Daffodils of different sorts, but this time planted 8 inches deep, as the basket during the summer is filled with yellow Marguerites, and it was not necessary to plant 1 foot deep. Gradually, if the experiment continues to answer, I shall treat a large herbaceous border in the same way.—M.

### THE PEACH-LEAVED CAMPANULA.

UNNECESSARY as it may appear to some, it is yet needful at times to urge the claims of some of our older plants on the attention of growers of hardy flowers. These older plants were too long neglected, and even yet there is a danger that they may be put into the background by novelties possessing less beauty than these old-time favourites. Thus it is at times desirable to write about comparatively common flowers in order that their merits may not be overlooked. One of these old plants is the Peach-leaved Campanula, which, with its several forms, is an indispensable garden flower. It is a native plant which, though absolutely hardy, rewards by its increased beauty those who give it due attention and the rich soil it appreciates. *Campanula persicifolia* is varied in form, size and colouring, and the original or typical blue form has been surpassed by the varieties which have sprung from it. Of these, none are more admired than the white forms. These vary much in purity, some being of thick wax-like texture and with a glossy surface, which adds much to their beauty. Seen in the mid-day sun in the height of summer the white Peach-leaved Bellflowers are beautiful, but it is in the evening, perhaps, that one realises the beauty of these long wand-like spikes clothed with their pure flowers. When twilight is passing into darkness they are most effective, whether they raise themselves from among other flowers in the borders or mingle with others in the wild garden. In the moonlight tall spikes look almost ghost-like.

Among the white-flowered Peach-leaved Bellflowers the one known as *Campanula persicifolia* Backhousei or *C. p. alba grandiflora* is perhaps the most admired. One can see no difference between the plants sold under these two names, so that I have not hesitated to write of them as one and the same. It is a moot point if there is not some of the blood of *C. latifolia* in the fine plant first sent out under this name, but whether this is so or not, it can hardly be left out of the list of our best garden flowers. Fine as this is, it shows a flimsiness of petal absent in some of the best seedlings, and it is doubtful if it will ever be more admired than a good form of the variety known by the unwieldy name of *C. p. coronata alba*, which has its corolla so doubled as to form what is familiarly known as a "cup-and-saucer" flower. A good form of this in my garden has the stout wax-like blooms which give the flowers an added charm. The double white—an old and favourite flower—is of exceptional beauty, if a little stiff in its way. It is not so easy to retain long in the garden without the help of frequent division and the aid of fresh soil. There are also several semi-double white varieties of more or less value.

The Peach-leaved Bellflower gives us also several blue shades, a colour always acceptable in the garden. Some are exceedingly pale, and the range gives us pale and deep lilacs as well as rather deep blues. There are now some fine large-flowered blue varieties quite equal in size to any of the large whites. The double blue variety is not so plentiful as the double white, but is to be had by those who like such flowers. There are also blue "cup-and-saucer" varieties and semi-double pale blue, lilac, and deep blue forms.

Besides their uses in the garden these Bellflowers prove of great value for house decoration, especially in the form of long spikes for placing in large vases. The taller Campanulas are nearly all of value for this purpose, and should be more largely made use of than at present. As already indicated, a rich soil is, if not a *sine qua non*, at least needful if the best results are to be reaped. A good loam, well enriched with decayed manure, will give taller spikes and larger flowers than a poor, starved soil. This Campanula increases rapidly at the root, but the double forms are apt to dwindle away if left too long without division and transplanting. It may be observed that new flowers will push from the dormant buds at the base of the old flowers if the latter are taken carefully off. It is also, I think, advisable to grow *Campanula persicifolia* in a position where it is partially shaded from strong sun. Too wet a situation should, however, be avoided if healthy plants are desired. S. ARNOTT.

**Pæonies and rabbits.**—I think Mr. Burrell may safely plant Pæonies in positions where rabbits are plentiful, as I have given them a fair trial in some such spots and never found any traces of injury either from rabbits or any other vermin. I presume that Mr. Burrell's inquiry is intended to embrace only the herbaceous section, and I fear that the results with these in rough herbage will only be successful in the case of the strong growers, such as *P. officinalis*, double and single forms. This has been my experience, and I have tried many named varieties, most of which have failed to make crowns strong enough for flowering. In the first place they do not like the root-disturbance, and before they have time to re-establish themselves fairly, the herbage, and possibly tree roots, have robbed the soil of all nourishment, so that the Pæonies go on producing only small leaves and flowerless crowns year after year. With *P. officinalis* the case is different, and some fine clumps have rewarded the efforts made to secure them, as the plants seem quite able to hold their own after the first year. Probably the others might be induced to do likewise if the surface could be kept clear of weeds for two or three years, but it is only the very strongest growers that will really establish themselves. I quite agree with Mr. Burrell's remarks as to the results obtained by mixing Daffodils and Pæonies together in beds or groups in cultivated ground; the crimson hue assumed by the young leaves and stems of the Pæonies forms a perfect setting for the Daffodil flowers, and the leaves of the latter will be sufficiently ripened by the time the former cover the ground. To such a bed a further carpet and edging of *Scilla sibirica* will be found very attractive, but it is useless to plant it where pheasants are numerous.—J. C. TALLACK.

### SHORT NOTES.—FLOWER.

**Everlasting Peas for cutting.**—These are very useful for cutting, more especially the white form. Having a big demand for cut flowers, I find the white most valuable. Another recommendation of the white form is the length of time the flowers stand in water. I noticed some in a warm drawing-room here during the hot weather were fresh when Bougainvillea and things of this kind were quite faded.

Wheu at Rousden some years ago I noticed an enormous quantity was grown for cutting.—DORSET.

**Senecio pulcher.**—This is a very striking late flowering perennial, the colour a reddish purple, and the flowers very bold and massive. The colour is peculiar that it does not do to mix with other flowers and therefore when cut should be placed in a vase by itself. In this fine autumn it has been peculiar good, and there is now (November 8) a fine truss of flowers in full vigour, the plant being about 2 feet high.

**Mina lobata.**—To those who want a plant for climbing over a rough place or making a screen, this can be recommended. I have not grown it till this year, and I resolved to try it in several situations on soils. Where the soil is rich and damp it is very showy and blooming and is of little value. When planted in pots and in a sunny place it blooms well. I have plants of this against the foot of the abbey wall and full sun, and here it blooms freely. Some plants of this and Canary Creeper mixed and allowed to intermingle have a fine effect.—DORSET.

**Physalis Franchetti.**—A good deal has been written lately about this, and it appears as if some people had found a difficulty with it. I can quite believe that in some cold soils and situations the might be a difficulty about it, but in most places where the soil is light it is easily grown. I am not quite sure that it will be such a weed as the older for *Physalis Alkekengi*; this will be no disadvantage. The new *Physalis*, which is distinct in colour from the older species, will be found very useful for winter decoration, and in most parts of our islands it will be found a hardy and easily-grown perennial.

### NOTES ON STRAWBERRIES.

I FIND the undermentioned kinds of Strawberry answer very well in this neighbourhood, viz. Noble, Royal Sovereign, Gunton Park, Dr. Hogg, Vicomtesse, and Latest of All. I have this year discarded Elton Pine, Anguste Nicais and Waterloo, as I find I cannot depend on them for a crop after the first season. Noble, though somewhat lacking in flavour, can always be depended on for an early crop of large, handsome fruit, but I think eventually Royal Sovereign will displace it as the best early Strawberry in existence. The two best kinds to follow, I think, are Gunton Park and Dr. Hogg, both being of excellent flavour and good croppers. Then come Latest of All, also a good cropper, large handsome fruit, but somewhat deficient in flavour. I have resolved to plant a large bed every season of young plants layered into pots, and treat them as annuals. I planted a bed last year, the first was in August, of the following varieties:—Noble, Royal Sovereign, Vicomtesse, Gunton Park, Dr. Hogg, and Latest of All; and gathered Nob June 14; Royal Sovereign, June 17; Vicomtesse June 20; Dr. Hogg, July 1; Gunton Park, July 1; Latest of All, July 8. The best fruits of Royal Sovereign weighed 1½ ozs., and Gunton Park 1 lb. to the pound, without any disbudbing. By growing young plants like this one can plant close and so secure a good weight of fruit the first season, as well as keeping much freer of spider. Of course, it is always necessary to have a two-year-old bed to follow these young plants.—A. G. GATLAND, *Comington Castle, Peterborough*.

— Strawberry culture is carried on only for home consumption, not for market, and the varieties named below are those which I find succeed best for the purpose, and which have been noted in previous seasons. A few others are tried from time to time, but either they do not succeed so well, or are so deficient in quality that the culture is discontinued. Four varieties are grown—Keens' Seedling, Vicomtesse H. de Thury, St. Joseph Paxton and President, and they are generally forced and ripen outside in the order named, though, of course, the season outdoors sometimes makes a difference. Royal Sovereign has been planted, but so far only on a limited scale, and the following have been added for trial next year: Gunton Park, Lord Suffield, Leader and Monarch. Noble has been left out this season; it produced very large fruits and a good crop, but did not find favour. A system of culture has been practised several years, and

answers very well. A new plantation is made each year by inserting young plants, that are layered immediately after those required for forcing so soon as they are ready, which is from the middle to the end of August. The first season all flowers are removed from a sufficient number of plants to produce runners for all purposes, and they come early and are strong. These plants produce a heavy crop the second, and sometimes an equally good one the third year; after this they are dug up and the ground planted with Broccoli or something else. Thus a new plantation is made each year and an old one destroyed, leaving about an equal amount of space in the garden occupied with Strawberries. It always seems a great advantage to secure runners from young plants and from plants which are not allowed to fruit, as they come earlier and need not be trampled upon in netting or gathering fruit. It is even more advisable to adopt this plan when it comes a dry season. The soil is fairly heavy, and Strawberries usually succeed unless injured by frost at the flowering period. The ground intended for Strawberries is first cropped with early Potatoes, or something that comes off in July or early in August.—J. GARRETT, *Batsford Park, Moreton-in-Marsh.*

—The best flavoured Strawberries grown here are Vicomtesse H. de Thury and a seedling from it called Glangarry. British Queen I do not grow, the soil being rather light for it. The best early kinds in this district are Vicomtesse H. de Thury, Hungary, and Royal Sovereign; best late kind, Elton Pine. This soil being rather light, the newer kinds do not seem to stand well. I find no kind so reliable as the true old Elton Pine; it is in sheet-anchor, and I depend mostly upon it. Usually plant in spring—about April. I lift the runners from young plantations in autumn, and lift them thinly in nursery rows for the winter. During the winter the ground is thoroughly prepared. I prefer the rows to be 3 feet apart, 2 feet between the plants in the row, two plants going together, one on each side of the line. The clumps when bearing stand each separate, the sun and getting well at the fruit. Mice are not so troublesome as when the plants are closer. I usually put down a plantation of early and one of the kinds each season, destroying a like amount of exhausted plants. I take a crop of Onions, Lettuce, or such like crop from between the rows the first year to make the most of the ground.—MELVILLE, *Denrobin Castle, Sutherland.*

—Two varieties that succeed best and are most liked for flavour are Sir Joseph Paxton and President. The best early variety is Vicomtesse Héricart de Thury, and the one most liked for preserving. The best late variety to succeed well here is Mr. Radcliffe. Amongst the newer varieties, Royal Sovereign, Stevens' Wonder, and Gunton Park promise to succeed well and to be of good flavour. I find the best results are to be obtained from plants layered into small pots and potted out in well-trenched and manured ground early in August and September as possible. I never keep the beds more than two years.—G. HURTT, *Theylou Grove, Epping.*

—The best Strawberries here are President, Sir Joseph Paxton, Royal Sovereign, and Elton Pine. The above-named varieties I find to answer best here, both for forcing and outside cropping; they also bear carriage well. The best time for planting Strawberries I find is August and September. I always layer into small pots as early as possible, and plant out as soon as the runners are filled the pots with roots, mulching the ground immediately afterwards.—A. STATHAM, *Block Hall, Cheshire.*

—The best all-round Strawberry for crop, flavour, and general usefulness is Vicomtesse Héricart de Thury; for flavour, I consider Dr. Hogg and the old Filbert Pine best. The best early kinds are, I consider, Vicomtesse H. de Thury and Royal Sovereign; the best late kinds are Laxton's Latest of All, Aromatic, and Sir C. Nier. The best time to plant Strawberries is during August, especially if the ground has been some time previously prepared, using good strong

runners from fruitful plants.—R. MAHER, *Yattendon Court.*

—The varieties I find best for early use are John Ruskin and Royal Sovereign. Garibaldi I consider the most profitable for preserving, as it stands the bad weather better than Keens' Seedling, although the latter has a grand flavour. Noble I have discarded, it does not ripen at the point and is of poor flavour. I consider Elton Pine the best late variety for either garden or open field. I always plant Strawberries if possible in the early part of August and after Potatoes without any digging of the ground, 2½ feet between the rows giving plenty of room for light and air to ripen the crows.—EDWARD TATE, *Belcarries, Fife.*

—To keep up the longest succession of best kinds of Strawberries I rely upon four kinds, and always grow them in bulk, viz., Royal Sovereign, President, Dr. Hogg, and Oxonian. Each of these if well grown on young plants cannot be surpassed for general purposes, whether for home consumption or sending to the family when residing in town. These are my sheet anchors, and being given high cultivation never disappoint. I say this after having tried a great many of the highly lauded new kinds as they are offered. British Queen is erratic with me, evidently not quite at home on our stiff soil, but Dr. Hogg is nearly equal to it in flavour; hence my fondness for that kind. Auguste Nicaise, James Veitch, and others of the huge, flavourless kinds have no quarter here, as highest quality and appearance are the chief objects. Vicomtesse Héricart de Thury and Stirling Castle make excellent coloured preserve. Sir Jos. Paxton is rather inclined to mildew, and never equals President. I treat the earliest crops of Sovereign as biennials, only taking one crop, planting a bed annually from the earliest possible runners on well prepared sunny borders. These produce fruit from eight to ten days earlier than the same kinds in older plants.—WM. CRUMP, *Madresfield Court.*

—Strawberries were later this season than usual. John Ruskin is a favourite by reason of its earliness and free cropping; when fully ripe its quality is good. Royal Sovereign fruited well, and is esteemed for its earliness, size, and fine flavour. President is valued more than any other; it bears abundantly, fruit large, and flavour first-rate here. Duke of Edinburgh is a late Strawberry, and has done better here than any other late variety. There is no resident proprietor here at any time, so that all Strawberries (as well as everything else grown in the garden) have to be packed and sent. They are gathered in the afternoon, placed thinly on wide shelves in the fruit room with air passing over them all night from widely open windows; they are packed in the morning and sent off by train (small dishes of the earliest are sometimes sent by parcel post). I have found every Strawberry I have grown travel well under such conditions, and I think the airing process improves the flavour. I plant for main crops those which have been forced, and as soon as they are hardened after the fruit has been gathered.—M. TEMPLE, *Carron, Stirling-shire.*

—The best sort I have is Royal Sovereign, a first-class fruit in every way. Auguste Nicaise is also very good and a heavy cropper. Dr. Hogg, though of excellent quality, is not a heavy cropper. Eleanor, late, is a good cropper. John Ruskin is a heavy cropper and of good quality. Princess Alice is a fine handsome late fruit and of good quality. Scarlet Queen is a heavy cropper and good in flavour. Jubilee, the latest we have, is a heavy cropper and of good quality, but deficient in colour. Crescent Seedling is a heavy cropper, early, and good for preserving. All the foregoing travel well, except Scarlet Queen. I find the earlier the runners are planted the better for a full crop next season.—JOHN D. NAUSCAWEN, *Whiteby, Chadleigh, Devon.*

—Keens' Seedling is a fine old kind, but Noble I will discard; it is big enough, but not good enough. I also have President, Sir Joseph Paxton, Scarlet Queen, and Elton Pine. These I

find all good, reliable kinds. One very good productive kind I have under the name of Leon de Lamur, which I think must be a synonym of some other kind. I have had it for years under that name, but do not find it in any catalogue. It is a good kind for any purpose.—A. MATHISON, *Addington Manor, Wiltshire, Bucks.*

—The Strawberries that find most favour here for flavour are Garibaldi, British Queen, Duke of Edinburgh, Sir J. Paxton, and President, Grove End Scarlet being a special favourite for preserving. The best earlies are John Ruskin and Eclipse; best late, Elton and Waterloo. Frogmore Late Pine and Loxford Hall Seedling are a failure. Of the newer sorts, I have planted this year Royal Sovereign and Latest of All, which are both highly spoken of in this district. I find, if I can get the ground cleared to receive the plants, early in August is the best time to plant; by so doing I get a nice crop of fruit the first year.—P. WILSON, *Orchardtown, Castle Douglas, N.B.*

—The best early varieties for flavour here are Duke of Edinburgh and Garibaldi. Royal Sovereign promises well, but did not prove a heavy cropper here this season. Of late varieties the best here for flavour are Dumbarton Castle, Waterloo, and Wizard of the North. The last, although a very old variety, is still the best, and a very telling dish on the table.—DAVID MURRAY, *Calzean Castle, Maybole, N.B.*

—The best Strawberries I have grown here are Vicomtesse, Keens' Seedling, President, and Elton Pine. I am trying Royal Sovereign, and from the few fruit I had this season think it will be good. I like to plant as soon as I can get runners fit to do so.—E. TAPPING, *Castle Upton, Templepatrick.*

—The best flavoured Strawberries are the British Queen section, but they do not do well on our light soil. For flavour I find Keens' Seedling still hold its own with President, Hélène Gloede, Sir J. Paxton, and Sir Harry. The best early kinds are Royal Sovereign, La Grosse Suerce, Keens' Seedling, J. Veitch, and President; late kinds, Oxonian and Latest of All. Of the newer sorts, Royal Sovereign and Monarch are good on our light soil. I get the best and earliest return from well-rooted runners, planted as early as they can be had in autumn, on well-prepared ground.—A. HENDERSON, *Thoresby.*

—The best flavoured kinds are British Queen, President, and Empress of India. The best early varieties are Black Prince and Royal Sovereign, and the best late Latest of All and Elton Pine. Of the newer sorts, Royal Sovereign, Gunton Park, and Empress of India are the best. I plant as early as I can procure runners in well-cultivated ground made firm. No Strawberry I consider equals President. I gathered Strawberries on June 12 last year, and continued gathering up to August of this variety and British Queen, in the height of the season 50 to 100 lbs. in a day. This year it was July before I commenced with these two varieties.—G. BOLAS, *The Gardens, Hopton Hall, Wicksworth.*

—The varieties I consider best for flavour and quality are Royal Sovereign, President, Keens' Seedling, and Noble. They will all bear carriage. The best kinds in this district for flavour are Garibaldi, Royal Sovereign, President, and Keens' Seedling. The best early sorts are Royal Sovereign, President, Keens' Seedling, and Noble. The best late varieties here are Monarch, Waterloo, Countess, and Elton Pine. The new sorts most worthy of cultivation are Royal Sovereign for an early sort, and Countess for late use. The best time for making new plantations is early in September, as the plants then get established before severe weather sets in. Old beds should be done away with after they are four years old.—GEORGE MACKINLAY, *West Park, Ampthill.*

—The best flavoured here are President, Vicomtesse Héricart de Thury, Sir Joseph Paxton, Waterloo, Loxford Hall Seedling, and Latest of All. The best early and late kinds for the open air are—early, King of the Earlies, Vicom-

tesse H. de Thury, President, Sir Joseph Paxton; late, Oxonian, Waterloo, and Loxford Hall Seedling. Of the newer sorts worthy of cultivation Royal Sovereign is the best I have tried. The best time to plant Strawberries is early in August or as soon as you can get the runners. By following this method I can always get a pound of fruit off each plant the following year.—ALEX. CUNNINGHAM, *Kirkcubrighton Hall, Yarm, Yorks.*

— Of the varieties I grow, British Queen, Latest of All, Dr. Hogg, Gunton Park, Jubilee, Sir Joseph Paxton, Waterloo, Monarch and Royal Sovereign are the best flavoured. The soil here is of a sandy nature and sloping to the south. The best early kinds with me are Royal Sovereign and Monarch, and indoors the only variety grown is Royal Sovereign. The best new varieties are Royal Sovereign and Monarch. Leader seems a promising variety. The best late kinds are Waterloo and Latest of All. The best time to plant is the end of September. I have found the best results follow from potting the runners into 6-inch pots before planting them out.—C. J. SALTER, *Woodhatch Lodge, Reigate, Surrey.*

— The sorts I grow are Royal Sovereign, President and Sir J. Paxton. I find these three sorts do better than many others I have tried on our stiff soil. Stevens' Wonder I use for early forcing in the place of Vicomtesse H. de Thury, which has been discarded, Stevens' Wonder being much larger and the flavour almost equal. Royal Sovereign I consider one of the best Strawberries that has ever been sent out, as here we have both size and flavour.—J. BOWERMAN, *Hackwood Park, Basingstoke.*

— The kinds of Strawberries I find the best for private use are John Ruskin, Auguste Nicaise, Royal Sovereign, Garibaldi, Sir J. Paxton, President, McMahon and Waterloo. Royal Sovereign is first-class here for all purposes. I am also growing Carmichael's Prince and Princess of Wales varieties, and I think they will turn out good. The best early kinds here are John Ruskin, Garibaldi and Royal Sovereign; the best late kinds, McMahon and Waterloo. I take off the best runners early in autumn, lay them in a nursery bed, and plant them in well-prepared soil early in April with a trowel in rows 3 feet apart and 20 inches between the plants. I keep all runners cut off except where plants are wanted.—G. DINGWALL, *Belmont Castle, Meigle, N.B.*

— President is my best flavoured Strawberry. I also consider Keens' Seedling, although not fine, yet one of the best for flavour. The best early kind is undoubtedly Royal Sovereign; the best lates are Oxonian and Elton. I find the best time to plant is, given favourable weather, as soon as one can clear off a crop of early or second early Potatoes. By this plan I had a capital crop of fruit this year from runners planted last August, and I have not failed to secure a good crop during the last six years.—E. FOX, *Garners, Herford.*

— I find the best kinds for early work are John Ruskin, Royal Sovereign and Keens' Seedling. Mid-season, Sir J. Paxton, La Grosse Sucrée and President; late, Oxonian and Waterloo. Of the new sorts that I have tried I consider Royal Sovereign by far the best. The best time for planting in this neighbourhood is August. From plants put out the third week in that month last year I have had splendid crops and plenty of runners for early forcing without injury to the plantation.—JAS. DAWES, *Ledbury Park, Ledbury.*

— I find the following best for forcing, and they ripen in the order given: Vicomtesse Héricart de Thury, Royal Sovereign, La Grosse Sucrée, Auguste Nicaise, President, Sir Jos. Paxton, and British Queen. The following have done best outside: Noble, Royal Sovereign, President, Sir C. Napier, Scarlet Queen, Auguste Nicaise, Sir Jos. Paxton, John Ruskin, Competitor, Dr. Hogg, and Waterloo. I consider the best time to plant is about the end of August or early in September, plants having been layered in July into small pots. I have had good results by planting runners from the open ground, but much prefer the plants being layered into small pots.

I always get my stock, about 3000, for forcing from young plants put in the previous autumn, pinching out the flowers, so that I get strong runners in June and July. I have had a good crop of fruit from a plantation put out from small pots on September 9, 1896. The soil here is very light, and not naturally a good Strawberry soil, but by dressing heavily with marl or old Vine-border soil you can get good results.—G. H. GREEN, *Enville Hall, Staffs.*

— I think the following may be safely relied upon as the best flavoured varieties in this district: British Queen, La Grosse Sucrée, President, Enchantress and John Ruskin. King of the Earlies and Vicomtesse Héricart de Thury are the best earlies, with the Albert and Waterloo for late work. Royal Sovereign is, in my opinion, the best Strawberry of recent introduction. It is an excellent variety, of faultless flavour, a robust grower, and thrives well in almost any locality. Laxton's Leader I consider is the next worthy of merit. About the first week in August is the best time for planting Strawberries, the runners having previously been layered into small pots. With a little care and attention these plants are sure to thrive well and give satisfaction.—EDWARD GILMAN, *Alton Towers, Stafford.*

— The best-flavoured varieties I have grown are British Queen, Sir Joseph Paxton, Captain, President Improved, Dr. Hogg, Keens' Seedling, Black Prince and King of the Earlies. Although all the above are of good flavour, some are very shy croppers. The best early varieties for this locality are Black Prince, King of the Earlies, John Ruskin and Noble. Late varieties are Elton Pine, Frogmore Late Pine and Waterloo. I always plant my early Strawberries in August if possible, but the midseason and late varieties I plant in the spring; I find they do best here.—WALTER YOUNG, *Caprington Castle, Kilmarnock, N.B.*

— Noble is worthless both as a fruit for preserving or dessert; its colour is not good enough for the former, while for the latter it is too soft and void of flavour. The only good quality it possesses is that it is a fair cropper. The three sent out by Mr. Allan are all good, and as a late variety Gunton Park is very good. Royal Sovereign is good in every respect. It is a vigorous grower, hardy, and a most prolific bearer. The fruit is large and well flavoured. It is good alike for forcing and for open ground. The flesh is firm and travels well. I should say this will prove one of the best all-round Strawberries we have had for a number of years. Monarch and Leader are both too soft to be of value to private growers who have to pack their fruit and send a considerable distance. For all-round purposes President is good, as the flesh is firm and the fruit travels well. With good cultivation this may be grown to an enormous size. John Ruskin is an early variety, is good for home consumption, but the flesh is too soft to travel any considerable distance. Commander, Competitor, Sensation, and Hélène Gloede are all worthless here; the fruit is soft and void of flavour both when grown in pots and in the open ground. There is plenty of room yet for a good late Strawberry of the Loxford Hall Seedling type that will succeed on cold, heavy soil, such as the majority of it is in this neighbourhood. There are four things essential to a good Strawberry—quality, firmness of flesh, robustness of habit, and hardy constitution. Unless all these are combined in a variety it cannot be said to possess the necessary qualifications to recommend it to the public. Unfortunately, many spurious varieties with long-sounding names are palmed off on to the public; many of them soon go out of cultivation, but not till they have caused a great amount of trouble and annoyance to those who have grown them. It is essential to those who have to pack the greater part of their fruit to choose only those varieties with firm flesh, either for forcing or cultivation in the open ground. Some varieties, however, will not force early, but both Ruskin and La Grosse Sucrée will travel fairly well when carefully packed; to succeed

these, President and Royal Sovereign may be chosen, while for late use Auguste Nicaise. The last, however, is of no use for the open ground unless in favoured places. The plan adopted here to obtain early fruit is to layer runners into 4-inch pots. To have these as forward as possible a few plants are specially grown to supply them; by doing, if layered early, they will be ready for planting out by the latter part of July, and make strong crowns by autumn. If left to the ordinary course of treatment there is not time for sufficient growth to be made before frost sets in for them to develop strong flower-stalks, with which it is impossible to obtain fine fruit. Plan of this description, if planted a foot apart on sunny border where they can be protected by glass in the spring, will give a supply of fruit when it is most needed, that is, just before the plants from the open ground is ready for use. The plants should be mulched in spring to keep the roots moist, and so avoid too frequent watering.—H. C. PRINSEP, *Buxted Park.*

## GARDEN FLORA.

### PLATE 1145.

#### GARDEN CARNATIONS.

(WITH A COLOURED PLATE OF SELF CARNATION)

1, GEORGE MAQUAY; 2, ARIEL; 3, ROSMARON.

THERE is still room for good kinds of garden Carnations, varieties that will live and grow freely under the varying conditions of English climate, and that will give in the season an abundance of fine sweet flowers. Within the last decade the Carnation as a garden flower has received more attention than ever and in many gardens is now given all the attention it so richly deserves; yet there is still room for improvement and room for more kinds, because even out of the present number it is impossible to make a selection right for all gardens and all places; hence the fault of the popular system of selecting the best varieties. Individual tests and trials alone teach the grower what will grow best with him, and in these trials it is found that many new kinds fail to sustain their character or bear out what was said of them at their first appearance.

A few simple, but essential requisites to make up an all-round garden Carnation are very few. Many have been raised and are grown for the sake of their flowers alone but in other respects are useless as garden plants. The failure of some of these has led to questions on the possibility of deterioration under cultivation. If the weak side is constitution and growth, early disappointment is sure to ensue. The old pink Raby Carnation and the old Crimson Clove when crippled by fungoid disease are not so robust as they were twenty or thirty years ago. The best Roses in our gardens to-day are the oldest, and it is a very small percentage indeed of the many new ones raised within recent years that have taken a permanent place in our collections. The same is true of Carnations, and results even more meagre. Witness the many that have been sent

\* Drawn for THE GARDEN by H. G. Moon, Gravetye Manor. Lithographed and printed by J. Goffart.

(thin recent years certified with the approval societies and committees and the few that have any permanent standing. I am not going to belittle recent acquisitions, as they manifest great improvements along certain lines. New varieties have been prolific in recent years, but they are nearly all selected on the standpoint of their conformity with the florist's idea concerning perfection, and are wanting in those qualities that fit them for the open air.—H.

\* \* \* The Carnations here figured were raised by Gravetye by Mr. Herrington, and are not distributed. The white variety, G. Maquay, is found the finest white tried there.—Ed.

THE WEEK'S WORK.

KITCHEN GARDEN.

**CELERY.**—Many will have deferred moulding up the main crop on account of the dry state of the soil about the roots, but it would hardly be advisable to delay doing so longer, as the foliage being dry and so much of it exposed, there is danger of rain or snow bending it down and exposing the centre of the plants to frost. In some cases it may be necessary to add a good depth of soil to try the leaf-stalks sufficiently, and the work may be done more expeditiously if a couple of men can work together—one arranging and holding the tops in position while the soil is worked under each plant. This not only allows of the work being done more quickly, but it is almost impossible for any of the fine soil to enter into the centres of the plants, which so often results in stunted growth, and, perhaps, early decay. If the work has to be done single-handed it would be better to draw the foliage together evenly and secure it with strips of matting. The soil can be easily worked between the plants. In some gardens where a large quantity of Celery is grown the mode of culture is the same as that allowed in market gardens, namely, growing four or more rows in one trench. The plants are moulded up by means of a couple of light boards, which are stood on edge across the trench to divide the plants. The soil is placed between the boards to the desired depth, when they are drawn carefully up and the soil settles round the plants. The latest plants, which will not be used until next March and onwards, need not have much soil drawn round them at present; indeed, it would be much better if the plants are sufficiently compact not to require it, as the leaf-stalks when not blanched are naturally more sturdy and better able to withstand severe weather. Overgrown plants in the autumn seldom last long in good condition after the turn of the year, hence the gain in having late supplies so sturdy as possible at the present time. Some varieties are recommended for autumn and early winter use, as they are not sufficiently hardy to stand through a hard winter; therefore they should be used first, leaving such well-known varieties as Major Clarke's Red and Sandringham White for later supplies.

**CABBAGE.**—Plants of Ellam's Early put out in September have made rapid growth, and are sufficiently forward for immediate use where they are appreciated in a young state. Should the mild weather continue, most of these should be used up before Christmas, or they may be damaged by frost later on. As pointed out previously, it is always best to make three sowings during July and August. This affords plants in different stages, and if the early lot gets too far advanced during a mild autumn like the present, those from the last sowing make a valuable succession to turn in during March and April. If it is already done, draw some soil round those put out last to protect them from trying winds, as they suffer more from these than from frost.

Take care of any small plants which still remain in the seed-bed, as they will prove most valuable for putting out next spring.

**MUSHROOMS.**—Beds made up in the beginning of October will now be yielding their first supplies if the spawn used was fresh and the temperature of the beds has not fallen below 70°. In examining the beds recently it was noticed that the centres had sunk somewhat, causing the sides to leave the walls. It is very necessary when this happens that the cavity be filled up with fine soil, or both heat and moisture will escape, to the detriment of the produce. When it is found that the beds are backward in throwing up a crop, sprinkle the surface with warm water, to which add a little salt. If the temperature of the beds is likely to fall below 70°, cover them with double mats or a layer of clean dry hay. The moisture arising from the manure causes the hay to decay quickly, and if not watched closely may lead to the small "buttons" damping off as they push through. I prefer keeping the hay at least 1 inch from the surface to allow steam to pass off, which is done by placing sheep hurdles over the beds for the hay to be placed on, the hurdles being supported by cross pieces. Collect more material and keep it under cover in readiness for future beds.

**POTATOES.**—It appears that these are not keeping very well. It is usual to defer sorting the tubers over till wet weather sets in, which finds employment for outside hands, but my experience this season is that not a day should be lost in carefully turning them over and throwing out the bad ones. Several lots which had not been examined since they were put into the bins in September were found to have gone very bad, although they appeared quite sound when they were stored; hence my reason for suggesting immediate attention before the evil spreads. Seed Potatoes, too, will need looking to now, as it may be found that growth has already commenced, especially if they have been placed in a heap in a damp shed or cellar. The tubers if possible should be spread thinly on shelves where they can be kept quite cool. A great quantity of sets may be stored in a small shed by placing them on end in shallow trays, standing one above the other, leaving a space of a couple of inches between each for a free circulation of air. By selecting uniform tubers and carefully preserving them during the winter in the way described, the first step is taken towards securing perfect crops next season.

**JERUSALEM ARTICHOKE.**—The tops of these should now be cut down, and after they are removed it may be noticed that some of the tubers have pushed themselves through the surface. It would be advisable to draw more soil over the ridges, so as to bury them at least 4 inches. A further covering of leaves or litter would prove an advantage when the tubers have to be dug up during hard weather, as this would prevent frost penetrating to any depth and much labour would be saved. It is generally considered that the tubers are of better quality when used direct from the ground, but when they are not protected in the way described, a bushel or so may be dug up and buried in moist sand in the root shed. These can be used during a spell of hard weather.

RICHARD PARKER.

HARDY FRUIT GARDEN.

**MORELLO CHERRIES.**—As these are generally grown on north walls, advantage should be taken of the mild weather to push on with the pruning, training, nailing, or tying, as the case may be, endeavouring to complete it before a change occurs. The old and dead spurs and as much as possible of the old bearing wood should be cut away and enough young growths retained to fill all vacant places without undue crowding, as the principal part of the crop is borne on these. The surplus wood may either be spurred back to three buds or be cut clean out in the same manner as in pruning Peach trees. These spurs invariably carry fruits the following season, and they can be cut out afterwards at pruning time. Crowded

trees will be all the better for a branch-pruning, which will give more space for the laying in of young shoots. As a matter of course, the oldest of the branches or those which can best be spared should be cut out in this case to give the necessary space. This condition of things, however, never occurs when the trees are properly trained and well looked after, as the aim of the cultivator should always be to avoid overcrowding and to lay in no more wood than will eventually be required for furnishing the tree with main branches. One good thing, the Morello is not so susceptible to gumming as are the dessert kinds, and the knife can therefore be used with greater freedom on trees which have been neglected than if the reverse was the case. The pruning finished, attention must be directed to the cleansing of both trees and walls. If the latter are very old and the joints open and full of nail holes, they had best be pointed and stopped. In this case the trees, after being well washed with an insecticide, must be liberated, the branches tied into bundles, and secured here and there to the wall to enable the bricklayers to perform their work the more easily and expeditiously. Sometimes the Morello is trained against old stone walls, which, as a rule, are very cold-looking. This may be remedied and made to look warmer by washing the surface with limewash coloured with a sufficient quantity of Venetian red to make it a warm brick-red. A small quantity of linseed oil should be added while the lime is slaking, as this renders the wash more adhesive, and sufficient should be mixed at one time to do the whole wall to ensure its being of the same tint. This wash, if put on warm, will last from nine to ten years before it has to be repeated, and in addition to the improvement in the appearance of the walls it kills a host of insect enemies as well. If the walls are in a good state of repair, the fact of washing the trees will cleanse them also if the insecticide used for the purpose is forcibly driven against the surface by means of the garden engine. A useful and inexpensive wash for this purpose is soapsuds, and this can be syringed directly on to the trees and repeated again and again while the trees are dormant. The washing should be done early enough in the day to allow the trees to dry before nightfall. Use as few nails and shreds as possible in the training, and secure all the main branches to the wall with tarred twine. Where the walls are wired, pay particular attention to the tying and see that space is left for the wood to swell without the ties cutting the bark.

**PLUMS AND CHERRIES.**—In the absence of colder weather these may next receive attention. Established Plum trees should have all spur wood cut back to three and four buds, the non-observance of which rule results in course of time in the spurs becoming disproportionately long. Old trees are apt to get into this condition, the only remedy for which is spur-pruning. This consists in cutting away every other spur to within an inch of the main branch. The stumps so left will break the following spring and make fresh growth, which when stopped will in due course form new fruiting spurs. When these begin to bear, the remainder of the old spurs may be cut away. By this means old but healthy trees may in the course of a few seasons be entirely clothed afresh with new spurs. Another matter that should have attention is the training in of young growths to take the place of worn-out and decrepit branches in trees which are deemed worth keeping, or which cannot well be dispensed with. Although grubbing and replanting would be the best methods to pursue in this instance, such trees if treated as advised can be made to do duty for some years to come. With regard to young trees, thin out and regulate the wood if too many shoots have been laid in, and leave no more than are actually required for the formation of main branches in all cases. Cordon trees will merely require spur-pruning in, unless the spurs are projecting too far from the wall, when they should be treated as advised above. The leaders of young trees should be tipped if the wood is ripe; if not, cut them back to where it is firm. Dessert Cherries being so im-

patient of the knife should be pruned as far as possible with the finger and thumb during the growing season. If this has been done, nothing but a general trimming up, in the shape of cutting away dead spurs or other portions of wood, and a shortening back of the wood on any spur which may have been left too long, will be needed. This reduces winter pruning, as far as dessert Cherries are concerned, to a minimum, while it tends in a very great measure to prevent that too fatal disease, gumming, which generally follows a too free use of the knife, especially on heavy soils. Growers having soils of the latter description to deal with should use plenty of calcareous matter at planting-time. Another cause of gumming is carelessness in driving the nails into the wall too close up to the branches, and in such a manner that the latter rest on them or come into contact with them. This must, therefore, be avoided when training trees out afresh. These and Plum trees may be well washed with soap-suds if they have been infested with fly only during the summer, but if the Plums have brown and mussel scale on the wood and branches, something stronger is needed. A fluid ounce of petroleum should then be added to each gallon of suds, and apply it in a warm state. The most effective remedy for both these pests is a solution of caustic soda and crude potash, which cleanses the trees of all parasitic growths as well as insect foes. This should be used at the rate of 1 lb. of each to 10 gallons of water, be boiled to ensure its being thoroughly dissolved, and applied afterwards to the trees in a warm state by means of a sprayer. The person applying it should wear leather gloves.

**SUNDRIES.**—The present is an excellent opportunity for wiring walls, also for dealing with old and defective walls, facing them afresh either with new brickwork, cement, or cement concrete. Wall copings should also be examined and made good with cement, or white lead all loose joints. Trellises for training espaliers to, also for Gooseberries and Raspberries, should now be erected. Wire staples and raddisseurs are cheap enough, and if iron standards and the intermediate supports cannot be afforded, Oak and Larch posts will answer equally as well. If creosoted, these latter will last from twenty to twenty-five years. On wet days get a good supply of shreds cut and burn the old shreds and nails taken from the Morellos. Sort the nails over afterwards, when all that have their points intact can be used again. A. W.

## KITCHEN GARDEN.

### EARLY PEAS.

THE practice of sowing Peas in the autumn has almost gone out of date except in gardens where there is but little convenience for raising the plants under glass. It is, however, not so much the raising of the plants in some places as protecting them from frost in the early part of May when in bloom. Peas, as most gardeners know, are fairly hardy, and will with the slightest protection withstand our winters. It is, however, the late spring frosts after a mild and growing time that check them the worst. I have on several occasions had them cut down even when the pods have attained their full size. This garden lies low, and is, therefore, more subject to these late frosts than those situated on higher ground; for this reason it makes one careful. Marrow varieties usually suffer more than the round-seeded kinds, hence the reason these were formerly so much grown for early supplies. Since the introduction of cheap glass, none of these are grown by the market gardeners, for these know full well which find most favour in first-class shops. For those who have no such conveniences as cold frames the task is a difficult one, and puts the gardener to

his wits' ends to know how to overcome it, and often after much trouble he finds his early or first crops destroyed either by the late frosts, ravages of birds, snails, or mice. To guard against the former, sheltered places are selected where a little protection can be afforded, but even then there is no chance of getting crops like those who have properly constructed houses. When sown in the open at this time of the year mice are often very destructive, as the plants make but slow progress. The plan I have adopted with success is to procure some matchboards about the same length as the rows of Peas, which are sown on a south border. The boards are stood up on their edges alongside the rows, those on the west side being about 2 inches lower than the other. They must be at a sufficient distance apart to allow of squares of glass being put over. This will keep off the heavy rains and protect the plants from frost and other enemies. On mild days the glass should be removed to give the plants strength and keep them sturdy. If pieces of wood or glass are put at the ends of the boards, these will make the Peas secure against mice or birds, and if looked over early in the morning any snails found may be easily destroyed. The cost of such boards is trifling, as they may be procured for about six shillings the 100 feet, glass is also cheap, so that these temporary frames are not expensive. Next comes the question as to

### THE BEST VARIETIES

to sow. The tall ones grow too rapidly for the frames, and therefore are not suitable, so that for this kind of treatment the dwarfs, of which there are numerous varieties, are the best. Chelsea Gem is one of these; it is a sure cropper and early. Carter's Forcing is also a first-class dwarf, early kind and an enormous cropper. Carter's Early Morn grows rather taller; the pods are, however, much larger and the Peas of splendid flavour. Sutton's Forcing and Sutton's Seedling are two first-class varieties; the latter, though not quite so early, has splendid pods of a deep green colour. The above may be grown in temporary frames till all danger of frost is past, when they may be exposed to the outside temperature. When sown in the open ground without protection it will be necessary to put in the seed a little thicker, as some of the plants may get destroyed by slugs and mice, both of which are very troublesome at times. Sowing at the foot of a south wall is a good plan, particularly where there are no large trees to overshadow the young plants. When sown in such places as these it is necessary to keep a sharp look-out in frosty weather, for often the bright sunshine in the day-time has a serious effect on the plants, being thawed rapidly by its rays, while at night they are frozen through. In such weather it is a good plan to shade them from the sun by placing a board or something of that kind up against the wall in such a manner that the light will not be excluded, at the same time keeping off the sun. All these contrivances, however, take up time, and in most gardens labour is not sufficient to cope with the extra work entailed; for this reason the seed is often sown and the plants allowed to take their chance, being often killed or crippled to such an extent that they are of no use. The old adage of whatever is worth doing at all is worth doing well should be taken into consideration, and those who find they are unable to afford protection had better not attempt it. In many places in an ordinary winter the plants will stand without any protection, and where this is so, the seed should be got in during the next week or ten days, that it may have time to germinate before severe frost sets in. When the

ground becomes frozen just as the plants are coming through the soil they usually suffer seriously. When such happens, a dusting of dry ashes along the rows will help to protect them, as the frost has not such an effect on this as on the cold, wet soil. H. C. P.

**Tomato Eclipse.**—I note "G. W." (p. 371) has a good word to say for this Tomato, and I can quite agree with him as to its merits. I cut more fruit from it than from any other kind, and its earliness, combined with the fact that every fruit on well-grown plants comes of good shape, should make it a favourite wherever grown. The fruits are of medium size and excellent flavour. It seldom cracks unless very overripe, while the colour is all that can be desired. My plants were put out about 18 inches apart, and naturally at this distance both ways a good deal of the foliage had to be removed. I think it one of the most useful varieties in existence. Many growers of Tomatoes even at this time give far too much soil and make this too rich and full of humus. My plants for the last three years have had nothing but a rather poor loam and the residue from a garden smother to start with. A depth of about 3 inches of this is placed on a bench, and rammed as firmly as possible both before and after planting. The plants are turned out of small pots just as the first bunches of flower appear, and the roots kept well on the dry side until the fruit has set. When this bunch is set and swelling freely there is no fear of a crop, and feeding may commence almost at once.—R.

**White Jerusalem Artichoke.**—The white Jerusalem Artichoke is not quite so satisfactory with me as usual, for the stems of a portion of the plants, after making good growth and just as the tubers were nicely formed, were attacked by a fungus just above the ground-level and killed. Those not touched have done well, and average something like three-quarters of a peck of tubers to a root. About 20 per cent. of the crop was attacked, and there seemed to be no method in the attack, as individual plants through the whole plot suffered, and scarcely, in any case, were there two contiguous plants affected. Out of several rows of the old purple stock growing on the same plot side by side with the white ones not one was touched. The exact condition of the plant had no bearing on the disease, as those which succumbed earliest had not yet formed tubers, others had them half grown, and others again, did not become affected till they had produced full-sized tubers. The appearance of this disease will prevent, for the present, my discarding the old purple form entirely in favour of the white one, as I had intended doing next year. Perhaps others may have experienced the same thing; if so, it would be interesting to hear of it.—J. C. TALLACK.

**Onions.**—It seems rather surprising that vast quantities of French and Italian Onions should be brought over here and sold freely especially in the rural districts, by equally imported hawkers, who seem to map out the kingdom, and then canvass it in squads. Can there be in these continental red Onions any qualities diverse from our own, or is it but another evidence of that business enterprise which characterises the foreigner, and thus enables him even to beard the British lion in his own den? Surely we ought to be able to grow Onions enough for our own needs, for there can be no doubt that, where cultivation is good, such as may be seen in gardens, and often on allotments, the crops are very heavy and the sample fine and sound. Whilst these Italian Onions are probably mild in that respect resembling the Spanish bulbs so plentiful now in grocers' shops, they are not long keepers. Our best bulbs produced under what may be described as ordinary cultivation are firmer, larger, and far more enduring. No doubt we grow too many varieties for satisfying market or public demands, but such a richly coloured variety as Crimson Globe or Southport Globe should satisfy all requirements both of growers

and purchaser for colour as well as solidity. Lancrop is a first-rate flattish round, and Excel or a capital globe-shaped of the brown or yellow tinned varieties. These three, were culture embarked in largely on good deeply-worked soils and well manured, should produce not only heavy crops, but good paying ones. Onions will only thrive well where the soil is deep. We have for the past two years had very little trouble from the maggot or mildew, and where the cultivation is good, these things as a rule do not give much trouble. It is important that seed stocks should be good and always grown from choice selected bulbs obtained from the finest strains of the varieties.—A. D.

**Cabbage sprouts.**—The discussion that has taken place in THE GARDEN of late on this vegetable has been interesting. Were I dealing with my own gardens, then probably I should adopt both methods, namely, allow the plants to remain on the ground to give a second crop and *in versa*. Much would depend on whether I had a large or small kitchen garden, if Cabbages were much in demand, and whether I grew big or nick-heating, small kinds. If the largest amount of material was needed, then I should plant small, nick-heating kinds on Onion land at the end of September, and get them off in time to plant the ground with Ashleaf Potatoes early in May. These could come off in time to sow winter Spinach, Bleworts, Tom Thumb Savoy, Endive, Lettices, &c. Another method may be adopted. When the Cabbage comes off in May, the land may be worked over, a little artificial manure added, and Carrots sown. But were I growing large kinds I should allow them to stand for overwintering, as they would not be off in time to eat the land as above. It is a simple matter to have a good supply of nice young Cabbages in autumn by sowing seed at the end of June, planting out after second early Potatoes in August, four apart each way.—J. CROOK.

#### WINTERING CARROTS.

I am aware there are diverse opinions as to the best way of wintering Carrots, but a visit to the present Garden next spring will convince anyone that the best Carrots for colour and flavour are those left in the soil where grown and lifted as required. A few years ago I lifted most of my Carrots, Carrots amongst them, and stored them in the orthodox manner. At lifting, a goodly number of roots were split, many being coarse and unfit for the cattle. To leave roots of the size named in the soil through the winter would not do. They would soon decay, and for kitchen use such large roots are never used whole. I determined to adopt a different system, and instead of making a large sowing of Carrots at the end of March or early in April, I make four or more, and set roots that will keep as long as required. There is no trouble in housing or storing and much better quality. I am aware in wet, clayey soils this may not be applicable, but there is no need to sow as early as advised even in heavy soils, and certainly no need with medium-sized roots to be in a great hurry to store. The Carrot is much harder than many imagine, and to show its hardiness I had roots which stood the severe weather three years ago, the only protection being a little light litter. I always sow a good breadth for winter and early spring supplies in the middle of July, and if these tender roots winter, there need be no fear of larger ones doing so. For ordinary winter supplies to remain in the soil, treat them like Parsnips, lift them as required, and there are very few bad ones. On the other hand, the sowing of what may be termed the main crop cannot take place as early as often advised. The first week in May will be quite early enough. Carrots grown thus are not protected; they have a fair amount of top growth and there is no splitting, as with those grown a much longer time in the soil. Carrots buried in the ground do not winter nearly so well as those left in their growing quarters, and in the early spring when new growth commences it is an easy matter

to lift those left and place under a north wall. If well covered with soil they remain sound till May. For winter supplies I like the Intermediate type; the long rooted kinds are not suitable; and for later supplies I rely on the useful Early Gem or Model, and so far have never failed to winter these varieties in the open. I think many of our winter roots which grow coarse could with advantage be sown later and left in the soil longer if the latter is well drained and not too rich.

G. WYTHES.

**Carrot Red Elephant.**—I have grown this Carrot for the first time this year and have been very pleased with it. I did not expect to find anything very large, as the bed was never thinned. I find on measuring some of them to be 20 inches long and 10 inches round. Another year I hope to be able to give it a fair trial. It is of a splendid colour and very sweet when cooked.—T. COCKERILL, *Wirksworth, Derby.*

**Winter Kales at Chiswick.**—Some forty-six stocks of these Kales have just been examined by the fruit committee. Growth has been strong and the character of each variety fully displayed. Some exception, however, must be made in relation to all the varieties of the Buda type, as each of these, some ten stocks in all, and comprising the Buda, Asparagus, Delaware, Ragged Jack, and Lapland, became so infested with a wart-like fungus, that plants were almost decimated, and scarcely anything was left to represent them. Oddly enough, this disease did not extend to the curled forms nor to the broad-leaved Chou de Milan or Cottager's varieties. Of the tall Scotch section, three marks, representing high commendation, were given to Victoria Kale (Dobbie and Co.), a very massive, large-headed stock, one of the very best; Cuthbertson's Famous Strain, a very fine dark-hued variety; Selected Tall Curled (Kent and Brydon), also fine, but paler in colour, and Culzean Castle (Hurst and Son), a very strong, large-headed form. There was no good form of the Dwarf Green Curled sent. Chou de Milan (Watkins and Simpson) represented a capital stock of this late hardy Kale; Cottager's Kale (C. Turner) was much the best stock of this fine variety; Dwarf Hearting (Hurst and Son), a large, solid-headed form, something resembling the Savoy Cabbage, and variegated Kale (J. Veitch and Sons), this being the best stock of the ornamental section. Two marks of commendation were given to Dwarf Purple Curled (Dobbie and Co.), and Exquisite (Barr and Sons), both alike, of dwarf, spreading habit, and very close to ground, but also identical with the well-known Arctic Kale. The green form was not grown. Three stocks of Brussels Sprouts were sent, but all were coarse and devoid of quality.—A. D.

## ROSE GARDEN.

### THE ROSE SEASON OF 1897.

On October 30 I cut a far better lot of Roses than can be found during August in many seasons. From the middle of June I have been able to cut Roses in quantity: not a glut of a few weeks only, but a plentiful supply for fully four months. This is not often the case, and although we are favoured with such valuable additions to our perpetual-flowering Roses as Mrs. W. J. Grant, Marjorie, Mrs. W. C. Whitney and many others from the Hybrid Teas alone, much of the pleasure has been due to a more than usually uniform temperature and an exceptionally favourable autumn. Early in the season, while pruning, there was a bright prospect before us, but adverse weather entirely altered this. It was not until after the cold wave of mid-June that Roses again promised well. An undisputable sign of this was the poor attendance of exhibitors at the Portsmouth meeting of the National Rose Society.

By no means the least surprising feature of the past season was the remarkable rapidity with which Roses came on after mid-June. There has been less mildew than usual. True, we had what

threatened to be a bad attack late in July, but this disappeared in a surprising manner as soon as the weather changed, and from that date there has been very little mildew in this district. Nor has red rust been so bad as in many seasons, although some few varieties among the Hybrid Perpetuals were badly attacked for a short time. In this respect we see how valuable the many beautiful Teas and Noisettes are, also many of the Hybrid Teas, red rust never attacking the first, and seldom attaining to anything serious among the last-named.

Some years stand out as especially favourable to the more double Teas and Noisettes, which require a considerable period of fine weather to open well; others are noted for the depth and intensity of colouring found among Hybrid Perpetuals, which prefer a cool and fine season for their better development. This year seems to have suited all classes. There are also pleasing prospects for 1898. Brier stocks took well, while I do not remember a season when the Rose budding was more successful or the stocks lifted so easily for a long period. The wood of the Roses is ripening very steadily and in a much better manner than usual, especially among the Teas and Noisettes. Many thousands of plants will have been transplanted before this note can appear, and even if carrying some foliage I would prefer to plant early while the soil is still warm and in such a favourable condition. If dry, water when planting, giving the water after the first layer of soil is placed over the roots. RIDGEWOOD.

**Rosa rugosa.**—When the type and the white form are planted together and allowed to intermingle they produce a nice effect. It is a mistake to plant these in beds. They should be planted together in good soil, several plants to make a mass, allowing the turf to cover the soil. In the pleasure ground I have them growing in this way, and they make a brave show when in bloom, and now (October 19) they are very beautiful, being full of the bright glossy red haws. Squirrels are most destructive to the fruit, as they carry it away.—DORSET.

**Rose Narcisse.**—I often wonder why this charming little Tea Rose was not more grown. During the present autumn it has been very beautiful, the whitish buds and blossoms having been produced with great freedom. It does well on Brier standards, making a lot of growth, but is far prettier in a sheltered position on its own roots or budded low down. In the west of England in a light, hungry soil, or rather sand, it was one of the few Roses that really grew and flowered well, and a handful of the half-opened buds and blossoms is very beautiful.—R.

**Climbing Roses.**—The old-fashioned Monthly Rose is now (November 10) very beautiful on a sheltered verandah here. Buds in all stages of development are here, full-blown flowers, and many more to come. I could not help contrasting this with the famous Crimson Rambler, which during the summer months gave us a fine show of pretty semi-double flowers, but since then has been anything but beautiful. There is a peculiar dead colour in the foliage of this Rose that does not go well with either the summer blossoms or the autumn tints on surrounding vegetation. I can see but few good points in Crimson Rambler as an outdoor Rose.—H. R., *Bury St. Edmunds.*

**Rose Isabella Sprunt.**—A short time ago this Rose was spoken highly of as blooming freely at Kew. I am pleased to add a word in its favour. Some may say it is an old kind. This I admit, but it is none the worse for that, and according to my observations it is better than many of more recent origin. I grow several kinds of Teas, and this I consider amongst the very best. It is free blooming, and for button-holes, &c., it is grand. My plants are growing against a wall facing east, and they have stood without protection during the last twelve years. Although injured in the very severe winters it soon grew away vigorously. During the autumn

months it has been a mass of bloom. It also makes a good pot plant and forces well.—DORSET.

**Rose General Jacqueminot in November.**—The finest lot of this Rose I have ever seen so late in the season was placed on the table by the president of the Scottish Horticultural Association on November 1, Mr. Todd, who grew them in his garden at Stonybank, Musselburgh, near Edinburgh. They were brilliant in colour, fresh and fragrant as in June. The plants are still clothed with buds in plenty. It was stated at the meeting that during October over 300 blooms had been gathered, while all through the summer and early autumn flowers were abundant. Mr. Todd considers this by far and away the best red Rose for market. He grows most of the plants on their roots, and these are pictures of health and free of mildew; whereas General Jacqueminot received from Derbyshire and planted within sight of those on their own roots in the same soil and given the same treatment had shoots badly affected by mildew.—D. T. F.

## TREES AND SHRUBS.

### DOUBLE-FLOWERED CHERRIES FOR THE GARDEN.

Our gardens owe much of their beauty in the early spring to the Cherries, and the double white-flowered variety illustrated (*Cerasus serrulata*) is one of the most charming. This is a tree that should be in every garden worthy of the name. It is very strong in growth, and when in bloom looks as if covered with snow. A synonym of this species is *C. Sieboldi*. Then we have the beautiful *C. Watereri*, a lovely early-flowering tree, especially when in front of Scotch Fir, as I saw it once in a southern garden. The common Cherry has two very fine varieties, *C. caproniana* and *C. Avium*, which are also known as *multiplex*. Then one can also have the St. Julian's Cherry (*C. Juliana*), which has tender pink flowers, each like a rosette, and freely borne. There are a host of names given to the above, but the ones mentioned are adhered to in most nurseries.

C.

**Cratægus [*Pyracantha Lælandi*].**—This charming dwarf form of the old *Pyracantha* is excellent for growing in the foreground of shrubberies, or for transferring to beds which have been cleared of tender plants early in the autumn. It fruits with great freedom on the tiniest plants and can be trained into almost any form, the most effective shape being that of loose-growing pyramids; these, when covered with huge bunches of brilliant berries, are very fine, and much more effective than the formal-growing dwarf conifers so often used for clothing, during autumn and winter, spots that would otherwise remain bare.—J. C. TALLACK.

**Autumn tints.**—Had "K." been with me when last week riding by rail through the Oxshott, Cobham, and Horsley districts of Surrey he would have seen Oaks glowing in the sunlight literally like burnished gold. The spectacle the woods presented near and far was magnificent. No other tree would have given such glorious colour. A fortnight previous Chestnut, Beech, and Birch were alike gorgeous with colour; indeed, there was not a tree that did not then or later lend itself to the production of these beautiful tints. But there can be no doubt that gravel, chalk, and sand give the best effects in trees at all autumn seasons, whilst trees on stiff clays are much less beautiful. Near towns, trees too seldom show that rich coloration found in purer atmospheres. Then the autumn, too, has been dry and warm, ensuring wood and bud ripening in a remarkable degree, and with it this superb leaf coloration. If the autumn be wet or white

frosts prevail, the leaves die off quickly rather than ripen as they have done so finely this year. Even the most favoured of trees, Liquidambars, American Oaks, Maples, Sumachs, and others, give the best colour on light or warm soils. *Vitis inconstans* has, in spite of its usually warm positions, rarely given richer colour than has been the case this year, and the colour has also been unusually prolonged, doubtless because the heavy rains of early September promoted new late growth, which in turn ripened so thoroughly during the warm, dry October.—A. D.

**The common Barberry.**—A great many of our hardy shrubs are remarkable for the beauty of their fruits at this season of the year, but among them all the common Barberry is the best. As a single specimen, and where allowed to develop into a large bush, this Barberry is seen at its best, for it will be now completely veiled with long sprays of berries of a brilliant red colour, which remain fresh and bright for some time. In the spring, too, the yellow flowers are very attractive and agreeably scented. A desirable feature in the case of the Barberry is that it will hold its own in dry, stony soils better than many other shrubs, and without any attention it forms quite a symmetrical bush. The berried sprays remain fresh for a long time when cut. Among the several varieties of this Barberry are two with white and blackish fruits respectively,

may be rooted in this manner, but it is scarcely ever employed for their increase, as seeds are readily obtained and germinate freely. At the same time the better varieties are usually grafted or budded on to seedling stocks, a union being quickly effected.—ED.

**Celastrus scandens.**—This is the Bitter Sweet or Climbing Waxwork of the United States, of which district it is a native, as it occurs more or less from Canada to Virginia. This *Celastrus* is just the thing for covering rough mound tree stumps, or for furnishing some parts of the bolder arrangements of rockwork, as it is of rapid growth and soon forms a dense mass of wiry shoots twisting here and there. The oval-shaped leaves are of a distinct glossy green, while the flowers play no part in the embellishment of the plant. They are small and of a greenish yellow colour, and being borne in short-stalked clusters are scarcely noticeable. The fruit, however, much like that of our Spindle Tree (*Euonymus europæus*); indeed, they are both nearly related to each other. In the *Celastrus* the exterior of the capsule changes to yellow, and soon afterwards the segments open and the bright red seeds are then visible, in which state they remain some time. It is an old plant in gardens, having been introduced in 1736. This *Celastrus* must not on account be associated with delicate subjects, as from its aggressive character the weak

A spray of the double-flowered Cherry.

but though distinct and curious, they are both much less attractive than the normal form.—T.

**Layering Laburnums.**—I have several fully-grown Laburnum trees on the edges of shrubberies and coverts which I should be sorry to cut down, but they are now beginning to damage the young trees, which have spread out towards them. Would it be possible to layer them as one does Laurels? If so, at what height should one cut them? and at what time of year is it best done?—ALICE WILSON.

\*.\* If the Laburnums in question are, as stated, fully-grown trees, it would be useless to think of layering, as, in the first place, they could not be brought down low enough for that purpose without a good deal of mutilation, and, secondly, much of the beauty of the Laburnum consists in the long drooping racemes of blossoms having ample space for their development, which would not be the case if the branches were brought down into contact with the earth. We should suggest cutting the plants back to a reasonable size, and what that is depends upon the surroundings and the position they occupy. The Laburnum will stand pruning fairly well, but, of course, if the trees are headed back the following season's display of bloom will be sacrificed. The winter months are the best for carrying out this operation. Though layering is not recommended in the case of these trees, Laburnums

neighbours will quickly suffer. As the seed-pods are for the greater part hidden by the foliage this *Celastrus* is more conspicuous after the leaves drop than it is before. A nearly allied species *C. articulatus*—has been introduced from Japan and the leafless branches covered with fruit are sold during the autumn in all Japanese towns where they are employed for indoor decoration for which purpose they are well suited.—T.

**Berberis Thunbergi.**—Very few of our deciduous shrubs can compare with this Chinese Barberry in the rich tints assumed by the leaves before they drop, as they are just now of a bright glowing scarlet-crimson hue, and seen in a mass this species forms a brilliant object in woodland scenery. It is in all respects a very distinct kind, being much less robust than the different forms of the common Barberry or the Asiatic *B. aristata*. Thunberg's Barberry, which, by the way, is also known as *Berberis sinensis*, is a somewhat spreading bush with arching branches, which give it a very pleasing outline. In the spring the leaves are when first expanded of a very delicate green and just as they are partially developed the flowers make their appearance. They are as a rule freely borne, but are not particularly conspicuous. The small, oblong sealing-wax-like berries are very bright, but they are often sparingly borne. When, however, they are pretty numerous, these berries form a valuable

ditional feature, for they remain fresh and bright a long time. It is quite hardy and will hold its own in poor soils where the leaf colour in autumn is of the brightest.—F. C. P.

—Just now this is one of the most brilliant deciduous shrubs. It is a splendid subject for massing, and one would not soon forget the fine colour-effect produced by a large quantity of it at this season of the year. The low-growing, spreading character of the shrub tends to bring it directly under the eye, and the numerous tiny leaves, so closely arranged, give the brilliant colour-effect so much admired.

FERNS.

DORYOPTERIS.

All the species belonging to this sub-genus of Pteris are of dwarf habit, and form a very distinct and interesting group. Though some are classed with the greenhouse Ferns, I find they succeed best under stove treatment and like more shade than many of the Pterises. They may be raised from spores, but it requires great care to succeed with some, especially *D. nobilis*, which is one of the finest of the group. I have only known of one or two instances of this being raised from spores, and then the greatest care is required to establish good plants.

*D. PALMATA* is the best known and most useful, being grown largely for market. If care is taken to select good spores they germinate freely and soon grow on into useful-sized plants. It is one of the best to use in a small state, and when about three plants are grown together they are very effective in a 4½-inch pot. Under good treatment they will grow about 8 inches high; the rich deep green fronds form a nice contrast to those of a lighter hue.

*D. LUDENS* is a distinct species, and the fronds vary much in shape. The barren ones are unspined, some being nearly triangular, others broader and lobed; the fertile fronds are palmate, and have long stipites growing much above the barren ones. I find after the second year it is difficult to keep plants in good character; therefore seedlings should be raised periodically, with care they come fairly well.

*D. SAGITTIFOLIA* is very pretty, but rather difficult to manage. Being of small growth, overpotting must be avoided and plenty of drainage should be provided.

*D. PEDATA* is a dwarf, free-growing species, which I have found come freely from spores and make useful little plants in small pots. It somewhat resembles *Pteris geraniifolia*, but has broader fronds, with short stiff stipites.

*D. HASTATA*, I find, varies very much when raised from spores. In its best form it is a useful fern, but often the fronds are irregular and imperfect.

*D. DUVALI* is a distinct species lately introduced from the Continent. It is somewhat after *nobilis*, but the fronds are more regularly lobed and of a rich deep green. I have not yet seen seedlings, but find it may be increased by division and is of free growth. If we can get seedlings it will undoubtedly become one of our most popular ferns. A. H.

*Blechnum occidentale*.—This is a useful Fern for decoration. Now that the Pterises have become so common it is necessary to look for something fresh, and in the above we have a most welcome change. It may be raised in any quantity from spores, and is a quick and free grower. It should be grown on in a stove temperature and well exposed to the light. Potted in a good loamy compost, it grows freely and makes fronds of good substance. The young fronds have a bronzy-brown tint. When thick bushy plants are required two or three may be grown together, but grown singly most symmetrical specimens may be had. It is hardly suitable for anything larger than a 4½-inch pot, but under good treatment it

makes a fine plant in this, and may also be recommended for small pots. Two other varieties which closely resemble the above are *B. polypodioides* and *B. glandulosum*. These are equally useful, the latter especially, as it grows taller, and when well exposed the bronzy-red tint in the young fronds is very bright. It is only when grown on freely from the time the seedlings are raised that these *Blechnums* make useful plants. Once let them get stunted or pot-bound they rarely make satisfactory growth afterwards.—A. H.

ORCHIDS.

PLEIONES.

VERY bright and effective during the dull days of winter are these charming little Orchids, and I have noticed that amateur cultivators are becoming much more familiar with their culture than formerly. They are by no means difficult to grow, and present a much better flowering return for the trouble bestowed upon them than many larger growing kinds. *P. lugenaria* is one of, if not the best known of all, and also one of the most useful. This, if brought along in successional batches, will keep the cool house bright for many weeks with its rose and white blossoms. *P. humilis*, again, is a very beautiful plant, and perhaps unequalled in the genus for the bright tints displayed on the lip. Pleiones, unlike most epiphytal Orchids, are not at all incommoded by being disturbed at the roots; in fact, an annual repotting is one of the usual cultural details. But it must be carried out at the right time, for to interfere with the roots just as they are in the middle of the season's growth would prove decidedly harmful. Most of the species throw up their flower-spikes from the base of the old pseudo-bulb just before commencing to grow, and the best time to repot is just after the flowers are past, but before any young roots are forming. The old pseudo-bulb—that is, the one preceeding the flowering one—will usually be found so far decayed as to be of no further use to the plant, and this may therefore be cut away. The roots from the flowering bulbs, too, will usually have performed their functions and might also be taken off, except a little tuft just to help to hold the pseudo-bulbs in position. The compost must be a substantial one, nice fibrous loam, peat fibre, and chopped Sphagnum Moss being mixed with plenty of finely broken charcoal and crocks. Let the drainage for pots and pans be ample, and protect it by laying a little rough Moss upon the crocks. It is usual to mass the bulbs in pans a foot or so across, and, culturally, no fault can be found with this way of growing them. But when they are required for grouping, these large pans are not nearly so useful as a larger number grown in small pots, because the absence of foliage on the plants at the time of flowering gives them rather a flat, not to say a garish, appearance. The smaller pots may be introduced among small *Adiantums* or *Pterises*, the soft tints of the blossoms showing very prettily among these. A very pretty mode of culture, too, was illustrated in THE GARDEN during the early part of the present year. This was to grow them on wood blocks, these being lightly dressed with compost and a few small Ferns planted with them. I cannot say I am partial to planting Ferns on Orchid blocks or in their pots, as is sometimes done, but, judging by the pretty photograph, the end in this case justified the means.

After the plants are potted, great care is necessary with watering, for if the compost gets moist and close, the little roots will have a difficulty in entering it. But this is not for long, and when once they have a good hold on the compost a very liberal supply is necessary. This must be continued right up to the time the pseudo-bulbs are finished, when they may again be kept drier. The foliage soon turns colour and falls off, and then for a short season they may be absolutely dry. Temperature is not, perhaps, a very important

point with these Orchids, and although they do not require more heat than *Sophranitis*, *Odontoglossum grande* and others that do not like the very coolest quarters, yet they do well with a nice shady, well-ventilated position in the Cattleya house. Insects are not particularly troublesome, the worst being red spider and brown scale, but these are easily kept under by ordinary vigilance. Pleiones are by some authorities merged into *Celogyne*, but though their botanical characteristics may be similar, they are quite distinct as garden plants. R.

*Trichopilia (Pilumna) laxa*.—In habit and shape of the blossoms this pretty species is not unlike *T. fragrans*, but the spikes are usually more pendent. I have seen it in several collections during the week, and in each case the fragrance was very noticeable. It may be best described as an intermediate house Orchid, as though it may be grown with the *Odontoglossums*, the bulbs are large and the flowers more freely produced when given a little more heat. It is best grown in medium-sized pots or baskets in a compost consisting of peat fibre and Sphagnum.—H.

*Cymbidium eyperifolium*.—There is a fine plant of this now in flower at Cambridge Lodge, the flowers being not unlike those of a small form of *C. Traceyanum*. The plant is healthy and strong, has fine large pseudo-bulbs with the characteristic narrow foliage, and the spike is carrying seven flowers. The sepals and petals are pale green, with lines of brownish crimson over their entire length. The lip has a white margin and many bright crimson dots. It is grown in a small annex at Camberwell in company with the hybrid *eburneo-Lowianum* and the reverse cross.

*Goodyera Rollissoni*.—Although this Orchid boasts nothing much in the way of flowers, the foliage is strikingly handsome, far superior, in fact, to many of the more expensive and rare *Anacochilus*. Not that this is very plentiful, and it is seldom that one comes across such a fine lot as that at Mr. Bull's nursery, where they are in fine foliage just now. It is a vigorous growing plant, with broad leaves of a rich dark green on the upper side. This is overlaid with stripes and blotches of a golden bronze, while underneath they are uniformly of a rich velvety purple. It should be grown in plenty of heat, a moist atmosphere, and given a shady position.

*Odontoglossum tripudians*.—This *Odontoglossum* I have noted in flower in several collections within the week. It is a bright and effective species, and I wonder it is not more grown. It may not be exactly in the front rank of the genus for size, but the bright yellow blossoms are very useful just now when the triumphans, luteo-purpureum, and other more popular kinds are conspicuous by their absence. It is imported occasionally with *O. Pescatorei*, and, like this well-known kind, thrives well in fairly small pots of peat fibre and Moss, with the usual treatment as recommended for cool *Odontoglossums*.

*Phalænopsis Regnieri*.—Flowers of this finely-coloured Moth Orchid—which does not really differ much from *P. Esmeralda*—come for an opinion from a Somerset correspondent. They are of average merit, though their freshness and bright colour show that they have been grown well out of the fog area. When produced at this late season they make a pretty show, though personally I would prefer more seasonable blooms. *P. Regnieri* thrives well in a warm, moist house and is not difficult to grow. It is a native of Cochin China, and was introduced in 1874, being distinct from most *Phalænopsids* in the erect flower-spikes.

*Oncidium Marshallianum*.—Though rather out of season, the beautiful golden yellow blossoms of this fine species are very pleasing and welcome. The tall branching spikes are very elegant, and they last a long time in good condition—too long in many cases for the health of the plant. It is a cool house Orchid, thriving in

company with *Odontoglossum* of the grande and similar types. Like the nearly-related *O. crispum*, it dislikes a large body of material about it, and about an inch for medium-sized plants is ample. The compost must be of good quality, and the drainage requires special attention, as the rather large fleshy roots require plenty of moisture all the year round.

**Angraecum citratum.**—I noticed this in flower recently with Mr. Bull, the pretty white blossoms with a pale creamy tint having a pretty effect. It is one of the dwarfest in the genus, rarely growing more than 6 inches high, but producing fine racemes of bloom from the leaf axils. It dislikes much material about the roots, and is safest in small wood baskets well drained, with a little clean Sphagnum Moss about the roots and base of the plant. Plenty of heat and a moist atmosphere are required, and it must never be dried at the roots.—R.

**Scaphosepalum gibberosum.**—This species and one or two others such as *S. oethodes* form a set of Orchids not much in favour with present-day growers. Yet where quaint and singular forms are appreciated they are worth a place, and one looks upon their going out of cultivation as rather a slur upon the collectors who sent them home. The other day at Cambridge Lodge I noted fine plants of several in this section, and when well flowered they have a pretty and graceful effect among the richly coloured and more popular *Masdevallias*.

**Dendrochilum Cobbianum.**—This pretty plant I noted recently in bloom at Mr. Bull's. It is a small-growing species, not above 8 inches in height, the pretty pale yellow blossoms having a light and pretty effect on the dark green foliage. It may be easily grown in a warm, moist house, delighting in a shady position while the growth is forming. Very little compost is needed, but this should be of good quality, the roots not taking kindly to frequent disturbance. It is a native of the Philippine Islands, whence it was introduced by Messrs. Hugh Low and Co. in 1879, and was dedicated by Reichenbach to Mr. Cobb, of Sydenham, with whom it first flowered.—H.

**Stanhopea eburnea.**—Almost every week I meet with this species, and although the flowers last but a few days in good condition, this is amply made up for by the number of them produced. Spike after spike is produced for months on end, and no appreciable harm is done to the plant by this freedom of flowering. It is a noteworthy fact, too, that although many *Stanhopeas* will not flower if pulled about at the roots, it makes not the least difference to *S. eburnea*. Give this species plenty of moisture at the root and a fairly good compost, keep it free of insects, and in a comfortable temperature, then flowers in plenty will be produced.—R.

**Habenaria carnea.**—This pretty plant I have noted in flower during the week, the delicate flesh-tinted blossoms having a nice effect upon the prettily marked foliage. The spikes rise about a foot high, the upper portion closely covered with flowers, each being furnished with a long pale-coloured spear. *H. carnea* is not a difficult plant to grow in a moist tropical house. It is strictly herbaceous, dying down annually in autumn, throwing up its growth and leafy flower-spikes in spring. The roots may be potted in a compost consisting of sound mellow loam, leaf-mould, and chopped Sphagnum Moss, plenty of crushed charcoal and finely-broken crocks being mixed with this. The bulb may go down fairly deep, so that the roots run freely among the drainage, and I noted during the summer that a batch of this Orchid was doing remarkably well in a bed of cocoanut fibre, this doubtless helping to keep the roots moist. Plenty of water is necessary as long as growth is active, and one of the most frequent mistakes in its culture is drying it severely in winter. There is a fine white variety of this pretty plant which has recently been introduced from Singapore. The type and variety formed the subject of one of THE GARDEN

plates in the issue for March 16, 1895, and the habit and general character of the plant are there well shown.—H.

### THE BLUE VANDA.

(*V. CÆRULEA*.)

THIS is one of the best of the *Vanda* tribe. It was discovered as far back as 1837, growing on large trees on the Khasia Hills, and fully exposed to sun, wind, and rain. In its native habitat it is found at an elevation of from 3000 feet to 4000 feet, being a little lower down than *Cypripedium insigne*. It is comparatively a cool-growing Orchid. The usual practice with this lovely *Vanda* is to grow it in teak-wood baskets, so that it may be suspended close to the roof-glass of the house, where it will be greatly benefited by plenty of sunlight and the best air currents at command. During active growth the plant should be supplied with

plenty of water at the root, and the atmosphere surrounding it should be kept moist. As soon as the flowers are ready to expand the plant may be removed to the coolest part of the house, and where the atmosphere is drier. During the winter months great care must be taken not to overwater the plants, or probably the foliage will become spotted and unsightly. The *Cattleya* or intermediate house will suit this *Vanda* during summer, but when at rest the cooler and drier atmosphere of the Mexican house will answer better. The baskets in which the plants are grown should be three parts filled with crocks or charcoal for drainage, surfacing up as near to the bottom leaves as possible with clean, fresh-gathered Sphagnum Moss.

At Cambridge Lodge there are many fine things to be seen, the very distinct Cambridge Lodge variety among the number. It has very large spots of purple on the dorsal sepal and is a grandly formed flower, quite distinct from the Chantini section. Several of the yellow forms were also noted, and these are among the most beautiful of all *Cypripediums*. Ernesti and many others, as well as a very fine batch of the typical form, will soon be a splendid sight.

**Trichosma suavis.**—A very fine plant of this species now in bloom at Cambridge Lodge, carrying twenty-two spikes of the characteristic little flowers, these, as the plant is strong and well established, being thrown well above the foliage. It is a pretty and useful plant when well cultivated, but being found growing naturally at considerable elevation on the Khasia Hills, cannot do with close, warm treatment. It likes a shady, moist house during the summer months and plenty of water at the roots, while during t

*Vanda carulea.*

abundance of water at the root, and the atmosphere surrounding it should be kept moist. As soon as the flowers are ready to expand the plant may be removed to the coolest part of the house, and where the atmosphere is drier. During the winter months great care must be taken not to overwater the plants, or probably the foliage will become spotted and unsightly. The *Cattleya* or intermediate house will suit this *Vanda* during summer, but when at rest the cooler and drier atmosphere of the Mexican house will answer better. The baskets in which the plants are grown should be three parts filled with crocks or charcoal for drainage, surfacing up as near to the bottom leaves as possible with clean, fresh-gathered Sphagnum Moss.

**Cypripedium insigne.**—The well-known flowers of this grand old species are already numerous in collections and a great variety may

winter abundance of light is needed. A very thin compost, consisting of equal parts of peat and Moss over good drainage, suits it well.

**Cypripedium tonsum.**—This is one of the finest *Cypripediums* at this time of year, and I have noted it in flower in a good many collections. It was introduced by chance a dozen or more years ago among an importation of *C. Curtisii* by the collector whose name the latter species bears. The foliage is large and prettily tessellated, the flower-stems being thrown well up. The dorsal sepal is whitish, with lines of greenish purple, the petals somewhat similar in colour, the pouch greenish, with purple and bronze markings. It comes from Sumatra and likes plenty of heat and moisture.—R.

**Oncidium ornithorrhynchum album.**—It is an extremely pretty and rare plant, none the less worthy of care because of the small size of the individual blooms. It is especially beautiful when seen in such form as I noted it in N

asures' collection at Camberwell recently. A remarkably fine specimen plant in the rudest of alth, with large, healthy pseudo-bulbs carrying venteen spikes of snowy-white blossoms, is here bloom. The spikes rise about 2 feet high, are much branched, and carry in the aggregate many hundreds of flowers, the only spot of colour on these being a yellow marking about the crest. This *Oncidium* is a native of Mexico and thrives in a moderately cool, moist, and shady house, being well watered at the roots while growth is active.—R.

## SOCIETIES AND EXHIBITIONS.

### NATIONAL CHRYSANTHEMUM SOCIETY.

NOVEMBER 9, 10 AND 11.

An exhibition of exceptional dimensions and also a thoroughly representative character was got together at the Royal Aquarium, Westminster, S.W., on the above dates. The opening of the exhibition falling on Lord Mayor's day brought together an enormous concourse of spectators, making it an exceedingly difficult task to get a proper view of the many fine exhibits staged. The whole of the ground floor space was utilised, chiefly for exhibits of a miscellaneous character, a few isolated classes only finding accommodation there. Both the galleries were brought into use, that in the south-west containing the leading Japanese classes, and that on the opposite side of the building the Anemones and a large number of the minor classes. St. Stephen's Hall was again requisitioned for the plants, these being arranged round the centre of the building with plenty of space allowed to satisfactorily set them off, fruit and vegetables being on tables on either side of the same building. The large circular groups were arranged, as last year, in the south-west gallery, and these, together with a remarkable display of table decorations, made this portion of the show one of the most interesting. Competition in the different classes was keen. In the open class for twelve Japanese blooms distinct there were no less than twenty-four competitors, and in the open class for three epergnes suitable for table decoration the entries were fourteen. Special mention must be made of the table of vases, &c., arranged by Mr. Norman Davis. This was probably the first exhibit ever put up by a trade specialist, the quality and the arrangement, too, being excellent and certainly meriting the gold medal awarded. Mr. Donald's plants were very fine. The miscellaneous display was very large and varied, and assisted very materially to make the exhibition such a success. The fountains at either end of the building were completely hidden by different trade exhibits, a great advantage from the public point of view.

#### CUT BLOOMS.

The "trophy" class, being the national competition of Chrysanthemum and horticultural societies, is one for forty-eight blooms, to consist of twenty-four incurved, distinct, and twenty-four Japanese, distinct. There were three entries, the Emley and District Chrysanthemum Society winning premier honours with a fine exhibit. The Japanese were large and even, of good form and colour, while the incurved also were large and fairly even. The best Japanese were Duke of York, Mrs. H. Weeks, Viviani Morel, Chas. Davis, International, Mons. Chenon de Léché, Mrs. Elsie Teichmann, G. C. Schwabe, Milano, Simplicity, Matthew Hodgson, and Mrs. Chas. Bek. The incurved were represented by these among others: Chas. H. Curtis, J. Kearns, W. Tunnington, J. Agate, Mrs. R. C. Kingston, Mrs. Coleman, Mrs. Heale, Princess of Wales, and a very handsome bloom of Duchess of Fife. The Singbourne and Milton Gardeners' and Amateurs' Association were second with a fresh and elegant lot of flowers, though smaller. The Holmes' Memorial challenge cups were easily secured by the veteran, Mr. W. Mease, gardener to Mr. Alfred Tate, Downside, Leatherhead, the Japan-

ese class for forty-eight blooms, distinct, containing a magnificent lot of flowers. These were very fresh right throughout. The best were Mme. Carnot, Etoile de Lyon, M. C. Molin, Phœbus, Mrs. H. Weeks, Mrs. W. Lees, Julia Searamanga, Sunstone, Baron Ad. Rothschild, Mrs. G. Carpenter, Modesto, M. de la Rocheterie, Eva Knowles, Mons. Chenon de Léché, A. H. Wood, Edith Tabor, Mrs. J. Lewis, and a very remarkable flower of Yellow Mme. Carnot. This latter bloom was selected as the premier Japanese bloom in the show, and certainly was one of great beauty and refinement. A nice exhibit secured second prize for Mr. Henry Perkins, gardener to the Hon. F. D. Smith, M.P., Greenlands, Henley-on-Thames. Mr. Mease secured the cup for thirty-six incurved blooms, distinct, with blooms of very high quality. The blooms in this class were large, massive, of even form, with splendid breadth of petal, and set up in the most approved style. His varieties were Duchess of Fife, Miss Violet Foster, J. Agate, Miss Dorothy Foster, W. Tunnington, Lucy Kendall, Major Bonallion, Mrs. R. C. Kingston, Princess Beatrice, Violet Tomlin, Lady Isabel, Robt. Petfield, Globe d'Or, Robt. Cannell, Miss Haggas, Chas. H. Curtis, and others. Mr. W. Higgs, gardener to Mr. J. B. Hankey, Fetcham Park, was a good second, many of his blooms being marvels of cultural skill, his flowers of Duchess of Fife, Bonnie Dundee, Robt. Petfield, and Geo. Haigh being very fine. A class to commemorate the 60th year of the Queen's reign was confined to the trade, two competitors only entering. This was for thirty-six blooms, twenty-four being Japanese and twelve incurved, distinct, novelties sent out during 1895, 1896, and 1897. Mr. W. Wells, Earlswood Nursery, Redhill, was first with a nice lot of flowers, but many of the varieties were seen in the leading stands of others. Ella Curtis, G. J. Warren, Souv. de Mme. J. Rosette, and Mrs. F. A. Bevan were among the best of the Japanese. Mr. Norman Davis, The Vineries, Framfield, Sussex, was a good second, John Neville and W. H. Lees being his best novelties in the Japanese. There were only two entries for the Turner Memorial challenge cup, which has to be won by the exhibitor two years in succession or three times in all. In this Mr. Norman Davis showed his superiority by taking leading position with his thirty-six blooms of white, yellow, and crimson Japanese in twelve varieties, three blooms of each. These were noted for their clear and bright colour. R. Dean, John Neville, Miss Dorothea Shea, Beauty of Castlewood among the erimsons; Western King, Mlle. Thérèse Rey, Mme. Carnot, Mrs. H. Weeks, white; and Phœbus, Edith Tabor, Modesto, A. H. Wood, in the yellows, made a fine array of colour. Mr. W. J. Godfrey was a capital second, Sunstone and M. Demay-Taillandier being his most striking flowers. A class for twenty-four incurved, distinct, brought out four competitors, Mr. F. G. Foster, Broekhampton Nurseries, Havant, securing first prize, Lady Isabel, Chas. H. Curtis, Miss Violet Foster, Miss Dorothy Foster, Bonnie Dundee, and Duchess of Fife standing out conspicuously. The second prize went to Mr. H. Butcher, gardener to Mr. C. J. Bass, Lodge House, Smeeth, Ashford, Kent, with a good lot of flowers, J. Agate, D. B. Crane, and C. B. Whitnal being his best. Eight entries for twelve incurved, distinct, made a capital display, and Mr. J. W. Barks, gardener to Mr. Pandeli Ralli, Alderbrook, Cranleigh, was deservedly placed first with Lord Wolsely, James Agate, Empress of India, Violet Tomlin, Mrs. S. Coleman, and Mrs. Heale in neat and good form and well finished. Mr. F. King, gardener to Mrs. McIntosh, Havering Park, Romford, was a good second, with large flowers, but inclined to be rough in appearance. The competition for six blooms, incurved, one variety, is always an interesting one, eleven entries on this occasion being forthcoming. Magnificent specimen blooms of Chas. H. Curtis secured premier position for Mr. W. Tebay, gardener to Mrs. Ryerfort, Everlands, Sevenoaks. These were large, deep and beautifully finished, but the forets were rather narrow.

Mr. F. King was second with the same variety with large flowers and broader forets, but not so even as the first prize stand. There was a falling off in the number of competitors in the class for twenty-four Japanese, distinct, six entries being forthcoming. This is always a strong class, Mr. W. Messenger, gardener to Mr. C. H. Berners, Woolverstone Park, Ipswich, securing first prize with a lot of blooms showing high quality. Conspicuous among them were Mme. Carnot, E. Molyneux, Edith Tabor, Miss C. H. Payne, Simplicity, M. E. André, Australie, Mons. Chenon de Léché, Phœbus, Snowdon, Iolene, and Chas. Davis. Good colour, even form, and fine variety characterised this exhibit. Mr. R. Kenyon, gardener to Mr. A. F. Hills, Monkhaams, Woodford Green, was a good second with Mrs. Hume Long, Mons. Hoste, Australie and Pride of Exmouth in excellent condition. The competition in the class for twelve Japanese, distinct, made a show in itself. There were no less than twenty-four entries, and these made an imposing display. In this Mr. W. Messenger again showed his superiority, although he had little to spare with his nearest rivals. His was a fine stand, Mme. Carnot, E. Molyneux, Australie, Phœbus, E. Tabor, Mons. E. André and International were all examples of high cultural skill. Mr. H. Shoemith was a very close second, this old grower only needing one flower of deeper colour to enhance his chances of success. However, they were very handsome, and included Mrs. J. Lewis, Edith Tabor, Phœbus, Thos. Wilkins and A. G. Hubbuck. For six Japanese, one variety only, white, Mr. Norman Davis showed six of the finest and most even flowers of Mme. Carnot ever seen. They were perfect specimen flowers, fresh, clean, deep, and of exquisite form. Mr. T. H. Lodge, gardener to Mrs. Meritt, Hoekerill, Bishop's Stortford, was second with a nice stand of Mrs. C. Blick. In the class for six Japanese, one variety, any colour except white, Mr. J. McKenzie, gardener to Mr. F. S. W. Cornwallis, Linton, Maidstone, was awarded first prize for Phœbus, in excellent condition, and Mr. T. H. Lodge second for six very fine blooms of Edith Tabor. Mr. W. Robinson, gardener to the Rt. Hon. Lord Ludlow, Heywood, Westbury, Wilts, showed the best six blooms, Japanese incurved, Duke of Wellington, Lady Ridgway, Pride of Madford, Oceana, Australie and Western King being his varieties. The class for six hairy-petalled was poor. Two entries only were seen in the class for twelve large reflexed, showing the little interest felt in these stiff and formal-looking flowers. To Mr. W. Robinson was accorded first position, Cloth of Gold and Cullingfordi being his best blooms. The second prize was won by Mr. G. W. Forbes, gardener to Mrs. Nicols, Regent House, Surbiton. Six competitors were in good form in the class for six large-flowered Anemones, Japanese included, Mr. John Justice, gardener to the Rt. Hon. Sir R. Temple, Bart., The Nash, Kempsey, being a good first. Beautiful blooms of Mme. Lowton, John Bunyan, Lady Margaret, Sir Walter Raleigh, W. W. Astor, Junon, Gladys Spaulding and Queen Elizabeth were typical of these unique flowers. Second honours were secured by Mr. W. Skeggs, gardener to Mr. A. Mosely, West Lodge, Barnet. For twelve large Anemones, Japanese excluded, Mr. Justice was again first against six competitors, with Acquisition, Glück, M. C. Leboeuz, Junon, Mrs. Judge Benedict, Delaware, Mlle. N. Brun, Lady Margaret and Miss Annie Lowe. Mr. A. Ives, gardener to Mr. E. C. Jukes, Hadley Lodge, Barnet, was second, Junon and Descartes being very fine. Twelve Japanese Anemones were a very charming lot, five entries being staged. Mr. Justice was again invincible with a beautiful lot—Mrs. Hugh Gardiner, Robin Adair, Sir Walter Raleigh, Queen Elizabeth, Owen's Perfection, John Bunyan, Enterprise, W. W. Astor, Nelson and Caledonia, each with their disc well developed and their guard forets neatly arranged. Mr. Skeggs was a good second, Enterprise being very good. The pompons were neat and pretty and not over-large. Mr. T. Caryer, gardener

Mr. A. G. Meissner, Weybridge, was a good first, having Prince of Orange, La Vogue, Pygmalion, Mme. Elise Dordan, President, Mr. Holmes, William Westlake, Osiris and others in fine form. The singles were very pretty, though somewhat formally arranged, and, regarding quality, distinctly better than they have been seen. The amateurs' classes were each well filled, blooms of exceptionally good quality being staged. The new arrangement separating the two large classes of amateurs evidently answered very well. The maiden growers' classes, too, were a splendid success, and justifies the executive in retaining them, as there was ample evidence of quality in many of the exhibits.

## PLANTS.

There was a good competition in the group of Chrysanthemums, mingled with fine-foliaged plants, and arranged in circular form 12 feet in diameter. Mr. J. Spink, Summit Road Nursery, Walthamstow, was placed first with a bold and handsome arrangement surmounted by Palms. Good flowers, bright and clean foliage, and general high quality were characteristic of this group. A close second was Mr. W. Howe, gardener to Mr. Henry Tate, Park Hill, Streatham, with a charming arrangement, and with bright flowers and foliage pleasingly disposed of. Mr. D. Donald was the only competitor for six trained specimens, large-flowered varieties, showing ideal plants of J. Lightfoot, J. Shrimpton, Florence Piercy, Col. W. B. Smith, Gloriosum, and W. Tricker. For four trained specimens, any variety, Mr. F. Gilks, gardener to Mr. A. Morris, Court Green, Leigham Court Road, Streatham, was a good first, Emily Silsbury, Col. W. B. Smith, Mrs. E. S. Trafford, and Vivian Morel being his best; Mr. W. Davey, gardener to Mr. C. C. Paine, Hillfield, Haverstock Hill, N.W., being second. For six standard-trained specimens, large-flowered, Mr. Donald was again to the fore, he being the only competitor, Eva Knowles, W. Tricker, Miss Alice Luckman (pale yellow), Cleopatra, Chinaman, and Col. W. B. Smith being splendid examples of cultural skill. Four similar plants were shown by Mr. Davey, and were awarded first prize in the succeeding class. Mr. Donald secured first prize for a single specimen plant for a beautifully fresh and neatly-tied plant of Col. W. B. Smith. For the prize offered by Mr. P. Waterer for a specimen grafted plant, Mr. Donald exhibited Chas. Davis, Vivian Morel, and John Lightfoot on one plant, and secured the first prize. He also won the first prize for six handsome specimen pompons in perfect form, neatly tied, freely flowered, and rich in colour. Sœur Melanie, Black Douglas, William Westlake, Yellow Martha, Antonius, and W. Kennedy were the sorts staged.

## DECORATIVE EXHIBITS.

A table of bouquets, wreaths, sprays, &c., illustrating the decorative value of the Chrysanthemum, brought out a goodly competition. Miss Nellie Erlebach, Chard's The Florist, Stoke Newington, was a good first with neat designs carefully and artistically executed, and showing correct taste and finish. Messrs. Harwood Bros., 176, High Street, Balham, were second with a nice assortment of designs, &c., but lacking the finish which characterised the first prize exhibit. Fourteen competitors entered for three epergnes suitable for table decoration. Mr. D. B. Crane, Highgate, was first. He had a handsome trio arranged with a proper regard for colour. The second prize was awarded to Miss C. B. Cole, The Vineyard, Feltham, Middlesex, for a nice light and graceful arrangement, showing exquisite taste. Two vases of pompons, or Anemone pompons, with foliage made a charming display, Mr. Mark Webster, gardener to Mr. E. J. Preston, Kelsey Park, Beckenham, being an excellent first with elegant sprays of blooms and foliage arranged with great taste in Oriental vases; Mrs. W. Green, jun., Harold Wood, being second with a pretty pair of vases. Mr. Mark Webster was again first with two bouquets, elegantly arranged. Eight entries for a hand-basket of Chrysanthemums,

open to ladies only, made a pretty display. Miss Easterbrook, Fawkham, Kent, showed a pretty basket of pompon Gertie Waterer, a lovely blush sport from Snowdrop. In the open class for six blooms arranged in a vase with foliage, Mr. J. Brooks, gardener to Mr. W. J. Newman, Tottenham Park, was first with fine flowers of Mme. Carnot.

## FRUIT AND VEGETABLES.

For three bunches of white Grapes, Mr. W. Tidy (gardener to Mr. W. H. D'Arcy, Stanmore Hall) was first with nice bunches, Mr. W. Taylor (gardener to Mr. C. Bayer, Forest Hill) being second with heavy bunches. For three bunches black Grapes, Mr. H. Howe was first with large handsome bunches of beautiful colour, and Mr. W. Tidy second. Three bunches of Gros Colman were well shown, Mr. W. Iggulden, Frome, Somerset, being placed in the premier position with handsome bunches, Mr. J. Bury, Petersham Vinceries, Byfleet, Surrey, being second. For six dishes of dessert Apples, Mr. G. Goldsmith (gardener to Sir E. G. Loder, Bart., Horsham) was first with a beautiful lot, comprising Adams Pearmain, Cox's Orange Pippin, Blenheim Orange, King of Pippins, Gascoigne's Scarlet and Ribston Pippin. For six dishes of cooking Apples, Mr. A. J. Thomas, Burgams Hill, Rodmersham, was first with Peasgood's Nonsuch, Bramley's Seedling, Prince Bismarck, Lane's Prince Albert, Cox's Pomona and Warner's King. For six dishes of dessert Pears a grand lot was staged by Mr. A. J. Thomas, who secured first prize. For a collection of nine distinct kinds of vegetables, prizes offered by Messrs. Webb and Sons, Mr. E. Beckett (gardener to the Rt. Hon. Lord Aldenham, Aldenham House, Elstree, Herts) was a good first with splendid examples. These were splendidly staged and were much admired. The second prize was awarded to Mr. E. S. Wiles (gardener to the Hon. E. Hubbard, M.P., The Rookery, Down, Kent), with a clean and nice exhibit.

## MISCELLANEOUS.

Under this heading a fine display was made. To Mr. Norman Davis belong chief honours, the gold medal awarded to him being richly deserved. Chrysanthemums arranged in large vases had associated with them rich autumnal and other foliage. The back was draped to harmonise and the effect was very good. Among the good things we noticed Western King, Simplicity, Mrs. Hermann Kloss, Mme. Carnot, Mrs. H. Weeks, Modesto, Phebus, and many novelties. Crotons, Dracaenas, and Palms were pleasingly associated. Small gold medals were awarded to each of the following: To Mr. H. J. Jones for a very handsome group of Chrysanthemums and fine-foliaged plants, arranged in a graceful and undulating way; Mr. W. J. Godfrey, Exmouth, for a very large table of Chrysanthemums, embracing many excellent new sorts, besides Carnations; Messrs. W. Cutbush and Son, Highgate, for a small group of Chrysanthemums, with a fringe of Begonia Gloire de Lorraine in splendid form; Messrs. H. Berwick, Sidmouth, Devon, for a fine lot of Apples and Pears; Mr. W. Wells, for a splendid group of cut flowers, representing a capital variety of single Chrysanthemums, together with recent introductions in the best of condition; Messrs. H. Cammell and Sons, Swanley, for a superb table of specimen blooms of Chrysanthemums arranged among Ferns, &c., a grand collection of zonal Pelargoniums and Cannas; Messrs. J. Laing and Sons, Forest Hill, S.E., for a fine lot of Apples and Pears, with small groups of Carnations and other plants; and Messrs. B. S. Williams and Son, Upper Holloway, N., for a beautiful collection of Orchids elegantly arranged. A gold medal was given to Messrs. Sutton and Sons, Reading, for eleven heaps and thirty baskets of Potatoes. Silver-gilt medals were also awarded to the Icthemie Guano Co. for their decoration of the southern fountain; Mr. H. J. Jones for a large table of Chrysanthemums arranged in vases and on boards, fine-foliaged plants being dotted all over the table; Messrs. S. Spooner and Son, Hounslow Nurseries, for a beautiful lot of Apples

and Pears; Mr. H. Deverill, Banbury, for splendid display of vegetables; while silver medals went to Mr. Thos. Ware, Tottenham, for Chrysanthemums; Mr. J. Agate, Havant, for Chrysanthemums Mary Molyneux and Mrs. J. Molyneux, recently certificated; to Mr. T. Williams for his pretty little table decoration Mr. R. Owen for Chrysanthemums (both new & choice sorts), Mes-srs. W. and J. Brown for a collection of Apples and Pears, and Mr. E. G. Reel Beckenham Hill, for Chrysanthemums. Mr. J. Shoemith also had four dozen handsome exhibition Japanese Chrysanthemums not for competition.

The floral committee met at the Royal Aquarium Westminster, on Monday last, 15th inst., at 6 o'clock, Mr. T. Bevan in the chair. There was capital lot of novelties, many excellent incurv sorts calling for special notice. The light was none too good by the time the committee finish their labours.

First-class certificates were awarded to the following:—

CHRYSANTHEMUM MASTER II. TUCKER.—A large Japanese incurved with broad florets; color deep crimson-chestnut, with chestnut-bronze reverse. From Mr. H. Shoemith, Claremont Nursery, Woking.

CHRYSANTHEMUM GEORGINA PITCHER.—A very handsome Japanese incurved, with long, broad incurving petals of good substance; colour pale lemon-yellow. From Mr. W. Wells, Earlswood Nurseries, Redhill.

CHRYSANTHEMUM Mlle. LUCIE FAURE.—This welcome addition to the incurved varieties, was neat, incurved and pointed florets; colour pure creamy white. The build of this bloom very much resembles that of Chas. H. Curtis. From Mr. W. J. Godfrey, Exmouth, Devon.

CHRYSANTHEMUM ERNEST CANNELL.—Another incurved bloom of immense size and depth, was neat incurving florets somewhat pointed at tips; colour a pleasing shade of buff-yellow. From Mr. R. Leadbetter, Elmstead Grand Chislehurst.

CHRYSANTHEMUM MRS. G. CARPENTER.—A large Japanese flower with long florets of medium width, prettily twisted. The colour is a pleasing shade of delicate rosy mauve with silvery reverse the colouring paling in the centre. Mr. G. Carpenter, West Hill, Byfleet.

CHRYSANTHEMUM Mlle. LAURENCE ZÉDÉ.—One of the finest of M. Calvat's introductions of the present year. It is a massive Japanese incurved with long, broad, curling florets, slightly hirsute the ends; colour bright rosy lilac with silvery lilac reverse. Sent by Mr. Wells.

CHRYSANTHEMUM EARLSWOOD BEAUTY.—Another beautiful addition, the large single flower having florets of good length and medium breadth. The colour is best described as creamy white, disc being yellow. Also from Mr. Wells.

Matthew Hodgson, a Japanese reflexed, medium size, of the brightest shade of crimson with a bright golden reverse, long and tapering Lady Northcote, a handsome Japanese, with large florets of capital substance, colour white, shaded off to pale rosy blush; Philip Mann, a very beautiful Japanese, with long, recurving golden florets of medium width, colour a lovely shade of deep rosy purple, with silvery reverse; A. W. C. Egan, an incurved bloom of considerable promise, colour white in centre, paling off to rosy-pink at the edges, and Mme. Ferlat, a unique and compact incurved bloom, pure white, florets tightly incurved, the committee highly commended.

They also wished to see again: Mabel Mill a large Japanese Anemone, with long creamy white guard florets with a yellowish disc; Arthur Ray, a pale yellow sport from Mlle. A. de Lambert, and Julia Scaramanga, a Japanese, with long spreading florets of a pleasing shade of bronze.

Mr. P. Waterer, Fawkham, Kent, showed a new exhibition board, and called the attention of the committee to his patent name-ticket holder.

It is a useful and simple contrivance for displaying the names of varieties staged. The names on cardboard slide in and out quite easily, and the whole is fixed securely with a neat little clip to the board. A commendation was unanimously granted to this invention. A small silver medal was awarded to Mr. Wells for the large collection of Chrysanthemums he exhibited.

**PUBLIC GARDENS.**

**CHRYSANTHEMUMS IN THE PARKS.**

**BATTERSEA PARK.**

The greenhouse here is a display of Chrysanthemums, comprising about 2200 plants in 250 varieties that may for all practical purposes be considered one of the best in recent years. The plants are arranged on a wide sloping bank, with paths none too wide for the crowd that passes through the building. The collection contains many first-rate varieties, which have been judiciously arranged with a view to set out to the greatest advantage the many finely-coloured varieties.

These Chrysanthemum shows in the public parks are a valuable object-lesson to the public in the art of flower-growing, but, of course, differ in many respects from the trade exhibitions, where novelties and new introductions mainly form the chief attraction. Still, among the older kinds seen at these County Council displays one can learn much, and the chief lesson undoubtedly is that a very attractive and popular show of the autumn queen can be made with material that an ordinary exhibitor for show has long since ceased to consider worthy of his attention.

In a densely crowded neighbourhood like Battersea difficulties of cultivation are not easily overcome, and only by great energy and unceasing attention can a collection of such extent be brought to anything like perfection, and these difficulties do not appear to have been wanting on the part of those responsible for the exhibition under notice.

The Japanese kinds of course are in the majority, and the first to be noticed are such well-established novelties of American origin as W. H. Lipin, yellow; G. W. Childs, crimson; Eda, pale flesh-pink; W. Tricker, rosy pink, rather like. Others from different sources, but belonging to the same group, although varying in size and form, are M. Freeman, very dwarf and of good size, colour rosy pink; Elaine, once a popular white show variety; Lady Byron, a new arg. white; Alberic Lunden, a fine deep shade of purple; Edwin Molyneux, crimson and gold; and M. Tarin, an old kind, pale rosy pink, and likewise for decoration. In yellows, Sunflower, Palma, and Yellow Dragon, together with some other well-flowered plants of the newer Edith Fair, are all of interest. Duke of Berwick, Marie Hoste, Avalanche, and Mrs. H. News maintain the reputation of the whites, and the crimsons are strikingly beautiful on account of the deep velvety richness of William Seward, John Shrimpton, William Holmes, the old cream Delaux, and several others equally meritorious. Varieties of different tones of purple are only to be referred to by name, Mme. de Bellevue being not the least beautiful. Edouard Auguier is another that was once to be seen on the show board at our exhibitions. M. Garnier, a bright golden yellow counterpart of Edouard Auguier. Gloire du Roehier and Val d'Andorre lead to the crimson-bronzes. Viviani Morel, of a mauve, is large and good, and several massive examples of the old Comte de Germiny, one of the earliest of the Japanese section, are also on view. Other Japanese, such as Charlotte de Montebrier, pink, La Triomphante, with broader core, but similar in colour, and Colonel Chase, of a delicate shade of creamy golden salmon, afford ample proof that the newest introductions are not always the best, and that many of the older sorts can still be used for effect in a

way that leaves little to be desired where softness and delicacy of colour are required.

Among seedlings of M. Ernest Calvat's raising, Louise is particularly noteworthy for size, compactness, and colour, and is almost always uniformly good. President Borel is large and deep in build, the colour being a peculiar mingling of deep rosy purple and gold. Mme. Carnot, a large well-known white, and M. Chenon de Lèché, large blooms of a very rich mixture of cream, golden rose and salmon-buff, both come from the same source and require no criticism. L'Ami Etienne, pale lilac-mauve, very globular, and of good size, is one of M. Calvat's varieties not often seen at the shows, but a very useful one in such groups as the one now under notice.

A few hairy varieties, mostly well-known standard sorts, appear to attract no little attention from the visitors. Louis Boehmer is much in evidence, and its white sport, faintly tinged with pale lemon-yellow in the centre, is in very good form. Hairy Wonder is one of the richest and most effective for large groups; its colour at Battersea is very deep and good, being a dark golden bronze. Esau is a close, compact, globular form, deep rosy pink, with a golden yellow centre, and close at hand we notice the forerunner of the whole hirsute section, Mrs. Alpheus Hardy, of which there are several very well-developed blooms in its peculiarly pure glistening white.

The old type of incurved varieties has many useful examples, although in a public exhibition they do not seem to cause the same degree of interest as the more showy and effective Japanese do. Most prominent in this section are such old-established sorts as Baron Hirsch, Mr. George Glenny (still one of the most perfect), C. H. Curtis (large and very rich in its shade of golden yellow), John Doughty, Mr. Bunn, Lord Wolsley and its relative Prince Alfred, Jardin des Plantes, Refulgens, Globe d'Or, Lord Brooke, the pretty, but medium-sized Mme. Darrier and several of the Queen family, without which no collection of Chrysanthemums can be regarded as thoroughly representative.

On the large bank are several fine plants of that charming little pompon, Mme. Elise Dordans, a variety that in our opinion has no equal. Other sections, such as the reflexed and Anemone-flowered varieties, are not wanting. In the first-named, Dr. Sharpe (an old-time favourite) is always welcome, while in the latter we noticed Descartes, a large, bold-looking, wine-coloured variety, with long guard florets and a velvety-looking shade of colour that makes it a valuable acquisition. Delaware, too, is not new, but it is of some value; colour white, with a yellow centre. Then in the same section come M. Charles Leboeuz (pale ochre-yellow) and John Bunyan (deep golden yellow).

**SOUTHWARK PARK.**

The collection of Chrysanthemums in this park, which is situated in a locality that is densely populated by the working and riverside labouring classes, is arranged with considerable taste in a T-shaped greenhouse. The plants are arranged on two sloping and serpentine banks with a winding path of good width down the middle. Interspersed are a few Palms, &c., to give effect to the display. If Battersea is an undesirable quarter of London in which to grow the famous autumn flower, we should think that Southwark is still more so. The disadvantages under which the collection at Southwark Park consist of want of pure air and an indifferent light, and these are manifest in the paleness of colour in some of the blooms of Etoile de Lyon, Charles Davis and Viviani Morel, but with these few exceptions the colouring of the others leaves little or nothing to be desired. Here, as elsewhere, the Japanese predominate, and offer most that is attractive both in size and colour. Some of the early October ones are rapidly passing their best, but the bulk of the collection will be in condition for some time to come. Large and well developed are the well-known Etoile de Lyon, Rose Wynne, Viviani Morel, Mrs. E. G. Hill and Louise, of the last named there being some very pretty pale bluish-

coloured blooms of good size and substance. This variety wherever seen seems to be uniformly good, and, indeed, is one of the most valuable of its type. We notice, too, Mlle. Lacroix and its pale yellow sport Mr. C. E. Shea, and close at hand several good crimsons, as G. W. Childs, J. Shrimpton and W. Seward, the last-named being very bright. Col. Bourne is another bright-coloured kind, and so, too, is Gloire du Roehier. M. Geo. Biron is a deep crimson, with golden reverse, and Alberic Lunden, a finely-formed, medium-sized purple-amaranth variety, is also very effective. A new yellow variety, Marjory Kinder, shows that English seedlings can hold a foremost place in spite of severe competition. It is large in size, incurving in build, and is of a very pure deep golden yellow. Florence Davis, with its peculiar greenish tint, is small, but the bright pink Wm. Tricker helps to brighten up the group in many places. So, too, does Puritan, large and massive and of a pale pink-mauve shade. There is a good proportion of large-sized whites, of which we notice Condor, once and for a short time popular on the show boards, and which was sent out by the same raiser as Etoile de Lyon; Mme. Carnot, Emily Silsbury, very large and good; Lady Byron, incurving in form, deep and solid; Mrs. H. T. Drewitt, Miss Elsie Teichmann, creamy white; Mrs. C. Blick and the old Lady Selborne. In yellows, Colonel W. B. Smith, Abbé Mendenhall, Sunflower, Gloriosum, Phœbus and Duchess of Wellington strike us the most, not forgetting Edith Tabor, of more recent introduction. For a good solid, incurving, globular Japanese of a golden yellow shade there are few to equal J. H. Runchman. Edouard Audiguier, deep purple-plum colour, with a silvery reverse, is very rich, and good use is made of La Triomphante, a well-known seedling of De Reydellet's, rosy pink and very attractive in a mixed collection. President Borel, purple-rose and gold; Mme. Ed. Rey, Charlotte Montebrier, pale pink; Hamlet, a beautiful shade of cerise-salmon, reverse golden; Prefet Robert, purple-amaranth, with reverse of silver, incurving and globular, and l'Ami Etienne, also large, round and compact, and of a rosy-pink shade, all commend themselves to the visitor's notice.

In incurved, the Southwark collection contains C. H. Curtis, M. R. Bahuant, large and of fine form, and Baron Hirsch in goodly numbers. Older sorts, such as White Beverley, Prince of Wales, Lord Wolsley, Refulgens, Prince Alfred, and Mr. Geo. Glenny, are well represented, not of course omitting Queen of England, Lord Alcester, and Pink and White Venus. Some years ago a capital collection of hairy novelties was exhibited at Southwark, and caused much interest. The collection at the present time does not apparently contain so many of these, but the section is represented. Quite distinct in this section is Mrs. H. Caldwell, which has very long tubular rigid florets, colour pale straw-yellow. Sautel 1893 is a fine one, for it is large, of the Japanese incurved form, and of a pretty deep rosy-pink shade, with a silvery reverse. Mrs. Dr. Ward, ochre-yellow, completes the number. Mrs. Judge Benedict, an Anemone with a yellow centre and disc of pure white flat guard florets, and Mlle. Cabrol, also a Japanese Anemone, with a few of the better-known pompons lend a charm to the display.

**WATERLOO PARK.**

Something like 1700 plants are grown to make the display here. The plants are housed in a large and lofty conservatory, in bold and handsome groups gently sloping to the front, and showing considerable taste in their arrangement and the association of the different forms and colours. Beyond this a long and disused viney also holds a fine lot of plants, with a continuous sloping group the whole length of the structure on one side. The colour seems to strike one forcibly as being much better than usual, this probably being accounted for by the buds having been retained somewhat late in the season. At the time of our visit the display was at its best, splendid examples of the Japanese sorts being

much admired. *Phœbus* (one of the best yellows) was very good; *Amos Perry* (another yellow) also is in fine form this season. Pretty little plants of *Souvenir de Petite Amie*, each carrying a number of blooms of a useful size, were often in evidence, while both *Vivian Morel* and *Chas. Davis* were remarkable for the splendid colouring and their handsome proportions. *President Borel* (bright carmine-rose, a popular variety of a few years back) was as good as we have ever seen it, both the length and breadth of the petals and the finish of the blooms comparing favourably with those of many of the newer introductions. A pretty flower is *Comte F. Lurani*, rose, striped white. This is an excellent sort for grouping, and a very easy sort to grow, too. Older sorts, such as *Mrs. C. Harman-Payne*, *J. Shrimpton*, *William Seward*, *Commandant Blusset* and *Mlle. Thérèse Rey*, were represented by clean and even flowers. Of the newer sorts, the best were *Lady Byron*, a large and handsome white Japanese of chaste appearance; *Edith Tabor*, a lovely soft yellow, of beautiful form; *Hairy Wonder*, particularly good; *Modesto*, a new incurved Japanese of deep rich yellow and most striking in the group; *A. H. Wood*, a beautiful yellow sport from *Primrose League*, and coming good this year; *Sunstone*, a promising flower of clear light yellow; *Mrs. Richard Jones*, pure white, large and of good form; *Western King*, a new American white incurved Japanese of the most chaste description; *James Bidencope*, a large rosy amaranth flower with silvery reverse, and a nice lot of late flowers of the lovely white *Mme. Carnot*, certainly the best of that type of the flower. Incurved varieties are somewhat largely grown here, splendid blooms of *Chas. Curtis* being always in evidence. *Mme. Darrier* (nankeen-yellow, very neat flower), *Mrs. R. C. Kingston* (white, tinted lilac-pink, splendid form), *Lord Alcester* (very fine), *Baron Hirsch* (the cinnamon-buff flower) and the different members of the *Rundle* family—*Mrs. Geo. Rundle*, *Mrs. Dixon*, *Mr. Geo. Glenny* (by far the prettiest flowers in the incurved section)—each assisted to make a pleasing variation. A nice lot of pompons is always accorded a welcome here, and a batch of plants of the best decorative sorts also receives a share of attention, and assists very materially to prove the value of the *Chrysanthemum* when grown in a free manner.

#### FINSBURY PARK.

Here all sections are well represented. Not only are the different types of the *Chrysanthemum* seen in excellent condition, but a delightful way of arranging the plants has been carried out. In the *Chrysanthemum* house the plants are grouped in a long series of semi circular bays, the background being made up of pretty decorative varieties, such as old *l'Île de Plaisirs*, with its narrow florets, crimson and golden yellow in colour. The groups slope gently down to the front, this being finished off with a capital lot of dwarf pompons, *William Westlake* (lovely yellow) and the old *Sœur Melanie* (white) being alternately used. The upright supports to the roof are to a large extent covered in with freely-flowered specimens of *Margot*, this old salmon-pink variety having preference given to it because of its keeping qualities. Old sorts which were doing well were *Etoile de Lyon*, in the best possible form; *Madame Rozain*, a refined Japanese incurved of pearly-pink; *Miss Margaret*, a free, large *Anemone* with pink guard florets and sulphur disc. *Golden Gate*, the late tawny-yellow Japanese, was growing in a free manner—quite unusual for this sort. *Miss Elsie Teichmann*, the delicate pearly-white, was in fine form, its fine habit being a point in its favour too. *Phœbus* is thought highly of here, and was doing very well. *Niveum* was represented by the purest white blossoms of grand substance. *Chas. H. Curtis*, the popular yellow incurved, was seen in neat and even specimens from late buds. A large batch of the American novelty *Philadelphia*, with its pale sulphur-yellow blossoms, seems to be appreciated here, and although not equal to the specimens sent over to a show of the National *Chrysanthemum* Society a few years ago, it is to be seen in

very fair form. *Mrs. E. G. Whittle*, with large Japanese flowers resembling in colour a beautiful *Malmaison* *Carnation*, deserves extended culture. *Miss Phyllis Fowler*, a beautiful yellow sent out as an incurved, seems too rough, even from late buds, to make a typical incurved bloom. *Shasta*, a charming white variety, with very neat tubular petals, was quite unique, and was always in evidence. *Edith Tabor* was also most effective, and the lovely *Mrs. A. H. Neve* is pleasing both in form and colour. *Australie*, the massive Japanese incurved, was represented by magnificent samples of high culture, its colour of rosy amaranth and silvery reverse being seen to advantage. *Western King* among the new sorts was specially noticeable, its large and chaste white Japanese incurved blossoms calling for special praise. Among the incurved sorts, *Mrs. R. C. Kingston* was in exquisite form, the flowers being neatly formed and of large size. *Globe d'Or*, *Princess Teck*, and *Barbara* were also freely distributed among the Japanese sorts, and the contrast most effectively brought about. Other Japanese varieties in good form were *Vivian Morel* (splendid colour), *Florence Davis*, *Louise*, *Marquis de Paris* (large white), *R. Owen* (neat flowers), *M. Pankoucke*, *Gloriosum*, *T. Wilkins*, and *Mlle. Marie Hoste*. The large conservatory was also requisitioned for the display, quite a large number of plants being pleasingly disposed among the fine-foliaged plants there. Singles were represented by the enormous blooms of *Sunset*, not by any means pretty, and by the charming flowers of the blush-tinted *Miss Mary Anderson*.

### NOTES OF THE WEEK.

**Chrysanthemum Golden Elsie.**—This is a very pretty variety with good light upon it, but at eventide the yellow shade pales to such an extent as to render it scarcely recognisable. For evening use the orange-gold shades are much the best and most effective.

**Hydrangea Hortensia.**—Some capital bushes of this were still yielding satisfactory heads of blossom in the open a few days since, some of the shoots apparently of the current season's growth, since the larger heads that made so fine a display a few weeks since have all but perished.

**Chrysanthemum Royal Standard.**—This variety would appear to be one of the finest of its colour, as recently seen at the Drill Hall, where its crimson-maroon shade shone out conspicuously against flowers of lighter hue. The blooms are very handsome and of fine proportions.

**Gaura Lindheimeri.**—If the gathering of the blossoms of this plant, as shown by *Mr. Ladhams* at the Aquarium show, at all indicates the general behaviour of this plant, then it must assuredly be flowering as freely as it does in the summer, since the plant was represented by a good-sized sheaf of its spikes.

**Dracæna Doucetti.**—A pair of exceedingly well grown plants of this were very conspicuous in a group of well-grown stove and greenhouse plants last week at the Royal Horticultural Society's meeting. The examples were faultless throughout, and being some 6 feet or 7 feet high stood out grandly at the corners of a fine variety of plants.

**Bougainvillea spectabilis.**—Quite recently we noted a large example of this flowering abundantly in the somewhat cool company of *Cacti* and *succulents* generally in the large house devoted to these things at Kew. The quantity of the flowers was in itself an attraction, while the colour was decidedly deeper than is the case when the plant is subjected to a much higher temperature.

**Saxifraga cortusæfolia.**—This late autumn-flowering species belongs more or less to the same category as *S. Fortunei*, while it is generally more hardy than this and less fleshy in its leaves and stalks. It is worthy of more attention for its late-flowering, and with deep soil and a sheltered position in the rock garden the tuft of white flowers is very pretty during the early summer and autumn.

**Cereus rostratus.**—For a long time past this handsome species has been flowering in the succulent house at Kew, where a very fine example is

trained to the roof. In this position ample light and sunshine are afforded the plant, and the numerous creamy white blossoms appear in profusion week by week. Some of the largest flowers we measure from 8 inches to 10 inches across.

**Galanthus octobrensis.**—This interesting variety appears to be lacking in one important quality, viz., constitution, so far, at least, as culture is concerned, in some gardens in the south of England. Indeed, some small clusters that a year ago had quite a nice display of blossoms and were then supposed to be fairly well established, have scarcely made their appearance all this season, the growth being much weaker than hitherto.

**Vinca acutiloba**, given to me by the late *Harpur-Crewe*, seems to be little known. It has large delicate pale blue flowers, and always remains in full beauty through the greater part of the winter. *Solanum jasminoides*, *Eccecropus scaber*, and *Abutilon vexillarium* are quite fresh, and *Clematis calycina* has already opened some of its flowers, and large plants of *Erica codonodes* are in full flower.—*T. H. ARCHER-HIND, South Devon.*

**Chrysanthemum Jules Lagravere.**—This old crimson variety is not now very frequently seen, the many recent novelties having in probability displaced it. At the same time it is worthy of note that it possesses a hardy, vigorous constitution, sufficiently so to come up year after year in the open garden. For these reasons it is worth retaining as a parent to raise other good hardy sorts from, such as are capable of taking care of themselves in the open.

**Seedling Nerines.**—One of the most brilliant coloured forms of this group was a seedling of *Mr. Elwes*, recently noted at the Drill Hall. It stands by side with the most brilliant forms of *N. Fothergilli*, it surpassed them in the intensity of its colour, which was of vermilion-scarlet hue, the truss large, as though *N. Fothergilli* had one of its parents. Very remarkable, too, the length of the stamens, these being of the same shade as the segments of the perianth.

**Convolvulus Cneorum.**—I do not remember to have seen this plant noticed in *THE GARDEN* and yet few are more beautiful and striking. I cannot say it is quite hardy, but I have had it many years in my garden on a warm border. This full season is in spring, but it flowers in autumn also, and now, in the middle of November, I have a large bush 4 feet or 5 feet high in great beauty and it will continue to expand its lovely pink-tipped blossoms till a severe frost comes to check it.—*T. H. ARCHER-HIND, South Devon.*

**Royal Horticultural Society.**—The fruit and floral meeting of the Royal Horticultural Society will be held on Tuesday, November 23rd, at the Drill Hall, James Street, Westminster, 1 p.m. At 3 o'clock a lecture on "Horticultural Exhibitions, Schedules, &c.," will be given by *John Wright*.

#### BOOKS RECEIVED.

Catalogue of plants at La Mortola, near Vigonza, Italy. Commendatore *Thos. Hanbury*.  
"A Text-Book of General Botany." By *Chas. Curtis*, Columbia University. London: Longmans, Green, and Co.

**Names of fruit.**—*B. B.*—1, Pear Marie Louise; 2, Apple Norfolk Beaufin.—*J. R.*—Impossible to name from part of an Apple only.

**Names of plants.**—*B. J. P. Bastard.*—1, *Caper Spruce* (*Euphorbia Lathyris*).—*Miss Young.*—A small flower of *Crocus speciosus*.—*J. C.*—1, *Abies numidica*; 2, *Abies Nordmanni*; 3, *Cedrus Deodara*; 4, *Cedrus Libani*.—*Com Reader.*—*Eryngium bromeliæfolium*, or some other species.—*Miss Yule.*—*Escallonia macrantha*.—*V. W.*—1, *Andromeda* sp.; 2, impossible to name from specimen sent. Please send when in flower.—*Springhill.*—1, *Lissocichlus* sp.; 2, *Dendrobium nopsis Schreoderianum*; 3, *Cattleya Trianae*; 4, better specimen.—*W. O.*—*Muhlenbeckia com.*

## CHRYSANTHEMUMS.

### GOOD SHOW FLOWERS.

Among the many striking sorts of Japanese Chrysanthemums more generally found in competition stands at the exhibitions recently, Australia was one of the most conspicuous. The colour, silvery lilac, is bright, and its shape distinct. The broad massive florets fall in all directions, and yet give a bloom of perfect outline. Australian Gold, about which so much has been written, is a magnificent bloom. It is a solid mass of interweaving florets of a purple-yellow shade, full, deep and rich. Charles Davis, now so well known, was abundantly represented, but the blooms did not appear quite up to the standard of those shown a year or two ago. Fine blooms of Edith Tabor were noted everywhere. It is a particularly handsome bloom. Edwin Molyneux, the most showy of crimson kinds, cannot be beaten. Eva Knowles has flowers of a distinct scarlet shade. This was seen in fine form in several instances. A sort usually coarse, namely, International, is a very fine flower when in the condition noted this season. The colour is salmon-pink tint, and the long florets hang down in a graceful way. Lady Hanham, a charming flower, is a sport from Vivian Morel, that I thought would not prove sufficiently distinct, but it is. The colour is a soft salmon-red, and it retains the fine formation and size of the parent. Mme. Carnot is undoubtedly the best white show Chrysanthemum. This was in evidence at all competitions. Mme. Gustave Henry is a very fine white of incurving form. This is easily grown, and is a distinct one. Mlle. Thérèse Rey was seen in finer form at country shows than in London, and is very striking in the excellent substance of its florets.

That splendid yellow, Modesto, appeared somewhat loose in build this year. Last season it proved to a solid centre. But in any shape

the flower is most telling. M. Chenon de Léché was represented by blooms of many shapes—that most effective was when all the florets reflexed and gave the rich colouring for which the sort is noted. M. Ed. André bears carmine-salmon blooms. It is very rich. The flowers are large and of pretty form, and it should be extensively grown for show. Mr. A. G. Hubbard, like the last named, can hardly be classed with those most generally seen, but it is so showy as regards colour that too much cannot be written of it. A very handsome bloom wherever met with was Mrs. H. Weeks. The florets are wide, of exceptional substance, usually inclining to the centre and forming a solid mass. Few blossoms have the remarkable beauty of this Chrysanthemum and its being so often seen, whilst but recently introduced, is something in its favour. Miss Elsie Teichmann is a splendid variety. The florets have a parchment-like texture, very rich, and when seen with a pink tint the flower always finds admirers. Mutual Friend has fine white blossoms, but these are somewhat flat. It is, notwithstanding, one of the choicest show kinds. Perhaps the most remarkable Chrysanthemum of recent years is Oceana. It is yellow and has florets so thick that they seem proof to damp. In fact the blooms last longer than those of any sort I know.

Phœbus was the best exhibited of any variety this year. Time after time it was the winning one in the class devoted to half a dozen blooms of one sort, as well as being judged the premier bloom of a show very frequently. Pride of Madford is not a good sort to keep, otherwise it is a most constant and handsome flower. A refined white is Simplicity. This will be very popular. Thomas Wilkins has blooms of a telling bronze shade and the form is good. Vivian Morel in its shade is very fine, although the blooms are not so good as seen a year or two back. H. S.

**Yellow Japanese Chrysanthemums at the National Chrysanthemum Society's show.**—It was

exceedingly interesting to note the names of the yellow Japanese sorts exhibited at the late show at the Royal Aquarium, as showing the change which each season takes place. Judging by results, a variety has a very short lease of popularity unless it possesses some distinguishing characteristic or has high quality. Phœbus was seen in magnificent form, flowers of great depth, rich colour, and splendid petal being seen over and over again. Edith Tabor (a most distinct yellow flower) was represented frequently by typical blossoms; Modesto, one of the newest of the yellow sorts, and of a particularly deep rich shade of that colour, has already found favour, its large and handsome flowers creating a splendid effect whenever staged. A. H. Wood (the yellow sport from Primrose League) was also often in evidence, this variety appearing to have developed very handsome flowers this season; and the yellow sport from Mme. Carnot, as seen in Mr. Mease's stand, and which was selected as the best Japanese bloom in the show, will long be remembered as an ideal Japanese flower.—D. B.

### CHRYSANTHEMUMS AT WOKING.

THE name of Mr. H. Shoemith, an old exhibitor, is by no means unknown to the readers of THE GARDEN. Having established himself at the Claremont Nursery, Woking, some time since, we have only just had our first opportunity of paying him a visit, and, as we expected, found him growing a very select and well-chosen collection of the best of the most recent introductions, although we were not a little disappointed to find the old florists' type of incurved considerably in the minority, so far as plants in flower were concerned. Situated away from the town, Mr. Shoemith's nursery occupies a very open position, and one that is no doubt conducive to the best results in the cultivation of the Chrysanthemum, of which he has some 200 or 300 varieties. He also grows zonal Pelargoniums with success, and of these there was a very bright display at the time of our visit. Other plants suitable for general purposes are not neglected, but at this season of the year the Chrysanthemum of course claims the premier position. Taken as a whole, the collection is beyond the average trade display, a large proportion of the plants being grown solely for the

production of fine specimen exhibition blooms, and not, as is sometimes the case, merely to produce a general effective display. Quality rather than quantity would seem to be Mr. Shoemith's motto, and with this in mind, our first inquiry was as to the relative merits of the season's novelties, to which his reply was very decisive and to the following effect, that he considered those received from M. Ernest Calvat to be of the highest order, and that the eminent French raiser had far outdistanced the whole of the other raisers of the same nationality. Certain it is that the Claremont nursery possesses a very choice collection of the Calvat seedlings, not the least interesting being those of most recent introduction. Among them, N.C.S. Jubilee is very large and finely developed, an incurving Japanese, colour lavender-pink, with silvery pink reverse. Mme. Gustave Henry is a beautiful white incurved Japanese, and Ma Perfection, of the same colour, but more nearly approaching the old type of incurved, comes from the same source. Lucie Faure is a grand addition, one of Calvat's very best, a large, solid, compact Japanese incurved, also white. Then we notice Mlle. Lawrence Zédé, very full and double, broad grooved florets, colour a beautiful shade of rosy mauve, with a reverse of silvery pink. Mme. Ed. Roger, the new green variety, is also in evidence; and not the least imposing among other white varieties are Baronne Ad. Rothschild and Mrs. J. Lewis, the latter of which is destined to become a very favourite variety. A variety of M. Calvat's that we do not remember having seen before is C. Delamotte, a big Japanese incurved with grooved florets, deeply built and of a rich golden yellow, just one shade paler than the American variety Modesto. M. B. Verlot (delicate rosy pink), Mme. X. Rey, Jouvin (pinkish mauve), Australian Gold, M. Chenon de Léché (enormous in size and beautiful in colour), and Perle Dauphinoise (golden buff, incurved, with pointed florets) must complete our notice of the Calvat seedlings, which are done as well here as anywhere we have seen.

Of others in fine form Phœbus deserves a special mention, for there are several blooms of it that are simply superb. Modesto is large, rich and good; Western King, Mrs. H. Weeks, Lady Byron, Mutual Friend, and Mrs. C. Blick among whites need no recommendation beyond a mention of their names. Mr. A. G. Hubbuck, a fine Japanese with long drooping petals, colour bright brick-red, is also good. The Australian novelties Oceana, Australie and Pride of Malford are immense in size and already well known. Lady Saunders, pale sulphur-yellow deepening towards the centre, and C. W. Richardson, of a rich golden-yellow, large and massive, are both exceedingly well done, but G. J. Warren, the pale yellow Carnot sport, will perhaps stand first in the list of the 1897 yellows. At any rate there will be only one serious competitor, and that is an unnamed pale sulphur-yellow sport from Vivand Morel that has just come into Mr. Shoemith's possession, and which promises to be quite as fine and as useful for exhibition as either Charles Davis or Lady Hanham. Sunstone is another yellow, very large and of an apricot shade. A. H. Woods is also a yellow, pale but clear. Master H. Tucker is a Japanese incurved, very rich velvety deep red inside, reverse golden-bronze, a large striking flower.

**Pompon Chrysanthemums.**—The rage for large blossoms of all kinds of Chrysanthemums still continues, and extends even to the pretty little pompon varieties, for the prizes are, as a rule, awarded to the largest flowers. At the recent Aquarium exhibition the pompon varieties were shown in threes, and the plants had been so rigidly disbudded, that each shoot carried but a single flower. These blooms were all fully expanded, with not a trace of a bud or partially opened flower to be seen. A board of pompon varieties is just as artificial as when furnished with the larger flowers, and pretty much the same may be said of the single forms, which grown naturally are very beautiful, but the fashion is

now to disbud them far too much. A few sprays of either of these with their blossoms in various stages of development are infinitely far more pleasing than the stiff, formal flowers as now shown. That favourite pompon variety, Mlle. Elise Jordan, which blooms profusely when grown as a bush, was disbudded to a single flower on a stout erect stem, and in this way it looked more like an arrangement for cleaning lamp-glasses than a pretty variety of Chrysanthemums.—T.

#### CHRYSANTHEMUMS AT LEWISHAM.

Mr. JONES, of the Rycroft Nursery, Lewisham, is known far and wide for the very fine displays that he makes at our exhibitions, and for the indefatigable manner in which he has worked to improve and popularise the autumn flower. In the two largest show houses at Rycroft, which are at the present moment filled with an immense number of Chrysanthemums in full bloom, are some very fine novelties of various kinds, the English, American, French and other raisers being all more or less well represented.

Home-grown seedlings find a fine addition in Mrs. L. Humphrey, a large, pale primrose seedling Japanese, which will be distributed next spring. Pride of Exmouth (large white) and G. J. Warren (the beautiful Carnot sport) are also in fine form. Mrs. Cotesworth Bond (a very delicate pale pink Japanese with large drooping florets, curly at the tips) is of great promise. Mrs. C. Orchard (pale sulphur-yellow), Lady Hanham (the new sport from Vivand Morel already described in these pages), Lady Isabel (the large new incurved), and many more besides all attest the up-to-date condition of the Rycroft collection. A few well-known and good varieties, such as Dorothy Shea (very fine in colour), Emily Silsbury, Lady Ridgway, Edith Tabor, A. H. Woods, Lady Byron, Miss Elsie Teichmann and Pallanza, will show that foreign growers do not alone receive attention at Mr. Jones' nursery. American novelties of recent introduction are well shown in Western King (the fine white Japanese incurved seen everywhere), Sunclad (pure golden yellow), Good Gracious (curious in its twisted narrow florets of pale pink), Simplicity (a lovely new white), Mutual Friend, Modesto, Snowdon, Lenawee (pure pearly pink), Autumn Bride (a very white Japanese) and several others.

Calvat's seedlings—M. Chenon de Léché, Louise, Amiral Avellan and the newer N.C.S. Jubilee, which is very fine—are all perfect specimens. So, too, are his Australian Gold, Ma Perfection, Mme. Carnot and the curious green variety Mme. Ed. Roger. From the same source come also M. Hoste, large white; M. B. Verlot, quite new this year, a fine Japanese incurved, colour deep rosy lilac, with reverse of silvery pink. Mme. Gustave Henry is large and good, and C. Harman-Payne, seldom seen in this country in anything like fair condition, is one of the best blooms we have seen. M. Ed. André, Mme. Berger, Werther and most of the old standard varieties of M. Calvat's are included in the collection. Mrs. G. W. Palmer and Mme. Eugène Testout, both sports from Mrs. C. Harman-Payne, do not seem to be synonymous, the former being very much deeper and brighter in its colouring of rosy purple and bronze. Triomphe d'Eve is an incurved white variety of very good form, and General Mauric belongs to the same category, but is prettier, being of a bright golden yellow in the centre, the outer florets bright pinkish rose. Oceana, the Australian Japanese incurved, is a grand pure yellow variety, and in size Australie is even superior, although its dull purplish colour is far inferior and its size alone will commend it to many exhibitors. Crown of Gold is one of Mr. Shea's seedlings, a fine large Japanese, with curly incurving and intermingling florets, colour deep golden yellow. Master H. Tucker is a reddish velvety crimson, shaded gold. Another Rycroft seedling of great size is W. Wright, certificated late last season. It is very large and has florets of immense length, the colour being white, shaded purple. Various shades of yellow may be

found in Lady Oporto Tait, large and globular King of the Buffs, Pride of Rycroft, a pure sulphur-yellow sport from Niveum; and C. Richardson, a big compactly-built Japanese incurved with grooved florets.

One of the old type of incurved may be found in Lady Gormanston, a colonial seedling of pure white and of very good form. M. Desblanc belongs to the same section, and is reddish-crimson with reverse of gold. In the incurved section may be mentioned Emile Nonin, Continental novelty, very regular in build, and a deep golden chestnut-bronze. Rena Duk, small, deep rose, tipped white.

In the Anemone section, Mrs. Caterer, a large white; Mrs. P. R. Dunn, same colour, but with the disc slightly tinted; and Mabel Mitchell, creamy-white, with a yellow centre, very large are the most conspicuous. Hairy novelties also to be found, but of these Hairy Wonder seems to be the best and most distinct. W. Louis Boelmer probably ranks next in popularity.

Like most of the trade displays this year, Mr. Jones' collection is chiefly made up of the Japanese type, other sections not being so freely played, although a stock of everything that is useful and good is kept up. Mr. Jones' collection, in spite of the serious disadvantage of illness for several weeks just before the beginning of the Chrysanthemum season, is in much better condition than we expected to find it. The collection is so extensive and so thoroughly representative, that it is only possible to give just briefest mention of all the good things to be there.

#### CHRYSANTHEMUMS AT BYFLEET.

At Westhall, Byfleet, the residence of Mr. St. John, the Japanese varieties are this season very large, the blooms being of great size, some of them exceptionally large, fine in form and colour. A striking one in this respect is Mme. Ricard, which carries immense blooms, the only defect being that they are rather too globular, and therefore somewhat formal-looking. Mrs. J. Lewis, or last year's novelty, also carries exceptional large blooms, and on this account is likely to be much in favour with exhibitors. Mrs. Carpet also a novelty, is very distinct, the bright shade of pink which characterises the flowers at its best being very pleasing. One of the most distinct in this section is M. Chenon de Leche: a mixture of apricot and sulphur-yellow renders flowers of this kind very attractive, and as blooms of high quality can be had on plants about 4 feet high without cutting down, this Chrysanthemum is likely to become a favourite for decoration. Fortunately the number of Japanese varieties do not exceed a height of 5 feet is increased, and in time we shall probably witness the extinction of those that must be allowed to grow above the tallest man's head to secure blooms of the highest quality. Miss Elsie Teichmann, creamy white; Lady Saunders, primrose; Aphisto, H. L. Sunderbruch, yellow; Lotus, bluish-pink; Mrs. F. Jameson, and Calvat's Boule d'Or produce flowers fit for exhibition stems from 4 feet to 5 feet high, and can therefore be accommodated in houses of quite limited dimensions where the tall-growing varieties are inadmissible. Edith Tabor and Modesto are in grand form at Westhall, and it will probably be some years before they are supplanted by varieties of superior quality. Hairy Wonder, the best in this class, is worth growing on account of its distinctness, but these hairy Chrysanthemums have to be much improved as regards colour before they become really popular. Souvenir Petite Amie, grown either for large blooms or bush form for cutting, is still one of the best of colour.

Among the incurved varieties, Golden Empress and James Agate are very conspicuous, the latter carrying magnificent white blooms, perfect form and of great size. Those who care for singles should make note of Annie Tweed which produces crimson blooms in great profusion, the inner petals of a lighter tint. Mr. Carpet

plants much of this for cutting, the flowers being effective in artificial light. King of the Plumes and Nocce d'Or are both distinct free-flowering plants, very useful for cutting. J. C. B.

### CHRYSANTHEMUMS AT SYON HOUSE.

CHRYSANTHEMUMS are not grown at Syon specially for exhibition, though, as is well known, many of them may be termed show blooms; indeed, some splendid flowers have this season been shown at the meetings of the Royal Horticultural Society at Westminster. Mr. Wythes does not grow for the usual mode of staging on flat boards, the flowers are shown with long stems on a framework of small plants, and most effective by arc, especially when the foliage is good. The 1500 plants are grown, 1000 as cut-backs, the blooms to a plant, and 500 as bush plants. These are mostly late kinds, about 100 only being early varieties. One of the best early kinds is Lady Mary Fitzwygram, the others being singles, My Anderson and Miss Rose being special favourites. The cut-back plants are staged in pot fruit houses at rest, not the best possible position certainly. The plants are well furnished with healthy foliage, and though the fog of the last few days has in a measure dulled the blooms and caused very many to damp, specially the curved types; there are later flowers which will give a good display for some time; indeed, the aim here to have the Chrysanthemums in quantity from September till the new year. Attention must be made of a few special flowers, though with such all-round good quality it is difficult to individualise. The old but still good King of Arc is very fine, the blooms large and perfect in shape. Brookleigh Gem is also excellent. Globe d'Or, a beautiful flower. Baron Hirsch is very fine, though some of the best blooms when shown were past their best. Lord Alcester, M.R. Bahuant, C. H. Curtis, Robert Cannell, Queen of England, Empress of India, Mr. Tunnington, Bonnie Dundee, Miss Violet Tomlin and Mrs. S. Coleman are specially good. Of course there is a much larger number of varieties in the Japanese section, and the collection includes a few of the varieties of great merit. International is a splendid flower of great depth. Many are charmed with the peculiar tint of H. L. Sunderbruch, a very large flower and a true Japanese. Lady Edolph is charming and a good-shaped flower; colour amarant-h-crimson, with silvery reverse. A trial is promised to make a grand flower and is a true grower. Kentish Yellow is one of the best novelties, with a charming shade of colour, and a sturdy grower. Lago Maggiore is another fine variety of good substance. Col. W. B. Smith is very fine, also C. Harman-Payne and Beauty of the South. Lady Esther Smith, a grand white bloom and a very perfect flower, is a favourite, and the well-formed Louise, a soft pink and very dwarf in growth. Elaine and Fair Maid of Gorse have been excellent, also Edwin Molyneux, not always an easy flower to finish. Eda, Mrs. John Lightfoot, Sunflower, Wm. Seward, M. C. Shea, Mme. Carnot, W. H. Lincoln, W. Tricker, W. H. Fowler, Vivand Morel, Philadelphia and John Shrimpton are all worth notice for their shape, size and colour, and sturdy growth. For late cutting W. H. Lincoln is a favourite variety, and Golden Dart this year is largely grown for its late flowers. Golden Dart is a splendid grower, and its rich colour is valuable. Mrs. Canning and Etoile de Lyon do grandly in pot form for late use. These figure largely, also Golden Gem and Princess Teck, with several others.

**Chrysanthemum Modesto.**—Although we have not met with blooms this season so exceptionally fine as a few were last autumn, enough of it is noted to judge of its merits. The colour is so very deep and rich that as a yellow it must become a generally grown variety. It is a free-flowering kind, and every bud produces a bloom of florets of much substance and thickness. It is not from its value as a show bloom, those who

cultivate Chrysanthemums for market should find it among the best for that purpose.—S.

**Chrysanthemum Lady Hanham.**—This was obtained from that well-known variety Vivand Morel. In its true character it has flowers of a charming shade of salmon-rose, but there will be some risk in exhibiting it in the same stand as another sport from the same parent, Charles Davis. The latter is most variable in colour, and, in fact, with all three a great deal depends upon the time the buds are "taken." When in their true character all are distinct and among the best of Chrysanthemums.

## ORCHIDS.

### ONCIDIUM VARICOSUM.

THE large showy lip and the pretty disposition of the blossoms make this one of the finest of all Oncidiums for grouping, the flat shape of the branchlets doing away with all possibility of a formal or stiff arrangement. It is a popular plant by reason of this and the fact that the flowers last long in good order and are useful for cutting. To grow *O. varicosum* well a good deal of care is necessary, the large branching spikes taking away a lot of nutriment from the rather small pseudo-bulbs. These latter are seldom above 4 inches in height, and each bears a pair of deep green leaves. In many cases the pseudo-bulb produces a couple of spikes and many scores of the bright and telling flowers. It is obvious that such a plant will not long be satisfactory if treated as a pure epiphyte; in fact, it needs much more feeding than most in the genus. Equal parts of peat fibre, free of all earth and sand, and clean Sphagnum Moss do well for compost, and it is very important that this is seen to at least once in two years, for if the roots have not plenty of fresh, sweet material to take to, they cannot carry the requisite nutriment to the bulbs. There is no need to repot or rebasket, for until the plants grow out of these the new compost may be given in the form of surface dressings when the plants are beginning to grow. When it becomes necessary to repot, let it be done thoroughly, clearing away every bit of spent compost and dead roots without disturbing any chance ones that may be clinging to pieces of charcoal or crocks in the old compost. Trivial as these bits of roots seem, they help materially to re-establish the plants. Keep the base of the plant an inch or more above the rim of the pot or basket, afford thorough drainage, and make the new material very firm. The best place to grow *O. varicosum* in is a light and airy position in the coolest part of the Cattleya house, suspending it from the roof if convenient in order to ensure the light reaching every part of the plant. The roots must be well watered as long as they and the growth are active, and the best rooted plants, of course, need the most moisture. A difference in the habit of the plants as to flowering will be noted where many are grown; some throw up a spike with the advancing growths, while others flower as soon as the pseudo-bulbs are finished. For this reason no very definite instructions can be given as to watering at this season. One thing is very important, and that is not to allow weak or badly-established plants to further weaken themselves by perfecting and carrying large panicles of flower. Only a day or two since in a local nursery I noticed a batch of plants that were literally flowering themselves to death. On mentioning it to the grower of the plants, he said they were required for a group at the Chrysanthemum show, so the plants were actually being

killed for the sake of the flowers. Of course this can only happen with badly-grown plants, so I may, perhaps, be excused for calling the attention of amateurs to the importance of keeping their specimens healthy by the requisite addition of compost mentioned above and the careful carrying out of all cultural operations. Healthy plants can stand a fair amount of drying in winter, and the rest thus obtained is beneficial to them. During the time they are in flower and until signs of growth are again apparent the plants are quite safe, and, in fact, best, in a house the night temperature of which seldom exceeds 50°. They are not so likely here to be troubled with insects, and especially a soft brownish scale that fastens itself on the under side of the leaves. Sponging with warm soapy water is best for dirty plants, but they may be kept clean by lightly sprinkling them with clear, soft water while growing and keeping up a moist atmosphere. There are one or two varieties of *O. varicosum*, that known as Rogersi being one of the finest and most popular. It is a native of Brazil, and was introduced in 1850. R.

**Cypripedium Leeanum.** This charming hybrid must always remain a popular plant. The best forms are those having *C. insigne* Maulei and similar varieties of the old species as one of the parents, these being larger and finer in every way than those raised from the type. Its other parent is the well-known *C. Spicarianum*.

**Lælia pumila.**—At the present time, in the nurseries of Messrs. W. L. Lewis and Co. at Southgate, there is one of the finest collections of this species that has ever been brought together. There are upwards of 500 flowers fully open. The variation is considerable, many of the flowers equal to those of the variety *Lælia pumila magnifica*, recently given an award of merit, while others are almost white. The good forms of this variety are often confounded with *L. præstans*, but the lip in the latter variety is trumpet-shaped, the side lobes overlapping to a very great extent, and the lines on the disc are scarcely discernible. The colour also differs considerably from that of the typical *L. pumila*.—STELLS.

**Cœlogyne fuliginosa.**—This is not a showy plant, but it comes in at a useful time; the growth, moreover, is fresh-looking and pleasing, being bright shining green on both pseudo-bulbs and foliage. Given a light position in a warm, moist house, the growth is very rapid and the flowers occur about three or four on a scape, though but one is usually open at a time. The sepals and petals are brownish, tinted white, the lip having a dusky brown central ridge margined with red. It likes a fairly liberal quantity of compost, and a little leaf-mould is of assistance. Plenty of water is needed while growth is active. It is a native of Northern India, and was introduced in 1838 by Messrs. Loddiges.

**Arachnanthe (Vanda) Lowi.**—A fine specimen of this lovely species was recently noted in flower in the collection of Mr. J. Gurney Fowler, The Glebelands, South Woodford. It has two spikes, each upwards of 9 feet in length, each having thirty-four expanded flowers. It has the characteristic yellow flowers at the base, one having two and the other three. They are bright orange-yellow, dotted with reddish-purple. The others are chocolate-brown, bordered and streaked with yellow. It requires East India house treatment, and should be placed in well-drained pots or baskets, the potting compost consisting of living Sphagnum, which should be made moderately firm about the roots. It requires a liberal supply of moisture both in the atmosphere and at the roots at all seasons of the year.—H. J. C.

**Cattleya labiata at Camberwell.**—This fine species is one of the principal attractions now wherever Orchids are grown, and many beautiful forms are now blooming in Mr. Measures' fine collection at Cambridge Lodge. Out of a large batch

of plants about eighty were flowering, and surely by now those who have been croaking about this fine Cattleya will have had cause to alter their opinion. It is wonderfully varied, one of the finest of all having unfortunately faded just before my visit. The beautiful albino—R. I. Measures' variety—was in flower, the blossoms large and of good substance, the sepals and petals of the purest white. The lip is marked in a very uncommon way, the ground being pure white, but the throat and front lobe distinctly veined with a deep rosy-lilac in place of the usual blotch. Another pretty form had all the segments of a pretty light heliotrope, with lines of deep rose on the lip. A nice plant of the old variety *pieta* was noticeable on account of the narrow, highly-coloured blotch, while other forms were nearly pure white on the outer segments, the lip having a very large, deep crimson-purple blotch. Many others, all more or less distinct, were noted.—R.

#### ORCHIDS AT HILDENLEY.

In the extensive and exceptionally well-grown collection of Orchids at Hildenley there are several batches of seedling *Cypripediums* of unusual merit. In one lot, a cross between *C. bellatulum* and *niveum*, a few have flowered, and the improvement on the parents is decidedly conspicuous. The flower stems are stouter and much longer, raising the flowers quite 7 inches above the foliage. The flowers have the colours of *niveum* and the size and substance of *bellatulum*. One flower I measured was  $2\frac{3}{4}$  inches across. In fact, if one were not told the parentage, one would say that it was a huge *niveum*. In the cultivation of all Orchids Sir Charles Strickland takes a keen and practical interest, and no doubt the knowledge he possesses of their requirements accounts for the more than usual vigour seen in some of the fastidious varieties in his collection. Most of the *Cypripediums* I noted were growing in a gritty kind of yellow loam, to which about an equal portion of very small pieces of broken pots had been added. So well does this root medium suit the plants that they were vigorous in growth and free-flowering, young seedlings springing up freely around the sides of the pots.

*Dendrobium Phalenopsis Schroderianum* in about 100 plants, and almost as many forms, was also very beautiful. Some were bearing very dark, nearly purple-coloured flowers, and others pure white, with the exception of a few light streaks of vermilion on the lip. This form of *D. P. Schroderianum* was certainly very beautiful and worthy of a name more than that it bears, even although, with such diversity of colouring met with in this grand Dendrobe, and the gratifying of almost every taste, named forms might have a tendency to become too numerous. Among them, too, was a very dark-coloured form of exceptional substance, with unusually large flowers.

*Vanda cerulea* was represented by several large plants bearing flowers of abnormal size, and much paler in colour than those I have seen. One of the specimens Mr. Smith, the gardener, told me had just been secured from Mr. Woodall's noted collection at Scarborough at a rather high figure. All the others had been purchased when imported, and grown by Sir Charles into the fine, healthy specimens of four or five growths, bearing grand spikes of bloom. R. C. H.

*Pleurothallis Barberiana*.—The tiny flowers of this Orchid, so lightly set upon the stems that they hardly appear to be attached to it, are now very attractive to anyone interested in these singular and beautiful little plants. The flowers, in fact, when large spikes are plentifully produced, look like a small swarm of gnats hovering over the plant, and this has led to the popular name of Gnat Orchid being given it. Botanically it closely resembles a *Masdevallia*, and is a dwarf tufted plant, the flower-scapes quite invisible at a short distance and bearing about half a dozen flowers on each. The plant is a native of Colombia; therefore a cool, moist house, such as plants from these

alpine localities delight in, must be allowed. Its blossoms at various times in the year, and should, if possible, be grown in very small wooden baskets suspended from the roof. Nearly fill these with drainage, reserving only about the upper inch for compost, and even with this a few nodules of charcoal mixed with Moss and peat are an advantage. During the summer months plenty of air and moisture is necessary, and the sun must not be allowed to shine fully on the plant until November. It was named after Mr. Barber, of Derby, by Reichenbach, and was introduced in 1880 by Messrs. Hugh Low and Co.

*Cymbidium Mastersi*.—This I have noticed in several collections recently, some plants at Mr. Bull's being especially good. In habit it is a good deal like *C. eburneum*, but the foliage is broader and longer. The bloom spikes grow erect, and have the flowers somewhat closely arranged; they are white, and have the lip spotted with red, and a yellow blotch in the throat. These last a long time in perfect condition and emit a pleasant fragrance all the while. It is a rather difficult plant to bring back to health should it get into bad condition, though only ordinary care is required to keep it healthy when once it is thoroughly established. Badly rooted plants should be shaken almost entirely free of compost and then repotted into a much smaller size than before used. The compost for these may consist principally of Sphagnum Moss and charcoal, so as to induce the formation of plenty of new roots, but for strong and healthy plants a good substantial compost may be used. It does best in an intermediate temperature, many plants having been ruined by placing them in strong heat, which always brings a lot of insects in its train. The atmosphere must be kept moist and plenty of water allowed at the roots all the year round. It comes from Assam, and was introduced in 1841.—R.

*Cypripedium H. Ballantine*.—The hybrid *Cypripediums* in which each owns *C. Fairieanum* as one of its parents, provide us with some of the most interesting and beautiful forms yet obtained. As *C. Fairieanum* has now become almost extinct, and to all appearance baffles all the efforts of the Orchid importers to re-discover, these hybrids must to a very great extent remain rare and valuable. Take for example *C. vexillarium*, the first of the section that was raised by the late John Pominy. It is still one of the most popular, and is likely to be one of the most sought after for many years to come. *C. H. Ballantine* is one of the most distinct and beautiful of the group, and was raised in Messrs. Veitch's nursery at Chelsea from *C. purpuratum* crossed with *C. Fairieanum*. Its dorsal sepal has the characteristics of *C. purpuratum* with broad purple, longitudinal lines extending from the base almost to the top. The petals also partake more of the seed parent's character than any of the other *Fairieanum* crosses. They are broader, straighter, and not nearly so deflexed, purple in colour, lined and spotted with darker purple. The growth is dwarf and has the intermediate characteristics of the two species used in its production. Unfortunately, it is of delicate constitution. I find it does best when grown in the cool intermediate house. A plant in fine condition was recently exhibited at the Drill Hall by Messrs. F. Sander and Co., of St. Albans.—H. C.

#### SHORT NOTES.—ORCHIDS.

*Cattleya marseillensis* (*C. aurea* × *C. Trianae*) is a lovely form, with pale blush-rose sepals and petals, the lip rich crimson-purple, margined with deep rose, the side lobes blush white, shading to yellow, heavily lined with purple at the base. A fine plant, carrying a raceme of three flowers, was recently in flower in the collection of the Rt. Hon. J. Chamberlain, High-bury, Birmingham.—H. J. C.

*Lælio-Cattleya broomfieldensis* (*L. Dayana* × *C. aurea*).—The general characters of the flower are intermediate between those of the two parents. The large lip is rich velvety crimson in front, the side lobes of the same colour, mottled with yellow and

lined with a deeper purple at the base. The growth has the intermediate characters of both parents. It was raised in Mr. N. Cookson's collection at Oakwood.—S. C.

*Cattleya Mrs. Endicott* (*C. maxima* × *Loddigesii*).—This is a lovely hybrid, the sepals and petals similar in shape to those of *Cattleya Loddigesii* the colour also being similar. The lip is deep rosy purple, veined, as in *Cattleya maxima*, with deep purple. It has a broad band of deep purple through the centre. A plant of this lovely hybrid was recently exhibited from the collection of the Right Hon. Chamberlain, Highbury, Birmingham.

*Cypripedium Memoria Moënsi*.—This is a lovely form of the *Leeanum* section. The dorsal sepal is white at the top heavily suffused with deep purple, which is darkest in the centre, the petals pale green heavily suffused with dark brown, the lip green suffused with purple. It is of continental origin, the parentage being doubtful. There can be little question about its having *C. Spicerianum* as one parent. It does best when grown in the warm intermediate department.—S. C.

*Phaius Ashworthianus*.—This is a cross between *P. Manni* and *P. maculatus*. The sepals and petals are yellow suffused with dark brown, the lip yellow lined from the front to the base with brown. The foliage has the intermediate character of both parents, with the characteristic spotting of *maculatus*. It is remarkably free-flowering. It was raised in Messrs. F. Sander and Co.'s nursery at Albans, where it was recently noted in flower.—S. C.

*Lælio-Cattleya Daphne* (*C. Mossiae* × *elegans alba*). In this the sepals are pale bluish petals white, veined on the edges with purple; the front lobe of the lip rich crimson-purple, the side lobes pale rose, with prominent yellow markings in the centre. The growth is intermediate in character between the two species used in its production. It has recently flowered in Messrs. J. Veitch and Sons' nursery, and is a distinct and desirable variety.—H. J. C.

*Cattleya Comfrey* (*C. Lawrenceana* × *Warszewiczii*).—This lovely hybrid has in many degrees the influence of both parents. The petals delicate rose, the lip rich crimson-purple, margined with rose; the upper lobes blush-rose shading white, which latter forms the two discs as in *Warszewiczii*. It has some yellow lined with purple at the base. A two-flowered plant of this hybrid was recently exhibited at the Drill Hall Mr. C. J. Ingram.—H. J. C.

*Cattleya Portia* (*C. Bowringiana* × *C. labiata*). The sepals and petals are deep rose, of fine shape and substance, the lip rich crimson-purple, the side lobes purple, shading to yellow, suffused with brown at the base. This is one of the most beautiful of the *Bowringiana* crosses, and the whole of this set of hybrids improves as the plants get stronger. This one of the most promising hybrids amongst them, was raised in Messrs. Veitch and Sons' nursery, where it was recently noted in flower.—S. C.

*Cypripedium insignae* (Harefield Hall var).—This is a gigantic form, the dorsal sepal 3 inches across, white at the top, the base two-thirds pale greenish yellow, heavily spotted with reddish brown, the lower sepal greenish yellow, thickly spotted with brown at the base; the large petals greenish yellow with a brown suffusion. The lip also is large, yellow, suffused with brown. It is a most remarkable variety, which originated in Mr. E. Ashworth's collection at Wilmslow.—S. C.

*Cattleya Eurydice* (*C. labiata* × *C. Aclandii*).—This is a distinct and desirable variety raised in Messrs. Veitch's nursery, and has the intermediate characters of the parents both in the flower and growth. The sepals and petals are deep rose, spotted with purple at the edges, the spoon-shaped lip deep crimson-purple, shading to deep orange-yellow at the base, the side lobes pale rose, shading to reddish brown at the base. Hybrids from *C. Aclandii* are rarely met with, but it deserves more attention from hybridists.—H. J. C.

*Cymbidium Winnianum*.—This, said to be the result of crossing *C. eburneum* and *C. giganteum*, is a distinct and lovely hybrid raised in the collection of Mr. C. Winn at Birmingham. The sepals and petals are creamy white, the lip similar in colour, with a broad band of yellow down the centre and thickly spotted with reddish-brown spots. A fine plant with two dense spikes of flower was recently noted. The density of the spikes and general characters of the plants suggest that there is some mistake in parentage, but *C. Mastersianum* is very prominent, and might possibly have been one of the parents.—H. J. C.

EXHIBITING ALPINE AND ROCK PLANTS.

SEVENTY years ago we were wont to see really good specimens of many alpiners in the early spring exhibitions both in London and Manchester, plants, moreover, that had been grown at least six months, and others a much longer period, in the pots as exhibited. These were always interesting because shown in a natural way—that is, in so far as their growth in pots permitted. Chief among the exhibitors of these things were Mr. R. Parker, Mr. Ware and the firm of Barr and Sugden. The last, at least once or twice a year, made a special feature of exhibiting in large boxes good representative collections of Sedums, Saxifrages and Empervivums, the plants invariably being in large tufts that would give a good idea of the established masses of such things in any ordinary rock garden. The plants attracted a good deal of notice. Exhibits of this kind, however,

the present time, however, and for the past few years a change has been noticeable in the mode of exhibiting these things, and occasionally those interested in the beautiful alpiners may turn with pleasure to the exhibits of rock plants that Messrs. Backhouse, of York, and the Guildford Hardy Plant Company in particular have made so pronounced a success. These exhibits have now become a portion of the Temple show each year, as also occasionally at the Drill Hall, to say nothing of provincial shows.

What strikes one most of all is the naturalness of these exhibits, and the pleasing manner in which the plants are disposed at once displays a knowledge of the subjects in their native haunts. Instruction of this kind is far better than words, for no amount of description could possibly portray what is contained in the accompanying illustration, which depicts a corner of one of these rockwork exhibits planted with alpiners in flower for the

kin and other Primroses, Sundews in variety, the alpine Anemones with their beautiful cups, vernal Gentians, *Mertensia sibirica*, mountain Columbines, *Lithospermum tinctorium*, alpine Forget-me-not, the American Maiden-hair (*Adiantum pedatum*), and numbers of others grouped in the charming fashion so well depicted in the illustration. By no means the least pleasing feature of these alpine exhibits is the established character of the examples employed, the complete furnishing, and the entire absence of new work. Even the selection of weather-beaten stones is not forgotten, and greatly assists the beauty of arrangements of this kind.

E. JENKINS.

Hampton Hill.

**Water Lilies in small tanks.**—You were good enough to publish one or two notes on these charming flowers in February, 1896, and I would now venture to trouble you again in hopes of stimulating more persons to take up their cultiva-

Corner in exhibit of alpine plants from the Guildford Hardy Plant Company. From a photograph sent by Mr. H. Selze-Leonardi.

...sel from notice after a while, and in their ad a collection of small pot plants, with ny flowers for the most part, or others haps with only a solitary flower, for a e seemed to be the order of the day. This method, as it justly deserved, was short- ed, and no doubt the frequent rebukes of the edening press assisted materially to this end. the present time, in place of the multitude small pots, the chief mode of exhibiting the bit hardy flowers is by bunches in a cut ste. And here also there is a want of thought as well as consistency, particularly in those nces where the large and small, the rare and amon, the good and the indifferent are all ight to the place of meeting simply because ty happen to be in flower on that particular d. In a very large number of instances h a gathering, too often crowded and over- de, receives no attention, even if a pass- h thought. Such collections are ruined by air density as much as their numbers. At

most part. The charming way in which the plants are disposed favours a natural ledge of rock on the mountain-side more than ought else. The beautiful flowering group of Edelweiss in the left-hand corner of the picture and the long-leaved Rockfoil (*Saxifraga longifolia*), so well represented by flowering examples, and the equally picturesque dormant rosettes are all so naturally placed, that they appear to have had possession for years. The same applies to the well-flowered *Ramondia* at the right-hand bottom corner and elsewhere. In some of Messrs. Backhouse's exhibits of this kind positions are made for the accommodation of a large number of plants, from the most elegant of the Bamboos in a small state and Filmy Ferns to the rare and choicest of mountain-side plants or shrubs. The usual date of the Temple show finds many good alpiners in flower, and from time to time I have noticed the hardy *Cypripediums*, a variety of alpine *Pinks*, *Soldanellas*, *Opuntias*, *Saponaria*, *Sik-*

tion and of eliciting the experience of those who do grow them. Finding the varieties I had do so well, I this year made my pond somewhat larger and added one or two new kinds, all of which have flowered. The first of the old ones to blossom was *N. Laydekeri rosea* on May 23, and it continued without intermission for several months; next came one plant of *N. alba*, the common white, then *N. pygmaea alba*, on June 6 *N. pygmaea helvola*, and then the others in a rush. The plants received in April—*N. Marliacea albida*, *N. M. carnea*, and *N. odorata sulphurea* flowered later. I would like to have the experience of others as to the odorata section. *N. odorata rubra* bloomed very well this year, one flower as late as October 2, but it often seems to have its buds deformed. *N. o. exquisita* generally flowers, but sparingly, in August. *N. o. alba* does practically no good. Of *N. o. sulphurea* I cannot say much yet, but it seems a tree grower. Mr. Burbidge tells me he cannot keep this group at all in his pond where *N. Marliacea Chromatella*, *N. M. carnea*, *N. M. albida*, and others grow magnificently. There is a constant current flowing though this pond,

which keeps down the temperature, which often in my pool rises to nearly 5° from sun-heat. I am inclined to think that the odorata section wants more warmth than the others, perhaps more sunshine also; or can it be that they want baking in the mud when at rest? With me they are always covered with water. In fact, the water is so warm, that gold fish breed freely. I had dozens of young ones this year. How many will survive the winter it is hard to say. If the facility with which these charming plants can be grown in quite little gardens were better known I am convinced many now ugly fountain basins would soon be covered with the leaves and blossoms of this charming genus.—GREENWOOD P.M.

## STOVE AND GREENHOUSE.

### BOUVARDIAS FOR CUTTING.

For some years I grew these in the best sorts for market both for cutting and for pot plants, and quite agree with what "R." has advanced at page 380 of THE GARDEN. That these things have fallen into neglect there is no doubt, but I incline to the belief that, from a mistaken view of the requirements of the plants, many have endeavoured to grow them in structures far too warm to be beneficial to the plants. And growing such things in houses that are overheated will quickly bring disease and insect pests. Few things are easier if brought on in the early stages of growth in a warm greenhouse instead of the stove, frequently, as I have seen them, in company with Gardenias and such plants, when as a fact the plants would have been far happier with the Pelargoniums. The soft fresh cuttings of course may be rooted in some warmth and on bottom-heat, but, so far as the after-culture is concerned, the finest bushes are those grown in a much cooler temperature, so long indeed as the plants require any heat whatsoever.

As a rule the private gardener permits his plants to become too leggy before any pinching is done, and if the aim, as is usually the case, is the production of cut flowers, this is a mistake. Take, for instance, a cutting just rooted of any of the perpetual bloomers, e.g., Hogarth or elegans, and having three pairs of leaves. Such a plant will be best potted at once into a 2-inch pot, and a week hence, when the roots have taken to the soil, take out the point. In a short time two shoots usually start from this stopping, and when these again have made two joints each, the points may be again taken out. This may be repeated till a sufficient number of breaks is apparent. Frequently by the time the plants are ready for 5-inch pots, compact bushes, carrying eight to a dozen growths, result, the plants often throwing up radical shoots also as a result of the continued stopping. These basal growths are usually strong and must not be allowed to go unchecked, or the smaller breaks will suffer in consequence. Cuttings rooted in January should make fine plants provided they are grown cool and are potted in good material and quite firmly. A good mixture for pot culture is two parts good fibrous loam, one part leaf soil, and one part peat siftings. To this may be added some sharp grit and about two pecks of finely-sifted manure to each barrowload of the soil, together with a shovelful of bone-meal to the same. This thoroughly mix and allow to become so dry that, without any adhesiveness whatever, it may be rammed quite firmly in the pots. Firm potting or planting, as pointed out by "R.," is most important, and frequently good plants are more or less endangered by the neglect of this simple rule.

Growth may be abundant, it is true, but it will be of a character that does not give the best return in flowers.

### PLANTING OUT.

Much the simplest way to grow these useful plants is to plant them out the first week in May in a frame with a hard ash bottom, into which a depth of from 4 inches to 6 inches of prepared soil has been placed. Make the soil moderately firm and arrange the plants a foot apart each way; afterwards make the soil firm about the plants and over the entire surface. In this the plants may not require any moisture for a few days, when a good watering may be given. As soon as all fear of frost is past the lights may be entirely removed and the plants left very much to themselves. Any further pinching should be completed by the middle or end of June at the latest. Late propagated stock of the previous year may be cut back and similarly treated in frames or a good position in the border. These plants will be best if, instead of being pinched, they are cut over with a knife at the end of June, allowing several strong shoots to grow on to flowering. Great care should be taken to keep the plants free of mealy bug, as once this obtains a footing it is most difficult to eradicate. Planting-out of Bouvardias is not indulged in to the extent it deserves, and particularly where the plants can be placed on a hard bottom they lift with but little loss of root. Even where no frame can be spared, a couple of boards will be found quite equal to the needs of the plants so long as the soil can be kept to the plants. During summer the frequent use of the syringe and occasional doses of soot water, both overhead and at the root, will be found helpful, and greatly conduce to all-round healthy growth. Although I have suggested a special mixture of soil above, such, indeed, is not essential for plants in the open ground. Indeed, the finest lot of plants in the open I have ever seen—and there were some hundreds in all the best kinds—was planted in strong loam on a south border, and though it was considered a much too heavy soil at the time of planting, it was only lightened by a free addition of leaf soil and short manure. The plants were young cut-backs, having been propagated in the previous May and flowered in 4½-inch pots the ensuing winter. When planted in the open border they were rather more than a year old, and, beyond being cut down some time previous, received no other stopping. As a result, the plants began to flower in August and produced a really wonderful supply till the end of the year. Even while still in the open the bloom taken from them was enormous, vastly superior to what one is accustomed to see in these plants; and I feel convinced, if gardeners more generally realised what could be done with Bouvardias in this way, they would take measures to obtain a constant supply for themselves. All the best of the perpetual-flowering kinds are worth growing in this way, as also jasminoides, but the more vigorous growers—viz., *B. corymbiflora* Humboldt and others of the same type—are of little value by comparison. E. J.

**Begonia Gloire de Lorraine.**—In the No. 7 greenhouse at Kew are many plants of this excellent winter-flowering kind. The plants here are quite distinct from the lovely examples recently brought to the Drill Hall, as they are untrained and produce their wealth of charming flowers in a natural trailing manner. Quite small plants when raised on pots are very beautiful in this way, and especially attractive are larger examples similarly grown when used in baskets. In a private garden lately visited some fine plants were raised

above a groundwork of *Adiantum Farleyense* an interspersed with *Asparagus plumosus nanus* and small *Geonoma gracilis*, a charming effect being obtained. All the plants were of light, graceful bearing, and a sort of transparent habit being aimed at, the effect was very telling.

**Vallota purpurea.**—As is usual at this season of the year, this handsome bulbous plant may be often seen flowering in the window of the cottager, who in many instances bestows but little care on it. While admittedly an easily grown plant, it does not follow that anyone can obtain anything approaching a good display of flowers by a system of general indifference and a more or less abundant supply of water at all seasons. By a little timely help and the addition of some good sweet loam, and above all things good drainage and firm potting, this old-fashioned flower may be made one of the most attractive window plants in its day. By potting the bulb every second or third year in August, at the same time sorting them into sizes, the amateur may soon possess a stock of bulbs that could not possibly all flower at the same time. Six large flowering bulbs in an 8-inch pot would make fine display, while the smaller bulbs may be planted six in a 5-inch pot for future use. After a season's growth in this pot a shift may be given and in this way clean flowering bulbs won result, instead of, as now, a crowded colony undersized bulbs in a large pot, and only an occasional one to produce a spike of bloom.

**Grevillea alpina.**—Several of the Grevillea are very pretty flowering greenhouse shrubs, and by no means exacting in their cultural requirements. Some of them bloom during the autumn and winter months, among them being *G. alpina* which forms a roundish bush that flowers freely when not more than a foot high. The oblong leaves, which are each about an inch in length are clothed with greyish pubescence. The flowers which are borne in small clusters at the ends of the shoots, are of a rosy-red colour tipped with yellow. This species is a native of the southern portion of Australia, being principally found in mountainous districts. It has been grown in this country for the last forty years, but, in common with many other plants of this class, it is not rarely seen. Another species still in flower, which stage it has been for some time, is *Thelemanniana*, which is of a loose, graceful habit of growth and has light, elegant foliage, the bright green leaves being divided into several narrow linear segments. The flowers are borne in dense clusters at the ends of the shoots, the weight causing them to droop considerably. The body of the flower is a kind of reddish pin while the prominent style is of a much deeper tint. It is a native of the Swan River territory in Australia, and is frequently met with under the name of *G. Preissi*.—H. P.

**Varieties of Bouvardia.**—On p. 380 under the heading of Bouvardias for cutting there are few varieties mentioned, but two or three are most certainly to be included. The first is the American-raised President Cleveland, which just ten years ago attracted a great deal of attention owing to the fact that it was greatly superior to any of the other bright-coloured kinds, leaving, it did, Hogarth and Dazzler, which then held the field, far behind. It is now largely grown wherever these beautiful flowers are cultivated. A second variety, which originated as a sport from the preceding, is Mrs. R. Green, the flowers of which are of a pleasing shade of salmon-pink. In freedom of growth, flowering, and habit it is the counterpart of the others. These two varieties were shown together on a coloured plate in THE GARDEN, March 30, 1889. The variety Vreeland met with also under other names, is well worth of inclusion in any list. The flowers of this are white, but in an exposed position slightly tinged with pink. Bouvardias are not so much grown in the neighbourhood of London as was at one time the case, for within the area of the sulphur-laden fogs they cannot be depended upon, as a plant at this time of the year will change a beautiful

of flowering plants into miserable objects, though all the leaves burnt as if by fire. The flowers not suffer so much as the foliage.—H. P.

FLOWER GARDEN.

ACHILLEA.

(MILFOIL OR YARROW.)

In this somewhat extensive genus we have many beautiful and useful kinds suited either for the border or the rock garden, while a few also

*Achillea filipendula.*

like *Eupatorium*, *A. macrophylla*, *A. magna* and *A. nobilis*, for example—should be much more freely grown. For this purpose perhaps none is better suited than the species mentioned above, and if not unduly crowded by other plants, and trees in particular, play a conspicuous part in the garden. By far the largest number of species are of quite easy culture, the majority succeeding perfectly well in deep and richly good sandy soils, and the more vigorous kinds in a somewhat heavier soil. Almost all the dwarf tufted species are of easy culture in light loam, made fairly rich, and when planted, they should be, freely in groups in the rock garden, care should be taken that a liberal depth of soil is afforded them. Too frequently

*Achillea macrophylla.*

In our lowland gardens the veriest alpine gems, many of which are of the easiest culture, suffer and perish because planted in the smallest scrap of earth. These plants really die of starvation—a lack of moisture and food generally, a mistake in measure due to their frequently minute growth. At the same time many of these things in their mountain homes send their

roots down in rocky crevices to great depths, and there receive a never-failing supply of nourishment. For these reasons plants under cultivation should, if we would see their best

*Achillea rosea.*

side, at least receive a good depth of suitable soil, according to their kind. The taller kinds better suited to the border are all readily increased by division, some of them to any extent, while the dwarfier kinds in many instances submit to the same treatment and also produce seeds with some freedom. Such kinds as *A. ptarmica* and *A. serrata* with their varieties, by reason of the abundance of stoloniferous shoots, should not be planted in the ordinary border, but in a plot set apart. These may also be naturalised in other parts of the garden. The following species are worthy of attention:—

**ACHILLEA AEGYPTIACA.**—A useful border perennial, growing from 1½ feet to 2½ feet high and producing large terminal corymbs of bright yellow, often 4 inches or 5 inches across. The plant is of excellent habit and valuable for its beautiful and effective silvery foliage. This useful perennial is of easy culture in any good sandy soil, and may be freely increased by division, preferably in the early part of the year. Native of the Levant.

**A. AGERATIFOLIA.**—The species referred to here has been hitherto described under the (I believe) erroneous name *A. ageratoides*, and again in the "Dictionary of Gardening" under *A. Ageratum* (the Sweet Maudlin), an obviously distinct and very old species with heads of yellow flowers from 1½ feet to 2 feet high. The above species, *A. ageratifolia*, for some years known as *Anthemis Aizoon*, produces beautiful rosettes of silvery leaves with crimped margins that lie close upon the soil. The flowers, too, each as large as a shilling when well grown, are pure white with pale yellow disc, and are borne singly on stems some 8 inches high. This lovely Grecian species is a gem for the rock garden, where it should be planted in deep, gritty soil in a sunny spot. Increased by very careful division in early spring,

*Achillea Ptarmica fl. pl.*

by cuttings in August, and by seeds, it is one of the choicest of this large race of composites.

**A. AGERATUM** (Sweet Maudlin).—A distinct species with green entire leaves and corymbs of yellow flowers. As implied in its specific name,

the growth, and the radical leaves in particular, bear some resemblance to *Ageratum*. It is from 1½ feet to 2 feet high, and flowers from August to October. South Europe.

**A. ASPLENIFOLIA.**—A North American species that is not in general cultivation, yet is worthy of more attention on account of its neat foliage and rose-pink blossoms. The latter are rather small, and produced in a compound corymb during the summer.

**A. ARGENTEA.**—A neat-growing and attractive species, sufficiently pleasing and effective on rock-work to merit its being freely grown for its pretty silvery foliage. This is produced in compact

*Achillea Clavenna.*

tufts, the numerous heads of pure white flowers appearing in spring. The plant may be increased by division or by cuttings.

**A. AUREA.**—This is placed here in order and in specific rank, though there is no definite information forthcoming concerning it. In the "Dictionary of Gardening" it is described as having "golden flower-heads, borne singly on stems 18 inches high, and sometimes confused with *A. ageratifolia*." The latter, however, has the ray florets white, not golden, hence little need for confusion arises. No such species, I believe, exists in the herbarium at Kew or in cultivation in the gardens. The plant, freely catalogued and grown in nurseries, is either a variety of, or identical

*Achillea tomentosa.*

with *A. tomentosa*, a species having corymbs of flowers at about 8 inches high or thereabouts.

**A. CLAVENNA.**—This is a very old and well-marked species from the Austrian Alps, and may readily be distinguished by its silvery tufted growth and bi-pinnatifid leaves. It is an excellent species for planting freely on sunny banks or on rockwork, and when in flower the large heads of white blossoms are most effective. This species is about 9 inches high and being of free growth is readily increased.

**A. EUPATORIUM.**—This is one of the boldest members of this family, a fine vigorous perennial that is well known and frequently seen in gardens. The plant grows about 4 feet high, and is specially

suit for grouping. The habit of the plant is good, and the large flat heads of yellow blossoms, often 5 inches across, retain their beauty for a long time. In large gardens this species should be increased and planted in bold masses. In such, if given a fair amount of space, no staking will be needed, and at a short distance the effect will surprise and please. Any quantity may be had by division of the roots in early spring. Caucasus.

**A. HERBA-ROTA.**—Though scarcely so worthy of a position in the border as many species, it is interesting on account of the perfume that follows the touch. It is a true herbaceous perennial, a foot or more high, and bears white flowers in loose corymbs.

**A. MACROPHYLLA**, as may be inferred, belongs to the larger kinds, producing small white flowers in rather large corymbs at 3 feet or 4 feet high. This species together with *A. magna*, with its large yellow heads at 4 feet or more high, would make good companions for *A. Eupatorium*. All are summer flowering and remain good a long time.

**A. MILLEFOLIUM ROSEA.**—In this instance the species is ignored for the sake of its superior variety, *rosea* or *rubra* as it is sometimes called. The plant is so well known that no description is necessary. This fine perennial, however, is worth a place in every garden for the effective mass of colour.

**A. MONGOLICA.**—This species bears masses of pure white elegant blossoms in May and June long before the other kinds are in flower. Very attractive are the blossoms by reason of their purity and most useful in the border or for cutting. The species should be grown in all gardens. It is 2 feet high, of easy growth, and readily increased by division. A native of Siberia.

**A. MOSCHATA.**—A low-growing alpine partaking of the leaf character and growth of *A. umbellata*, and requiring the same treatment. The leaves are woolly and deeply cut, stems sub-shrubby, flower heads white, 4 inches to 6 inches high and flowering from June to August. Europe.

**A. NANA.**—A very dwarf Italian species not often seen in cultivation, yet a very pretty kind for the rock garden. The plant is reputedly difficult to grow and flower in low districts on account of a somewhat weakly constitution. The foliage, deep green and in a clustered rosette, lies closely upon the earth; flower heads white.

**A. NOBILIS**, with Tansy-like leaves, is of robust growth, and better suited to the woodland or shrubbery.

**A. ODORATA.**—A Spanish kind with white flower heads. It is a dwarf species of half a foot high.

**A. PTARMICA FL-PL.** (double Sneezewort).—This useful variety is, perhaps, the best known of the entire genus, and provides a great supply of pure white blossom in terminal corymbs throughout the summer. As it produces stoloniferous shoots freely, the plant should be given a place apart from the ordinary border subjects. For cutting it is very serviceable, and, again, in the shrubbery it would give a mass of bloom for a long period. The plant is 2½ feet high, and grows freely in almost any soil. Several modern forms of this plant are now catalogued, The Pearl, *elegans plena*, and *Snowball* being of the number.

**A. RUPESTRIS.**—This species I regard as among the most important of dwarf kinds, for the reason that its pretty heads of pure white flowers spring from a low prostrate tuft of leaves. In many species the white flower-heads and silvery leaves render the plants less attractive, though the foliage and flowers are in themselves pretty enough. The above species is worthy of care, and should be planted in a warm position in the rock garden in a mixture of gritty loam and leaf soil. It is a native of Southern Italy, growing 4 inches to 6 inches high, and commences to flower in May. The plant may be increased in early spring by careful division and by seeds.

**A. SERRATA PLENA** in many respects resembles *A. Ptarmica plena*, differing from it in the deeply serrated leaves. It is a creeping kind like the double Sneezewort, yet scarcely so free-flowering

or generally useful. The typical species belongs to Switzerland.

**A. TOMENTOSA.**—A well-known species of low tufted growth, and one of the most useful for forming edgings or planting freely in masses in the rock garden. The plant reaches about 9 inches high, producing many flowers in large compound corymbs from amid a dense tuft of greenish and rather woolly bipinnatifid leaves. The rich glow of its large flower-heads renders it a useful plant, and for many positions and purposes its perfect hardiness and freedom are among its best attributes. It flowers in early summer and may be increased to any extent by cuttings or by division. The latter is very simple, as the plant not infrequently roots freely from the under surface of the stems, and by pegging down to the soil may be depended upon to root in a few weeks, particularly early autumn.

**A. TRANSYLVANICA.**—A strong-growing species of about 3 feet high, the deeply-cut foliage covered with a rather dense pubescence. The flower-heads are of a golden yellow hue, and in shape partake of the character of the better-known *A. Eupatorium*. It is a good border plant, of free growth.

**A. TRAUTMANNI.**—A very pretty and useful species from Austria, producing freely its umbels of white flowers at 6 inches or 8 inches high. The tufted growth is composed of rather long, linear and deeply serrated leaves, the latter strongly resembling those of the taller border kind, *A. serrata*, in this respect. In this kind the deep green leaves with white flowers form a welcome change. It is a species that with advantage may be utilised for hybridising, being of free growth, easy culture, and quite hardy.

**A. UMBELLATA.**—A low, almost sub-shrubby alpine with silvery foliage regularly and deeply lobed, the lobes, which are entire, extending to the midrib. In light warm soils the growth of this species is free, and in the rock garden in large patches it is sure to catch the eye. In the Tooting nurseries the growth was so free, that edgings 150 feet long were formed to the beds, and in this position the plants spread out into mounds of silvery white leaves, that were an attraction when the mass of white flowers was past. It is a Grecian species, of easy culture in light soils, and may be increased freely by division in early spring.

**A. VALLESIIACA.**—A pretty Swiss species with white flowers and pinnate leaves, growing about 9 inches high. It is a rare plant in cultivation.

The foregoing are the most important of those in general cultivation. A few others—such as *atrata*, *decolorans*, *Huteri* and *Richardiana*—are worthy of mention. Beyond these, however, an important series, some of which are quite new species and others of hybrid origin from distinct parentage, should prove of great interest in the coming year. All that is known of the hybrid portion is their parentage, and, judging from the remarkable character of their foliage in some instances, some valuable additions to this group may be expected, and their flowering will be eagerly looked forward to.

E. J.

**Helleborus altifolius.**—The earliest blooms of this handsome perennial are now nearing expansion, and those who value these valuable flowers will take care the clumps receive some timely covering. Near London during the past week or two the beauty of almost everything in the open has been marred by the dense fogs that have been so prevalent. With such weather we can only hope to preserve the true beauty of these winter flowers by some temporary covering so soon as the flowers burst away from the crowns, which in the case of the above variety is very early indeed. In the border, however, the effect produced by a few well-grown and established clumps of these things is great, and no plant better repays a special depth of good soil to root into. At least 2 feet deep of this and a position

not too much exposed to the sun should secure good plants in the course of a couple of the years. Mr. Wilson sends us from his garden Wisley some very fine flowers of this as well several bunches of Primroses.

## FLOWERS IN NOVEMBER.

WITH us this extraordinary open weather has given quite a second summer to the flowers, and there are now over sixty different varieties of plants and shrubs in bloom in my garden. I enclose you a list of those I noticed this morning (November 14), thinking it might interest you readers.

## SHRUBS.

Chamaecerasus Morrowi	Fuchsia pumila
Clematis Henryi	coccinea
flammula	Riccartoni
Ceanothus Gloire de Ver-	Genista tinctoria
sailles	Hypericum Moserianum
Diplopappus	Spiraea Anthony Waterer
Also Roses, H.T., T., and H.P.	

## HARDY PLANTS.

Anemone (Japanese) Lady Ardilaun	Henchera sanguinea
Achillea Eupatorium	Helenium striatum
Auricula alpina	Linum flavum
Aster Nova-Angliae and Novi-Belgii	Matthiola (Brompton)
Astragalus major	Oenothera Youngi
Borago officinalis	fruticosa major biennis
Coreopsis grandiflora	Primrose hybrids
Chrysanthemum maximum	Phlox (tall white)
Campanula pyramidalis	Pansies
Backhousei	Potentillas
Centauria cyanus	Polemonium reptans
Doronicum plantagineum	Papaver chinense
excelsum	Rudbeckia nitida
Dielytra eximia	Reseda odorata
Dianthus barbatus	Stenactis speciosa
Erodium	Scolymus hispanicus
Erigeron caucasicus	Scabiosa caucasica
Funkia marginata	Senecio pulcher
Geranium sanguineum	Thalictrum glaucum
Endresi	Tagetes erecta
Geum montanum maximum	Tradescantia virginicaea
coccineum	Tropeolum majus minus
Gaillardia maxima	Viola californica
Helleborus	Veronica prostrata the shrubby forms.
Hieracium aurantiacum	

—F. MITCHELL, *Rush Green, Hertford.*

— I notice some correspondents have sent you a list of plants still in flower. I find the following plants in bloom:—

Alonsoa	Honeysuckle
Ageratum	Jasminum nudiflorum
Agrostemma coronaria	Lobelia (blue)
White Arum in ponds	Love-lies-bleeding
Aponogeton	Mignonette (tree and annual)
Anemone japonica	Mallow (perennial and annual)
Annual Phlox	Nasturtium
Bladder Saxa	Oxalis (purple)
Berberis Darwini	Eurotia and varieties
Chrysanthemums (various)	Paris Daisy (yellow and white)
Tropeolum carariense	Yellow Scotch Daisy
Ceanothus	Pansies
Gloisya	Pernettya
Cotoneaster and varieties	Roses in great variety
Dahlia (various)	Romneya Coulteri
Daphne	Sweet William
Eryugium amethystinum	Spiraea (one variety)
Eschscholtzia (various)	Snapdragon
Escallonia macrantha	Stocks
montevicensis	Salpiglossis
Fuchsia	Schizostylis
Flax (common and red)	Shirley Poppy
Glaucolobus	Stokesia
Gaillardia (various)	Tritoma (two varieties)
Godetia	Valerian
Gaultheria Shallon	Weigela (white)
Hydrangea	
Hypericum	
Heliotrope	

—MEDWAY.

**Flowers in Derbyshire.**—It is very interesting reading in THE GARDEN the flowering of various plants, but most of the notes are from

ourable localities. When we get such results North Derbyshire as we are still enjoying at its date it seems more remarkable. Roses (minas), 400 to 500 plants on their own roots, are full flower and are a mass of buds. China Roses cottages all round are yet full of flower. Tea rose Opbir is one of the best for buds grown out-let. Every plant is still producing good flowers, from cuttings. Marie van Houtte, too, on a west wall is full of fresh buds, that open well gathered and put into water. Rosa rugosa me. Geo. Bruant does grandly here; the beautiful pure white buds are still with us, in massive bushes in sunless aspects. Isaac Periere (climbing) is a massive flower. I find the best cuttings for striking are the flower-stems, after the flowers have done their work in water or on the plant. These Roses are grown in the open orchard, laid out in beds and grass walks. I have noted, amongst the many lists of late flowers in THE GARDEN, no mention is made of Gladioli. I gathered a few good spikes on November 15. They have been plentiful up till now, mostly our own seedlings, all sown in the open ground and planted in rows amongst dwarf Apple trees. Every three or four years they are taken up, tested and replanted in early spring. All varieties seem to be perfectly hardy here. The Bride is marvellously in all sorts of places; it is several inches high already, also General Scott and other early varieties. G. Colvillei has been in leaders here in one place over twenty years. Sweet Peas are still flowering, and some varieties possess later constitutions than others. Venus, the best call for cutting, is good yet. I have four glasses of flowers by me now; it is deeper in tint, with a distinct edging. America is another good late one, though, being flaked, is not a favourite. I have just gathered a good handful of Heliotrope flowers and a bunch of Aloysia citriodora. Carnations (Marguerite) planted and hanging down a wall are full of buds and partially opened flowers. This is a happy way of planting Carnations.—GEO. BOLAS, Hopton Hall, Wirksworth.

## NOVEMBER ON THE RIVIERA.

ALASSIO, a primitive and delightful little place, perhaps the greenest spot on the Western Riviera. The remarkable shelter of its little bay, combined with a good water supply, makes it a paradise for those who love a garden. There are now quite a number of villas in what is prettily called the "Happy Valley," built by Englishmen who care for their gardens, and who show that by energy and skill most wonderful results can be produced in the shelter of Alasio, equal, if not superior, to any other place on this favoured coast. Nowhere else have I seen such trees of the stately *Salvia frutescens*, now laden with heavy branching panicles of bloom which weigh down the long leafy stems till they look as if they must break. Why its beautiful scarlet-calyced blooms are so little known and grown in England is a mystery when once one has seen how superior it is to any neat bush, even of the finest form of *Salvia splendens*, for a big conservatory. There is, of course, "room for both," but while the former needs planting out, the latter is content with a pot. *Tecoma jasminoides* flowering freely, but not merely content with showing a pink eye-flower here and there, is so pretty that even the brilliant *Tecoma capensis* with its scarlet heads, has to yield in beauty to it. A fine *Monia* with large pale pink trumpets and a red throat is new to me, and its name as pronounced by Italian lips is so extraordinary, I dare not put it on paper till I have verified it. Its beauty is undeniable, whatever its name may be. The deep blue and the red *Lochromas* are so splendidly handsome just now, their long summer buds rich in foliage and clusters of pendent bloom.

All these lovely things, however, pale before the brilliant beauty of the rich blue-purple *Ipomoea* *holia*, perennial in growth and greatly superior to the annual Morning Glories so well known in

England; and when one sees as I did, a tree-like bush of *Datura arborea*, laden with its white trumpets, half covered with the brilliant spikes of *Mina lobata* that had clambered up through it and mingled above with the standard *Clive* and *Ipomoea* behind, it is impossible to deny the superior charms of autumn in this climate to the keener air of spring, even though one may miss the charm of the familiar Banksian Roses and rich purple *Bougainvillea*. *Dahlia imperialis* with its tall Lily-like spikes of bloom stands out in stately beauty from a groundwork of *Zinnias*, splendid in colouring and so dwarf in habit that they would be invaluable in England, where they really succeed. All around are Roses in profusion with *Heliotropes*, *Plumbago* and *Geraniums* in such abundance of bloom and beauty that one longs for a sixth sense, not only to enjoy it the more, but to enable others to do so also, and failing that, the next best thing would be to persuade others to come out and see for themselves what the clear skies and hot suns of November can produce on these southern shores not two days' journey from "foggy" Albion. E. H. W.

## OCTOBER IN SOUTH DEVON.

LITTLE rain fell during the past month, the total fall amounting to 0.94 of an inch on eight days, a particularly small record for October, and comparing with 3.99 inches on twenty-one days in the corresponding month of 1896, the October average being 4.35 inches. During the past ten months the rainfall has reached a total of 27.87 inches, or nearly an inch in excess of the average fall for that period, which is 26.98 inches, while it exceeds by almost 10 inches the fall for the corresponding months of 1896, which amounted to 18.61 inches. The mean temperature of the month has been very high, having been over 6° warmer than October, 1896, and 3° warmer than the average mean temperature for the month, the readings being, October, 1896, 47.8°; average for month, 51.1°; October, 1897, 54.2°. The highest sun temperature recorded was 112.2° on the 2nd, and the highest screen reading 62.9°, while the lowest screen temperature was 37.9° on the 7th, and the lowest reading of the grass thermometer 36.8° on the same date. In my notes for September, through a *lapsus calami* or a printer's error, the mis-statement appears that the thermometer on the grass never fell below 31.0°. This should read 37.9°, as during the present autumn the mercury on the grass has on no occasion fallen as low as 36.0°. Although the month has been so warm it has been very sunless, only 97 hours 45 minutes of sunshine having been recorded against 119 hours 40 minutes during the wet October of 1896, and an average for the month of 116 hours 20 minutes. The sunshine records for 1896 and 1897 and the average for the period show a remarkable similarity, the totals for the ten months being 1589 hours 5 minutes in 1896, 1593 hours 20 minutes in 1897, and the average 1595 hours 5 minutes. The total horizontal movement of the wind has been 5592 miles against 7732 miles in October, 1896. The greatest daily speed, 501 miles, was recorded on the 16th, and the highest hourly velocity, 25 miles, between 3 a.m. and 4 a.m. on the same date. The mean amount of ozone in the air has been 36.9 per cent. against 36.1 per cent. in October, 1896, the prevalence of easterly winds accounting for this diminution. In the garden the tall *Acanthus* spires remained effective through a great portion of the month, and *Achillea ptarmica* fl. pl. The Pearl was still in blossom, while *Anemone japonica* *Honorine Jobert* expanded its simple white flowers in continuous succession. On the 20th a belated flower-scape of the hybrid *Alstroemeria* came into bloom, and during the early part of the month the *Belladonna* Lilies showed long lines of pink in sheltered situations. Of the perennial Asters, or *Michauxias* Daisies, a large number have been in bloom, most, however, being past their best before the closing days of the month. With the exception of *Aster grandiflorus*, which handsome subject expands its large,

purple, golden-centred blooms very deliberately, *A. Novi-Belgii* *Archer-Hind* is one of the latest to attain full perfection, the rich purple-blue, profusely-blossomed clumps being at their brightest after the beauty of most of their companions was on the wane. Although the terminal blooms of *Aster grandiflorus* had expanded ere the close of September, the plants are not even yet (November 1) in full bloom. This subject might prove valuable for conservatory decoration if lifted carefully and potted subsequently to bud-formation. The graceful and tall-growing *Aster N.-B.* *Robert Parker* was past its best before the month was many days old, and the darker-flowered varieties *Pluto* and *Flora* waned in beauty as mid-October approached. *Aster Amellus* *bessarabiensis* is one of the most lasting of the Starworts, and though among the first varieties to open its buds, will bloom into November. *Aster N.-B.* *Harpur-Crewe* and *niveus*, having blossomed throughout September, were hardly presentable during the past month, *polyphyllus* being the only large-flowered white that retained its beauty sufficiently to be utilised for indoor decoration. *A. puniceus pulcherrimus* at the commencement of the month had its tall flower-shoots thickly starred with blossoms of the palest lavender-white, and the inconspicuous blooms of *A. diffusus* *horizontalis*, which was in full flower in September, show as yet no loss of freshness. The dark red *Aster Novae-Angliae* *ruber* and the purple *A. N.-A.* *Melpomene* have been in bloom throughout the month, as have the graceful *cordifolius* and *cordifolius elegans*, with their small blossoms set on curving sprays; while the still smaller-flowered *ericoides* has borne a profusion of minute white stars on its Heath-like foliage. The tuberous *Begonias* show as yet no sign of diminishing splendour, the months of September and October having been singularly free from gales and frost, either of which work havoc in the autumnal garden. The new race of *Cannas* bloomed throughout the month with but little-impaired brilliancy, and *Canna Ehmanni* *iridiflora* produced a succession of its drooping, rose-lake flower-clusters. The *Marguerite* *Carnations* still expand their blossoms of varied tint among their grey-green foliage, and *Coreopsis grandiflora* in sumptuous gold is not yet withdrawn from the garden. The earlier *Chrysanthemums* of the *Mme. Desgrange* type have been very effective, having been unmarred by wind and rain, while the later varieties are beginning to show colour in the open, and in nurseries large glasshouses are white with the blossoms of lately-lifted plants of *Lady Selborne* and other semi-early varieties. *Caryopteris mastacanthus* has produced its purple-blue flowers with freedom and survives the winter in favoured localities. The *Duhlias*, untouched by frost—which often prematurely closes their display towards the end of October—have been wonderfully effective throughout the month. Many of the new *Cactus* varieties—to some of which I referred in my August notes—are of distinct value. To the scarlets and crimson then mentioned, *Gloriosa*, *Professor Baldwin*, *Starfish*, *Mayor Haskins* and *Harry Strudwick*, may be added *J. E. Frewen* and *Miss Annie Jones*. To the yellows, *Lady Penzance*, *Blanche Keith* and *John H. Roach*, desirable additions are *Daffodil* and *Eileen Palliser*, while *Night* is, if anything, an improvement on *Matchless*. *Alfred Vasey*, *Fusilier*, and *Mrs. Wilson Noble* are good flowers in varied shades of salmon, and *Island Queen* is of a charming lavender-pink tint. A few light blue spikes of *Delphinium* were to be seen here and there, and some flowers remained open on *Erigeron speciosus*, this plant and the little *Erigeron mucronatus*, or *Mexican Daisy* as it is sometimes called, not having been bloomless since early June. At the commencement of the month *Erythrina Crista-galli* was attractive with its large crimson flower-spikes, and in cottage gardens giant bushes of *Fuchsia Riccartoni* were in bloom. A note of bright blue shows where a dozen autumnal blooms of the *Gentianella* have expanded, while the flowers of *Geum coccineum* brighten the border at infrequent intervals, and *Gaillardias* afford, though in lesser quantity than

of late, their red and gold. In a sheltered corner, backed by a cliff, a large bush of *Habrothamnus* is bearing its clusters of dark crimson flowers. *Helleborus altifolius* expanded the first of its white blossoms on October 23, thirteen days later than last year. A red *Helianthemum* is now in bloom, and the Everlasting Flowers (*Helichrysum*), though treated with indifference when the gardens teem with floral gems, are bright and effective as the days rapidly shorten. *Hypericum Moserianum* is still in flower, and the first-scented blossom has been cut from a clump of *Iris stylosa*. Here and there the *Kniphofias* bear a few brilliant flower-heads, and until the last ten days of the month *Lobelia fulgens* has held its vivid vermilion, while the softer-tinted *L. rosea* has but just shed its last blossoms. Marigolds are still bright, and self-sown plants of *Nicotiana affinis* are now in full flower, their blooms as the days close in opening early in the afternoon. *Oxalis floribunda rosea* flowered well into the month, and on the great bushes of Paris Daisies the yellow and white flowers are still produced in abundance. *Pentstemon*s are not yet over, and *Phgelius capensis* has carried its flowering well into October, while the Winter Cherry (*Physalis Alkekengi*), with every shoot studded with calyces of bright orange, lights up the foot of a long wall with its striking colouring. The blue *Plumbago Larpente* was in evidence during the earlier portion of the month, and now and again the glare of a great Oriental Poppy would for a day or two light up the garden, while the slender flower shoots of *Pyrethrum uliginosum* were crowned with a white coronal of wide-rayed stars, that associated well in arrangement with the darker Starworts. Breadths of orange have been provided by *Rudbeckia Newmani*, whose black-centred flowers have the merit of lasting in beauty through long spells of rainy weather, which, fortunately, we have not experienced during the past month. The deep blue of *Salvia patens* has slowly lessened through October, but *S. fulgens* and *S. coccinea* remain, the former of which is perennial in sheltered spots of South Devon, while the latter has passed the last two winters in the open unharmed. An occasional light blue blossom of *Scabiosa caucasica* has appeared, and the Winter Flag (*Schizostylis coccinea*) has produced its crimson flower-scapes. *Sedum Sieboldi* has bloomed profusely, and *Stokesia cyanea*'s deep purple blooms have opened well in the fine weather. In a secluded corner *Sparmannia africana* has carried a few flower clusters. Of the perennial Sunflowers, *Helianthus latiflorus* and *H. rigidus* Miss Mellish brightened the first half of the month with their golden blooms, and *Tradescantia virginica* perfected an autumnal flowering of triangulated purple blossoms. Many *Yuccas* bloomed well in October, the varieties being generally *Y. gloriosa* and *Y. pendula*, though an occasional spike of *Y. filamentosa* was sometimes to be observed. Some of the former variety are now throwing up bloom-spires that will never reach maturity. The Tea Roses have lasted well through October, the best blooms being produced by wall plants, *Safrano* being especially noteworthy in this respect and furnishing many an exquisite handful of rosy-saffron blossoms. Some of the new China Roses of the *Laurette Messimy* type have also continued their flowering, the blooms, being but semi-double, opening better from the close bud than do the flowers possessing a larger number of petals. The single white *Macartney* Rose has been in bloom throughout the month, and, given the same weather, will open some November blossoms. Violets both in the open ground and in frames have been in fine bloom. The new single, *Princess of Wales*, is at the present time exceedingly fine, bearing, on stems about a foot long, broad-petalled blossoms, many of which when measured are found to exceed  $1\frac{1}{2}$  inches in diameter. Another large single Violet, named *California*, which in size and length of stem is fully up to *Princess of Wales*'s standard, is not as yet at its best. It differs from *Princess of Wales* chiefly in its petals being narrower. The old

clumps of *Doronicum plantagineum* Harpur-Crewe continue to throw up occasional great golden stars. The Ivy-leaved *Pelargoniums* *Souvenir de Charles Turner* and *Mme. Crousse* are still gay, and many annuals are yet to be found in bloom, such as *Coreopsis Drummondii* and *C. sanguinea*, the delicately beautiful white *Cosmos bipinnata*—large plants of which were in full flower at the commencement of the month, and which is admirably adapted for artistic table decoration—*Eschscholtzias*, *Salpiglossis*, *Scabious*, *Phlox Drummondii*, and *Zinnias*, while the dark-coloured *Heliotrope* is still flowering well in some gardens. *Abutilon vexillarium* is still in bloom in South Devon, and *Choisya ternata* is here and there to be seen in full flower. The *Lycyesteria* held its pendent flower-clusters with their purple bracts and white blossoms, though in many cases the blooms had been succeeded by berries. The *Lamrstinus* has begun its season of bloom, and great bushes are crowned with hosts of half-opened flower-heads. The blossoms on the standard *Magnolia* have been almost as abundant as in September, but now that the penultimate month of the year has commenced, the succession of white chalcies can hardly be expected to continue for long. *Tropeolum tuberosum* is now very beautiful, a space of wall some 7 feet high being clothed with its orange and scarlet blossoms, which on long footstalks stand out well beyond the luxuriant leafage, that forms an effective background to the brilliance of the numberless flowers. On *Tropeolum speciosum* the vermilion blooms have been succeeded by blue berries, but *T. canariense* and *T. Lobbianum* are still breadths of gold and crimson. *Solanum jasminoides* is a mass of pendent white flowers, which sway on long lithe sprays from the eaves to the lower windows, and bid fair, should frost not intervene, to last in beauty for another month. Both white and red *Lapagerias* are blooming in South Devon against a north wall, and the blue *Passion Flower* is bearing both orange fruit and blossom, while *Plumbago capensis* may still be seen flowering in the open in a sheltered site. The autumnal tints, though perhaps not so brilliant as in some past Octobers, have formed delightful colour-schemes. In the garden the *Virginian Creepers* (*Ampelopsis hederacea* and *A. Veitchii*), with their crimsons and scarlets, the saffron and orange of the *Plantain Lilies* and *Aralia spinosa*, the purple-red of feathery *Samachs* and the pale yellow of the *Vine* leaves that canopy the pergola and hide the numerous bunches of *Grapes* from which from morn till eve the blackbirds take incessant toll. In the country the light gold of the *Elms*, the glowing orange-brown of the *Beeches*, and the *Oaks* with their intermediate shade of russet. Many of the latter have, however, as yet not even changed colour, and a large portion of the *Elm* leaves have fluttered earthward still green. Although up to the present we have had no frost and the winds have been slumbering, numberless leaves were wavering downwards from the lofty boughs during the last two weeks of the month. Watching their indeterminate descent, wafted now hither, now thither, but ever nearer the ground, one recalled a myth of childhood, to the effect that the capture of twelve falling leaves with the hands ensured, if the captives were threaded on a string and hung up, twelve happy months in the ensuing year. In the hedges the *Bryony* berries shine in crimson skeins, and at the borders of the wood the coral-red fruit of the *Spindle tree* overtops the *Hazels*, while here and there the dark foliage of the *Holly* glows with scarlet. The weather has been wonderfully open during the past month, and as yet there seems no indication of a change. Should the next fortnight prove frostless, we may look forward, according to tradition, to a severe winter later on.

S. W. F.

**Lilium Wallichianum.**—Wallich's Lily has this season flowered with me in a more satisfactory manner than usual, and given greenhouse treatment it seems more amenable to culture than most of the Indian Lilies. Three years ago I had

half a dozen small bulbs sent me from India, of which only two became established, and they have increased in size year by year. This season they each produced a solitary flower, and a few large bulbs imported in the early part of the present year also bloomed. The compost used consisted principally of good yellow loam, lightened by an admixture of peat and sand. They were kept in the same structure and given similar treatment to a *Pelargonium*. In the winter the soil is just kept slightly moist. The long narrow foliage of this Lily reminds one much of *L. philippinense*, while the flower has the same slender tube, but in *L. Wallichianum* the segments of the bloom are quite revolute, and the colour is a kind of creamy white with a greenish tinge on the exterior. The two established plants flowered early in August, while the imported ones did not bloom till a month later. The blossoms possess the pleasant fragrance common to several forms of the longiflorum group. I have never been able to induce *L. Wallichianum* to flourish at all when treated as other than a green house plant, but the late Mr. Niven, of Hull, some years ago in *THE GARDEN* stated that it was quite hardy with him and flowered year after year.—H. P.

## GARDEN FLORA.

## PLATE 1146.

## TWO ROSES.

(WITH A COLOURED PLATE OF KAISERIN AUGUST VICTORIA AND PRINCESSE DE SAGAN.\*)

THE two beautiful Roses illustrated this week are excellent examples of true garden varieties and one can readily conceive what a fine effect might be produced by blending together in large masses such Roses of totally opposite colour and forms. In *Kaiserin Augusta Victoria* we have a variety remarkable for the beauty of its form, its stately habit and delicate cream white colour. Since its introduction in 1891 it has steadily advanced in popular estimation and it now bids fair to become as great favourite as *La France*, *Gloire de Dijon* or *Maréchal Niel*. On the other hand, *Princesse de Sagan*, introduced in 1887, is not so much known as it deserves to be. It is, with the exception of *Cramoisi Supérieur*, the most brilliant Rose we at present possess. If in some respects it closely resembles the *Chinas*, there is that refined character about the blossoms that at once stamps it as a pure Tea. The colour is very brilliant crimson, heavily shaded with velvet maroon, and the form of the flower is very quaint and irregular. This variety is extremely free-flowering and the habit of growth is rather spreading, a fact that enables its more upright growing rival, *Marquise de Salisbury*, to obtain a little more notice; but when the plants of *Princesse de Sagan* are established in well-drained soil, the colour produced by a quantity of this variety massed together is very gorgeous. I can see no objection to planting two varieties of Roses together in one large bed, and the general effect, if the varieties are carefully selected, should be as brilliant as any that can be produced by other denizens of the garden. But supposing an objection be raised to this combination, these Roses could still be planted in groups in juxtaposition to each other, so that the vividness of the one would tend to enhance the delicate beauty of its neighbour. One of two varieties that could be fitly combined, in addition to the two illustrated, would be *Mme. Pernet-Ducher* and *Marquise de Salisbury*. *Augustine Guinoisseau* and *Camoens*, *Princesse*

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**FORCING VEGETABLES.**—However plentiful outdoor vegetables may be during the winter, there is always a demand for a more choice variety, and provided there are suitable convenience and material to work upon, there is no great difficulty in meeting it. Without doubt the most difficult vegetable to obtain in any quantity for the next few months is French Beans, as without plenty of light growth is weak and many of the flowers which form fail to set, especially when there is an absence of sun and foggy weather prevails for days together. The most suitable house must be selected if these have to be produced, such as a well-heat Melon house, where the plants can be kept close up to the roof-glass and a temperature of not less than 70° can be maintained. In other low houses are an advantage, as the temperature is not so likely to vary with a change of weather, especially when cutting winds prevail, while it is an easy matter to use tanned blinds to cover the roof at night during severe weather. This proves a great gain, as the desired temperature is more easily maintained without overheating the pipes, and a more humid atmosphere is secured. The next step to consider is whether to resort to pot culture or to grow the plants in the beds recently cleared of Melons. The latter course might prove an advantage if the bed is sufficiently near the roof to prevent the plants from growing up weakly, as undoubtedly, the roots to be confined and having free run of a rich rooting medium, growth would be stronger and the Beans produced finer, while with careful syringing and keeping the surface of the bed uniformly moist, there is less danger of red spider attacking the foliage—the greatest pest the grower has to contend with, and which it is difficult to prevent when the plants are situated on dry airy shelves. If such a house as described above is available, a gentle hotbed of leaves and straw might be made up, as for Cucumbers. The material should be brought well up to the glass to allow for sinking when the soil is added. By using plenty of leaves the heat produced will be more steady and lasting, while there is less danger of any delicate plants which may be in the house at the time being injured by ammonia, which escapes from a body of stable manure. Having made the material as firm as possible by treading, cover this with a layer of soil at least 9 inches in thickness. The compost used, especially during the dull days of winter, when it is necessary to encourage root action as much as possible, should be light and airy and also of a gritty nature, as roots form in it more quickly and there is less danger of the soil turning sour than when that of a heavier nature is used. Fresh loam containing a certain amount of fibre, spent Mushroom manure, partly decayed leaves, and some sharp road grit will be necessary, using each in proportion so as to form a nice light compost. It may be necessary to range some 9-inch boards round the edge of the bed to form, as it were, a frame to hold the soil. The seed should be sown in rows, and, of course, the more room the plants can be afforded the stronger will be the growth. A foot at least should separate the rows, while the seed should be sown in about 3 inches apart and at about the same depth. The rows, too, if possible should be in the same direction as the rafters, so that

what little sun there is will strike the soil between them. As growth even under these favourable conditions will be naturally weak compared to that made when the days become longer, early supports should be afforded in the shape of a few light twigs placed on either side of the rows. This not only keeps the plants upright, but the flowers are exposed to light, and being dry they have a better chance to set. Where only one house is available another sowing could be made later in small pots, and transplanted immediately the former lot of plants became exhausted, and thus save to some extent the time which much elapse between crops. Pot culture, however, is the method chiefly resorted to in private gardens, as the Beans can be grown on shelves in Pine stoves or Cucumber houses. For mid-winter I prefer pots about 7 inches in diameter, as they take up less room, and better results follow in having these well filled with roots than are obtained by using larger ones only partially filled. The soil in the first instance being full of roots, more moisture and feeding can be employed, and there is less danger of the plants damping off, which often results if soil is used for moulting them up when grown in 9-inch or 10-inch pots. Several varieties are now recommended for winter work, but those of a natural dwarf and free-bearing habit should be selected, such as Osborn's Forcing, Syon House, and Fulmer's Early Forcing.

**CARROTS.**—Only a very gentle heat is required to force these, and the delicate young roots are highly appreciated in the winter. A steady warmth produced from a body of leaves and well-made frame, with a few mats for night covering, are all that is required, and where these are available they could hardly be put to a better use. To maintain a steady bottom-heat from now on till spring from 3 feet to 4 feet of leaves will be necessary, and the bed made sufficiently wide, so that more leaves can be packed round the sides of the frame. If it is thought the leaves will not generate sufficient heat in themselves, a little fresh stable litter mixed with them will promote fermentation. Having prepared a suitable bed and placed the frame in position, about 9 inches of rich sandy soil should be placed in the bottom and the frame closed for a few days, so as to allow the compost to be warmed through before the seed is sown. A plunging stick should be used, and when this is found to strike warm to the hand sow the seed thinly and evenly over the surface, and cover with a slight sprinkling of sand. A light watering through a fine rose will settle the soil and assist germination, especially if afforded at a temperature of 70°. At this season, Parisian or French Forcing Horn should be sown. Ventilation will not be required until the seedlings push through, when it should be given with care, varying it according to outside conditions of the atmosphere. It is a good plan to place a mat or strips of tiffany over the aperture, as this allows moisture to pass off without a rush of cold air entering the frame. From first to last this must be observed, as the least chill checks growth and poor results follow.

**RADISHES.**—These, too, are never more appreciated than when produced during winter on a gentle hotbed, as the flavour is milder and the roots more tempting than those grown in the open during summer. Exactly the same conditions should be followed as recommended above for Carrots, only a less depth of soil is required, but this, if possible, should be brought to within 6 inches of the lights. These really suffer more from the want of light than from any other cause, as without this they draw up weakly and serviceable roots fail to form. Lights with large panes of glass should be used, and no dirt or rubbish should be allowed to accumulate on them. Wood's Frame is a reliable variety for present sowing.

**MUSTARD AND CRESS.**—A good supply of this can easily be kept up with the aid of an ordinary warm greenhouse. A sowing made twice a week in shallow boxes will furnish a nice daily supply. This is looked upon as the most simple thing possible to grow, and for this reason it often lacks

the attention needed to have it in the best condition. A mistake made is that of using the same compost repeatedly, instead of giving fresh, rich soil at each sowing. Strong growth with nice white stems looks more tempting in the salad bowl than the puny article often used.

**MINT AND TARRAGON.**—These useful herbs are often required when least expected; hence it is advisable to lift a number of roots, place them in pots or boxes, and store them in a cold frame in readiness should a spell of severe weather set in. They can then be introduced into moist heat of about 55° as required, keeping them close up to the glass, or growth will be weak and of little value.

RICHARD PARKER.

### FRUIT HOUSES.

**WINTER CUCUMBERS.**—The singularly fine autumn through which we have passed has had a good effect on winter Cucumbers, as hard firing has not at any time been necessary to keep up the requisite temperatures. Red spider and thrips—insects which generally infest Cucumbers to a greater or less extent when the hot-water pipes have to be kept heated to a high degree, perhaps for weeks together—are therefore absent, and with care the plants can be kept clean until after the turn of the year. The syringe, which should have been abandoned for the past few weeks, may then be brought into use again. In the meantime overhead syringing must be discontinued, and the necessary moisture created by damping the floors and sprinkling the surfaces of the beds with tepid water. The vapour troughs too must be kept constantly filled for the same purpose, and where the bottom-heat pipes are contained in a brick chamber underneath the bed in which the plants are growing, it is a good plan to run water amongst them once or twice a day. The moisture so created then rises and penetrates the bottom part of the bed, and prevents the materials composing it becoming too dry. Green fly is apt to prove troublesome at this time of the year, but this can always be subdued by mild fumigations. Mildew sometimes attacks the leaves when the house occupies a low situation, or when the internal atmosphere becomes stagnant through not being changed by the admission of a little fresh air, if not daily, on every favourable opportunity. The best cure for this is flowers of sulphur, and to prevent future attacks keep the air buoyant and sweet by the admission of fresh air, which, if tempered by having to pass over the hot-water pipes on entering the house will be all the more beneficial to the inmates. Pay particular attention to the training and stopping of young growths. Do not allow a quantity of these to develop, and then stop in a wholesale manner, as this means loss of energy, while the plants suffer a decided check from so doing. To guard against this, look the plants over twice a week, when the necessary stopping, tying and removal of decaying foliage or cutting away portions of worn-out bine can be done without the plants suffering any ill-effects. Give every attention to root watering, applying stimulants as often as the condition of the plants demands it. The water should never be given at a lower temperature than 80°. Top-dress with fresh loam, to which add a little charcoal broken small, and bone-meal, which are preferable to animal manure. Maintain a day temperature of 70° to 75°, 65° at night, and a bottom-heat of 80°. Should any of the plants show signs of exhaustion, or appear unlikely to keep up the supply until spring, make preparations for raising a batch of plants at once. For this purpose sow seeds singly in 2½-inch pots and raise them in a brisk heat, keeping the seedlings well up to the light afterwards to ensure sturdy short-jointed plants. In the interval between seed sowing and planting time, well cleanse and prepare a house for their reception.

**STRAWBERRIES.**—Where ripe Strawberries are required very early, preparations for starting should at once be made, selecting a well-proved early variety for the purpose. If the plunging system finds favour, a pit should be filled with

leaves, which should be trodden as firmly as possible. The mild heat generated by tree leaves is preferable to fire-heat, and is well suited to the initial stage of Strawberry forcing, as it stimulates the roots and induces the plants to push up their flower-spikes before much leaf-growth is made. However, all cannot obtain leaves, even if a pit can be spared, and the next best method is to take the plants either into a vinery, Peach, or Fig house just being started. This plan answers well if the plants are placed on shelves close up to the light, and here they may remain until they have flowered and set. In either case the plants will require a little preparation before taking them into the houses or plunging them. They should first be relieved of dead leaves, also Moss and weeds. Examine the drainage and see if all is in working order, and wash the pots. Then dip each plant in a mixture of warm soapy water and sulphur, and top-dress if necessary, using good loam with some proved artificial manure mixed with it. Regarding plunging, much will depend on the size of pit and the quantity of leaves that it will hold. If it should hold a large mass, the plants should only be stood on the surface until all danger of over-heating is past. On the other hand, if the pit should hold no more leaves than will generate a genial warmth, then the pots may be plunged to the rims at once. Keep the plants well up to the light—as this is a most important matter—and introduce more leaves as the plunging proceeds rather than allow them to remain some distance away from it, and run the risk of both flower-spikes and foliage becoming drawn. As a rule plants that are plunged require but little water until growth becomes active; all the same, they had better be looked over every few days. Those standing on shelves in forcing houses, occupying, as they do, more airy positions, dry more quickly, and should therefore be looked over daily. These will also derive a good deal of moisture from syringing, which should be done at the same time that the legitimate occupants of the houses receive attention in this way. All batches of plants intended for late forcing should now either be housed, planted in pits, or plunged in coal-ashes outdoors. Have bracken or litter ready to hand to throw over the plants in the latter case, should severe weather set in.

**EARLY PEACH HOUSE.**—In the calendar for October 23 it was advised that early Peach trees should be started by the middle of the present month if ripe fruits are required next April and May. Assuming that preparations have been made accordingly, close the house at once if this has not already been done. Examine the border, and give it a thorough moistening with water at a temperature of 85°, should the tester give indication that water is needed. Then introduce a good body of fermenting materials, placing it on shutters or boards, or anything that will keep it off the border should the latter be situated, as it should be, inside the house. Failing this, employ just sufficient artificial heat to maintain a night warmth of 40°, with an additional 5° more for the day. In the first case, little or no syringing would be required for the first week or so, as the vapour given off by the fermenting bed will supply ample moisture, but in the latter instance it will be necessary to dew the trees over with tepid water. This may be done twice daily when the weather is bright, but once only when dull, and omit it altogether when fogs prevail. The second syringing must be done early enough to allow the trees to dry before darkness sets in. To keep up a regular succession another house must be got ready for starting, not later than the end of the year, and between now and then get all preliminary operations such as pruning, tying, cleaning, &c., carried out. A. W.

**Jasminum nudiflorum.**—While, as it were, the evidences of a tardy dying summer still appear in the garden, a forcible reminder of the near approach of winter is with us in the flowering of this wall shrub, each twig amply covered with the pleasing yellow flowers. In one instance

in particular an excellent effect resulted from the association of a true climber, *Ampelopsis Veitchi*, where for the past two years the unchecked growth had spread itself beneath the above plant, carpeting, as it were, the walls for some considerable area, and just now the two are beautiful in the extreme, the richly coloured leaves of the *Ampelopsis* more than fully compensating for the characteristic nakedness of the *Jasmine*. Doubtless there are many instances where on walls these two plants could be more or less associated, so that in such seasons as the present a pretty effect may be secured.

## FERNS.

### HARDY BRITISH FERNS FOR GROUPING.

**ALLOSORUS CRISPUS** (the Parsley Fern) is an interesting species, and should always when possible be planted in clumps. Its fronds are usually only 4 inches to 6 inches high, but as they grow in dense tufts the effect is pretty and the contrast with the larger growing kinds striking. It is, as most Fern-lovers know, a mountain Fern, revelling in a damp position, but requiring full exposure to wind and weather. It is desirable to plant this species among stones firmly wedged together, the interstices being filled with compost. This will provide good drainage, for although it likes plenty of moisture about its roots, it must not be stagnant moisture. The fertile fronds grow rather taller than the sterile and are more contracted, owing to the formation of the spore cases. The common name is by many people thought to be misleading, as it causes them to expect the plant to have the appearance of curled Parsley used for garnishing. It has, however, evidently received its name from its resemblance to the wild or sheep Parsley.

**ASPLENIUM ADIANTUM-NIGRUM** (the black Maiden-hair Spleenwort) looks very pretty when a number of plants are together forming a clump. The fronds are dark glossy green, and in a congenial position grow each 8 inches or 9 inches in length.

**A. ALTERNIFOLIUM**, or **GERMANICUM**, and **A. SEPTENTRIONALE**, when grown as single plants, are rather insignificant, but a number of plants together forming a clump become at once distinct and effective in contrast with the larger growers. The same may be said of

**A. TRICHOMANES** and **A. VIRIDE**, the black and the green-stemmed Spleenworts. It is only by planting a number together that a satisfactory effect can be obtained, as they are among the smallest-growing British Ferns.

**THE LADY FERN** (*Athyrium Filix-femina*) is one of the prettiest native Ferns we have. Its fronds are light, graceful, and feathery, often 2½ feet to 3 feet in length. As it is a free-growing species, a few strong crowns planted together will soon form an exceedingly pretty clump. There are two distinct types, one with green and the other with red stems, this feature being perpetuated in the varieties, which are almost of every imaginable form and number several hundreds. Of these some are specially suitable for the purpose under consideration, while others, owing to an unavoidable similarity, may or may not be considered desirable according to individual taste, while a few do not lend themselves at all satisfactorily to grouping. These latter require isolation, and when planted singly in prominent positions, by their particular characteristics and distinct appearance, serve to make more prominent the peculiar beauties of other varieties as well as their own. *Athyrium F. f. corymbiferum* has large spreading fronds, nicely crested at the tips and along the sides. There is a very handsome form of this variety called *purpureum* which has pink stems and rather darker foliage, which should have a place in every fernery. *A. F. f. curtum multifidum* grows rather erect in habit; its fronds are narrower than those of the preceding and nicely

crested; the colour is bright green and its habit gives it a very neat and attractive appearance. *A. F. f. plumosum* of Horsfall and *plumosum* of Jones are exceedingly beautiful; their fronds are large, broad, feathery and graceful. *Plumosum multifidum* is of the same style, but every pinna and the apex of the frond are crested, while *plumosum elegans* is elegant beyond description. The fronds of the last are finely cut into lace-like divisions, the colour is a charming pale green, and altogether it is one of the most lovely hardy Ferns in existence. *A. F. f. todeoides* is another lovely variety, well named from its finely-cut, *Todea*-like fronds. Its foliage is bright green and produced profusely.

The foregoing are all large or medium-sized growers, and as it would be a mistake to have only such in the fernery, the following varieties of the same family should be interspersed to produce contrast and enhanced effect: *A. F. f. congestum cristatum* is a dwarf, compact crested variety, which produces fronds 6 inches to 9 inches in length. *A. F. f. crispum* grows usually about 6 inches high and is a mass of branched and crested fronds and very pretty. *A. F. f. Edwardsi* is a lovely little Fern, growing 6 inches or thereabouts in height; its fronds are pale green densely congested, but not crested, and particularly pleasing in its neat appearance. *A. F. f. Frizelle* is commonly called the Tatting Fern. It has very narrow fronds, usually a foot or so long. The uninitiated would not recognise in this one of the Lady Ferns, as its appearance is so utterly unlike the type. It is a very interesting as well as a pretty variety. Half-a-dozen plants of the should be put together and they will form a very attractive object. The fronds consist of a number of small half-moon-shaped pinnae arranged closely along the main stem, and are usually less than half an inch in width. It is a variety which is rather prone to sport or produce fronds showing a partial reversion to the type. These should always be pinched out, as if allowed to remain the tendency grows stronger, and in course of time the plant will probably lose entirely its true character. The tendency referred to seems to be most common if the soil in which it is planted is too rich; a poor soil would seem to be desirable to prevent the fault. *A. F. f. minimum* is a pigmy form of the type, being in every particular except size, like it. It is neat and pretty, and a few plants put together will soon form a thriving colony. *A. F. f. Vernone cristatum* is a very compact, dwarf variety which grows about 10 inches or 1 foot high, very neat in appearance and remarkably pretty. There is one exceedingly handsome variety (*A. F. f. Victoriae*) which must not be omitted from the list of Lady Ferns, although it is probably one of those which should not be massed. It appears most suited for planting singly in a conspicuous position, where its fronds can develop without hindrance or being crowded by other varieties. They grow from 2 feet to 2½ feet in length; the pinnae are narrow and arranged apparently in twos on each side of the stem, one branching upwards and the other downwards; this causes them to cross and form a kind of lattice-work the whole length of the frond. Many of the pinnae are crested, as is also the tip of the frond. A good plant of this will form a very handsome ornament to the fernery and well deserves the best position therein. There is no other Fern approaching in unique appearance this variety.

**BLECHNUM SPICANT** makes a distinct and pleasing group. In a nicely sheltered position it will retain its foliage through the winter. The barren fronds spread out horizontally, while the fertile, much larger fronds stand erect. The varieties *ramo-cristatum* and *trinervo-coronans*—both crested, the latter, however, much more lightly than the former—are probably the most effective of the varieties when planted some half-dozen together, each kind separate, of course.

**CETERACH OFFICINARUM** (the Scaly Spleenwort) is a very interesting dwarf species, and looks well in a nice-sized clump. It requires rather a dry position, open to the sun and wind.

*CYSTOPTERIS FRAGILIS* (the Brittle Bladder Fern) and *C. montana* (the Mountain Bladder Fern) are two charming species. They must be in the shade, and, surrounded by larger-growing kinds, they will certainly prove worthy of their position. One of the prettiest species for grouping is

*LASTREA ÆMULA* (the Hay-scented Fern). The pleasing green fronds, with their crisp appearance and dense habit of growth, cause it to be universally admired. Coupled with this is its peculiar perfume, reminding one of new-mown hay, more noticeable in autumn when the season's growth has been made. This combination of appearance and perfume causes it to be a general favourite for the hardy fernery.

*LASTREA DILATATA* is somewhat like *æmula* in form of foliage, but grows much larger and is darker in colour. This is a capital species for effect. There is one variety of this (*grandiceps*) which is very heavily crested and more compact in habit, which may be planted with advantage.

*L. FILIX-MAS* (the Male Fern) is well known as an effective, showy species. This grows to a large size and makes a bold and substantial background for the finer kinds. Another form of this fine Fern, now distinguished by the name *L. pseudo-mas*, is very handsome. The fronds are bright yellowish green, the stems are densely clothed with golden-brown scales, the texture is thick and leathery, causing it to be an evergreen in sheltered places. The fronds are produced almost in the form of a shuttlecock, very symmetrical in their arrangement and of large size. This is certainly one of the most noble-looking British ferns. There are a number of very effective varieties of both these forms of Male Fern; among them are *L. F.-m. Barnesi*, a large, bold form; *L. F.-m. Bollandæ*, equally large, but more foliose and the most feathery or plumose of this section; *L. F.-m. fluctuosa*, otherwise named *crispatissima*, dense in habit and remarkably crisp in appearance; *L. F.-m. grandiceps*, a splendid, heavily crested variety, which makes a grand show; *L. F.-m. cristata*, crested all along the sides and at the tip; and *L. F.-m. polydaetyla*, also a fine crested variety, broader in the frond than the preceding. These are all admirably suited for planting in groups and produce a fine effect.

*L. MONTANA* (the Mountain Buckler Fern), also known as *L. Oreopteris*, and commonly called the Lemon-scented Fern, is pretty; its fronds are pale green and grow 2 feet to 3 feet in length, according to position. It likes a moist position and plenty of light and air.

*L. RIGIDA* is of smaller growth, rather stiff, but distinct.

*L. THELYPTERIS* (the Marsh Fern) requires a damp position and produces a forest of light green, erect fronds. Nearly everyone knows the Royal Fern,

*OSMUNDA REGALIS*. This is a grand Fern, and in marshy ground or planted by the waterside, where its roots may obtain an unstinted supply of moisture, it will make a more massive specimen than any other hardy Fern. In the early part of the season the fertile fronds are very remarkable in appearance, the spikes of spore cases standing prominently at the ends of the fronds. This gives rise to the misnomer, "the flowering fern." The variety *cristata* is a very handsome crested form, much lighter green in colour and heavily crested. The cresting in this Fern does not spoil it, as it does in some cases. This variety is a dwarfer and more compact in habit than *regalis*, but, notwithstanding this, when planted in a favourable position it makes a beautiful specimen.

*POLYPODIUM DRYOPTERIS* (the Oak Fern).—In native habitats this species carpets square yards of ground with its pale green triangular fronds. It appears to be everyone's favourite, and is well deserving of its universal admiration. It is extremely hardy, and when planted in nice light compost in a shady, sheltered position it thickly spreads and produces a mass of lovely foliage.

*POLYPODIUM PNECPTERIS* (the Beech Fern) is another pretty species equally quick in growth and as dwarf in habit; its foliage is darker and more woolly-looking than that of the Oak Fern, and forms a nice contrast to it.

*POLYPODIUM VULGARE* (the common Polypody) is totally different from the two Polypodies just referred to, and while they invariably clothe the ground, often growing in rocky or stony places, this one very frequently clothes the branches of trees and forms masses of foliage on the roofs of old buildings and on walls. These facts suggest that this species may be planted with success where most other kinds would not live, and pretty clumps may be established on projecting rocks, where, provided it obtains a reasonable amount of moisture at its roots, it will soon be at home. When, however, it is planted in less exposed and more shady positions, its growth is more luxuriant and its fronds larger. It may here be mentioned that the Polypodies are all very partial to good leaf-mould, and should be supplied freely therewith. The variety *cambricum* is a very beautiful variety of this species; its fronds are much more massive and deeply cut into large overlapping divisions; *P. v. cristatum* has fronds like the species, but crested; *P. v. grandiceps* is very heavily crested and a handsome variety; *P. v. pulcherrimum* is large and exceptionally handsome; *P. v. semilacerum* is not so heavy in foliage, but nearly as pretty; while *P. v. trichomanoides*, which is a selected form of *P. v. cornubiense* Fowleri, is cut up into countless segments and is very beautiful. All these should be planted a few of each together, and they will prove very pleasing.

*POLYSTICHUM ACULEATUM* (the hard Prickly Shield Fern) and *P. ANGULARE* (the soft Prickly Shield Fern) grow to a large size. The former has dark, glossy green foliage, and the latter softer, paler green fronds; both are evergreen and very handsome. There are some exceedingly beautiful varieties of these species which make fine effective masses when planted in clumps. Among them are *P. aculeatum pulcherrimum*, than which it would be difficult to find a more handsome Fern; *P. angulare divisilobum* (several forms) with fine large drooping fronds, and, notwithstanding its rather alarming name, *P. a. divisilobum plumosum*, an exceedingly beautiful variety with massive fronds cut into countless overlapping pinnae; *P. a. polydaetylum splendens*, a very handsome variety, well named; *P. a. plumosum*, with very large plumose fronds and one of the noblest-looking British Ferns.

*POLYSTICHUM LONCHITIS* (the Holly Fern) is dwarf and compact in habit and very pretty, each pinna being like a miniature Holly leaf.

*PTERIS AQUILINA* (the Bracken) may be considered by some people too common for cultivation; nevertheless it is a desirable kind to plant where there is plenty of room. *P. a. cristata* and *P. a. grandiceps* are fine varieties to which the objection of being common cannot be applied; these, with their tree-like habit of growth and more or less heavily tasselled fronds are very desirable.

*SCOLOPENDRIUM VULGARE* (the Hart's-tongue) should be planted, if only to compare with its numerous progeny, beautiful and otherwise, to which it has given birth; but it is also well worthy a place for its own sake. Its bright green undivided fronds are quite distinct from those of all the other British species, and when well grown are really pretty and produce a telling effect. The wonderful and unlimited resources of Nature are not more evident anywhere than in the large number of varieties of every imaginable form which have been developed from this simplest of all species. Mr. Lowe in his "British Ferns" enumerates some 450 or more varieties of it. A very large number of these are scarcely recognisable as different from others, but at the same time there are many very remarkable, and some exceedingly pretty ones among them. It must suffice here, however, to specify just a few of those most desirable for the particular mode of planting now under consideration. Unquestion-

ably the most handsome section of the various divisions of this large family is that made up of the crispum forms. These are of many forms, found wild in most cases, and in others raised from spores in cultivation. Some are narrow, others broad; some erect, others drooping; some slightly crimped or frilled, others very densely frilled, others fimbriated, and some more or less heavily crested as well as frilled. The most striking and beautiful are *crispum* of Grey, *crispum* of Wills, *crispum* of Moses, *crispum* of Bowden, *crispum* of Cowburn, *crispum majus* and *crispum robustum* of Jones, *crispum fimbriatum* of Stansfield, and *crispum fimbriatum* of Cropper. *Crispum* of Stabler is also a nice variety. There are several crested forms, but the cresting in their case rather detracts from than adds to their appearance. Among the crested forms which are not crested the best are *capitatum*, heavily crested; *cristatum*, neatly crested; *digitatum*, bearing a flat, broad crest; *grandiceps* and *ramo-cristatum*, both branched and crested; *cristulatum*, a very pretty form of *ramo-cristatum* style; *Kelwayi*, densely branched and crested; *Kelwayi densum*, exceedingly dense and compact, so much branched and crested as to be like a ball of Moss 3 inches or 4 inches in diameter. Unfortunately, this variety is very liable to damp off unless some means are adopted to keep the wet off the foliage during winter. Another very pretty variety is *ramo-marginatum*, which combines the characters of *marginatum* and *ramo-cristatum*. Of different character are *laceratum*, with broad fronds deeply cut, lacerated, and sometimes crested, and *sagittatum grande*, with very broad, projecting lobes at the base of the frond.

The wonderful variety of foliage represented by the various Ferns in the foregoing category planted and arranged judiciously would make up a fernery possessing a beauty and interest that it would be impossible to surpass by means of any other plants. There are, of course, many others suitable for the special purpose for which these are recommended, and a very large number of other very beautiful and equally interesting kinds, which, however, are not so suitable for planting in groups as these here enumerated. These may form the subject of other notes in course of time. B.

## TREES AND SHRUBS.

### TREES AND SHRUBS IN AUTUMN.

THE brilliant autumn scenery of the North American woods is proverbial, and many of the species so remarkable there are among the brightest of our trees on this side of the Atlantic, where, however, the leaf-colouring is, as a rule, less pronounced than on the western continent. The dull, damp weather which frequently prevails at this season of the year leads in many instances to a far more sombre display than that experienced when the weather is bright and clear. Position, too, and individual peculiarities both play a part in the variations of colouring that are to be found among trees and shrubs in the autumn, while some subjects possess a quiet beauty of their own in ever varying shades of yellow, brown, and russet, which render them equally worthy of admiration with their more brilliantly-tinted brethren. When a number of trees and shrubs of one species are grouped together, and all, as far as can be seen, under similar conditions, their individual features are then brought more prominently forward, some changing colour a week or two before the others. That this is not an accidental circumstance is shown by a fact I have several times noted, that the same trees show this peculiarity year after year. Among trees and shrubs remarkable for brilliant autumn effects may be mentioned many of

the Oaks, particularly the several forms of the Red Oak (*Quercus rubra*), *Q. coccinea*, and *Q. tinctoria*. In brightness of colouring they leave our own European Oaks far behind. The different Sumachs (*Rhus*) are, irrespective of their native country, all remarkable for their autumn tints. The sturdy-growing species with long pinnate leaves, such as the Stag's-horn Sumach (*R. typhina*) from North America, with *Rhus Osbecki* and *R. succedanea* from China and Japan, vie with the simple-leaved bush forms, the Venetian Sumach (*R. Cotinus*) and the United States *R. codonoides*, in their vivid hues, while the brightest among them are equalled by the curious climbing Poison Oak (*Rhus toxicodendron*), which is such a conspicuous feature in some parts of the American woods, where it clothes the stems of lofty trees. This has acquired such a bad name as a virulent poison, that it is not grown so much as it would otherwise be. It is frequently met with under the names of *Ampelopsis Hoggi* and *Ampelopsis japonica* (for it also occurs in Japan), and as such it is more often planted. The mention of *Ampelopsis* reminds one of the brilliancy of the Virginian Creepers. Nearly the whole of the Vines are remarkable for their autumn tints, particularly the Claret Vine (*Vitis vinifera purpurea*), whose leaves about the end of the summer acquire a deep purple hue, which is retained till they drop. The large-leaved *Vitis Coignetiae* has attracted a deal of attention within the last few years owing to its beauty in autumn, and some of the others are little if anything behind it in this respect. The autumn tinting of *Vitis inconstans* differs greatly, there being certainly two or three forms of it in cultivation. That with neat growth fixed closely to the wall is much brighter than in the larger-leaved form, whose foliage frequently dies off a dull brown.

The Maples, which largely contribute to the beauty of the North American forests, have in most cases a considerable amount of yellow in their decaying leaves, though in many instances it is flushed more or less with red. In most of the European species a brownish hue predominates. The Cockspur Thorn (*Crataegus Crus-galli*) has long been noted for its autumn display of both fruits and decaying foliage, and several other species are very ornamental in this respect. *Crataegus pinnatifida* is remarkable from the fact that the leaves die off a clear yellow, in which it differs from most of its associates. Other rosaceous trees or shrubs that may be especially mentioned for their autumn tints are the Bird Cherry (*Prunus Padus*), some of the Pyruses and particularly the little *Pyrus arbutifolia*, *Cotoneaster horizontalis*, the Amelanchiers, and several of the Plums and Cherries.

The Burning Bush is the American name for *Euonymus atro-purpureus*, and it well expresses the bright autumn tints of its foliage. It is by no means the only member of the genus remarkable in this respect, as our own native Spindle Tree (*E. europæus*), together with the South European *E. latifolius*, are both particularly conspicuous, and so is *E. Thunbergianus*, a little-known species from Japan. The American Hickory nuts and the Yellow Wood (*Cladrastus* or *Virgilia lutea*), a native of the same continent, are all remarkable for the clear, self-yellow of the decaying leaves, while the Tupelo Tree (*Nyssa sylvatica*) is of a clear scarlet tint, but the foliage soon drops. The Sweet Gum (*Liquidambar styraciflua*) whose leaves are usually of a deep purplish-red lit up more or less with orange, is one of the brightest coloured of all our trees at this season, and throughout the year it is very ornamental.

The Dogwoods (*Cornus*) are all bright and pretty in the autumn, while after the leaves have dropped the shining red bark of some of them is very ornamental. Ericaceous plants include among their number a great many worthy of note, including several of the *Vacciniums* and their allies, the hardy Azaleas of all sections, and, in particular, the North American *Oxydendron arboreum*, known also as *Andromeda* and *Lyonia arborea*, whose leaves acquire a brilliant shining red tint, in which stage they remain some weeks before they drop. This needs a cool peaty soil to do it well. The purple-leaved forms of the Japanese Maples all intensify their colouring some time before they shed their foliage, hence during the last month or so they are particularly rich. Though in many cases they are less

(red). While other subjects equally bright and effective may have been passed over, there is in addition, quite a host of trees and shrub whose decaying leaves are, though less brilliant very beautiful. Such as these are not only valuable for the quiet beauty that they themselves possess, but from this circumstance, they serve as a foil to those with more vivid tints.

T.

### DAISY TREES.

(OLEARIAS.)

Most of the kinds of *Olearia* in cultivation are natives of New Zealand. But amongst the Australian species there are many beautiful shrubs which would pay for their introduction. The species already in cultivation are real

*Olearia (Eurybia) Gunniana.*

bright than the North American trees and shrubs, yet our British kinds all acquire an additional beauty in autumn. Thus the Elm usually changes to one of the many shades of yellow, and often branch by branch instead of all at once, as most of the others do; while the Oak, Ash, Lime, Beech and Birch each possess their own particular features, with individual variations. The Guelder Rose serves to brighten up many a copse and hedgerow, being, in some seasons at least, particularly brilliant. A few other plants worthy of note are the common Barberry, and *Berberis Thunbergi* (red), *Liriodendron tulipifera* (yellow), *Ptelea trifoliata* (clear yellow), *Gymnocladus canadensis* (yellow), and *Spirea prunifolia flore-pleno*

useful and handsome shrubs, easily cultivated evergreen, very free-flowering, and of good habit. The only drawback is their not proving hardy, except in warm localities. Still, they are a great many gardens where they will grow and thrive perfectly, and there is also the chance that in time most of the kinds will be acclimatised sufficiently to bear an ordinary English winter. Besides, some of them, as, for instance, *O. insignis*, are good greenhouse plants.

*OLEARIA INSIGNIS* is the most remarkable species yet introduced. The flowers are on erect peduncles, as thick as a goose-quill, and from 6 inches to 9 inches long. The yellow flower heads are a little over 2 inches across, and remain

h on the plant for about six weeks. This is one of the most interesting and prettiest of the composites which are found in Australia, New Zealand. It is a native of Middle Island, in New Zealand, where it is said to grow on the driest rocks.

**DENTATA** is cultivated in the Scilly Isles and other favourable localities, where it forms a large bush. The flowers are each over 1 inch across and numerous, in terminal racemes; the ray florets number about twenty, each half an inch long, curved upwards, and forming a saucer-like head; they are white, tinted with rose, the disc being bright yellow. This is a most beautiful flowering shrub, and would probably thrive in the south of England in sheltered situations.

**GUNNIANA** (see cut) is quite hardy in the south of England. Against a sunny wall it ought to do in almost any part of England. It forms a bush, with small, toothed, green leaves, the upper surface and other parts of the plant covered with white felt-like tomentum. The flowers (as shown in the illustration), and which appear with those of the Hawthorn, are very abundant, clothing the branches with a mass of white Daisy-like blooms, which are borne singly at the ends of hundreds of tiny branches on the upper part of the large branches, and they are 1 inch across, with about a dozen ray florets, which are half an inch long and white, the disc being yellow. This species is also a good greenhouse plant. It is a native of Tasmania.

**HAASTI**.—Whether grown as a pot plant or against a wall or in the open border, or even as a specimen on lawns, this shrub almost invariably gives satisfaction. It is hardy in most parts of England, growing to a large size in the more favoured localities. It has been recommended as a suitable plant for sea-side gardens by several who have tried and proved it. If planted in large clumps it has a good effect when covered with its thousands of Aster-like flowers, and even out of bloom it is attractive. In New Zealand, where it is found at altitudes of about 4000 feet, it grows in a small shrubby tree. Here, however, it forms a compact bush, not unlike a Box plant. The leaves are oval, leathery, shining green above, white beneath, where they are covered with felt-like hairs, as also are the stems. The flowers are very numerous, in terminal corymbs, the ray florets each a quarter of an inch long, white, the disc yellow. The plants usually bloom in August and remain in perfection several weeks.

**MACRODONTA**.—This was introduced from New Zealand. It is the *O. dentata* of the New Zealand flora, there being another *dentata*, the true one, native of Australia, and described above. The plant has large, silver-green, Holly-like foliage and dense heads of whitish flowers. When first grown it attains a height of 20 feet, the stem 2½ feet in diameter at the base, the branches stout, and forming with the leaves a round, somewhat flattened top, which is hidden by the dense heads of white flowers developed in the month of August. The foliage smells agreeably of Musk.

**RAMULOSA** is a handsome little shrub which has been in cultivation about twenty years under the name of *Eurybia ramulosa*. The flowers are very numerous on long, curving branches, forming elegant sprays of pretty, stary blossoms; each one is small, but they are so abundant and prettily arranged that the effect of a well-grown plant when in flower in September or October is charming. The species is a native of Tasmania, New South Wales, &c.

**STELLULATA** was one of the first species introduced into England. It grows to a height of about 5 feet; the leaves vary in length from half an inch to 2 inches, the upper surface green, the rest of the plant covered with a rusty tomentum; the flowers in leafy panicles, which are long and very graceful in form; each flower is small, Daisy-like, pure white, with about a dozen ray florets. When grown against a wall this species blooms very freely in June and July. It is a native of Tasmania and New South Wales. There are several varieties of it described by botanists.

*O. ilicifolia*, *O. myrsinoides*, *O. corymbosa* and *O. gummosa* are less important than those described above.

**Strawberry tree** (*Arbutus Unedo*).—This is one of the most striking shrubs in flower. It grows to a height of about 20 feet, and forms a well-balanced ornamental tree. Its white bell-shaped flowers are borne in panicles, and when properly expanded have a charming effect against the deep green foliage, and large red Strawberry-like fruits, which are borne very freely. It delights in a sandy, well-drained soil, and though perfectly hardy, prefers a sheltered spot. *A. Unedo* is suitable for planting on the outskirts of the lawn.

**Chimonanthus fragrans**.—The first flowers of the Winter Sweet were picked on November 6 close to the wall with the tree still in full leaf and showing only a faint tinge of yellow, the mild autumn being responsible for the early expansion of the one and the long retention of the other. This picking was from the variety usually found in gardens. It is a trifle earlier than *grandiflorus*, but in size of bloom and in fragrance not up to the standard of the latter. Where the blooms are prized for shallow bowls or vases it is desirable to make provision for obtaining them as far as possible all through the winter, and if the trees are on a wall, this may be effected by the aid of a piece of tiffany fastened to stout laths, the latter being temporarily secured both to the top of the wall and in the ground. This affords sufficient protection from snowstorms and from any ordinary frost, and can easily be removed during spells of mild weather.—E. BURRELL.

**The Sassafras**.—This has been this autumn unusually beautiful. But it is not in autumn alone that the Sassafras is attractive and interesting; in winter its bright green, lustrous branches make a cheerful note on the margin of the forest; in spring it is charming, with its drooping clusters of delicate yellow flowers surrounded by the enlarged and showy scales of the expanding buds; all summer long its variously shaped fragrant leaves retain their healthy luxuriance; and the fruit, which birds rarely allow to remain long on the branches, is showy, with deep blue berries and much thickened and scarlet caps. Few people plant the Sassafras, perhaps because it is a native tree, and nurserymen rarely offer it for sale. Large plants are difficult to transplant, as the thick, fleshy roots are scantily provided with rootlets, but small plants, which can often be found in abundance along fence-rows and wood borders, are easily managed, and grow rapidly when set in good soil.

**The Swamp Magnolia** (*M. glauca*).—In the notes from America (p. 377) *Magnolia glauca* is said to vary from a deciduous shrub at its most northern limit to an evergreen tree in the extreme south. Though this may be so, there are certainly two forms of the Magnolia in question in this country, one being quite deciduous, and the other, unless the weather is very severe, sub-evergreen in character. This latter is the more desirable, as it continues to flower much later than the other. The Swamp Magnolia is well adapted for a single plant on a small lawn that is not a parched up spot, as it is naturally of medium growth, and flowers from midsummer till autumn. The cream-coloured blossoms are only about 3 inches across, and are not particularly showy, but sweetly scented. As the plant blooms freely when 6 feet high or less, the fragrance of the blossoms can be more readily appreciated than if it attained tree-like dimensions before flowering. At no time are many blossoms expanded on the one plant, but a succession is maintained for the above-named period.—T.

**The Japanese Prunus Pseudo-cerasus**.—Of the trees recently introduced into American gardens one of the most promising is this, which has for several years proved hardy in the Arnold Arboretum, where it is growing rapidly. Forms of this tree or of some allied species with double flowers are now common garden plants in the United

States and Europe, but these are less hardy and of much slower growth than the wild type which appears to be rare in American collections. It is the largest tree of the family in Japan, and, next to the Apricot, more cultivated for its flowers by the Japanese than any other tree. In the forests of Yezo, where it is very common and sometimes 80 feet high with a trunk three feet in diameter, it resembles in the appearance of the bark and in habit the wild type of *Prunus Cerasus*, the Cherry tree of our gardens, and it might be mistaken for that species. In autumn it is particularly beautiful, as the leaves turn deep scarlet and light up the forest before the Maples assume their brightest colours. For centuries this Cherry has been used in Japanese gardens and temple grounds, and near Tokio there is a Cherry avenue more than a mile in length along the banks of the Sumi-da-gawa, and at Koganei ten thousand of these trees were planted a century and a half ago in an avenue several miles long.—*Garden and Forest*.

CUPRESSUS.

This genus is widely scattered over the Atlantic and Pacific coast regions of the United States, Mexico, and Lower California, and in the Old World is distributed from South-eastern Europe and the Levant, along the Himalayas to China.

**CUPRESSUS THYODES** is the White Cedar of the Eastern States, where it grows in cold swamps on the Atlantic and Gulf coast plain, usually immersed during several months of the year, from Southern Maine to Northern Florida and the valley of Pearl River, Mississippi, covering them at the north with pure forests of wide extent, and at the south mingling with the Bald Cypress and other moisture-loving species. It is a slender, pyramidal, fragrant tree often 70 feet or 80 feet high, with a stem rarely more than 2 feet in diameter, thin, spreading branches clothed with open, flat, fan-shaped spray and dark, dull blue-green foliage, becoming rusty brown at the north in winter when exposed to the sun. The White Cedar, which is rarely cultivated in our gardens, for the reason, perhaps, that it is a common native tree, is of course perfectly hardy, and in drained or in undrained soil grows rapidly into a slender, shapely, graceful, open pyramid. European nurserymen propagate several forms of this tree with glaucous and with yellow-marked foliage, and others with fastigate and pendulous branches.

**C. NOOTKAENSIS** (the Sitka or Yellow Cedar) is a common inhabitant of South-eastern Alaska, where it is scattered through the forests of Spruces and Hemlocks which cover the coast mountains, and ranges southward through Western British Columbia and Washington to the valley of the Santiam River, in Oregon. It is the most valuable timber tree of Alaska, where it sometimes grows to the height of 120 feet, with a trunk 6 feet in diameter. Its light, close-grained, pale yellow wood has no superior in our forests as material for the cabinet-maker, and in its lasting quality when put into the ground. The slender branches of the Yellow Cedar, sweeping outward and upward in long curves and furnished with long, gracefully drooping frond-like bright yellow-green branchlets, make this tree lovely in its native forests; but to develop all its beauties it requires the humid climate of the north-west coast, and in drier regions displays little of the grace and vigour which make it one of the handsomest of our conifers. In gardens, both in the United States and Europe, the Yellow Cedar is usually known as *Thujaopsis borealis*, and is still generally seen only in juvenile form with dense pyramidal habit and blue-green foliage. It appears to be quite hardy from New York southward, but east of Cape Cod, although it can often be kept alive for some time, it usually succumbs at the end of a few years to the hardships of its surroundings, and is never really satisfactory in this part of the country. The largest of all the Cypress tribe and one of the great timber trees of the world,

C. LAWSONIANA, is now a familiar ornament in the parks and gardens of all temperate countries, although it is less than fifty years since its discovery. Its great size—for specimens 200 feet in height, with trunks 10 feet or 12 feet in diameter, are common—the remarkable thickness of its deeply-lobed bark, surpassing in this all other members of the Cypress tribe, its graceful beauty in youth, with its delicate feathery branches and drooping leading shoots, and the nobility of its port at maturity, give exceptional interest to this tree. Restricted in distribution to a narrow strip of the Southern Oregon and Northern California coast, with outlying stations on the head-waters of the Sacramento River, Lawson's Cypress exists under very different conditions from those in which it flourishes naturally, and from New York southward it may be seen in a fairly vigorous condition, although it never, perhaps, grows so luxuriantly in the Atlantic States as in Western Europe. In New England, unfortunately, it merely survives in sheltered positions, and we shall have to give up the idea of using this tree here in general planting. The tendency of Lawson's Cypress to variation is remarkable, and more than sixty varieties have been named by European nurserymen. This tree is universally known in the forests of Oregon and the lumber-yards of San Francisco as the Port Orford Cedar, from the harbour on the Oregon coast, where the lumber is largely shipped to San Francisco. The wood is light, hard and strong, and abounds in a fragrant resin, which makes it exceedingly durable. For many years it has been used in large quantities in California for the insides of houses and in boat-building, and from this wood the matches used on the Pacific coast are made.—*Garden and Forest.*

#### A FALSE GENUS.

THE Retinosporas now familiar to the cultivators of coniferous plants all belong to Cupressus, and are all forms of two Japanese trees, Cupressus obtusa and C. pisifera, although some of them appear so distinct that it is sometimes hard to realise, until the appearance of a normal branch discloses the secret of their origin, that they are merely monstrosities that have been cherished and propagated, perhaps, for centuries by the Japanese.

CUPRESSUS OBTUSA (the Hi-no-ki of Japan) is a native of the southern mountain provinces and the most valuable timber tree of the empire. It is planted in the neighbourhood of all Shinto temples, which are built of its wood. It is also cultivated for its timber in the mountain forests of Central Japan, where it often attains the height of 100 feet, with a tall straight trunk 3 feet in diameter near the ground and free of branches for 50 feet or 60 feet. The wood is light, strong, tough, and very durable in contact with the soil, pleasantly fragrant like that of the other species of this section, and white, straw colour or pink. The palaces of the Mikado in Kioto were made from the wood of this tree, which also serves for the frames of Buddhist temples and the interior finish of expensive houses. In Japan Cupressus obtusa is one of the favourite subjects for dwarfing, and is often cut into eccentric shapes, and several abnormal varieties or juvenile forms are cultivated. Cupressus obtusa aurea gracilis is a free-growing and beautiful form of this tree introduced into our gardens a few years ago. There are dwarf bushy forms in cultivation in this country and Europe, some with leaves of normal colour and others with yellow foliage. These are highly prized in Japan, and can be seen in almost every Japanese garden. A distinct form known as Retinospora lycopodioides has stout erect branchlets densely clothed with bluntly awl-shaped, very dark green leaves, and another, Retinospora filicoides, is peculiar in its long, slender, spreading branches covered with short, broad, light green sprays of quadrangular branchlets.

CUPRESSUS PISIFERA (the Sawara of the Japanese) is planted in their forests and temple grounds

with Cupressus obtusa, and produces redder, coarser-grained, and less valuable wood. The common Golden Retinospora (Retinospora pisifera aurea) is a form of this tree, and is here, perhaps, the most frequently cultivated of the Japanese Retinosporas. A more remarkable form is the so-called Retinospora squarrosa, in which all the leaves are short, pale blue-green, and spreading or slightly bent toward the branchlets. This is a low, broad, dense bush or small tree with large divided and forked stems. Almost as remarkable is Retinospora filifera, another form of this tree with long, slender, pendulous, thread-like branchlets clothed with dark green leaves arranged in remote alternate pairs; there is a yellow-coloured form of this plant. This is certainly one of the most remarkable of all pendulous-branched conifers, but, unfortunately, it is very capricious, sometimes flourishing with great luxuriance, but more often perishing from the cold of severe winters.—*Garden and Forest.*

**Spiræa arbuscula.**—This handsome Spiræa is an alpine shrub with erect, wiry, branching stems

*The White Bullace.*

terminating in small, compact corymbs of bright rose-red flowers. Its affinities are with Spiræa lucida, which is a larger plant with looser corymbs of white or pale rose-coloured flowers, and which grows at a low elevation in dry woods from the Black Hills of South Dakota to Southern Alberta and Eastern Washington, with Spiræa corymbosa of the Southern Alleghanies and with the Siberian and eastern Asiatic Spiræa betulifolia. It differs from Spiræa lucida in its dwarfer habit, in its smaller and much more compact flower-clusters, in its bright red stems covered with thin lustrous bark, and in its smaller leaves. Spiræa arbuscula grows at Glacier, on the Selkirk Mountains, in British Columbia, and southward along the Cascade Mountains and the high coast ranges of Washington and Oregon and along the Sierra Nevada of California to the centre of that range. On the Olympic Mountains in Washington it forms dense low mats at the timber-line at an elevation of 5000 feet above the sea, while on Mount Ranier, on the opposite side of Puget Sound, it ascends 2000 feet higher, enlivening in August rocky cliffs with its brilliant flowers.—*Garden and Forest.*

## ORCHARD AND FRUIT GARDEN

### BULLACES.

BULLACES are seldom met with, this fact being no doubt attributable to the erroneous idea that the quality of the fruit is far inferior to that of the Damson. Even were this true, Bullace would, I maintain, pay for growing, not on account of their free-bearing character, but because the fruit hangs on the trees long after Damsons have fallen, even well into November and when once the markets are cleared of the general run of popular Plums and Gages, the public, having no other alternative, eagerly buy any late consignments. Probably no Bullace trees are grown in Essex, Suffolk and Norfolk than in all other counties put together. The variety most commonly met with is the Small White, round in shape, and mottled with red on the exposed side. A three varieties ripen in October, but impro-

in flavour if allowed to hang on the trees till November. Bullaces also make delicious jams are excellent when bottled, and in East Ang Bullace pie is held in high esteem amongst farm labourers and cottagers generally.

Bullaces, more especially the common white variety, are not particular as to soil, grow and thriving fairly well in a compost that would almost starve the Damson. One of the chief recommendations of this fruit is the extreme hardness of its blossom, it being but seldom that the crop is lost through frost. On the account those who grow Bullaces for sale usually plant them on the margins of orchards as a screen for more tender fruits. On one estate in Sussex there are rampant hedges formed of Nut trees and Bullaces. They both grow well together, and in autumn the joint crops are both profitable and interesting. In South Notts the name Bullace is almost unknown, the fruit being known by the term Wint Crack. The Essex Bullace is somewhat larger than the common white, having a yellowish

en skin and a more juicy, sweeter flesh. The Royal Bullace has much larger fruit, the yellowish skin carrying a thin grey bloom, the flesh brisk, but refreshing, and splendid for its.

**Early Peaches.**—Without the expense of heat and only a little protection afforded by glass case sufficient to keep out frost, and with a little management in the way of taking advantage of every bit of sunshine, ripe Peaches can now be had from at least the end of June until the end of September. Certainly this early date has been attainable now for many years by the aid of Early Beatrice, but it is a very small fruit and not comparable to the newer Alexander, Waterloo or Amsden June. It would be interesting to learn from practical experience which of the three is really the best, as in the majority of gardens not more than two first early trees would be planted, and there is not much difference in them from a flavour standpoint. The preference should decidedly be given to the best and most persistent cropper. It may be that they vary on different soils; certainly one hears very different opinions expressed as to their respective merits. Personally, I have found Waterloo the best, and sold hold fast by this as the first early. Alexander is fairly good, Amsden June poor. For succession, therefore, I should recommend Alexander, Early Louise, Hale's Early and Early Osse Mignonne, the first and third under the best case with two early Nectarines to keep them company, and all four of the Peaches outside. Early Louise is only included because it sometimes fills a gap before Hale's Early is ready. Of soil being naturally light, with sand not far below the surface and no facilities for supplying a stronger compost in quantity, is not an ideal one for Peaches. A mixture of stiff road sidings and cow manure, both with the natural soil at planting and as an occasional top-dressing, is a great assistance. The sorts already enumerated succeeded by Alexandra Noblesse, Dymond and Goshawk, three of the most reliable mid-season varieties on this soil, and these in their turn by Barrington and Walburton Admirable. Princess of Wales does well under glass, but is not a success out of doors.—E. BURRELL.

**PLANTING THE FLOWER GARDEN.**

I enclose a rough sketch, which is not drawn to scale, of flower beds laid out here two years ago, which I should be very glad to receive a little glance. The beds are cut out of the turf, and on a slightly lower level there are two other terraces exactly similar, both terraces being enclosed by a Yew hedge. I first planted all with perennials. I found, however, that the beds were too small to allow large showy perennials to grow, and the smaller ones proved to be ineffective. As this formal piece of garden is just under the windows of the house and has a lawn on each side of it, I require some bright masses of colour, and yet at the same time I wish to avoid long intervals of barrenness and also the necessity of constant planting. This year I planted the upper terrace with Tulips for the spring and Phlox Drummond and Verbenas for the summer. The latter have done exceedingly well, but have absolutely killed the lower terrace with its perennials by contrast.

Will you kindly advise me whether I should persevere with perennials only, and, if so, with what kinds, or should I employ annuals? If the latter, I should be much obliged for any suggestions, as I wish to avoid Geraniums, Calceolarias, &c. and yet I want to have the beds in beauty at the same time. I also desire to avoid planting them with bulbs, as that is costly, and I have bulbs in other parts of the garden, especially in the wild garden.—C. A. C.

As no doubt your case is a typical one of many, we propose to answer it a little more at length. You rightly see the need of getting rid of the two plantings a year, which is fatal to all

permanence in flower gardening and lands us in bare earth in spite of all at some of the most interesting times of the year, as, for instance, an autumn like the present, when in any real flower garden there is much beauty of Tea and Monthly Roses and even Carnations. Any system which pulls all this up to put in bulbs and other things in September or October must for ever be a bad one. We have seen flower gardens in October or November this year which were quite beautiful. The mixed way is the only lasting and artistic way in the flower garden—that is to say, that while one may have leanings to one beautiful race of plants, as Roses and Carnations, the best way is to support these with the choicest of all other things, from rock plants to Tea Roses, to thoroughly prepare the beds to last at least seven years, and in some way to plant them permanently, whether with choice shrubs, Roses, or very choice perennials and rock plants as carpets.

Very coarse perennials and those of short bloom, as many of them are, should never be put very near the windows of a house, excepting those that have some beauty of foliage to last them through the year. Annuals are an excellent aid, but they are best for borders in the kitchen garden, or in some place apart, owing to the need of annual sowing and preparation of the ground, which is impossible in a beautiful flower garden. Another reason for the permanent planting of the flower garden is that there is so much to be done if we are to get in all the best that can be got in. It cannot be done at any one time of the year, but we must have the whole of the winter for the work, because each bed should be prepared and planted with much more thought than in the scratch way so common. If, however, you wish for colour in flat masses, in circles or lines, you cannot have it in this way, but colour in natural and artistic ways may be had easily and even effectually by grouping.—Ed.

**PLANTING SHORE LAND.**

(1) I LIVE near Land's End and close to the sea, where the wind has enormous power and the sand, unless bound together by some vegetation, is continually blown inland. Part of my land is composed of this loose sand, much of which, however, is covered with a species of coarse grass, sending out long knotted shoots under the surface, thus tending to bind the sand together. I am anxious to clothe more of the sand in the same way, and have been recommended *Panicum arenaia*. Can you tell me where the seed of this grass or any other equally suitable can be had at a low price, so that it could be freely used? What should be the price per lb.?

You must buy this plant where it is commonly used for planting the sandhills, or seed may be bought from some of the large seed houses at about a shilling a pound.

(2) On other portions of my ground I have sown common Furze, and the plants are doing extremely well. I wish to vary it with the dwarf Furze. Where can this seed be procured cheaply and what should be the price per lb.?

You might save it yourself with some trouble, but it would not be worth while, and may be obtained from large tree seed houses, value about 1s. per pound.

(3) I wish to sow with the dwarf Furze some seed of the common Ling and Heath, so that in time they may grow to such perfection of exquisite beauty as they do on the Cornish cliffs and downs. Is there any place in Scotland where the seed can be got cheaply?

Better plant Ling and Heaths. Common Ling may be had on commons near you; the other Heaths from good shrub nurseries.

(4) I sowed Broom at the same time as the Furze which has done so well, but none of the Broom came up. What is the right time to sow it, and will it stand the sea as well as Furze?

Sow Broom in April and protect from rabbits. It will withstand the sea breeze.

(5) I have succeeded very well indeed with Tamarisk cuttings and plants, particularly with the former, but should like to know what other shrubs there may be easily raised from seed or cuttings which will stand the salt gales as Tamarisk does. I find the Veronicas do well in shelter, but that no shrubs will live in exposed places but Tamarisk, Furze and Heath.

See Buckthorn and small-leaved Willows.

(6) Will Sea Holly grow well from seed, and when should the seed be sown?

Yes: sow in spring or in early autumn as soon as seed is ripe.

(7) Is the Sea Pine mentioned as growing on the French sea-coast likely to do well?

Yes, we should say so.

The ground referred to is for the most part rough and sandy and with but little shelter. It slopes steeply to the west and has to bear the full brunt of the Atlantic gales. In the summer it suffers a good deal from want of moisture, and it contains a great deal of granite. But where there is shelter the vegetation is luxuriant. My chief object is to bring the ground back to what it once was in part, the very beautiful cliff land, glowing with the mingled blossom of Heath and Ling and dwarf Furze in autumn, and in spring brilliant with the larger Furze, with great patches of Foxgloves and other flowers here and there among the granite. The usual attempts at ordinary flower gardening are made in the neighbourhood, and in exposed places are, from a picturesque point of view, lamentable failures, whereas at the same time the cliffs, downs and lovely old granite ledges are indescribably beautiful and luxuriant. A. H. P.

Cornwall.

**SOCIETIES AND EXHIBITIONS.**

**ROYAL HORTICULTURAL SOCIETY.**

NOVEMBER 23.

THERE was a most marked improvement in the extent of the exhibition on the above date. The three long tables were well filled, and on the sides also were numerous exhibits. The work of the committees appears to have been fairly well distributed, each having a good attendance. Chrysanthemums were still in the ascendant, making a brave show. Of these the finest group came from the Rycroft Nursery, constituting a most instructive lesson in floral arrangement, the noble effect produced by associating large exhibition blooms in appropriate vases of massive outline and chaste design being an object-lesson to growers of the Chrysanthemum for decoration as well as for exhibition. Other exhibits of the Chrysanthemum were likewise in good character, notably those from the Earlswood Nurseries. Again we have the pleasure to record a finely-grown exhibit of *Begonia Gloire de Lorraine*, on this occasion from a private garden. Another reasonable exhibit was a group of well-cultivated *Poinsettias*, dwarf plants with fully-developed heads of scarlet bracts. Of reasonable plants for out of doors, note should be made of the profusely berried plants of *Pernettyas*. Another exhibit was that of decorative arrangements of Chrysanthemums combined with autumnal foliage, too much crowded to be seen to the best possible advantage.

Amongst Orchids, the most interesting exhibit by far was the group of hybrids from Messrs. Veitch, which in itself constituted an excellent illustration of the progress made by the hybridist during Her Majesty's reign, more especially in the last decade. *Cattleyas* and *Cypripediums* abounded here. Other good groups and minor exhibits assisted in making an excellent display in spite of the very unfavourable weather of late. Fruit, as regards extent, was not largely shown, the most noteworthy exhibit being that of pot-grown examples of Apples from the celebrated

Sawbridgeworth collection, perfect in finish. A new Grape from the same source to which an award was made, commends itself by its flavour alone, to say nothing of its colour. The competitive classes still produce a good contingent of exhibits, the best known kinds from the point of flavour still holding their own. These compared most favourably with an exhibit of a new Apple, to which an award of merit for some reason was made, possibly for its colour, certainly not, we should think for its flavour as a dessert fruit, and positively not from the point of size as a kitchen Apple. There was also a finely grown exhibit of Onions, in size immense and well ripened, useful no doubt to save for seeding another year, but from the utilitarian point of view of far less importance.

The weather being most gloomy by reason of the dense overhanging fog the light in the Drill Hall was very bad, it being almost impossible to take correct note of colours in many instances. Surely it would be possible to cleanse the glass on the roof and otherwise decorate the interior of this gloomy structure so as to ensure at least the maximum of light possible on all such occasions.

The afternoon lecture on exhibitions, with suggestions as regards the management of shows and points of note to exhibitors and judges, was delivered by Mr. John Wright to a poor audience; the attendance no doubt at this meeting being far less than it otherwise would have been by reason of the fog.

#### Orchid Committee.

Awards of merit were adjudged to the following:—

**ODONTOGLOSSUM DAYANUM.**—A distinct and pretty variety, undoubtedly a natural hybrid between *O. gloriosum* and some other species. The sepals and petals, about  $1\frac{1}{2}$  inches in length, are pale greenish yellow, thickly spotted with small reddish brown spots; the lip greenish yellow, with a broad blotch of brown in the centre and a white crest, with numerous prominent bristles. A plant with seven flowers was sent from Baron Schroeder, The Dell, Egham.

**CATTLEYA LABIATA WHITE QUEEN.**—In this the sepals and petals are pure white; the lip white, with a slight rose blotch in the centre and some yellow at the base. A fine plant with four flowers came from Mr. W. P. Birkenshaw, West Hill, Leeds.

**CATTLEYA EMPRESS FREDERICK VAR. LEONATA** (*C. Mossie* × *C. Dowiana*).—A lovely hybrid with deep rose sepals and petals, of fine form and substance. The large lip is deep crimson-purple with a fringed rose margin, the side lobes rose-purple, heavily veined and lined with the yellow of the *Dowiana* parent through the throat. It is one of the finest hybrid *Cattleyas* we have seen. From Messrs. J. Veitch and Sons, Ltd.

**LÆLIA OLIVIA** (*L. crispa* × *L. xanthina*).—The sepals and petals are pale yellow about  $2\frac{1}{2}$  inches in length; the lip orange, heavily suffused, and lined with crimson; the side lobes lighter veined with yellow. It is a distinct and lovely variety, giving promise of a fine thing as the plant becomes stronger. From Messrs. Veitch and Sons.

**CYPRIPEDIUM BECKMANI.**—The parentage as recorded was considered doubtful. It was said to be the result of crossing *C. Boxalli superbum* and *C. bellatulum*, but no trace of the latter parent could be observed. The dorsal sepal is green margined with white, and thickly spotted with dark brown; the broad fine-shaped petals green at the lower halves, becoming suffused with dark brown and pale green, spotted with brown at the base. From Messrs. Linden, Brussels.

Botanical certificates were awarded to Mr. R. I. Measures, Cambridge Lodge, Flodden Road, Camberwell, for *Cirrhopetalum refractum*, a distinct form with long yellow connected sepals and purple petals; also to Messrs. F. Sander and Co. for *Maxillaria elegantula*; the sepals white at the base, and suffused with purple at the apex, the petals white, yellow spotted with purple at

the apex, the lip light yellow in front suffused with purple at the edges.

Messrs. J. Veitch and Sons sent a choice and interesting group. The most prominent amongst the numerous fine hybrids were two good forms of *Lælio-Cattleya Pallas* (*L. crispa* × *C. Dowiana*), the sepals being creamy white slightly suffused with rose. The petals having the twisted characters of *L. crispa* are of a delicate rose shade of colour; the front lobe of the lip deep crimson purple, heavily fringed and margined with white; the side lobes rose lined with yellow, becoming suffused with a deeper shade of colour at the base. *L.-C. Statteriana* (*C. labiata* × *L. Perrini*) and *L.-C. Decia* (*C. Bowringiana* × *C. Dowiana*) with extra dark sepals and petals, were also shown. Among the numerous *Cypripediums* were grand forms of *C. Leeanum*, *C. Niobe*, *C. cænanthum superbum*, *C. Acteus* (*C. Leeanum* × *C. insigne Sandere*) in which the flowers are considerably lighter, *C. Prospero* (*C. Spicerianum* × *C. insigne Sandere*), a good form of *C. lo grande*, *C. Tityus*, and numerous other fine forms. Finely-flowered *Zygopetalums* and *Oncidiums* were also included. A silver Flora medal was awarded. Messrs. F. Sander and Co. sent a small but choice group, which contained numerous fine forms of *Cypripedium Leeanum*, *C. Calypso-Leeanum*, derived from the parents indicated in the name, and having the intermediate characteristics of both hybrids, *Habenaria carnea*, *Dendrobium Johnsonæ*, and a fine plant with two spikes of flower of *Cymbidium Winnianum*. Amongst *Calanthes* were fine spikes of *Calanthe bella* and *C. Florence*. *Phaius Ashworthianus*, and *Chondrorhyncha Chestertonæ* with creamy sepals and petals, the heavily fringed lip creamy white with numerous brown spots on the disc, were also sent (silver Banksian medal). Messrs. H. Low and Co. sent a large and interesting group, amongst which were several fine forms of *Cattleya labiata*, finely-flowered *Odontoglossum crispum*, numerous *Cypripediums*, finely-flowered *Oncidiums*, and *Vanda cœrulea*. A silver Flora medal was awarded. The Right Hon. J. Chamberlain was awarded a silver Banksian medal for a choice collection of hybrid *Cattleyas* and *Lælio-Cattleyas*. The most prominent was *L.-C. Clive*, the sepals pale rose, the petals deeper in colour than the sepals, of fine form and substance, the lip rich crimson-purple, veined with darker purple, mottled and fringed with yellow. It is the result of crossing *Cattleya Dowiana* and *L. prestans*. *L.-C. Gotoiana* (*C. Warneri* × *L. tenebrosa*), with three flowers; *L.-C. albanensis* (*L. grandis* and *C. Warneri*), *L.-C. corbeilensis*, a form of *L.-C. Aurora*, with a dark front lobe to the lip; and *L.-C. Ophelia* and *C. Miss Williams* were noteworthy. Mr. R. I. Measures sent a new *Cypripedium* named *Siron* (*C. niveum* × *C. venustum Measuresianum*). The ground colour of the flower is white, thickly covered with reddish brown spots, the dorsal sepal and petals veined with green. Mr. W. B. Latham, Birmingham Botanic Gardens, sent a new hybrid *Cypripedium* named *C. Dudmanianum* (*C. Spicerianum* × *C. Chamberlainianum*), in which the characters of both parents are apparent. Mr. P. Crowley, Croydon, sent two good forms of *Cattleya labiata*. The Hon. P. Allsopp sent forms of *Cypripedium insigne montanum*. Captain Holford, Westonbirt, Gloucester, sent cut flowers of *Cypripediums*, and a collection of cut Orchids was sent by Mr. W. H. Lumsden, Balmedie, Aberdeenshire.

#### Floral Committee.

Awards of merit were made to—  
**BEGONIA JULIUS**, one of the hybrids resulting from crossing the winter-flowering *B. socotrana* with the tuberous section. The plant in question shows a most distinct advance both in habit of growth and in freedom of flowering. The leaves are of moderate size only, more robust than in the tuberous type, being also set on short foot-stalks. The plant shown bore several stout trusses well furnished with blossoms of average size, the colour being a soft shade of rose-pink; the flowers are also double and of good form. From Messrs. J. Veitch and Sons, Chelsea.

**CHRYSANTHEMUM MARY MOLYNEUX** (Japanese incurved).—A very promising exhibition variety having the essential elements, of extra size in fine form, being also very full. The colour is pale blush-pink with silvery reverse. From Mr. C. J. Garnier, Rookesbury Park, Fareham (gardener, Mr. N. Molyneux).

**CHRYSANTHEMUM MRS. H. FOLKES** (Japanese reflexed).—A pure white variety, with close, full flowers, the petals prettily curled and the form good. This was shown in good condition to From Mr. J. E. Strachan, Hemel Hempstead (gardener, Mr. Folkles).

**CHRYSANTHEMUM JULIA SCARAMANGA** (Japanese reflexed).—A remarkably fine new variety, an one of the very best additions of the year. The flowers, grand examples of culture, were equal in size to large blooms of *Mme. Carnot* and of some what similar outline and form. They are of colour a rosy-shaded terra-cotta, the graceful character of the flowers adding to their beauty. From Mr. Wells, Earlswood Nurseries, Redhill.

**CHRYSANTHEMUM GEORGIANA PITCHER** (Japanese incurved).—A very fine and most distinct variety with broad and massive florets, which incur sufficiently to avoid any undue formality in outline. The colour is a pale lemon-yellow, and the flowers of extra size. From Mr. Wells.

**CHRYSANTHEMUM MRS. F. A. BEVAN** (Japanese reflexed).—A beautiful variety, not of too large dimensions, being what may be termed in an exhibitor's phraseology, "a deep front-rose flower." The colour is a soft silvery pink, very distinct and most attractive by reason of its colour. From Mr. Wells.

A vote of thanks was accorded most unambiguously to M. Anatole Cordonnier, Bayona, France, for a promising white Japanese variety named *Don de la Madone*, of which more was possibly be heard.

A superb group of cut *Chrysanthemum* arranged with exquisite taste, was staged by Mr. H. J. Jones, of Ryecroft Nursery, Lewisham, S. It occupied both sides of a table running the length of the hall, and formed one of the most attractive and striking features of the show. The arrangement was carried out with rare judgment and skill, the result being a display not only most artistic, but calculated to exhibit the bloom to the best possible advantage. Down the centre of the table ran a line of graceful *Crotons* and *Palms* interspersed with large and handsome arrangements of massive blooms in vases of very suitable form and material. On the tables were boards of flowers in exhibition style, each board being separated from the next by about half a dozen varieties in bunches of three, these being much higher than the boards, and thus avoiding any monotony or formality. Nowhere was there any suspicion of over-crowding or of clashing colours. The Ferns, small *Dracenas* and *Crotons* used for groundwork, were all likewise of the highest quality. As regards the *Chrysanthemum* themselves, they deserve the highest praise. The blooms were splendidly grown and finished, and in the freshest possible condition. One of the most striking things was a box of grand flowers of *Western King*, one of the finest whites in cultivation; every bloom was excellent in form, perfectly pure, and delightfully crisp in the petal. Mr. H. Godfrey, Mrs. A. Cross, Duchess, Wif, a splendid white incurved; *Mlle. Théa Rey*, W. Wright, a remarkably graceful bloom, Japanese reflexed, with long, loose, rather narrow petals, the colour a delicate pink with creamy white centre; *Mlle. Laurence Zédé*, large and very pretty incurved Japanese, of colour shaded lilac; *Yellow Mme. Carnot*, a large bloom with narrow and intermingling florets and *Australie*, of great size and beauty, of lilac in colour, the backs of the petals silver were also good. This exceptionally fine exhibit was awarded a silver-gilt Flora medal. Another very fine group of cut *Chrysanthemums* was staged by Mr. W. Wells, Earlswood Nurseries, and contained Japanese, incurved, singles and pompons. A few of the best varieties were *Jas Scaramanga*, a new and very striking brot

low Japanese; Surpasse Amiral, G. J. Warren, Duchess of Fife, Georgiana Pitcher, a huge light yellow bloom with thickly twisted petals; Mlle. Laurence Zedès, very fine blooms; Oceana; a new pale green variety, incurved Japanese in form. M. Edouard Roger; Mrs. F. A. Bevan, a new Japanese reflexed of delicate rosy lilac colour; Eastone, a loose incurved Japanese, yellow and gold; and Australia. A word of praise must be given to the beautiful singles which Mr. Wells always shows in such good form and such great variety. They are excellent for cutting, while their lasting qualities are unrivalled. This very interesting group obtained a silver-gilt Banksian medal. Cut blooms were shown by Mr. R. Owen, of Maidenhead, among the finest being President Carnot, Glory of Maidenhead, Royal Standard, and Glaring, a vivid orange and yellow variety (bronze Banksian medal).

A small, but pretty collection of cut Chrysanthemums was staged by Mr. A. H. Rickwood, gardener to the Dowager Lady Freake, Fulwell Park, Twickenham. The blooms were clean and fresh, though not large (silver Banksian medal). M. F. Cubberley, gardener to Mr. J. W. Temple, Leewood, Groombridge, was awarded a silver-gilt Banksian medal for an excellent group of Bona Gloire de Lorraine. The plants, which were strong and well grown, were literally covered with their bright pink blooms and made a gorgeous display of colour. A silver Banksian medal went to Messrs. Cripps and Sons, of Tunbridge Wells, for a group of admirable plants of Poinsettias. The beds of scarlet bracts were very dazzling and made a very effective group. Messrs. Veitch and Sons exhibited a small group of Begonia Mrs. H. J., a pleasing rosy-red variety with handsome and substantial foliage. Messrs. Hugh Low and Co. again showed their new Carnation Winter Comet, which was described in these columns at the last meeting. Messrs. Cutbush and Son were awarded a silver Banksian medal for a group of Plectya mucronata seedlings, all dwarf, bushy plants, very heavily berried. Mr. L. H. Calcutt staged stands and vases of Chrysanthemums, the arrangement in most cases being very graceful and in light. A silver Flora medal was awarded.

#### Fruit Committee.

There was a fair quantity of exhibits before the committee. The light was bad and some of the best fruits could not be examined. The Messrs. Rivers had grand Apples well meriting the award given, also a new Grape. Vegetables were not numerous. The Veitch prizes for flavour were well contested, but brought forth nothing new. Awards of merit were given to

**RAFE DIRECTEUR TISSERAND.**—Berries round, good size, bluish black in colour and of good flavour. It is a very distinct variety and evidently a good keeper. From Messrs. Rivers and So Sawbridgeworth, Herts.

**APPLE LADY FALMOUTH.**—A medium-sized fruit, somewhat flat, with large open eye, scarlet on the exposed side, flesh firm and of good quality, a good winter dessert variety. From Mr. G. Chambers, Beech Farm, Mereworth, Maidstone.

Messrs. Rivers and Son sent six baskets of Apples in as many varieties. Peasgood's Nonsuch was remarkable for colour and finish, King of Topkins Co. was very fine, and the newer Bijou, a very pretty small Apple, was very well grown and brilliant in colour. This is a favourite for the pot culture. There were grand Cox's Orange and Gibbon Pippin with the less-known Buckingham, an American Apple, handsome, and of excellent quality. Gradiska, a white Grape, berries transparent and very refreshing, was also shown (silver Banksian medal). Mr. W. Bayford, Glewston Court Gardens, Ross, Hereford, sent thirty varieties of Apples, excellent as regards colour, variety, and size. Peasgood's Nonsuch was very fine, also Gloria Mundi, Warner's King (a little superior to its best), and Tower of Glamis. Striped varieties, Golden Noble, Queen Caroline, and other Peasgood varieties, with Cox's Orange and Bannockburn's Red Winter Reinette, very highly coloured, were also sent (silver Banksian medal).

Mr. E. Beckett, Aldenham House Gardens, Elstree, Herts, staged a collection of Onions, large bulbs, sound and shapely, and arranged in heaps in quantity. Ailsa Craig was one of the best, and Anglo White Spanish, a flatter bulb, was very large, as were Prizetaker, Cranston's Excelsior, Sutton's A 1, Cocoa-nut, and Barnet Hero, the last a very solid bulb and long keeper (silver Banksian medal). Apples were sent by Mrs. Jackson, Beechwood Lodge, Carshalton, and Messrs. Jefferies and Sons, Royal Nurseries, Cirencester. The Cape Gooseberry was sent by Mr. Batchelor, Harefield Park, Uxbridge, nice fruits and well grown. Potatoes in variety (seedlings) were sent from the Surrey Seed Co., Redhill, but of no special merit.

The prizes for flavour brought forth nine dishes of Apples and five of Pears, the best Apple being Cockle Pippin, from Mr. Woodward, Barham Court, Maidstone, excellent fruits of this old favourite being staged, the second prize going to Mr. Bayford, Glewston Court, for good Cox's Orange. The best dish of Pears was Winter Nelis from Mr. Crook, Forde Abbey, Chard, Mr. Woodward being second with Nouvelle Fulvie.

#### NATIONAL CHRYSANTHEMUM SOCIETY. NOVEMBER 22.

The floral committee of this society met at the Royal Aquarium, Westminster, on the above date, Mr. T. Bevan occupying the chair. The display of novelties was less numerous, and the varieties awarded first-class certificates were as follows:—

**CHRYSANTHEMUM J. CHAMBERLAIN.**—This is a large spreading flower with long, broad florets, incurving at the ends. The colour is a brilliant reddish crimson, with a light bronze reverse. It should be a very effective bloom on the show-board. Sent by Mr. H. Weeks, The Gardens, Thrumpton Hall, Derby.

**CHRYSANTHEMUM MME. FERLAT.**—A large flower of massive build, with medium florets, tightly incurving, and making a bloom of capital substance. It is a splendid white companion to such sorts as Chas. H. Curtis, and a good back row flower. From Mr. W. Wells, Earlswood, Redhill.

**CHRYSANTHEMUM JULIA SCARAMANGA.**—A very large, loosely built, and spreading Japanese flower, with long, rather narrow curling florets, twisting and intermingling in a pretty manner. The colour from early and late buds varies considerably, flowers from the former being a pale rosy bronze, those from the latter being almost a rosy terra-cotta. Also from Mr. Wells.

A commendation was made in favour of Don de la Madone, a pretty medium-sized white Japanese bloom, with innumerable florets of only medium width, flat, recurving and twisting in a unique manner. This was sent by Mons. Anatole Cordonnier, Roubaix, France. The committee also wished to see again Mrs. A. E. Peaver, a promising incurved flower with fairly broad florets; colour bronzy yellow, inside of florets lined crimson.

A vote of thanks was accorded Mr. Chas. Gibson for an exhibit of six blooms of a white incurved Japanese named Mustapha. This was certificated last season. In its present form the blooms showed a number of crowns. Promising novelties were Japanese Mme. J. Chaure, a very deep maroon-crimson, bronze reverse, long florets, curling at the ends; Mrs. J. J. Glessner, rich golden yellow, tinted bronze, and staged as a market variety, having been grown in bush form; Lucien Remy, a medium-sized flower of a pleasing rose-pink shade, and admired for its colour; Surpasse Amiral, a bloom of massive build and having broad, slightly incurving florets of splendid substance, colour golden yellow, paler reverse.

Several dozen boards of blooms were exhibited by Mr. Wells, these including the latest novelties.

The general committee of this society held a meeting on Monday evening last at Anderton's

Hotel, Fleet Street, Mr. T. W. Sanders occupying the chair. The meeting was rather a lengthy one, and most of the time was taken up in discussing matters connected with the society's shows and other formal subjects, not the least important being the question of the bad light at the Aquarium on the occasion of the last show, and the illegibility of many of the labels on the exhibits. At shows of such a character no exhibitor ought, in Mr. Harman-Payne's opinion, to be allowed to write the names of the flowers in his exhibit in lead pencil.

The small gold medal recently decided upon was submitted for approval. On the motion of Mr. Dean, it was resolved that Mr. Higgs fill the vacancy on the classification committee caused by the death of Mr. R. Owen, and that the committee hold a meeting some time late this year or early next year to decide upon several varieties of doubtful classification.

Meetings of the general committee will be held next season on the following dates, viz., August 29, September 26, October 24, November 28, December 19, 1898, and January 16, 1899. The fixtures of the floral committee are September 6 and 26, October 11, 24, and 31, November 14, 21, and 28, and December 6 and 12.

The election of a number of new members brought the meeting to a close.

The annual dinner of this society took place at Anderton's Hotel, Fleet Street, on Wednesday evening, when the chair was occupied by Mr. T. W. Sanders. The large room was filled to its utmost capacity and the lengthy programme was not got through until a late hour. Amongst those present were Messrs. H. J. Laing, W. Wells, R. Dean (secretary), D. B. Crane, Leonard Browne, T. Bevan and those named below.

After the chairman had proposed the usual loyal toasts, "The Glorious Chrysanthemum" was the next on the list, which we presume signified the National Chrysanthemum Society. Mr. Sanders very ably reviewed its past history. Mr. Gordon proposed "Donors of Special Prizes," to which Mr. H. J. Jones, of Lewisham, and Mr. P. Waterer responded.

Much enthusiasm was shown when Mr. Scott, on behalf of the Bromley Chrysanthemum Society, received the national challenge trophy, won for the second time at the last November show at the Royal Aquarium. Mr. Mease came in for hearty praise when receiving the valuable awards, Holmes' cups, and other prizes won at the recent exhibition. He also received a painting of a Chrysanthemum flower. Mr. Norman Davis, of Framfield, also received a cup and gold medal.

With the many other toasts we must associate the names of Messrs. R. Ballantine, C. Harman-Payne, H. J. Cutbush, and Mr. Pearson, who replied for the horticultural press. The toast of "The Chairman" was thoroughly well received, as also was the one of the president, Sir Edwin Saunders.

In the course of the chairman's speech he mentioned that the number of affiliated societies was now 118, thirteen of which were from Kent, eleven from Essex, and seven from New Zealand.

We may well ask, however, if the old officers of the society, those we knew not many years ago, have forsaken its ranks. There seems a sad lack of support by the men who formerly worked hard to make the society worthy of its national character.

**The weather in West Herts.**—The weather has lately been singularly changeable, but, taken as a whole, the past week was a very warm one for the middle of November. On two days the shade temperature rose as high as 58°, and on one night the minimum thermometer in the screen never fell lower than 50°, which is about 2° warmer than would be seasonable at midday. On the other hand, on three nights the exposed thermometer showed 4° of frost. At 2 feet deep the soil is now 2°, and at 1 foot deep 3°, warmer than the November average. Rain fell on three days, but

the total fall for the month up to the present time is only one-third of what may be regarded as a reasonable amount for the same period. A little rain water has come through both percolation gauges the last two days, but before this there had been no measurable quantity for nearly three weeks. During the past fortnight only about five hours of clear sunshine have been altogether recorded.—E. M., *Berkhamsted*, November 19.

— Another mild and dry week. On two days the shade temperature rose to 56°, or about 10° higher than is reasonable. On the only really cold night the exposed thermometer showed 6° of frost, which is the lowest reading that has been indicated by it as yet this month. Notwithstanding the recent high day temperatures, the ground, both at 1 foot and 2 feet deep, is at the present time only about a degree warmer than is reasonable. No rain fell during the week, while the total measurement for the month, as far as it has gone, only amounts to about half an inch. The last six days have been very calm, the average rate of movement of the air at 30 feet above the ground being only 1½ miles an hour, and on the 21st the total record was only 6 miles, making this the calmest day in November, with one exception when the record was the same, for at all events the last twelve years. The past week has been a very foggy one. At 9 o'clock on the mornings of the 19th and 22nd, a house became quite invisible at a distance of respectively 10 yards and 11 yards. Notwithstanding the gloomy character of the weather generally, the sun shone brightly on one day for nearly six hours, and on another for four hours. My Dahlias, which had been lingering on in a crippled condition since October 7, were entirely killed by the frost of the night preceding the 19th inst., which is eighteen days later than the average date of their destruction in the previous twelve years, and, with the exception of 1894, the latest recorded during that period.—E. M., *Berkhamsted*.

## NOTES OF THE WEEK.

**Chrysanthemum Incomparable.**—This old variety with stiff florets of a yellow and red shade freely sprinkled with crimson spots, presents an attractive appearance. It is still worth cultivating, though little seen of late.

**Androsace macrantha.**—This is a very distinct species with large sessile leaves, which are slightly formed at the tips. It produces rather stout spikes and numerous pure white blossoms. The species is as yet scarcely in general cultivation, but appears to be a vigorous grower and free bloomer.

**Poinsettia pulcherrima.**—A magnificent group of Poinsettias, from the nursery of Messrs. Cripps, Tunbridge Wells, was a feature at the Drill Hall on Tuesday last. The heads were very fine all round, splendidly coloured, and the handsome foliage came down to the pot. Throughout the plants were uniform in size and of great brilliancy.

**Chrysanthemum Mignonette.**—This is one of those small varieties with Thistle-like heads of florets, which in an arrangement of cut flowers are not only light and elegant, but almost unique in effect. More than this, they are a welcome change from the host of Savoy-shaped heads that so often represent this group of autumn flowers.

**Pelargonium A. Tutlet.**—This is a fine scarlet variety, said to be a sport from the well-known Raspail Improved. So far as distinctness is concerned there is little doubt, the blossoms being very large, exceedingly brilliant in the scarlet hue, and the outer petals well formed and clearly defined. The flowers of the variety are much larger than those of the type.

**Bouvardia Maiden's Blush.**—A very pretty and useful kind for pots or for cut blooms that should be grown freely by all who have to supply useful flowers for personal adornment. When well grown and a few of the lower lateral flower buds removed it is easy to secure a nice spray of blossom and ample stem. In a cut state these flowers take up water more readily if a clean cut is made, but if broken they are sometimes bruised.

**Sweet Pea Celestial.**—A large bunch of this variety appeared at the Royal Horticultural Society

this week. The gathering came from Exmouth, and was said to be cut from a fully exposed position in the open. So far as the flowers were concerned these were quite fresh and good, almost equal to summer flowers. Near London, however, the few remaining blooms in the garden appear as though a shower of soot had fallen upon them.

**Chrysanthemum Mrs. H. Folkes.**—This variety obtained an award of merit on Tuesday last at the Royal Horticultural Society, and is a Japanese of the purest white. The variety came from Mr. C. E. Strachan, Hemel Hempstead, and some half-dozen of its handsome flowers with fully 2 feet of stem quickly attracted attention. Good points in the variety are the length and strength of the peduncle, the blooms being shown without any support.

**Skimmia Foremani.**—Some branches of this handsome berry-bearing shrub from the garden of Mr. A. Kingsmill were brought before the floral committee of the Royal Horticultural Society the other day. The berries are exceptionally bright and effective, and appear in large clusters amid the pale green leathery foliage. Even in pots these plants are of considerable value, when it is remembered they retain their berries for many months in succession.

**Paper-white Narcissus.**—At the present time there is quite a glut of this in the London and provincial markets—so much so that it is hawked throughout London at almost every turn at one penny per bunch of twelve sprays—a fact that tells its own tale. There is also a bountiful supply of Roses, mostly French, of course, but really very charming for the season, and lovely buds of these are freely offered at two for a penny.

**Begonia Julia.**—This promises to open out a new era in winter-flowering Begonias. The variety in question is of a salmon-pink shade and double, and is the outcome of a cross between a tuberous-rooted variety and *B. socrotana*. It distinctly favours the tuberous section: indeed the plant in question, save for the fact that it is in the prime of its flowering at the end of November, differs but little from a tuberous kind in midsummer.

**Pernettya mucronata.**—A large number of Pernettyas, mostly seedlings in variety, from Highgate, was sent to the Royal Horticultural Society on Tuesday by Messrs. Cutbush. In some instances the bushes were very compact and carried immense quantities of berries in clusters. These plants are highly attractive in those gardens that suit them, and for winter work are especially valuable. Some fine bunches of the pure white kind were sent from Mr. Kingsmill's garden at Harrow Weald.

**Carnation Countess of Warwick.**—We have seen blooms of the above which was referred to at p. 398. It is certainly a very fine variety, the flowers large, well formed, and of a peculiarly bright shade of colour. It is a seedling from Winter Cheer crossed with Uriah Pike, and has the free branching habit of the seed parent. The colour is not quite so deep as in the pollen parent. It has a rich Clove perfume, and is likely to become a general favourite with those who grow Carnations for winter flowering.

**Carnation Wm. Robinson.**—When seen in good condition this is certainly a fine scarlet of the tree or perpetual class, and for such there is plenty of room. The habit of the plant, however, is somewhat tall, and, like all the scarlet-flowered kinds when giving their flowers in winter-time, it produces many discoloured and therefore useless blooms. The prevalence of fog during the past few weeks has not in any way improved it in this respect. A race of winter-flowering Carnations capable of enduring London fog would be indeed a boon.

**Primula verticillata.**—In the greenhouse at this season the fine whorls of yellow blossoms of this plant are always attractive, more so where the plants have been grown with this object in view. It is an Abyssinian species, and therefore quite unreliable for the open garden. But, given the same treatment from seed as the forms of *P. sinensis*, it is quite as attractive as these when in

flower, and possesses a beauty of foliage that quite unique. Grown in a rather rich sandy loam, the plant is strong and robust, and flows profusely for weeks in succession.

**Primula obconica fimbriata.**—The variety forms that are produced from a small packet of seed of this variety hold out additional hope that in a few years considerable improvement may be expected both in size and colour. Even now the flowers are much larger than in the original, and coming in equal, if not even greater, number prove much more attractive than those of the type of some fifteen years ago. In some of the forms of the above there is a distinct eye, greenish yellow, almost paste-like substance, in the Auricle, only much less pronounced.

**Calla Little Gem.**—Though considerable was made when this variety was introduced, can scarcely be said to have kept up its reputation. The flower by itself is certainly pretentious enough, but, unfortunately for those who grow it, not only are the spathes small, but the colour of these is distinctly poor also, and therefore unlikely to please those who have to produce flow in quantity. More than this, in a large batch seedlings of the old form there are many which while being produced with much greater freedom are scarcely distinguishable from the above, and from their smaller stems are well suited for qu small glasses.

**Carnation Flora Hill.**—This is an American variety with pure milk-white flowers, and belongs to the tree or perpetual-flowering section. Tuesday last several plants of it from Mr. G. Frey came before the floral committee of the Royal Horticultural Society. The variety, however, failed to obtain any award, as owing to the manner of packing scarcely a flower remained unbroken so much so that it was impossible to form an opinion respecting its general freedom of blooming. The habit is somewhat tall and the growth medium. The flowers are fairly large and generally distinct, so far as could be determined from the unfortunate condition of the plants.

**Begonia semperflorens rosea.**—As a winter-free-flowering kind with vigorous constitution this easily-grown plant should commend itself all. Strictly speaking, the variety gigantea, which the remark applies, appears more or less perpetual flowering, and to secure winter blooming examples, stock must be grown to that end. With successional batches of cuttings, occasional pinching, and growing in the open in rat sheltered frames, a good bloom may be ensured during the greater portion of the winter. Even quite small plants contribute their quota of blossoms, and with continued growth the flowers produced at every lateral. Very attractive, they are the large somewhat succulent leaves.

**Schizostylis coccinea.**—I send you a spike of *Schizostylis coccinea* from the open. I do not remember ever having the flowers fine as this year. I have grown the plants usually in front of a vinery or any warm sunny position as well as in pots, although in pots they seem quite satisfactory. The position the plants now occupy is a south border in front of the Peach wall. They have been planted two years. This season they had the advantage of a good watering once or twice throughout the dry summer and once a dose of liquid manure. At present time I could cut several hundred spike-brilliant scarlet flowers, these being useful for house decoration. They go on expanding all being cut and placed in water. If the fact flowers are picked off and fresh water given they will last a long time.—A. LEE, *Baulieu, Southampton*.

**Names of plants.**—J. C.—1, *Cupressus sempervirens*; 2, *Retinospora obtusa*; 3, *Cupressus Lawsoniana* (seedling form); 4, *Abies pectinata*; 5, *Cupressus Lawsoniana*; 6, *Retinospora pisifera*. G. T. W.—*Desfontainia spinosa*.—E. O.—*Convolvulus minor*.

**Names of fruit.**—J. C. Tallack.—Peach, Hogg.

## FERNS.

### RESTING FERNS.

There are many Ferns which, though not deciduous, are much better kept quite cool and dormant during the winter. I have found in several instances that those kept in a warm drying temperature will continue to make fronds throughout the autumn, but when spring comes they have exhausted all their strength, and cannot make the vigorous spring growth which is natural to them. In some cases I have found that giving too much warmth during the autumn and winter has proved fatal. I may mention *Pteris scaberula* as an instance. Although this beautiful Fern will make better growth by giving a little extra warmth during the spring when it is natural for it to be in a state of active growth, it is almost certain death to keep it in a warm house after it has completed its season's growth. When good plants of the varieties of *P. serrulata* and *P. cretica* are required for early spring it is better to select plants with strong crowns and keep them dormant until, say, February, and then if given a good start in heat they will soon overtake those that have been growing throughout the winter. Of course this does not apply to young seedlings; these must always be kept going until they have made good crowns. Gleichens are another class which it is absolutely necessary to keep cool during the winter. I like to avoid frost, though they will stand a few degrees. There is perhaps no other class of Ferns which baffles the ordinary cultivator more than these. They love a cool, moist atmosphere with plenty of light and air above. In many instances it is difficult to provide this during the summer, as to give them sufficient light means to expose them to the sun. An old-fashioned, deep brick pit, where the lights can be tilted so as to let in light and air and at the same time exclude the direct rays of the sun, suits them well, or, better still, a lean-to house with a northern aspect.

Many of the *Adiantums* which are required for spring use will be better if partly dried off and kept just above freezing point. If the roots are kept healthy, they will start away vigorously if given warmth early in the year. All the old fronds should be removed previous to starting them, and it is necessary to be careful with regard to watering until they have begun to grow. *Cyrtomium falcatum*, one of our most useful Ferns for decoration, will continue to grow throughout the winter, but those with strong crowns, if rested during the winter, will, when started in warmth, throw up strong fronds, and soon make well furnished plants. *Lomaria gibba*, although naturally evergreen, may be dried off early in the autumn, that is provided the plants are well established and have strong crowns. The roots must be in good order, and while they are kept cool the crowns must be quite dry. With good treatment they soon make well furnished plants when started early in the year.

With all Ferns in a dormant state it is essential to avoid wetting the crowns, and to keep them sufficiently moist at the roots to prevent shrivelling. I believe our British Ferns would be much more popular if those who attempt their culture would study their natural requirements. When grown in pots they often continue to grow late in the autumn, and are sure to suffer more or less if we get frosty weather. Generally when growing in their natural habitats they are not only protected by their own old fronds, but other leaves, &c., help to cover and protect them, and this is one important point which many who attempt their culture quite overlook.

### DECIDUOUS FERNS.

Now that these will be losing their fronds, care should be taken that they do not get consigned to the rubbish heap. I have known more than one case where this has happened, therefore a warning may not be out of place. Of *Adiantums* which are quite deciduous, the

beautiful *A. palmatum* is one, also *A. speciosum*, *A. Henslowianum*, *A. amabile*, and *A. lunulatum*. *Nephrolepis pluma* and its variety *Bausei* are very beautiful during the summer, but lose all their fronds about this time, and are liable to get lost altogether if not carefully treated. They should be kept in a moderately warm position, and must not be allowed to get too dry, or the roots will perish.

Of *Davallias*, *D. Bullata* and *Mariesi* are both deciduous, but if kept in warmth the latter will start into new growth almost before the old fronds are off. *Leucostegia immersa*, which makes such a beautiful basket Fern, may also be referred to. This may be kept rather on the dry side while dormant, but not too much so. *Lastrea erythrorosa* and *L. Richardsi multifida*, both very desirable Ferns, should be kept quite cool and fairly moist, and may be started in warmth early in the year. *Athyrium Goringianum pictum*, the hardy tricolor Fern, requires similar treatment. *Struthiopteris germanica* and many of the beautiful North American Ferns are deciduous; the latter include the beautiful *Adiantum pedatum*, *Oncoclea sensibilis*, several *Osmundas*, *Lastreas*, &c., besides many of our beautiful English Ferns, which, though quite hardy, are better with the protection of a pit, for if we get mild weather they start prematurely, and then the frost cuts off the young fronds, and the plants will be disfigured for the season. By keeping them as cool as possible during the autumn and fairly moist, and then starting them in a gentle heat early in the year, they make fine plants early in the season. A. H.

**Aralia Sieboldi in flower in Ireland.**—At the close of November, when the branches of the trees that have borne aloft their leafy banners through all the sunlit hours of summer's golden prime lie in dark tracery against the evening sky, we turn with joy to these blossoms that are expanding. To-day the *Aralias* are exquisite. They are growing in the shade of Laurels, they are growing on a sunny bank, but alike in each position are sending up their branching spikes of silvery bloom. Resembling as they do the flowers of Ivy in their rounded growth, they are etherealised by their pallor,

To what may one liken them? They are as white blossoms seen in the moonlight, as stary nebulae set in their own dark shining leaves. These plants, put out five years ago, have been growing in the open ground ever since without any protection save that afforded by overhanging boughs. One plant, older than the others, has now attained a height of almost 7 feet, and measures through the centre 8 feet.—A. L. L.

## CHRYSANTHEMUMS.

### MARKET CHRYSANTHEMUMS.

A FLORIST in this neighbourhood recently remarked that he had no need to buy Chrysanthemums just then; he could get as many as he wanted in Covent Garden for nothing. This remark was made not jestingly, but in sober earnest, and I was assured that in the beginning of the month the amount of bloom brought into the London market was so great, that thousands of bunches remained unsold, and were offered to anyone who chose to clear them off. As a friend who grows for market observed "How can you expect to sell indoor Chrysanthemums when fields and gardens everywhere are full of them?" People seem to be growing the hardy outdoor kinds more freely than a few years ago, and the number cultivated for market has increased wonderfully. The frost we had in October, although it killed the buds of indoor varieties that were still in the open, had little or no effect on the hardy ones that are employed for open-air blooming. Since then the genial summer-like weather has developed the blooms, and probably not more than twice in twenty years do we get the tall-flowering Chrysanthemums in such abundance and perfection. A few days since I was looking through a lot of well-grown plants in pots, mostly late varieties, and was surprised to see how forward they were. Niveum was fully expanded quite a month before its time, and W. H. Lincoln would be in full bloom by the end of November. The grower is naturally by no means pleased at this precocity, as blooms that ought to have been in good condition at Christmas and the new year will have to be marketed several weeks earlier. The plants are grown in bush form for the production of from eighteen to twenty-four good-sized flowers, which in midwinter make from 1s. to 2s. 6d. per dozen, but, being so early, I am doubtful if they will make half that amount. Had the sharp touch of frost not occurred in October, the plants could have remained in the open for another fortnight, and this would have made all the difference. We have to reckon with about 10° of frost one night towards the end of that month, and the right way in the case of plants that are required for midwinter bloom is to devise some form of protection that will guard the plants against its effects. The frost we had was just enough to cripple the buds on plants not protected, but a screen of canvas was enough to ensure their safety. It was curious, however, that neither wood nor foliage was in the least affected, and when plants that were unprotected were housed they began to push out fresh buds from the axils of the leaves, so that we shall probably after all have a good supply of very late Chrysanthemums, for these buds cannot open before January, the danger being that many of them will not open at all. Good yellow Chrysanthemums are in brisk demand through January and in the beginning of February, prices going up considerably after the middle of January, but this is not always the case with white ones, which frequently decline in value as February ap-

proaches, the reason, I suppose, being that white Azaleas, Spiræas, Hyacinths, &c., are plentiful then, whereas yellow flowers, that can be forced and are suitable for cutting, are comparatively scarce. It would, I think, be possible to sell a waggon-load of yellow Chrysanthemums at the close of January at good prices; in fact, yellow and bronze seem most in favour still for room and table decoration, as they show up so well by artificial light. As regards late white Chrysanthemums, we have not yet got one that can be said to realise the market grower's ideal. Lady Lawrence, L. Canning, and Mrs. Camell are late enough, but need good culture to make them profitable. They are not suitable to the cultural methods pursued on such a large scale in the London market gardens. Niveum is much better, but it seems to be more a late December than a mid-January kind, and I am told that the blooms do not keep so well as could be desired.

To those engaged in raising new varieties I would suggest crossing the old Ethel with the above-mentioned kinds. Ethel is everything a late Chrysanthemum should be except in quality of flowers. It shows an eye, or would never have been discarded. If with the habit of this variety we could get the flower of Lady Lawrence, we should have nothing more to desire in the way of late white Chrysanthemums. Late varieties generally are very liable to mildew, and from this pest Ethel was with me, at least—quite free. Of mid-season whites, Souvenir de Petite Amie is one of the most useful, it is so dwarf, yet vigorous; and the new Mytchett White will, I think, come to the front. For December Lord Brooke is very good, flowering in great profusion, and those grand yellows, Western King and Modesto, should get a good trial.

J. C. B.

**Reflexed Chrysanthemums.**—It is becoming more evident each season that the reflexed Chrysanthemums are a declining class. The limited competition points to the fact that the interest in this form of the flower is on the wane. At most shows one class is provided for these flowers and generally three prizes offered. There are never more than two competitors, and at the November exhibition of the National Chrysanthemum Society, out of all their members no more than two competitors staged exhibits in the class for twelve large-flowered reflexed blooms in not less than nine varieties. In trying to find a reason for this decline one cannot very well come to any other conclusion than that, owing probably to the lack of novelty and variety in this type of the flower, and the somewhat stiff and formal character of many of the older sorts, they fail to please the majority when contrasted with the varied character of the Japanese varieties. There are some very pretty sorts among them, the brilliancy of the colouring of Cullingferdi, for instance, in well-developed blooms, standing out distinctly from that of almost all other Chrysanthemums.—D. B.

**The old purple Chrysanthemum.**—I have often wondered whether the purple-flowered variety so common in gardens as a hardy herbaceous perennial was the old purple, and a white-flowered form, practically a reproduction in habit and form of flower, also plentiful, was the first sport. I have seen these varieties, the purple especially, largely grown in forecourt gardens about Kingston. I have seen it also very abundant elsewhere. It would be very interesting could some society, such as the Royal Horticultural Society, for instance, succeed in gathering up plants of all these old forms and grow them along with the best representatives of the Chrysanthemum of to-day. I do not know how long the Christines have been in commerce, but these are probably very old. It is, however, certain that if the old purple and its original sport to white be those I

have mentioned in the larger pompon section, such great progress has been made, as the varieties have flowers as good, comparatively, those of Mme. Marthe, for instance, still a capi pompon. It is remarkable how these old varieties in the forecourt gardens named go on growing and blooming from year to year with surprising energy and vigour.—A. D.

### CHRYSANTHEMUMS AT EARLSWOOD

MR. W. WELLS, of the Earlswood Nursery Redhill, has several houses full of Chrysanthemums in bloom, the largest of which is a span-roofed structure about 160 feet in length by 22 in width. The blooms are very fine, and afford abundant evidence of the greatest possible skill in their cultivation.

The varieties are in the main novelties of recent introduction and principally of the Japan type, although a few of the other sections are represented. American, home-grown, French, Italian and some colonial novelties make up the display, but by far the largest number, of course come from the other side of the Channel, and these, the well-known grower and raiser, M. Er Calvat, is a very large contributor. Mr. W. enthusiastically declares that it is quite impossible to bestow upon this successful raiser much praise for the way in which he has improved the Chrysanthemum during the past few years. In this expression of opinion everybody who has watched the eminent Frenchman's progress must concur, and from what we saw on the Continent last year we feel confident in predicting that there is even now more to expect from the Calvat race than some people might think.

The collection is arranged with a double-sloping bank of plants down the middle of the greenhouse and a row of dwarf plants round the sides, and the number thus employed must be considerable. All shades of colour in the pompon flower are to be found, but the whites and yellows are perhaps more uniformly good than some of the higher tones. In varieties belonging to the Japanese section sent out by M. Calvat, the following must be considered as of the highest order of merit, and grandly maintain the raiser's reputation, viz., Directeur Liebert, a very fine globe bloom having grooved and curly florets large size, and of a deep lilac-mauve colour. N. Jubilee is simply a grand addition; it is so compact, and finely incurved with grooved florets colour silver pink, reverse inside, florets lavender pink. Mme. Ferlat is a noble new white, compact and massive, with grooved incurving florets pearly white. Mlle. Laurence Zédé is another large compact variety, with grooved pointed florets of medium width, colour inside yellow amaranth, silvery pink reverse. M. Massang Louvrex is a fine new yellow. Souvenir de F. sette is an incurving bloom with pointed florets colour plum coloured amaranth, with silvery amaranth reverse. Mme. X. Rey Jouvin is a pretty incurving bloom with broad grooved florets rather blunt at the tips, of good size, and in colour a charming shade of deep rosy pink, and slightly hairy at the tips. Werther is a rich purple amaranth; Surpasse Amiral, a large new yellow; Souvenir de Molines, crimson bronze tipped, reverse of gold; Princesse de Galles, very large white, with great length of floret; Comte de Bourges, deep purple curly incurving floret. One of the greatest novelties, and one which when well distributed will be certain to excite some curiosity from the outside public, is M. Ed. Roger, a pale sea-green incurved Japan. Mme. A. Rousseau, Mme. G. Bruant, Isère, Mlle. Lucie Faure (a large fine white), Vicomte Roger de Chezelles, Topaze Orientale (a fine yellow), Mme. Deis (white), Fée de Champsour (white florets), are all this year's novelties from Calvat. But if the novelties are a source of interest, what can we say concerning some of the older and well-tried sorts already in general cultivation? Some magnificent examples of Chenon de Leché, M. Hoste, Mme. Carnot, M. André, M. Pankoucke, Capt. L. Chauré,

Perfection, Louise, Admiral Avellan, Antoinette, Mrs. J. Lewis, one of the grandest whites in the display, Mlle. M. A. de Gialbert, Calvat's Australian Gold, Le Mouchebotte, Mlle. Thérèse Rey, Boule d'Or, and probably a hundred others, all equally good, attest the overwhelming supremacy of the Calvat seedlings. Some years ago several Italian growers sent over new varieties to this country, but they seemed to be unable to compete with the French, and nothing much has been seen until last season of novelties from that country. Mr. Wells has, however, a few new ones, viz., Louis Sirtori, Piémont, and Count Cavour, raised by the gardener to H.M. the King of Italy, who will be remembered, exhibited at the National Chrysanthemum Society's Jubilee show last year. We were gratified to see, among other Continental novelties, several from our old friend, M. de Leydellet, Mlle. Lucie Mathieu de la Drome, an old-fashioned incurved and of a fine shade of pale golden yellow, being one of the best. The same raiser is represented by M. Haguer, pale rosy mauve, Japanese incurved, large in size and having a silvery pink reverse. Mme. Desblanc is another of the same type, the florets of which are grooved, twisted and intermingling, and the colour a pretty shade of bright pink. Don Pietro Baragiola, a golden yellow, shaded carmine, is another, very effective and striking.

English novelties well represented are the white Mrs. C. Blik, Lady Hanham, a very pretty almon and rose-coloured sport from Viviani Morel; G. F. Warren, a grand full-sized pale yellow sport from Mme. Carnot; Royal Standard, dark crimson and gold; Royal Sovereign, golden yellow; Mrs. D. Dewar, white; Pride of Maidenhead, white; Mrs. H. Weeks, Edith Tabor, yellow, &c.

Miscellaneous novelties in the Japanese are to be found in three sports from Mrs. C. Harman-Payne, viz., Mrs. G. W. Valmer, Mme. Eugène Testout and Mme. Louis Remy. The two first-named are rosy bronze, and are probably identical, one having originated in France and the other in England, the third is distinct and pure white in colour. Parachute is old rose, shaded carmine and almon, very pretty. There is a goodly number of unnamed Australian seedlings, and of colonials that are already in favour here, Pride of Madford, Australia and Oceana need only the briefest mention. Mme. Ph. Rivoire is a large white Japanese; Ella Curtis, a deep golden yellow, dusted carmine; Georgiana Piteher is very fine, large and heavily built, and of a pale canary-yellow. A new hairy variety is Maurice Boissard, pale golden yellow. Mrs. C. B. Freeman, a sport from Louis Brehmer; Floire Lyonnaise, Capt. L. Chauré, bronze-yellow, and M. Alfd. Thierrard, salmon-gold, are new additions to this class.

American novelties comprise some really choice varieties, although they are not nowadays quite so numerous as they were. Sunstone, rather tall, with globular, incurving blooms, and of a beautiful shade of apricot or golden ochre-yellow, is perhaps not so well known as Modesto, deep golden yellow. Lenawee (white, faintly tinted blush, long loose florets) and Mutual Friend (large white), also come from the other side of the Atlantic. Snowdon (large white) and Simplicity (very long white florets) are two more; Western King (white) is another.

In one of the houses there was a capital collection of single-flowered varieties coming on. Many of these are light in build and very useful for decoration, vases and artistic combinations. Parity, a large white, was large in size; Miss Lary Anderson (white, tinted blush) and Miss A. Holden (a yellow counterpart) were very pretty. Lizzie Mainwaring (very pretty pale blush) is worthy of a note, but one of the deepest and richest is the Rev. W. E. Remfrey, a deeply plumed, velvety dark amaranth. Then Virgin Queen, a pure white single Japanese, attracts attention; Emily Wells (rose-pink), Edwin Veller (large in size, with long florets, colour olden buff), and Rose Pink (a variety whose name is sufficiently descriptive, but shaded white to the base of the florets) forms an excellent com-

panion. In Annie Tweed the blooms are of a deep rich velvety crimson, but have broad flat florets. Gus Harris (an old variety, very pretty, but small) and Buttercup (pale lemon-yellow) both help to brighten up the group.

#### CHRYSANTHEMUMS AT FRAMFIELD.

At The Vineries, Framfield, Sussex, Mr. Norman Davis grows some 30,000 plants. A very effective method of arranging the plants has been carried out here. Most of the plants of a sort are grouped together, impressing one with their respective value and their usefulness for various purposes. Rich and striking contrasts are by these means easily effected, and the value of a sort for its form or colour, &c., is immediately made apparent. There are eight large houses, one alone covering half an acre, and six of these are filled with exhibition blooms and those plants intended for market. In the first house, some 200 feet long, a fine lot of Modesto with its large and handsome Japanese flowers of the deepest and richest shade of golden yellow made a fine display, and convinced one of its value as an exhibition sort; close by and making an effective contrast was a grand lot of Australian Gold with massive heads of bloom. The colour was a pale straw-yellow, deepening to the centre. Mrs. H. Weeks, so highly thought of two years ago, was represented by flowers of immense size and substance, the broad florets prettily incurved. Pearly white is the best description of its colour this season. A new American Japanese incurved and in promising form is Mrs. J. J. Glessner, with broad petals of golden yellow-tinted apricot. This was grown in a very free manner, and doubtless when freely disbudded will make an invaluable exhibition flower. M. B. Spaulding, introduced some years ago, is a pale canary yellow, with long twisting and curling petals, making a large flower, and promises to make a useful addition to these colours. The light chestnut blooms of Mrs. Hermann Kloss were represented in many stages of development, and proved that when the right bud is selected its rich golden tint assists to make it a distinct gain to the exhibition sorts. Plants of Louise, each carrying a dozen flowers of beautiful incurved form and a lovely pale flesh-pink tint of colouring, pronounced it as a good decorative sort as well as one for the exhibition table. Miss Elsie Teichmann was rather later than most others, yet its pearly white blossoms were very refined. By far the largest bloom of Hairy Wonder we have seen was here. One peculiarity was its regular colouring of deep fawn throughout, stamping it as the best of the hairy-petalled varieties. Of the beautiful ivory-white Lady Byron there was a fine lot of plants, each carrying large flowers of grand substance. This sort is evidently easy to grow. Madeline Davis is a seedling raised this year, and undoubtedly a flower of the most chaste description. It is best described as silvery white, tinged throughout with rosy violet, this colouring deepening at the edges. The shape is somewhat like Phœbus, with longer and rather broader florets and more tapered. Remarkably fine were the flowers of Miss Dorothea Shea. The most handsome display was made by between 200 and 300 blooms of Mme. Carnot in two rows on either side of the house, and produced on plants taken on the third run, *i.e.*, the second crown bud. Mr. Davis has used 8-inch pots for these plants, which are quite 10 feet in height, and one and all the blooms are fit for the exhibition table. This feature of the display is in itself quite unique. A charming new incurved Japanese was seen in Mrs. S. C. Probyn, this being a very neat and even flower of easy culture, with broad incurving florets of great substance, and possessing a nice habit. The colour is a beautiful flesh-pink. Belle of Castlewood is another large incurved Japanese of a faint flesh colour, with long broad incurving and curling florets, one of this season's American introduction. Simplicity is no doubt a chaste white flower, and makes a bloom of graceful

appearance when fully developed. Mrs. F. A. Bevan is another incurved Japanese, of refined appearance and a pleasing shade of flesh-pink, with a paler reverse to the florets, of medium width. Klondike, the new rich yellow early decorative Japanese, is a decided acquisition to the early sorts. Mrs. A. H. Wood, the deep yellow sport from Primrose League, is in better form than in other seasons, and promises to make an immense spreading flower of good depth and lovely form. Western King is another of the very best things here, its pure snow-white incurved Japanese blossoms of grand substance looking very fine as the lower florets begin to droop. This is essentially an exhibition flower, its size being all that is desired, while as a decorative sort it may be grown quite freely with the best results. The new rosy-bronze sport from Mrs. C. Harman-Payne, Mr. G. W. Palmer, was in capital form, the colour being very bright. As a flower it is distinctly superior to the parent. M. Ernest Calvat's novelties are much better this year than formerly, the majority of the sorts being of high quality. The most striking of the set is Beauté Grenobloise, a large ivory white, with long florets twisting and incurving at the tips, fairly dwarf habit; Souvenir de Mme. F. Rosette, carmine-purple, with silvery reverse, is of sturdy habit; Fée du Champour is a clear white of good substance and very chaste; Mme. G. Bruant, a large flower with broad pointed florets, is white, centre striped and flushed pale rosy lilac; Secrétaire Fierens, something like John Seward, has long florets, colour reddish crimson, and golden reverse; President Nonin, somewhat in the way of Sunstone, has prettily incurving florets of good substance, colour chamois-yellow; N.C.S. Jubilee is a dense flower with short florets, colour silvery mauve; and Mlle. Laurence Zédé, an immense rosy purple, with silvery-lilac reverse. Such sorts as Dorothy Seward, John Neville, Phœbus, M. Chas. Molin, Mlle. T. Rey, Viviani Morel, and its sports maintain their high reputation as exhibition flowers.

Incurved varieties are grown in large numbers, though more for the purpose of keeping stock together than for producing high-class flowers, and these, together with the market sorts, make up a display of exceptional merit.

#### CHRYSANTHEMUMS AT DOVER HOUSE, ROEHAMPTON.

For some years past there has been a remarkably fine display annually made of the Chrysanthemum in these gardens. During a recent inspection I was gratified to find such a representative collection, for not only are the large-flowered varieties, both Japanese and incurved, grown extensively, but the smaller or decorative varieties also find much favour for every-day cutting in large quantities. The plants throughout are remarkable for healthy development, with short-jointed, sturdy growth, healthy, dark-coloured foliage of good substance and free from mildew in a notable degree. Both cut-backs and taller plants find a place in this collection, which also, by a process of annual selection, contains only the very best kinds as regards colours, good constitution and general reliability. The plants when seen were most effectively grouped in the range of vineries and Peach houses, which are by reason of their loftiness well calculated to display every plant to the best possible advantage. I noted that Mr. McLeod had carefully guarded against an overcrowded condition; each plant stood so as to allow of a free circulation of air amongst the foliage. This is as it should be, for if the foliage be not preserved in a healthy state, how can one reasonably expect the flowers to be perfectly developed? It was noted that a slight amount of shading was given, as the foliage of the fruit trees was all cleared off, or nearly so; thus any undue rise of the thermometer was avoided, and thereby the plants preserved from any undue strain upon their resources. In a conversation with Mr. McLeod I soon ascertained that he is no believer in the dressing system so much in vogue with exhibitors.

It is worth their while that others also who grow the Chrysanthemum well should take note of this and abstain from this ridiculous waste of time in altering the character of their flowers (dressing being oftentimes termed "building up," as if it were a mechanical process). Of course in an exhibition, if no dressing is practised, the exhibitor stages at a great disadvantage to himself, but it had better be so, I am disposed to think.

The following varieties were noted as of special excellence at the time of my visit, amongst which will be found a few of the best novelties, viz.: Edith Tabor, very rich in colour; Chas. Davis, large and fine; Lord Brooke, earlier than usual; Baron Hirsch, Miss Haggis, Vice-President Calvat, and Oceana, both extra fine in the petals; Lady Saunders, a beautiful primrose; Mlle. Marie Hoste, C. H. Curtis, specially good; and Major Bonafion, which is too much like it. Col. W. B. Smith, Louise, Lord Wolsley, G. C. Schwabe, Mutual Friend, a beautiful white; John Seward, yellow, extra; Egyptian and Surprise, two good dark colours; John Myers, distinct and fine; Mrs. Geo. Palmer, a sport from Harman-Payne; Vivian Morel, E. G. Whittle, flesh colour, distinct; Mrs. C. H. Payne; Abbé Mendenthal, extra, yellow; Eva Knowles, M. Gruyer, Etoile de Lyon, Pride of Madford, fine dark; Duke of Wellington, bronze; Mrs. S. C. Probyn, blush-pink; Mme. Thérèse Rey and Mrs. Bhek, two fine whites still worth every attention bestowed upon them, were also excellent.

VISITOR.

#### SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Earlswood Beauty.**—This is a single variety of most attractive shape. It is pure white, the florets of extra length, so that the blossoms are larger than many of the class. The disc is prominent, which gives the flower a distinct feature. This variety appears to me much the best single Chrysanthemum of its colour.—H.

**Chrysanthemum Mme. Ferlat** is a new sort, the blooms of which incurve regularly, and it is likely to prove a capital addition to that class. The pure white flowers are quite 6 inches across and of proportionate depth. It is dwarf and easy to grow. This being the case, there is little doubt that it will replace such old favourites as Empress of India, now so seldom seen in good form.—S.

**Chrysanthemum yellow Mme. Carnot**—The bloom picked out at the Aquarium show as being the best single specimen exhibited was a very fine one, of a light shade of colour. It originated, I believe, with Mr. Mease, the exhibitor, and seems paler in tint than G. J. Warren, the yellow sport more generally distributed. Perhaps the latter will prove the better when by an early start one can obtain strong plants. It had been propagated too freely to give the best results this year.—H.

## TREES AND SHRUBS.

### THE RED CEDAR.

(*JUNIPERUS VIRGINIANA.*)

COMMON from Nova Scotia to Southern Florida and Central Texas, and from the shores of the Atlantic to the valley of the Missouri River, the Red Cedar assumes many forms under various conditions. In the valley of the Red River, in Texas and Arkansas, it is sometimes 100 feet high, with a tall straight trunk 3 feet or 4 feet in diameter; usually it is much smaller, however, and generally 40 feet or 50 feet in height. Sometimes, especially during its early years, the slender branches are pressed close against the stem from the base upward and form a narrow pyramidal head, which in time usually broadens out and finally becomes round-topped and irregular. This pyramidal form is especially common in the valley of the Hudson River, and in some parts of New Jersey and Eastern Pennsylvania. In New England, after the first twenty or thirty years, when the Red Cedar is nearly always pyramidal, the stems often become naked below and the head a broad-based pyramid of slender

branches spreading below nearly horizontally and ascending above; and in the swamps of Florida, where this tree is common and grows to a large size, the branches are long and often pendulous. The foliage of the Red Cedar is dark yellow-green, or often pale glaucous, becoming bronze-coloured at the north during cold weather, and in autumn and winter, when birds do not eat them, the branches are loaded with the small berries, which are covered with a whitish bloom.

*JUNIPERUS VIRGINIANA* has usually been considered to cross the continent to the shores of Puget Sound and Vancouver Island, and to be pretty widely distributed through the interior Rocky Mountain region from the northern border of the United States to Northern New Mexico and Arizona. Having seen a good deal of this western tree, I am inclined to believe that the so-called western Red Cedar as it grows in Wyoming, Montana and Colorado, at least, and perhaps everywhere, will have to be considered another species, and should this supposition prove correct on further investigation, I should propose the name of *Juniperus seopulorum* for it. The habit of the Rocky Mountain tree is very unlike that of any form of the eastern Red Cedar. It has the slender branchlets and opposite leaves in pairs of the eastern tree, but the fruit is larger, and does not ripen until the second year, while that of our Red Cedar ripens during its first autumn. The branches are stouter and covered with more scaly bark, and the bark of the trunk, which is often forked near the ground, is unlike that of the eastern tree, which separates into thin, narrow scales fringed on the margins, but, like that of some other western Junipers, divides into irregular, narrow, connected flat ridges, which break up on the surface more or less freely into persistent shreddy scales. The wood has the same fragrance as that of the eastern tree, although it is rather less powerful, and the colour is a duller red. The habit and the character of the bark may be due, perhaps, to differences of soil and climate, which might also affect the colour of the wood, and the only really tangible character by which the western tree can be separated from the eastern is the biennial fruit. Before the question of the distribution of the Red Cedar can be satisfactorily determined, more observations should be made on the time of ripening of the fruit, especially in Colorado, Utah, New Mexico, and Arizona, in the valley of the Columbia River and on Vancouver Island, for it is, of course, possible that the proposed *Juniperus seopulorum* may be confined to the Northern Rocky Mountains, and that *Juniperus virginiana* really reaches the southern part of that range and even the Pacific coast. The Red Cedar, although usually regarded as a slow-growing plant, increases rapidly with generous treatment; it is easily transplanted while young, and with care plants 10 feet or 12 feet high can be safely transplanted, although an idea prevails in this country that the Red Cedar is difficult to move and unsuited for cultivation.

*JUNIPERUS CHINENSIS*, which is occasionally found in our gardens and is perfectly hardy as far north as Eastern Massachusetts, is in every way inferior as an ornamental plant to the native Red Cedar, which it somewhat resembles, and at the end of a few years usually becomes ragged and shabby in appearance. *Juniperus chinensis* is widely distributed in Eastern Asia, from the borders of Thibet to Japan, where it does not appear to be generally scattered, although it is common on the high volcanic ridges at the base of Asama-yama, in Central Hondo; here it becomes a shrubby tree 30 feet or 40 feet high, with straggling contorted branches and grey-green leaves. Two venerable and picturesque specimens, 70 feet or 80 feet high, with hollow trunks some 6 feet in diameter, before the temple of Zenkogi, in Nagano, show that this Juniper sometimes attains a large size. Another form, usually known in gardens as

*J. JAPONICA*, is in early life a compact bushy plant with many erect branches and acicular blue-green leaves. This shrub is perfectly hardy and

very distinct in appearance from other Juniper retaining for several years its peculiar compact juvenile habit, it too often becomes thin and ragged before it is 12 feet high and loses its value as an ornamental plant. This is, perhaps, one of the most difficult of all conifers to transplant. Many recent authors the so-called Juniper japonica, which does not appear to be known in wild state, has been confounded with the prostrate littoral Juniper of Japan and Corea (*Juniperus procumbens*, Siebold—*Juniperus chinensis procumbens*, Endlicher), now usually considered a variety of *Juniperus chinensis*, although perhaps it will, when better known, be found distinct enough to be given a specific position. This shore plant forms dense mats on low glassy blue fully exposed to ocean gales, sending out for long distances its prostrate creeping stems clothed with bright green scale-like leaves. From sea gathered near the Aino village of Horobetsu, the coast of Yezo, a number of plants have been raised in the Arnold Arboretum, but it is too soon to speak of their hardiness. Another prostrate Juniper,

*J. SABINA VAR. PROCUMBENS*, is an excellent garden plant with wide-spreading stems which hug the ground and are clothed with bright green foliage. This is now usually considered an American variety of *Juniperus Sabina*, which an erect shrub or small bushy tree, occasionally 12 feet or 15 feet tall, and is widely scattered through Central and Southern Europe and Siberia. If it has ever been properly tried in our garden it has probably not proved hardy. The American plant is distributed from Southern Maine to the shores of Hudson Bay, and westward in British America from Newfoundland to the Rocky Mountains of Southern Alberta, and through Northern New England and New York along the shores of the Great Lakes to Northern Minnesota and over the mountain ranges as far as the eastern slopes of the Rocky Mountains in Montana. This is the hardiest and most beautiful of all the prostrate Junipers which can be grown in our gardens, where it might well be seen much more frequently than it is. The prostrate form of

The Himalayan *J. recurva VAR. SCAMATA* a favourite garden plant in Europe, and has frequently been planted in this country. In Massachusetts it is not very hardy, although it can usually be made to grow in sheltered, shady positions; in New York and southward it is, however, perfectly hardy. *Juniperus recurva*, which is widely distributed from Afghanistan to Sikkim and Bhota is sometimes tree-like, but at high elevations remains shrubby and covers large areas with low decumbent stems running on or just below the surface of the ground and sending up numerous short, erect branches.—*Garden and Forest.*

**Populus trichocarpa** (Torrey and Gray). This is a handsome species of Poplar, native of British Columbia, and introduced into Europe for the first time in the year 1889 to the arboretum of Zoschen, near Hersebourg, in Germany, which Dr. Diek is the director. It is only three or four years since its culture commenced in France, where it was put into commerce, in the year 1893, by MM. Simon Louis frères, of Metz who had obtained specimens of it from M. Lou Spath, of Berlin. Now all our leading nurseries grow it. This new species (or, more properly speaking, one that was only recently introduced amongst our cultivated plants) is distinct from the species and varieties hitherto grown by us, and if we might compare it with any of these, we would say that it somewhat resembles the Balsam Poplar (*P. balsamea*), from which, however, it differs very appreciably. In vigour of growth it appears to surpass such vigorous-growing kinds as the Swiss Poplar, the Italian Poplar, the Improved Poplar, &c. *Populus trichocarpa*, moreover, appears to adapt itself to all kinds of soil and has the great advantage of not being liable to become diseased, as sometimes happens in the case of the other species and varieties.—*J. Fossing in Le Jardin.*

FLOWER GARDEN.

MESEMBRYANTHEMUM ROSEUM.

The Mesembryanthemum in the illustration is given to me under the doubtful name of M. roseum. I first saw it at Madeira, where its light rose-crimson flowers hung down from any a mirante just as the Carnations do from the balconies in Spain. It is a charming plant for English gardens, and has a preference for the sea-side, where its growth is more compact and its flowers most abundant. It is the only one of its race I have found hardy enough to live out during a mild winter on the north-west coast of England, and it makes such an effect of colour the second summer that friends who are familiar with the big Mesembryanthemum pomeridianum, so abundant on the shores of the Mediterranean, have been surprised into thinking it the same plant. In reality it is, however, a much better thing, flowering continuously for six months at least, while the big species hardly lasts six weeks. There is also a pure white form of M. roseum which is even more lovely in some folks' eyes than the type, and makes an excellent groundwork to a dark crimson like Jacoby when thinly planted.

although much paler in colour. Heliotropes are full of flower, and many annuals have lately made quite a fresh start into growth and flower. Beds of Mignonette that had got quite a seedy look in September are now covered with a fresh growth of flower-heads. Corocopsis tinctoria, Sweet Sultan, white and purple, Chrysanthemums and many others too numerous to mention are flowering freely. Open-air Chrysanthemums have not for many years had such a fine flowering time, even the very latest kinds that we never attempt to bloom (except under glass), look like finishing their season without any protection. L. Canning, Niveum, Princess Victoria and other white varieties that are spoilt with even a few degrees of frost are flowering splendidly, and growers with a quantity of these on hand for the Christmas market are at their wit's end to keep them back. Gloire de Dijon Rose keeps flowering as freely as in June, and some of the varieties like Souvenir de la Malmaison are really good in form and colour. I must not omit to mention how useful the white and yellow Marguerites are, I think the blooms are individually much finer than they were in their usual open-air season.—JAMES GROOM, Gosport.

**Cactus Dahlias.**—In reply to W. E. Endicott (page 401), the following I consider the best: Alfred Vasey, salmon-rose; Beatrice, rose-pink; Bertha Mawley, cochineal colour;

desire to say a word or two. This is C. lavigatus, from the Cyclades and the Greek mountains. It has been in flower here since the end of October, and, although suffering from the recent stormy weather, is likely to give blooms for some little time to come. It is a pretty little species, perhaps all the more pleasing on account of its flowers appearing before its leaves, which come in autumn, have withered away. It is rather variable in colouring, and some more or less defined markings and shades have been selected by bulb growers. The segments vary from white to lilac, and the diversity is added to by the difference in the feathering or suffusion with purple of the outside of the outer segments. The anthers are white, and the stigmata yellow or orange. The flowers are, like those of nearly all the species, considerably inferior in size to those of the Dutch Crocuses, but have, by way of compensation, a neatness and simple beauty which make them more pleasing in the eyes of many. One merit of C. lavigatus is the comparatively little sun it requires to persuade it to open. If the flowers can be kept dry they expand more readily, but many do not care to see glass protectors in their gardens. This Crocus is too choice to be grown in the border until it becomes more plentiful, and a sunny, sheltered place in the rock garden is what it should have.

S. ARNOTT.

Mesembryanthemum roseum in a Scarborough garden. From a photograph sent by Mr. E. H. Woodall, St. Nicholas House, Scarborough.

POLYGONUM SPHEROSTACHYUM AND ASTER DIPLOSTEPHIODES.

ONE is disposed to agree with the remark of Rev. C. Wolley-Dod that P. spherostachyum "will not yet be a common plant, even if it is destined ever to be so." The latter part of the sentence quoted implies a doubt with which one is especially inclined to express agreement. It is not a good sign of the amenability of a flower to cultivation when it rises considerably in price instead of becoming cheaper. A temporary increase in value may arise from an unexpected demand, but one finds, as a rule, that a plant which advances in price some time after introduction is either difficult to propagate or unsatisfactory in some other way. This appears to be the case with this Knotweed, although, as has been said, every one of the flowers on the spike is a possible plant. It is rather a favourite flower with me, but a good many opportunities of observing its behaviour in gardens have given me cause for disappointment. Mr. Wolley-Dod is more successful than many in retaining his plants for ten years, as this is a feat reserved for comparatively few. Grown in a half-shady position in peat soil in this garden it is not very long-lived, and one has to depend mostly upon self-sown seedlings to keep up the stock. These are not plentiful, but come up among a patch of Sedum acre which covers the nook in which Polygonum spherostachyum grows. In nine out of ten gardens in which one has seen it attempted it is a complete failure in a year or two. In a few it, however, succeeds, and in some of these it has been grown with more sun than one has been disposed to think that it requires. Perhaps we may have erred in thinking that it needs so little sun in this climate. Its neat habit and bright colouring are strong recommendations, and the former quality is one in which it has an advantage over P. amplexicaule, although, as your correspondent remarks, the latter is sometimes as bright in colour. It is certainly much easier to grow, and its fairly free growth makes it more useful in the garden, especially if its spikes are required for cutting. P. affine, also mentioned, is, if anything, a little too free in its way of spreading in the garden, but it is well worth growing, and gives flowers over a considerable period. It is frequently met with under the name of P. Brunonis.

together these two varieties deserve more notice than they have yet gained, being nearly hardy, most effective, easily propagated, and lasting in flower from June to December in any sunny sea-side garden. E. H. WOODALL.

**Lilium superbum.**—In a swamp near Laurel, Prince George's County, Maryland, says the *Plant World*, there is a form of Lilium superbum with stems 7 feet or 8 feet tall and clear lemon-yellow flowers without spots, but with large bright green angular markings at the base of the perianth segments. The leaves are described as similar to those of the common form, although perhaps more scattered, and the flowers are similar in size and shape. Although not abundant, it appears that this plant has been known locally for many years, and that a few specimens can be found every year.

**November flowers in the open air.**—It is only that we can, even in the south of England, find such a wealth of flowers in the open air as we have at the present time. Looking round to-day (November 20) I find the Dahlias still as fresh and green as at mid-summer, and the old scarlet cactus variety Juarez covered with bloom,

Bridesmaid, white, tinted lemon; Cinderella, purple; Charles Woodbridge, crimson; Cycle, ruby-red; Daffodil, yellow; Frances Humphries, orange; Fusilier, coral-pink; Gloriosa, scarlet; Harry Stredwick, dark crimson; Harmony, bronzy-yellow; Keynes's White; Island Queen, mauve; J. E. Frewer, vermilion; Lady Penzance; Marquis, maroon; Matchless, dark crimson; Mrs. A. Beck, salmon-red; Mrs. Barnes, lemon, tinted pink; Mrs. John Goddard, rich crimson; Mrs. Wilson Noble, salmon-pink; Night, dark crimson; and Starfish, scarlet.—S.

CROCUS LEVIGATUS.

COULD we only induce the sun to break more frequently through the clouds which shroud it from view on so many of our November days we might have our gardens brighter than now. Even as it is, we do not take sufficient advantage of the material at command, so that when a bright day comes we may have some flowers which will respond to its charming influences. Even if we have only two or three of such days in the month, we can find in some of the Crocuses flowers which will give us what we require. Of one of these—only a variety of C. Boryi, according to some—I

Mr. Wolley-Dod's experience with *Aster diplostefioides* will but confirm many in their poor opinion of this fine flower so far as its perennial habit is concerned. One would, however, like to know if it is still grown by Mr. Marshall at Bexley Heath. That gentleman received a first-class certificate for the plant at a meeting of the floral committee of the Royal Horticultural Society on July 26, 1892, and the illustrations which appeared in the gardening press at the time led to considerable inquiry for this *Aster*. At that time it was also grown at Kew and at Chiswick, where it was seen by the floral committee on July 22, and certificated then also. I have seen something of and heard a great deal about *Aster diplostefioides*, but can, unfortunately, give little hope that it will prove anything but a biennial in all save a very few gardens. If Mr. Wolley-Dod could induce the owner of the garden in the Peak of Derbyshire to tell us something about the conditions under which he succeeds in preserving this *Aster* he will confer a favour upon many of us. S. ARNOTT.

*Cursethorn, Dumfries, N.B.*

### PEONIES.

In a note concerning these plants at p. 402 Mr. J. C. Tallack refers to the named kinds of Peonies in such a way as to cause them to be regarded as of weakly growth and constitution. The passage to which I refer runs thus: "I have tried many named varieties, most of which have failed to make crowns strong enough for flowering." It is not that I dispute the truth of this statement. As I well know, there are plants of this kind that no treatment would ever induce to flower in any way satisfactorily with the best methods of culture. The plants that fail to flower with years are usually not worth the time they take to plant, for they throw many more shoots from the clump, yet all are weak in the extreme. We have no group of hardy plants possessing greater vigour of constitution with perfect hardiness than the section of Peonies including *P. officinalis*, *P. albiflora*, *P. sinensis*, &c. Without exception the named Peonies are the most vigorous, in this respect surpassing the old crimson form in general robustness and vigour. Indeed, when established, the Chinese Peonies—which, I take it, are those referred to as the "named varieties" by Mr. Tallack, will readily attain 3 feet or more high. A dozen to a score of stems is what a good clump of Peony should produce at the fifth year from planting, provided the plants are well done at the start, the magnificent blossoms in their well-nigh endless shades of colour being borne profusely, and often on branched stems where the culture has been attended to. To begin with, a fair example of Peony for planting should possess two or three good eyes or crowns of the size of a small acorn, and if with young, recently-formed tap roots not hardwooded or cankerous, should in a year or two make fine plants. Indeed, a good plant of *Peonia sinensis* has in a large number of varieties as large, plump crowns as the *P. officinalis* group, only that the former vary in their strength occasionally. It is, however, quite clear that Mr. Tallack has not had to deal with such plants as these, which, if planted at the end of August or early in September, would be sure to give satisfaction. Peonies are among the easiest things to cultivate, provided we adopt a few simple rules, the most important of which is planting or transplanting in early autumn with as much of the foliage as it is possible to retain.

Valuable plants of these noble garden flowers are sacrificed year after year by dividing and planting when growing in early spring. It is not possible to select a worse time, as the plants rarely take to the soil during that season, and virtually exhaust themselves by existing on the stored-up energies of the plant. Nor is this all, for a plant moved at such a time will scarcely be

able to form anything but the weakest bud at the base, resulting in a weak growth another year, and so on for three or four years before the plant has properly recovered. It is in this way the Peony, which is certainly among the grandest of garden flowers, is often lost.

The best guide to purchasers of Peonies is the size of the current growth above ground and the size and number of crowns below. Plants with two or three good growths are quite large enough to start with, and with a depth of 2 feet or 3 feet of heavily-manured soil there need be little fear of the result when planted in the early days of autumn. E. JENKINS.

*Hampton Hill.*

**Rabbits and Antirrhinums.**—I would be very much indebted if you will tell me whether rabbits will eat Antirrhinums.—G.

\* \* I have not as yet found anything in hardy plants except Daffodils that rabbits will not either eat or nibble. Carnations and Starworts are perhaps the favourites. All, however, are mutilated to some extent except in the very rare cases where the foliage is very objectionable to them, as the Daffodil and (nearly always) Poppies and Foxgloves.—E. B.

**Daisy Snowflake.**—Early in the spring of this year I divided and replanted a bed of this and coloured Daisies. I had previously given the ground a liberal dressing of manure and the plants made good growth, covering the surface by the time they came into bloom. This Daisy is probably the best of its colour, and when in full bloom the mass of pure white flowers was certainly very effective. What impressed me, however, was the length of time the plants remained effective and the duration in good condition of the individual flowers. My soil is light, and the weather was very hot and dry for several weeks, but this Daisy bed was a sheet of white bloom for upwards of two months. A bed of Rob Roy close by did not last out nearly so long, in fact was quite over when Snowflake was still in fine order.—J. C. B.

**Hardy hybrid Water Lilies.**—The notice of various kinds of Nymphaeas which appears in last week's GARDEN over the signature of Mr. Greenwood Pim may be supplemented by the experiences of others who have attempted to grow a few of these lovely flowers under other conditions. I have often had the pleasure of viewing Mr. Pim's collection, and can testify to his success in growing robust and free flowering plants of many of M. Marliac's varieties in a shallow artificial pond of small size, the crowns of the plants being not more than 8 inches below the surface of the water, which has been at least on one occasion coated with 3 inches of ice. I have been less fortunate. On the margin of a small lake I dug a pond for the growth of interesting aquatics such as these, and filled the bottom with rich mud, leaving 18 inches of water above it (winter level). The pond communicates with the lake, but is protected against water fowl by wire netting. Four plants of *Nymphaea Marliacea Chromatella*, *carnea*, and *odorata sulphurea* were first planted, and they threw up leaves in due course, but later on the leaves kept diminishing in number, until in the autumn only one (*N. M. carnea*) survived and flowered. This year I added two more and kept a more careful watch over their development, and discovered that a number of caddis worms were in the pond, and that they preyed on the young leaves, and were the cause of failure. Curiously enough, they do not attack the young growth of the common white or yellow indigenous species. I then surrounded the plants with perforated zinc cylinders which successfully protected them; but as the water level rises and falls, this is insufficient, and during this wet summer while I was absent from home the larvæ took advantage of the zinc being submerged, and again destroyed all the plants except one. It would appear, therefore, that these larvæ which abound in all waters, whether running or stagnant, will prevent the general introduction of these charming

water plants to our lakes and ponds in country. In artificial pieces of water near town where the stone flies do not exist, there seems difficulty in successfully cultivating them. I inclined to make a further attempt by closing communication between my pond and the lake and putting some perch into the former to feed upon these larval pests.—W. DE VISMES KA *Drumruske House, Monaghan.*

### FLOWER GARDEN NOTES.

**TUFTED PANSIES.**—Evidence of the mild autumn is to hand in many thoroughly good flowers. Tufted Pansies, the sorts responsible for the same being Bullion, William Niel, Annie King, Crisp King, Archie Grant, Iona (a good flower the Countess of Kintore type and more inclined to the tufted growth), and a lavender sport from White Swan, always the largest flower I have. All are from strong, late August-struck cuttings and whether transplanted to the positions they are to occupy another season or still in the cutting frame, are alike very healthy and vigorous; in fact, so vigorous are they that, given a fair open winter, we are sure to get a grand display. They are just about the type of plant that have obtained in damp seasons from early July striking, and if they hold their own well they will be no necessity for division, except in one or two cases where the stock is limited. Will a writer well versed in Tufted Pansies tell me the origin of Annie King? Alike in density of habit and from a flowering standpoint, it is one of the best; the smooth, shining foliage also is very distinct, but in hot, dry seasons it runs out bare, assuming markings after the York and Lancaster type of flower, and leading to the inference that must be a sport from one of the striped varieties. It would be interesting to know how far sports will preserve their true character through the season in ideal Pansy soil. Here they begin to run out with the first spell of hot, dry weather and although by mulching and watering in the flowering season is well sustained, the tendency to colour-running is not checked. This is not great moment in large mixed beds, but is naturally somewhat awkward if particular shades have been planted to contrast with other things. A sport from White Swan, for instance, which in early stages is a fine lavender with a black eye, and in that form makes a splendid contrast with plants like Mangels Pelargonium, is at the end of a dry time almost unrecognisable, producing flowers very like those of the parent, only with darker eye.

**MIXED FLOWER BORDERS.**—Although a general mixing up of plants, either hardy or tender, is not to be recommended for the flower garden proper, it may be practised with good results on outlying borders mainly for the purpose of supplying colour in quantity, and if this is the chief consideration a close companionship is not objectionable so long as it does not interfere with fair good growth and the production of good flowers. I have, for instance, just cleaned through a long border that was planted in the summer of 1896 with seedling Polyantheses, and between the latter later in the year with Spanish Irises, Snowdrops and Daffodils in variety. A very fair result was obtained from the bulbs this spring, and the earlier of them are just now pushing through very strongly, giving promise of a still better supply for the flower basket in the spring of 1898, towards which end the Polyantheses in many colours will also materially assist. The bulb planting was effected without injury to the Polyantheses by working a fork straight down its entire length immediately in the centre of the rows, so that the planting stick was easily inserted and a little of soil from the potting bench placed in each hole so that the bulbs rested on a sound bottom. I may note that the Daffodils were chosen to represent a long season and include *obvallaris*, *princeps*, *Horsfieldi*, *Queen of Spain*, *Barri conspicuus* and the single and double forms of the late-flowering poeticus. This particular border has a west aspect, and so the Spanish Irises come in a bit late

those planted in the open quarter. At the end of his mixture are large clumps of *Chionodoxa* lutea and *C. Tmolusii*, the latter a deeper blue than the better-known variety, also a clump of *Anemone fulgens*. As the *Glory of Snow* is in considerable request, I am trying a path on a due north border with the view to still further lengthen the season. Other stretches border that will, I think, look well, and also furnish a very acceptable supply, are planted respectively with the taller *Campanulas* and *Doronicum*, with a goodly carpeting of *Saxifraga umbrosa*, a humble flower, but wonderfully useful and light in a cut state and standing well. With respect to flowering plants of taller growth than the majority of those already mentioned also required for the flower basket, there is no reason why they should not be planted in special beds in the flower garden if space is not available elsewhere, only if general mixtures are made the planting must be well done, for even with heavy weekly cuttings a certain amount of flower will remain of different things requiring careful grouping to ensure a pleasing contrast in the beds. In the case of small gardens I would, however, recommend a greater number of small beds, and at the most two or three species in each rather than a great variety in one bed, as there are few flowers that do not show to the best advantage when grouped together in quantity. This applies to the flower garden proper, and, as I have said, when a pleasing display is as much a question as securing cut bloom for other parts of the garden where the latter is the main consideration, a general mixing together is not objectionable, although even here a little care may be shown in the arrangement.

**CHOISYA TERNATA.**—The planting of sundry well-rooted cuttings of this beautiful evergreen against a low wall has led me to draw attention to its merits. Its inclination is more towards assuming a bushy habit, but it covers a wall well if lightly fastened to the side and the very slight protection necessary is thereby afforded. Introduced from Mexico as far back as 1825, it figures in old garden books as a stove evergreen, and is therefore one of the many instances of plants utilised for outdoor work that in bygone days were only grown under glass. Given a warm position on a south wall and a sandy loam with gravel or sand below, it grows luxuriantly and flowers freely, requiring no protection. It is produced readily from cuttings, but good large plants may be obtained much more expeditiously from cuttings, the only treatment necessary, if low shoots are available, being to slice them a third through and peg into the ground at the part of the shoot where they can be most easily and permanently secured, keeping the ground fairly moist for a year until root action has commenced. The fact that this Mexican plant can be grown thus easily on the side leads to the inference that in its native habitat it must be found on high ground where the night temperature is occasionally low, and is an illustration of the importance of obtaining accurate information as to the conditions under which new plants are found. Take for instance the case of the *Choisya* under consideration and the lemon-scented *Verbena* (*Aloysia citriodora*), occasionally used as an outdoor wall plant, and introduced from Chili. The latter country, taken as a whole, is some 10° further from the equator than Mexico, and yet the *Choisya* is the hardier plant of the two—an evergreen, too, whilst the other is deciduous.

**CARNATIONS.**—As an outcome of the recent communication as to the baneful influence of fog on

Carnations, I shall watch the progress of my plants this season with a certain amount of interest. We have already had much more than the average amount of fog—nasty fogs, too, that have left their mark on everything outside in the form of a black sticky deposit of sufficient thickness to necessitate washing all lights of houses and pits in which plants are housed. The Carnations look remarkably well at present, and occasional blooms, such as they were, have testified to the mildness of the season. Ernest Ladham's Pink has also given us a few very fair flowers.

Claremont.

E. BURRELL.

### AN AIRY BOWER.

This little creeper-clad bower with its stone table is pretty, and in the country it comes from (Portugal) no doubt its shade is very welcome; but it would not be less so in our country in points and positions commanding good views. With our present stock of climbers such things are always very welcome supports for such plants, which need not be the commonest. And why should we not have more like it, which give a little shade, yet allow freedom to the air, which the mouldy, close wall in summer rarely does? Notwithstanding the pains people take with their summer-houses in pleasure grounds, it is surprising how little

An airy bower in a Portuguese garden. From a photograph sent by the Marquis de Fronteira, Lisbon.

they are used, and partly, no doubt, owing to the want of air and sweetness, being, indeed, better fitted for earwigs and woodlice, walls and roof being often full of dusty decay. Why should we not use our beautiful climbers to make these roofs as in the case of this little bower? All we want is a stout framework and a few bamboo or other sticks over it, and in that way we should be rid of decay and insects, and also to some extent the cost of the roof. Ivy makes a good evergreen roof, as we may see now and then on an old farm hovel, where it plants itself; but it is easy to form bowers of these handsome Ivies and summer-leaving climbers like Vines, as we occasionally see them about French inns. To get rid of the rustic work as used in our summer-houses would be a gain, as that begins to rot before it is put up. We also like the use of the stone table.

**Lobelia cardinalis.**—Doubtless "A. D." has been unfortunate in his experience with this plant, for there is no question as to its hardiness here in the coldest part, perhaps, of Suffolk. I have wintered it here for several seasons, and in a neighbouring garden it withstood the very severe

winter of 1894-95 without the least protection, and flowered profusely in the autumn of 1895. I am of opinion that it is far more easily managed on a somewhat moist, heavy soil than in a light and sandy one, for on a much lighter soil than mine about ten miles distant a nurseryman friend cannot keep it through the winter. Possibly the soil that "A. D." grew it in was unsuitable, though it seems strange that what suits a plant in the summer should not do so in winter. The young shoots are now about an inch above the soil here, and I should be very loth to disturb the plants, though if I was not pretty sure of their living I should certainly take your correspondent's advice—doubtless given in good faith—and lift them. Those growers having a very light soil to deal with may with advantage dig in a little marl and clay, as this would certainly increase the vigour of the plant even if it had no bearing upon its hardiness or otherwise. The firmer the root-hold the plants have and the more thoroughly they are established the more likely are they to succeed.—R.

### BASAL ROT IN DAFFODILS.

So far as my experience goes in respect to this much vexed question, I fear Mr. Docker (p. 400) is still a long way from a correct solution of the difficulty. At the outset it should be noted the variety mentioned, viz., *Mary Anderson*, is among the most difficult to satisfy in a large number of gardens, and therefore could scarcely be considered as representative of this lovely group of hardy flowers, and I think Mr. Docker's contention fails somewhat to convince by the rather conflicting statements in the note here referred to. For instance, these very bulbs are referred to in one passage thus: "A finer-grown sample of bulbs I never saw," while a little later this sentence occurs, "There was evidence of unripeness to support this view," evidently inferring that the bulbs were lifted before fully mature. If this was the case the bulbs could scarcely have presented the appearance indicated in the first quotation, because *Mary Anderson* is by no means the most vigorous rooting variety of this group. Indeed, in many soils it is a feeble grower generally, and, lacking constitution, frequently disappears in a year or two, though its behaviour is very curious even in this matter at times, and conflicting also. But, assuming the theory of "too early lifting of the bulbs" to be a correct one, then basal rot should be non-existent where the bulbs are permanently planted. The very contrary is the fact, not only in the case of *Mary Anderson*, but with the Tenby Daffodil, as also some strains of *Van Sion* double, or even our common *Lent Lily* where attempts have been made to cultivate it. So also many of the white-flowered varieties, and *Ard-Righ* among others. For these generally considered weak growers annual lifting has been advanced as the best means of keeping them in good health the longest time, and, if coupled with change of soil also, I can answer for its utility. And, so far as lifting is concerned, most growers are content to take the foliage as their guide, for with the decay of this there is little further use for the roots, since no further supplies of sap, even if forthcoming, could be elaborated. The difficulty in this direction comes to those who largely grow the flower in question when a wet season occurs and the foliage remains green and fresh far into July. At such times, though fortunately they do not occur frequently, the late-flowering varieties, poeticus for example, have to be raised before the foliage decays, otherwise renewed root action would ensue. These instances are, however, rare, and in a year like 1897 no such cause need exist. But with some of the poeticus varieties it is difficult to know, even in a year like the present, when there is an entire cessation of roots. Even when the leaves are quite gone, you may raise the well-known ornatus and find root-fibres of all lengths, from one-sixteenth of an inch to several inches long; fibres, moreover, that do not perish when out of the soil, as they do in the great majority of kinds. Usually, where the base of a bulb is badly cankered by this disease, it so

covers the area of rooting as to hermetically seal it, and thus effectually prevent the emission of roots altogether. Nor is it wholly external, as frequently the disease penetrates the birthplace of the roots or fibres, and the points becoming affected, the whole is quickly enveloped by the disease. It is quite a different matter when from a partial attack of this canker space still remains for the roots to descend, and so long as the fibres remain healthy it will make little or no difference whether their descent is perpendicular, or whether they radiate around the bulb. Indeed, in this connection it is surprising how the root-fibres of bulbous plants often shift for themselves, bulbs, for instance, that have been accidentally turned upside down, and notwithstanding that their natural descent is straight down. Such bulbs I have repeatedly found with the roots turned right over, and instead of going direct into the soil, as might be expected, have pierced through their own skin and descended in that way, emerging into the earth at the narrow portion of the neck of the bulb. The latter meanwhile, after producing a crescent-like curve at the apex, has started the upward growth as usual.

Hampton Hill.

E. JENKINS.

### SHORT NOTES.—FLOWER.

**Fampss Grass in Wales.**—I am sending photo of clump of Fampss Grass grown on the lawn here; it has forty-five spikes of bloom. There is another similar clump within six yards. The plants are growing in a very damp soil and partially shaded with trees and heltered from north-east winds.—J. D., Peniarth.

**Linum narbonense.**—Permit me to call attention to the wrong spelling of *Linum narbonense* (see page 401). The adjective ought to have three "n's," not four. It is true the modern name of the town is Narbonne, but the Latin name was Narbo, and the adjective derived from it, which has good classical authority, *narbonensis*; neuter, *ens*.—C. W. Dob.

## STOVE AND GREENHOUSE.

### POINCIANA PULCHERRIMA.

The flowers of this stove plant are very pretty and bright, produced on showy corymbs during the late summer and autumn, and, taken all round, it is a plant deserving of attention. The graceful Fern-like foliage, when the plants are healthy, is a nice set-off to the flowers, and these occur in a fairly long succession on the same spike. Its culture is not so easy as that of some other stove species, but, given healthy plants, it is not difficult to keep them so. It grows into a large, rambling tree 8 feet or more high if left alone, but by cutting back after flowering, may be kept more within bounds and makes nice showy pot plants. It is grown from seeds and cuttings, the former being sown in strong heat. The cuttings should be made of young half-ripened wood and furnished with a short heel of older wood if possible. Place these not too deeply in a firm compost, about three around the edge of a small pot, and before the foliage has time to flag put them into a gentle bottom-heat in a propagating frame. It is not free-rooting under any circumstances, but with care many of the cuttings will strike. The plants should be slightly hardened before potting, but very carefully guarded against cold draughts, or probably many of the leaves will drop off and the plants be weakened. From the first, pot very firmly, using a compost of peat and loam, with coarse sand and crushed charcoal rather freely added. A little of a good concentrated manure may also be added at the second potting, this being more to their taste than natural manures and not so likely to clog the compost. The first flowers usually appear

when the plants are about a foot high, and in this stage they are very pretty for grouping or table decoration, but a better plant is obtained by pinching once or twice and taking up four or five stems. Overpotting must be guarded against, anything like a sour or water-logged soil being fatal, and until a good spread of foliage is produced water must be very sparingly applied. The atmosphere of the house should be kept moist and light syringings are helpful on bright days in keeping the growth free of insects. But a good light and moderate circulation of air are also important factors, these tending to a hard, solid, yet free growth that is sure to flower more freely than very soft sappy shoots. I have seen *P. pulcherrima* grown as a pillar plant in a large stove, and it had a very pretty effect. It is rather apt to get bare of foliage beneath, but this will not occur if the lower part is not too much shaded. Many err in getting this class of plant to cover its space too quickly, running the shoots a long way each season and taking no pains to cover the lower part, but if some nice stubby side branches are secured as the plant is growing, these may be cut back occasionally, and by keeping the top thin will break and give plenty of young wood. Even as a climber on a trellis it does well, and here it should be planted out in a medium-sized border, this being well drained and filled with a similar compost to that described. It is sometimes grown in a rather wild way, and just before the flowers open tied in to balloon and other shaped trellises, many of the stems being usually broken or twisted in doing so. This is the least satisfactory way of all. The scale is very fond of the rough older bark, and red spider sometimes attacks the foliage, but with ordinary care neither of these pests gives much trouble. Old plants that have been cut into shape after flowering, or others headed back for propagation or otherwise, must not be watered for a time, but kept well on the dry side until the cuts are healed. H.

**Posoqueria fragrantissima.**—This very sweet-scented stove shrub is not much grown, but the blossoms are very pure and chaste-looking when the plant is healthy. They occur on loose corymbs at the ends of the shoots, each flower having a long tube and recurving petals. It is happiest under cultivation in a light, sunny house where there is plenty of heat and moisture, the sun shining full on the leaves in the afternoon doing no harm. Small plants are very apt to damp off if heavily watered. It is best grown in equal parts of peat, loam and leaf mould with a good sprinkling of sharp sand and a little manure for strong plants.

**Luculia gratissima.**—Where the occupants of the greenhouse are confined altogether to pots it seems useless to expect a thriving specimen of this *Luculia*, but if it is planted out under similar conditions to those that are so successful in the case of the *Camellia*, then it may justly be claimed for it that it is one of the finest winter-flowering shrubs we have. It does not bloom at all freely when small, but as a bush from 6 feet to 10 feet high it will at this season of the year be studded with large Hydrangea-like heads of beautiful pink, deliciously fragrant blossoms. Like the *Camellias*, this *Luculia* needs liberal watering and syringing during the growing season, hence the bed in which it is planted should be thoroughly well drained. The soil, too, must be of a good open nature, say two-thirds turfy loam to one third of fibrous peat, with a liberal admixture of silver sand and nodules of charcoal. After flowering it should be pruned back and in the spring encouraged to grow away freely.—T.

**Carnation rust, cure for.**—When in Germany the other day I visited some large and well-kept gardens, partly English, partly German,

Going round the greenhouses I was particularly struck with the unusually healthy, strong appearance of a large quantity of Tree and other winter-flowering Carnations, and turning to the gardener, a German, who was kindly showing me round, I said, "These are wonderfully healthy plants." The blurbloom on them is what sometimes see in a well-grown Carnation before an autumn morning, but never before had I seen Carnations grown indoors. "What do you do to these?" said I. "Syringe them," he replied, and if you like I will write you out the mixture we use." I give it for the information of readers who are Carnation lovers to try what can make of it. I have not used it yet. Mixture for killing the Carnation disease (Carnation rust): 1, 2 lbs. of vitriol; 2, 4 lbs. of (freshly slaked); 3, 27 gallons of water 2 lbs. of sugar. 1, 2, and 3, mix well together clear (not blue); add No. 4 and well mix. Syringe once a week early in the day. The syringing should be done quickly, finely, and evenly. M. T. E., Woodlands, Cobham, Surrey.

**Rust on Malmaison Carnations.**—Some years ago I took the old Souvenir Carnation in hand, I experienced no difficulty in keeping the plants clean and healthy all the year round. At length rust appeared, and for some time of opinion that it could not be classed as a disease, but was a symptom of defective culture the result of torpid root action arising from continuous rain when the plants were in the air. The first appearance of this pest was a lot of potted layers which I knew had been watered, and I have invariably found that of moisture at the roots will bring on an attack. From what has come under my own observation I am convinced that were the plants kept all the time through under glass they would seldom be attacked by rust. I have had plants which placed in the open after blooming remain healthy until heavy rains came at the close of summer, and then become badly spotted. I have more than once been struck with the difference between these plants and some which have remained under cover, the latter being quite free from disease, the foliage having that blue tint that characterises this Carnation when in best form. The roots of Malmaison Carnations are extremely sensitive to excess of moisture; a succession of heavy rains renders them tender, and brings the foliage into an unhealthy state, thus inducing an attack of rust. I would advise who can do so to keep their plants either in a well-ventilated house.—J. C. B.

**Yellow Callas.**—"D." (p. 398) is, I feel, the only one who might truthfully confess to a certain feeling of disappointment in connection with the yellow Callas, as there is a very good idea that they are in all respects, save colour, the counterpart of the common Arum Lily, and the same treatment; whereas it has been several times pointed out in THE GARDEN (notably the coloured plates of *Richardia Elliottian* and *R. Pentlandi* respectively were issued), they were totally dormant throughout the winter and during the growing season they need the temperature of an intermediate house, cool end of the stove. As summer advances this is not necessary, but about February when as a rule they start into growth, the plants grow more kindly in an ordinary greenhouse temperature. I cultivate a considerable number, and just now the dormant tubers in the pots they have grown in stood on a shelf at the warm end of a greenhouse—that is to say, a structure that does not fall below 50° during the winter. They are kept almost dormant in February, when the tubers are shaken out of the old soil and repotted in a good compost, such as loam lightened by an admixture of well-decayed manure, leaf-mould and charcoal. The tubers are placed at such a depth that the upper part is about an inch below the surface of the soil; then in an intermediate temperature and slightly moistened they soon start into growth. The roots are produced in the manner of a *Caladium*—that is to say, o

over part of the tuber just at the base of the new growth. When shaken out for repotting it will be sometimes found that an offset or two can be separated without injury, and if these are potted singly and placed under favourable conditions they soon reach flowering size.—H. P.

### CROTONS.

Another class of fine-foliaged plants is so richly varied in colour as Crotons when grown under favourable conditions; but unless they receive the necessary attention and a genial atmosphere they are far from being attractive. It is probably owing to the trouble that insects give, especially when plants get old and stunted, that Crotons are not such general favourites. Large specimens when kept clean and healthy are very imposing, though it is as young plants that I think their full beauty is seen. They may be grown from 2 feet to 3 feet in one season, and with well-coloured cuttings to start with they will have highly-coloured foliage down to the base. Cuttings may be taken at any time during the winter, the stronger the cuttings the better. Where good propagating accommodation is not at hand, the tops may be rooted before taking them from the plants. A few cuttings should be removed, and the stem cut about half through and the knife run up so as to split the stem about half an inch or rather less, a small wedge being inserted to keep the cut open, and then some peat, Sphagnum, and sand bound round. If this is kept moist, but not too wet, roots will soon make their appearance. If taken out and potted carefully they will only require to be kept close for a few days. After they are established, the most essential points towards success are light, heat and moisture. They should be potted on before they have become root-bound, until they are in the largest size which is intended to give them. Very effective plants may be grown in 4½-inch pots, but for larger specimens pots should be used according to convenience. Crotons are not so particular as many subjects with regard to soil. I have seen them grown successfully in various composts. I prefer good loam, leaf-mould, a sprinkling of sand, the addition of a little horn-savings or bone-meal being beneficial. If attention is paid to watering, they may be fully exposed to the brightest sunshine, and the more they are exposed, the brighter will be the colouring. Clear soot-water may be recommended both for watering and syringing with, besides being one of the best fertilisers, it is destructive to insect pests. It could not be depended upon to eradicate mealy bug or scale, but if plants are clean to start with it will prove a thorough preventive, provided the syringe is used so as to thoroughly wet the leaves underneath as well as above. Although Crotons require a high temperature and plenty of moisture while growing, if carefully hardened off they will last well for a considerable time in a low temperature.

**VARIETIES.**—When required for table decoration the narrow, drooping-leaved varieties are most appreciated. Of these *superbus* is one of the best. Countess closely resembles it, and is perhaps better known. Of the two I prefer the latter. In *caudatus tortilis* the twisted leaves are a most beautiful plant. *Prince of Wales* is of similar habit, but a stronger grower. *Thomsoni* is a beautiful Croton when well developed, but one of the most difficult to do. The same may be said of *Aigburth Gem*, which I lately saw some beautiful plants of this, which is comparatively new. *Golden King* is another variety with narrow twisted leaves. Of those with medium-sized leaves which change

to a bright red hue, *Musicius*, *Etna*, *Lady Zetland*, *Flamingo*, and *Mortfontainensis* are among the best, and of those that retain the yellow variegation, *aneitnensis* and *Weismanni*. The latter, though a very old variety, still holds its own. Of large-leaved sorts *Thomsoni* is the best yellow. *Alexander III.* colours very richly. *Newmanni* should always find a place where Crotons are grown. *Bergmani* and *Baron Frank Selliere* are large-leaved varieties with creamy-white variegation. *Reedi* is a later addition, and one of the best. Many more varieties might be named as being equally desirable, but those making a selection cannot do wrong in growing the above. A.

***Panicum plicatum.***—For the decoration of large halls or similar spaces in the house I find this a very useful plant when sown early in the year and grown on freely. An excellent way of getting big Palm-like specimens early is to prick off the young seedlings into pans, and then transfer the whole of the plants in each pan bodily into a large pot of fairly rich soil. In a few weeks they grow into huge specimens 5 feet high and nearly as much through, and these are very useful throughout the summer. To keep the plants green and healthy-looking, an abundance of water is necessary through the growing season. I find this green-leaved form far superior for general purposes to the variegated form which is used to be more commonly grown, but both make handsome plants when grown in a mass and not as single plants.—J. C. TALLACK.

***Ceropegia elegans.***—I enclose a few blossoms of this interesting and apparently little-known climber, which was figured in *THE GARDEN* in vol. xviii., and seems to have been scarcely ever mentioned since. It is a slender twining plant with opposite leaves, growing freely in an intermediate temperature such as suits the majority of *Adiantums* and many *Orchids*. The flower is not very showy, but quaint and attractive to those who can admire quiet beauty. It is trumpet-shaped, the base being nearly spherical, then suddenly narrowing and gradually widening to the mouth where the petals are folded inward so as to meet in the middle, and are here furnished with a delicate fringe of hair. The ground colour is creamy white, densely spotted with chocolate. Several flowers are produced at each joint, and with me plants in 6-inch pots are never (or hardly ever) out of bloom. It seems easily propagated from cuttings.—GREENWOOD PIN.

***Bouvardia corymbiflora Humboldtii.***—For some unexplained cause this well-known plant is almost universally referred to in plant lists as *B. Humboldtii corymbiflora*, thereby reversing its specific rank. Why this is so is not at all clear, as by a moment's thought the specific title is at once obvious. As an autumn-flowering plant it is of especial value, being not only free in growth, but decidedly vigorous and easy of culture. As an early autumn flowering plant, however, it is worthy of note, and, being of easy culture, there is no reason why long sprays of it should not be abundant in private gardens during the early autumn months. It is quite easy to make capital flowering plants in six or seven months, and where very early cuttings are obtainable, handsome bushes with ten or a dozen stems may be grown. For early work, however, this kind is best as a pot plant. The plant is of erect growth and attains to fully 2½ feet or 3 feet high when well grown, with a terminal corymb of pure white blossoms.

***Schizostylis coccinea.***—Some plants of this useful plant lifted from the border a week or two back are now providing a valuable lot of spikes that are particularly serviceable. It is one of those easily grown plants that are too frequently neglected and allowed to remain too long in pots without attention. But if planted out in early spring in good soil it is surprising how quickly the plants recover, while those with

any strength are sure to flower the following autumn. In some gardens the clumps are simply parted and planted out in this way, but having given both systems a trial, I can speak strongly in favour of planting single crowns in preference to the clusters. By selecting the strongest pieces some very fine spikes may be relied upon each autumn. When it is remembered how few such things exist, they are more than worth the trouble their cultivation involves. The planted-out single crowns always have a fresh, clean look about them, and by placing half-a-dozen in a 6-inch pot a good display is secured. Where needed only for cutting, the plants do equally well if planted into boxes and placed in cold frames in September.—E. J.

### SHORT NOTES.—STOVE & GREENHOUSE.

***Begonia Gloire de Lorraine.***—In referring to the parentage of the above in *THE GARDEN* (p. 354) I inadvertently gave *B. Martiana* as one of the parents; it should have been *socotrana*. I find the raiser gives *socotrana* and *Dregéi* as the parents, but the general habit certainly suggests some affinity to *Martiana*.—A.

***Carnation Snowflake.***—The flowers of this are of medium size and pure white. The great recommendation appears to be the free branching habit of the plant. We are always wanting good white Carnations during the winter, and if the above proves to be of good constitution, it will be a welcome addition to this useful class of flowering plants.

***Panercium fragrans.***—This is a very beautiful plant; the lovely flowers, produced on large umbels every season, are always anxiously looked for. They are fine either on the plant or cut, and although some florists have an objection to them, as hiding other flowers in bouquets or wreaths, I fail to see it. It is one of the easiest grown stove plants, thriving under almost any treatment if not over-watered.

***Lily of the Valley fruiting.***—With reference to Mr. F. W. Burbidge's note on *Lily of the Valley* in fruit, and the excellent illustration of the same that appeared on page 319, I may mention that last year I saw a large bed quite red with berries at the Devon Rosery, Torquay. On inquiry I found that fruit had set occasionally in former years, but never in such quantity as in 1896. The occurrence was attributed to the excessively dry spring and summer.—S. W. F.

### A MILD NOVEMBER.

THE mild weather experienced in November, I should imagine, is almost or quite without a parallel. Peas and Runner Beans could be gathered in the open garden, and Globe Artichokes and summer Lettuces cut so late as November 25. In the flower garden, too, Dahlias, the tenderest of all summer flowering plants, have been gathered after the middle of the month, while Sweet Peas, Roses, Marguerites, Wall-flowers, Polyanthus, and Anemones among others have been playing their part in giving evidence of the unusual mildness of the rapidly passing winter. *Chrysanthemums*, too, in cottage gardens have been a fine feature, and bid fair to continue until some time into December. There are advantages and disadvantages conveyed even in such beautiful weather. Everything has been flourishing and plentiful, but the soft and late growth of winter crops is sure to suffer from cold, chilling frosts and winds. The present aspect of plenty may be changed into one of scarcity as regards vegetables and salads, so that it becomes a duty on the part of those from whom a large demand is expected to provide for contingencies. Opportunities for advancing the winter's work outdoors were never better; trenching and digging, pruning and nailing of fruit trees, clearing up and surface digging of flower borders, storing of roots, and other routine work have had but very slight hindrances from the weather.

The rainfall constituted a record for November. At the time of writing there has not been more than half an inch here, and the barometer is higher than in any month of the year. Springs are very low. In some country districts a very short

water supply is no unusual experience, and in some cases entails a deal of labour and inconvenience. In large country houses where extensive decorations with cut flowers are carried out, what a vast contrast the present autumn has been compared with many of the past. So far as material has been concerned, there could not be any complaint, for the work has been comparatively easy compared to that of some years, and Chrysanthemums, which take up so much time from spring till autumn, have lost much of their value in consequence. To the large market grower there must have been serious losses from this cause alone, but what has been the loss of the few must have proved an enormous gain to the many, especially those dependent on their own productions. In the fruit gardens and orchards the fine autumn has had a beneficial influence, judging from the well-ripened appearance of the season's growth and the prominent buds on Apple, Pear, Plum, and other trees. Planting of young and root-pruning of older trees have been carried out under the best of conditions. W. S.

Wills.

## GARDEN FLORA.

### PLATE 1147.

#### TWO WATER LILIES.

(WITH A COLOURED PLATE OF—1, *NYMPHÆA MARLIACEA ALBIDA*; 2, *N. ROBINSONI*.)

AFTER another season's experience of these additions to our lakes and ponds, I am more than ever impressed with their beauty, their utility and their novelty. No such additions as these charming hybrid Lilies have been made to our lists of aquatics for very many years past, nor indeed has any other plant come so prominently to the front in our gardens for a great length of time. From the many letters of inquiry I have received I have abundant proof of the desire that exists to enter into their

Part of group of *Nymphaea Marliacea albida*.

culture. From both letters received and visits paid to other gardens, I find that preparations are being made to take up their cultivation as speedily as possible. With regard to their beauty, they have, methinks, only to be seen to be admired; even when displayed in horticultural exhibitions in a cut state they have been greatly admired. To see them at their best, however, an inspection must be made of them in their natural element. The combinations of colouring can

\* Drawn for THE GARDEN by H. G. Moon at Gravetye Manor, Sussex. Lithographed and printed by J. L. Goffart.

then be more fully realised. The common white Lily (*N. alba*) we all know, but there is in addition the white variety to be seen in the accompanying plate, *N. Marliacea albida*, a veritable giant in its way with its individual flowers fully 9 inches in diameter (my plant of this Lily has had as many as fourteen flowers on it at one time up to and approaching these dimensions). Its purity, too, is quite remarkable by the side of the old white save in the bronzy flush upon the outer segments. *N. Robinsoni* is another notable hybrid Lily; with me it assumes deeper tints than in the coloured plate, is very free-flowering, and lasts in an expanded state longer than most kinds. Being a moderate grower as regards vigour, but at the same time of rapid growth, it produces a fine effect in shallower water than the preceding kind. *N. odorata sulphurea* and its larger form have this year much improved in freedom of flowering, but they do not commence to bloom so early as most kinds. The individual flowers, however, stand up well above the foliage, and are thus seen to the best possible advantage. From the narrower seg-

*Nymphaea tuberosa*. Engraved from a photograph of young plants in the open water in Sussex.

ments and their numbers these two Lilies are quite distinct, the sulphur-yellow pervading both the segments and seed organs. Of the newer kinds tried this year for the first time especial note should be made of *N. Ellisiana*, a lovely variety, and one which will be greatly sought after. It flowers freely, has flowers of large size (and handsome foliage, too); the colour is a brilliant carmine-purple. *N. Aurora* with me is of a primrose-yellow shade, a deeper tint than in the more common *N. Marliacea Chromatella*. *N. Andreana* in colour is a purplish red, and is also of large dimensions; the leaves, possessing singularly long petioles, float upon the water quite by themselves. *N. Marliacea rubro-punctata* is well defined by its prefix; in size, however, it bids fair to approach *N. Marliacea albida*. There are other kinds on the water here which I hope to report upon later. One of these has flowers which for size are equal to those of any other kind, whilst the colour is a deep crimson. This and others will no doubt next season be seen much finer as they gain strength.—JAS. HUDSON.

\*\* From the "Water Garden," by W. Tricker, of which a review will be found on page 451 of this issue, we quote the following:—

I.—HARDY NYMPHÆAS.

*NYMPHÆA ALBA* (white Water Lily).—This species, native of Great Britain, has long been in cultivation. It is a vigorous growing plant, with

dark green glossy foliage, and large, white, cup shaped flowers. It is well adapted for use in either artificial or natural ponds, and shallow or deep water, but is being superseded by new varieties and by hybrids of greater merit.

*N. A. CANDIDISSIMA* is like the preceding in every way, except that it has larger flowers with broad petals. It is one of the best for planting in large ponds where bold effect is desired, its massive foliage and flowers standing out well above the water.

*N. BLANDA* is a vigorous and free-flowering species, somewhat similar to *N. a gigantea* flowers of dazzling whiteness, in which respect it is unsurpassed by any other white-flowered Water Lily in cultivation.

*N. CANDIDA* (syn., *semiaperta*).—A Bohemian species, similar to *N. alba*, but of moderate growth. Flowers of snowy whiteness, 2½ inches to 3 inches across, sepals tinged with green.

The Laydekeri varieties are among the choicest of hybrid Nymphaeas; their flowers are medium-sized (2½ inches to 3 inches diameter), the plants are vigorous, but not so robust like the *Marliacea* forms. They are admirably adapted for ponds of moderate size

where space is limited and the greatest variety is desired; they are also well adapted for growing in tubs.

*N. L. FULGENS*, as the name indicates, is of glowing brilliant colour; petals crimson-magenta, stamens garnet-rose; flowers beautifully cupped glowing like a brilliant in the sunshine.

*N. L. FULVA* has large star-shaped flowers; the four sepals are greenish yellow, petals cream yellow, suffused with red, stamens golden yellow leaves dark green, mottled with red.

*N. L. LILACEA* has a delicately formed and chaste flower of a soft rosy lilac colour with yellow stamens. It is exquisitely fragrant, resembling a Tea Rose. Leaves deep glossy green with occasional dark blotches.

*N. L. PURPURATA* is somewhat larger than the others of this group and the petals longer and more sharply pointed; flowers very symmetric of a rich rosy crimson colour, stamens orange-red.

*N. L. ROSEA* has proved a universal favourite the peculiarity of the flowers changing from rosy pink to rose-purple as they age affords most pleasing combinations and gradations of hue. Where several plants are grown together the numerous flowers of various shades give a charming feature not elsewhere known in Water Lilies. This variety is well adapted for large aquariums and will produce its dainty flowers even when growing in a 4-inch pot, but its true character, size and colour are seen only when planted in a natural pond and left undisturbed for at least two seasons.

*N. L. LUCIDA* has large flowers of a rosy-vermillion colour, with orange stamens; leaves beautifully mottled with chestnut-red.

*N. ROBINSONI*, with flowers larger than those of the Laydekeri varieties, is distinct and unique in colour; the yellow ground colour is overlaid by purplish violet-red, deepening toward the centre of the flower; the stamens form a crown of orange-red colour. The leaves are dark green, spotted with chestnut-brown.

*N. SEIGNOURETI*.—Flowers delicate yellow, edged with soft rose and carmine, borne on erect stems, and stand about 6 inches above the water. Leaves spotted with chestnut-brown.

The *Marliacea* hybrids mark the introduction of hybrid hardy Water Lilies, and include the very best forms. Although other gems have since been introduced, they do not compare with these for general utility; the plants are vigorous and robust, flowers large, very effective in groups and masses in large ponds or as single specimens.

*N. M. CARNEA* is in every respect, save colour, similar to the preceding variety. The flower is a soft flesh-pink colour, which deepens toward the base of the petals, sepals rose-pink, with a delicate fragrance of vanilla.

*Nymphaea Marliacea carnea.*

*N. M. ALBIDA* has all the good qualities of *N. M. candidissima*; the flowers are larger and more fragrant, of a dazzling, sparkling whiteness, and produced very freely until frost. The stamens are occasionally flushed pink, especially when grown in stiff soil.

*N. M. CHROMATELLA* has flowers of a lovely primary-yellow, with deep yellow stamens, large and handsome, and is undoubtedly the best yellow hardy Water Lily. Leaves bronzy green, with chocolate-red markings. Plant very vigorous, inclined to be bunched or crowded, and should therefore have plenty of room and be in permanent quarters where it is not likely to be often disturbed. The water should be 2 feet or more deep.

*N. M. FLAMMEA* and the following varieties are of recent introduction, and are yet but little known in the United States. The flowers of *Flammea* are bright amaranth-red, shaded white; the outer petals pink, the colour deepening towards the centre, stamens deep orange.

*N. M. ROSEA* has the same vigorous habit as the preceding varieties; the flowers are of the largest size and a beautiful deep rose colour; the young foliage is purplish red, changing to deep green. All things considered, this is the best hardy pink Water Lily, large flowers, fine colour, and free flowering.

*N. M. IGNEA*, one of the most striking of recent introductions, has flowers of magenta-red and stamens orange-red. It is a brilliant flower in the sunshine, and is highly spoken of in England, where it apparently does well. At present it has not proved to be a vigorous grower nor so satisfactory under cultivation in the United States.

*N. M. RUBRA PUNCTATA* has a beautiful flower of moderate size, flowers deep rosy purple, spotted carmine, with orange stamens.

*N. ODORATA*, our native sweet-scented Water Lily, is widely distributed, and can be found in many ponds, lakes, and slow running streams. Under cultivation, associated with other species, it has been fertilised from them by insects; in this way and also by other means several forms and gradations (some very choice) in size and colour have resulted. The best forms are very desirable for their large, pure white flowers and delicious fragrance. The sepals are very often edged with pink, giving the appearance in bud of

sionally very large and hard. The flowers are large and pure white, somewhat incurving, and lacking the delicious fragrance peculiar to the type. It requires a deeper water than the type to grow it to perfection.

*N. O. MAXIMA*.—This is entirely different from the type; the flowers are large and cup-shaped; petals broad at the base, and without a tinge of

*The Florida Yellow Water Lily (Nymphaea flava).*

red on either sepals or petals. A most beautiful variety, found in New Jersey. This is probably the same as the variety *N. O. superba*. (Some doubt exists as to this and the preceding variety belonging to the *odorata* group.)

*N. O. MINOR* is, as its name implies, small. Leaves only 2 inches to 5 inches across, and flowers two to three. A very pretty plant and well suited for growing in tubs. It is found true in some sections of New Jersey in shallow water of cold bogs and poor soil. There are other forms of *N. O. minor* with somewhat cup-shaped flowers and only slightly fragrant.

*N. O. ROSACEA* in habit and general appearance resembles *N. O. exquisita*; it is, however, more vigorous. Flowers bright rose, lighter towards the centre, the rich yellow stamens producing a soft salmon shade of colour; the petals are narrow and pointed, the flower being like a pink star floating among the leaves. A very desirable variety.

*N. O. ROSEA* (the well-known Cape Cod pink Water Lily) is indispensable in any collection.

*Nymphaea dentata.*

Flowers deep pink and very fragrant. Early and free flowering; its season is somewhat shorter than that of some varieties. It produces seed freely, and to prolong the season the dead flowers should be taken off and no seed allowed to ripen, which can be easily accomplished where only a few plants are grown. In extreme hot weather the flowers are apt to bleach, but in cool sections and districts like Eastern Massachusetts the plants and flowers are to be seen in perfection.

a pink flower. A grand Water Lily for naturalising.

*N. O. CAROLINIANA*.—A natural cross that originated with Dr. Henry T. Balmson, of Salem, N.C. The petals are of a delicate soft pink and the golden stamens reflect a lovely salmon tint. It varies through several shades in colour under certain conditions and soils. The flowers are of the largest size. It is a choice and select variety, and has proved a great acquisition where it has remained undisturbed for two or three seasons.

*N. O. EXQUISITA* has large, rosy-carmine flowers, much deeper in colour than those of *N. O. rosea*, and is the darkest coloured Lily in this group. Foliage dark red. Moderate grower. A hybrid of French origin and very beautiful.

*N. O. GIGANTEA*, sometimes called the Southern *odorata*, being common from N. Carolina to Florida, and the only white variety indigenous to this section, differs from *N. odorata* in being a more vigorous grower. Large, handsome, green foliage, under side bright red. Root-stock occa-

*N. O. SULPHUREA* is distinct from any of this class. The large, handsome yellow flowers stand about 6 inches above the water; the young leaves are beautifully mottled with chesnut. A free and vigorous plant of French origin.

*N. PYGMAEA*.—This is the smallest species in cultivation; the flowers, which are pure white, are among the first to be seen in spring, and continue a long season. The species is well adapted for tub culture, also for the aquarium, and it will produce its dainty white flowers in a 4-inch pot. When planted out and left undisturbed for two or three seasons the flowers are larger and very pretty, making a beautiful contrast to the other giant species. It forms no runners or side shoots, and does not spread rapidly.

*N. P. HELVOLA*.—This is in truth more of a pigmy than the species; flowers, however, a trifle larger, canary-yellow, produced very freely. Especially recommended for cultivation in tubs and aquaria. Leaves beautifully mottled with reddish brown and smaller than in the type.

*N. SPHEROCARPA* (Caspary's Lily).—The true Swedish Lily. A distinct and beautiful species, and very unlike *N. alba*, of which some claim it to be a variety. While it is a very desirable form and highly spoken of in England and in Europe generally, it is very scarce, and does not flourish as do others under general cultivation. It has been flowered in the United States, but is apparently very impatient of removal, the least disturbance causing a check to its growth and stopping its flowering. Another drawback to its cultivation is its dislike to hot weather; if it were plentiful it would doubtless succeed in ponds where cold springs are a hindrance to the successful cultivation of other desirable species. It blooms quite early in the season; the flowers are rosy carmine, with orange stamens, deepening in colour the second and third days.

*N. TUBEROSA* (syn., *reniformis*) is a native species of the Western and North-western lakes, where it grows in deep water. A strong and robust plant. Leaves 8 inches to 15 inches wide; flowers white,  $\frac{1}{2}$  inches to 9 inches in diameter, slightly fragrant. The root-stock bears numerous spontaneously detaching, often compound tubers. This should be excluded from small ponds and should be planted by itself.

*N. T. PLANA*.—Flowers white, large and full; petals very numerous, the stamens being converted into petals, which are fluted in the centre of the flower. Plant less vigorous than the type. All *N. tuberosa* forms should be grown in deeper water than other types.

*N. T. ROSEA*.—A natural cross. Flowers are a lovely pink, standing well above the water, somewhat less vigorous than the type.

#### II.—TENDER WATER LILIES.—DAY BLOOMING.

*NYMPHLEA CERULEA* (syn., *stellata*).—This is the ancient blue Lotus of the Nile, but is not a *Nelumbium*. The flowers are light blue; petals long and narrow, sepals greenish white, suffused blue; stamens light yellow, tipped blue; leaves light green, spotted in the young state, changing to green; the underside of leaf also green. A distinct and beautiful species.

*N. ELEGANS*.—A pretty Mexican Water Lily of moderate size, 3 inches to 4 inches over. Colour white, tinged with purplish blue; the stamens yellow, tipped blue. A charming flower. Leaves long and narrow, deep green, spotted purplish brown. Well adapted for tub culture, and producing its dainty flowers very early in the season.

*N. FLAVA*.—The well-known Florida yellow Water Lily, and the only known yellow species. This has been introduced into many States and sections of the country, but has not been a success under any kind of culture. It is hardly as far north as New Jersey, a moderate grower, and produces numerous runner-like shoots forming young plants. Its greatest merit consists in its being undoubtedly one of the parents of Marliac's magnificent yellow hybrids, which are now widely known, and are many times more desirable for all garden purposes.

*N. GIGANTEA*, the Australian species, is sometimes confounded with *N. odorata gigantea*. This is probably the finest, most handsome and distinct of all *Nymphaeas*. The colour is a soft satiny-purplish blue, shading to white at the base of the petals; the stamens are silk-like, soft yellow, incurving, unlike any other species. The flower is carried well above the foliage on a stiff stalk, and is of the largest size. The leaves are green, with purple reverse. This species is very impatient of removal, repotting, or transplanting during its early stages. It should not be allowed to get pot-bound, or subjected to sudden changes of temperature, which will cause a check and a suspension of active growth. Plants, seedlings, or tubers in their early stages should be grown in a temperature of 80° to 90°; later, a temperature of 75° to 80° will suit them.

*N. GRACILIS*, a Mexican species of great merit, has large, handsome, star-shaped, white flowers, which are borne on stout stems well above the foliage. It is worthy of special note as being the only white day-blooming tropical or tender species; a very vigorous plant, free flowering, the flower possessing a delicate fragrance, resembling Lily of the Valley.

*N. MEXICANA*.—This is possibly a form of *N. flava*, which it resembles in most respects. The habit is the same, but the runner plants not infrequently produce flowers during the first season. The plant is altogether freer flowering, and the flowers are brighter and deeper in colour. The plant is as hardy as *N. flava*.

*N. PULCHERRIMA*.—Very vigorous and free flowering; possibly no other equals it. The flowers are very large under high cultivation—10 inches to 12 inches across—of a beautiful light blue, with deep yellow stamens tipped blue; the sepals are irregularly striped dark red. Unlike *N. zanzibarensis*, this variety opens its lovely flowers at early morn, and remains open until other species are mostly closed. The leaves are large, and often exceed 2 feet in diameter, having long tapering lobes and irregularly crenated margin. Garden hybrid of American origin.

*N. SCUTIFOLIA* (syns., *versicolor*, *cyanea*, *radiata*).—This is a beautiful star-shaped distinct species. The flowers are clear pale blue, shading to white at the base of the petals. Flowers very fragrant. Leaves variable, green, sometimes with a purplish tint, the underside occasionally bright red, with brownish red markings; margin smooth. Native of Cape of Good Hope.

*N. ZANZIBARENSIS* (the Royal Purple Lily).—This and its several forms are among those that might be styled everybody's flowers. They are the simplest to manage, easily raised from seed, will flourish in a tub even if the leaves are high and dry. Tubers and plants are no longer held at an exorbitant price, and they give the greatest amount of pleasure for a trifling cost. Flowers of the true form are of the largest size under high culture; the sepals and stamens are purple, with red margin; petals intense blue. One of the most beautiful and free flowering of all Water Lilies. Highly fragrant. The foliage is dark green, with blotches of reddish brown and bright purple underneath.

*N. Z. AZUREA*.—Similar to the type, but varying in colour from a light to dark blue; sepals never purple; leaves green, with dark markings, the underside green, shaded more or less with purple.

*N. Z. ROSEA*.—Similar to the type save in colour, varying from deep carmine to pink; leaves shaded red on the under side. All the Zanzibar Water Lilies are very free flowering, and are useful either for tub culture, ponds, or lakes.

#### III.—TENDER WATER LILIES.—NIGHT BLOOMING.

*NYMPHLEA COLUMBIANA*.—A deep, rich, dark red-flowered variety of medium size, 6 inches across; stamens cardinal; the colour deepens each succeeding day. Foliage dark bronzy red. Plant of moderate growth.

*N. DEANIANA*.—A robust plant with large bronzy green foliage; petals of a beautiful pink, with darker sepals; stamens red. Very free

flowering, requires plenty of room for leaf spread and a depth of water 12 inches to 18 inches above the crown of the plant. Hybrid of American origin.

*N. DELICATISSIMA*.—A delicate and choice flower of a distinct and pleasing carmine-pink colour; the foliage has a bronzy green lustre. The plant is vigorous, yet moderate compared with some others. Desirable for all purposes, and has proved one of the best for cutting, and also for winter culture.

*N. DEVONIENSIS*.—This, one of the oldest, is also one of the choicest night-blooming Water Lilies in cultivation, and is indispensable in any collection of moderate size. Under liberal cultivation a single plant will cover about 200 square feet of water surface, and produce numerous flowers. One plant has been known to have on it at one time as many as thirty-six flowers and buds in different stages of development. The flowers are large, 10 inches to 12 inches across, of a brilliant rosy red, a most pleasing colour by artificial light, and are borne on stems well above the water. The leaves are red, changing to bronzy green. The first hybrid of note, and was raised at Chatsworth, England, and named in honour of the Duke of Devonshire.

*N. DENTATA* is the largest and best white of this class. It has long pointed buds, the flowers of the largest size, opening horizontally, and measuring 10 inches to 12 inches over. The leaves are deep green with serrated edges. Native of Sierra Leone.

*N. KEWENSIS* is not generally met with, but it has established itself as a first-rate and desirable variety in any collection. The flower is a beautiful rosy red of the first size. Plant vigorous, with bronzy-green foliage, purplish underneath. A hybrid of English origin.

*N. LOTUS* (syn., *thermalis*).—An ancient species, indigenous to lower Egypt, and is associated with the Egyptian and blue Lotus, being held sacred to Isis and was engraved on the ancient coins. The flowers are white, with sepals and outer petals flushed pink, large and incurving, somewhat cup-shaped. A strong and vigorous plant, with leaves of deep green with serrated edges.

*N. O'MARANA* is of recent introduction, and has achieved a grand reputation. The flower is above the average of large flowers, attaining a size of from 12 inches to 15 inches; it is borne well above the foliage on a stout stalk, and as it opens to the full, the sepals and outer petals droop. The colour is a beautiful rosy red, with an indescribable glow produced by the rays of the rising sun. The leaves are large and of a dark bronzy red, heavily dentated. Under high cultivation it is a robust plant without any appearance of coarseness, and is also very free flowering at a very early stage. The largest and best of the red *Nymphaeas*. Hybrid of American origin.

*N. RUBRA* is a beautiful red species, somewhat resembling *N. Devoniensis*, but the sepals are broader at the base and deeper in colour, the petals being less pointed. The leaves are rounded at the apex and mottled purplish on the reverse, otherwise the plant is similar to *Devoniensis*.

*N. RUBRO-ROSEA* in general characteristics resembles the preceding and is liable to be confused with it. The flower is much the same, but is larger and brighter in colour, with longer buds, and is more pointed.

*N. SMITHIANA*.—All the tropical Water Lilies delight in a high temperature, and if this one can be grown in a Victoria pond or in a temperature corresponding, the true character and chaste colouring will be very greatly developed. The flower is of medium size, perfectly cup-shaped, creamy white, with yellow stamens; petals broad and of great substance; the reverse or outer side of the petals is delicate pink. The higher the temperature the deeper and brighter the colour. American hybrid.

*N. STURTEVANTI*.—A superb variety with large, bright rosy-red flowers of massive proportions, petals broad and the flowers more cup-shaped. Requires a high temperature to develop its true character. Plants should be started early, as they

do not flower until well developed. A magnificent Water Lily and worthy of additional care to bring it to perfection. American hybrid.

IV.—THE VICTORIA (THE ROYAL WATER LILY) AND EURYALE.

**VICTORIA REGIA.**—This is the most wonderful of all water plants. It inhabits the tranquil bays and lakes of the great streams of South America. The plant is of gigantic proportions; the leaves grow to an immense size—from 6 feet to 7 feet across—with a vertical rim from 3 inches to 8 inches high. The flowers are from 12 inches to 15 inches in diameter, with very numerous petals. The colour of the flower is white on the first opening day, changing on the second day to rosy pink.

**V. REGIA VAR. RANDI** was discovered and introduced by Edward S. Rand, Jun., of Para, Brazil, and it differs from the original in several particulars. The whole plant is more robust; the young leaves are of a darker bronzy colour; the vertical rim on well-grown plants is 5 inches to 6 inches high, giving the plant a striking and novel appearance. Leaves are produced 6 feet to 7 feet in diameter. The flowers of this variety are white on the first day, changing on the second day to a deep crimson.

**VICTORIA REGIA** (Tricker's variety).—A new distinct Victoria with well-marked characteristics provisionally named as here given, but may be differently entitled on further knowledge. Among its peculiarities are: First, the early cupping of the leaves, the turned-up rim being shown by quite small plants; the full grown leaves are large, of a lustrous bright green colour, and the rim is from 6 inches to 8 inches deep. The flowers are also produced much earlier than on the other Victoria forms and are larger, measuring from 15 inches to 18 inches over; they are white on opening, changing to a lively rose-pink on the second day. The sepals in this variety are smooth, whereas the others are spinous to the tips; another striking characteristic is that it can be successfully grown in a much lower temperature than is usually advised for other Victorias. The seed will also germinate in a lower temperature; in fact, the plant does remarkably well treated precisely the same as the tropical *Nymphaeas*.

**EURYALE FERON** was the noblest aquatic in cultivation prior to the introduction of the Victoria; its large circular leaves are from 2 feet to 3 feet in diameter, with prominent spiny veins on the rich purple underside, the upper side being olive-green, puckered and spiny. Flower small and insignificant, of a deep violet-blue.

V.—NELUMBIUMS (EGYPTIAN AND JAPANESE LOTUS).

**NELUMBIUM ALBUM GRANDIFLORUM.**—A magnificent large white Lotus; its pure white flowers tower above the handsome foliage and contrast conspicuously against the carmine-pink of other *Nelumbiums*. Given the same soil as *Nymphaeas* and located in a warm, sheltered spot, and not moved too frequently, this plant will produce flowers in plenty.

**N. A. STRIATUM.**—A large and bold flower; petals white, tipped and striped rosy carmine; it is a vigorous and robust variety, and flowers very freely under liberal culture.

**N. LUTEUM**, the well-known American Lotus or Water Chinquapin, has flowers of pale yellow, though occasionally in stiff clayey soils the colour is as deep as in *Nymphaea Chromatella*. Plant but a moderate grower, and under artificial conditions should receive liberal treatment. Where established in natural ponds and lakes it is vigorous and free.

**N. ROSEUM.**—The flowers of this have the deepest colour of any Lotus in cultivation: in form they are more globular than others. Deep rose-pink. Plant vigorous and not as tall growing as in *N. speciosum*.

**N. SHIMOMAN.**—A Japanese Lotus of recent introduction; of robust growth, producing leaves and flowers of gigantic proportions. The leaves are from 36 inches to 40 inches across, supported on stout stems 5 feet to 6 feet high. The large

double white flower is a marvel of Nature's production. It is as free flowering as any single form and deserving of the best and most liberal cultivation.

**N. SPECIOSUM.**—The world-famed Egyptian Lotus now so well known throughout the United States, and as hardy and as easily grown as the native Water Lily, except, perhaps, in extreme northern sections. The flowers are rose-pink, creamy white at the base of the petals, but on first opening the flowers, or rather the buds, are a lovely shade of deep rose-pink; the flowers are not fully expanded till the second day, when they are in their best form. *Nelumbiums*, like *Nymphaeas*, are three-day flowers, but, unlike *Nymphaeas*, they only partially close at night.

**N. KERMESIANUM.**—A Japanese plant of great merit. The flowers are of a beautiful carmine-rose colour and satiny texture, of large size. Vigorous, free flowering, and early.

**N. SEIBAKUREN**, a pigmy among *Nelumbiums*, has leaves 6 inches to 8 inches across, on stalks about 1 foot in length. The flower is pure white, the long-pointed bud resembling a large Tulip. Can be grown in a small tub or large pot standing in water.

## ORCHARD AND FRUIT GARDEN.

### NOTES ON INDOOR PEACHES.

Now that the *Chrysanthemum* season, so far as the exhibition flowers are concerned, is past, the fruit grower's thoughts settle down on the preparation of his trees for another year's work, and where Peaches and Nectarines are represented in fairly large numbers, there is a deal of work to get through between the present and the early spring months. Almost invariably there are some trees that need attention at the roots from one cause or another. With me it is required in the suppression of strong growth that comes from deep root-action. This in some gardens is a source of a great deal of heavy labour, and tempts one to ask why roots of trees have such a tendency to ramble away from borders over which gardeners take so much trouble, and in which so many ingredients, natural and artificial, are incorporated. This tendency to ramble seems particularly strong where the subsoil is of a clayey nature, and, unless concrete bottoms are provided, I find it impossible to keep the roots from penetrating deeply. What the chemical constituents of clayey subsoils are I cannot state, but there seems to be an attraction in them for roots of fruit trees almost or quite as strong as that of leaf mould naturally deposited on the surface or placed there for their benefit. Possibly some of your readers may give some explanation relative to the attraction of subsoils for roots. Such soil brought nearer the surface does not have the same influence; indeed, roots would seem to avoid rather than utilise such a provision. In borders neglected both in the matter of moisture and surface mulching in summer, the natural conclusion would be that the roots penetrated deeply in search of moisture, but such an argument cannot hold good when the weekly routine of syringing and watering is rigorously carried out. It is only too true that the resultant strong growth from deep root action is fatal to regular and full crops, and the only alternative that remains for securing such desirable ends is to periodically examine and shorten the thong-like roots that are responsible for the vigorous shoots made during summer when left alone.

The value of lime refuse has been so often repeated by the many practical contributors to THE GARDEN, that it would seem almost

superfluous to further extol its virtues. Not one word has been advanced in favour of lime refuse that it does not deserve in the cultivation of stone fruits. I had a case in point lately when removing some fairly large Peach trees from one house to another. One had been planted two years since and a good quantity of lime had been used; the other had been planted mostly in new maiden loam without any addition; and while one had abundance of fibrous roots, the other had large fleshy ones rambling away in search of something the new loam did not contain. This is a proof of the value of lime for the production of fibrous roots, and in the maintenance of these, good crops of fine fruits follow when the daily routine is duly attended to. At this time of year there is a tendency to allow the fruit borders to become unhuly dry, and although this may not absolutely explain bud-dropping in spring, it no doubt accounts for some of it in many cases. A dry border in winter is entirely opposed to natural laws, although it would scarcely be prudent to follow up natural courses in the matter of watering indoor borders in winter. At the same time, a uniform state of moisture can be maintained without much effort in winter, and is certainly needed when one considers the short period in which trees are dormant between the fall of the leaf and the movement of the sap and buds in winter.

I have almost as great faith in the virtues of burnt refuse for fruit trees as lime, and invariably give a dressing to the surface in winter if there is no need for deeper excavations. In root treatment this is always mixed with the soil in the course of filling in. There is a distinct advantage in carrying out all planting and root-pruning of Peaches and Nectarines in the autumn or early winter. By early attention the trees invariably make some root growth, and this at once constitutes semi-establishment, which ensures a better prospect for the future. A light crop can often be taken the following year without any material disadvantage. On the other hand, by late winter planting the prospects of a crop are not a safe prediction, and the growth on trees hampered with the strain of fruit-bearing is not such as to raise very good hopes of a profitable one the following season. In the autumn of last year I had occasion to remove a large tree of Waterloo Peach from the early house, where it had ceased to be profitable for forcing, and was agreeably surprised in the spring to find it had retained and actually developed almost every flower-bud in the cooler house in which it had been planted. Its growth was so satisfactory that a light crop was retained in the course of disbudding, and its general condition at the present moment is such that very few would credit its recent removal. The same remark applies to a younger tree planted at the same time, and which also ripened some very excellent fruits.

For winter dressing most gardeners have their own favourite prescriptions, but, strange as it may seem, and with all the excellent insecticides now available, red spider and scale still remain. Scale seems to possess a remarkable trait of appearing in the winter, as if to justify the annual investment for the winter dressing. Flowers of sulphur play an important part in my preparation for scale, and I am convinced, from continuous observation, that if tree stems were coated with this in conjunction with other ingredients, scale would have a difficulty in eking out an existence. For red spider sulphur is an old and well-tried remedy.

In the pruning and training of Peach trees there seems a general tendency to retain more growth than is necessary for the production of

a full crop. Few gardeners can keep their trees so thinly trained that room for summer shoots is assured without any suspicion of

us hope they have not erred this time. At present the Muscat of Alexandria is the only really good late white

Grape, and this has several drawbacks. It is not easily or cheaply grown, more failing than succeeding with it. Premature shrivelling of the berries takes place in many vineries every season. Keeping well on the Vines or in a darkened room, it yet travels badly, one journey to the dining-room or a few hours' exposure in a shop window leading to discoloration of the berries. So much is this the case, that the majority of fruit salesmen and leading fruiterers usually advise growers with whom they are "in touch" to hold back their Muscats and supply them as orders are received. Those who can grow Muscat of Alexandria to perfection may rest assured that it is their own fault if high prices, or say 2s. 6d. to 4s. per lb., are not realised for the bulk. If, therefore, the latest novelty should prove a fairly good, easily grown, and a good keeping (after travelling long or short distances) substitute for the Muscat of Alexandria, market growers at any rate will fully appreciate the boon. If discarded by the fruit committee it would most probably have never had a good chance to come to the front. True enough, other white Grapes, several

that it is one of the best late black Grapes in cultivation. Lady Downe's is its only rival, and that stands but a poor chance against it till after mid-winter. "But what of the Ivy-like flavour noticeable in the berries of Gros Colman?" some of my readers will ask. My reply is to the effect that this wholly disappears after the Grapes are perfectly ripe. Without being actually richly flavoured, Gros Colman of which many tons are annually sent to Covent Garden alone—is when well ripened firm, luscious and agreeably flavoured, or just what meets the popular taste. The berries are not mere bags of sugar and water, as in the case of Alicante, nor so poor in flavour as Appley Towers and Alnwick Seedling, and for invalids they are fully equal to West's St. Peter's, not elojing the palate. In the case of well-ripened Gros Colman berries the skin breaks up and dissolves with the flesh, which I also consider a good quality.

Private gardeners will do well to pay little or no heed to any disparaging remarks that may be passed upon Gros Colman. If my experience is any criterion, no other Grape meets with greater approval at the dining-table, always provided it is presented in good form. It is very certain no other late variety is more easily grown or better repays for what trouble may be taken with it. If my advice is taken Alicante, Alnwick Seedling, the uncertain though richly flavoured, Mrs. Pince's Black Muscat, Gros Maroc, White Nice, Trebbiano and Golden Queen will be gradually weeded out, and also Gros Guillaume, Mrs. Pearson Lady Hutt, and any other late variety that fail:

House of Grape Lady Downe's.

crowding, and yet there is no need for this, for in selecting the fruits, the greater difficulty is usually found in reducing their numbers sufficiently for obtaining full size and quality in individual fruits. It must be said, however, that in spite of this there is no lack of good Peaches and Nectarines when the roots and borders are well attended to and red spider is rigorously suppressed by the daily syringing in summer. Except to old and exhausted trees, animal manures are best used only as a mulching, artificial preparations being much more preferable, and of these there is now an abundant choice. Liquid manure is very helpful to old trees when carrying heavy crops, as this reaches every root. Young trees planted in fresh soil should have clear water only. W. S.

Wills.

#### WINTER GRAPES.

Much that "A. D." has to say about different varieties of Grapes on page 396 is no doubt correct, and it certainly is to the point. I am not concerned to defend the action of the fruit committee of the Royal Horticultural Society. In all probability the majority of the members of the committee are anxious that a good white late-keeping Grape should be found, and welcomed the latest candidate for distinction accordingly. Their action partakes more or less of the character of a leap in the dark, but let

of which "A. D." mentions, have been brought forward and distributed with a flourish of trumpets, only to disappoint. The nearest approach to a rival to the Muscat of Alexandria I have yet tried is Golden Queen. As easily grown as the Black Alicante, this variety has only one fault—the muddy appearance of the berries when ripe—and that simply places it "out of the running."

Without condemning the idea that a trial of new Grapes should be held at Chiswick, I would yet point out that even that would not afford conclusive proof of the merits or demerits of the varieties tried. Soils, houses, and positions all have a marked effect upon different varieties, and what might be deemed a failure at Chiswick would probably enough under different circumstances be considered a success. For instance, "A. D." says Gros Colman is a tolerated Grape because of the size of its berries and the weight per rod it produces to the market grower. On the score of flavour it ranks amongst the lowest." In his estimation it may do, but I hold exactly the opposite views, and am prepared to prove

Grape Muscat of Alexandria.

to come up to expectations, their places being assigned to Gros Colman and the longer-keeping, invaluable Lady Downe's. A rich border is not required for either of these two varieties. Mine is on the poor side, and they have done remarkably well in it up till now. It can be

ade richer when the Vines show signs of requiring more assistance in the way of manure. Muscat of Alexandria may share a house or buses with these two black varieties, and if all be started early or not later than the first week in March—a fortnight earlier from choice—all will be well advanced in colouring in August. Where so many err is in retarding instead of rewarding their late Grapes, and also in being sparing of fire-heat during dull weather in June, July, and August. My Gros Colman not uneventfully commences colouring late in July, and this I hold to be a distinct advantage. It is abundance of warm air that grapes require to bring them to perfection, and this they can have when the ripening takes place, principally before September. Muscats succeed remarkably well under this treatment, but if these are studied most, receiving much fire-heat and fresh air in comparatively small quantities, then the Gros Colman berries will never colour beyond a “foxy d.”

Late ripening not only militates against the quality of any variety of Grape, but it is also prejudicial to long keeping. I have had bunches of Lady Downe's fresh and plump in June, Gros Colman in a presentable condition in March, Alicante and Muscats to much about the same time, all cut from Vines that had commenced growth early in March. They might possibly have kept longer, but only Lady Downe's had an opportunity of hanging in the fruit room late by way of experiment. Plenty of time should be allowed for colouring and abundance of air admitted while it is going on. This may mean a slight falling off in the size of berries, but if some of the writers who have recently expressed their views on Grapes are to be believed, great size of berry is not particularly desirable in Grapes. I was under the impression size of berry was a point seldom overlooked on the dining-table, in the exhibition hut, or in the open market.

W. IGGULDEN.

**Pear Josephine de Malines.**—This, one of the most delicious Pears, keeps for any length of time, is a very sure cropper, and not at all stitious as to soil or situation. I find it makes splendid bush tree, and carries a good even crop of serviceable-sized fruit almost every year. I have never yet been able to keep it so late as it is set down in fruit catalogues, where it is usually classed with the very late sorts. With me it is usually at its best about Christmas. Possibly a well-drained warm soil may have something to do with its early maturity, as many other kinds classed as late are ripe long before their usually accepted date. For instance, Easter Beurré is with me a Christmas rather than an Easter sort.—J. G., *Esport.*

**The advantage of netting fruit trees.**—The sale by auction of the Grapes on the famous *Veille du Roi* (King's trellis) in the garden of the Château de Fontainebleau has this year produced the sum of 3583 francs (£143 6s.), far exceeding the return of last year, which amounted to 870 francs (£34 16s. 8d.). The 30,000 bunches of Grapes gathered this year were put up in 137 casks, each weighing from 55 lbs. to 66 lbs. This result was more or less owing to the special attention which the new head gardener, M. Guthier, had bestowed on the trellis this year in protecting the fruit from wasps and sparrows by means of a netting particularly adapted for that purpose.—*Revue Horticole.*

**Peach Tardive du Mont d'Or.**—On November 9 of last year I received from M. Franque Morel, nurseryman, of Lyons, a splendid peach under the name of Tardive du Mont d'Or. Mont d'Or is the name of a group of hills situated on the right bank of the Saône about six miles from Lyons, and the name of the Peach in

question has nothing to do with Mont Dore, in Auvergne. M. Morel's Peach was appreciably later in ripening than the Salway or even the Belle de Saint Geslin Peach and its white-skinned variety. The quality of the fruit is in keeping with its fine appearance. Very often at this time of the year, when the sun's heat has declined, fruit is deficient in sugar and the juice is somewhat insipid, but I am glad to say that the Tardive du Mont d'Or Peach preserved its high flavour and true Peach aroma. The tree is vigorous-growing, with erect spreading branches and large leaves. The fruit is large or very large, of a depressed-globular shape, over 3 inches in height and nearly 4 inches in width, deep red on the side exposed to the sun, and yellow tinged with red on the shaded side. The flesh is creamy-white streaked with pink at the centre, very juicy, sugary, and perfumed. It ripens in the beginning of November, sometimes as late as November 15. This variety, which was raised at St. Didier au Mont d'Or, will fully deserve the reputation which it is sure to obtain when it is better known in collections and walls are furnished with its fine-flavoured late-ripening fruit.—Ed. ANDRÉ, in *Revue Hortico.*

#### FIG CULTURE.

Figs are in greater demand now than used to be the case some twenty or more years ago. In many establishments at that time the only attempt made in cultivating the Fig tree was outdoors against walls. In some instances, or in favoured parts of the country, this outdoor culture still obtains and yields good returns. In less favoured districts the crop is such a precarious one that Fig culture hardly pays for the time and labour involved. In places where the Fig is greatly appreciated, this latter cause has been one of the prime factors in its being grown so much more extensively under glass. Figs have, of course, been grown under glass for a long time past, but for every house which existed at the time quoted above, the number has now increased tenfold. The reason for this is not far to seek. In addition to the Fig making variety in the dessert at any time when in season—which fact alone creates a great demand—it is now more largely partaken of than used to be the case, especially by people who have lived abroad. Its wholesomeness as an article of diet is a well recognised fact, and in addition to its being served at dinner, it often has to appear on the breakfast table as well.

Although much more grown than formerly there are still some very erroneous ideas as to the correct method of cultivating the Fig. Some people run away with the idea that the Fig cannot be grown unless subjected to great heat, and that it requires a deep, rich border to root in. To all who put these queries to me, and they are many in the course of the year, my answer is always to this effect. Give Figs a poor soil to grow in, confine the roots either to narrow borders or in brick pits, and with regard to the application of heat, this depends entirely on the time that the fruits are required to be ripe, as no heat is needed at all if they are not wanted until the end of the summer or in the autumn. Heat is, as is well known, an essential if the trees are to be forced, but when the produce is not required until the middle of July and from then onwards, Figs can be grown without its aid. With the assistance of heat, two crops of fruit can be secured from the same trees in one year; without it, one only, but that a very heavy and excellent one. It is a well-known fact that the best results are obtained from pot trees if very early fruits are wanted. These trees should be well established, and if they are pot bound so much the better, as they are not so liable to cast their fruits when subjected to

heat. Very often two crops are taken from these pot trees before they are turned outdoors to rest, to prepare them for the ordeal of forcing the following winter. Suitable varieties for this purpose are White Marseilles, Brown Turkey, Osborn's Prolific, St. John's, and Black Ischia. To succeed there it is usual to start a house of planted-out trees either in January or February, and in not a few instances where accommodation cannot be found for pot trees, this is really the first house. In this case the number of varieties is but limited, very often consisting of only one, and that the Brown Turkey. All the same, these trees under skilful management give excellent returns in the shape of good crops of fruit in the spring months, which are always greatly appreciated, particularly during the London season. The time for starting in both the above-mentioned cases of course depends upon the time the fruits are required, but as a rule it is generally about the middle of November or beginning of December. Where forest-tree leaves are plentiful they play an important part in Fig forcing, as when mixed with a little manure they give off a genial warmth and obviate the necessity of employing much fire-heat in the initial stages of forcing. If the one house is started to succeed the other as indicated, these two houses of trees will keep up the supply until midsummer. By the time the last of the fruits on the pot trees are gathered, those on the permanent trees in the second house will be fast approaching maturity, if not actually ripe. In any case there would be but a few days' break in the supply. If the second crop is to be taken the houses are closed so soon as the last fruits of the first crop are gathered. They are then subjected to a high, moist temperature and are abundantly syringed. Under these conditions the fruits swell rapidly, and although not so fine in point of size, they are always very luscious when ripe, and much sought after. If not necessary to have the fruit ripe so early in the year, the starting of the pot trees may be deferred until the beginning of January. The next house need not then be closed before the first week in February, and if there is another house which can be started about the middle of March, there will be a constant succession of fruit right through the season, as two crops of fruit can be taken in all three cases. Very little heat would be required for the third house, and as soon as June is reached it could be dispensed with altogether. The fact of closing early with plenty of solar heat would prevent the temperature from falling too low at night. The fruits would ripen on the trees in this third house about July or the beginning of August, according to locality and aspect, and the second crop about the end of September or second week in October. With careful ventilation and by insisting on the atmosphere being kept dry, this latter crop will ripen gradually and prove invaluable at that season. If the house is but a cold one, only one crop of fruit could be expected, but this would be a very heavy one, and with care the supply would last for several weeks.

#### COLD HOUSES

should never be closed until the last minute, as it were, as it is usual to have the fruits mature in these as late in the season as possible. When the point buds begin to break is quite soon enough, and even then there should not be the slightest semblance of forcing. The house should be freely aired during the early part of the day, but may be closed about 4 p.m., when the trees may be given a refresher in the shape of a syringing. The ventilators should be opened again at 6 p.m., if not widely, sufficiently to allow of a free circulation of air throughout the

night, and by adhering to this course of treatment magnificent fruits may be grown at little trouble and expense. On wet days and chilly evenings or nights the ventilators are best closed, but beyond this afford the trees all the air possible. For cool house culture nothing will equal Brown Turkey and Negro Largo as far as varieties are concerned, and if the roots are kept restricted, they can be depended on to give excellent results. In some instances the late crop is obtained entirely from pot trees which are grown as cool as possible right through the season. To anyone having a large house or the space at command, this would afford an excellent opportunity for growing and testing the different varieties of the Fig. In addition to the varieties already quoted, the latter may be added for this purpose: *Violette Sepor*, *Singleton*, *Brunswick*, *Bourjassotte Grise*, and *Grosse Verte*. Anyone requiring a more extended list than this could not do better than visit the Royal Horticultural Gardens at Chiswick and inspect the fine collection grown there. This collection is a most complete one, and all varieties worthy of cultivation are included in it.

A. W.

**Apple Reinette du Canada.**—I noticed some very fine examples of this variety recently at Livermere Park, these having the characteristic cone shape and russet appearance on the sunny side that stamp it as so distinct from most other large Apples. It is not, perhaps, quite in season yet, but the fruit keeps at least four months into the new year, when its value for cooking is great. It is fit for use perhaps as long as any known kind, and bears well under any form of training. A warm position suits it best, as unless the fruit is well ripened before being gathered it is apt to shrivel.—R.

**Apple Lane's Prince Albert.**—This is one of the very best cooking Apples, and appears to have given a good account of itself everywhere during this season of scarcity. So free-bearing is it in most places, that somewhat heavy thinning has to be resorted to. The tree is not a very vigorous grower in many places, and it is one of the few kinds I have seen doing well under the espalier system. Free, open bushes or standards give better results, and such require practically no pruning. Not only is it an excellent cooking fruit, but if kept until the new year there are many dessert kinds that do not equal it for this purpose, the flesh being melting, juicy, and of a brisk and pleasant flavour.—H.

**Strawberry Royal Sovereign.**—I have not seen any reference in the many reports of Strawberries that have appeared of late to the hardness or otherwise of this popular variety, but I could not help being struck with the damaged foliage after the spring frosts of the present year. From the same cause most of the flowers of this variety were destroyed, as were others open at the same time, but I noticed, particularly in my neighbours' gardens as well as my own, that Royal Sovereign was not so hardy as some others, neither in yearling nor older plants. Latest of All, on the other hand, escaped unhurt both in foliage and flower, and gave much the best crop of the year.—W. S., *Wills*.

**Highly-coloured Apples.**—"Visitor" (page 396) expresses surprise at the high colour of dessert Apples at Livermere, and suggests that as the soil is light and porous it is not the best for Apples. From my own observations, it is in light sandy or gravelly soils that the most highly-coloured fruits are produced, although there are exceptions in this as in everything else connected with gardening. A great deal depends on the treatment of the trees and their roots. Some wonderfully fine-coloured fruits have been shown this autumn, both Apples and Pears. At the late Bristol Chrysanthemum show the classes for Apples were keenly contested, as many as a dozen

staging collections of six and four dishes. One particularly good Apple I noticed at Bristol was Hubbard's Pearmain, a variety I had not previously seen shown. There were also very finely-coloured Ribston, Blenheim, Cox's Orange, and other standard sorts.—W. S.

#### PRUNING AND NAILING FRUIT TREES.

WITH the beautiful weather we have been experiencing of late, it has been possible to make good headway with this work, for though mild, it has been dry both to the feet and overhead. Many gardeners commence to prune and nail trees on south and east walls, leaving those on the north walls till last. This, in my opinion, is a mistake, for those trees on warm aspects that are nailed and pruned early com-

bright sunshine in early spring after a frosty night or a sharp frost follows a bright day, the sap, being active, gets frozen and causes a check. This, no doubt, is in great measure the cause of Apricots growing against south walls doing so badly in the southern counties. If these were left unnailed till late in the season they would doubtless considerably retard in their growth. I commence on the Morello Cherries, and follow with all the trees on north walls. Those western aspects are next done, then those to the east, leaving the south walls till last. Morello Cherries have been taken in hand during the late mild weather the work will have been done with more comfort and in much less time than when deferred till cold, fro weather sets in. The walls, too, can

Grape Gros Colman. (See p. 448.)

mence to grow too soon, while those on the north are retarded. To show that this is so, you have only to hang a thermometer against them to determine this. Last Friday (November 19) the sun shone bright in this district, so much so that it was uncomfortably warm standing against a south wall. I fetched a thermometer and hung it against the wall. To my great astonishment the heat registered was 96°; at the same time one in the shade registered only 52°. It will be seen from this that the walls get warm, and as the heat is absorbed they will retain it for some time, giving it off later in the day when the sun has declined. Here, then, is the cause of so much mischief from early nailing on these walls. We often experience these bursts of

cleansed more effectually than when they are frozen. One of the great secrets in the successful cultivation of this fruit is to rid the trees of all insect pests during the winter, and this can readily be done as soon as the leaves have fallen. It should be the practice to unnailed and liberate all growths every second year. Half be done each autumn the task will not be so great as when all are left to be done at once. When liberated the walls should be washed with strong soft-soap water to which a little sulphur has been added. New shreds should be used which should be cut as narrow as possible. Stout branches should be fastened to the wall with pieces of golden willows, as these are much neater than shreds, and not so liable to cut in

wood as tarred twine. It is not well to over-crowd the shoots, as the trees would not be able to support all the fruit that is set. Where trees are not liberated the walls should be thoroughly syringed with soft-soap water after the work is completed. Plums on north walls should receive attention, the wood being washed and made clean. All dead spurs should be removed and others cut back to two or three eyes. Where trees receive due attention during the summer months, and the ground is light there will not be over-much growth to remove, but if neglected and the soil is stiff, strong growths will have been made which are by no means the most useful. Having completed the Plums, attention should next be directed to Peas. Trees should be freed from scale and other pests, every shoot being examined to make sure that the shreds or ties are not defective for when the fruit is approaching maturity this is very annoying to find that some of the branches are broken down by its weight. By the time such trees are nailed the winter will be being advanced, so that it will be safe to prune and nail Cherries on the various aspects. These may be followed by the Apricots, and finally Peaches may be taken in hand. The advantages of leaving these till the last are manifold. Not amongst the least is the retarding of the blooming period by keeping them from the warm walls as previously noticed. Pruning then forms an important part in the successful cultivation of fruit, in the south at least, and those who make close observations of fruit and seasons will be able to note the difference between the growth of trees that are pruned early and those that are left loose till late in the season. H. C. P.

BOOKS.

THE WATER GARDEN.\*

The very words of the very interesting theme of this book suggest that people are waking up to better ideas than the old ones of the pattern garden and its stereotyped monotony. Mr. Tricker's book is devoted to the cultivation of the more beautiful kinds of aquatic plants, the warm sun of America enabling growers not only to have the hardy kinds in perfection, but also to grow in the cool air with a little extra care many Water Lilies which in our country and Europe generally are commonly seen only in hot-pots. Mr. Tricker's book deals with soils, planting, hybridisation, propagation, destruction of plants by insects, heat, plants out of doors, &c., and describes the kinds also and the plants that go best with aquatic flowers, such as Papyrus, Grasses, Ferns, and also perennial and ever hardy shrubs. His work is very well done, and the book generally is attractive, although we rather object to process cuts with coal-black backgrounds, often showing the distant parts stronger than the foregrounds. The clayed paper and the binding are not quite worthy of the subject; but on the whole we feel grateful to Mr. Tricker for his work. A great advantage of the American climate is the power of growing the beautiful Lotus, or Sacred Bean, not possible in the open air in our country. So far as we have tried even the supposed hardy varieties, it is a total failure from the want of heat. The cut of this is a very bad example of process work. There is an interesting feature in the varieties of Vic-

toria Lily, of which there are two pictures, disfigured, however, by the blackness of the backgrounds, which surely cannot be necessary even in a process cut. The instructions for making artificial ponds are full and useful, though of course all these things are subsidiary to taking advantage of the natural water which occurs in so many parts of our country, and almost all northern countries, in the shape of backwaters of streams, lakelets, and ponds. A very pretty and well-figured Water Lily is gracilis, although unhappily tender.

A descriptive list of Water Lilies, with cultural memoranda extracted from Mr. Tricker's book, will be found on page 444 of this issue.

KITCHEN GARDEN.

YELLOW TOMATOES.

YELLOW-FRUITED Tomatoes are certainly unpopular. Why this should be the case is difficult to determine. I can quite understand why they were so little cared for in former years, or when the old Large Yellow was the only variety of its colour generally available, but during the past twelve years a great improvement has been effected among yellow as well as red-fruited varieties, and the best of the yellows equal in point of flavour those of any other colour. Some people maintain that certain yellow-fruited Tomatoes are more delicately flavoured than the red ones, and readily admit them as dessert fruit. "Give a dog a bad name and hang him" is, however, an old truism that may safely be applied to yellow Tomatoes. I blame the coarse, soft, flavourless Large Yellow for all the distrust with which yellow Tomatoes are still regarded by the general public. As far as market growers are concerned, they must still stick to bright red Tomatoes. Foreign fruit has quite spoiled the mass of people who regard Tomatoes as an important part of their diet during about five months in the year for pink or cornelian-red Tomatoes, and as a consequence they are not grown other than in private gardens. All the same, two of the best flavoured and otherwise good pink sorts, when gathered from plants growing against garden walls, are Dedham Favourite and the large-fruited Mikado. Not one purchaser in a hundred has had an opportunity of tasting a good yellow Tomato. Amateurs who grow Tomatoes for home consumption and many private gardeners ought to be able to say a good word for yellow fruit. If yellow Tomatoes are ever popular, it will be owing to their exertions. The revolution will not be brought about by growers for sale, simply because their own private opinions have always to be subordinated to the public taste, against which they cannot afford to run.

During the present year I gave most of the best yellow Tomatoes a fair trial with a view to being able to express an impartial opinion of their merits, and if possible to popularise them in this part of the country at any rate. The plants were raised in March and got into their fruiting quarters in a heated lean-to house before they became stunted in growth. They were placed in 11-inch pots arranged each side of the house on a border, and allowed to root out into the latter. A distance of 15 inches apart was allowed each plant, and all were confined to single stems, these being trained straight up the roof, meeting at the ridge. By this it will be seen that a perfectly fair trial was conducted (twenty plants of each variety were grown), the conditions generally being favourable to the production of a heavy crop of fruits

Some varieties were disappointing and will not be grown again, unless it can be proved by other growers that I have arrived at a wrong conclusion as to their merits. In Sutton's Prince of Wales we have an ideal dessert Tomato. It is of a free yet woody disease-resisting growth, and produces a heavy crop of comparatively small, smooth, round fruit, rich orange-yellow in colour, and of a brisk yet delicate flavour that found favour with all lovers of Tomatoes I gave fruit to. Plants of this variety covering the roof and closely cropped with clusters of ripe and ripening fruit are most ornamental and attractive and worth growing on that account alone. Golden Perfection is the other variety singled out for special mention. Golden Sunrise, which I received from America before it was offered in this country, I regard as nearly or quite identical with Golden Perfection, and it succeeded admirably with me both under glass and in the open. This type of Tomato may be briefly described as a yellow form of Perfection. It is of the same robust habit of growth, good crops set, especially if fertilisation is resorted to daily while the flowering period lasts, and if the precaution is taken to early remove the large malformed flower that shows on each strong bunch of bloom, the rest of the blooms will be followed by moderately large, handsome fruit that would be very hard to beat if competing in any class for yellow Tomatoes. It is not on account of its handsome appearance alone that I recommend Golden Perfection, but the quality is also first-rate, rivalling, if not surpassing, that of the best-ripened fruit of Red Perfection. For flavour, Carter's Green Gage is yet hard to surpass, but the fruit does not set freely, and in other respects I prefer the Prince of Wales. Two named Golden Queen were grown, one producing medium-sized, smooth round fruit rich yellow in colour, the flesh firm and of moderately good quality, and the other gave both corrugated and nearly smooth round fruit, pale yellow in colour, flesh soft and wanting in acidity. Neither form cropped satisfactorily, and I cannot recommend them. Blenheim Orange, a variety that has done well in previous trials both under glass and in the open, was not a success this time; the crops were too light. Selected fruits, rich yellow with a tinge of pink colour where most exposed, form a very handsome dish, and not much fault can be found with the quality. I wish the latter remark could be applied to Sutton's Sunbeam. This novelty set heavy crops of fruit each about the size and form of a Victoria Plum. The colour is a clear pale yellow and the fruit attractive in appearance, but with me the quality was most disappointing. What it would be like if the fruit were ripened in the open air I am unable to say. Under glass it was bad. Nor does my opinion of the merits of Golden Nugget agree with that expressed in various other quarters. In spite of the certificate of the fruit committee of the Royal Horticultural Society and the favourable comments in the horticultural press, I maintain that Golden Nugget is a greatly over-rated variety. No fault can be found with its habit of growth or cropping, and the numerous racemes of small, richly coloured fruit are most ornamental, but the quality with me was of the poorest. Very few that I gave fruit to cared for a second helping. My treatment may be at fault, but Golden Nugget was arranged next to Prince of Wales, the variety that did so well with me.

So much for the trial of yellow Tomatoes. I question the wisdom of certificating a novelty

\* "The Water Garden." By Wm. Tricker. (D. Appleton and Company, Limited, New York.)

shown at the Temple show and earlier. Very solid fruit, as in the case of Golden Sunbeam, I object to, nor do I care for any "with few seeds," as that, instead of being a recommendation, goes to prove that a maximum of core is most undesirable. Seeds may be thought objectionable, but it is the pulp surrounding the seeds and not the solid core that gives character to the fruit. Soft, flabby fruits, however, are not wanted, as these travel and keep badly.

W. IGGULDEN.

**Onions.**—I am sure many will agree with "A. D." (p. 406) that we should grow sufficient Onions for our own needs without importing them from the Continent. When visiting recently a popular watering-place in the south I noticed no less than four foreigners with these roots, taking the town in sections in a leisurely manner. I at once ascertained the price of Onions in shops and found them just three times as much as one would expect, thus giving every encouragement to the foreigner. On the other hand, growers do not get much encouragement, as last spring, after storing till March, the price obtained for large quantities was very poor. I do not think it is a matter of cultivation, but rather distribution, as when huge quantities are consigned to the salesman, producers are at his mercy. I admit Onions sell well, or better, after a severe winter when vegetables are scarce. I know last spring many never were sent to market owing to the carriage being great and the returns so poor.—GROWER.

**White Jerusalem Artichoke.**—I am sorry to see (p. 406) Mr. Tallack notes the prevalence of disease among the white Artichokes. This is to be regretted, as the white is so much more shapely than the older kind and of better quality. I have this year grown a goodly number of the white variety, and found no disease of any kind. Owing to drought the tubers are not so large as one could wish, but quite large enough, as with the white variety there is less waste in preparation. It will be interesting to know if others have suffered like Mr. Tallack. Mr. Tallack does not mention what variety he grew. I know three distinct white kinds, and they differ greatly in quality, in appearance also. One, an elongated root, is a grand vegetable. Last season I had roots each 9 inches to 12 inches in length, and they are only a little less this year. I prefer the shorter ones, as these are best for table. This variety I had from the Continent, and like it very much, as it is very smooth and even.—G. WYTHES.

**Tomatoes and fog in winter.**—Few plants suffer sooner than Tomatoes during foggy weather, and in the metropolitan area we have this year had fogs earlier than usual, and, unfortunately, of longer duration. Many would think a little extra heat would counteract the fog. Not so; it only makes matters worse. I find it best to keep the plants as cool as possible, and by so doing lose less bloom. With heat the foliage suffers so much, that the fruits at times will drop also and the crop is lost. Young plants that were in bloom and have lost the crop owing to the fog will, with a little coaxing, next February give a good return and set freely, so that there is a great gain in growing winter Tomatoes, as no matter how much attention may be given seedlings raised at the end of the year, they are rarely strong enough to fruit till April is well advanced, often much later. For some years I have gone into the question of winter fruiting, and in the end the gains balance the losses, as the plants, though crippled now, soon recover as soon as the days begin to lengthen. I find the best fruiterers are plants grown in not too large pots. I have also found seedlings stand the dark weather much better than plants raised from cuttings, which I find soon succumb. In more favoured localities much better plants may be grown and fog will not be felt. I am sure the plants soon repay the cultivator when they can be kept healthy all the winter, as Tomatoes early in the spring command

a good price, and they continue to fruit if not too crowded or neglected in any way.—G. WYTHES.

**Beetroot in winter.**—These roots, often lifted early in October and stored in dry soil, grow out badly early in the new year and lose quality. I am aware the advice is frequently given to store the roots early to prevent frost doing damage, but from close observation I find worse results follow from early lifting than from frost. I admit very severe frost, such as we experienced three winters ago, would spoil the roots if they were large and exposed above the soil, but not if they were covered with earth. Late-sown roots are not so likely to be far out of the soil as those sown early. Even when sown late in rich soil some kinds come coarse, and it is well to avoid sowing in such land if the roots are required for keeping. Few roots are so unpalatable as coarse Beet, and for winter and spring supplies I have found May or even June sowings the best, as then there is no difficulty in keeping the roots till May if they are kept cool and frequently moved to prevent growing. They may with advantage be placed under trees or a north wall if the store is warm in gardens where the soil makes storing a necessity. Beet is not so tender as many think. For years, having a special variety, I left a few roots in the open for seed and they wintered well, the only protection being earth drawn well over the crowns. This led me to adopt the same plan with roots for use. There was never any difficulty about colour or quality when cooked, as wintered thus they did grandly. I have often stored Beet in the same way as Potatoes, in a clamp, and the roots were not given extra cover in severe weather, and so far turned out well.—G. W.

#### AMERICAN NOTES.

[From *Garden and Forest*.]

**THUJA Plicata.**—The plants commonly cultivated under the name of *Thuja plicata* are garden forms of our eastern *Arbor-vitæ*, and must not be confounded with the *Thuja plicata* of Don, which is more frequently known as *Thuja gigantea*, although Dr. Masters has recently clearly shown that *Thuja plicata* is the older name. This is the *Arbor-vitæ* of North-western America, the Red Cedar of Oregon and Washington, the greatest of all the *Thujas*, and a veritable giant among conifers. Near the shores of Puget Sound it is a common occurrence to see this tree 200 feet high with a massive trunk gradually tapering from a base 15 feet or 16 feet in diameter. As it grows in its native forests it is one of the most beautiful and graceful of the American conifers, with bright cinnamon-red bark and a narrow spire of branches, which sweep out gracefully from the stem, and are clothed with great Fern-like, pendulous, yellow-green branchlets. Nowhere forming pure forests, the western *Arbor-vitæ* grows singly or in small groves generally on low, moist bottom-lands or near the banks of streams, and less commonly on dry ridges and mountain slopes, which it sometimes ascends in the interior to considerable elevations, although it is only at the sea-level and under the immediate influence of the ocean that it grows to its greatest perfection. Ranging along the coast from Southern Alaska to Northern California, it penetrates also eastward along the banks of mountain streams through Southern British Columbia and Washington to the western slopes of the northern Rocky Mountains, and is abundant on the Bitter Root and Cœur d'Alene ranges and in the territory north of Flat Head Lake. Plants obtained several years ago from this interior and comparatively dry region have proved hardy in the Arnold Arboretum and in Mr. Hunnewell's pinetum, where they are now growing rapidly, and promise to become large and handsome trees.

**THUJOPSIS** chiefly differs from *Thuja*, which some authors unite it, while others sider it a *Cupressus*, in its ligneous cones much thickened and dilated at the apex, bearing five seeds. The only species, *Thuja dolabrata*, which is one of the most beautiful conifers of Japan, is easily recognised by broad coriaceous leaves, which are bright green above and silvery white below, and arranged in four ranks in opposite pairs, those on the upper and under side of the branchlets being closely appressed against the stem, while the lower leaves are more or less spreading. In Central Hondo this tree is common between 5000 and 6000 feet above the sea-level, growing as an under-shrub in the dense shade of Hemlock forests, and every year buried in snow for four or five months. Sometimes it rises, however, when its crown reaches the light, to a height of 40 feet or 50 feet, with a slender trunk covered with bright red bark, long, gracefully drooping branches and a narrow pyramidal form. It evidently requires shade and protection at least while young, and in its native forests the largest plants are surrounded and overtopped by taller trees.

**WISTARIA MULTIFLORA.**—This differs from ordinary *Wistaria chinensis* in its narrow leaflets, much longer and looser racemes of fragrant flowers and in their lateness, as flowers of this plant open two or three weeks later than those of *Wistaria chinensis*. In autumn the two species can be readily distinguished, as the leaves of *Wistaria multiflora* turn clear yellow comparatively early, while those of *Wistaria chinensis* remain green late that they are almost invariably destroyed by frost before changing colour. *Wistaria chinensis* is a common Japanese forest plant and is also a native of China. *Wistaria multiflora* does not appear to be indigenous in Japan, judging from the fact that it is a hardier than *Wistaria chinensis*, it probably came originally from Northern China. Whatever the right name for this handsome plant may be, it is evidently in every way distinct from the common Japanese *Wistaria* the plant universally cultivated in this country and Europe as *Wistaria chinensis*.

**PRUNUS SUBHIRTELLA** is a Japanese *Chamaecyparis* which promises to become a valuable ornamental plant in our northern gardens. Like *Prunus pendula*, which it resembles also in the structure and size of the flowers, it blooms before the appearance of the leaves. In the Arnold Arboretum, where *Prunus subhirtella* proved hardy and flowered abundantly for last two or three years, it is now a broad bush with slender, erect branches and dark green leaves from 2 inches to 3 inches in length. About the first of November these turn a rich purple-red, making this plant a beautiful object at this season of the year. Altogether *Prunus subhirtella* is one of the hardiest and most promising of the small trees recently introduced into our gardens.

**PYRUS NIGRA** and **PYRUS ARBUTIFOLIA** both good garden shrubs. At this season of the year, when the former has already shed its leaves, and its fruit, although still hanging on the branches, is much shrunken, *pyrus arbutifolia* is the more attractive plant. It is a tall, slender bush bearing abundant white flowers, which open about June 1st, and small fruits which do not ripen until the end of October, when they become bright scarlet and remain on the branches without loss of colour or brilliancy until well into the winter. The leaves turn dark red about the time the fruit becomes ripe, and at this season this is one of the most attractive of our native shrubs.

It is not so good as in some others, but, in spite of this drawback, *Pyrus arbutifolia* may well find a place in any garden for the beauty of its autumn colours and the winter effects produced by its fruits.

## NOTES OF THE WEEK.

**Chrysanthemum Western King.**—At the meeting of the Royal Horticultural Society this, now well-known variety, was shown in plenty, the blossoms, though only of medium size, being well proportioned and very pure and compact.

**Grigeron speciosus.**—This is one of the very best perennials in the open that continue to give a few flowers. The growth made by this species this year in good garden soil has been really remarkable, and, as is natural where the growth is abundant, the flowers appear also in great profusion.

**Epacris carminata.**—This is a very brilliant shrub for winter flowering, producing long sprays of blossoms, the latter individually being nearly as long as the flowers of *E. miniata*. The brilliant carmine tinge with its white tip renders the above variety more than usually attractive just now.

**Coprosma Baueriana variegata.**—This pretty shrub is very useful in the cool conservatory or winter garden, where it will readily create a pretty result by reason of its variegated foliage. In these positions very little moisture will be required, the plants quickly shedding their leaves if over-watered.

**Iris alata (Scorpion Iris).**—Mr. Wilson sends us from his garden at Wisley a very fine form of this Iris, which flowered in the open border. The flowers of this variety are of a deep azure blue, and will be found very useful in the cold house. A snug nook in the rock garden would suit it, or it may be grown in shallow pans in a cold frame.

**Choisya ternata.**—This beautiful evergreen is flowering on a wall at the present time, where a fine plant spreads out over many feet, the pure white blossoms appearing now and then among the pleasing foliage. A wall with a south or south-west aspect suits it well, while occasionally it is seen in capital form on a north wall.

**Rhododendron Maiden's Bush.**—By reason of its free-flowering qualities this should constitute a really good companion for *R. Princess Alexandra*, and as both kinds flower at the same time a certain variety is afforded by the varying shades in the two kinds, the one now referred to being of a bush-pink with white.

**Galanthus octobrensis.**—A little cluster of this interesting plant is bearing a few blossoms in the rock garden at Kew, though the tuft appears to gain little either in stature or the number of its leaves at this time. A more vigorous variety would certainly be most welcome at this time, when flowering plants are so very rare in the open garden.

**Impatiens rubro-cerulea.**—This very attractive water-flowering climber is now in bloom in the warm conservatory at Kew adjoining the Victoria house. The blossoms, which are some 3 inches across, are of a lovely deep sky-blue and very striking, while the older flowers assume a reddish tinge at the margin. In its early stages the flower is indeed beautiful.

**Verine Manselli** is certainly one of the most brilliant of these autumn-flowering bulbous plants. The colour, which is a brilliant carmine, is singularly effective with so few plants in flower, and the spikes, sending well out on nearly 2 feet of stem, are especially valuable for cutting. It is surprising how long the buds of flowers remain in good condition in a cool, fully-ventilated house.

**Leleborus orientalis.**—The long-continued spell of mild weather has started this to flower, the spikes being at the end of November more than 6 inches high. The old foliage is in capital form this year, owing possibly to the limited rainfall and the absence of cold nights. In their present stage, however, the flowers would suffer considerably should a heavy fall of snow come upon them.

**Hyacinthus grandiflorus.**—In the open and fully exposed, plants of this species vary considerably in growth and subsequent flowering. Fully a month ago I noted it in full beauty, but this was an instance of an established plant. Last week, however, we observed some plants that had been put out in the

spring of the present year only just opening their flowers—too late to be of much service this season.

**The Strawberry Tree (Arbutus Unedo).**—I am surprised to read in issue of November 27 that this is perfectly hardy. Of course it is in favoured parts of the country, but here, in the Cambridge Botanic Garden, it has been repeatedly killed. This morning (Dec. 1) I have been interested to learn that at Baltham, a few miles from here, at about 350 feet elevation, it is fruiting profusely.—R. J. LYNCH.

**Chrysanthemum Sam Caawell.**—This belongs to a class of flower known as spidery Chrysanthemums, the peculiar fantastic appearance of the blossoms suggesting this description. The florets are fairly long and tapering, being deeply cut at the ends. The partially developed florets, too, have a pretty pointed and wiry look, making a pleasing diversion in form from the more orthodox sorts. Clear rose-pink is a good description of its colour.

**Rhipsalis Cassaytha.**—A very curious species with pale green forked branches nearly 2 feet in length, and occasionally furnished with small, nearly milk-white berries of the size of those of Mistletoe. During summer the above plant flowers somewhat freely on the sides of the secondary shoots, and if a greater number of berries resulted, it would certainly constitute a very interesting plant for autumn decoration. The species belongs to the West Indies.

**Chrysanthemum Mrs. W. Butters.**—This is a pretty little Japanese, and grown freely produces a number of pure white blossoms from lateral growths. In a cut state a spray may contain a dozen blossoms, and as such makes a pretty display in small vases. The form of flower is somewhat unique, the narrow florets being deeply cut at the ends, giving the bloom a fimbriated appearance. The National Chrysanthemum committee commended it as a late sort for cutting.

**Chrysanthemum Mrs. J. R. Tranter.**—A refined Japanese flower, not over large, but sufficiently so to be considered a useful bloom for the exhibition board. As exhibited at the National Chrysanthemum Society's floral committee early buds developed creamy white flowers, faintly suffused and tinted rose, but a bloom from a late bud was freely streaked and edged rosy purple. It grows about 4½ feet high.—C. A. H.

**Chrysanthemum Violaecum.**—This is the latest addition to the Japanese varieties for exhibition, and as shown before the National Chrysanthemum Society's floral committee on Monday last appears to be a promising flower. The bloom is not particularly deep, but of great breadth, and had an immense number of undeveloped florets when seen on this occasion. The colour is best described as pale rosy violet with a cream centre. In height the plant is about 4 feet.—C. A. H.

**Agave dasylyrioides.**—This species, while not differing very materially in the large succulent leaves from others of its genus, possesses in great degree an individuality of its own by reason of its giant inflorescence. This latter, including the scape, is some 8 feet in length, the pale greenish yellow flowers emitting a very peculiar and not pleasing odour. A strange feature of the inflorescence is the manner in which it folds itself into complete rings. The species is now flowering in the large Cactus house at Kew.

**Solidago virgaurea nana.**—This dwarf member of the Golden Rod family is scarcely so well known as it deserves, and being the only kind that could figure in the front row of the border is certainly worth greater care and attention. Not that the plant is in any degree tender or even difficult to grow: far from it, as it is quite a vigorous grower for so dwarf a plant. Good specimens continue a long time in flower, this year especially. Indeed but a few days since it was still carrying many of its golden sprays of blossom.

**Othonna cheirifolia.**—There is a good deal of character about this plant when seen in large spreading patches during winter, whether on rockwork or the level ground. It is, however, always best in the former position, and the silvery-grey tone of its rather succulent leaves is decidedly pleasing when freely planted. There are some people who have doubts concerning its per-

fect hardiness, but there is little need for fear when the plants occupy a slightly raised position and are firmly planted in sandy loam. A sunny slope covered with this plant is very striking.

**Skimmia Formani.**—In your note as to this in last week's GARDEN you speak of the persistence of the berries. Probably this persistence is carried to a greater extent than many of your readers are aware. The first plant of this *Skimmia* which I ever saw was in the conservatory at Melville Castle, and the head gardener explained, on my expressing surprise at the enormous quantity of berries upon the plant, that the berries remained upon it for three years. A careful examination satisfied me that this was correct, and I have since found that, if protected from birds, some of the berries will remain for two years out of doors. The plant is a most beautiful object in a cool house, and should certainly be more frequently seen.—A. KINGSMILL, Harrow Weald.

**Physalis Franchetti.**—This handsome species has been referred to frequently of late, and certainly a plant that so long remains in excellent condition cannot be too well known. The two groups of it in the Kew herbaraceous ground were on November 26 conspicuous at 100 yards distant. On a closer view, the majority of the brilliantly-coloured calyces that so completely furnish the plant appeared little worse than a month ago, though at this time with foliage intact the plants were better furnished than at present. This species, both by its height and freedom of growth, promises to be a great acquisition to our gardens. It is also equally free-fruited, while the large and handsome calyces are at least three times the size of those of the older kind.

**Lapageria alba.**—This well-known climber is not usually seen flowering abundantly at this late date, yet it is even more precious now that such things are scarce than during the summer months when flowers are more plentiful. Quite recently, however, we were struck with the beauty and purity as well as freedom of a large plant occupying what may appear at first sight a not very favourable position. The plant had been put out in a prepared bed of soil beneath the stage in the greenhouse, the growths being drawn through the woodwork of the stage when long enough. In this position, trained to a glass partition between two greenhouses, the plant has prospered, and some fine vigorous shoots made during the present season were flowering abundantly, the long racemes of wax-like flowers very pure and beautiful. Judging by the vigour and freedom of flowering in these young growths, it is not improbable that the flowering of this plant may be enhanced if a judicious thinning out of small shoots were adopted, removing these at the base.

**Hellebores from seed.**—As a rule the seeds of the Christmas Rose are somewhat slow to vegetate, though an instance to the contrary came under notice a few days since. In the spring of the present year a gathering of seeds was taken from some good-sized clumps that had furnished many flowers during the preceding winter. For two or three years past a similar gathering has been made, and the seed which was sown in boxes never vegetated. This year, however, instead of sowing as usual in boxes, the seed was sown at once haphazard in the open, the spot selected being at the base of a thick broad hedge of Privet, which was naturally dust-dry for weeks together. In a few weeks some 200 or 300 seedlings appeared, notwithstanding the surface was very uneven and had several times been subjected to a rather rough watering. At the present time these seedlings are large enough to transplant and are but little over six months old. This is the most successful attempt I have seen, as the seeds frequently remain dormant a whole year after sowing.—E. J.

**Boeckonia cordata carnea.**—This new variety of *Boeckonia cordata* is mentioned by Mr. E. Burrell in his interesting and valued "Flower Garden Notes" on pp. 400-1. As Mr. Burrell says he has not seen it, I may perhaps be allowed to re-

mark that I fear it scarcely bears out the description of the catalogues. I grew it here during the past season, and have been disappointed with the colouring. It is, perhaps, hardly fair to judge a plant by its first year's behaviour and appearance, but I must say that I do not think that this variety will become popular either with the general public or, what is even of more consequence, with the more informed class of growers of hardy flowers. The colouring is not distinct enough and looks dull and ineffectual. It is not deeply-coloured, as Mr. Burrell appears to have been informed, and I can hardly think it suitable for contrasting with lighter things. These remarks are to be taken as subject to modification from further experience, and have been formed with some regret, as a distinct variety of the handsome Plume Poppy would be a decided acquisition.—S. ARNOTT.

**Convolvulus Cneorum.**—Quite recently reference was made to this beautiful species in THE GARDEN, suggesting that it was worthy more general cultivation. This is certainly true, for we have few plants more beautiful and interesting. Even for its silky leafage the plant is worth growing. The above *Convolvulus*, however, is not sufficiently hardy in all gardens to be worth the risk of growing in the open air. In favoured localities, such as the Isle of Wight and parts of Devon, the plant would not only prove quite easy of culture, but a complete success. In many gardens where ranges of glasshouses exist this would constitute a capital plant for training to the wall on a south aspect, preferably against an Orchid house. In such a position, given a light, warm soil, the plant will usually grow and flower freely. Planted against a warm wall at Kew there is a fine example of this species that has flowered abundantly during the past summer, and even now the tips of the shoots are freely covered with flower-buds, and in a few instances nearly expanded blossoms also. This year the growth has been so abundant that much has been removed, as the example has exceeded its allotted space.

**Flowers in November.**—The phenomenal absence of frost and storms and the fine summer weather experienced in this district up to the present time (November 27) have prolonged the blooming of summer-flowering and tender plants to a remarkable extent. Up to the present we have not had anything approaching a frost, and up to within a week ago (when a heavy storm of wind and rain occurred) the occupants of beds and borders were as gay as at any time during the summer, and even in some cases more so. To send you a list of plants now in bloom would be to mention the whole of the summer and autumn-flowering plants and shrubs, tender and hardy. Such a dry, warm season has brought some late autumnal bloomers into greater prominence and beauty than usual. I refer to such as *Schizostylis coccinea*, which is more valuable and beautiful than I have ever seen it in the open. Many of the shrubby *Veronicas* are just now grand, notably *Marie Antoinette* (pink), *Blue Gem* and *Vernicosa* (white). Bold masses are very telling, and so is a large specimen of *Aralia Sieboldi* in full bloom and fragrance, most attractive on the lee-side of tall Bamboos.—Jno. ROBERTS, *The Gardens, Tan-y-burh, N. Wales.*

**Reinwardtia trigyna.**—This is perhaps one of the most valuable of small shrubby plants that flower during the autumn and winter. The plant would in all probability be even more popular were it less susceptible to attacks from red spider, which very much disfigures the plants and causes the foliage to fall prematurely. The showy blossoms of orange-gold are very attractive when the plants are grouped freely in the cool conservatory at this season; indeed it is one of the few dwarf plants of this colour obtainable during the winter months. In most private gardens endeavour is made to maintain a supply of plants from year to year by means of cuttings. Better and more satisfactory results follow the raising of this plant from seed. By carefully fertilising a few flowers

plenty of seed may as a rule be secured. The chief advantage the seedlings possess over cuttings is their greater vigour and freedom of growth in the first year, while not only are the flowers considerably larger, but the plants do not in the same degree suffer from red spider. Where the plant is grown in quantity, free syringing with soot-water during summer will be found of much service. Compact bushes of this Indian shrub are now covered with a profusion of buds and blossoms.

## SOCIETIES AND EXHIBITIONS

### NATIONAL CHRYSANTHEMUM SOCIETY.

A MEETING of the floral committee of this society was held at the Royal Aquarium, Westminster, on Monday afternoon, Mr. Thos. Bevan presiding. Very few novelties were staged on this occasion, and only two varieties received first-class certificates, viz.:—

**CHRYSANTHEMUM MRS. J. R. TRANTER.**—A pretty refined Japanese bloom, with fairly long, curling, and slightly twisted florets of medium width; colour creamy white, edged and streaked rosy-purple. From Mr. J. R. Tranter, nurseryman, Henley-on-Thames.

**CHRYSANTHEMUM VIOLACEUM.**—An immense Japanese bloom with innumerable florets of medium width; colour a pale shade of rosy-violet with white reverse. Awarded to Mr. E. Beckett, The Gardens, Aldenham House, Elstree.

Commendations as late varieties were granted to *Chrysanthemum Mrs. W. Butters*, a pure white decorative Japanese variety with narrow florets deeply fimbriated, and making a chaste little flower, and *Sam Caswell*, another pretty little spidery Japanese variety with fairly long, narrow, and deeply cut florets; colour clear rose-pink.

Mr. G. W. Forbes, Regent House, Surbiton, staged a dozen small vases of very pretty single sorts, but too freely disbudded, thus losing the charm which characterises this form of the flower. Six blooms of a variety named *Moor Park* were staged by Mr. Haggart, Ludlow. This is a medium-sized flower, reddish-crimson inside the florets, with a reverse of a pretty shade of nankeen-yellow, the florets being broad, pointed and incurving. A rich golden-yellow sport from the bronze *La Triomphante* looks like making a useful decorative variety.

**The weather in West Herts.**—A week of stormy, changeable weather, but on the whole warm for the time of year. On the warmest day the shade temperature rose to 53°, and on the coldest night the exposed thermometer showed 11° of frost—the greatest cold indicated by it during the past autumn. At 1 foot deep the ground is now about reasonable in temperature, but at 2 feet deep it is about 1° warmer than the average. Rain fell on five days, but only to the aggregate depth of about half an inch. During the twelve hours ending 6 a.m. on the 29th ult. the wind was blowing at the mean velocity of 21 miles an hour, and between 6 and 7 p.m. the record reached 25 miles—direction, W. The velocity last-mentioned shows a stronger gale than any recorded here in November since 1891. The wind, however, was on two days in March of the current year quite as high. The past month was a warm November, but during the previous eleven years there have been three Novembers in which the mean temperature has been higher. Rain fell on eleven days and to the total depth of an inch, which is 1½ inches below the average for the month, making this the driest November since 1879. October and November taken together come out exceptionally dry; indeed, with two exceptions, 1871 and 1879, drier than the same two months, during the preceding forty-one years. The last five days were windy, but taking the

rest of the month, the mean rate of movement of the air only amounted to about three miles an hour. During the last twelve years there have been only two Novembers with such a small record of sunshine, the average duration being less than 1½ hours a day.—E. M., *Berkhamsted.*

## OBITUARY.

### MR. JAMES BATEMAN.

ON November 27, Mr. James Bateman, a distinguished botanist and gardener, died at Worthing. Mr. Bateman was born in 1811, and as a young man took great interest in the cultivation of tropical fruits. His chief claim to recognition is his work in connection with Orchids. His first Orchid was purchased when he was a gentleman-commoner at Magdalen College, Oxford; in 1833 he sent, at his own expense, the collector Colley to Demerara and Berbice to collect plants. Shortly after this he induced Mr. G. Ure Skinner, a merchant trading with Guatemala, to send him Orchids, with the result that within ten years the finest Orchids of Guatemala were in cultivation in English gardens. In 1837 Mr. Bateman commenced the publication of his work on the "Orchidaceae of Mexico and Guatemala," which he completed in 1843; this book comprised the most remarkable series of coloured plates which had up to that time appeared. His "Monograph of *Odontoglossum*" appeared between 1864-7. He was not only the pioneer of Orchid culture, but he was one of the first to insist on the rational cultivation of these plants. He contended that the then prevailing system of cultivation was essentially wrong, and his lectures on "cool Orchid cultivation" gave an impetus to the popularity of these plants which can hardly be realised now. Mr. Bateman, who was a man of considerable wealth, was fond of experimenting, and his "Chinese garden," his "Egyptian court," and his "Wellingtonia avenue" at Biddulph Grange were among the first and most interesting experiments of the kind attempted in this country. Of late years he had resided at Home Lodge, Worthing, in the garden of which he formed a miniature alpine garden, in which many rare and interesting plants were grown. He was a J.P. and D.L. Staffordshire, and J.P., Cheshire.—*The Times.*

**Royal Gardeners' Orphan Fund.**—We are asked to state that Mr. P. C. M. Veitch, of The Nurseries, Exeter, has consented to preside at the annual friendly dinner of the committee of the Royal Gardeners' Orphan Fund at Anderton Hotel, on February 18, 1898.

**Tree Pæonies.**—Will some reader of THE GARDEN kindly name a few single light-flowering Tree Pæonies that are worth growing?—S. P.

\* \* The following, or at least some of them, should suit your purpose: *Margaret Attwood*, pure white, golden centre; *The Mikado*, rose and buff; *Cælestis*; *Regalis*, rose-flesh; *Phebus*, salmon and rose; *Luna*, white; *Antigonus*, French white and lilac; *Odonata rosea*, *Glory of Shanghai*, soft cerise; *Mammoth*, pink; *Mme. Rattier*, cream and flesh; *Morris*, soft rose; *Jupiter*, salmon; and *Duhamel*, lilac-rose.—Ed.

**Names of plants.**—*Latimer Clark*,—1, *Streptocarpus* var.; 2, should like to see better specimen.—*J. McK*,—1, send better specimen; 2, *Retinospora pisifera*.—*Lumister House*,—*Lycaste lanipes*. *J. R.*,—1, probably *Mesembryanthemum roseum*; 2, *Cupressus Lawsoniana erecta viridis*.—*Mrs. Elliott*.—A small flower of *Cymbidium giganteum*.—*J. C.*,—1, *Cupressus Lawsoniana* (seedling form); 2, *Juniperus rigida*; 3, *Thuja gigantea* (*Lobbi* of gardens); 4, *Juniperus chinensis* mas. We can only undertake to name four specimens in any one week.

## CHRYSANTHEMUMS.

### INCURVED CHRYSANTHEMUMS.

THESE have certainly been seen in better form this autumn than during several seasons past, but it is not so much that kinds like Impress of India, Lord Alcester, and so on, which were formerly the leading ones, have been noted in finer condition than usual, but new varieties that are fast taking the place of established ones that did duty so long. Take for example the yellow sort Chas. H. Curtis, which the Aquarium recently all the prizes in a class of half-a-dozen of one variety were taken with flowers of this. They were all very fine, but wanted a little more patience bestowed upon them in the matter of arranging their petals more evenly. Incurved Chrysanthemums require more time, if not greater skill, than other classes to exhibit them to the best advantage, and they will repay extra pains in a generally neat and finished look. The new kinds which have come forward this year will, I think, give a further impetus to their culture, and will alter the appearance of stands of this class. I sometimes think it is the increased use of the Japanese sorts that has dwarfed the incurved and made them seem so much smaller than we saw them a few years back. However, as far as size goes, Mme. Ferlat is a remarkable one. It is white, perfectly incurving, and of no substance. The blooms come 6 inches across and of proportionate depth, the habit of the plant being very dwarf. It is also easily grown. Mlle. Lucie Faure was certificated as an incurved variety. It comes close and solid from late-formed buds, but loose, with a Japanese-like form, early in the year. Hence if this matter of buds be neglected, it may prove disappointing. This variety, too, is of a pure white and has first-rate quality. Ernest Amell, an English raised variety I believe, is another notable addition. It bears large, full, well-formed incurving blooms of a pretty light

buff shade. Lady Isabel is a large blush-pink bloom. This is a fine acquisition. It really takes the place of the old Queen of England. Duchess of Fife has large, deep, solid white flowers, tinted blush, however, from late buds. It is rather tall in growth, but very strong. Miss Dorothy Foster and Miss Violet Foster are both very nice new sorts. They have violet-rose blooms of different tints. Rena Dula is a perfectly formed incurved flower. The blooms, of medium size, full, and solid, are blush-white in colour. Ma Perfection is an excellent pure white. It is a dwarf and very free grower. This is a neat and taking flower. Mrs. R. C. Kingston bears blooms of a white, tinted-pink colour, and is of good form. The blooms are large, deep, and solid. Miss Phyllis Fowler is a light yellow. I saw it in good form on several occasions this autumn although generally it comes a bit rough in shape. King of Orange has blooms of a charming tawny-yellow tint. It is somewhat late, but still a very useful addition. Bonnie Dundee does not produce flowers of large size; they are, however, nicely incurved, and the colour, bronzy yellow, rich and distinct. Neither Mrs. F. Hepper, Ideality, nor Perle Dauphinoise, although new, appear likely to prove worthy of extended culture, but George Haigh, a fawn-coloured sport from Robert Petfield, is a neat and excellent kind. Triomphe d'Ève was seen in more than one exhibition in Kent. As yet it does not appear to be known out of that locality. It is white, of medium size and capitally formed. By the way, those fine old types, Lord Alcester, Golden Empress of India—in fact, the group designated the Queens—were noticed in better condition at local shows in the above-named county than at more important meetings in London and elsewhere. I always thought the white J. Agate too uncertain. It is also tall in growth, but a good incurved when at its best. Nor is C. B. Whitworth certain enough to become esteemed. It is at best an imperfect flower. Major Bonaffon has fine yellow incurved blooms, but it

is somewhat late. Wm. Tunnington, J. Fulford, and Owen's Crimson are rough in form and will never become leading types. M. P. Martignac, light yellow, and D. B. Crane, buff colour, are nice forms when well grown. Among older kinds, the Princess of Wales group, which includes Mrs. Reale, Mrs. S. Coleman, Lucy Kendall, Miss M. A. Haggas, and Violet Tomlin, are yet very fine. Princess of Teck also, and the sports, Hero of Stoke Newington, Mrs. Norman Davis, and Lady Dorothy, besides a few others, are worth keeping. But such sorts as Lord Walseley, Prince Alfred, Princess Beatrice, John Salter, Mrs. Shipman, Lady Hardinge, Refulgens, Alfred Lyne, Barbara, and a host of others are not good enough to be cultivated in these days. H. S.

**Chrysanthemums from September to Christmas.**—Will any reader of THE GARDEN kindly give me the names of twenty-four sorts of Chrysanthemums in different colours, with dwarf habit and easily grown for cut blooms and decoration? I have tried about 100 sorts picked out from catalogues, but have found very few of them suitable. Vivand Morel, W. Seward, Florence Davis, Ch. Davis, Lincoln, G. W. Childs, Golden Gate, Beauty of Exmouth, La Triomphante, Sunderbruch, Kentish White, and Commander Blusset, I think, are very good ones.—A LOVER OF THE GARDEN IN SWEDEN.

**The crown bud.**—Is the crown bud in Chrysanthemum the first bud that is formed after striking, or is it the first bud that is formed after the break?—A. F. C.

\* \* \* The bud which causes the natural break in Chrysanthemum plants is really a crown bud, because it is surrounded by little growths instead of other buds. However, it is not recognised as such, for the reason that the break bud does not give perfect blooms only in one or two exceptional instances. The first crown bud, therefore, is that which is formed after the natural break or after a plant has been topped back in early spring.—Ed.

**A change of stock.**—Now that the time for striking cuttings for another year is at hand, it

will be well to point out how advisable it is to have a change in the case of some notable sorts. Edwin Molyneux, Vivand Morel, Charles Davis, Mlle. Thérèse Rey are common examples of those that exhibit a want of vigour, probably through being continually propagated from highly-fed plants. In these and other instances of debility a plant or two of each should have been allowed to grow the whole summer in the open ground. If protected now they give a good supply of healthy cuttings which are likely to give improved results another year.—H. S.

#### SOME NEW CHRYSANTHEMUMS.

ALTHOUGH one might have expected finer examples of G. J. Warren than were seen this year, it has, perhaps, hardly had time to get thoroughly established, and with an early start from strong cuttings, next season should see it, with the parent, Mme. Carnot, quite at the top of the list of show varieties. The sort named Yellow Mme. Carnot, which won the rare distinction of being the best bloom at the Aquarium in November, is a separate sport, having originated with the exhibitor, Mr. Mease. It is a shade or two lighter in its yellow, but whether both can be placed in a stand as distinct varieties without risk is a question to be settled when they are grown side by side. Any coloured variety from so fine a type as the grandest of all white show blooms is welcome, and a yellow, now it is fixed, may be considered the greatest gain of the year in Japanese Chrysanthemums. Ella Curtis has very long, broad, thick petals. These are flat and build up a flower of remarkable beauty; colour yellow, with bronzy streaks. As an exhibition kind this is an acquisition. Mary Molyneux, like the last-named, is an English seedling. The florets, long and of good substance, incurve in an irregular way and form a bloom of fine depth; colour a clear shade of pearly pink. Georgiana Pitcher is hardly new, but is comparatively unknown. The colour is rather a deep shade of yellow, not over-bright, but pleasing. It is a full, deep, slightly incurving form, the lower florets drooping, of massive build and fine substance. It will be valued as an exhibition flower. J. Chamberlain is a large, handsomely-formed flower, the inside of its florets having a most vivid colour. The back part, however, shows too much by the habit of curling. This slightly detracts from its value, but if by extended culture it can be made to exhibit the inside tint only, it will prove one of the very finest of recent introductions. Mme. G. Bruant is a very large bloom of drooping formation, colour white, tinted rose on the first opening florets. The extra colour makes it appear a bit dull—neither a white nor pink—but its immense size will find it many admirers as a show bloom. Robert Powell has incurving blooms of fine width and depth, colour a deep bronzy shade of yellow. Although we are not wanting in such tints, this is a most excellent new kind. Master H. Tucker has very sturdy growth, without which any new Chrysanthemum is wanting in one of its important qualities. This is a first-rate gain because of its colour. Chestnut-crimson describes its shade, and as some of the florets curl inwards a lighter shade is seen, but the former predominates. It is a large, full, massive flower, and one that is likely to become popular. Mlle. Laurence Zédé is quite one of the best of the year, perhaps the finest of M. Calvat's new set; colour a lovely shade of mauve-pink. The flowers are extra large, full and deep. Its florets incline to incurve, and the habit of the plant is excellent. Mrs. F. A. Bevan is not a large flower, but the colour, flesh-pink, is particularly pleasing. The florets droop gracefully. Mrs. S. C. Probyn is a pretty sort, but not one of the largest; colour a charming shade of rose-pink. Its petals incurve slightly, the growth being dwarf and sturdy. Apart from its value as a show flower it is likely to become one of the most esteemed for the supply of cut blooms in quantity quite late in the autumn. George Foster is a large yellow incurving Japanese flower. Its massive build and substance will

make it a valuable exhibition variety. N. C. S. Jubilee is a decided acquisition as regards colour. The shade may be called lavender or heliotrope. Its shape is incurving and the blooms are large, whilst the habit of the plant is dwarf and sturdy. President Nonin, after a full season's growth, will, I fancy, prove a most beautiful new kind. The colour is a very rich and distinct shade of bronze-yellow, the bloom being large and well formed. Mrs. Charles Bireh bears flowers of a lilac shade, the form incurving. The bloom is large, full, and has fine substance. Of Werther I fancy the best has not yet been seen. Its colour, a purple-crimson tint, is one that is welcome. The bloom is a bit flat, but broad, with petals of exceptional thickness. Julie Scaramanga, a recently-raised English seedling, is a flower of some merit. It has blooms of drooping shape, large, full, and striking. The colour is a rich shade of bronze or old gold tint. Earlswood Beauty is a single Chrysanthemum, and, to my thinking, the handsomest of all singles. It is pure white. The florets are long and have a light appearance, the centre or disc being bold and showy. For all kinds of floral decoration additions like this are most valuable. H. S.

#### GROWING CHRYSANTHEMUMS.

WILL any of the contributors to THE GARDEN kindly assist me in my difficulty over the growing of Chrysanthemums? I took up their culture last year, and the result is not satisfactory. I do not aim at exhibition blooms, such as I saw in London on the 9th ult. I simply wish to grow, first, good cut blooms for home decoration; secondly, neat bush plants for the conservatory; thirdly, dwarf plants with some good blooms to stand on the front of the stages. I am quite at sea as to stopping, timing, and taking the buds, whether first, second crowns, or terminal buds. A simple cultural note directing me how to proceed, from the taking of the cutting up to the flowering period, would be much valued by many more besides myself, if I may judge by the conversations I had with amateurs at the recent show. An up-to-date list of say three dozen of the best and most easily grown Japanese sorts for the above purposes would also, I know, be of much service.—IGNORANT.

\* \* \* There is no reason why "Ignorant" should not be successful in the culture of Chrysanthemums for the purposes named without being much troubled with such terms as first or second crown buds, which certainly have an important meaning in connection with the production of the large specimen blooms seen at recent exhibitions. First as to

#### PROPAGATION.

Cuttings may be rooted from September up to March. The early date is the better if large bush plants are desired, but the latter time is suitable for growing neat little, dwarf plants in small pots, say those 6 inches across. Chrysanthemum cuttings root freely if not coddled. They are mostly rooted in boxes about 9 inches deep, kept air-tight by a covering of glass. This plan is by no means the safest for those who are not experienced, because the cuttings may become too moist, or may be left in the boxes so long as to get drawn and weakly. I would strike them in the following way: Get a shallow box or boxes (it matters not how large or small so that the depth is not more than 3 inches), and fill to the brim with loam and leaf-mould in equal parts, with just a sprinkling of silver sand. This should be run through a fine sieve and pressed in level and firm. Then dibble in the cuttings (which may be 3 inches or so in length) a couple of inches apart. Give a thorough watering to settle the cuttings properly, and stand the box in any convenient part of a greenhouse, which is only heated to keep out frost, or if in a structure which is made warm for other occupants, put the Chry-

santhemums on a shelf near the glass, where of course, the air will be comparatively cool. The leaves will flag a bit for a time. This, however, will not hurt them. I would not sprinkle the leaves with water unless fire-heat is applied. In a month or so the cuttings will have pricked up and rooted. They should then be potted singly into small pots, the soil being similar to that named above. As the attention needed will be not to let the young plants suffer through want of water, and air must reach them on all favourable occasions—that is to say, when it is not freezing. These conditions may continue up to the end of March. The earlier-struck plants will then require another shift. Use pots 5 inches in diameter. For this and a later shift the soil should be of a strong character. Loam may form two-thirds of the whole. This varies, but it is generally understood to be the top spit of pasture land, dug a few months before use so that the green grass may decay. This is chopped or broken up and the fibre not removed. Instead of leaf-mould a rotted manure sifted and a slight addition of coar sand. From April to the end of May the plants grow better in frames than in greenhouses. The bottom is moist and cool, and one may give air greater abundance. When potting, it should be said, making the soil firm is a matter of some importance. The plants up to this time will have but one stem, and when each has reached 6 inches the point may be nipped off so as to induce short, bushy growth. Watering is always a matter which must be carefully watched. After the plants have been potted, a soaking shower at once be given; but for a time, until the roots get hold of the new soil, guard against making the soil sour by over-abundant supplies. As the season advances, however, and the plants become large, daily attention must be given to moisture at the roots. Nothing can make up for neglect watering plants in pots, but it is also as important that too much shall not be given. A ringing sound, by tapping the pot with one's knuckle, indicates the need of water; then enough should be given to moisten the whole ball and the plants be left till dry again—not "just a little" on the surface each day, as is sometimes done.

Allow the plants plenty of room. Do not let the leaves of one touch those of its neighbour and stand them in an open position during the summer. The side shoots may have their points nipped off when 6 inches long. This pinching may continue to the end of June. By that time the capital bushes will have been formed. The first potting should take place about the end of May. One need not mention the necessity of using sticks to keep the growths upright or safe from damage through winds, nor impress upon the amateur that green-fly must be kept away throughout the season. Tobacco dust is the best remedy for the pest. As regards the flower buds, let them come in a natural way. They may be thinned at the will of the cultivator. The number of blossom-plants is allowed to perfect will affect their size and the time of flowering will vary slightly with different varieties. When the flower buds are swelling, the roots need stimulating with manures. Strong doses are not required, but weak mixtures and often, so as to carry the plant through in perfect health after the roots have exhausted the potting soil. In giving the

#### VARIETIES

I shall name those that blossom from October to December, so as to give a lengthy season, and at the end I will select a few of the best as being dwarf in habit, sorts which would prove useful for giving nice little specimens in small pots when struck late in the spring: A. E. Fewkes (yellow), Bonle d'Or (bronze), Australia Gold (light yellow), Charles Davis (bronzy rose), Col. W. B. Smith (terra-cotta), Emily Silsbur (white, early), G. J. Warren (yellow), Golde Gate (tawny yellow, late), Hairy Wonder (but novel), John Shrimpton (crimson), Lady Byron (white), Lady Saunders (primrose), Lonise (blush), Madame Carnot (white), Madame Ferlat (white), Madame Gustave Henry (white), Madame N.

licoud (pink), Modesto (yellow), Matthew Hodgson (crimson), M. Ch. Molin (bronze), Master H. Becker (crimson-brown), M. Chenon de L'éché (salmon-rose), M. Ed. Andre (salmon red), Mrs. J. Lewis (white), Miss Elsie Teichmann (white tinted), Nyanza (late, crimson), Niveum (late, white), N. C. S. Jubilee (heliotrope shade), Phœbus (yellow), Rycroft Glory (early, bronze), Pride of Madford (amaranth), Source d'Or (bronze), Souvenir de Petite Amie (white, early), Viviani (mauve), Wm. Seward (dark crimson), and Western King (white). *Dwarf sports*.—A. H. Lewkes, Boule d'Or, John Shrimpton, Lady Saunders, Louise, Madame Ferlat, Modesto, M. Chenon de L'éché, N. C. S. Jubilee, Phœbus, Pride of Madford, Souvenir de Petite Amie, and Rycroft Glory.—H. S.

**CHRYSANTHEMUMS—NEW INCURVED VARIETIES.**

THE classification of the incurved varieties as now recognised by the National Chrysanthemum Society will assist the growers of this type very materially. During the last two or three years there have been several introductions of a very subtle character, but now the whole appearance of the incurved stand of blooms seems likely to be altered. Of course a grower would exclude from his stand such an immense and coarse-looking bloom as The Egyptian. This variety would vary most others on the same board, and on this count would be better left out until others usually large and less coarse could be set up as check row flowers. Lady Isabel, which has been of much assistance this season, is one of the finest of its kind, with grand broad florets neatly curved, early buds producing blush-white flowers, while those from later buds are of a beautiful blush colour. Mlle. Lucie Faure is another immense flower, creamy white in colour, with big and pointed florets. Early buds of this sort of flowers which are inclined to be rough, those from later buds being very neatly finished. Ernest Cannell, catalogued by some trade growers as a Japanese variety, was recently certified as incurved, and a very handsome flower it is. The florets certainly are not rounded at the tips, being somewhat pointed in fact, but the colour is one that should be very serviceable—viz., buff-flow. When finished it is a bloom of grand proportion. Another immense flower is Mme. Ferlat, put out by Mons. E. Calvat. This is a pure white bloom, of capital substance and great proportion. This is also a very full flower, with innumerable florets. A distinctly pretty one is Mrs. W. C. Egan, of true incurved form, and of goodly proportions. The colour is very pleasing, being a pale shade of rosy pink with a white centre, altogether a very promising one. Mrs. N. Molyneux is another very large popular flower, and as recently exhibited inclined to be rough; there is little doubt, however, that with proper treatment this creamy-white flower will be in great demand. Thos. Singleton is another pearly-white bloom, edged a pretty rosy pink, and although so far seen only in fair form, there are great possibilities for it. It will thus be seen that in the course of another season the whole character of the incurved displays may be altered, and many of the present pretty medium-sized blossoms be superseded by those of more pretentious quality. C. A. H.

**Yellow sports from Chrysanthemum Mme. Carnot.**—This handsome variety has sported in all sorts of places. Last season when the yellow sport first appeared in two different places the question was often asked. Are they one and the same variety? After a trial this year there seems little doubt now that they are identical in form and colour too. In addition to the foregoing, there is evidently a third sport, as it is now generally understood that the bloom of yellow Mme. Carnot which secured for Mr. Mease the prize for the premier Japanese bloom at the late exhibition of the National Chrysanthemum Society was none other

than a sport in that grower's collection. During the present season sports of a similar colour have been heard of in different parts of the country, and within the past few weeks a sport of the same colour has been developing in my collection of plants. This plant, together with several others, was from cuttings taken from a plant of Mme. Carnot, so that there is no doubt about it, both the flowers of the sport being a lovely soft pale yellow. This only emphasises the sporting propensity of the parent variety, and it is pretty safe to assume that in a short time we may secure other sports, which cannot fail to be of immense service to growers for exhibition.—D. B.

**SHORT NOTES.—CHRYSANTHEMUMS.**

**Chrysanthemum Madeline Davis** is a very lovely and refined Japanese flower, in build somewhat like Phœbus, but possessing longer florets, also more tapered than those seen in that variety. The colour is best described as silvery white, tinted throughout with pale violet and edged pale rosy violet. The habit is dwarf and the constitution of the seedling plant very robust.—D. B.

**Chrysanthemum Mrs. John J. Glessner.**—This is a new American variety of a pretty shade of colour, being a rich golden yellow, tinted apricot. The florets are rather broad, neatly incurving. Mr. Norman Davis thinks the flower a very promising one. It should make a capital exhibition variety, and, being free flowering, should prove useful for decoration. Unfortunately, the growth is rather tall, but exhibitors will not consider this fact very seriously.—D. B.

**ORCHIDS.**

**CALANTHES.**

IN speaking of Calanthes one usually includes only the epiphytal kinds, such as *C. vestita* and the many choice varieties and hybrids related thereto. Than these there are few more useful winter-flowering Orchids, especially in country districts where the blossoms come pure and rich in colour, and do not suffer from the effects of the baneful fog so prevalent in the metropolitan district and in the vicinity of large towns generally. They are well-known and popular plants that may be grown in an ordinary plant stove quite as well as in the Orchid house proper, provided due attention is given to cultural details. A light position, only lightly screened from the sun's rays, must, if possible, be allowed. Some cultivators, indeed, grow the plants almost entirely without any shading, but, unless very great care is taken with the ventilation, especially during the earlier part of the season, the foliage will be ruined, and the whole system of the plant checked in consequence. There can be no doubt, on the other hand, that the more sunlight allowed, the more free-blooming will the plants be, and the more satisfactory in every way. To heavily shade the plants from the first and allow too little air is one of the commonest mistakes in the culture of Calanthes. It is usual to repot the bulbs in early spring just as growth commences, but as a matter of fact they may be repotted at any time after the flowers are past. I have never found the least advantage accrue to the plants by starting the pseudo-bulbs in Moss or in very small pots, subsequently shifting into the flowering size, or in any other of the ways that some cultivators think necessary. If dealing with any choice or rare kind, and one that had been closely propagated before reaching me, I may endeavour to encourage it by a little nursing treatment, but a good stock of healthy, strong bulbs cannot be better managed than by being placed at once in their flowering

pots. These must be clean, and exceptional care taken with the drainage, for the quantity of water required by these plants is very considerable. Good sound fibrous loam, Sphagnum Moss roughly chopped, and peat in equal proportions will form the basis of the compost, and to this may be added a little dried cow manure in varying quantity according to the quality of the loam, and plenty of roughly broken charcoal and potsherds. Finish the line of compost well below the rim of the pot, and the base of the pseudo-bulbs must be just below the compost, being held in position by a few of the old roots which may be left on for the purpose. One good soaking of water may be given to settle the soil about the base of the bulbs, but after this the compost should be kept perfectly dry until roots are forming. When the plants are potted early this will be, perhaps, a month or more, but if left until growth commences, it is not long before root-action follows, when water will be needed, sparingly at first, but in increasing quantity as the roots get hold of the soil. Plenty of heat and a brisk, yet moist, atmosphere must now be maintained, then growth will be rapid and clean. See that each plant stands well clear of its neighbour, as it is important that air and light play with freedom about the forming growths and foliage. When there is a good number of leaves and the roots have taken hold of all the compost, a little weak liquid manure may be given once a fortnight or oftener, according to the amount of manure in the compost. This must not be over-done, for the big plethoric bulbs produced by over-feeding are by no means the most satisfactory in the long run. The first sign of the approaching flower-spikes is seen in a whitish swelling at the side of the bulbs, and when this is noticed the leaves often commence to fade, and water must be given in less quantities. Atmospheric moisture is not now so necessary, but must not be dropped too suddenly, as the more gradually the foliage dies off the better. All the time the spikes are forming take care the water does not lodge in the cleft at the base of these, as it is apt to cause and encourage the black rot, so much feared by growers of Calanthes. Very little moisture at the roots in fact is needed, for these have almost fulfilled their functions by this time, and the stored-up nutriment in the bulbs keeps the spikes going. The most mischievous practice connected with their culture is placing them about in draughty corridors and passages in the house. Many Orchids stand this treatment with little detriment, but it is fatal to Calanthes. The pseudo-bulbs should never be in a temperature much below 55° if good results are looked for; they may not show anything wrong at the time, but they are sure to start weakly in consequence. The most troublesome insect pest is brown scale, this much affecting the lower side of the foliage and the old bulbs.

The treatment noted above is of course not suited to the *veratrifolia* and *masuca* species and varieties, but only to those above indicated. The number of fine hybrids is now very large, and anything like a full description would take up far too much space for the present note, but may be referred to later.

**Phalænopsis Schilleriana vestalis.**—This, the white form of *P. Schilleriana*, is exceedingly rare. A fine plant, said to be the only one in the country, was recently noted in bloom in Sir F. Wigan's collection at Clare Lawn, East Sheen. The flowers are pure white, with the exception of the basal halves of the lower sepals, which have a very faint indication of light brown spots, a

few yellowish-brown ones near the base of the side lobes of the lip, and a yellow crest. It is a chaste and lovely form. This unique variety was named by the late Professor Reichenbach in 1882 from the collection of Messrs H. Low and Co., by whom it was introduced.—C.

**Dendrobium Aspasia.**—This handsome hybrid, raised in the collection of Messrs. J. Veitch and Sons, first flowered in their Chelsea nurseries in 1889, under the name of *D. Wardiano-aureum*. It is the result of crossing *D. Wardianum* with the pollen of *D. nureum*. The sepals and petals are creamy white tipped with light rose-purple, which is more prominent on the petals. The front lobe of the lip has a broad area of creamy white tipped with purple shading to crimson, with some orange on the disc. It requires careful watering during the resting season, to avoid undue shrinking of the bulbs. Excess, on the other hand, will be liable to cause the bulbs to decay at the base.—H. J. C.

**Ornithocephalus grandiflorus.**—This distinct and lovely species was recently noted in flower in Messrs. J. Veitch and Sons' nurseries at Chelsea. The spikes, 5 to 8 inches or more in length, are produced from the axil of the last made leaf. The sepals and petals are white, with a bright green spot at the base, the lip white, with a horse-shoe-shaped blotch in the centre. It is a native of the Organ Mountains, of Brazil. It requires a cool intermediate house, and succeeds best when grown in pans suspended from the roof, the potting compost consisting of good fibrous peat and living Sphagnum Moss in equal quantities. It requires a liberal supply of moisture during the growing season, and a fairly dry atmosphere when at rest.—STELIS.

**Cirrhopetalum refractrum.**—This is a remarkable species. The flowers are produced on a raceme 15 inches long when the plant is in a deciduous state. The lower sepals are open in the centre at the base for about half an inch, combining from this opening to the apex, the whole being about  $2\frac{3}{4}$  inches in length, pale greenish yellow, longitudinally lined with brown. The upper sepal is about three-quarters of an inch long, pale green, heavily suffused with purple, with numerous bristles on the edges. The petals are about half the length of the upper sepal, covered with small hairs, and similar in colour. The movable lip has the appearance of a miniature spotted spider, about half an inch in length, the colour being yellow in front, shading to rich purple, and barred with white. There are some twenty of these flowers on the spike. It requires cool-house treatment, placed in such a position that it can obtain the maximum amount of light. A plant of this I recently noted in flower in the Cambridge Lodge collection.—T.

**Epiphronitis Veitchi.**—This lovely bi-generic hybrid was raised in the nurseries of Messrs. J. Veitch and Sons at Chelsea. It is the result of crossing *Sophrontis grandiflora* with the pollen of *Epidendrum radicans*. It first flowered in 1890, and was exhibited at the meeting of the Royal Horticultural Society on June 24 of that year, when it received a first-class certificate. Although the blooms were small when first shown, as the plants have become stronger the flowers have also increased in size. The character of the blooms shows the influence of the pollen parent in a remarkable degree both in shape and colour, with the exception that the sepals and petals have an additional dash of crimson; the flat lip also has a larger amount of yellow on the disc and numerous crimson spots. The flowers are produced from the apex of the growth. The growth is similar to that of the *Epidendrum* parent except in the height, which does not exceed 15 inches. I find it remarkably free-growing and of good constitution. It should be grown at the moist end of a warm intermediate house and placed in such a position that it can obtain the maximum amount of light, shading only during summer from the direct rays of the sun. The potting material consists of fibrous peat and living Sphagnum Moss in about equal quantities. To increase the stock the growths may be cut off

after they have flowered, just below the roots, which are produced at intervals up the stems. These should be placed in small pots, using living Sphagnum Moss and rough sand as the potting compost. They should then be placed in a warm and moist position, and every encouragement given to induce them to break into growth.—STELIS.

**Odontoglossum Kramerii.**—This pretty and uncommon species is well worth growing on account of its distinctness, and the colour is unusual in the genus. The flower-spikes appear in autumn, being now in good order in several trade collections around London. From three to four is the usual number of blossoms produced on a spike, the sepals and petals rather short, bluntly pointed, pale rosy violet in the middle, the margins very much lighter—nearly white, in fact. The lip is rounded in front, also pale purple in colour, the centre being bright golden yellow and having brownish and white markings at the base. The species takes its name from a German collector. Being found on the coast or near it, it is one of those kinds that advancing civilisation has almost exterminated. A few plants are still sent home from time to time, and among these have appeared one or two well-marked varieties. Few *Odontoglossum* require so much heat as this kind to do it well, the warmer end of the Cattleya house suiting it well if rightly treated in other ways. It used to grow well with me in an ordinary plant stove under a Stephanotis, and this broken light appears to suit it better than either heavy shade or a glaring light. Small baskets or pans may be used, as these are more easily suspended, and in this position air plays more freely around growth and roots. With regard to atmospheric and root moisture, these must be nicely balanced: the more there is in the atmosphere, the less will be required at the roots. But while growth is active it will be found that a liberal supply is necessary to the latter, and during the blooming season it is well to be sure of plenty of moisture, owing to the dry atmosphere of the flowering house. When the plants are quite at rest very little will be needed, but at no time must the pseudo-bulbs be allowed to shrivel, or the plants will be badly weakened. The compost may consist of the usual peat and Sphagnum mixture, not a great thickness of this being used.—H. R.

#### ODONTOGLOSSUM CERVANTESI.

THERE are few more beautiful species in the genus than this, although the flowers are not so large and showy as those of some others. The pseudo-bulbs are roundish, small, and deep green, the flowers proceeding from the sides of these on three to six flowered spikes. In the typical form these are white on the sepals and petals with a few streaks of reddish-brown at the base of each. There are many varieties, the best perhaps being *O. C. decorum*, *O. C. punctatissimum*, and *O. C. roseum*. The first has large and handsome flowers, the streaks on the segment being purple; *punctatissimum* and *roseum* are sufficiently descriptive. The culture of all these is similar, and depends a good deal more upon timely attention to small details than any prescribed mode. All these small growing plants cannot do with a dry or draughty atmosphere; it is apt to check them and is conducive to insect pests. What *O. Cervantesi* likes is a moist and cool atmosphere all the year round, with a free circulation of air on all possible occasions. It is quite a mistake to throw the house widely open in very hot, dry weather, when the outside temperature is above what it should be inside. At this time of year it is better to air very freely early in the mornings, and later on lower the blinds and keep the house somewhat close. At night, too, the house may be freely ventilated and the floors and stages well damped the last thing at night. This often causes a dew to fall upon the leaves which will be found on them in the morning, and this without a doubt is a good deal like the conditions that obtain in their native habitat. During winter the plants should hang as close to the glass

as possible, owing to their liking for light, and the roof glass must be kept clean. They are best grown in small pans or baskets well drained and in the usual mixture of peat and Moss. This should be placed firmly about the roots with a dibber, the base of the pseudo-bulbs just resting on the cone of compost. Frequent disturbance is unnecessary and harmful, leading to deterioration in the size of the bulbs and weak flower-spikes. It is wise to be on the look-out and place a little new material whenever any slight loosening of the bulbs is noticed, for a plant cannot be healthy when swinging by the roots. This and careful watering will keep the plants in health for several seasons without much disturbance, but when this is seen to be required it should be set about a once, for it is much easier to get these small growers into bad condition than to restore them to health. *O. Cervantesi* was named after Mexican professor of botany by its discoverer, but was not introduced to British gardens until 184

**Rodriguezia planifolia.**—This is a pretty little plant I noted in flower this week, not unlike *R. secunda*, but rather different in habit and having blossoms of a rosy crimson shade. They are produced very freely on short side-spikes, although small individually, make a pretty show. Not being a very vigorous plant, it may be given small pots or pans or even blocks, provided the are well looked after as regards moisture, but in any case about an inch of compost over good drainage is ample.—R.

**Cypripedium polystigmaticum.**—This fine hybrid I noticed in flower during the week. It is a cross between *C. Spicerianum* and *C. venustum* and shows a good deal of the former fine species in form and colour. The dorsal sepal is whitish with the line as seen in *Spicerianum* and a purple venation. The sepals are greenish at the base, with small black dots, shading to reddish brown and purple, the lip being rather pointed brownish, with a yellowish tinge in front. It is a free grower, thriving well in an intermediate house.—H. R.

**Masdevallia Davisi.**—In its best forms this species takes rank with the finest of garden Orchids, the rich orange-yellow being very unusual in the genus. The plant is of tufted habit, like *M. Harryana* and the leaves are each about 6 inches in length. Each flower measures near 2 inches across, and when several are open on the same plant they make a fine display. Its habitat high up on the mountains in Peru, whence it was introduced in 1873 by Messrs. Veitch, and named after their collector who found it. It thrives under cultivation in a cool, shady house during the summer.

#### SHORT NOTES.—ORCHIDS.

**Cypripedium Trianowskyanum.**—This is a free, strong-growing *Cypripedium* and a very tall flower. It is the result of crossing a good variety *C. insigne*, possibly *Chantini*, with *C. lo*, and much resembles the former species in shape. The dorsal sepal is broad and handsome, the long wavy petal bright purplish rose with hairy edges, the pouch brownish-purple, the whole flower glossy and shining.

**Zygopetalum Mackayi.**—I noticed some very fine spikes of this plant in one of the groups at the Bury St. Edmunds show recently. It is a useful free flowering old plant of which many fine specimens exist up and down the country, not so much in plantations as in old-fashioned collections of stove plants. It thrives well under stove treatment and should be grown by all who require choice flowers in winter.—H.

**Miltonia Roezli alba.**—This is a very charming and beautiful Orchid, the yellow centre enhancing the beauty of the white, nearly all pure white species varieties having rather a dead look about the specimens that produce a dozen or so of the flowers are very handsome. Such an one I noticed at the week. *M. Roezli* and its variety require more heat than *M. vexillaria*, and should be grown in medium sized pots in a good substantial compost.—R.

## COTTAGE GARDENS.

THROUGH the beauties of rural England are many and diverse, there are few that afford such sense of pleasure and restfulness as a picturesque cottage garden. There is no straining after effect, no undue exactitude in the composition of these little plots that come upon one accidentally, as come all the sweet surprises of life, on rounding a turn in the village road. Some of them are very small, for beauty is not synonymous with size; but one sees at a glance that the owners love their flowers. Love and a little labour are all that the cottager has to give; but, as with the widow's mite, the work of his offering is not to be measured by its intrinsic value, and the flowers themselves evidently appreciate this fact, repaying the labourer who, after a long day's work, mounts the rickety

porch, festooning the white-washed walls and thatched eaves, or clambering up the gable to the very chimney.

One of the chief charms of the beautiful pictures afforded by some cottage gardens is that the details are few. No extended system of beds stocked with multitudinous varieties of plants, evidencing the care of a well-trained staff of gardeners, but a few flowers, sometimes only one or two sorts, growing unrestrainedly, and as if planted by Nature.

In one garden a large Apple tree in bloom stands before the porch. Beneath the tree a wide bank of purple Iris is blossoming; the effect is perfect; nothing more is wanted. Here, in the time of the Roses, "It hastes, it wastes, the month of the Roses." The walls are covered with the flowers and buds of Rêve d'Or and Maiden's Blush, while a great bush

of Myrtle bushes, and the Myrtle bushes, throw up tall spikes of flower between the Myrtle bushes.

As I write, a recollection comes of a still evening in early summer after a day's rain. The sky was clear of clouds, and the sun sending level rays between the tree trunks as I leant over the gate of a cottage garden whose proprietor had gone away for the day. The moist air was full of the scent of double Rockets and Sweet Brier, on the leaves of which the rain-drops still glittered. The martins were flying to and from their nests beneath the eaves, the cuckoo calling in the orchard below, and the thrushes singing from the Elm tops. It is only on occasions such as this, few and far between in the rush of the present day, that the presence of the Soul of the World becomes an assurance.

In these times the decadence of thatch as a roofing material is so marked that it is a difficult

A Devonshire cottage and garden. From a photograph by Mr. S. W. Fitzherbert, Torquay.

adder to nail in the shoots of his climbing Rose, and the old dame who, with the help of her little grandson, waters the Pansies from the cracked earthenware jug with no niggard hand. To his credit, be it said, it is mostly the old-fashioned flowers that the cottager affects. The old Crimson Clove, with its absolutely satisfying scent, often grows there with a luxuriance and hardiness unknown in the spacious parterres of the wealthy. The white Lily, the emblem of purity, the Lily of the Madonna and of the Annunciation —

The wand-like Lily that lifted up  
Like a Mænad its moonlight-coloured cup,

reserves the perfection of her beauty for the gardens of the poor, while the Rose never seems so happy as when garlanding a cottage

of the old Cabbage Rose by the gate greets the wayfarer with its perfume. Here a *Maréchal Niel* produces year by year its splendid golden blooms. Here one side of a cottage is wreathed with odorous Jasmine, a mauve Clematis threading the thick growth, in which the spotted flycatches have made their nest, mingling its blue stars with the white clusters of the Jasmine flowers. In this garden a giant Lyre flower (*Dicentra spectabilis*) grows, a good 5 feet through, a model of symmetry, its long racemes of rosy hearts (the Bleeding Heart, the cottagers call it) swaying with every breeze. In another a *Wistaria* rambles up to the latticed windows, and the white Pinks that edge the path from porch to wicket fill the days with fragrance, while clumps of *Campanula grandis*, both purple and white, and, later on, the Chimney Cam-

matter to find a cottage roof where slates or tiles have not replaced reed, but the subject of the accompanying illustration lies in a village which, though but ten minutes' walk from the station where the London express stops, is untouched by innovation. The old thatched cottages, in their setting of Elm trees and orchards, stand back at different angles and distances from the winding road, each with its little garden and its speciality of flowers, while in the spring the valley is filled with the fugitive beauty of Lilac, Laburnum and pink Thorn. S. W. F.

Torquay.

**A new way of watering avenue trees.**— We have recently seen at Berlin the trees planted on the new boulevards and avenues growing vigorously and, apparently, well attended to.

With the exception of the celebrated Lime trees of the old promenade Unter den Linden, where the ground in the centre has never been renewed and where nothing is done beyond replacing dead trees from time to time, the trees under municipal control are well looked after. These trees do not shed their leaves so soon as the trees at Paris, the mean temperature in summer being lower at Berlin than it is with us. All the side walks are not composed of impervious asphalt, but many of them are made with a road metal which allows the rain water to sink through its interstices. Besides the waterings which are given in the basins hollowed out at the foot of the trees, as at Paris, the following plan, which appears very suitable for large towns, has been devised: Around each tree and at some distance from the base of the stem small well-like excavations are made, and the inside of each is lined with earthen tiles, the sides of which are perforated with holes. These tiles are set vertically, their ends being closed with plates of cast-iron like those used for stopping up the ends of water pipes or gas pipes. When the tree is to be watered, the well-like excavations are filled and the water is thus distributed exactly on the outside of the circle, where the rootlets of the tree occur. In this way a saving of water and of labour is effected.—*Revue Horticole.*

## FLOWER GARDEN.

### WATER LILIES.

THE appreciative note from Mr. Greenwood Pim respecting these lovely flowers, particularly his request for the experience of others with the varieties of *N. odorata* and the hybrids raised from them, has induced me to pen a note *re* the family in general, and combine therewith the results of my observation.

In the early part of 1896 I was favoured by the publication in THE GARDEN of a few somewhat emphatic notes regarding what I concluded to be essential conditions for success with these Lilies, although the primary object of those notes was an endeavour to point out the fallacious ideas existing that *Nymphaeas* would thrive anyhow and anywhere in water. I do not remember on what date these notes appeared in THE GARDEN, but I recollect the circumstance that they followed immediately after Mr. Greenwood Pim's eulogistic account of his first experience of the hardy members of the genus. Perhaps it may interest to repeat the opinions expressed respecting these varieties of *N. odorata* and the hybrids with an infusion of *odorata* "blood," and to recapitulate the principal points of those notes.

In the summer of 1894 I planted and flowered what I thought was at the time a comparatively unknown hybrid in *N. o. caroliniana*, and, personally, considering it amongst some two dozen species, varieties, and hybrids of *Nymphaea* and *Nuphar*, to be the most beautiful I had flowered, I endeavoured to draw attention to it in the notes I forwarded, adding to my opinion of its beauty the provision that it required additional seasonable warmth which I believed absolutely necessary for all the varieties of *N. odorata*.

Probably a description of the conditions under which these *Nymphaeas* were grown will afford a better idea of how varying were the circumstances conducive to their welfare; first, an open pond some 9 feet below ground level, made by enlarging and dredging a disused gravel pit. This pond, some 50 yards by 10 to 15 yards, had a level of water which was constantly fluctuating, owing to percolation through its gravel bed of the outer river water; consequently, owing to this subterranean circulation, the temperature of the water supply was always

varying. In this various native aquatics were more or less at home, particularly, on the sunny side, *N. alba*. The Cape Pondweed thrived surprisingly, but our native species of *Villarsia*, collected by myself in its Thames home from 9 feet depth of water, was never in such happy condition as in the river bay where it was luxuriant. In this pond I planted eight or nine divisions from my first plant of *N. M. Chromatella*, but they were scarcely recognisable compared with the original in position—No. 2. My first plants of the finer and less common aquatics were accommodated in an open break of water between a somewhat elongated concreted bog bed, the water supply of which was utilised for the working of a very small spray fountain. In this, *N. Chromatella* grew magnificently. *N. alba*, sent to me as *N. candida*, flowered profusely, and its seedlings appeared literally by hundreds in its second season. *N. odorata* never seemed to thrive at all; its variety *rosea* grew well, but never flowered, and the same may be said of *N. o. sulphurea*. The Pickerel weed, planted round the base of the fountain, grew rampantly, likewise our native *Bladderwort*, *Villarsia*, *Water Soldier*, and *Frogbit*; but one thing I could not fail to notice was that the longer time the fountain was stopped—although its capacity was less than three gallons per minute—the better these aquatics seemed to thrive, and this circumstance led me to infer that higher temperatures were necessary for some of these plants, *Nymphaeas* in particular. With the object of obtaining this essential, a third tank was made. This tank, about 60 feet in length by from 12 feet to 16 feet in width, was made in a position assuring the power of every ray of sunshine, a position where, on the northern side, shelter—a great help to good results—was afforded by tall conifers and a 10-foot wall not far behind them. On the bottom of the tank, from 1 foot to 1½ feet of turf with a small quantity of manure added was placed, which allowed when the tank was full from 1½ feet to 2 feet of water above the crown of the plants. In this provision there was nothing different from that adopted in the first planting, except, probably, slightly more shelter, but in the subsequent treatment of these Lilies I believe I found that which may account for the vast improvement they made, and in which also Mr. Greenwood Pim may discover the reason why the *odorata* section in particular fails. I do not wish to leave an impression that the treatment I adopted will so alter the nature of some of these varieties and hybrids that they will vie with such as *Chromatella*, *Laydekeri rosea*, *pygmaea* and its offspring, *Helvola*, in freedom of flowering. It would be unwise to do so, recognising the fact that some of the species are not profuse in flower, and that a transfusion of blood of two species of similar character, although producing a variety of coloration, may not always be conducive to a prolongation of the flowering of their offspring.

If I remember rightly, I planted directly into the soil some fourteen different kinds, maybe one or two in duplicate, in this tank, and after allowing them to start in about a foot of water the tank was filled to its utmost capacity, and during the whole of that, a roasting, summer the only additional water which was allowed intentionally to enter the tank was admitted with the sole object of replacing that evaporated by solar heat; moreover, this fresh addition was always thoroughly sun-warmed before its admission from tank No. 2, on a somewhat higher level. It is obvious from this that my object was the retention of all possible warmth by excluding water of a much lower temperature than that contained therein, and how far

I succeeded may be judged from the fact that, although I never made a record of the temperature, there were days during which the upper portion of the water was positively hot, a condition which would have been impossible to obtain with a current of colder water constantly flowing through.

Now, as to the growth of the particular *Nymphaeas* which had failed in tank No. 2, I moved *N. o. rosea* and *sulphurea* into this new position, where, without the occasional playing of so small a fountain, before the summer was past *sulphurea* was almost as robust in foliage as *Chromatella* and had flowered profusely. *Rosea*, too, had grown amazingly in comparison with what it had done, and surprised me with the number of flowers it bore. Marliac's selected *sulphurea* variety *grandiflora* bore the largest *Nymphaea* flower I have seen in its first season in this tank, where the massive yet beautiful flowers of *carnea*, *albida*, and *rosea* were revelations in water garden progress. *Chromatella* did not equal in its first season the original plant under the other conditions. *N. o. rubra* and *exquisita*, very small when received, made fine plants and flowered well before the arrival of cooler weather; while the almost crimson *Laydekeri rosea*, *pygmaea*, and *p. Helvola* surprised with the profusion of their flowers, and under these conditions *N. caroliniana* impressed me as the prettiest Lily of them all.

It may seem strange there were two plants of the rose variety of *N. alba* included in the planting of this collection, which, much as they might be acceptable owing to their price and comparative rarity, were by myself greatly begrudged the room they occupied, lacking, as they did, any claim as water garden ornaments; yet I am convinced that, although heat is an essential in the growth of some, these particular varieties would have displayed their characteristics more fully in cooler quarters. They would have been more at home in association with the typical *N. alba*. As to the

### HARDINESS

of these Lilies, there can, in my mind, be no doubt if this warmth in season is afforded them, or if something like a steady water temperature is aimed at, for I believe there is something in this conducive to what I may term a ripening process in their particular way. If we recognise such a condition of growth in vegetation on terra firma, why not in aquatic life? though I confess it difficult indeed to say whether some of these hybrids rest at all during a mild winter. However, the fact remains that Mr. Greenwood Pim tells us of the failure of *odorata* vars. to survive in water constantly agitated and, I infer, fluctuating in warmth. For my own part, so far from chronicling a loss, I can say that I could have stocked three or four more tanks with divisions of these plants the second season after planting with the exception of *Laydekeri rosea* and *pygmaea*, which, as is well known to cultivators, are not prolific in affording offsets. The only loss I can record was the non-survival of *N. odorata*, which I left in tank No. 2 during the frost of 1895, and, by the way, masses of Pickerel weed were killed in the same place, but not a plant was injured in the place where these Lilies were also untouched. *N. pygmaea*, *N. sulphurea* and *N. Chromatella* I have had frozen into, as one might say, solid blocks, not by design, and I could not see that they were affected.

It has been my experience to see these *Nymphaeas* in every conceivable condition, thriving in sunken tubs, languishing in running streams, and I have seen the survivors of a small collection which were thrown into something very

like a well, but I can honestly say that nothing gave better results than the "dead" water system, not even the protection of a tropical house, as at Kew.

Although circumstances have placed me in, to use a parliamentary formula, "another place," and I am not in contact with these lovely lilies, I shall always be pleased, believing as I do in the possibilities of a future water garden, to advise their cultivation and to deprecate the idea that aquatics require to be deluged or, as have observed, planted under an arboreal umbrella.

J. BLENKINSOP.

Wateringbury, Kent.

CONTINENTAL NOVELTIES.

M. ERNST BENARY includes among his novelties the following, descriptions and illustrations of which we herewith give from his catalogue :

**LEPTOSYNE STILLMANI** (ASA GRAY).—This beautiful Californian annual comes from the Sierra Nevada where it (seed of which has not hitherto been offered) grows at a height of from

Anglonia grandiflora alba.

4000 feet to 6000 feet. With graceful thinly-cut foliage and growing about 1 foot high, the habit of the plant is bushy and compact, and each of the numerous flower-stems is crowned with a splendid golden-yellow blossom, of elegant shape and over 1½ inches in diameter, which remains five to six weeks in full beauty. A characteristic of this Leptosyne is that it blooms from four to five weeks after sowing, surpassing in this respect almost every other annual. It is best to sow in the open air in sandy ground in a sunny situation. This fine Leptosyne will be found excellent for cutting and making striking groups.

**MYOSOTIS PALUSTRIS** TOM THUMB. This is quite a pigmy form of the widely known Marsh Forget-me-not, the plants forming little tufts, like *Spergula pilifera*, from whence springs an abundance of delicate sky-blue flowers. It

comes true from seed, blooms uninterruptedly from May until frost comes, and is admirably adapted both for borders and for pots.

**ANGELONIA GRANDIFLORA ALBA.** The type is a graceful sweet-scented greenhouse plant and bears lilac flowers, which appear the same season as the seed is sown. The white variety is far more beautiful than the type, its extremely numerous pure white flowers standing out in handsome contrast with the elegant dark green lanceolate foliage. This beautiful new plant is especially adapted for room or conservatory decoration, being a good winter bloomer, and it also makes a charming ornament for the table.

**Cactus Dahlias.**—In THE GARDEN for November 20 (p. 401) W. E. Endicott writes as to confusion caused in America by the tendency of exhibitors regarding the decorative Dahlias as Cactus varieties. As he is anxious to remedy this condition of things, he inquires for a list of true Cactus Dahlias. The following is a list of true Cactus Dahlias drawn up for 1897. As so many new varieties are sent out every year, this list will be subject to annual revision: Annie Jones, Apollo, Beatrice, Beauty of Arundel, Beauty of Wilts, Bertha Mawley, Blanche Keith, Charles Woodbridge, Countess of Gosford, Cycle, Delicata, Earl of Pembroke, Ernest Cannell, Fantasy, Fusilier, Gloriosa, Harmony, Henry Stredwick, Iona, Irene Cannell, J. E. Frewer, Juarez, Kaiserin, Keynes White, Lady Penzance, Mary Millier, Matchless, Mayor Haskins, May Pietor, Miss A. Nightingale, Mrs. A. Beck, Mrs. A. Peart, Mrs. Barnes, Mrs. Francis Fell, Mrs. Gordon Sloane, Mrs. H. Cannell, Mrs. Leopold Seymour, Mrs. Montefiore, Mrs. Wilson Noble, Professor Baldwin, Purple Prince, Robert Cannell, Royal George, Starfish and Violet Morgan. — C. F. KEEP.

**Imported Lilium auratum.**—Immense numbers of the golden-rayed Lily reach this country from Japan. The earlier importations if sound realise, as a rule, good prices, but as a set-off to this must be taken into consideration the fact that the attempt to get them here early sometimes results in the loss of a considerable number, if not the whole of the importation. This year a large quantity was announced for sale on November 10, but upon opening them it was found that they were in too bad a state to offer. Such being the case, the importation disposed of on November 30 must be considered as the first of this season. The bulbs taken altogether were in a very satisfactory state. In a general way, however, the earliest bulbs are not the best, doubtless owing to the fact that they are not allowed to ripen thoroughly before packing. Such being the case, although an advocate of the early potting or planting of Lilies, I feel sure that of those imported from Japan the bulbs obtained about Christmas are likely to prove more satisfactory than the earlier ones.—H. P.

**Solidago virgaurea nana.**—This is mentioned on page 453, and it fully deserves the favourable notice there taken of it. It is sometimes offered in catalogues with the addition of *compacta*, which is, though true, superfluous. It must not, however, be confused with the *S. virgaurea* var. *cambrica*. I have collected dwarf specimens on ledges of rock high on the mountains of North Wales, which in cultivation either exalt their stature or produce seed which does so, and I have been doubtful whether these have really been var. *cambrica*, though that variety is said in Sowerby to grow on ledges of rock on mountains in North Wales. What I believe to be the true var. *cambrica* grows abundantly in the valley of the Lledr, near Bettws-y-coed, and has been sent to me from there by Mr. Buxton, Bettws. It is, however, not only less dwarf than var. *nana* of gardens, but bears its flowers rather in spikes than in panicles. The var. *nana* came to me at least twenty years ago—I think from Mr. Harpur-Crewe under the name of *Cineraria alpina*, and I soon found it to

be a valuable rock plant, though the name was corrected for me on the best authority. It differs from var. *cambrica* in being never more than 6 inches high, in flowering very early, beginning in May, in having a broadly-branched panicle, very full of flower, and in coming quite true from seed. It is one of the best of plants for alpine rockeries. I may add that it hardly increases its stature even in a border of rich soil, but becomes more leafy and less flowery.—C. WOLLEY-DON, *Edg. Hall, Malpas.*

FLOWER GARDEN NOTES.

**PLANTING HERBACEOUS BORDERS.**—The best way to plant borders of hardy flowers, that is on a large scale, when the object is to provide a

Myosotis palustris Tom Thumb.

general mixture of things, has often been discussed in THE GARDEN, but it may not be out of place to offer a few remarks on the subject at the present time when in the majority of places any such work that has been contemplated will doubtless be in full swing. I note above in the majority of places, because there are objections, and naturally as an outcome exceptions, to autumn planting, notably on stiff, heavy land where it is pre-

Leptosyne Stillmani.

ferable to incorporate a goodly proportion of lighter material with the natural soil and turn it up, leaving it in the rough to be pulverised by frost, planting as early in the new year as the ground is workable. Here, on the other hand, with a light soil and sand not far from the sur-

face, I find autumn planting much the best, a recognised rule also being to plant firmly and to mulch at once and heavily. The desirability of any regular edging of flowers will depend on the natural edging of the border: if it is grass, nothing more is required, and the respective clumps of dwarf plants can come down to the same. If, however, the borders are in the kitchen garden and the walks are edged with tiles or material of a similar nature, then I think a live edging just inside the tiles is advisable, and have personally used for the purpose the old double Chamomile, the green and silvery Sedums, and the two forms of Ajuga reptans, from all of which spring in the early season masses of Crocus in different shades. The only objection to a dense edging of this description is that weeds are troublesome, but a good cleaning twice a year in late autumn and spring is generally sufficient to keep them under. If the borders are of good size, say 7 feet or 8 feet across, the several clumps can be large enough to show off the different plants to the best advantage, 4 feet in length by 2 feet 6 inches in depth being a very good size. Carnations, Pinks, dwarf Campanulas, Veronicas, Tufted Pansies, Iberises, and Linums are among the plants that can be utilised to form the first set of clumps, remembering that if a good display is the principal consideration, well-known plants that can be depended on to give a mass of bloom and to last out well alike in flower and foliage are preferable to others that may be more rare, but that either do not flower so freely or that are comparatively short-lived, whilst with the same end in view the planting should be fairly close rather than thin. Objection is sometimes raised to planting bulbs on such borders, but I think occasional clumps of early-blooming things should be admitted, as they help to make the border bright when other flowers are scarce. They should be planted deeply, and a batch of some dwarf annual, as, for instance, Portulaca, raised to plant on the surface when the bulb foliage is gone. The number of species available for selection for the central part of borders, those for instance that range from 2 feet to 4 feet in height, is so large, that it is impossible to enumerate them all. A few indispensable are the dwarf Phloxes, Pyrethrums, Pentstemons, Lobelias, some varieties of Lupins, Lychnis, Coreopsis, the dwarf Starworts, and others, the selection, it will be seen, being based on the same principles as for the dwarf subjects, and the clumps may be of the same size, or perhaps a trifle larger. The inclusion of such moisture-loving plants as Spiraeas, Irises, Trolliuses, and the like will depend entirely on soil and situation. They are nothing like so satisfactory with me on the open border as in a damp, partially-shaded place, nor does extra attention in the way of a stiffer compost with heavier mulchings benefit them to the extent required. A little care is necessary in the formation of the central portion of the border to see that these clumps are in keeping with the dwarf subjects immediately in front of them and the taller that are to come behind, also to distribute the various flowering seasons well—that is not to group several species or varieties of the same flowering season in close proximity, or the result will be occasional big gaps in the otherwise continuous show of flower.

In case of acquiring occasional plants that are quite or nearly—at any rate, so far as the herbaceous border is concerned—the sole representatives of a species, put them on some small, snug border that has been specially prepared for them until the stock can be increased—such things, for instance, as Stokesia cyanea, Romneya Coulteri, Senecio pulcher, and Tiarella cordifolia. No difficulty is ever found in providing for the back of borders, the many varieties of Starworts and Helianthus, together with Solidago, the varieties of Chrysanthemum maximum, and similar things furnishing a plentiful supply: it is well, however, to give the reminder that with the number available the best things should be selected to the exclusion of rubbish. In connection with all the

species named for different positions, it is gratifying to note the ease and rapidity with which they can be increased either by cuttings, layers, or division, and this is a point worth remembering when planting on a large scale is contemplated, especially if a start is being made with hardy flowers and everything has to be purchased. Under these circumstances I have heard the remark on more than one occasion, "We had no idea that a collection of hardy plants would cost so much." The remedy, as indicated above, is easy to find. Planters should anticipate their wants, and, instead of purchasing plants to fill large borders throughout, should acquire in the previous season something like one-tenth the quantity of each particular species or variety required, plant them in some well-prepared border, look after them thoroughly well, and, from the time Carnation layers and Pink pipings or layers are ready, be busy propagating. It is astonishing the amount of plants one can obtain in a season in this way, all, too, without protection in the way of glass or cost in fuel, save, perhaps, a cold frame and a few mats to keep out frost. The greater part thus obtained may not be ready for planting until the following spring, but it will be good stuff, flowering well the first year.

Claremont.

E. BURRELL.

#### NOTES ON HARDY PLANTS.

**Pyrethrum uliginosum.**—Referring to "J. C. B.'s" remarks (p. 400), he takes quite a wrong view of what I said about this coarse-growing plant, and for once I must reply by way of argument. We all know about the vigorous habit of the plant; indeed, it may be said to be a plant that will grow anywhere. Further, my remarks implied that the very vigour of the plant was the cause of the want of flowers—good flowers—which was the one and almost only point of my note. If "J. C. B." will read my note again, he may find out his error, for obviously no one who has grown the plant could ever write about the want of root vigour of this plant. I scarcely need say that my notes are written with the assumption that GARDEN readers know ordinary plants and their habits; hence it was not needful to mention the habit of this plant only in relation to the fact of occasional failure of its usual fine late crop of flowers.

**Polygonum sphærostachyum.**—It may be to the advantage of this plant, and I feel sure of some interest, to give my experience of this rare and lovely Knotweed. Whilst I know many have failed to keep it, perhaps more have failed to grow and flower it well for a number of years in succession, *i.e.*, the same individual. Here it flourishes year after year, seeds well—well in the sense that it germinates freely when sown in pans—so that I am never without plenty of it. Far be it from me to claim any special skill, but to make this note practical I give also the conditions under which it thrives. Almost the whole secret, if it is one, is told when it is said that here it is treated as a bog plant; the soil loose and springy. A sunny place I think in connection with a damp root run is to its advantage. Three-year-old plants flower all the summer. I find, however, that the earlier flowers yield but little or indifferent seed, and I never collect it now, but depend on the midsummer flowers. Seed, well ripened and sown at once, often germinates in the autumn. That, however, is inconvenient if one cannot grow the plants on, which implies housing the pans. So I now take the spike entire and leave the seeds in the husks, so as not to get scorched when placed in the sunshine. This plan, I have fancied, retards germination, as well from the mere lapse of time as by the harder ripening of the bulky seeds. I consider this of some importance, because when you have got what seems to be, and really is, a lot of good seed, if it cannot be grown before winter into what I may term a perfect (if small) plant, it simply dies. What I mean by a perfect plant is a plant so much and timely grown, that you get the tuberos development of the root in which to

carry the life germ through the winter. I took the hint as to the preferences of this plant from the behaviour of my original plant of ten or more years ago. With all plants the knobby root grow long or somewhat rhizomatose in the form of a turned-up pot-hook or the letter J, the shorter turned-up limb being the thicker and sprouting point, and in time I have seen the longer upper point rise above the surface in a attenuated condition. This habit suggested to my mind that the plant loved a moist, but rich vegetable soil and to dwell near the surface, and I am now quite sure moisture and humus suit it, and that an annual mulch of rotte leaves may induce it to get stronger year by year. I may also add that I have propagated by root division. This I did before I found I could rely on good seed every year. My plan was to bar the root-stock of the stronger specimen, which then grew in the gutter of a bed on grass. Several cuts half way through the rhizomes were made on the under side about June, the soil was replaced, and by the following spring the sections were found to have each an eye or break. At that time they were broken asunder and planted separately, and with the summer before them they furnished me with my first batch of stock. This plant flowers with me from June to November—at least it has done so this season.

**Polygonum amplexicaule.**—The Rev. Mr. Wolley-Dod states this is, I think, almost as fine in colour as the above rarer species, the spike being bigger and rather more lax, and until a few days ago it was abundantly in flower, having been so from July. It is the habit of this species that makes it so unfit for the more conspicuous border, and yet you cannot easily find more useful material for cutting. The carmine-red in itself is at once effective, pleasing, and uncommon; the spiky form of the flowers fits them so well for vase work. It is one of the most telling things for the Michaelmas season. Unfortunately, very different plant often does duty for it in trade lists, a tall plant with very late white flowers. I have experienced these errors with both home and foreign nurseries.

J. WOOD.

Woodville, Kirkstall.

#### NOVEMBER IN THE GARDEN.

TO-DAY has come the first touch of winter. A keen wind blows from the north-west, a shower of sleet has just swept by, and the sun breaks from beneath a cloud, while the last golden leaves on the Apple boughs glisten against an inky sky, and the stems of trees, Lichen-clad and still wet, gleam in the sun's rays. Now that the wind brings with it the surge of the waves as they beat on the shore we count as joy gone from us the days of gentle air and pleasant sunshine with which until now November has unfolded us. Only last week the feathery Bamboos were swaying in the soft south wind. The night breeze was fragrant with the blossoms of the white Nicotiana, a thrush was singing in the wood, and the starlings were sounding their tiny castanets in the tree tops. Let us look around the garden and count our treasures ere they are hidden from our sight by snow wreaths.

Brightest of all with their firelight glow are large groups of *Schizostylis coccinea*. These have been sending up their spear-like blossoms for the last two months, and are now radiant masses of bloom. When torn ruthlessly asunder every couple of years or so in spring-time and replanted in clumps 2 inches or 3 inches between each divided portion, the increased vigour is remarkable. Treated thus, the spikes of blossom are tall and strong, and continue in succession for a considerable time, lighting up whatever part of the garden is fortunate enough to possess them in the darkened daylight hours of winter. In replanting,

some leaf-mould or well-decayed manure should be added to the soil, and sand if necessary, as they flourish best in rich, friable ground where they will find moisture in summer. Next to the *Schizostylis* in brightness come the *Fuchsias*. The various hardy species of these planted permanently in the borders are beautiful in autumn until cut off by frosts. Their persistent glossy leaves bear the rude winds without harm, and their charming blossoms glisten in the sunlight with a most delightful freshness, for ere it withers the habit of the *Fuchsia* is to let fall each dainty flower. Permanent beds of *Fuchsias* might well be made with bulbs planted among them, so that they would be gay in spring-time before the *Fuchsias* are well awake. Some leaf-mould spread round their base will protect the roots from frost, and should the stems be killed by the winter's severity, when cut down in spring-time they will sprout again from beneath.

The Monthly or China Roses, the old favourites of days gone by, are well in blossom still. They are a lovely race, quite a garden in themselves, and the only really "perpetual" Roses we have, as there is hardly a month in which you will find them without either bud or blossom, and their shining evergreen leaves are so cheerful in dull, wintry days. The pink Monthly Rose is the one best known, never failing to give us the earliest and latest bunch of Rose buds. But besides this well-known favourite there are many other varieties of vivid hue crimson, carmine and rose, and some with a blue metallic lustre in their leaves which is lovely in itself, even if they never added a Rose to the picture. As well as their constant habit of bloom, the China Roses possess a power of endurance which does not belong to the hybrid varieties. This fact is proved by their being found still healthy in old gardens, where it is known they were planted fully half a century ago. As they do not require the gross feeding of other Roses, they make good permanent beds, and among them spring bulbs can be planted with success.

The early *Chrysanthemums* are just over. The yellow kinds, such as *Gustave Wermig* and *Mrs. Burrell*, were beautiful among the *Asters* and *Michaelmas Daisies* and beside the great white *Daisy* (*Pyrethrum uliginosum*) and the starry *Marguerites*. Now the bolder crimson kinds, such as *W. A. Holmes*, are in bloom and light up marvellously at eventide, touched almost to fire by the sun's last rays.

Just gone from us also are the blue African *Lilies* (*Agapanthus unbellatus*). The wet summer was much to their liking, the flowers being plentiful, as many as sixty-six flower-heads being in bloom together in the two beds. The lasting power of these *Lilies* is valuable. The beds were quite beautiful for two months, and the flowers when cut just as they are expanding will last fresh for some weeks. The beds in which they grow have been undisturbed for several years, but each November the *Lily* stems are well covered up with leaf-mould and some branches of *Yew* stuck among and bent over them as protection from the frost. In the month of May, when the *Yew* branches have been gradually all removed, plants of the blue *Daisy* (*Agathæa ecclesiæ*) are placed among the *Lilies*, as they come into blossom much earlier and are of the same lovely shade of blue.

But if the *Lilies* are gone from us, we have still some bits of "true blue" in the garden. The flowers of *Plumbago capensis* nestle amid their leaves, that bear the ruby touch of autumn. Over the perennial *Flax* its blue butterfly blossoms yet hover, and on *Salvia patens* are yet blossoms clinging like blue

perennants to a mast. *Doronicum Harpur-Crewe*, divided in spring-time, has now a second crop of flowers much larger than the earlier flowers; in fact, they measure 4 inches across, and if cut when just expanded, last well indoors, where their gold rays are precious in the shortened hours of daylight. To ensure this fine autumn growth, the old flowering stems of early summer should be cut or pulled away, so that all the vigour may go to the forming of fine young crowns. Annual division is also needed to have this plant in perfection.

On the garden wall hangs the winter *Jessamine*, its drooping sprays like a shower of gold, down which the blossoms creep. This *Jessamine* requires freedom of growth to look its best, and as it bears its finest flowers on the fresh shoots of the year, it should be pruned just after flowering, before new growth begins, and then it needs only the removal of superfluous wood.

The *Myrtles* are still in flower. *Choisya ternata* has an autumn bloom, while at our feet the *Christmas Roses* are uprising and *Violets* and *Oxlips* are in blossom, so the garden, at least, bids us forget that we are within two days of bleak December. A. L. L.

#### DISEASE IN LILY BULBS.

My attention having been drawn to an article which appeared a few days ago in one of our daily papers, I should like to say a few words regarding this so-called Lily disease (*Rhizopus necans*) referred to in the *Kew* bulletin. This disease has been known as long as *Lily* bulbs have been exported from here, and the results have been sometimes very disheartening for the consignees as well as for the shippers, but of losses like those referred to in the article before me I have never heard. I imagine that the great loss is probably the result of some Japanese or other speculators, in order to catch best and fancy prices, shipping at the wrong time of the year. The climate of Japan is such, that during and after the hot and sultry summer months, July, August, and September, during which we have from 85°-95° Fahrenheit, the rainy season sets in which produces—easily imaginable—a real hothouse temperature, the air being saturated with moisture, which is splendid for growing, but not for harvesting field products. The moisture is so great, that not only out-of-door things get affected by fungoid formations, but even in our houses—clothes, books, shoes, &c., in short, everything which is not in daily use.

It is, therefore, easily imaginable that during such a season, bulbs taken out of the field and imperfectly ripened, if packed into boxes and shipped through the tropics to Europe, must be affected by fungi, which have during a two months' voyage on board a steamer, sometimes close to boilers, sufficient time to do their deadly work. The danger would not be so great if the bulbs could be brought from the fields into the boxes without injury. This seems, however, impossible. Even with the greatest care, with such tender articles, a little injury to their scales is unavoidable. This is generally the beginning of the fungoid diseases, which very soon take hold of the whole bulb. However, after this sultry weather the autumn season sets in during October, with fine dry days, warm during the daytime, but brisk and refreshing during the night. The earth gets dried, the season for harvesting being regulated by Nature itself. The *Lily* bulbs are now perfectly ripe and dormant, and in a proper stage for export. The climate being dry and cool, any bruises the bulbs may receive during the handling will dry off and heal quickly, and satisfactory consignments will be the result. There are also a few very tender varieties which even the most careful treatment will not protect against the hardships of a long voyage through such different climates as the route over India, the Red Sea, and the Suez Canal offers.

Taken, however, as a rule, the results will be satisfactory, as I can prove by hundreds of letters and testimonials which I have received from customers.

I therefore claim that unsatisfactory results are not on account of a disease the bulbs possess when they are shipped, but simply the result of several factors which, taken all together, must ruin these lovely plants. I recommend, therefore, the following remedy: First, place your order with a respectable firm—one which knows the business; second, do not give instructions, if possible, regarding time for shipment, but leave this to the shippers, who will guard your interest and will know best the time the bulbs are ripe and the best time for packing and shipping; third, try to induce the steamship owners of Eastern lines to provide a few steamers during the principal export season, with cold storage arrangement, to get the shipments through the trials of change of climate, and I will guarantee that the bulbs will always arrive in the best of condition and not infected by any disease. A. MEYER.

Yokohama.

#### RANUNCULUS ACONITIFOLIUS PLENUS.

ONE of the most important items in connection with the success of this plant under cultivation is planting it at a seasonable time. Many plants, the more vigorous and continuous-rooting perennials in particular, may be successfully planted at almost any season of the year. There are others, however, including this plant, that should be planted at the right time. Like many other members of *Ranunculaceæ*, this pretty herbaceous kind, well known by the familiar name of *Fair Maids of France*, sends out its long tapering fleshy roots horizontally from the crown. In single tufts the roots often radiate all around the crown. When such things are replanted in full growth, these roots are usually gathered in bunches in the hand and laid into a spade-cut trench, not infrequently to perish, as little or no soil comes between them. A much better way than this would be to open a hole a foot across, and, having carefully laid out the roots in a natural way, to replace the soil about them. Better still, plant the roots as early as possible in autumn, or at any rate while the crowns still remain in a dormant condition. With the soil deeply dug and manured, a good group may be planted thus: Remove the soil to about 4 inches deep for a space of 2 feet across, or as large as the material at disposal will allow. Place in the crowns at 6 inches apart, spreading the roots out horizontally, covering again gently when all are thus arranged. If the soil be wet, much treading should be avoided, but a fair firming with the fingers about the roots may be indulged in with advantage. If a shady and quite moist spot is available, such a place will suit this plant as well as the single or typical kind. Indeed, the latter plant possesses quite a fairy-like appearance when fully established in semi-boggy places, the plants being literally covered with snow-white flowers for weeks together. E. J.

**Herbaceous Lobelias.**—When writing my note on these plants (p. 362) I had no intention of laying down the law as to their winter treatment in soils and climates differing from those in which my experiences have been gained, and have no doubt but that "A. D." is a far better judge of their requirements in his locality than I should prove. The intention of my note was to emphasize the fact that light soil and freedom from severe frost did not ensure safety to plants left to winter in the open ground, and that when I lived in a locality where both of these conditions obtained in a marked degree, I was unable to preserve the plants even during a frostless winter. In dry and wet seasons the result was the same, and I had great difficulty in keeping up a stock, although I used to winter some in boxes in cold frames, as described by "A. D." and others, by potting single suckers in 2½-inch pots and growing them in the greenhouse. In my present gar-

den, however, where, as I mentioned, the *Lobelias* are growing in damp, heavy loam close to water, and where the winter temperature has on several occasions fallen 12° below the lowest temperature registered in my former garden, the plants appear absolutely hardy. They have often been divided in October and have never had the slightest protection in the way of mulching, while they stood the long-continued frost of 1895 and 21° of frost for two nights in 1893 with impunity. Without the experiences I have detailed I should most certainly have given my vote to the light soil and warm nook on the banks of the river Dart, as more suitable to the wintering in safety of the herbaceous *Lobelia*, than the damp, heavy soil and severer frosts of probably the coldest winter garden in the Torquay district, as hardness is not induced by light soil and warmth, but is seemingly in Devonshire by heavy soil and greater cold. I should advocate others, even though they live in colder counties, experimenting with a portion of their plants by leaving them in the open for a winter, when it may be that they will give them a pleasant surprise by proving hardy under this method of culture. In cases where this method has been tried and has failed, as in "A. D.'s," I should be the last to advocate its being persisted in.—S. W. F.

## TREES AND SHRUBS.

### RETINOSPORAS.

FROM a horticultural rather than a botanical standpoint, the different *Retinosporas* alluded to on page 430 under the heading of "A False Genus" might well be allowed to stand, as cases of reversion to the normal form are in most instances so rare that they need not be taken into consideration as far as the ornamental qualities of the plant are concerned. The fact, however, that nearly all the *Retinosporas* might be traced back to two species only has been now recognised for years, and notes on the subject have from time to time appeared in *THE GARDEN*. Our botanical authorities have been by no means of one accord with regard to the position occupied by the *Retinosporas*, for while they are in the above-mentioned article and in the Kew list referred to under the head of *Cupressus*, a few years ago they were regarded as belonging to the genus *Chamaecyparis*, and one authority at least included them in the genus *Thuja*. The differences of opinion do not end here, for, while the word is generally spelt *Retinospora*, it is altered at Kew to *Retinispora*. This last spelling is of recent adoption. One can readily understand that the *Retinosporas* known as *R. lycopodioides* and *R. filicoides* are but varieties of *R. obtusa*, for they do not differ from each other or from the type to a greater extent than is the case with some of the numerous forms of *Cupressus Lawsoniana*. *R. squarrosa* furnishes in this respect one of the greatest surprises, and that it is but another stage of *R. pisifera* seems at first difficult to believe, as the comparatively long spreading, greyish green leaves of *R. squarrosa* do not appear at all related to the small scale-like foliage of the other. Instances, however, have occurred, though rarely, of *R. squarrosa* producing fruiting branches which were indistinguishable from those of *R. pisifera*.

The origin of such a form as *R. squarrosa* is to be accounted for in this way. When conifers are raised from seeds, the first leaves are long and needle-like, and in many cases they bear no resemblance whatever to the foliage of an adult plant. This character is especially noticeable among Junipers, Cypresses, and the different forms of *Arbor-vitæ*, which bear long

pointed foliage when young, succeeded by small scale-like leaves closely adpressed to the branches. In seedlings even from the same source there are great individual differences as to the time and size of the plants before they assume their adult character, some quickly breaking away from the seedling state, while others remain a long time and reach a good size before doing so. If cuttings are taken from a plant that shows a disposition to retain the juvenile character of its foliage longer than the others, they will often grow some time without showing any disposition to produce the small scale-like leaves of the adult plant. *R. squarrosa* thus doubtless originated as a seedling from *R. pisifera*, its peculiarity being the fact that the juvenile foliage only is produced, except on such rare occasions that need not be taken into consideration in estimating its ornamental qualities.

On p. 430 it is stated that all the *Retinosporas* belong to *Cupressus*, and are all forms of *C. obtusa* and *C. pisifera*, but such is not the case, as the dense growing *R. ericoides*, with pointed leaves arranged cross-ways on the branchlets, is nothing more nor less than an undeveloped form of the Chinese *Arbor-vitæ*. This has been shown in one or two instances by the production of a fruiting branch, which differed in no respect whatever from the *Arbor-vitæ*, while never by any chance has the plant in its ordinary form borne fruit.

A *Retinospora* that has caused a good deal of controversy is *R. leptoclada*, which is said by Gordon to be a native of Japan. This statement is now conclusively proved to be an error, and *R. leptoclada* is believed to have originated at Andelys, in France, among some seedlings of *Cupressus thyoides*, or *Chamaecyparis spheroides*, as it is often called. The general appearance of the plant would suggest that it is a form of the last named. *R. leptoclada* is certainly a very pretty little shrub, bright and cheerful at all seasons.

A form of the American *Arbor-vitæ* (*Thuja occidentalis*) usually met with under the name of *Thuja Ellwangeriana* is remarkable from the fact that the process of transition can be readily traced, for, as a rule, the lower part of the plant is clothed with the long spreading leaves, while the topmost branches, with their small scale-like foliage, differ in no way from the American *Arbor-vitæ*. This *Thuja Ellwangeriana* is often classed with the *Retinosporas*.

T.

**Berberis Thunbergii.**—Your correspondents do well in calling attention to this shrub, for even amidst a wealth and variety of beautiful autumnal tints it surpasses in brightness almost anything in dwarf shrubs, large groups of it on dry banks and among rocks being especially conspicuous. It takes on colour early, and if occupying sheltered positions the fading leaves are very persistent, thus making a bright display for a prolonged period. It is easily propagated; cuttings of ripened shoots inserted (now) in the open in light soil strike root as freely as Currants.—J. R.

**Desfontainea spinosa.**—The illustration of this charming Chilean shrub as growing in Major Gaisford's garden, Offington, Worthing, which appeared in *THE GARDEN*, January 16 of the present year, is sufficient to make one long for such a climate as that of this well-known southern watering-place, for the *Desfontainea*, which is now in bloom in several places, is in this stage totally distinct from any other shrub that we have, though when out of bloom it might readily be mistaken for a variety of Holly. Where it is not sufficiently hardy this *Desfontainea* may be treated as a greenhouse plant, but it is not very amenable to pot culture, though if plunged out of doors when frosts are over and allowed to re-

main till the autumn it will, as a rule, succeed fairly well. Of course, regular attention in the matter of watering and other details will be needed. The flowers of this *Desfontainea* are drooping, nearly a couple of inches long, and of a thick wax-like texture, their colour being bright scarlet, tipped with yellow, somewhat after the manner of a *Blandfordia*.—H. P.

**Autumn tints.**—One point that may be useful to "K." (p. 385) in the planting contemplated is that indigenous trees are finer in their autumn dress than exotics. There are exceptions, but this may be taken as a rule. I mean, for instance, that, given a score of exotic trees in variety, the majority would not produce autumnal effects approaching those to be seen on the Oak in great variety, Beech, Birch, and others. So far as the autumn leafage is concerned, the exotics are mainly represented by two types, those whose foliage is tender and comes down wholesale with the first frost, say of 10°, without much change of colour, and others on which the leaves are long retained, but are ultimately shed without putting on anything in the way of bright colour, the *Pterocarya* and *Gymnocladus* being examples of the former, and the *Wistaria* and *Judas Tree* of the latter. In cases where the foliage changes and is fairly well retained I have noticed that the prevailing autumn tint is either very pale yellow, as in the *Salisbury*, or a dull, dingy brown, as in the *Cucumber Tree* (*Magnolia acuminata*) and the *deciduous Cypress*. There are a few foreign trees that may be used either for bright colouring, as some of the newer Maples, or for their unique foliage alike in summer and autumn, as the *Maiden-hair Tree* already noted and the huge-leaved *Magnolia* (*M. macrophylla*). Many large shrubs are often very bright, *Forsythias*, *Weigelas*, some of the *Spireas*, and of course *deciduous Azaleas*. Soil and situation, as mentioned in the editorial note, have in almost every individual case, whether it be species or variety, a lot to do with the autumn colouring and the season quite as much. Some few trees will successfully resist frosts of 10° or 12°, but with the majority this is enough to produce a premature fall of the leaf when it has only commenced to assume its autumn garb. A certain amount of advice is doubtless always acceptable in planting operations, but in a case of this kind it is only, I think, a secondary matter to a careful study by the planter of soil, situation, and the probability of early or late autumn frost. In notes on tree-life in a recent number, for *Elder*, please read *Alder*, and for height of *Abies brachyphylla*, 34 feet instead of 24 feet.—E. BURRELL, *Claremont*.

## GARDEN FLORA.

### PLATE 1148.

#### SINGLE ROSES.

(WITH A COLOURED PLATE OF—1, ROSA MACRANTHA; 2, ROSE PAUL'S SCARLET. \*)

SINCE the National Rose Society introduced competitive classes for these they have rapidly gained in public favour. Many really good old varieties have been brought to the front once more, and not a few of them saved from extinction. In addition to this, we have recently had several grand introductions, most of which might have been thrown away a few years back had not the beauties of these single Roses been recognised by a few rosarians, and their grand effect shown by the stands which invariably attract great attention at the National Rose Society's exhibitions.

When the rage for large and double forms set in, a single or even semi-double Rose, that would now be popular and worth cultivating by

\* Drawn for *THE GARDEN* by H. G. Moon in Messrs. Paul's nursery at Cheshunt. Lithographed and printed by J. L. Goffart.

trade growers, was so useless, that I have no doubt a vast number of beautiful seedlings were cast on one side. Happily, we are not likely to find this the case for some time to come, and there is little fear that our grand singles will again go out of popular favour. We have many grand single forms with not only greater vigour and hardness, but the sweet-scented foliage of our native Sweet Brier. A few of the best singles include the following:—

**ROSA MACRANTHA**, a form of *Rosa gallica*, is a very vigorous grower, with large and boldly-carried golden yellow stamens, and one of the finest climbers.

**PAUL'S SINGLE CRIMSON**, also figured, is a grand fellow climber to *macrantha*. The yellow stamens of this grand Rose are considerably more prominent than shown in the plate, the drawing of the flower being made in a way that does not exhibit them so fully as in the case of *R. macrantha*.

**PAUL'S CARMINE PILLAR**, another grand single from Cheshunt, was figured in *THE GARDEN* of October 27, 1894. It has been exceptionally good this season: in fact, since its introduction I have never found it fail. The flowers are each from 3 in. to 4 in. across and of the brightest and clearest rosy carmine. It is a grand pillar Rose, and difficult to beat when planted singly or in small groups upon the lawn. Shoots from 10 feet to 12 feet in height are produced each season, and covered with large trusses from every eye. These open in succession, and give a much longer display than is usually the case with singles. To many the somewhat fleeting character of the single forms is a great disappointment, but with this variety, also the hybrid Sweet Briers and others producing large trusses of buds, freshly-opened flowers rapidly follow those that are shattered. There is also the great advantage derived from renewed beauty after a heavy storm which would completely ruin the more double Roses; whereas such singles as *Carmine Pillar* open more of their buds as soon as the disturbance has passed, and again afford a charming display.

**PAUL'S SINGLE WHITE** is a most valuable climber, as it not only flowers during summer, but gives a grand display during autumn, a time when our singles are too often bare. I have no doubt we shall ere long have an almost equally good autumnal as spring or early summer display from varieties obtained by careful hybridisation.

**ROYAL SCARLET** (also emanating from Cheshunt) was successful in gaining a card of commendation as a new single at the National Rose Society's Crystal Palace show this year. It is an intensely deep scarlet Hybrid Perpetual, and being a H.P. cannot be exhibited among the so-called garden Roses, although very few would be able to distinguish the difference as regards class. *Royal Scarlet* will certainly become one of our most popular single Roses. It is a very compact and dwarf grower, bearing immense trusses greatly improved by handsome foliage.

**POLYANTHA GRANDIFLORA** (*R. multiflora grandiflora*) is a most rampant climber, producing large, pure white blossoms each 3 inches across. It is one of the best for arbours, arches, and the formation of Rose hedges or screens. The flowers are produced in clusters. In

**POLYANTHA SIMPLEX** we have a miniature form of the above, the trusses of which are of pyramidal form, the whole plant being one mass of star-like blossoms. When planted in masses or allowed to ramble among the stems of an old Thorn hedge, this and a few more varieties are very effective. Indeed, I know of few easier, quicker, or cheaper ways of securing a charming and natural hedge of Roses than a judicious mixture of our strong-growing singles, and such others as *Alice Grey*, *Aimée Vibert*, *W. A. Richardson*, with the majority of the Ayrshire, Boursault, and *sempervirens* sections.

**ROSA LUCIDA** affords us a bright red, and one which contrasts well with the many whites and pale pinks found among singles. The foliage of this variety is also showy and handsome, being a

glaucescent red, so that the whole of the plant heightens the effect of lighter colours. There is a variety called *R. lucida Vivid*, the leaves of which are of a very high colour during autumn. Both are vigorous climbers.

**R. MOSCHATA NIVEA**, or *ALBA*, our Musk Rose, is a grand climber with large trusses of small yellowish white flowers. The inflorescence of this variety is peculiarly pubescent. It can be recognised by that feature and its musky odour alone.

**R. BRUNONIS MOSCHATA** (the Himalayan Brier) is another variety of Musk Rose. This is a pure white, with very prominent golden yellow stamens, produced in immense clusters, and one of the best for arches or any position in which it can ramble.

**R. PISSARDI** produces immense clusters of small, pure white flowers. The growth is vigorous, but the slender, spiny branches droop over quite distinct from those of other Roses. It is very sweet scented, and has the merit of more continuous blooming than other singles. This variety varies between single and semi-double forms.

**BARDOL JOB** is not quite a single, but is so slightly beyond this that I give it a place, more especially so as it is undoubtedly our best large glowing crimson, often heavily shaded with deep maroon. It is very vigorous, the petals of immense size, and we have few more perpetual blooming climbers.

**HEBE'S LIP**, one of the Hybrid Sweet Briers, is another of those varieties so slightly semi-double as to be classed among singles by many growers. It is one of the most distinct and beautiful garden Roses we have. It bears medium-sized blossoms, pure white in the centre, with a distinct edge of purple that is suffused into the petals in the form known as *Picotée* edge.

**R. GIGANTEA**, the giant single Rose from India, must be mentioned. This makes growths of 50 feet: the flowers are pure white and each 5½ inches across. I have not yet heard of its flowering in England, but many plants are being grown here.

**R. LEVIGATA** (syn., *R. nica*) is a very large, pure white flower. The plant is rather tender and needs a south wall. The yellow stamens in this variety are very showy and prominent.

The beautiful Austrian Briers are well known. More distinct singles than the Austrian Copper and Austrian Yellow cannot be found; the former a bright reddish copper with a distinct metallic tinge, and the latter a pure canary yellow. Then we have a large number of Hybrid Sweet Briers that, as already noted, possess the additional charm of sweet-scented foliage. Nor must I omit the manifold charms of the Japanese Briers or *Rugosa* Roses, with their remarkable foliage, always free from mildew and red rust, the first and last to bloom, and eventually forming one of our best autumnal-berried plants. A coloured plate of these will be found in the issue for November 13 of the present volume, and to that, with the accompanying article, I must refer my readers. When noting a few of our best single Roses it would not be right to pass over the beauties of our own species and their great variety.

Uckfield.

A. PIPER.

**Dracæna Lindenii**.—The plants commonly cultivated in gardens as *Dracænas* (some of which are really *Cordylines*) show a great diversity of character, as several widely different forms occur amongst them. Thus we have a group of coloured-leaved kinds, of which *D. terminalis* was one of the earliest forms. Then there is the curiously mottled *D. Goldiana*, the branching *D. Godselliana* with its pretty spotted leaves, the quick-growing *D. Sanderiana*, whose rather short foliage is beautifully variegated with white, and lastly, this under notice, *D. Lindenii*, which is apparently a variety of the old *Dracæna fragrans*, a stout, sturdy-growing species, with broad, gracefully recurring foliage. Instead of the leaves being green, they are, however, in *Lindenii* beautifully

variegated with rich yellow, which covers the major portion of the leaf, being divided into two parts by a greenish stripe down the midrib. This central band is broken up into different shades of green, varying from a deep lime to a pale greyish-green tint. This *Dracæna* needs ample room for the broadly arching leaves to develop, and it also requires a fairly light position, as if too much shaded it is less brightly coloured.

—H. P.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

SELDOM, if ever, can a more favourable autumn be remembered, as, apart from there being an absence of frost, the ground has been in splendid condition for digging, and it has also given late-planted crops an opportunity to make not only free, but firm growth, which should be in a better condition to resist frost than when this follows an abundance of rain. I advised a few weeks ago pushing forward both digging and trenching, and where this was done, especially on retentive soils, much of the laborious work which so often proves trying in the spring will be well advanced and the soil will also be all the better for a long exposure when the time comes round for sowing and planting. Now is the time to select sites for the different main crops and have the ground treated accordingly. Peas being perhaps the main summer crop, a good open position should be selected, as they are never so satisfactory when grown in close proximity to fruit and other trees. It has been frequently pointed out that when these can be planted in single rows or grown wide apart the crop is not only heavier, but the haulm continues in a full bearing condition much longer. In arranging for such sowings trenches could be prepared now similar to those for Celery. These could be marked off in different parts of the garden, or if necessary to have several on one quarter, remove them from each other as far as possible, and the space between them will answer well for any other crops of dwarf habit. Time can be found now to do such work; whereas, if left till spring, ordinary digging would probably have to suffice, owing to so many other things requiring attention. If the soil can be broken up a couple of spits deep, burying plenty of decayed manure in the bottom, healthy growth and heavy crops will be forthcoming. Should we experience a dry time, such as proved so disastrous to the Peas the last two summers, strips of ground a yard wide, and treated as advised above, will form a capital seed-bed for all the strong-growing varieties, such as *Ne Plus Ultra* and others. A shallow trench should be made to receive the early batch when planted out from pots. The first favourable day can then be taken when they are sufficiently advanced to plant them, and being naturally tender the sides of the trench will act as a screen against trying winds, while should it be necessary they are easily protected if a few degrees of frost threaten. Another advantage gained by planting this crop in trenches is being able to afford copious watering during dry weather, and also mulching. For some reason Jerusalem Artichokes are generally allotted the worst position in the garden, but treated more generously, both as regards site and preparing the ground properly, finer shaped tubers and much heavier crops are obtained. A single row planted last spring in a favourable part of the garden has yielded an enormous crop of handsome-shaped tubers, as many as a peck being taken from one root, and all fit to be sent to table. This points to the penny-wise-and-pound-foolish method of neglecting this crop, which, if grown under favourable conditions, would prove one of the most profitable in the garden.

**GLOBE ARTICHOKE**.—These will soon need attention in the way of protection before they are injured by severe frost. As yet the foliage is as strong and healthy as in summer, but as this dies

down it will be wise to spread some light dry litter around the crowns. This is better than applying a great thickness of decayed manure, which may cause the crowns to rot should there be a quantity of rain. It would be well also to be on the alert and have suitable material at hand for other things which may require it, such as Rhubarb, Seakale, and even Celery, while salads, Cauliflower, and the like, growing in unheated pits and frames, will be kept safe by having double mats to place over them when frost does come.

**SEAKALE** that has been grown for lifting to be forced early should be got out of the ground at once, or at least a good portion of the crowns, so that no delay arises during hard weather. Failing this, a breadth should be covered with litter or bracken to allow the roots to be forked out at any time. Celery, if properly banked up now so as to throw off rains, will require very little protection, as when the foliage is much exposed rain collects and drains to the centre of the plants, which are then easily injured should frost follow. A final moulding up should be given at once, as no further leaf growth is needed.

**GREEN VEGETABLES.**—Although these are plentiful now, some regard should be paid to varieties, and the less hardy ones used up first. Most of the early Savoys are well forward; many of them, owing to the open weather, are ready to burst. No one, then, should think of leaving these and commence cutting the hardier Kales. The latter should be preserved as long as possible, as after a severe winter these may be found the only green vegetable left in a serviceable condition, and prove most valuable through March. Spinach is very plentiful just now, but where the foliage has become so large that it overlaps that in the next row, its removal at once would be an advantage, as such a bulk of leaves is more apt to suffer after snow than is the case where the plants have more room to become dry, and sun and air can act on the ground between them. Look over the Broccoli breadths frequently, and lift any that are ready for use, but which may not be required just at the time. Their removal to a sheltered place will not only preserve them from frost, but a continuous supply is in a great measure ensured.

R. PARKER.

#### HARDY FRUIT GARDEN.

NEVER in the whole of my experience do I remember a more propitious season for planting than the present one. The soil being in a medium state of moisture is in the best possible condition for planting, as it crumbles down well and does not stick to the feet of the planters. I had an instance of this when superintending the planting of an orchard last week. The soil is a very heavy loam overlying the old red sandstone, and almost unworkable in a wet time. I was agreeably surprised to find it in such excellent working order, and the planting having been performed under such favourable conditions, I am very sanguine as to future results. As this will be a grass orchard, the trees are being protected with guards made of strips of 2-inch wire mesh netting 30 inches wide, No. 16 gauge, with a single strand of barbed wire run round each guard.

**PEARS.**—These trees have ripened their wood thoroughly and are in a most promising condition. Established trees should have all young wood pruned in to three buds, but any young growths which spring direct from the main branch should be left a trifle longer. These will eventually make fruiting spurs, and will in time enable some of the oldest of the original spurs to be cut out. Older trees having very long spurs should be spur-pruned, as recommended for Plums. Pears lend themselves more readily to this kind of treatment than any other fruit tree, and by its means old trees can be effectually furnished afresh with a complete set of new spurs. In the case of fan-trained trees the main branches should be kept evenly disposed at regular distances, and the intermediate ones kept

thin, or about 6 inches apart, so that crowding does not occur. Thin and regulate the wood in young trees, spurring back all not required for extension, and either tip or shorten back the leading growths at the ends of the future main branches, according to the amount of growth they have made and the space at command. Young horizontally trained trees should have two young shoots left for forming a new tier of branches. These tiers of branches should be trained out at right angles to the stem, and stand 1 foot apart from one another. The leader in this case should be left about 15 inches long. This will allow for the topmost shoot being taken up to form the new leader next spring, when the two below it will furnish growths for forming the next tier of branches. Cordons require but little pruning if they receive attention at the hands of the grower in the summer and early autumn. A general look over suffices now, when any piece of young wood missed or which was not shortened back sufficiently, can be attended to. Those varieties which are prone to make a superabundance of fruit buds should have the same partially thinned out. A little timely attention in this way, also in keeping the roots in working order, prevents such trees from getting into a debilitated state. These remarks also apply to trees other than those grown as cordons. Cut back the leaders on young cordons to firm wood, and select a good prominent wood bud. It is necessary to draw the attention of young beginners to this matter, as these leaders oftentimes make more fruit-buds than wood-buds. Regarding training, it is not necessary to enter fully into it here. Pay attention to the manner in which the nails and shreds are used, and allow ample room for the branch round which they are placed to swell properly. The same remark applies to tying, and in this case place a shred between the string and bark should there be any strain upon it. Tanned twine is very durable for this purpose, particularly for securing cordons. With regard to insect pests and the remedies to apply for their extermination I must refer the reader to the first page of THE GARDEN for November 20.

**APRICOTS.**—The fine autumn, coupled with the fact of the trees in many cases having had a partial rest during the past season, has had a most beneficial effect on them. The young wood and spurs are well clothed with blossom buds, which are firm and as brown as a nut. Some growers disbud their trees and grow them in a similar manner to Peach trees, while others rely on spurs to furnish the crop. I favour a system which is a combination of both, and find it answer remarkably well, the invariable result being heavy crops of fruit. Pruning in the case of Apricots consists in shortening back all spur growths, thinning out the young wood where too much has been laid in, and cutting away any dead snags or spurs. If a piece of young wood has to be shortened back for any purpose, see that the cut is made at a wood bud, or the branch will die back. Cut out dead branches in a careful manner, injuring the live bark as little as possible. Young trees should need no pruning beyond a regulation of the young wood, as all other matters should have had attention during the growing season. Neglected trees, whether old or young, must not be too severely dealt with in one season, otherwise gumming will be the result. At the same time, and in the latter case the young wood must be shortened back to restore the proper balance, and attention paid to the trees during the next season in the stopping of all gross shoots to ensure a more even growth. Regarding older trees, spurs on these may have been allowed to grow out a long way from the face of the wall. A judicious spur pruning will be of great value here, but it must not be overdone, or the object in view will be defeated. When training out Apricot trees afresh, pay great attention to the following matter. Unless absolutely necessary, never remove a full-grown branch from its original position. Apricot wood is of such a brittle nature that if such branches are bent round and moved about too much the sap vessels become ruptured

and the branch ultimately dies. Use narrow shreds for fastening young wood to the wall, and see that the nails are so driven in that they do not come into contact with the branches. Older branches may be secured in the same way as recommended for Pears. Brown scale being partial to Apricot trees, wash and spray the trees as soon as training is completed. If not already done remove the summer mulch from the alleys when raking up the prunings, after which top-dress the border if in need of it. Use good loam if it can be spared, and to ensure porosity mix plenty of lime rubble or old plaster with it. If the trees are in need of a stimulant add a fair amount of bone meal, but eschew the use of rotten manure. In some localities there is still a scarcity of water, owing to the meagre rainfall. It is in such instances as these that there is a danger of Apricot trees getting dry at the roots; a condition most trying to them. They should, therefore, be examined, and if found to be at all approaching a dry condition, well water at once.

A. W.

## STOVE AND GREENHOUSE.

### THE CULTURE OF HYDRANGEA HORTENSIA.

SOME amateurs, who were struck with the great difference between the growth of my Hortensias which they saw in the exhibition at the Tuileries and that of the plants which are usually seen in the markets, have asked me how I obtained such good results. To all of these I have much pleasure in replying, through the medium of the *Revue Horticole*, in the following notes:—

**PREPARATION.**—First of all, cuttings of Hortensias may be put in either in spring or in summer, but, for good culture, it is essential that this should be done in the month of May, when the cuttings should be struck under bell-glasses and on a spent hot-bed. When they have taken root well, they may either be potted or pricked out in the open ground, the latter being by far the better course to adopt, as it is the chief condition of success. In the climate of Paris, Hortensias require to be grown in sandy heath-soil, while, at Versailles, in certain well-drained sandy clays these plants do well when the soil is mixed with a proportion of leaf-mould. In all these cases lime should be rigorously excluded, and therefore care should be taken that in watering the plants no well-water should be used except such as has been proved to contain no such injurious ingredient. Most of the wells around Paris are strongly impregnated with carbonate of lime, but some growers may have the good chance of getting water from a well sunk in a stratum of clay. In such a case the water is more likely to be impregnated with sulphate of alumina and with sulphate or oxide of iron, and these are precisely elements that are favourable to the culture of Hortensias. After the young plants are pricked out in the open ground in heath-soil they are watered lightly twice a day. About the end of August the shoots are pinched and when winter approaches the plants are taken up, potted, and placed in a cool house or under a frame, where it is important that they should receive as much air and light as possible. After this first wintering, the plants are taken out of their pots and again placed in the open ground, as in the year preceding. At the same time they are pruned severely, the stem being cut back to the best two eyes at the base, from which fresh wood will start that, later on, will produce seven, eight, or even ten ramifications. Of these not more than five or six of the best formed should be retained, if fine large flowers are desired. The rest should be pinched back to three or four leaves at the most. While the plants are growing, it is important not to allow the branches to become immoderately long, and for this purpose it will be sufficient to diminish the amount of water about the month of July. This precaution, moreover, is indispensable, in

order that the plants may form flower-buds better, as the flowering, being strongly induced by the temporary check to the growth of the plant, attains its maximum of preparation by the production of a very great number of flower-buds.

About the end of August or early in September the plants are again placed into pots six or seven inches in diameter, according to their strength. Care must be taken in doing so not to break off any of the leaves, and the plants should then be placed in shade, so that the sun may not act on them injuriously during the period of striking root, which lasts for a fortnight. They are to be watered lightly twice a day and well watered whenever there is occasion for doing so. When they have thoroughly taken root again heavy watering is discontinued to allow the wood to ripen and the leaves to fall off. The plants are wintered under frames or, preferably, in a cool house. It is still more necessary now than in the preceding year to give them as much air as possible, as without this precaution the flower-buds would soon damp off. Diffused light also is necessary, but I cannot too strongly impress the warning that the light by itself is not sufficient, and that there must be added to it the greatest possible amount of air. The plants are thus in their period of rest during the first part of the winter; they come naturally into growth in spring, and if the flowers are wanted only at the normal flowering season, all that is necessary is simply to assist the growth, so far as this can be done, by keeping up such a temperature as will exclude frost. In this case a constant heat of from 45° to 50° Fahr. will be sufficient to maintain the growth of the plants and to ensure their flowering at the time desired.

**FORCING.**—Should the object, however, be to obtain Hortensia blooms at an earlier date, the period of rest must be abruptly terminated by the operation of forcing. From two months and a half to three months must be calculated for between the time the plants commence to grow and the time when the flowers make their appearance. Suppose, for instance, that you require the flowers for March 19, you must start the plants into growth about January 10 by raising the temperature of the house to from 60° to 70° Fahr. This rise in the temperature need not prevent the free admission of air whenever the weather outside will allow of it. On the contrary, Hortensias, like all other plants which must be grown under glass, can only be maintained in a healthy condition under a good system of ventilation.

**COLOUR IN THE FLOWERS.**—All is not done in striving to produce Hortensia blooms of a blue tint unless the colour obtained is brilliant and uniform. Nothing, in fact, is uglier than a panicle of the flowers only coloured blue in one part, pink in another, and green in the centre, with vague intermediate shades all simply combining to produce a dull, wan shade of colouring. The flowers also should be large and, as far as possible, all expand at the same time. Good results in all these matters may be obtained at the same time by the following means: (1) At the time of the second repotting, just before the winter of the second year, wash the roots and rootlets thoroughly, so that not a single portion of the soil in which the plants passed the summer may be left adhering to them. Repot the plants at once in a proper ferruginous compost, having for its base sandy heath-soil, with which are incorporated 10 per cent. of iron slag, pounded fine, 1 per cent. of sulphate of iron, and 5 per cent. of dried night-soil. Instead of this may be employed 10 per cent. of pounded slate, 1 per cent. of sulphate of iron and 1 per cent. of ammonia. The plants are to be well watered twice a week with water in which sulphate of iron has been dissolved, in the proportion of from 10 grains to 16 grains (Troy) to the quart. [Some growers, in order to obtain certain results, employ exclusively soil taken from ground in which slate quarries are found, which is rich in sulphate of alumina. The effect, moreover, which is produced by pounded slate is entirely owing to the

presence in this slate of from 25 per cent. to 35 per cent. of alumina, and of from 6 per cent. to 12 per cent. of sulphide and oxide of iron. The slate also contains potash to the extent of about 4 per cent. It is also owing to the combined presence of the sulphate and oxide of iron with alum (bi-sulphate of alumina and potash) that some argillaceous soils naturally produce the blue colour in Hortensia blooms. We know, besides, that the alum of commerce is extracted from plastic and potters' clay by leaching those clays after they have been dried and reduced to powder. A fine blue colour is also imparted to Hortensia flowers by placing in the bottom of the pot, when potting the plants, a small quantity of crushed alum. In this case, however, it is necessary to be sure that the potting soil itself does not already contain a sufficient proportion of alum. Even if it does, that does not diminish the necessity of watering with a solution of sulphate of iron and dried night-soil, H. D.] (2) Admit air as much as possible in proportion to the light. The darker the day, the less air should be given. On the other hand, the brighter the sunshine, the greater the amount of air that should be admitted, if frost should not prevent the opening of the frames while the sun is shining.

**SPECIMENS IN SMALL POTS.**—People fall into raptures when admiring huge flowers of Chrysanthemums, or of Hydrangea Hortensia, H. Otaksa or other kinds, growing on a short, unbranched stem rising from a small pot. Nothing is more easily obtained. Take the pinched-off shoots which were removed from crowded branches, choosing those which have the thickest wood, as these certainly have a flower-bud; make cuttings of them, and when they have taken root prick them out into small pots. Place these pots on a warm hot-bed and under a bell-glass, so as to have the air excluded. The cuttings will have struck root in about eight days' time, and soon afterwards you will have a grand display of flowers. In this case, should you desire blue flowers, the cuttings should be pricked out in ferruginous soil, and they should have been taken from parent plants which were also grown in the same kind of soil.

Lastly, those who devote themselves to this special culture should possess very vigorous-growing parent plants with very thick wood, and which have been brought into this condition by a plentiful application of manure.—GEORGE BOUTCHER, in *Revue Horticole*.

**Croton Van Cœrstedt.**—This is a very freely-branched, small-growing Croton, quite distinct, and very useful when grown in small pots for the edges of groups and positions where dwarf-growing kinds only would be suitable. It cannot lay claim to any particular grace or elegance, as the leaves though narrow are short and stiff, their colour being a rich deep green thickly sprinkled with tiny spots of yellow. It is also occasionally met with under the name of aureo-punctatus. This Croton branches so freely as to form even when young quite a dense bush. Neat and effective little plants may be grown in pots only 4 inches in diameter.—H. P.

**Abutilon Boule de Neige.**—A great number of hybrid varieties of Abutilon have been raised and distributed within the last few years, among them being several with white blossoms. None of them, however, has proved equal to the old Boule de Neige. Apart from its own individual merit Boule de Neige has proved most valuable to the hybridist, as the now popular race of garden Abutilons owe their origin to the intercrossing of this and the old bronzy-red Abutilon Darwini. It is somewhat singular that the union of these two should result in varieties with pink blossoms and other allied shades in which the red of Darwini is completely eliminated. An exactly similar result, however, is to be found in the Javanese Rhododendrons now so popular, for the crossing of the orange R. javanicum with the white R. jasminiflorum produced the pink R. Princess Royal. Abutilon Boule de Neige may

be grown in various ways, as it does well clothing the wall of a greenhouse, the handsome deep green foliage serving to show off the pure satiny-white blossoms to the best advantage. Again, trained to a roof or pillar it is very effective, while in bush form it will flower with equal freedom. Good-sized plants may be sometimes seen put out in the London parks during the summer months, and so treated they flower well.—T.

**Pinguicula caudata.**—When visiting a short time since the Queen's Road Nursery of Mr. James Cypher at Cheltenham, my attention was attracted by a large batch of this. The plants, of which there were many, were growing in small pots. They had quite dense rosettes of leaves close down on the surface, and from the centres of the plants rose long scapes, each one crowned with a bright deep rosy carmine-coloured corolla. On young plants the leaves are arranged in the form of dense rosettes, fleshy, long, narrow, the tips slightly incurving, but when the plants age the leaves change considerably in character; they then become few, large, and take on a dull yellowish green colour with stained margins. This does well in a cool Orchid house where there is a command of a plentiful moist atmosphere, and at this season of the year a temperature of 45° to 50° by night. The plants at Cheltenham were in what is known as 3½-inch pots; they are potted lightly in a compost of peat, sand and Sphagnum Moss in about equal parts. The plants bloom in autumn and up to Christmas. They are then rested for a time, during which they require but little water. When they begin to make growth in the spring more water is required, and then increase can be made by division. In addition to this method of propagation, plants can be increased by means of the leaves, as in the case of Gloxinias; they will strike freely in the compost recommended for potting.—R. D.

#### BOUVARDIA HUMBOLDTI CORYMBIFLORA.

IN THE GARDEN (p. 443) reference is made to the specific name of the above, and it is stated that corymbiflora should take precedence. At one time I was under the impression that it should be so, but have since found that I was wrong, corymbiflora being an improved variety of the original species (B. Humboldtii). I do not remember to have seen the old form. I met Mr. P. Henderson, of Maida Vale, a few years ago, and he informed me that the firm raised (or introduced) corymbiflora, which was a great improvement on the species, which never produced its flowers in such large corymbs or trusses. To be quite correct, I imagine that the name should be written B. Humboldtii var. corymbiflora, yet as there appears to be only the improved variety in cultivation, it is hardly necessary to use both names. In the trade it is generally spoken of as Humboldtii only. At a recent meeting of the Royal Horticultural Society a further improved variety was exhibited and gained an award of merit under the name of Humboldtii grandiflora. This has a stouter tube and broader lobes; the leaves are also broader than in corymbiflora. I was at first inclined to think that culture had made the difference, but on comparing the two I found a decided difference, particularly in the foliage, and it should undoubtedly supersede the older variety. As to culture, I find Humboldtii requires different treatment from that given the varieties of other species. It requires more root-room; cuttings struck early in the year will flower the following autumn; the plants should be grown where they are fully exposed to the sun, and should not be stopped so late in the season as the other sorts. When grown for cut bloom, old cut-back plants are preferable. I have seen it flowering freely when planted out of doors, but to have nice clean blooms it is necessary to protect from rough weather. I believe many growers fail to flower this Bouvardia through not treating it liberally enough. With plenty of pot room and a liberal supply of manure, the same plants will

keep up a supply of bloom for a considerable time. In the country it might flower up to Christmas, but in the neighbourhood of London I have never been able to do much good with it after November comes in. A.

## ROSE GARDEN.

### ROSE COMTESSE DE NADAILLAC.

A GREAT number select this Rose from flowers that are staged for exhibition, and consequently Comtesse de Nadaillac is well known, has many admirers, and yet disappointment is almost an inevitable consequence of any first attempt at its culture. Who can fail to admire those wonderful boxes of blooms of this Rose so varied in colour that Mr. Prince shows from his nursery in Oxfordshire? Soil and situation must be considered in the production of such flowers, and a breadth of this kind in a nursery such as we have seen with Mr. Prince is something to remember. After many trials, however, it must be admitted that this lovely Rose is fickle, and if we were asked for a selection of twelve or twenty-five of the best garden kinds, even then we should leave this one out. Still, it will continue to draw admirers, and those who like to give it a little extra care will find themselves abundantly repaid when its many-tinted flowers appear. It must have a warm and sunny spot and open-air culture to get its full beauty. At the foot of a wall it is sometimes very happy, and in the Colchester nurseries we have seen grand flowers produced by plants so situated. It is only a moderate grower at the best, and cannot be effectively grouped in the garden, unless soil and situation are specially favourable to it. It was raised by M. Guillot, and sent out in 1872.

**Rose Rainbow.**—This has been very lovely this autumn, a season of the year that one sees its parent Papa Gontier in greatest perfection. Rainbow has all the characteristics of Papa Gontier, only that it is striped and flaked with the rosy-crimson colour of the latter on a pale peach-coloured ground. I consider it a very valuable addition to the Tea-scented class.—E.

**Rose Queen of Bedders (Bourbon).**—Even now the plants of this variety are covered with large red buds that would produce a fine show were they not hindered from expanding by the damp and foggy December days. These hard-opening Roses are not so suitable as the Teas for late autumnal displays, but in the waning summer, when many of the Hybrid Perpetuals have yielded their first crop, they come in very useful. The colour of Queen of Bedders is deep crimson, the flowers are rather flat, and the growth is very similar to that of Souvenir de la Malmaison.—E.

**Rose Perle des Rouges (Polyantha).**—This latest novelty among these exquisite miniature Roses is a very acceptable acquisition. The colour is velvety crimson, and although not quite up to our ideal of a scarlet-crimson variety, it is, nevertheless, a great gain. Hitherto the deepest colour in this section has been the variety Blanche Rebatel, but the purplish shading has hindered it from obtaining much popularity. I believe Perle des Rouges will be extensively employed by gardeners for massing, and it will probably rank with Gloire des Polyantha for effectiveness.—E.

**Colour in Mme. Faleot Rose.**—It is pleasant to read of such splendid specimens of this fine old Rose as related by "J. R." in THE GARDEN lately. I think the secret of the intense colouring that he refers to is mainly attributable to old age, and consequently a very abundant supply of roots which such twenty-year-old plants would possess. Then again, the covering of glass and abundance of air would ensure a thorough ripening of the

wood, an essential factor in the production of fine flowers. "J. R." says the border was entirely re-made two years ago. As this operation must have been very carefully performed, judging by results, I should have been surprised indeed had he not obtained these richly-coloured flowers from such rejuvenated and doubtless highly-fed plants.—PHILOMEL.

**Potting Roses.**—Now is a very good time to pot up a few standard, half-standard, and bush Roses to provide a supply for filling up gaps in the late spring. It is not always convenient to plant at the proper time, and somehow the work is delayed until too late; consequently a season is lost; but if a few plants are held in reserve in pots the result will be the same as if the plants had been put out in autumn, provided they are carefully turned out of their pots and the ball of earth left intact. Some well-flowered standard and half-standard Roses in pots are also found to be very useful upon special occasions. As the standard Brier has a peculiar root, ample pot room should be afforded. A 10-inch or 12-inch pot will be found none too large. The pots should be plunged in some ashes or cocoa-nut

I would recommend gardeners to meet the demand by potting up a quantity for this purpose. Grow them on under cool conditions the first year until well established, then they can be forced to meet any requirements. After flowering, cut away some of the old flowering shoots and grow on in heat with plenty of moisture during the summer. This treatment will quickly bring forth young growths that will flower from every eye. Those plants intended for pillars may have their shoots bent down for a time to ensure a thorough breaking of all the buds, afterwards training them in pyramidal form.—PHILOMEL.

**Rose Alfred K. Williams.**—Not only is this one of the best of the autumn Roses, but it is also a superb variety for summer flowering. It is true the constitution of the plant is not altogether what one would desire, but we can afford to overlook this failing in an otherwise grand variety. Some really wonderful flowers are produced from one-year-old plants on the Manetti, and for exhibitors this may seem a sufficient excuse for growing this Rose on that stock, but as a permanent plant I would most decidedly recommend obtaining this beautiful variety on the seedling or cutting

Rose Comtesse de Nadaillac. From a photograph by Messrs. Byrne and Co. Richmond.

fibre refuse quite up to the rim, and if frosts are severe, a covering of straw or leaves will be beneficial.—W. E.

**Standard and pillar Roses in pots.**—Frequenters of exhibitions must have noticed the growing tendency of exhibitors for more natural training, and in no instance is this more observable than in the national flower. The giant specimen Roses exhibited in the palmy days of South Kensington were objects of wonderment, but no one could truly say he admired them. On the other hand, let anyone place before the public a fine standard of some of the best coloured Teas, the branches pendent with the weight of the lovely blossoms, or a superb example in pillar form of such chaste and elegant Roses as Claire Jacquier, Crimson Rambler, Alistair Stella Gray, Adelina, Vivian Morel, Aglaia, Longworth Rambler, with many others, and he will quickly discern the trending of popular taste. No plant can be more suitable for conservatory decoration than a well-flowered pillar or standard Rose, and

Brier, the former for preference. The great fault of the Manetti from a gardener's standpoint is the early maturation of its growths, and consequently little or no autumnal display, but on the Brier, especially plants on the seedling, this Rose is oftentimes seen at its best in autumn.—E.

**Climbing H.P. Roses.**—The climbing or extra vigorous forms of this fine hardy class possess considerable value to denizens of large towns or bleak and cold situations. It is true they have not the rambling nature of the Tea and Noisette, Sempervirens and similar classes, but they are hardier. Where possible they should be obtained on own roots, as, indeed, should all Roses that are destined for such permanent positions as climbers on walls or pillars. Mention should be made of Climbing Victor Verdier, for although scentless it is a useful Rose, with prettily formed rose-coloured buds. Climbing Jules Margottin is certainly the most rampant of them all, and very serviceable it is, although its fragrant flowers never appear so fine as on the dwarf

variety. Then again we have that beautiful old Rose Princess Louise Victoria, with its charming flesh-coloured flowers that almost rival those of Captain Christy in loveliness. Bessie Johnson in climbing form is yet another worthy variety, if only for the delicious fragrance of its bluish-coloured blossoms, and Climbing Mlle. Eugénie Verdier is not quite so vigorous as the above varieties, but it will make growth in one year 4 feet to 5 feet long, and a well-established plant of it covered with its delightful flesh-pink flowers on a low wall or grown on a pillar produces a very fine effect. Yet another excellent salmon-coloured variety is Climbing Pride of Waltham. Not only do these climbing Hybrid Perpetuals provide us with good hardy ramblers, but they, together with some of their allies in the Hybrid Teas, such as Climbing La France, Climbing Captain Christy and Pink Rover, give us some of the very best climbing pink Roses, a colour of which the pure Teas of climbing habit are very deficient. Undoubtedly if it can be fixed, the Climbing La France will become a grand acquisition. I recently saw some plants that had made 6 feet to 7 feet shoots the first season from the bud, but a large proportion in the row had reverted to the dwarf type. The varieties I have named, together with such a fine scarlet as Gloire de Margottin and, for white, Paul's Single, will give a selection of excellent climbers. —PHILOMEL.

## ORCHARD AND FRUIT GARDEN.

### MARKET GRAPES.

I FANCY that more difficulty will be experienced in keeping Alicante and Muscat of Alexandria than has been the case for some years. The former in many places was fully coloured and quite sweet by the middle of September. In an ordinary year this would not much matter, but all through October and in the early part of November; day and night temperatures have ranged unusually high, and although Grapes to keep should be thoroughly ripe, they should be kept as cool as possible after they are ripe. Shrivelling and decay of berry are more apt to be troublesome when the berries have been exposed to a month or more of summer heat after ripening than when the weather has been in the cool side through the autumn months. The dense fogs which prevailed necessitated the application of artificial heat, for without this a large number of berries must have decayed. The best trying month for late Grapes in a general way is November; the Vines being clothed with foliage, the circulation of air is impeded, and a large amount of evaporation is going on. As soon as the leaves fall, the amount of moisture to be got rid of is much less, and it is easier to perceive decaying berries. Later on there is apt to be a difficulty in another way. In a time of hard frost, especially when the days are bright, evaporation from the berries is too rapid and the bunches lose in weight and appearance. One of our largest Muscat growers covers his houses with thick netting after the turn of the year. This serves a twofold purpose, lessening the need for fire-heat, thereby economising fuel, and in some measure screens the berries from the action of bright sunshine. When the pipes have to be made very hot, the bunches near them are apt to shrivel, and the dried atmosphere which they create seems to destroy the bloom and perfect finish of the fruit. There is undoubtedly nothing like bottling, where this can be done, and I wonder that this way of keeping Grapes has not been practised to a greater extent by those who grow this fruit on a large scale for profit. The initial expense would, it is true, be considerable, but there should be good interest on money expended in this way.

The amount of fuel and the labour required to keep say 5000 bunches from December onwards are very great, and these would in a great measure be saved. Not only is this the case, but the Vines are relieved of their burden at an early date, and the work of pruning, cleansing, manuring, &c., can be done at a time when most convenient. It is also, I believe, a fact that Muscats and Gros Colman keep longer in better condition when bottled than on the Vines, which has a direct bearing on that all-important item, marketable value. After the middle of March there is generally a considerable rise in price. Muscats which in February have been selling at from 3s. 6d. to 5s. per lb. will frequently suddenly run up to 10s. per lb. by April. Last spring upwards of 10s. per lb. was obtained in Covent Garden for Muscats, but these came from a Grape room. I doubt if any so good were forthcoming direct from the Vines at that late period. If a man could obtain from 6d. to 1s. 6d. per lb. more by bottling he would get a good return for his outlay, and be saved a lot of troublesome details which are indispensable when the fruit hangs so long on the Vines. Gros Colman is admittedly the best variety for long-keeping when it can be brought into a highly-finished condition. Perfectly developed it will keep longer than any other Grape, but herein lies the difficulty which comparatively few manage to conquer. Those who may be thinking of taking up the profitable culture of this variety cannot be too fully impressed with this fact. Partly coloured, Colman is not so valuable as the more easily grown Alicante in its best form, and all advantages to be derived from its superior keeping qualities are lost, for imperfectly matured fruit will not remain in good condition for any length of time. Gros Colman even under the best management is apt to be disappointing; whereas the Alicante with fair treatment seldom refuses to yield good crops of finely-coloured fruit. A house of Alicante containing thousands of bunches in perfect bloom and colour is worth going a long way to see, and, taking one year with another, I doubt if any Grape is more profitable. J. C. B.

**Pear Nouvelle Fulvie.**—This Pear is not grown so much as it deserves, as it is really an excellent variety and not at all fastidious as to soil. Its season is given as from December to January, but I find it is ripe in November and early December. It is only fair to add the fruits are from cordon or dwarf bushes and pyramids in a warm soil, this affecting their keeping. It cannot be called a handsome Pear. It is free from coarseness, of excellent quality, and the fruits have a delicious flavour. With me it does best as a pyramid. Doubtless the close stopping needed for cordon training is not favourable to cropping, and in bush or pyramid form it rarely fails to bear; indeed, in some seasons so freely, that thinning is necessary to obtain good-sized fruits. It is not a gross grower, and is therefore well adapted for gardens where space is none too plentiful. —G. WYTHES.

**Apple Cockle Pippin.**—This old variety, which recently secured the award for flavour at the meeting of the Royal Horticultural Society, is well worth space in all collections. I admit it is not a showy Apple by any means, and in collections of fruit two or more months ago it would have passed unnoticed. The variety in question does well in most soils. In a light soil on gravel the tree creeps freely, but the fruit lacks the size of that grown under more favourable conditions. I find it does not keep so well from trees on the Paradise stock. I should be glad to know if other growers have this difficulty. Though its season is from November to the end of the year, when I had trees of this variety in Gloucester-

shire I kept the fruit well into March. The fruits were from standards. I have no idea on what kind of tree or on what stock the dish of this variety referred to was grown, but the fruits were excellent and the flavour superb. Even in standard form this variety does not make a large tree—at least I have never seen very large trees—and on the Paradise it is one of the most shapely and prolific varieties I know. This variety I often noticed did well at Chiswick in the society's gardens, and Mr. Barron had a high opinion of its quality. I believe it is a Sussex fruit, and may be kept a long time, given cool storage. As a market fruit I fear its appearance would not be in its favour.—GROWER.

**The fruit flavour prizes.**—I do not remember to have seen issued so far any statement as to the varieties of Apples and Pears that have been awarded prizes in connection with Messrs. Veitch and Sons' flavour classes for these fruits at the Drill Hall and the Crystal Palace. It seems as if the competitions for the present season will have very little merit after the January meeting, the last one in the Royal Horticultural Society's year, that a favourable opportunity would then present itself for the issue of a tabulated report, giving not only the various dates on which each variety received an award, the number of times in each year totalled, the name of the exhibitor and place of growth, nature of soil and such other information as may be found useful. The competitions have been running two years, and each of the years has seen many repetitions. These would have been more frequent in some cases, notably Cox's Orange Pippin in Apples, but for the limitation put on exhibitors with respect to the number of times they can exhibit the same variety. Probably the number of varieties that have won prizes will be with both Apples and Pears found to be rather few compared with the large number of varieties in commerce. Were the competitions continued for other two years, it is doubtful whether any better flavoured varieties of either fruit would be found. Certainly there have been none put into commerce for some time that equal those already so well known. It may be worth while, should Messrs. Veitch and Sons purpose continuing the competitions, to withdraw from them all varieties that have received awards in their season two years in succession, and thus give room for the introduction of other good varieties that have so far been put into the background by superior rivals. We know now which are the best, but there may be some others yet comparatively undiscovered.—A. D.

### PLANTING FRUIT TREES ON WALLS.

Would you kindly inform me at what distance apart Apples, Plums, and Pears should be planted on walls and as espaliers.—J. McK.

\*\* The distance apart for planting fruit trees depends a great deal on the soil, the position where planted, and the stock on which the trees are worked. Take soil first. If this is what is termed a good loam of a fair depth and not wet or too stiff, trees in such land will grow very quickly. Apples come first. Pyramids or bushes on the Crab stock may be planted 9 feet to 12 feet apart, the latter distance in good land and if the trees are well balanced and healthy. Trees on the Paradise stock need less space. Here 6 feet to 9 feet will suffice, as this stock will not produce large trees. Six feet is often allowed bushes, but it is rather too close when the trees are in well-worked soil. For espaliers horizontally trained, 12 feet to 15 feet apart is a good distance. Cordon Apple trees may be planted on a wall at 2 feet apart if placed as an edging in double form 12 feet to 15 feet apart. This allows of from 6 feet to 7 feet of growth each side the tree, and this is sufficient if the trees are on the Paradise stock. Single cordons will only require half the distance of the double tree, 6 feet to 8 feet being ample, the smaller distance for small growers on the Paradise. Pears, pyramid or bushes on Quince stock, should be 6 feet to 9 feet

apart; if on the Pear and strong growers, 9 feet to 15 feet cordons the same as advised for Apples, and espalier trees 15 feet to 20 feet, the former distance for slow growers or those on the Quince. Plums need more room. For bushes and pyramids, 10 feet to 12 feet is none too much, and trees against walls 15 feet to 20 feet. Plums often grow very quickly, but if kept root-pruned every half dozen years a distance of 15 feet apart is ample. The trees also are more prolific. The Peach and Nectarine need the same treatment. I would advise 15 feet to 20 feet; the latter is none too much if trees are well done and grown freely, that is plenty of young wood laid in. Young trees at the start are often planted at 4 feet apart, in time every other tree being removed. Indeed, with most kinds of fruits this close planting may be adopted if there is no neglect in after years in removing.—Ed.

### JARGONELLE PEAR.

This is one of the most delicious Pears in cultivation, and if flavour alone is to decide the selection, it may well head the list. Unfortunately, the Jargonelle is of the worst habit of growth imaginable, and that is the greatest objection gardeners have to it. A pyramid worthy of the name is very rarely met with, and presentable standards can only be obtained by re-grafting old trees of less approved varieties with the Jargonelle. Nor are good horizontal trees of it easily grown; in fact, it would appear to object to almost any set form of training. When once this is realised and the trees allowed to have their own way somewhat, an improvement is soon effected both in the quality and quantity of the fruit. What a Jargonelle Pear tree needs, and what it must have, is plenty of head-room. The trees should be treated much in the same way as fan-shaped Plum trees, the system simply consisting in laying in a branch wherever there is space to be filled, allowing these branches to grow unpruned till the limit is reached. It is the young, well-ripened growths that give the most bloom and the finest fruit, the former, at least, invariably being formed on the unpruned two-year-old wood. The Jargonelle will not fruit satisfactorily on either a north or north-east wall, in this respect failing where Marie Louise, Louise Boume, and other Pears succeed. The best way to form good standards is to cut over the head of some less valued tree, grafting all the points with the Jargonelle.

The Jargonelle flowers earlier than most Pears, being as a consequence more often damaged by frosts. A tree well set with fruit-buds would always pay for some kind of temporary protection. Trebled fish-nets suspended over the trees, and kept clear with the aid of long poles, will frequently save the crop.

**Planting Strawberries.**—Is the present a safe time to make a permanent plantation of the different sorts? Is there any danger of them suffering should the weather become severe afterwards?—J. McK.

\*\* December is the worst season of the year to plant Strawberries, no matter what the variety, as the plants are now at rest. If you plant now and severe weather follow, you will lose many plants. You will gain in the end by leaving the planting till March, or even April should the former month be wet, cold or frosty. You do not say if your plants are in the soil, in pots or otherwise. If in pots, plunge well over the rims of the pots in lines, well pressing the soil to the plants. This will prevent frost damaging the roots, and if in beds a little cover over the roots in the way of ashes or short litter will do good. The best month to plant for permanent plantations is August, or as soon as runners can be obtained. If planted then you will get fruit next

season, as the plants make a nice growth by the middle of October and go away freely in the early spring. If planted in spring you must not allow them to fruit the same season. You must remove all flower-trusses as they show, the plants needing all their strength to form roots and make a good crown growth for the next season. With spring planting, watering must be carefully attended to during dry weather. A mulch of rotten manure is also of great benefit.—Ed.

**Apple Cox's Orange.**—At p. 397 "Grower," in a brief note, gives us a very practical suggestion regarding the severe pruning of this Apple, and I thoroughly agree with his remarks. Some years ago I planted cordons of Cox's Orange, partly as a finish to a fruit border and with a view to obtaining fine fruits. From half a dozen trees, now at least ten years old, I have not had a peek of fruit. Cox's Orange treated thus does not fruit freely. On the other hand, from bush trees given a certain amount of freedom I rarely fail to get fruit in quantity and of a good size also, and I find the trees soon bear. Even small trees have

apparently quite a home, and I saw some very fine fruit of it there recently. The flesh is remarkably firm, of a brisk, but not very acid flavour, and this is less pronounced as the season advances. In shape it is sub-conical, and at the stem there is often a club of flesh like that in the fruit from which it takes its name. The skin is yellowish streaked with russet, the fruit solid and heavy. The tree is a free bearer, and I have noted it good in several gardens this scarce season. It does better when allowed a certain amount of freedom than if closely pruned.

**A good stewing Pear.**—I am aware we have no lack of good stewing Pears; in fact many of the dessert varieties are only fit for cooking. For autumn and early winter supplies few varieties can surpass Gilgil. This on the Pear stock is one of the hardiest of all the Pears, as in the far north it is a favourite, and rarely fails. I am aware there are later, also larger cooking Pears, but none superior in quality. The above when cooked is, I consider, our best Pear, in season from October to December. The fruits are large

*Pear Jargonelle.*

this season given fair crops. I am inclined to think severe pruning may have a great deal to do with scarcity in some places, as this variety on the Paradise stock, treated as advised, has borne grandly on the new wood of the previous year.—S. H. B.

**Pear Princess of Wales.**—The flavour of this Pear is almost as good as that of any at this season, and its handsome appearance should recommend it. The skin is rough, yellow, with dots of a greyish russet, and the flesh is very melting and pleasant. It appears to do well under any form of training, and should be worked on the Quince. If a wall can be afforded it it is of better flavour, but in a season like that just passed it is sure to ripen almost anywhere. Trees here with a south-west aspect have carried a good crop and the fruit has been much liked. It is a healthy and vigorous grower and should prove a profitable variety.—R., *Suffolk*.

**Apple Lemon Pippin.**—This is a useful late dessert Apple, good now and keeping well into the new year. In the light soil at Livermere it is

round, with a yellow skin covered with russet when ripe. I have seen very fine fruits on bus trees. It also bears well as a standard. I making new additions this Pear should find place.—S. H. B.

**Early Peaches.**—I do not quite agree with Mr. Burrell (p. 431) when he considers Amsde June poor. In the note I presume he does not refer to cropping, but to quality. The variety in question in our soil is better than either Alexandre or Waterloo and earlier. This is important. I am aware Mr. Burrell is not at all singular in his estimate of the three Peaches in question; other think the same; and I have therefore made a special study as regards the flavour of these varieties and I can see little difference. I do admit on drawback with Amsden June. It is the first of the trio to lose quality. It will not keep so long as either of the two others named, and even on walls if left too long it loses flavour. I find it necessary to go over the trees when the fruit ripening every day and not allow ripe fruits to remain an hour longer than is necessary; in fact

if anything, to gather before quite ripe if the fruits are needed for a special purpose. Of late I have been planting early varieties of Peaches in quantity, and have given Amsden June the preference. Size, colour and earliness have been considered in the selection. I find either of the three named is none too highly flavoured if grown in gravelly soil, and I also notice these early varieties need a great deal of moisture, much thinning to get fine fruits and the wood also well ripened. Early Beatrice is so poor it is not worth growing. I have an excellent variety, Early Canada, which forces well. I am now growing this in the open. I have very large trees of Amsden June, and have never yet failed to get fine fruits.—GROWER.

**Apple Seaton House.**—In many gardens of late years Apples have been largely cultivated for their size and appearance, and probably the above variety is less seen at exhibitions than some of the showier kinds. It is a grand fruit, and one of the best for gardens of limited size where many varieties are not required. Although not one of the largest Apples, with me on old trees it is above medium size and a very solid fruit. It does well in any form of tree. In light, warm soils its season is October, but in the north good fruits may be had in March. I generally use it after Cellini. It is not unlike Stirling Castle, but a better grower with me. By some it is known as Niton House. The fruits are pale green with darker streaks. Trees on the Paradise stock give earlier and larger fruit, but for keeping I advise bush trees.—G. W.

**A new white Grape.**—At page 396 "A. D." condemns the fruit committee for giving an award to the new Grape Marchioness of Downshire, and says the committee gave the award in opposition to the judgment of the best authority on Grapes in the kingdom. I think this latter remark uncalled for. The authority in question would be the last person to put his knowledge as superior to that of all others. If the fruit committee made a leap in the dark it is not the first time, and I fail to see why "A. D." should condemn a body of men simply because he ("A. D.") does not agree. I certainly voted in the majority, and consider it an excellent keeping Grape, and I know it crops well and sets well. Several good Grape growers voted for it. I think such notes as the one at p. 396 are very unfair to the raiser. As the committee were informed the variety in question cropped well and set well, I fail to see how it got an award, as "A. D." states, without particulars.—ONE OF THE MAJORITY.

**PREPARING FORCING STRAWBERRIES.**

A FEW years ago I had occasion to go into a large market garden where Strawberries are forced largely, and noted what rough-and-ready treatment the plants received in comparison to those in private gardens. As the crops were superior and the labour much less, it was an object lesson and one I was glad to follow. The old-fashioned plan of top-dressing the pot plants did not find favour, and I fail to see its utility. In my opinion food given at the surface in the form of liquid is preferable to all others. I do not believe in the strong doses of artificial manure often given to plants in fruit, as I think it affects the flavour; indeed, after many years' trial I find ordinary liquid manure from stables the best food, with occasional supplies of soot water. In many gardens it is considered necessary to top-dress each plant before starting. This in inexperienced hands is the forerunner of blind plants and weak flower-trusses, the plants in some instances being unable to throw up strongly. I am aware excess of heat, want of air, and other defects contribute to the above evils, but the top-dressing is often the first and can readily be avoided. The usual plan of removing 2 inches or so of soil from the surface also is quite unnecessary, and where there are thousands of plants it takes much time. The plants when placed in their forcing quarters do not need this new soil for many weeks, the result being it is more difficult

to water those with a portion of new soil added, as this remains moist. The older soil, being a mass of roots, dries quickly. It is necessary to remove any weeds or mossy growths from the surface. Should food be necessary (which is rarely the case at the start), it may be given in a liquid state in preference to top-dressing. In an excellent note on pot Strawberries, "J. C. B." at page 391 dwells upon the importance of good plants, and gives cultural details how to secure them, and though he but briefly touches on the forcing, I note he lays stress upon the importance of good plants, and deprecates strong stimulants. I quite agree with him. The best fruits I have ever had were from plants fed with soot-water only. I think the strong fertilisers used now, mixed with soil as a top-dressing, harmful, as the plant having but few leaves is unable to absorb the food, and the plants cannot be forced hard to get new growth.

G. W.

**BOOKS.**

**THE PRINCIPLES OF FRUIT GROWING.\***

THIS, the latest addition to the Rural Science Series, edited by L. H. Bailey, of the Cornell University, New York, is, I think, the most valuable. Without being actually a new departure in the literature of the fruit garden, it is yet conceived and conducted on original lines, and compares most favourably with the dry matter-of-fact attempts in a similar direction to which we are accustomed on this side of the Atlantic. It is not a case of attempting too much and doing nothing thoroughly, but every page is replete with matter that both interests and instructs the reader. Professor Bailey has the happy knack of conveying a mass of valuable information in the most simple manner. Too often experts wrap up what they wish to convey in so much verbiage, various technical and scientific phrases accompanying their remarks, much of which might frequently be dispensed with, together with numerous tables and statistics galore, all of which confuse the issues and bewilder the average reader. These mistakes are not made by the majority of American writers. "The Principles of Fruit Growing" contains a surprising amount of original and selected information, conveyed in a condensed, yet perfectly understandable form. Not content with the experience gained on the fruit farm connected with the Cornell University, Mr. Bailey has hunted up and quoted freely from all the best American and English authorities on fruit culture, also collating information upon various important points from the leading fruit growers all over the United States, hence the great value of his painstaking work. Local experience is all very well in its way, but it is not generally reliable. What answers admirably in one district may fail conspicuously in another part of the country, and the difficulty is met by giving the "Principles of Fruit Growing" an almost universal character.

When shall we be favoured with an equally well-thought-out and clearly-written work on hardy fruit growing in this country, published at a popular price? (The book under notice is sold at 5s.). Mere reports on experiments or descriptions of fruit culture conducted in any one given locality do not, for reasons already hinted at, meet the case. We want reliable information upon various points. We ought to learn more about the behaviour of both kinds and varieties, and which are the most profitable to cultivate in different parts of the country; the effects of soils and manures upon the trees and bushes and their produce; the positions that give the most satisfactory results; protective measures found the most efficacious against frost, diseases, insect pests; marketing, packing, and the like. This information should be collected from all parts of Great Britain and Ireland and edited by an ex-

\* "The Principles of Fruit Growing." By L. H. Bailey. London: Macmillan and Co.

pert who, like Professor Bailey, is also a practical fruit grower. Perhaps this will come when we have State-aided training and experimental farms. At present we are quite left in the lurch by our rivals and friends in America.

One point is always observable in Professor Bailey's writing—he never misleads, and in particular guards himself against raising false expectations. He maintains, and rightly so, that both pleasure and profit are to be derived from fruit culture, but never omits pointing out that it is all a question of capability for the line pursued. Where one man would succeed another would starve. Personal superintendence is everything. This is what he says as to the prospects of beginners:—

It is indisputable that there is always a demand for the best. There is not enough of the best in any commodity. A man cannot make the best unless he has the ability for it. It is more important, therefore, that the first tillage and fertilising and pruning and spraying should be applied to the man and not to the land nor the crops, and whilst the man is acquiring discipline for the direct prosecution of his business he is at the same time opening his mind to all the sweetest pleasures of living. On the other hand, there is always a surplus of the ordinary. In fact, it is the ordinariness of it which makes the surplus. . . . This demands that we define what is commonly meant by the best. That kind of fruit usually sells the best of which there is the least. It may not be intrinsically the best. It is simply that in which there is the least competition. The key-note to the business, therefore, is diversification or individuality. The grower should aim to have something which his neighbours do not do, although it may really not be any better than what they do. . . . He need have no fear of his success if he grows what people want or puts it up so as to make them believe they want it.

Much more is written in this strain, and the sound, practical advice given ought to be carefully read and acted upon by many comparatively "old hands" as well as beginners.

The chapter on "The Location and its Climate" is specially interesting to me, and doubtless will be to many other British readers. I have recently been engaged in a small way collecting information on the effect of locality upon the crops, or, in other words, the best positions for orchards, the value of shelter trees, wind-breaks, and other points for the benefit of Gloucestershire and Somersetshire farmers, and to this now can be added what Professor Bailey has published on the subject. Opinions vary considerably as to the best positions for orchards as well as the value of wind-breaks. On the whole, the balance is in favour of shelter trees and wind-breaks, but there is a surprisingly strong case against them. We have not the same difficulties to contend with in the matter of injuries from severe frosts while the trees, bushes, and plants are at rest, and it will be news to many readers that in various parts of the States they are nearly as much liable to have their prospects marred by frosts as we are in this country. Spring frosts are among the worst of our drawbacks, but a perusal of Professor Bailey's work will convince readers that we have not a monopoly of that particular bugbear.

Equally interesting and instructive is the chapter on the tillage of fruit lands. What is said on this subject both for and against tillage among fruit trees is well worthy of careful attention, but there is no mistaking the fact that tillage of the ground has a most beneficial effect upon the trees occupying it, and ought not really to cease for at least ten years after planting. This rule applies to our country as well as to America, and this season the difference as regards the weight and soundness of fruit in favour of trees on cultivated ground compared with those obtained from trees in uncultivated orchards is more marked than usual. Here is what we find advanced on page 139 on "The Philosophy of Tillage":—

1. Tillage improves the physical condition of the land: (a) By tining the soil, and thereby presenting greater feeding surface to the roots; (b) by increasing the depth of the soil, and thereby giving a greater foraging and root-hold area to the plant; (c) by warming and drying the soil in spring; (d) by reducing the extremes of temperature and moisture.

2. Tillage may save moisture (e) by increasing the water-holding capacity of the soil; (f) by checking evaporation.

3. Tillage may augment chemical activities (a) by aiding and setting free plant-food (h) by promoting nitrification; (i) by hastening the decomposition of organic matter; (j) by extending these agencies (g h i) to greater depth of soil.

The chief beneficiaries of the experiment of treating fruit trees similarly to forest trees, planting thickly and not cultivating between, of which there are innumerable instances in this and adjoining county of Gloucester, are said by Mr. Bailey to be bugs, mice, and fungi, all of which would vote the method a success. I should have added grubs or the larvae of several most destructive insect pests. In this connection we are given full accounts of all the methods in vogue of tillage and cropping between fruit trees, with remedies for unprofitable orchards. Next we come to an exhaustive chapter on "The Fertilising of Fruit Lands," and many and easy to follow are the hints given. Of the necessity for manuring orchards there can be no two opinions, and owners ought first to read the information of this important part of the subject, and judge for themselves which of the many methods on fertilising the ground will best meet their case. At the end of this chapter, among the summary conclusions occur the following instructive remarks:—

The grower should also remember that the plants need all the elements of plant growth, and not one of them alone. For example, a heavy application of nitrogen upon soil which is deficient of potash and phosphoric acid cannot be expected to give useful results. In the same way, the application of potash to the soil which is very poor in nitrogen or phosphoric acid would be comparatively useless. The heavy loamy or clay lands nearly always contain an abundance of potash and phosphoric acid in a more or less unavailable condition, and much of these materials can be liberated to the plant by careful tillage and the incorporation of humus. However, it is nearly always advisable in orchards which are bearing to add these materials in the shape of manures or concentrated fertilisers. The quickest results following the use of fertilisers will be seen upon the sandier lands. Two or three years often elapse after the application of chemical fertilisers to heavy lands before any decided results are observed. In other words, clay lands ordinarily show quicker results from tillage than they do from the application of fertilisers. The farmer should bear in mind that he should never rely exclusively upon chemical plant foods, because they contain no humus and the soil is apt to become hard and lifeless. They should be used in judicious rotation, or in connection with cover crops, or stable manures, or applications of muck or some other organic dressings. It is not necessary that the chemical fertilisers should be mixed before application; in fact upon lands of varying soil and conformation, it is ordinarily better to apply different ingredients separately, because different parts of the plantation may need different amounts of the various materials. The low lands will ordinarily need less of the nitrogen and perhaps more of the potash and phosphoric acid. In general it is advisable to buy the plant foods separately as advised in the preceding page.

"The Planting of Fruit Ground" is the heading of another long chapter, and this is followed by "The Secondary and Incidental Care of the Fruit Plantation," both chapters being exhaustive and to the point. The effects of frosts upon both the trees and the flowers are dwelt upon at considerable length, various illustrations of frost effects accompanying these remarks. Diseases, insects and spraying all come in for a full share of attention. Then follows much good advice upon harvesting and marketing fruit, with diagrams of every appliance used in connection with this important work, and there are also various illustrations of the best forms of storage houses to be found in America. Near the end of the book may be found much that is interesting concerning the distribution of the vast quantities of fruit grown in America, and once more I would quote a passage for the benefit of the slovenly and not unfrequently fraudulent packer of fruit in this country. All that is advanced under the sub-heading "The Grower and Consumer" is worthy of reproduction, but

I must content myself with this selection from it:—

It should first be said that the fruit itself is the best business card which the grower can have in the long run. Fruit which is well grown and well packed is already virtually sold. If the consumer is convinced of the honesty and good faith of the grower and the packer, then his suspicions are allayed, and he is willing to purchase freely and at a fair price. . . . The time is certainly coming when an inferior grade of fruit cannot be put upon the market with profit. Competition is gradually increasing, and it is only the better grades which can pay for the expense of shipping and packages and selling and leave a margin of profit to the grower.

I am afraid Professor Bailey would have but a poor opinion of the methods and practices of the bulk of those who consign fruit to Covent Garden Market. Surely no such primitive, rough, and in many cases tricky methods of packing, nor such large quantities of inferior produce could be found in any American fruit market. W. I.

## SOCIETIES AND EXHIBITIONS

### NATIONAL CHRYSANTHEMUM SOCIETY.

On this occasion the whole of the exhibits were arranged in the south-western gallery, and although the display will not bear comparison with that made last year, yet, considering the damp and foggy weather lately experienced, it may be considered an interesting one. A few changes made in the schedule of prizes offered on this occasion, were not productive of any particular change. Looking at the show from the point of view of bringing out varieties which may be characterised as being naturally late, there was nothing noticeable in this respect, but instead a repetition of sorts staged at both the October and November shows appeared to be the rule. This is to be regretted, as there is plenty of room for improvement in the late-flowering varieties, and it is only natural to expect that one of the chief points of interest in a display made so late in the season should be to give prominence to the sorts naturally late-flowering. A class for plants (single varieties) bush grown, trained or untrained, failed to attract a satisfactory entry, only one exhibitor making a display, and this with plants distinctly unworthy of the occasion. The trade display assisted very materially to compensate for the poorness of the entries in the competitive classes, both Mr. H. J. Jones, Lewisham, and Mr. W. Wells, Redhill, staging handsome exhibits. The decorative exhibits, too, in the non-competitive classes were very pleasing, and these, together with tables of miscellaneous plants and others containing Cyclamens and Primulas, each contributed in no small degree to make an interesting display. It is pleasing to record an improvement in the lighting arrangements, the recent remarks in this respect evidently having had the desired effect.

#### PLANTS.

Only one entry was forthcoming in the class for six specimens, single varieties, bush grown, trained or untrained. These were a very poor lot indeed, and quite unworthy of a national show. A third prize was awarded to Mr. W. C. Pagram, gardener to Mr. J. Courtenay, Weybridge.

#### CUT BLOOMS.

The class for twenty-four Japanese Chrysanthemums, not less than eighteen varieties and not more than two of a variety, brought out four competitors, Mr. W. Messenger, gardener to Mr. C. H. Berners, Woolverstone Park, Ipswich, being an easy first with a very handsome lot of blooms. His best were Mme. Carnot, E. D. Smith, Simplicity, Rose Wynne, Ialene, C. W. Richardson, Col. T. C. Bourne, Silver King, Etoile de Lyon, Mlle. A. de Galbert, G. C. Schwabe, and a grand flower of Golden Gate. The second prize fell to Mr. W. Slogrove, gar-

dener to Mrs. Crawford, Gatton Cottage, Reigate his most conspicuous blooms being Waban, Oceana, G. J. Warren, Miss Maggie Blenkinson, Mme. Carnot, Niveum, Bellum, and M. Chenon de Léché. Mr. Norman Davis, The Vineries, Framfield, Sussex, was the only competitor in the class for twenty-four bunches shown in bottles provided by the society. These, almost exclusively Japanese varieties, were very informally arranged, and included many of the leading novelties. The flowers were large, full, of good colour, and fresh. Four nice boards of blooms were shown in the class for twelve Japanese distinct, the margin of superiority in the first prize stand being very narrow indeed. This was awarded to Mr. Messenger, who had fine examples of Mme. Carnot (probably the best Japanese in the show), E. D. Smith, Etoile de Lyon, C. W. Richardson, G. C. Schwabe, Silver King, Golden Gate, Niveum, Snowdon, Phœbus, Miss Maggie Blenkinson, and Mutual Friend. Mr. R. Kenyon, gardener to Mr. A. F. Hills, Monkams, Woodford, was a close second, his stand being a remarkably even one, and his blooms fresh and of good colour. Julie Scaramanga, Australie, Mrs. W. H. Lees, and Col. T. C. Bourne were specially deserving of praise. A brisk competition for six Japanese followed, leading honours going to Mr. C. Cox, gardener to Mr. J. Trotter, Brickenden Grange, Hertford, with a capital stand of flowers. Edith Tabor was very fine, its pure yellow and exquisite form being much admired. Mme. Carnot, Mrs. W. H. Lees, Mrs. Chas. Blick, and a splendid bloom of M. Chenon de Léché call for special notice. Mr. Kenyon was again second with blooms noticeable for their fine colour. The class for twelve incurved, not less than six varieties and not more than two of one variety, produced four capital lots. First prize deservedly went to Mr. W. Neville, gardener to Mr. F. W. Flight, Cornstiles, Twyford, Winchester, for a stand containing flowers of large size and very neat and even. We very much doubt if a finer lot has ever been staged at this show in any previous year. His varieties were Ma Perfection, The Egyptian, Miss Dorothy Foster, Major Bonafon, John Fulford, Mrs. R. C. Kingston, and Bonnie Dundee. The second prize was secured by Mr. T. Robinson, gardener to Mr. W. Laurence, Elmsfield House, Hollingbourne, for a less even lot of flowers. For six incurved, distinct, Mr. R. Basil, gardener to Mr. D. H. Evans, Shooters Hill, Pangbourne, had a nice lot of flowers. Chas. H. Curtis, Mrs. J. Gardiner, and a splendid flower of Bonnie Dundee were among his best. Very closely followed Mr. Neville, who had a very neat lot of flowers, Mrs. R. C. Kingston being in fine form. Only two competitors entered the list for twelve bunches Japanese, not less than six varieties, three blooms in a bunch, shown in bottles. Mr. W. Howe, gardener to Mr. Henry Tate, Park Hill, Streatham Common, had a beautiful lot of blooms in wonderfully fresh condition. These were admirably set up. Mr. Norman Davis was second, his blooms not being set up so well as the first prize lot. Four competitors staged exhibits in the class for six bunches Japanese, three blooms of one variety in each bunch. Here Mr. Norman Davis was first with capital examples of Georgiana Pitcher, Geo. Seward, Oceana, Western King, Etoile de Lyon, and Mlle. J. Bernard. Mr. W. Slogrove was a good second, C. W. Richardson and Oceana being two of his best sorts. In a class for twelve bunches large-flowered single varieties, three blooms only of one variety in a bunch, Mr. G. W. Forbes, gardener to Mme. Nicols, Regent House, Surbiton, Surrey, had a magnificent lot of flowers, though too formally set up. They were large, of good colour, and the colours pleasingly disposed, Admiral Symonds, Miss Grace Rennie, Tuscols, Rudbeckia, and Rev. W. C. Remfrey being the best. To Mr. A. Felgate, gardener to Her Grace Elizabeth, Duchess of Wellington, Buthill, Walton-on-Thames, second prize was awarded, Yellow Giant and Captain Felgate standing out conspicuously in his exhibit. For six bunches of the same type

Mr. W. Felgate, Jun., nurseryman, Burhill Road, Walton-on-Thames, was first, being the only exhibitor. The small singles were charming, the class for twelve bunches, three blooms in each bunch, again finding Mr. Forbes in the leading position. Mr. A. Felgate followed with less even flowers. For six bunches small-flowered singles, three blooms in a bunch, Mr. Felgate was again first, C. Pearce, Arthur, and Fragile being very pretty. A special prize offered by Mr. C. W. Richardson, Sawbridgeworth, open to single-handed gardeners only, for twelve Japanese blooms, distinct, found only one competitor, Mr. F. Bush, gardener to Mr. W. T. Lister, F.R.C.S., Rose Hill, Totteridge, showing an indifferent lot of flowers. A new division for amateurs who mainly, if not entirely, cultivate their plants was made this year, and contained three classes. No exhibitor, however, was forthcoming. In the amateur classes, division B, open to those who grow the plants themselves, four competitors entered for six Japanese, not less than four varieties and not more than two of one variety, Mr. Geo. Heal, Holly House, Compton, Guildford, was placed first, Mons. Gruyer, Golden Gate, and Mons. Chenon de Léché being his best examples. For six bunches only one lot was staged, and this was very poor. The class for a vase of Chrysanthemums, arranged with foliage, berries, and grasses, brought out only one competitor, Mr. D. B. Crane, Highgate, showing a bold arrangement.

## CYCLAMENS, PRIMULAS, &amp;c.

Mr. William Orpwood, nurseryman, Uxbridge, exhibited a fine table of Cyclamens in pots in the class for a collection of Cyclamens. These were a grand lot of plants, fresh and healthy, freely flowered and of good colour, securing first prize. For twelve Cyclamens in pots, from which nurserymen were excluded, Mr. W. Frost, gardener to Mr. G. Ashley-Dodd, Godington, Ashford, Kent, was placed first for a splendid lot of plants with large blossoms freely produced. Mr. W. Rapley, gardener to Mr. H. Grinling, Harrow Weald House, Stanmore, was second with much smaller plants, but fresh. For a collection of *Primula sinensis* (open) Mr. J. Gibson, gardener to Mr. E. H. Watts, Devonhurst, Chiswick, secured leading position with a large table of plants very tastefully arranged, and edged with *Panicum variegatum*, with *Crotons* and *Cocos Weddelliana* associated to produce effect. Mr. Orpwood was second, with small market plants, and tied in a very stiff manner. For twelve *Primula sinensis* (nurserymen excluded) Mr. W. Mease, gardener to Mr. A. Tate, Downside, Leatherhead, was an easy first with freely-flowered double sorts and beautifully finished, Mr. Gibson following with single-flowered forms. The new class for nine winter-flowering *Begonias* (open) does not appear to have found favour, no single exhibit being in evidence. For a collection of flowering, berried and leaf-foliated plants, arranged for effect on a table 1 feet by 6 feet (open), Mr. W. Howe made a very handsome display. Surmounted with a fine specimen *Cocos Weddelliana* encircled by wonderfully fine *Poinsettias*, the table space was splendidly arranged with *Bouvardias*, winter-flowering *Begonias*, *Solanums*, *Roman Hyacinths*, *Crotons*, *Primulas* and other useful flowering and leaf-foliated plants with an edging of *Panicum variegatum*. The whole arrangement evinced much taste. Special interest was manifested in the class for a basket of autumn foliage and berries, in which there were no less than ten competitors. The first prize ultimately went to Mr. A. Newell, gardener to Sir Edwin Saunders, Fairawn, Wimbledon Common, for a rather cumbersome arrangement, which included a fine variety of berries. Second prize fell to Miss C. B. Cole, The Vineyard, Feltham, for a neat and lightly-ranged basket in which the new *Physalis* played an important part. A very lovely basket, given an extra prize in this class, was well worthy of a higher position.

## MISCELLANEOUS.

Mr. H. J. Jones, Rycroft Nursery, Lewisham, had an immense table, in which each type of the

Chrysanthemum was represented. Large vases, each filled with one variety only, were arranged down the centre of the table, the spaces on either side being filled with small tubes and an immense number of boards of specimen exhibition flowers. Fine-foliated plants were pleasingly associated, giving the necessary finish to this welcome display. We noticed among the novelties *Mary Molyneux*, the now mauve-pink Japanese incurved; *W. Wright*, a capital late sort; *C. W. Richardson*, a Rycroft seedling; *Julie Searmanga*, and *Mrs. R. Jones*, a fine white (small gold medal). Mr. W. Wells, Earlswood Nurseries, Redhill, also had a fine display. Large Japanese incurved and singles, besides decorative varieties, were each represented (silver-gilt medal). Messrs. H. Cannell and Sons, Swanley, set up a grand bank of zonal *Pelargoniums* in great variety, each bunch exhibiting fine form, splendid colour, and large trusses. *Cannas*, decorative *Chrysanthemums*, and a capital collection of vegetables secured an award of a silver-gilt medal. Mr. W. J. Godfrey, Exmouth, Devon, had a large collection of cut *Chrysanthemums*, mostly shown in bunches, and including such sorts as *Mrs. H. Robinson*, *H. W. Rieman*, *Jeannie Falconer*, *Georgiana Piteher*, and *King of Plumes* (silver medal). Mr. J. R. Chard, The Florist, Stoke Newington, N., exhibited a very handsome table of his many devices and designs, arranged with *Chrysanthemums* and other flowers, besides bouquets, &c., each showing splendid taste and artistic skill, receiving a silver-gilt medal. Mrs. W. Green, jun., The Florist, Harold Wood, Essex, had a similar table, but a considerably less quantity of devices, &c. (silver medal). Mr. J. Williams, Ealing, had his pretty rural designs set off on a large table. Mr. W. Neville exhibited thirty incurved blooms of large size, good colour, and very neatly finished, a small silver medal being awarded. Mr. T. Robinson also staged, not for competition, eighteen Japanese and incurved blooms in variety. Mr. R. Bassil exhibited an interesting collection of salads (small silver medal); Mr. J. R. Tranter, Henley-on-Thames, twelve blooms new Japanese *Mrs. J. R. Tranter*; Mr. A. Merridew, The Gardens, Camberwell House, Camberwell, S.E., an *epergne* of *Chrysanthemums* and *Orchids*, and Mr. R. Owen, Maidenhead, a grand table of *Chrysanthemums* with a front of eight dozen exhibition blooms (small silver medal). A most delightful hand-basket of *Mrs. William Filkins*, decorative yellow *Chrysanthemum*, arranged with exquisite taste, by Miss Easterbrook, Fawkham, Kent, secured a bronze medal. Mr. W. Taylor, gardener to Mr. C. Bayer, Tewkesbury Lodge, Forest Hill, S.E., staged eighteen bunches of *Grapes* in excellent condition, including *Muscat of Alexandria*, *Gros Colman*, *Lady Downe's Seedling*, &c. (silver-gilt medal).

The floral committee met at 1 o'clock, when the following awards were made. A first-class certificate was given to—

**CHRYSANTHEMUM MISS PHYLLIS FOWLER.**—A large incurved with florets of medium width, somewhat pointed; colour primrose-yellow. Sent by Mr. T. Robinson, gardener to Mr. Watkins Laurence, Elmsfield House, Hollingbourne.

*Mrs. Caterer*, a beautifully chaste, pure white, large *Anemone*, and as a decorative variety invaluable, from Mr. H. J. Jones, Rycroft Nursery, Lewisham, S.E.; *Red L. Canning*, a useful reddish crimson Japanese variety and commended as a market sort, from Mr. A. Felgate, The Gardens, Burhill, Walton-on-Thames; and *Mrs. M. Simpson*, a large Japanese reflexed, paper-white, with florets of medium width, erect, and of good substance, from Mr. N. Molyneux, Rookesbury Park, Fareham, were commended.

The committee wished to make a correction. At their last meeting a bloom was certificated under the name of *Violacemum*. Its correct name should be *Dennis Smith-Rylands*. It will be sent out by Mr. H. J. Jones.

**Royal Horticultural Society.**—The last meeting this year of the above society will take

place next Tuesday, the 14th, in the Drill Hall, James Street, Victoria Street, Westminster, when the committees will meet as usual at 12 o'clock. A lecture on "Sporting in Chrysanthemums" will be given by the Rev. G. Henslow, M.A., at 3 o'clock.

## NOTES OF THE WEEK.

**Chrysanthemum Tokio.**—Among decorative varieties this kind, though old, is still worth attention for its fine effect when grown in bush form. If the plants are stopped twice, a dozen good flowers and of a useful size may be secured.

**Chrysanthemum Oceana.**—This handsome variety is probably one of the finest of its colour—a rich golden yellow—that has been introduced into the Japanese incurved section. The very broad florets are a special feature of this, while its whole form is bold and massive.

**Agathæa cœlestis.**—This is one of the few blue flowers that come freely in winter, or, indeed, at almost any season of the year. Established pot plants that have been pinched during summer produce quantities of the deep sky-blue flowers for a long time. A few of these with *Fern* or *Asparagus* in small specimen glasses are always pleasing.

**Acacia armata.**—For forming into small, compact bushes for autumn and winter flowering this is one of the most useful of a rather extensive genus, the dark green bushes freely laden with golden blossom rendering the plants quite attractive. It is also a vigorous species, and calculated to endure a certain amount of hardship with impunity.

**Centropogon Lueyanus.**—This old-fashioned greenhouse shrub is now flowering in small pots in groups in one of the greenhouses at Kew. It is one of the old-fashioned things that a decade or two back were often seen blooming in the cool conservatory at this time, but which in many instances have been discarded because the flowers are not suitable for cutting. We should rather welcome plants that cannot be thus ruthlessly cut down the moment the heads of blossom are expanded.

**Hæmanthus pubescens.**—This is one of the large, ovate-leaved section, the broad blades of deep green recurring as soon as they are freed from the bulb. A little later a fine bold truss of snow-white flowers issues from the centre, and, attaining a height of 6 inches or 8 inches, remains in good condition a long time. The above is now in flower, and very attractive are the large pure heads of blossoms. A cool house and a dry, airy atmosphere are best suited to these plants.

**Senecio junceus.**—This is a very distinct species of *Groundsel* from the Cape of Good Hope, with, as implied in its specific name, Rush-like stems and growths generally. These growths, rising from a clustered tuft, are dark green and smooth, the small bright yellow blossoms appearing on the sides of the stems. The very peculiar habit of the plant, the stems being destitute of any leafy growth, renders it a curious and interesting species.

**Crassula lactea.**—As a basket plant, flowering during the winter months, this species with its creamy white flowers is always welcome. To ensure flowering at this season it is necessary to make an early start with the cuttings, selecting for this purpose the nearly full-grown rosettes that cluster around the large established plants. Prior to rooting very little moisture is needed, if at all, and at any time only moderate watering is necessary.

**Lonicera Standishi.**—Those who have large plants of this know full well the value of its fragrant blossoms in the winter when such things are by no means plentiful. Its chief drawback perhaps is that the plants lose the bulk of the leaves at this season, but still the fragrance greets one in passing a few bushes or even a solitary one in the open where the position is sufficiently favoured for it to blossom. As a pot plant in the cool greenhouse it is also worth attention.

**Diplacus glutinosus.**—An old-fashioned greenhouse plant that is well known and often met with at this season of the year. In pots 5 inches across a good-sized plant will develop

many of its curiously coloured flowers. If placed in the open garden it is always pleasing, and provides an informal group not of daily occurrence. Quite recently one or two new varieties have appeared, and though differing in shade of colour somewhat, are not a great advance on the old form.

**Lily of the Valley in fruit.**—A group of Lily of the Valley in fruit has certainly a very pretty effect when the fruits are ripe and in good large clusters, but it is gained only at the expense of great weakening of the crowns, and should not be encouraged by those who want good flowers, or permitted in any case except where the plant is naturalised. In the light soil here seeding is more or less common every year, and if a plentiful crop of seeds is left to mature, the flower-spikes are less than half their normal size in the ensuing season.—J. C. T., *Livermere Park, Bury St. Edmunds.*

**Nerine crispa.**—Notwithstanding there are many varieties of this group with much larger and more brilliant flowers, the kind here mentioned surpasses many of them in its simple grace and beauty. Happily, too, it is of very easy culture, and the bulbs being of small size, several may be grown in a 5-inch pot. Given ordinary treatment, there is no reason why a large number of tubers should not flower. Another very useful kind in the same way is *N. undulata*, in which the sepals are wavy more or less throughout their length, and it is quite easy to have four or six flowering bulbs in a 4-inch pot. In a cut state these smaller forms, even if less brilliant, are quite effective when associated with suitable material.

**Callipsyche aurantiaca.**—A very distinct and attractive member of the Amaryllidaceæ, though not often seen beyond the limits of the botanic garden. The above species is one of the most striking, and usually flowers during the late autumn months. At this time a tall scape fully 2 feet long rises from the bulb, and is crowned by an umbel of deep golden yellow flowers, the latter in form resembling those of a small Day Lily. Like many other plants of this order, the scape, as also the flowers, which are each fully 2 inches in length, appear in advance of the foliage. The species belongs to the Andes of Ecuador, and delights in loam and peat with plenty of moisture during the season of growth. The plant is well suited to the warm greenhouse.

**Iris reticulata in pots.**—When well grown there is a charm about this lovely Iris that renders it unique, more particularly the strong violet perfume of its flowers. For some two or three weeks past the leaves have been above ground, which in this locality is earlier than usual. Those who grow this Iris in pots will be glad to know that if bulbs are now introduced into slight warmth, such as the shelf of the greenhouse quite near the glass, flowers may be expected early in January. In sheltered positions in the open in mild seasons the flowers appear early in February, so that slight warmth, or little more than the exclusion of frost, should make the difference named above. A couple of dozen pots would keep up a succession of flowers for a long time.

**Chrysanthemum naturally grown.**—For late bloom the variety *Niveum*, beautiful sprays of which come to us from E. Molyneux, Swanmore Park, is invaluable. The medium-sized flowers, of the purest white and produced in clusters, are very useful at Christmas for table decoration and such like. In order to obtain such results, Mr. Molyneux strikes the cuttings in February, pinching out the points of the plants when 1 foot high, all the shoots resulting from this check being retained. When all fear of frost is over, the plants are put out in an open piece of ground and kept well watered if the season be dry. They are lifted in October, and all the buds that form are allowed to develop. One valuable characteristic of *Niveum* is the freedom with which it throws up cuttings.

**Carnation Reginald Godfrey.**—So far as the size of blossom is concerned, this variety is

larger than most of those of its shade of colour, which is pink. I do not know the history of this variety, but it appears to be of the same strain as *Mme. d'Albertina*, but more refined than this, which is of American origin. Both are of the fringed class and quite devoid of fragrance: indeed, the latter item would appear to be quite disregarded by raisers of the winter-flowering section, as scarcely one variety in ten is sweet-scented. A good looking pink variety recently noted was named *Pride of Exmouth*. It is a full-centred flower, a large Joliffic type in both colour and form. It is, however, uncommonly near to another pink variety, *Mrs. H. Little*, if not indeed identical. As we have only seen flowers of these we are unable to say whether they are perpetual flowering or not.

**Nursery rubbish.**—The quickness with which weedy shrubs grow is taken by many as a sign of their merit, and the use of the really good hardy evergreens is set aside for some rapid growing forms of the Privet, which is a weed among shrubs. The town of Leicester is one of the places which we have lately seen overrun with it. In the parts of the town with many villas and not ugly gardens there are miles of this rank-growing Privet, forming hedges between the gardens and the roads. The hedges, having got a little old, are now decayed in parts, show a bad, poor colour for a background, and are absolutely useless as a fence. Unless supported by iron, the Privet is useless for fulfilling the work of a fence. The time it appears to save is really lost, because the years that brought it to its present pass would have led to a stout, handsome growth of Holly, Box or Yew, while the result of using Privet is deplorable.

**The alpine Clematis (Atragene alpina).**—In your "Wild Garden" *Atragene alpina* is mentioned as a plant apparently easily grown and likely to succeed. I have three or four strong plants here in different positions, but have never been able to induce them to grow. Mr. Wolley-Dod tells me he has half-a-dozen plants with a like result, and adds that he has never seen the *Atragene* succeed in cultivation. Most things will grow here, and I should be much obliged for any hints on the above plants through THE GARDEN.—E. C. BUXTON, *Bellus-y-coed.*

\* \* The alpine Clematis is really very easily grown, and as hardy as a Bramble. We have had it on both the north and south sides of the same wall, quite happy without any attention for years. Get healthy young plants and you need have no trouble with them. One of these plants growing in a gravel walk flowers profusely every year.—Ed.

**Begonia Veitchi.**—It is about twenty-five years since the first tubers of this handsome and nearly perfectly hardy species came into my hands, the tiny tubers certainly not larger than a fair-sized Pea. I grew one of these till it was nearly or quite 5 inches across, when, unfortunately, it came quite suddenly to grief. During the last year of its existence the plant was grown in a 9-inch pot. Happily, too, I was able to secure a large quantity of seed of this lovely plant, and though by this time it had been reduced in price, it was by no means common. Such a tuber of this species I have never seen before or since. These comparatively hardy sorts, e.g., *B. Froebeli*, *B. octepetala*, and the above, may be safely wintered in a frame from which frost is excluded, and by laying the pots on their sides and withholding water entirely, the tubers are quite safe in the pot and soil in which they flowered. I have frequently wintered the above in a cold frame, merely putting a handful of cocoa fibre over the crown of the tuber.—E. J.

**The weather in West Herts.**—During the past week the temperature has been remarkably changeable. The highest readings in the screen ranged between 34° on the coldest day to 53° on the warmest, while the night temperatures were equally variable. On the night preceding the

4th, the exposed thermometer indicated 13° of frost, which is the greatest cold registered by it since the end of March. The soil is now about 1° warmer than is seasonal at 2 feet deep, and about 3° warmer at the depth of 1 foot. Since the month began there have been frequent falls of rain and snow, and the total measurement has amounted to about an inch. About three-quarters of an inch of rain fell on the 7th. This fall, although in no way remarkable in itself, was nevertheless noteworthy as being the heaviest in any single day for exactly six months. Throughout the night of the 7th the wind remained high, and during the hour ending 3 a.m., the mean velocity reached 20 miles, direction W. The two first days of the present month were remarkably sunny for December, but since then the sun has shone for altogether only about a quarter of an hour.—E. M., *Berkhamsted.*

**Royal Horticultural Society's awards.**—At p. 394 I notice severe strictures are passed on the awards given at the meeting on the 9th ult. Of course it is impossible to please all. I am aware at times the exhibits before the floral committee are numerous, and the judging of groups is in consequence delegated to two or three persons. Could the chairman go round, it would be all right. Could not the authorities delegate members knowing the plants and place more members at the work—in fact, the whole committee whenever possible? The names of exhibitors should not be exposed to view till the award is given.—A LOOKER-ON.

## PUBLIC GARDENS.

**Metropolitan Public Gardens Association.**—At the monthly meeting of the Metropolitan Public Gardens Association, 83, Lancaster Gate, W., Lord Teynham, deputy chairman, presiding, on the motion of Sir William Vincent a resolution was unanimously passed expressing great regret at the death of the vice-chairman, Lord Dorchester, who had taken an active interest in the work from its commencement fourteen years ago. It was agreed to make some improvements in St. Nicholas's Churchyard, Deptford, with a view to its use by the public, and to prepare a plan for the further laying out of St. John's Churchyard, Hoxton, and to replant some trees and shrubs in Whitechapel Road, and in St. Stephen's Churchyard, Bow. Progress was reported in the laying out of the East Street Recreation Ground, Walworth, the disused burial ground in Kipling Street, and St. George-the-Martyr Churchyard, and it was decided to commence as soon as possible the laying out of Charles Square, Hoxton, and Albion Square, Dalston. It was announced that the Oval, City Road, had been completed and opened to the public by the St. Luke's Vestry, the association having provided seven seats. A number of other schemes in connection with the acquisition and laying out of grounds in Camberwell, Blackfriars, Walworth, Ratcliff, New Kent Road, Putney, and other places occupied the attention of the meeting.

**The Eucharis mite.**—I shall be obliged if you will tell me if the enclosed *Eucharis* bulbs are infected with the mite. The leaves are all going yellow and dying away. The plants have not been disturbed for years, and I find on turning them out of the pots the soil has got very sour. They have been growing in a stove all summer with very little ventilation. I have grown and flowered *Eucharis* successfully for several years, so if the enclosed bulbs are infected with the mite it is the first time I have had to deal with it.—GARDENER.

\* \* The *Eucharis* bulbs you sent were not attacked by the bulb mite. I examined them very carefully and could not find a single specimen on them. As far as I could see, the bulbs appeared perfectly healthy. Probably the sour soil and want of proper ventilation have caused the leaves to die away.—G. S. S.

## CHRYSANTHEMUMS.

### STAGING CHRYSANTHEMUM BLOOMS IN VASES.

At the late Jubilee exhibition held in Edinburgh the numerous exhibits of Chrysanthemums staged on long stems arranged in vases were quite a feature. If my memory serves me right, it was the Scottish Horticultural Association who initiated this method of staging both Japanese and incurved blooms on long stems about three years since. It is a step in the right direction of making the autumn shows much more interesting. There is certainly a drawback even to this plan, viz., the difficulty of conveying the blooms to the shows. To illustrate what energy can do when stimulated with some tangible reward, the whole of the six prize-winners in that one class resided some 90 miles from the show. In fact, one travelled some 500 miles, and staged his blooms so well as to secure the fourth prize in a strong competition. The wording of the class was as follows: "Twenty vases, three blooms in each, twenty varieties, Chrysanthemum foliage only to be used." It has been found that Chrysanthemum blooms staged on long stems, each, say, from 1 foot to 2 feet long, absorb so much of the moisture from the stems when cut that the leaves quickly become limp. To obviate this defect, the executive allowed exhibitors to arrange foliage with their blooms from other Chrysanthemum plants. Exhibitors strip the hole of the leaves from the stems bearing the blooms and tie the stem to another carrying the leaves; thus the blooms and foliage remain fresh a considerable time. All the exhibitors, however, do not need to make use of added foliage, as the first prize collection was staged with the foliage and stems as grown.

Eleven entries were received, but two failed to put in an appearance. However, the nine competing made the finest display of its kind ever seen. The first prize blooms from Mr. Haggart,

Moor Park Gardens, Ludlow, were without a doubt the finest Japanese specimens seen this year at any show. They appeared to be timed to a day, were of large size without being unduly coarse, the colours bright, and the whole beautifully staged. Every bloom could be examined with ease; not one was crowded. The stems showed about 15 inches of foliage above the vases. The tables were so arranged as to take two rows of vases. These being placed anglewise, examination could be effected easily and without injury to the blooms.

Without a doubt the classes for Chrysanthemums in vases, of which there were several, created infinitely more interest than those in which the blooms were arranged on the ordinary boards or stands, cut with short stalks and set up by the aid of cups and tubes. One exhibitor mixed incurved blooms along with Japanese in the large Jubilee class. Comparison of the two sections for decorative effect was here easily made. It was plain that incurved blooms do not lend themselves to this purpose nearly so well as the less formal Japanese. The bruised condition of some of the blooms, too, proved that they are not so easy to carry to a show on long stems as are the Japanese.

Prizes were also offered for what are here termed "decorative" varieties. The stipulation was that they were not to be disbudded, and to be shown with their own foliage. Although there were several competitors, the blooms lacked quality, and except in but one instance the colours were not of the best. Taken as a whole, the classes noted at this show were a distinct break away from the ordinary method of staging Chrysanthemum blooms.

E. MOLYNEUX.

**Chrysanthemums G. J. Warren and Mrs. W. Mease.**—"H." (p. 438), draws attention to these two sports from Mme. Carnot. Certainly that known as Mrs. W. Mease is paler than the golden-yellow sport G. J. Warren. They are as distinct as possible. Both are of the finest form, as might have been expected from such a parent.

I look upon Mrs. W. Mease as the finest introduction of the current season. No doubt, as "H." says, the stock was over-propagated last spring to admit of the plants giving anything like satisfaction the first year. We shall expect to see good blooms in quantity next year.—E. M.

**The old purple Chrysanthemum.**—If "A. D." could secure some blooms of what he thinks may prove to be the old purple variety, the first of all the large-flowering Chrysanthemums grown in Europe, I do not think there would be much difficulty in definitely pronouncing its genuineness. All the Chinese Chrysanthemums imported from the Far East a century ago or thereabouts were very fully and carefully described, and so when the old tasselled lilac was discovered in a Cornish garden a few years since, we were enabled, by reference to the descriptions and a comparison of the blooms submitted, to say that it was the variety it purported to be. Another old-time favourite, Mme. Poggi, was also soon afterwards discovered, but this unfortunately turned out to be wrongly named, and was no other than King of the Crimson, a variety that was lost for many years. The Christines are very old, as "A. D." says. The pink or peach form is believed to have been raised by Captain Bernet, who first raised seedlings about 1827. Golden Christine was a sport obtained by Mr. Merry in the days of the old Stoke Newington Society, and the white form also known as Mrs. Forsyth came later.—C. H. P.

**Reflexed Chrysanthemums.**—I quite agree with "D. B." (p. 436) when he says there is an apparent decline in the popularity of this section of the Chrysanthemum. I cannot agree with him, however, when he makes the sweeping assertion that "there are never more than two competitors for the three prizes offered." He evidently is referring solely to the shows of the National Chrysanthemum Society. The scarcity of blooms may be true in that case, but I think it hardly right to brand all societies with failing to obtain more than a couple of entries in the class. At Hull several grand exhibits were staged, and as the blooms in all the stands were first-class an interesting display was the result. In the neighbourhood of Asect and Windsor, reflexed varieties are especially well cultivated. For years special encourage-

ment has been given to this section at Ascot in the shape of a silver challenge cup, and which has had the desired effect in stimulating competition. Most of the reflexed varieties do not lend themselves to decorative effect, mainly owing to their stiff and formal appearance, and also to the weakness of their peduncles. Artificial supports are objectionable to flowers employed for the filling of vases in rooms, not only on account of the unsightliness, but for the extra time involved in providing such. Some few varieties, however, are specially adapted to decoration, either in a cut state or when growing on the plants by reason of their free-flowering, colour, and general usefulness. Elsie, primrose, one of the best in every respect; Mrs. Home, pale yellow, a sport from the incurved variety George Glenny, which in itself is remarkable, as there are so few instances of one variety sporting to a distinct type of bloom; Cloth of Gold, bright yellow, another worthy of attention; Cullingfordi, too well known to need any praise, and King of Crimsons, as its name implies, are desirable. Progne with its violet perfume, as well as the stocky-growing, late-flowering old variety Julie Lagravere; Emperor of China with its silvery-pink blossoms; Chevalier Damage, orange-yellow, and the brightly coloured Putney George, all make up a creditable display if the plants are well grown.—E. M.

#### POMPON CHRYSANTHEMUMS.

For some time past there has been cause for regret that the useful and pretty little blossoms of the pompon Chrysanthemum have not received a larger share of attention. The greater variety both in form and colour, as represented in the Japanese and other large-flowered Chrysanthemums, doubtless has contributed very much to their popularity.

In looking through a number of lists of prizes offered by different societies throughout the United Kingdom, one may trace a cause of their discouragement. In most schedules of prizes it appears to be the rule to have just one class in which these charming little flowers are asked for. Often, too, the prizes are most inadequate, and quite out of proportion with the money offered for other types of the flower. The primary object of most Chrysanthemum societies is to encourage the cultivation of the different forms of the flower, but those responsible for their existence evidently think that flowers of large size have such an overwhelming claim, that the pompon has come to be almost excluded from their exhibitions. One class very often has to suffice for their proper representation, and in such a class both pompons and Anemone pompons are set up together. This is most unsatisfactory. One exhibitor may stage all true pompons, another Anemone pompons, while a third may show a proportion of each kind. Can a satisfactory judgment be given in such instances? The relative merits of the three boards of blooms would be anything but an easy matter to determine, thus showing the need of each type of the pompon being represented in a class by itself. The National Chrysanthemum Society certainly provides classes for pompons at its first three exhibitions, and on the occasion of its November display in the open classes, is generous enough to offer prizes for twelve trebles of pompons, and an equal number of Anemone pompons, in two distinct competitions. Smaller classes in the amateurs' division, also those open to maiden growers, show an improvement upon what existed a few years ago. Still this is a poor representation when one considers their value and the somewhat monotonous repetition of Japanese blooms at the same show. The very formal and stiff manner in which the blooms are arranged in threes and set up with such rigid uniformity—the blooms, too, often like small flowers of varieties belonging to the large-flowered sections, through a severe system of disbudding—represent the pompon in anything but a pleasing form. The beauty and usefulness of the pompons might be much better represented in classes where sprays, only partially disbudded, could be ex-

hibited in small vases, or small earthenware or glass receptacles. Half a dozen sprays neatly and lightly arranged in this way with their own foliage, and the vases given sufficient space to set off the arrangement, would make a far prettier exhibit than the formal system now generally practised. Here and there in different parts of the country a society has made this departure from the orthodox method of staging, with the result that the culture of the pompons has been encouraged. An object-lesson has in this way been given as to the decorative value of these small flowers when grown in a free manner, and with little, if any, disbudding.

By all means let the pompons be exhibited in a way that high quality may be represented, such as is now the case, but let them be set up differently, and, unless a better method can be proposed, it would be wiser to follow on the lines suggested for those exhibited in sprays. At the present time there is room for a class in which the free-flowering and useful qualities of the very small blooms, as represented by such sorts as Snowdrop, Victorine, Marion, Lune Fleurie, and Yellow Gem could be exhibited. These sorts are not large enough to be put into competition with those which now find favour, and consequently are never seen except at the display of a trade specialist, or in the collection of an enthusiast. For arranging in a fairly large vase, and cut with long stems, sprays of these miniature sorts make a very charming and welcome change. Those responsible for the arrangement of a Chrysanthemum show would find it worth their while to give a fuller consideration to the claims of the pompon flowers, which may by a judicious arrangement of classes be calculated to quite alter the appearance of an exhibition, and make such far prettier and more interesting than it would otherwise be without them. C. A. H.

#### ORCHIDS.

##### CATASETUMS.

THERE are several beautiful Orchids in this genus, the flowers partaking largely of the characters that have made the family so popular—that is, quaintness of form and structure with a delicate texture and handsome appearance. The genus is peculiar to Tropical America, many of the kinds occurring in Brazil, and although many are easily enough grown, they require care to ensure freedom of flowering and a long life under cultivation. Some of the larger growing kinds, such as *C. macrocarpum* or the nearly allied *C. tridentatum*, need only to be placed in a warm house and they will grow like weeds, but more trouble has to be taken with the smaller growers generally. All may be grown in a hot, moist house where the sun is allowed to enter rather freely until nearly mid-day, and the blinds are only used when it is absolutely necessary to prevent injury to the foliage. The heat must be allowed to rise gradually in the mornings with air on, so that the leaves do not get hot all at once, plenty of moisture being ensured by plentifully sprinkling the stages and paths. When the foliage gets warm, lower the blinds, but as early as possible in the afternoon, or say about 3 o'clock for span-roofed houses running north and south, take off all the air and syringe the plants somewhat heavily, damping every part of the house and roll up the shading. This creates a very quick, stimulating temperature, and growth under these conditions will be very rapid. As the growths get ripened a little more sun may be allowed, but the temperature must be steadied a little by more air and less atmospheric moisture. Keep the roof moisture going until the pseudo-bulbs have quite finished swelling, as any slackening at this time leads to shrivelling in the winter and consequently

weak growths in spring. In many cases the leaves will begin to turn colour soon afterwards, and then the water supply may be greatly reduced, the plants hung up or arranged on the stages in the full sun and the temperature sensibly diminished. Any that are pushing their flower-spikes may with advantage have a little more encouragement. During winter hardly any water need be given, especially to well-ripened plants, but the pseudo-bulbs must not be allowed to shrivel. Too little heat is not advisable, a night temperature of 60° while at rest being quite low enough, though a slight drop on cold nights is preferable to pushing the fires and causing a stuffy atmosphere. In early spring when the young growths are starting it is important that water be carefully applied and kept away from these tender shoots as much as possible. Even when further advanced, unless the weather is really bright, syringing must be very carefully gone about, as the water sometimes collects in the heart of the shoots, to their detriment. There is no doubt that when the sun is shining on them on hot summer afternoons a thorough washing with tepid water from the syringe is very refreshing and of immense benefit to the plants.

The treatment of the roots depends considerably upon the habit of the species, the weaker growers of course needing less in the way of compost than the larger. Three parts of good fibrous peat to one of Sphagnum Moss may be given, and where pots over 4 inches across are used, a free addition of clean crocks and charcoal broken in rough lumps should be made. For the smaller sizes it will be found more convenient to mix the peat and Moss and to add a few suitable crocks as the potting proceeds. In each case let the drainage be perfect, for Catasetums abhor anything close or spongy about the roots, yet require a very liberal water supply when in full growth. The fleshy roots, too, are very easily injured by disturbance, and when the drainage is good and clear one may easily remove most of the compost and replace it with new without disturbing a single root. Before potting clear every bit of old and sour material none the less, for if this is left, the whole of the new compost soon gets into a bad state. Newly-imported plants are sometimes rather difficult to establish; they keep alive and look fairly sound, but it is often many months before either a new bit of root or growth makes its appearance. Nothing can be done to hurry them, and the best way to manage them after being thoroughly cleaned is to pot them up in clean crocks at first, surfacing these with a little Moss when the roots are well plumped up. When the growths appear, press a little compost around the plants and trim off neatly, almost entirely withholding water until the shoots begin to root. In a proper atmosphere insects usually give little trouble, but when allowed to get dry, red spider often puts in an appearance. Thrips, too, like the young shoots, and soon cripple them if allowed their own way. For the latter, use the vaporising fumigator on two consecutive nights, and sponge the plants thoroughly afterwards. Clean, soft rain-water is the best thing to use, and is preferable to any other insecticide, though in really bad cases of thrips a little tobacco-water may be used. The leaves, though hard-looking and not apt to be injured by sunlight, are, notwithstanding, easily spoiled by rubbing with an almost dry sponge, as sometimes practised by careless or ignorant cultivators.

*Lælio-Cattleya Gottoiana*.—This is undoubtedly a natural hybrid between *Cattleya*

arneri and *Lælia tenebrosa*. The sepals and petals, about 4 inches in length, are pale rose, seeming pale green at the base; the lip rich purple, margined with rose, and veined with darker purple in the centre; the side lobes rose, fading to yellow, and lined with brown at the base. It was introduced with *Lælia tenebrosa*, and first flowered in 1891 in the collection of Mr. E. Gotto, the Logs, Hampstead Heath. It was exhibited at the meeting of the Royal Horticultural Society on June 23 of that year, and has since flowered in her collections. A plant was exhibited by the late Hon. J. Chamberlain at the Drill Hall meeting of November 23 last.—H. J. C.

**Lælia peduncularis.**—A fine spike of this plant comes from a correspondent. It bears six flowers, each about 2½ inches across, of a deep lilac-se on the sepals and petals, the lip having an oblong blotch in front. It is quite distinct from the anceps section and a useful and beautiful hybrid. Keep it in a light, sunny house, giving a very free water supply while growth is active and much less while at rest. The temperature need not be so high as that of the Cattleya house and abundance of air should be given all the year round. It is a native of Mexico.

**Scuticaria Steeli.**—As a garden plant this could scarcely be worth growing, except for its distinct appearance, the flowers not being produced very freely. They are, nevertheless, very singular and beautiful, the ground of the flower being clouded white, with large chocolate blotches, the lip having purple stripes. The flowers are produced from the base of the long terete leaves, the latter often growing considerably over a yard in length. It does not require much compost, and may often be seen thriving well on almost any blocks. It likes plenty of warmth and light and a very moist atmosphere, being a native of British Guiana, whence it was introduced in 1834.

**Lælio-Cattleya Clive.**—A plant of this noble hybrid was recently exhibited at the Drill Hall under the above name from the Rt. Hon. J. Chamberlain's collection. It is the result of crossing *Lælia pumila* Dayana with *Cattleya bowiana* aurea. This was raised in the collection of Mr. N. Cookson, Oakwood, Wylam-on-Tyne. L.-C. Normani also came from the collection of Mr. Cookson, as also did L.-C. broomfieldensis (the reverse cross), exhibited by Mr. M. Wells at the Drill Hall meeting of the Royal Horticultural Society on August 14, 1894, when it was awarded F.C.C. by the Orchid committee. Previously to this Mr. C. J. Ingram had raised from the same parentage as the two first named L.-C. Ingrams, which was awarded a first-class certificate in August, 1892. This was by far the finest form of the four. This is truly an example of the plurality of names, which cannot be anything but misleading to the expert, to say nothing of those whose opportunities are less favourable. Surely the original name might be maintained, with names added where the variety deserved distinction.—ONE OF THE ORCHID COMMITTEE.

**Arpophyllum giganteum.**—It is late for this plant to be in bloom, but I recently saw a large specimen bearing quite a couple of dozen of the long, dense spikes of rosy purple flowers. The plants grow in dense tufts of upright stems, each bearing a single sword-shaped leaf, from the base of which the spikes issue. The plants are very free rooting, and consequently like a fairly substantial root-run. The drainage requires very careful attention, and in the rather deep pots that the sorts like should come at least two-thirds of the way up, covering this with a layer of rough Sphagnum. Equal parts of peat and chopped Moss with a little fibrous loam for the stronger plants suit it well for compost, and in planting place a few pieces of roughly broken crocks and charcoal along with the peat and Moss. Give a little water only until the roots begin to run freely, after which and as long as growth keeps active a full supply is needed. It is not a fastidious plant as to temperature, but being a native of some of the most exposed parts of Mexico and Guatemala, must not have too great heat.

Plenty of light is quite a necessity in its culture, so heavy shading must not be allowed at any time. It may be grown with Cattleyas if this is not lost sight of, or even with the Mexican *Lælias*. It is an old plant in cultivation, having been sent to Chiswick in 1839 by Hartweg, who discovered it growing on high trees in Mexico.—R.

#### ONCIDIUM HÆMATOCHILUM.

The blossoms of this plant are very bright, and, as long as the plants are healthy, very abundantly produced. They occur from ten to twenty or more on erect spikes, and are yellow on the sepals and petals, spotted with rich chestnut-brown, the lip bright rosy-erimson. It is not often seen in good condition, though if healthy, vigorous plants are once secured, it is not difficult to keep them so for some years at least. The plant has no pseudo-bulbs, but consists of large thick-textured leaves, each about a foot in length, from the base of which the flower-spikes proceed. It thrives well in a hot, moist house while making its growth, and should have a light sunny position not far from the roof-glass. Commencing to grow in early spring, the leaves unfold slowly, and by the autumn should be fully expanded. The flower-spikes occurring at this time, it is not wise to reduce the water supply much, but let the plants have as much air as possible, and be only sufficiently shaded to prevent injury to the foliage. The flowers over, less water is needed, for though the plant is bulbous, the large leaves store up a lot of nutriment that keeps it going through the winter with only occasional waterings. If the Moss used for compost has grown much about the base of the leaves, it is as well to remove a little of this before winter, as otherwise it is apt to hold moisture in excess of the needs of the plant. And here it may be noted that in preparing the compost for *O. hæmatochilum*, which greatly dislikes root-disturbance, it is well to use plenty of Sphagnum Moss rather than peat. Not that it is any more lasting, but decayed Moss is easier to remove than peat, and possibly by its decay furnishes a certain amount of food to the plants not obtainable from peat, which when decayed is always injurious. The plants when newly imported are very vigorous for a season or two, and this vigour must be taken advantage of to get them thoroughly established in their pots, baskets, or whatever they are grown in. Give them fairly good room and a large percentage of clean crocks in the compost, then it will be easy as time goes on to add to this without disturbance or unduly thickening it. It is not very important what class of receptacle the plants are grown in, and I have seen good pieces grown on Tree Fern stems, but careful treatment of the atmosphere, especially during winter, is necessary. A very moist atmosphere, especially should the temperature run down a little, is apt to cause an attack of spot, which renders the plants very unsightly. A warm, dry circulation of air at midday is what this *Oncidium* delights in, and has a very great deal to do with building up a solid growth that will bloom profusely in due season. It is a native of New Grenada, and was introduced in 1847.

**Masdevallia triaristella.**—The tiny flowers of this and several similar species have a great charm for those who like quaint and structurally interesting flowers. In this case the plant seldom exceeds 2 inches in height, and the flowers, with their elongated sepals and peculiar concave formation at the base, are brown and bright yellow. Being a true epiphyte, it must be grown either in very small pans or baskets, preferably suspended not far from the roof, where they have the benefit of plenty of air.

**Restrepia antennifera.**—The very singular and beautiful blossoms of this species are produced on slender spikes from the base of the leaf. The upper and lower sepals are pale yellow, the latter joined and forming a boat-shaped cavity; the petals are very narrow and slender, and all

the segments are closely covered with purple-brown blotches and spots. It is a native of New Grenada, where it was discovered many years ago by Humboldt growing at great elevations on the tree trunks. A cool, moist atmosphere and shallow root-run are therefore the most natural treatment for it.

**Lælia præstans.**—This was in capital form recently with Mr. Bull, the bright and effective blossom being very large compared with the size of the growths. Like all the *L. pumila* section, it dislikes a large body of compost and does well in small pans suspended from the roof in a warm, moist house. Fill the pans to within an inch of the rims with clean crocks, planting in peat-fibre and Sphagnum. It is not exactly constant in its time of flowering, but usually grows away in early spring, blooming in autumn upon the growth made. It must be kept moist all the year round, but not too heavily watered during the winter months.

**Oncidium pelicanum.**—This useful Mexican species is in flower with Mr. W. Bull, and is very pretty. The pseudo-bulbs are deep green, the spike rising to a considerable height and being very freely branched. The individual flowers are not large, but showy, the sepals and petals are pale yellow, blotched with reddish brown, the lip much paler in colour, with a crimson crest. It does well under ordinary conditions of culture, and should be potted up in peat-fibre and Sphagnum Moss over good drainage. It thrives well in the cooler part of the Cattleya house, and must have plenty of water at the roots while growing.

**Vanda suavis.**—There is a very fine collection of Vandas of the larger-growing section at Cambridge Lodge, and several of this fine species were recently in bloom there. The plants are large healthy specimens, many of them 2 yards in height, their long white roots spreading in every direction, catching hold of each other's pots and running over the stage. It is just this freedom both of root and branch that I have so often advised for these beautiful plants, and they are well worthy of it. Cooped up in small houses with their heads close to the glass, they are quickly covered with insects and unsatisfactory in every way, but treated as indicated they are noble objects.—H.

**Miltonia Moreliana atropurpurea.**—This is one of the brightest and deepest tinted of all the spectabilis group, and this, too, was recently good at Chelsea. The sepals and petals are a deep rich vinous purple, the lip having many radiating lines of rose on a light ground. It does well on rafts or in shallow wood baskets with only an inch or so of compost. It likes a good clear light, but must not be exposed to bright sunshine, and the temperature of the Cattleya house suits it well. During the time growth is active it can hardly be over-watered, and even when at rest the roots must never be kept dry for long together.

**Masdevallia macrura.**—This is one of the largest growing of Masdevallias, and produces very fine flowers. They are freely produced and singular in outline, the sepals being elongated into tails nearly 6 inches in length beyond the tubular portion. The colour is a tawny yellow inside, the outer part brown, and the whole of the tube is closely covered with minute purple dots. It is one of the best growers and thrives well in rather larger pots than the Harryana section. The credit of its discovery is due to Roehl, who found it growing on Moss-covered rocks in New Grenada. It was not until some years later, however, that it was introduced to cultivation, Mr. Bull's collectors sending it home in 1876.

**Oncidium varicosum.**—This mid-winter-flowering *Oncidium* is largely grown in Mr. Cypher's nursery at Cheltenham; many of the spikes are 3 feet in length, and bear from fifty to sixty flowers. These are very large individually, of the brightest yellow, with a distinct brown centre. It is a cool Orchid and of a free habit of growth. It ought to be grown largely

by all in need of flowers of the kind at this season. I know many amateurs are afraid to buy Orchids, as they think they would not grow unless under special care and conditions, which is no doubt the case with many of them, but this *Oncidium* proves itself to be a noteworthy exception.—M.

#### SHORT NOTES.—ORCHIDS.

**Cypripedium Deedmani.**—This distinct hybrid is the result of a cross between *C. Spicerianum* and *C. Chamberlainianum*. The dorsal sepal is white at the top, green, spotted with purple at the base, and having the broad characteristic band of purple seen in all *C. Spicerianum* hybrids. The petals are green, thickly spotted and lined with brown, the lower sepal pale green, the lip rich rose-purple, shading to green. It was raised in the Botanic Gardens at Birmingham, where it has recently flowered.—H. J. C.

**Lælio-Cattleya albanensis** (*L. grandis* × *C. Warneri*).—This is a lovely free-flowering and distinct hybrid. The sepals and petals are delicate rose, of fine form and substance; the lip rich crimson-purple, margined with rose; the side lobes rose, becoming suffused with the rich purple at the base. A plant with three flowers was recently shown at the Drill Hall from the Highbury collection of the Rt. Hon. J. Chamberlain. This is a natural hybrid and was introduced by Messrs. F. Sander and Co., of St. Albans, in 1893.

#### BOOKS.

##### PRACTICAL FORESTRY.\*

SINCE the first edition of this work was issued, the subject of forestry, we are told, "has made no great advance." To read the book, one might imagine that between Curtis the first and Curtis the second nothing whatever had been done except what he has done himself in conjunction with the "Land Agents' Record." Although Schlich, Fisher, Marshall, and a completely revised and reversed edition of Brown's "Forester" have appeared in the interval, and quite a revolution been inaugurated in forestry teaching, not to speak of the forestry press, which has done and is doing so much, the author ignores them all, or else he has never heard of them. In a book manifestly derived from common sources, not a word of acknowledgment is to be found, so far as we can see. One might well rise from a perusal of "Practical Forestry" in the belief that its author was an arboricultural Rip van Winkle who had been asleep for years. Much of the advice given is old, and has been condemned by all acknowledged teachers of the present day. He states (page 12) that in a long experience at home and abroad he "has seldom seen that display of knowledge and system that we all desire to see." Mark the "all." No writer would venture to put his name to such a statement who knew really anything about forestry abroad, especially in Germany and France. Strong doubts as to his expert abilities are engendered by his undisguised bid to landowners to treat over the heads of their competent head foresters. Here is a sample of the author's simplicity and vague knowledge of his subject: "Some trees require more room than others—for example, Oaks, because it is important they should attain a large girth with a medium height" (pages 55 and 56). What consumer, I wonder, ever objected to an Oak because it was long in the bole. The longer the bole the greater the value, while a short bole means a useless top and loss to the producer. How a Schlich or a Dr. Sommerville must grin to see it advised that in rearing hardwoods (page 59), "the distance between the trees may range from 12 feet to 20 feet," that is, 4 yards to nearly 7 yards apart. In such a case our expert "would make up with conifers 4 feet apart"—"nurses," I presume, some half dozen or more profitless nurses to each hardwood. No particular conifers are preferred, and with most varieties

the probable effect would be the smothering of the Oaks. On thinning he is apparently quite oblivious to advanced opinion and practice. At page 72 he proceeds: "Trees when growing need air and light and ample room below, otherwise they crush out one another and the strongest and fittest only survive." Exactly. . . . "Where from the earliest period careful thinning has been carried out, very different results are manifest. Each tree stands firm and independent of its fellow, the lateral branches are retained until they have performed their functions and do not wind-whip each other, but give support without dependence; the growth is rapid and uniform, and the trees being of equal height obtain their full share of light and heat. . . . There is at once the appearance of prosperous development, which to the landowner is an accumulation of capital or a silent influx of revenue." This is Brown at his worst. The worst season in the whole year is recommended for planting (page 41), viz., to begin with November and end with April, and the vile "notching system" of planting is advocated energetically. At page 53 we are told to bear in mind that the life of a tree depends on the vitality of its root fibres, and that everything should be done that skill can devise to keep them healthy and active, and the author's way of doing this is to transplant throughout the dead season of the year, when the chance of the mutilated roots keeping "healthy and active" is reduced to the vanishing point. No distinction is made as to species; evergreens and deciduous all go in pell-mell together. At the same page it is also interesting to learn that on large areas small trees "should not need staking." Biggish trees would, we presume, have to be staked. Now, what practical joker could have suggested staking young plantations, under any circumstances, to an expert who is great on economy by planting thin? At page 60 the author appears to have got a momentary inspiration from some source of the newer forestry, and introduces in italics the words "unbroken leaf canopy." Quite forgetting his earlier thinning operations, in which his trees stand sturdily aloof from each other, with no canopy whatever, he writes, speaking of Nature, "Throughout the future the forester should endeavour to obtain an unbroken leaf canopy. . . . True forestry greatly consists of this uniform and regular growth, this mutual dependence on each other for support." How an unbroken leaf canopy is to be maintained throughout without the "wind-whipping" spoken of is a puzzle.

The book does not appear to be what it pretends to be—a safe book for those for whom it is written. It does not display personal familiarity with forestry operations, and it is by no means up to date. I have rarely read a book so pretentiously written, and yet so poor or conceived in such bad taste. W.

##### MODERN CHRYSANTHEMUM CULTURE FOR THE MILLION.\*

THIS is another recent addition to the rapidly increasing literature of a popular flower. It is a very neatly got up little sixpenny paper-covered cultural manual of sixty odd pages, well printed and containing about a dozen typical and explanatory illustrations in black and white. The chapters are in most cases brief, but to the point, and, considering the price, "Modern Chrysanthemum Culture" is one of those little books that neither author nor printer need feel any compunction in submitting to the public estimation.

The subjects dealt with are many, and may be summarised under the following headings: Propagation, the various pottings, summer treatment, insects and mildew, feeding, top-dressing, taking the bud, housing, damping, dressing, staging, judging and other allied subjects.

In a table of Chrysanthemums the author gives

\* "Modern Chrysanthemum Culture for the Million." By George Garner. (Blake and Mackenzie, Liverpool.)

what may be very useful to many who are desirous of growing for show. This table comprises a selection of some of the best varieties, and gives an indication of height, season, size of pot required, the proper bud to be taken and the date, when to house the variety and the size of bloom. These details in their fullest form apply principally to Japanese and incurved, but other selections in all the sections are given without perhaps being quite so comprehensive.

Mr. Garner's treatise is handy and portable, and we do not remember any other that can be compared with it at the price, and its style should ensure it a ready sale.

#### JADOO.

I HAVE been experimenting this season with jadoo, a soil prepared from soot, peat, gypsum and a few other ingredients. When sowing my spring Onions I drilled in with the seed in each row a layer of fine jadoo about half an inch thick. I did the same when sowing Cabbages, autumn Onions and other seeds, including Asparagus. My plants came up so thickly and regularly, that I came to the conclusion that not too much was claimed for jadoo in this respect and that all my seeds germinated. Next year my sowings will be much thinner. As regards pot plants, I had very few plants in pots, but I repotted four plants in my windows, a Palm, a Vallota and two Asparagus nanus, in the spring that were in bad health. The Vallota was almost dead; it has now made a bulb half an inch in diameter and is looking vigorous. The Palm has put forth three fresh leaves, and the Asparagus has rooted well and grown vigorously. In all, the root action has greatly developed, and I have found the statement as to watering but seldom absolutely correct; the danger rather is that one may give too much water. As to cuttings, I cannot speak from my own experience. I planted a number of Lilies, some in a frame where jadoo had been largely introduced and others in the open air with jadoo round their roots. In all cases the bulbs had thriven better than in former years in the ground, had made better growth, and had developed much greater root action. Amongst the Lilies were *L. Krameri*, *L. odorum*, *L. Henryi*, some *speciosum* and others. My Gladioli were treated in the same way. When planted in the spring, a layer of jadoo was placed about them. I have not yet lifted them, but they have done well, and especially the little bulbs and bulbets. During the autumn I paid a visit to Teignmouth, where Col. Hallford Thompson resides. I saw in his conservatory a fine lot of Begonias, Cannas, Lilies, &c., all growing in jadoo and in fine condition. The blooms were very highly coloured and very abundant. I saw a plant of *Tacsonia Van Volxemi* whose roots were radiating in all directions in a small brick pit inside one of the houses. The jadoo in the pit was simply one mass of roots, the plant in fine condition. In another house I saw a small Coffee plant in perfect health and foliage. This plant had come to him three years back much diseased with the fungus that had done so much harm in Ceylon. Grown in jadoo the fungus has disappeared and the plant had regained perfect health. In 6-inch pots were some *Lilium Harrisii* that had bloomed well two years running. One of these bulbs was turned out sound and firm; it had made good growth, had borne five flowers, with stems 2 feet 3 inches high and had a fine bulb 9 inches in circumference. Potted again in jadoo, I have no doubt it will flourish equally well next spring. I admired the healthy, robust look of his dwarf Apple and Pear trees growing in pots in jadoo and covered with fine fruit. What I saw convinced me that jadoo put beneath the surface and round the plants encouraged root action and greater luxuriance of growth and power of flowering. I much admired a bed of Violets in great round clumps 8 inches to 10 inches through; they looked like a bed of Strawberry plants.

ALEXANDER WALLACE, *Physician*.

## THE BAMBOO GARDEN AT KEW.

THE Bamboo garden formed a few years ago at Kew has proved so well adapted for the plants, that a few notes as to its position, soil, &c., may be of value to the numerous readers who intend to, or have already commenced, to grow the Bamboos. A very short experience in the cultivation of Bamboos is sufficient to demonstrate the importance of shelter as a means to success. It is, possibly, the factor of chief importance. Recognising this, the director of Kew selected a position in the middle of a wood near the Rhododendron dell, and taking advantage of a hollow already existing there, had the ground lowered some 5 feet or 6 feet below the surrounding level. A belt of shrubs on the north and east sides, between the trees and the Bamboos, together with the low level on which the latter stand, affords them a shelter almost as perfect as can be furnished out of doors. Even the bitterest north-easter loses a good deal of its sting before it reaches these Bamboos. It has been pointed out before in these columns that what the cultivator of Bamboos has most to fear is not a low temperature

growth is indicated by the unrolling of the young leaves, which may be in April or May, according to the mildness or otherwise of the winter. Bamboos are very difficult to kill outright, but treated improperly they are apt to get into a stunted, one might term it sulky, condition, which it takes them a long time to recover from. I would advise those who wish to try these plants to obtain them from the nurserymen in autumn or winter, if they have been grown in pots, and to give them greenhouse treatment till the end of May, when they can be planted out in a growing state; but, on the other hand, if they have been planted out in the nursery ground, not to have them sent off till the end of April or later, when they can be set out at once. A yearly clearing out of the older, worn-out stems, dead leaves, &c., prevents that choked-up appearance one sees so often in ill-tended Bamboos, and whilst giving a lighter and more graceful aspect to the plants allows freer play to the young growths. It should be done in spring before the latter have grown long enough to risk injury.

Such, briefly, has been the system of cultiva-

days are at their shortest and darkest, there is nothing out of doors that equals the best Bamboos in the fresh greenness and beauty of their foliage. The following is an extract from Mr. Freeman-Mitford's book, "The Bamboo Garden," p. 209. It refers to some sheltered corner at Batsford Park, where Bamboos play no inconspicuous part, and it has a special interest at this season:

A tiny rill trickles over the green velvet of the rocks, with Ferns peeping out of crannies in which many an alpine treasure is hushed to rest, waiting the warm kiss of spring and the song of the birds, that, like Orpheus with his lute, shall raise the seeming dead from the grave. Tall Rushes and gracefully arching Bamboos, hardly stirred by the wind, nod their plumes over the little stream from which the rays of a December sun have just strength to charm the diamonds and rubies and sapphires; a golden pheasant, all unconscious of a human presence, is preening his radiant feathers by the water-side. It is a retreat such as the fairies might haunt, and where in the bitter Christmastide a man may forget the outside world, and for one too brief hour revel in a midwinter day's dream of glorious summer.

W. J. BEAN.

## NOVEMBER IN SOUTH DEVON.

DURING the past month 1.25 inches of rain fell on twelve days against 0.84 of an inch on six days in November, 1896, the average for the month being 4.04 inches. For the first eleven months of the present year the rainfall has amounted to 29.12 inches with 146 rainy days, against 19.45 inches on 135 days during the same period of 1896, so that the year's rainfall up to the present time exceeds that of the corresponding period of 1896 by nearly 10 inches. It is, however, almost 2 inches below the average fall for the eleven months, which is 31.02 inches, and as there is no probability of such a heavy rainfall during the present month as occurred during December, 1896, when 7.37 inches fell, the year will doubtless close with a rainfall slightly below the average. The temperature of the month has been high, the mean of highest and lowest temperatures being 49.4°, or over 2° above the average, which is 47.1° and more than 7° higher than the mean of November, 1896, which was 42.8°. Both October and November have been unusually warm, their mean temperature being 6.8° above the mean of the corresponding months in 1896. The highest screen reading was 60.3° on the 18th, and the lowest 34.0° on the 30th. The highest sun temperature was 95.4° on 18th, and the lowest grass reading 30.9° on the 30th. This is the first occasion since the preceding winter on which the grass thermometer has registered frost, whereas on December 1, 1896, the mercury on the grass had already recorded frost on twenty-three occasions. The month has been phenomenally sunless, the sun having shone for only 33 hours 55 minutes against 83 hours 20 minutes in November, 1896, and an average of 64 hours 5 minutes. What we have gained in warmth we have lost in brightness, for the dulness of October and November has thrown us back in our sunshine record, and from being 20 hours above the average on October 1, we are, on December 1, over 30 hours below. For the past eleven months the sun has shone for 1627 hours 15 minutes, the average being 1659 hours 10 minutes, and the record for the same period of 1896, 1672 hours 25 minutes. The total horizontal movement of the wind has been 6621 miles, that for November, 1896, having been 6316 miles. The greatest daily speed was 55.4 miles on the 27th, an average for the twenty-four hours of 23 miles an hour, and the highest hourly velocity of 34 miles was reached between the hours of 6 and 7 a.m. on the same date. The past month is remarkable from the fact that the highest and lowest barometrical readings of the year occurred during its course. On November 21 the highest reading, 30.7, was recorded, and on the 30th the lowest of 29.5.

In the Bamboo garden at Kew. Engraved for THE GARDEN from a photograph by Mr. J. Gregory, Croydon.

merely—most of the Bamboos will stand 20° or 25° of frost with impunity in a still atmosphere—but the dry, biting winds of spring. The first requisite, therefore, at any rate where the climatic conditions are on a par with those at Kew, is shelter from north and east.

With regard to soil, I should say that Bamboos like best a free, open, sandy loam. The greater part of the soil at Kew is poor and sandy, but there is, in one part, a belt of good stiff loam extending for a few hundred yards, and it is on the border of this that the Bamboo garden is situated. At the commencement the ground was trenched to a depth of 2 feet to 3 feet, and during the process was enriched with leaf-soil, and where necessary lightened with sandier soil. Another point to remember is that these plants can scarcely be over-fed, and in well-drained soil can scarcely be over-watered. An annual mulching with rich manure is of the greatest advantage.

In regard to transplanting, it is important to note that disturbance at the root is most harmful during autumn and winter, and that it is safest to defer this till root-action has commenced in spring. The renewal of

tion pursued at Kew. That it is the right one is shown by the luxuriant growth of almost all the kinds—so luxuriant, indeed, as to be rather embarrassing in the somewhat restricted space occupied by the collection. The Bamboo garden was made in 1892, and the following are the lengths of a few of this year's growths, exceeded, of course, by specimens in older collections and in warmer parts of the country, but of some interest, perhaps, as showing the rate of growth of Bamboos in a district which has not proved particularly favourable to the growth of tender shrubs as a rule: *Arundinaria Simoni*, 17 feet; *Phyllostachys viridi-glaucescens*, 17 feet; *P. Henonis*, 15 feet; *Arundinaria nitida*, 13 feet; *A. japonica*, 12 feet; *Phyllostachys aurea*, 12 feet; *P. nigra*, 12 feet; *P. fastuosa*, 11 feet 6 inches; *Arundinaria Hindi*, 11 feet 6 inches; *Phyllostachys Boryana*, 9 feet; *P. Castillonis*, 8 feet 6 inches; *Arundinaria anceps*, 7 feet 3 inches; *A. tessellata*, 4 feet 6 inches; *A. Fortunei* (variegated), 4 feet.

Bamboos are not all of equal merit, but some of them are the most beautiful of evergreens. Just now when Christmas is at hand, and the

In the garden the unusual warmth of the month and its freedom from frost until its concluding night have favoured the close of the season of the open-air flowering plants. Rarely have Chrysanthemums made a finer display, for their blooms have been marred neither by rain nor frost, and it is wonderful, under such conditions, for how long a while they remain in beauty. Plants of the early-flowering Mme. Desgrange and G. Wernig I noticed still ornamental in November, while Lady Selborne, whose loose, flimsy petals are the first to be injured by wind and weather, enjoyed an unusually protracted season of immunity. Of white Chrysanthemums, both for culture under glass and in the open, the new Niveum appears to hold the palm. Its reflexed flowers are large, symmetrical, and show no eye, although grown as bush plants in the open. Even the cheek inseparable from lifting the plants from the open ground and replanting under glass just as the flowers are opening seems to have no detrimental effect on quantity or quality of bloom. This year, both this and other varieties are decidedly earlier than in 1896, the majority of blooms of Niveum being past their best fully three weeks earlier than was the case last year. Other good whites that have done well in the open are the two old favourites Elaine and Mlle. Lacroix. The wonderfully open weather has made the culture of these under glass, for marketing purposes, quite profitless, as with such wealth of blossom on outdoor Chrysanthemums and Dahlias the supply in most cases exceeded the demand, and the glass-sheltered blooms rarely did more than pay their carriage to market, in many instances, indeed, failing to effect this. The sulphur-white Elsie makes a good garden plant, and Mrs. J. S. Fogg is an effective yellow, but the sturdy W. H. Lincoln, which has been so satisfactory for several seasons past, appears in a portion of the south-west district to have lost its constitution, as this year it has lost almost all its foliage and has produced but few blooms, although other varieties grown under precisely similar conditions have been pictures of health and freely flowered. Peter the Great is a light yellow that flowers abundantly and is well adapted for open-air culture, while Jardin des Plantes is always valuable from its peculiarly rich golden tint. The new Modesto, an excellent exhibition bloom, also possesses the same striking colouring, but whether it will succeed as a garden variety can scarcely be determined for a season or two. The semi-double yellow, Admiral Sir T. Symonds, has been very beautiful in the garden during the past month, its colour being this year free from the deep bronze tint that suffused its petals in 1896. The appearance of this ruddy colouring in 1896 on plants raised from cuttings taken from subjects bearing clear-coloured flowers, and the production this year by all the plants of clear-petalled blooms, though all were raised from plants bearing bronzed flowers in 1896, is difficult of explanation, especially as the treatment has been identical in each year. The single white, Mary Anderson, makes a pretty bush plant, and the ruddy gold of Source d'Or is most ornamental, while of darker colours, Tokio, Cullingfordi, and the beautiful small-flowered Julie Lagravère, a very ancient introduction as Chrysanthemums go, can scarcely be beaten for outdoor effect.

Dahlias bloomed continuously throughout the month, though the blossoms of the scarlets and crimsons, perhaps, lacked something of their early autumnal brilliance; still, a bright gathering could have been made up till the last day of November, when the first frost put an end to their display. In "E. H. W.'s" delightful "Trip to Fairyland" (p. 389) he mentions the devastation wrought by frost weeks ago among the Dahlias in northern lands. Well, at all events there are spots in England where King Frost did not commence his rule at such an early date, the sea-board of South Devon, for example. Cannas bloomed well into November, and before the end of the month some of the single Poppy Anemones had opened their blossoms, while late-sown seedlings of Sweet Alyssum were in bloom, and

here and there a spire of bloom showed on the Antirrhinums. Aster grandiflorus was at its best at the commencement of the month, its large purple-gold-centred blossoms making an attractive spot of deep colour in the garden. The giant Christmas Rose (*Helleborus altifolius*) appears in its loveliest guise in November, and yields its chaste cupped blossoms in profusion. Gazing at their purity, one recalls the legend of the little shepherd-maiden of Bethlehem, who, when the wise men from the East brought their rich treasures to the infant Christ, stood without, weeping, in that she had no gift to offer. As she wept the Angel Gabriel appeared before her and asked her why she sorrowed. "I am so poor that I can bring no gift," she answered. The angel, bending, struck the bare earth with his wand, and there before her bloomed the white flowers of the Christmas Rose. "Gather them, little maid, and bear them in," the angel said, "pure blossoms, emblem of a love as pure." So mild has been the season, that the Lenten Roses commenced to bloom before the end of the month, at the commencement of which *Coreopsis grandiflora* was still in blossom. Many annuals have been in flower during November — blue Cornflower, *Eschscholtzia*, Mignonette, Marigolds, blue Lobelias, *Salpiglossis*, Sweet Sultan, Stocks, and Sweet Peas, while now and again in the hedge-rows a scant gathering of pale Primroses was to be found. A few great golden stars of *Doronicum plantagineum excelsum* Harpur - Crewe glowed from time to time in the herbaceous border, while *Erigeron speciosus* and *E. muconatus* were both in flower in November. *Fuchsia Riccartoni* was crimson with flower at the commencement of the month, when many late spires of the Cape Hyacinth (*Galtonia candicans*) held aloft their ivory bells. In the rock garden the deep blue *Gentianella* flowered sparsely, and *Geranium sanguineum* bore many bright blooms, while a delicate blossom was now and again to be found on *G. striatum*. *Gaillardia grandiflora* produced a few late blossoms in the early part of November, as did *Hypericum Moserianum*, and the *Heliotrope* still flowered in sheltered spots. The lovely *Iris stylosa* gave many a gathering of its scented lilac-blue blossoms, which when cut ere they are fully expanded last well in water, and are invaluable at this time of the year for indoor decoration. The Paris Daisies, both yellow and white, though not so free-flowering as earlier in the year, kept in bloom, and a few Pentstemons remained in flower. The Winter Cherry (*Physalis Alkekengi*) was a brilliant object with its strings of bright orange calyces ere cut for winter decoration, for which its more graceful growth renders it of greater value than the new *Physalis Franchetti*. That the Oriental Poppies had not quite composed themselves for their winter's rest was shown by the appearance of a giant belated blossom here and there. The white Macartney Rose opened a few blooms during the first week of the month, and a few Tea Roses could be gathered from wall plants, Safrano being especially noteworthy in this respect. In gardens where the soil is not heavy and damp the Winter Flag (*Schizostylis coccinea*) bore its crimson flower-spikes, and an occasional light blue blossom opened on *Scabiosa caucasica*. *Stokesia cyanea* expanded a few purple flowers in November, and on southern rocks a tint of red evidenced a flowering remnant of *Valerian* (*Centranthus ruber*). *Vinca* minor and its double variety, the flower of the latter almost resembling a Marie Louise Violet, showed infrequent blossoms amid their shining leaves, and during the earlier weeks of the month the Violets bloomed profusely, becoming rarer, however, towards November's close.

Against a sheltered wall *Abutilon vexillarium* remained in bloom, not having been flowerless since June. The white and red *Lapageria* blossoms still hung on a northern wall, and the *Habrothamnus* still produced its red flower-clusters. The Winter Jasmine (*Jasminum nudiflorum*) is covered with its blossoms of bright gold, its brilliant effect being heightened when it is associated with *Cotoneaster microphylla*, now

crimson with its myriad berries. Many a wall is now brightened with the orange fruits of *Passiflora coerulea*, which hang like countless lamps among the dark foliage. *Solanum jasminoides* remained in bloom throughout the entire month, though the number of its flower-clusters and the size of the individual blossoms show some diminution. This is *par excellence* the flowering climber of the south-west, commencing as it does its blooming season in June and remaining in blossom till mid-December should the weather continue open. *Colletia cruciata* I saw the other day in profuse bloom, and on the banks of the Dart Correas were in flower early in the month. *Choisya ternata* has been in many instances a November flowerer and the Winter Sweet (*Chimonanthus fragrans*) has expanded the first of its sweetly-scented blooms. Shrubby Veronicas and the *Laurustinus* have also added their quota to flowers of the month. After a protracted season of blossoming the last white chalice was cut from the standard *Magnolia grandiflora* on the 15th, the first having been gathered on June 22, during the interval between which dates some hundreds of ivory-white blossoms have been produced. S. W. F.

### THE AUTUMN.

This has been a wonderful autumn indeed. I say has been, but really, judging from the present state of things generally outdoors, autumn can hardly be said to have passed away yet. There are, so far, few indications of the near approach of winter. The last two months have been exceptionally dry and mild. No touch of frost has as yet been felt here. On Thursday, the 18th inst., at 7 a.m., the thrushes were singing as on an April morning, and one was almost tempted to believe that, after all, the calendar must be wrong, and that a peep out of the window would reveal hedges and trees aburst with green. Starlings, perched on the chimney-pots, were whistling joyously and preening their feathers, which just caught the glint of the rising sun, and shone a metallic burnished green. At 10 o'clock the sun burst forth with an almost summer-like power. The yellow Jasmine in full bloom attracted the honey bees, which were out in numbers, together with a few of their larger relatives, the "bumbles." The Ivy blossom is yet fragrant in places, and, like the creamy bloom-heads of the *Aralia*, teems with wasps and flies. The sweet-scented Tobacco plant is still in flower, but at this season seems more generously disposed, and refrains from closing up its petals and hanging down its head in the despondent manner it adopted during the hot summer days. "Grand weather," you say to a passing son of the soil. "It han't zazonable," he replies. "We be gwint to suffer fur this bynby, zhur enf." If ever we have a fine autumn this is certain to be a very popular opinion. I am not quite sure that it is justified by experience.

Why should a good crop of berries in the hedges be considered a certain forerunner of a very severe winter? It seems to me that the presence of wild fruits and berries rather reflects the past than foretells the future. It signifies a summer favourable to the development of the flowers and the perfecting of their seeds or fruit. *Senecio pulcher* has had a good time for blooming, and is still pushing up fresh heads. Roses keep on opening here and there, and even the blue *Salvia patens* is not yet altogether flowerless. As for Primroses, they look as if they would flower themselves out before next spring arrives. The *Gentianella* has thrown up a few solitary blue bells, but they seem out of place and lack the intense colour so noticeable in the early year. Wild flowers are wonderfully numerous for the time

of the year. Only a few days ago I could have collected quite a nosegay from hedgerows by lanesides. The red Campion and wild Carrot, Scabions and Ox-eye Daisy were to be found amongst plenty of others, while a patch of red Valerian in a railway cutting was visible from quite a distance.

The trees, too, have donned many a tint, and held their leaves longer than usual, owing to the absence of early frosts and autumnal gales, which quickly whisk them off the branches, whirling and scurrying them into many-coloured heaps in nooks and corners. It is curious that though individually some of the October tints are really intense and brilliant, yet an autumnal landscape, seen on never so fine a day, seems, at least to me, somewhat sad and sombre.

There is a very delightful view close by me, to be obtained by a ten minutes' walk up a most charming Devonshire lane. In October especially it is a lovely spot. The trees on either side of the way meet to form a leafy arch, shady and cool in summer time. After surmounting a rather steep incline at the end of this lane, a charming sight meets the eye, for the road suddenly dips down into a valley, the opposite rising side of which is a piece of common or waste land, covered with Bracken and Gorse, and dotted with Ash, Beech, Oak, and other trees. A stream runs across the bottom, sometimes dried up in summer, and on the right is a cider orchard, the trees, some old and gnarled, smothered with soft grey Lichens and always beautiful, especially so in spring and autumn. Away to the left the road, continuing up the hill, is lost in a mass of foliage, amongst which one may distinguish the thatched roof of a pretty old cottage. The Beeches give wonderful colouring to the landscape, and so, too, do the tall, dying fronds of the Bracken struggling up through the undergrowth. The leaves of the Medlar are now of a rich old gold, but most of them have fallen. Thorn trees and bushes are of a lighter shade, contrasting well with the blackness of their twigs. Some of the green-leaved Japanese Maples give grand colour in the fall—yellows, orange, and browns. Brambles in the hedgerows assume many lovely tints, that require closer examination to appreciate. On a piece of an old stone wall, dotted here and there with Navelwort, one sees masses of Ivy-leaved Toadflax, its long trailing, delicate stems covered with bright green foliage, such a contrast to the deeply-cut and glowing red leaves of the Herb Robert growing, perhaps, next to it.

Many of the gardens in the neighbourhood are gay with outdoor Chrysanthemums, which the fine weather of the past month has brought to perfection. Nothing can be prettier now than large bushes of different coloured varieties, loosely staked or hitched to sunny walls. The dark crimson W. Seward is especially handsome thus, and comes of a splendid colour. In a wet autumn, however, the blooms suffer and present a miserable appearance. Then it is that one appreciates and sees the beauty in a garden well stocked with ornamental-leaved plants and shrubs like the Palms, Yuccas, Aralias, Bamboos and Ivies, especially bushes of the variegated kinds, which look extremely bright in wet weather. The common Hart's-tongue Fern never looks so well as when on some dreary autumnal day it is surrounded by a lot of its deciduous allies—a veritable oasis in a desert of withering fronds.

Autumn is a busy time, yet a time of reflection. It has, as a season, many beauties, and is always full of promises. Some are fulfilled, some broken, but hope remains. We are always looking forward to the future, and in

that lies the essence of pleasure—expectation. —M.

— One of the showiest of our deciduous shrubs this autumn has been *Acer polymorphum atropurpureum*. When planted facing the sun and backed up by some light evergreen foliage the effect was charming. The leaves assumed that deep crimson hue so often seen on the *Ampelopsis Veitchi*, but never before have I seen them so rich as they have been this season. Many of the Maples have finely cut leaves, which look well during the summer, but they will, if planted in situations exposed to the sun, assume most glorious hues in the autumn. *Liquidambar styraciflua* has been more beautiful this season than ever, particularly the foliage on old trees where but little growth was made. On such the leaves were not so large, but they ripened much earlier, and therefore attained a brighter colour. We are apt to try to make things look too prim, but were we to allow more naturalness there would certainly be far more pleasure derived from these half-wild places. At one bold corner I noticed that an *Ampelopsis quinquefolia* that was planted near by had taken possession of a Holly tree standing close by: the growths had extended from branch to branch so that the foliage of the *Ampelopsis* became intermingled with that of the Holly, and as autumn approached the leaves of the former changed to a bright crimson, which

*Ostrowskya magnifica*. From a photograph sent by Mrs. Burroughes, Lower Berkeley Street, S. W.

was shown up to great advantage amongst the green. At a distance one would have thought the tree was covered with berries. *Quercus coccinea* has also been very fine this autumn. What a pity it is that this is not more planted in our woods. Not only is the tree beautiful in itself, with its peculiar fissured bark and large deep-cut foliage, but the leaves assume those glorious hues in autumn most difficult to describe, and as they remain for such a length of time before falling, make quite a feature in the landscape. A large tree growing not far from here has been most beautiful this autumn. There are of course many noble trees that have bright foliage, but most of them shed their leaves the first sharp frost that comes, while others cling more closely, and are only removed by strong gales. It is, however, amongst the shrubs that we must look for the brightest foliage. Some of the *Andromedas* are very conspicuous in this respect, their leaves turning a glowing crimson, which colour they retain for weeks. *Berberis thunbergii* is also very peculiar in this respect, particularly when planted in exposed situations on poor soil. Most people know the common *Viburnum Opulus*, *Cornus sanguinea*, *C. atro-sanguinea*, and the common varieties,

all of which assume bright colours in the autumn. The foliage of *Euonymus europaeus* along the hedgerows at the present time is most conspicuous, for, as most of the other leaves have fallen, there is little else to gladden the eyes in the way of colouring. *Rhus Cotinus*, *R. glabra coccinea* and *laciniata* have this autumn been grand. The leaves of *Koeleruteria paniculata*, *Rhamnus Frangula*, *Mespilus canadensis*, and many others have also been beautiful. As the time for planting is now here, many of the things mentioned would be most useful for planting alongside carriage drives or woodland walks. The situations chosen for them should be such as would be suitable for their growth, and at the same time give them room.—H. C. P.

## FLOWER GARDEN.

### THE GIANT BELLFLOWER.

(*OSTROWSKYA MAGNIFICA*.)

I SEND a photograph taken on July 1 of a small group. It will be seen that the plants are too near together, for of the fourteen flowering stems those at the two ends of the line far surpass the others in height and strength. They are growing in the garden at Ketton Cottage, Rutland, on a south border about 4 feet from the wall in front of a row of Crown Imperials. The plant at the west end of the line is considerably more than 6 feet in height. The roots were planted either in 1894 or 1895, where they flowered last summer. Two of them had flowered more than one season before, and the others, four or five in number, had never bloomed. The ground was dug out about 2 feet in depth, and first some manure and fresh loam from a pasture mixed with a good deal of sea sand were put into the hole and carefully packed round the slender and very brittle roots, of which the best were at least 15 inches long, the crowns being some 6 inches below the finished level of the bed.

The situation is naturally dry and is fully exposed to the sun, and the ground is well drained. In winter, Pine needles were strewn on the surface, and in frosty nights in spring an awning was drawn down from the wall, in front of which it will be seen the plants stand, but it is doubtful if either precaution is necessary, as young seedling plants in another bed quite unprotected have not suffered from the effects of frost. Of other care this beautiful stranger appears to require none.

A coloured plate with a full description of this handsome plant will be found in THE GARDEN of December 29, 1888.

STAN H. BURROUGHS.

16, Lower Berkeley Street, S. W.

**Iris stylosa.**—The Algerian Iris, to which, by the way, the cumbersome specific name of *unguicularis* is sometimes applied, is flowering very freely at Kew in the narrow border outside the Orchid house where the *Belladonna Lily* flourishes. Sheltered in this way, not only does this Iris flower well, but the blossoms are not injured by rough winds, which may happen where exposed, as the petals are fragile. While this may be justly regarded as the last Iris of the season, the small bulbous species with their exquisite blossoms soon make their appearance with the advent of the new year. The flowers of *Iris stylosa* emit a very pleasing fragrance.—H. P.

**Seed-sowing in boxes.**—Not infrequently it is advised to sow the seed in shallow pans or boxes when instructions are being given for certain work. Such advice is doubtless given in good faith, though so far as the boxes are concerned some thought should be given as to their suitability for the work. Such things as batches

of cuttings being lost just as they were rooted, or seedlings going suddenly off soon after they are germinated, are too frequently known while the reason is still far from clear. In such cases often the true cause of failure is not discovered. Where boxes are freely employed, I have reason to believe they are most detrimental to success on account of the frequent rapid out-growth of fungus from decaying wood. Very often the damage is complete before the evil is discovered. Much trouble and anxiety may, however, be saved if all boxes intended for seeds or cuttings were of sufficient size and strength to admit of their being charred sufficiently to kill any fungus that may be present, or, better still, where wood is largely used for these purposes to put the lengths into a pickle of creosote. With the wood cut into lengths ready for placing together, the ends as well as the sides would receive the dressing, which would act in the twofold capacity of saving the timber as well as safeguarding the cuttings or seeds.—E. J.

### HYPERICUM REPTANS.

THE St. John's Wort, or Rose of Sharon, as it is called by some, is a favourite with many. The genus contains a large number of plants. Nearly all have fine yellow flowers, which, in olden times, from their fancied resemblance to the sun, gave the *Hypericum* its reputed magical powers as the dispeller of evil. The St. John's Worts are varied in habit and stature. Some are tall and weedy-looking; some are of graceful habit and with beautiful flowers. Some are herbaceous, and others are of shrubby or sub-shrubby habit. A number are of dwarf, tufted or trailing growth and of great value for the rock garden. Among the last, none are more pleasing than *Hypericum reptans*, the subject of this note. The size of the flowers is large in proportion to that of the leaves, and it is a pleasant surprise to many to see so small a plant have such large blooms. It forms a close carpet, although of trailing habit, and soon covers over with its pretty foliage a perpendicular or sloping stone where so placed that it can droop over and on to the rock. The plant is so close-growing that it only rises about 2 inches above the level surface of the pocket in which it grows. The neat little green leaves, with a slight glaucous tint upon them, are not more than three-eighths of an inch in length, and the bright and almost perfect flowers are each quite an inch across. The blooms are of a clear yellow. The only fault I can find with the plant here is that the flowers have a tendency to hide themselves in the foliage instead of rising above it. *H. reptans* gives very little trouble here, but cannot be moved readily when the plants become large. When I have had occasion to remove a large plant, the plan adopted was to water the soil about it and then to press the earth firmly about the roots. The trowel is then inserted deeply all round so as to cut off the ball thus formed from the adjoining soil. The plant can then be lifted with a small spade or a trowel. This method cannot, as a matter of course, be adopted where the *Hypericum* is growing in a crevice, and in this case it may be found better to let it alone unless the stones can be carefully removed, so as to leave the roots intact with as much soil as possible attached. Young plants are easily raised from seeds, which are sometimes slow of germination, or by cuttings of the branches or slips taken off with a heel. It comes from the Himalayas, and, like many other plants from the same quarter, does not flourish everywhere in our climate. It occasionally looks unhealthy in spring, where it has been fully exposed to all weathers during winter. To preserve it, a

number of good growers of alpines cover it at this season with glass or other protection, and say they cannot keep it otherwise. With me it does not require this. For several years it has been quite exposed to the freaks of our climate. If it should look a little shabby in the beginning of spring the unhealthy appearance disappears when fine weather comes. I grow it in very sandy peat, and it thrives best in this garden in one of the pockets of a rock garden facing almost due south. This rock garden is a little too dry, and in consequence the alpines planted in it are treated in spring and summer to occasional copious supplies of water. The drainage is, however, perfect, and the watering is very beneficial to this St. John's Wort. It is not to be found mentioned in ordinary works of reference. Those who have access to Sir J. D. Hooker's "Flora of British India" will find it there. It is named in the "Index Kewensis" and the Kew "Hand-list of Herbaceous Plants." It is a choice little plant worthy of a place in good collections of alpine plants.

*Carsehorn, Dumfries, N.B.* S. ARNOTT.

### PEONIES NATURALISING.

MR. E. JENKINS (p. 440) has not apparently given himself the trouble, nor done me the honour, of understanding why my note on the above was penned. It is all very well to say that these Peonies can be well grown "when established," but he carefully avoids, or has overlooked, the question which my note was penned to answer, viz., as to their establishing themselves and succeeding well when planted among rough herbage with a view to their becoming naturalised. If Mr. Jenkins can show me where this has been successfully done, I shall readily admit that I am wrong, but my experience is that very few indeed of the named varieties are strong enough to rough it in this way, and the few that do tolerably well are not nearly so robust as the double form of *P. officinalis* planted under the same conditions. It is hardly to be expected that a plant which, as all authorities combine to tell us, enjoys a rich and moist soil away from the roots of trees will be seen to the best advantage in situations where these facilities to good growth cannot be given. I do not quite understand Mr. Jenkins' allusion to "named kinds" of Peonies. One would think that I had been condemning the whole genus out of hand, whereas I wished to convey my experience only with those members of the herbaceous section which have been given varietal names. Of these I have under my charge here something over forty varieties, growing in cultivated ground, and most of these would leave Mr. Jenkins' "good specimens" of five years' growth well in the rear. I only allude to these as Mr. Jenkins appears to doubt if I quite know what a good Peony is. I must reiterate, however, that among these there have not been found for naturalising any so satisfactory as *P. officinalis* fl.-pl., even though strong crowns have been planted in August in well-prepared soil, from which, moreover, the surface herbage has been cleared away twice a year since planting to give them a better chance of growing strongly. I fear that, in his haste to restore the good character which I never took away, Mr. Jenkins has overlooked the point of the notes penned by Mr. Burrell and myself.

J. C. TALLACK.

**Lily of the Valley var. Fortin.**—In THE GARDEN, September 4 of the present year, a beautiful coloured plate of this giant variety was published, with a very short notice, under the erroneous name of var. Fontin, instead of Fortin. The history of the plant is as follows: About 1878 M. Blondeau, the head gardener in a large private garden near Paris, had a large bed of Lily of the Valley made of a mixture of half a small variety and half a very large one. He discarded the former and carefully selected the latter; the

result was the origin of this splendid variety. Shortly after he gave some crowns to a neighbour friend named Fortin, who grew the plant with great care, exhibited it at a meeting of the Société Nationale d'Horticulture in Paris, where the plant was named var. Fortin in honour of the exhibitor. As to priority, the name var. Blondeau ought to prevail, but var. Fortin has been accepted by the public and the trade, although the term giant would be the best. This is by far the finest and largest variety known, being a free bloomer, robust grower, perfectly hardy, as sweetly scented as the type, and forcing well. As regards foliage, spike, and flowers, it is double the size of the type and much larger than any other kind in cultivation. The true stock is still very scarce and somewhat expensive, and great care must be taken, as several French and foreign growers and merchants are persistently supplying fine Berlin, Hamburg, or Dutch strains for it, which may lead to disappointment. There is but one species of the favourite Lily of the Valley (*Convallaria majalis*) profusely found in English woods and other countries. All other varieties or forms are merely accidental, or due to selection or improvement on the type. In 1858 M. Duchartre mentioned a giant variety which has not been observed since. The Dutch and German strains are famous, but none can compete with the variety Fortin. The following varieties, double white, rose coloured, and double rose, are very old sorts, seldom seen in gardens. The white and yellow variegated-leaved kinds are interesting on account of their foliage, but are not generally grown.—D. GUMENEUF, 48, Rue St. Merri, Paris.

### ACONITUM.

(MONKSHOOD.)

THE kinds of *Aconitum* that receive attention from cultivators of hardy plants are really very few. Happily, all the kinds worth growing for effect in the garden are of the easiest culture, being quite content in what is often the very poorest of soils. These perfectly hardy subjects will be quite at home in any ordinary garden soil, such as is usually found around shrubberies, on the lawn, in the woodland or such places. It will, I think, readily be admitted that, so far as colour is concerned, these everyday subjects are very striking, particularly so when seen at a short distance off. In the ordinary hardy plant border what is usually seen does not impress one, frequently from lack of material and other causes. It is quite another thing when broad masses of these things are seen with suitable surroundings. Many may have been deterred from employing these plants to the full in gardens generally owing to the poisonous character of their roots, and for this reason it is always best to keep them entirely free of the kitchen garden. For obvious reasons also should these things be kept from children's gardens, where perhaps greater danger exists than in any other direction. In the case of gardeners generally ordinary care will prevent any waste material being carelessly cast aside when division or replanting has been done. These plants may be increased freely by division, preferably in early spring with returning growth, when the numerous small tubers quickly take to the soil. Seeds are also produced very freely, and if sown as soon as gathered will germinate almost immediately. The following are among the best of these, the majority of which attain to 4 feet or 5 feet high, and from their usually vigorous stems are quite self-supporting:—

**A. ANTHORA.**—This very distinct species is abundant in the Pyrenees, Switzerland, &c., and is followed by several very distinct varieties, all of which, like the type, have yellow panicles of flowers. It is about 2½ feet high. **A. A. grandif.**

florum has larger flowers, these, as indeed the whole panicle, being pubescent.

**A. CAMMARUM.**—A blue-flowered species from Hungary, Austria, &c., the panicles usually few-flowered. A well-marked variety of this, *A. C. Starkianum*, is a capital garden plant, rather dwarf in habit, with few flowers, and foliage not unlike that of the Fair Maids of France.

**A. FISCHERI.**—As a garden plant this fine species is at once among the boldest and best worth growing in any good collection of hardy plants. The growth will attain from 4 feet to 6 feet, terminated by a fine panicle of blue flowers. The foliage of this is also attractive. It is an autumn flowering species abundant in Asia and North America. It is synonymous with *A. autumnale* and *A. californicum*.

**A. FORTUNEI.**—This is also called *A. chinense* and *A. japonicum*, and by the latter is freely cited in hardy plant lists. The plant is one of the most valuable for the intense bright blue shade of its flowers, which are produced on stout stems and in large compound panicles. It is a handsome kind, attaining to 4 feet high.

**A. HETEROPHYLLUM.**—This is a distinct Himalayan species with pale yellow blossoms that are shaded with blue at the front. The usually much-divided foliage of many species is replaced by broadly cordate and coarsely toothed leaves, not unlike those of the Nettle. It is also said to be non-poisonous. Height 2½ feet.

**A. JAPONICUM.**—A synonym of *Fortunei*.

**A. KUSSVEZOFFI.**—A tall-growing species, 6 feet high, from Kamtschatka, with large and dense compound panicles of pale violet blossoms. A most effective plant for the woodland.

**A. LYCOCTONUM.**—Under this name a rather tall and slender-growing species, with finely-cut leaves and pale yellow flowers, is somewhat freely given in hardy plant lists. In at least two text-books published at wide intervals this species is described in the same precise terms as having "livid-violet" flowers. Whatever the correct name may be, the plant is well known in gardens and freely met with. I believe the plant grown in the Royal Gardens, Kew, under the above name has also yellow flowers.

**A. NAEPELLUS.**—This fine species, with its numerous varieties, is the best known and perhaps the most widely grown of this extensive genus. At the same time it is one of the most virulent of poisonous plants. Its varieties bicolor and versicolor are of more value in the garden than the type, the two named being very distinct in the varied hues of their blossoms.

**A. ORIENTALE.**—A fine species, with creamy yellow flowers, from the Caucasus, also Persia and Georgia, is in the way of *A. lycoctonum*; indeed, *A. orientale* var. *altissimum* is regarded as synonymous with *A. lycoctonum* var. *altissimum*; hence possibly the confusion referred to above. Like the last-named, the eastern *Aconite* is of tall growth, and this with the more heavily dissected leaves appears to coincide generally with *A. lycoctonum*.

**A. PANICULATUM** is in a measure allied to *A. Napellus*, but possesses a much looser and more spreading panicle of violet-blue flowers.

**A. PYRENAICUM**, a yellow-flowered species from Siberia and the Pyrenees, is only some 2½ feet high, the rather hispid leaves being distinctly parted. It is a compact growing kind, with a dense raceme of flowers.

**A. UNCINATUM** is a tall species, upwards of 6 feet high, from North America, with lilac-blue flowers in a large loose raceme. It is an excellent kind for the wild garden or similar place.

**A. VARIEGATUM.**—This is a well-known species, and with its varieties, *A. v. bicolor* and *A. v. albidiflorum*, is frequently seen in hardy plant collections. The two kinds named are perhaps among the most effective for grouping of this genus.

The foregoing are but a selection from a genus of some eighty or more species, and possibly as

many varieties. All the kinds, with the exception now and then of *A. lycoctonum*, multiply quite freely at the root, and should be increased in this way rather than by seeds, as the seedlings are frequently inferior to the parent.

E. J.

#### THE FAILURE OF GLADIOLUS CORNUS.

I HAVE been a grower of hybrid *Gladiolus gandavensis* for upwards of forty years, and I must confess that it is as great a mystery to me as ever it was. I have grown it in various situations and in different localities, I have followed out the instructions of the best growers, and yet year after year I have had to deplore the failure of a very large percentage of my corns. This failure may be attributed by other growers to many and various causes, and yet I have never found any of these causes give a satisfactory solution of the puzzle. I remember many years ago asking M. Souchet as to the best soil to grow them in, and he said that ordinary market-garden soil was as good as any; the soil in which he grew his at Fontainebleau was of this character, light and friable, and, so far as I could see, with a deal of humus in it. When thus I ventured on their culture at Deal in a garden which had been for a long time a vegetable garden, I thought I had obtained what was needful. And so again when I took up my residence here thirty years ago, with a garden which had been considerably neglected, but which was mainly composed of alluvial deposit, I hoped that my failures were at an end, but every year has told its tale of disaster; sometimes more heavy than at others. I recollect one year at Deal when my whole collection nearly failed, while in other seasons a large percentage had always gone wrong. One very experienced grower tells me there is too much humus in my soil; others have told me that the failure arose from growing exhausted bulbs, and that I had grown them year after year and allowed them to flower and in some cases to ripen seed, and consequently the corns were exhausted. This does not strike me as being a correct view of the case. Others have said that taking them up and drying them off tend to weaken them, and had they been left in the ground they would not have decayed. My own impression has been that a great deal is due to the uncertain character of our climate. In the autumn months when the corns are harvested, I have every year received some corns from Fontainebleau. I have remarked on the silky texture of the outside covering, which I attributed to the fine time they had for ripening, but my views on the subject have been considerably damped by the experience of the present season. We have had one of the driest and most sunshiny autumns I ever recollect, so that when I began to lift my corns and saw fine and well-conditioned bulbs, I thought that this was the consummation of my views; but when I came to clean off the corns I found out how vain a thing it is to trust to appearances. I have already said that I received some bulbs yearly from Fontainebleau, and last year I had a few of the novelties sent out by M. Souchet in the autumn of 1896. These had no time for deterioration, and yet in more than one instance the corns had entirely perished. In another case, I lifted six fine-looking bulbs of one variety, and of these five were perfectly sound and in every way good corns, while the sixth was completely gone. Although the outside skin appeared good, it was mouldy and rotten. In another case, four out of nine bulbs of one variety had in the same way perished, and, therefore, as I have said, I

am as greatly puzzled as ever, for if it was the humus in the soil which caused the damage, why should the other bulbs have escaped; or if it was exhaustion, why did not all perish from the same cause? There is no sign of the existence of anything like the *Eucharis* mite to cause all this, therefore I am quite at a loss to account for it. I have tried all sorts of remedies, but I am convinced that there is no cure when once the bulb is affected.

I may be told that all this is very discouraging, and enough to deter anyone from growing this beautiful flower. To this I may reply that it is always better to know our difficulties than to ignore them, and that owing to the large quantities which are grown from spawn, corns can now be obtained at so reasonable a price that all losses may be easily replaced. Growers of *Hyacinths* do not scruple to consider their bulbs as simply good for one year, and do not grudge buying fresh bulbs every season, and the corns of *Gladioli* can be obtained at quite as cheap a rate, if not cheaper. It is a curious fact that whether in France or England the wholesale culture is in so few hands; you may write to any nurseryman in France to order bulbs, but he will not supply them from his own culture. It is the same in England. These same firms also grew a number of seedlings from carefully hybridised flowers; these unnamed seedlings are to be had at a very reasonable rate, and I can testify from my own experience that many of the flowers produced from these roots are quite as good as the named varieties of two or three years back, so that lovers of the flower have always the opportunity of growing them in their gardens without much expense. My observations, of course, only apply to the corns of the *gandavensis* section, and not to the earlier *G. ramosus* or to the so-called hardy varieties of the *Lemoinei* and *Nanceianus* type. The former are only suited for greenhouse culture, while the two latter are apparently hardier, I think not nearly so beautiful, and when the hybrids develop more of the *gandavensis* strain and less of the *Saundersi* type, they become less hardy. I think it must have been for the reasons that I have brought forward that the late Rev. Joshua Dix, who was a great admirer of the flower and who wished to have a special society to promote its popularity (as has been done in the case of other florist flowers), failed in his object. DELTA.

**Primroses.**—It is not often that these simple but beautiful hardy flowers give us such a fine early winter display as they have done this year. Each year I raise a few from seed, and these are planted about in any spare bit of shrubbery or herbaceous border and the best ones propagated. By this means one gets a nice variety both of self-coloured and edged flowers, while even the worst are useful for brightening up odd corners. In the moist, heavy soil here they luxuriate and form large spreading masses that one can cut handfuls of flowers from daily in spring, and the rich dark crimson and purple tints are difficult to beat then in outdoor flowers of their colour. The seed may be sown at any season, but preferably soon after it is gathered. Sow thinly in a frame or in the open air, keeping the seed-bed moist and leaving the seedlings until they have made a couple of rough leaves before pricking out on a shady moist border. Slugs and small snails are very fond of them, and will soon clear them off if allowed to. Soot and lime in equal proportions are the easiest preparation for these pests, sprinkling this about rather freely on damp evenings, when the slugs are likely to be abroad. From this bed the plants may be raised and planted in their flowering quarters, or they may be left and selected from the first trusses of flower they throw up.—R.

GARDEN FLORA.

PLATE 1149.

ANTHEMIS AND ERIGERON.

(WITH A COLOURED PLATE OF ERIGERON SPECIOSUS AND ANTHEMIS TINCTORIA (PALE VAR).\*)

In the coloured plate to-day we have representatives of two important genera among hardy plants. The two families are well known and largely grown. Indeed, so worthy are they, that they are among the most frequently seen of summer-flowering subjects. Especially is this true of the Erigeron, a plant almost sure to be found in a collection of hardy plants. In short, this particular species is to the early summer garden of the greatest importance when arranging the flower groups in the garden—precisely that of the Italian Starwort (*Aster Amellus*) and varieties in the latter part of the summer. For the purpose of grouping this Erigeron is among the best of its tribe and is very free flowering. It is reliable in all soils, growing vigorously and flowering freely even in the year of planting. Even quite small plants if put out into good ground early in the year, say during the latter part of February, will

*Erigeron macranthus.*

make fine flowering bushes the same season. It is not many hardy plants that do so much in so short a time, and once its season of flowering begins it is continued for many weeks. No other species of Erigeron produces the same mass of flowers week after week, and this, as also its convenient height, has rendered it a useful plant even in the smallest gardens. Where it is so desired, either in autumn or

\* Drawn for THE GARDEN by H. G. Moon at Gravetye Manor. Lithographed and printed by J. L. Goffart.

spring, this species may be increased to any extent by division. Several other species are of quite different character, and to these I will refer in detail later on.

The following will be found the most impor-

*Anthemis macedonica.*

tant species of Erigeron and well worthy of general cultivation:—

**E. AURANTIACUS.**—This charming species was received from Turkestan nearly twenty years ago. The colour of the flower-heads was so entirely novel and distinct from that of any other known species, that its flowering was looked for with some interest. The species, however, proved true to its colour. It is not more than 9 inches high in its most vigorous condition, and only attains this by the best cultural methods. In the rock garden or the front of the border the plant should be grown freely in groups where the orange-coloured heads display themselves to advantage. Slugs are rather partial to this kind during the winter, and will speedily devour it if left to themselves. The species, as is well known, is of close tufted growth after the manner of the alpine Starwort, while the growth is not so abundant as to permit of frequent division like the last-named. The above species may be raised freely from seeds. These if sown now would flower during the ensuing year; indeed, in this connection the plant is worthy of special care, as by raising seedlings at intervals during the spring months the flowering period may be prolonged.

**E. CAUCASICUS.**—A very pretty species, introduced to cultivation early in the present century. It attains nearly or quite 2 feet high, and bears masses of rosy-purple Rhodanthe-like heads of flowers. These are not large, but their abundance creates a very pretty effect in the border.

**E. GLABELLUS.**—A free-growing species from the North United States, and bearing a cluster of purple flower-heads on stems about 15 inches high. It is a useful border kind, readily distinguished from others of its kind by the numerous florets composing the ray encircling a yellow disc. Readily increased by division and seeds.

**E. GLAUCUS** (syn., *Aster bonariensis*).—This is one of the gems of this genus, notwithstanding it is a rare plant in cultivation to-day. Many years ago in the Tooting nursery of the late Mr. Robert Parker I had charge of the finest masses of this plant I have ever seen. The species usually sold under the above name is a form of *E. speciosus*, a totally distinct plant. Singularly enough, while the above species is well and truly described in the "Dictionary of Gardening," the plant figured as *E. glaucus* has nothing in common with this kind. An excellent coloured drawing of the true plant may be found in Wooster's "Alpine Flowers," plate xvi. In this drawing the shrubby character of the plant is well shown, as also the oblong-ovate, spatulate form of the

distinctly glaucous entire leaves. These latter are slightly clammy to the touch, a characteristic not found in all forms of the Fleabane. For the rock garden I regard this as one of the finest of all. The florets of the ray are much broader than usual, as also the flower-heads. It is a vigorous sub-shrubby evergreen species with free-spreading branched habit, and when well established will attain 18 inches high and 2 feet across. The sturdy lilac-purple flower-heads appear on leafy

*Erigeron multiradiatus.*

stems a little above the rosettes of leaves. It is an easily grown species, and may be increased freely from cuttings or division when large enough, and doubtless seeds, though of this species I do not remember collecting any. It is said to belong to North America, and was introduced in 1812.

**E. GRANDIFLORUS.**—This is also an excellent species, with dwarf evergreen tufts close upon the earth, after the manner of the alpine Aster. The flower-heads are large and of a purple shade,

*Erigeron glaucus* in Messrs. Veitch's nursery at Exeter. From a photograph sent by Mr. F. W. Meyer.

and in warm soils this handsome species thrives admirably. There is a pure white form of this plant not very plentiful in cultivation, yet a capital companion to the above. This white form is usually regarded as synonymous with the white of the alpine Starwort (*Aster alpinus albus*). It

Illustration of a bouquet of flowers, likely daisies, with pink and white petals and yellow centers.

certainly somewhat resembles this in growth and its large handsome flower-heads.

*E. MACRANTHUS*.—An excellent North American species, attaining about 18 inches high, and producing freely its large heads of violet-purple.

*Erigeron aurantiacus.*

Among the midsummer-flowering kinds this should always be found.

*E. MICROANTHUS*.—This pretty little plant with its abundance of Daisy-like blossoms, varying in their tints with age, will be better known perhaps by the synonym *Vittadenia triloba*. It forms patches 2 feet across that in late summer and early autumn will be literally smothered with vari-coloured pink and white blossoms. The patches of leaves are quite close to the earth, while the blossoms attain to 6 inches or 8 inches high.

*E. MULTIRADIATUS*.—A species of recent introduction from the Himalayas, differing from the rest of its tribe in the great number of its ray florets. These are of a purplish shade and the disc yellow. The plant grows from 1 foot to 2 feet high.

*E. ROYLEI*.—A dwarf growing and tufted species also from the Himalayas, with handsome flower-heads of a bluish purple hue, each about 2 inches across, and disposed in a loose corymb. It

*Erigeron glabellus.*

is about 9 inches high, and an excellent plant for the rock garden in good deep soil.

*E. SALSUGINOSUS* (Gray).—There are at least two distinct plants in gardens bearing this name, the one coarse and weedy, and, by comparison with that under notice, not worthy of cultivation. One of the few places we have seen the true plant

is in the Winehamo Hill collection, and as there grown it is one of the gems of the genus. This species flowers in early summer, and produces large handsome heads, each fully 3 inches across, on erect branching stems some 18 inches high. The ray florets are of a pleasing grey-mauve tone, distinctly pleasing, and very striking and effective. Indeed, the very size of the flower-heads renders this one of the most valuable. The root-stock is composed of a creeping and rather dense tuft close to the earth.

*E. SPECIOSUS*.—At once the best known and most widely grown of the whole family of the Fleabanes. The plant, from its easy culture and the great, almost endless supply of blossoms that it produces for months in succession, is well deserving the popularity it enjoys. It is also known as *Stenactis speciosa*. Several forms of this excellent plant may be found in hardy plant lists, the one figured being the type. A variety known as *E. s. superbus*, or *splendens*, as it is sometimes called, is of lighter hue, and is perhaps the most profusely flowered of this group. Another distinct kind, *E. s. glaucus*, referred to in lists as a possible hybrid, is doubtless but a good form of the plant under notice, the florets of the ray deep purple. The foliage in this is of a glaucous grey tint, the plant being of the same height and equally free flowering. The typical species inhabits North-Western America, and has long been known to cultivation.

These are the most worthy of this group in general cultivation, yet apart from these are several hybrid forms that will doubtless be heard of in the near future. What seems to strike one, seeing the large number of seedlings raised, is that as yet no white form of *E. speciosus* has made its appearance. Such a plant would prove an acquisition to our gardens.

ANTHEMIS.

The other genus represented, viz., *Anthemis*, is equally well known, and either in its annual or perennial forms is frequently seen in gardens. Its greatest value perhaps is the ease with which the forms of *A. tinctoria* may be raised from seed in the early spring, and during summer and autumn provide a great abundance of elegant flowers that are bright and cheerful in a cut state, and equally valuable in the mixed border in the open.

*ANTHEMIS ALBOON*.—The plant bearing this name has been referred to the *Achilleas*, where it is now described as *Achillea ageratifolia*. It is, however, somewhat difficult to reconcile the specific term here employed with the group known as *Ageratum*, since the *Anthemis* is composed of compact rosettes of very narrow, silvery leaves that lie quite close upon the soil, the large white and yellow-eyed blossoms being produced singly on stems at 6 inches to 9 inches high. It is a capital alpine and requires the very warmest and sunniest spot in the rock garden, always in deep gritty loam.

*A. BIEBERSTEINI*.—A Caucasian species with large white flower-heads, the leaves being covered with a silvery pubescence. It is a neat, attractive species. Another very charming alpine with pure white flowers is

*A. MACEDONICA*, which forms spreading tufts and flowers freely late in summer at 6 inches high.

*A. MONTANA* is also of the silvery leaved section, of tufted growth, and has pure white heads of flowers.

*A. TINCTORIA* (Ox-eye Chamomile) is a well-known British plant some 18 inches high. The flower-heads are yellow and produced in corymbose heads in summer. A variety known as *A. t. Kelwayi*, with large, bright yellow, almost circular flowers, is very fine, while another—*A. t. pallida*—is similar to, if not identical with, that figured in the accompanying plate. All the forms of *A. tinctoria*, while being true perennials, may be raised from seed, and give a welcome variety for the garden. Not the least noteworthy feature of these forms is their adaptability to rather dry positions. At the same time, in the

ordinary mixed border they are free flowering and useful.—E. J.

With regard to *Erigeron glaucus*, here figured, Mr. F. W. Meyer, of Exeter, writes:—

Coming from the westerly part of North America, this plant is very hardy, and I have

*Erigeron speciosus superbus.*

always found it easy to grow. The plant represented in the engraving was photographed in Messrs. Veitch's nursery at Exeter, where it has been planted out about two years, and forms a spreading mass about 2½ feet across and 9 inches high. It bloomed most freely during July and

*Anthemis tinctoria.*

August, but even now (in December) its leaves form quite a handsome object. *Erigeron glaucus* has long prostrate stems, bearing in summer an abundance of flowers on stalks 6 inches to 9 inches long. The ray florets are of a mauve colour, and the disc florets bright yellow, somewhat after

the style of the alpine Asters. The whole flower—or, more correctly speaking, flower-head—is about the size of a half-crown piece. The alternate leaves are from 2 inches to 3½ inches in length, and 1 inch to 1½ inches wide near the apex. They are smooth, but have very minute hairs on the margin, which is either entire or sometimes slightly dentate. The plant here illustrated is growing in a westerly aspect, where it flourishes to perfection, but I have seen it do equally as well in other positions.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

**WINTER WORK.**—Apart from the general work, such as digging, trenching, and manuring vacant quarters, there are many other jobs which, if not taken in hand now, stand little chance of being done if deferred until spring. Such work, of course, varies according to what is necessary in different gardens, but among other details mending or entirely forming new edgings, turning over and re-gravelling of pathways, as well as clearing out catch-pits and the renewal of drain-pipes where required can be done. As regards edgings, Box, when kept in perfect order, always looks neat and less formal than tiles. When allowed to become too high and thick, it not only becomes untidy but forms a safe lurking-place for slugs and other vermin. In forming the margins to paths in new gardens, or repairing those in old ones, it is very necessary when Box is used that the ground be properly prepared and levelled some weeks or so in advance of planting. It is an easy matter to do this when the paths are straight and are at right angles to each other.

**DRAINING.**—Calling to mind the drought of recent summers, many crops no doubt would have been better able to resist its effects had less draining been attempted. In connection with this one garden is recalled to mind which was formed some fifteen years ago. The site selected was quite level, and lay in rather a hollow. The soil, too, was cold and ungenial, and nothing could be done in the way of digging for weeks after rain. Trenches were cut about 12 yards apart, 3 feet deep, and 2 feet across. These were filled in with clinkers about 9 inches in thickness, and the soil replaced. Each year since the ground has received a good dressing of waste garden soil, burnt rubbish and lime, with the result that these additions of compost have become incorporated with the natural soil and greatly improved the staple, while the drainage as it were was only temporary, sufficient to relieve the surface of moisture while the work of improvement was going on. Had an elaborate system of drain-pipes been used, it may have led, together with the addition of more porous material, to the crops feeling the effects of a drought. This is quoted to show that too much may be done in the way of drainage, and those who have retentive land to deal with and are in doubt how to drain it and find a suitable outlet would do well to follow the above plan, which will prove a sure and cheap way of overcoming the difficulty, and find a useful means of doing away with a quantity of clinkers which generally accumulate in most gardens. As regards draining paths much depends on the way these are made and maintained. When properly formed, with the centre some inches above the sides, there is little need of surface drain and catch pits, which are continually getting choked up. It may be necessary at the lowest point in the garden to make some provision to conduct the surface water into some suitable channel after heavy rains, but whenever possible this should be into an open tank or pond, and although it may prove of more trouble to apply such water to crops during the summer than that through a main, there is a wide comparison in the beneficial effects of the former, and

for that reason it well repays for any methods that may be devised to store it.

Other useful work which should be done now is laying in a good store of Pea sticks and getting them ready for use. It takes some little time to trim and sharpen them properly, which is only too evident when the work is delayed until the moment they are required. The best and tallest of those used last season should also be looked over, repointed, and put into bundles in readiness for the early and dwarfier varieties, while Scarlet Runner supports should also be overhauled and new ones obtained if necessary. These may appear tritles, but it is by keeping these well in hand now that pressure of work is surmounted later on, and all tends towards securing good crops at their right season.

RICHARD PARKER.

### FRUIT HOUSES.

**POT VINES.**—If these were started in the middle of November, the buds will now be bursting. Such being the case, all which have broken satisfactorily may be tied to the trellis forthwith, and discontinue syringing them. If the point buds of any are inclined to grow away in advance of those lower down, or at the base, still keep the canes bent down, and syringe them until they are induced to make a more even growth. Leave surplus shoots on the canes until the bunches can be properly discerned, when all spare ones may be pulled off. As soon as the buds have fairly broken, raise the temperature to 60° at night and to 65° by day, and as the shoots and bunches lengthen out a further rise of 5° should be allowed. These will be safe temperatures to employ until the Vines come into flower, when the night heat may range from 65° to 70°, according to outside influences, but never exceed the first-mentioned figures if hard firing has to be resorted to. When in flower the day temperature should be raised to 75°, with a rise of 10° more with sun-heat, and the damping down, &c., greatly modified, if not altogether dispensed with, so that the atmosphere may be dry and buoyant and favourable for setting. In addition to this, the camel-hair pencil must be requisitioned, and each bunch fertilised with the pollen of the free-setting varieties. Between now and then such matters as the pinching of the shoots at the second leaf beyond the bunch, and the gradual tying of them down to the wires, must have attention. With regard to surplus bunches, although it is a good plan to allow the canes to develop a fair number, so that a selection can be made when setting is completed, it is folly to over-tax them, particularly at this stage of growth. The experienced grower will at once detect which to leave and which to cut off, but those who may be essaying a first attempt at forcing pot Vines should first reduce the number of bunches to one where there are two on one shoot, and that the best. With regard to the remainder, cut off all the weakest, and leave sufficient so that from six to nine bunches can be selected from among them finally, after they have flowered and set. Keep the fermenting bed made up with fresh materials, and see that the vapour troughs are kept filled. Attend to the damping of footpaths and syringing of walls and beds, which will require more frequent attention if fire-heat alone has to be depended on. As growth advances, more water will be required at the roots, and this must always be given in a tepid state. As soon as new roots begin to appear on the surface of the soil, apply an inch or so of rich top-dressing immediately after affording water, and water it to settle it down, when the hungry roots in search of food will soon take possession of it. Strips of zinc or pieces of turf should be employed to hold this top-dressing in position, also to afford space for holding water. When starting of pot Vines is deferred until the beginning of the new year, make preparations accordingly, and if the Vines have not yet been shortened back, do it at once and apply styptic to the wounds.

**EARLY PERMANENT VINES.**—These will not be in such an advanced state as the preceding, but, should mild weather continue, the buds will be breaking shortly. The temperature must then be raised, as soon as the buds burst and begin to get green, to 55° at night and 60° by day, advancing the temperatures 5° more when the young shoots are about 3 inches long. Syringing of the rods should cease as soon as a good even break has been secured. If a bed of leaves has been introduced as an aid to forcing, this should be turned frequently and added to as often as required. The best time to do this is in the early part of the morning, when if a chink of air is put on at the apex the steam liberated in the turning soon escapes. This steam continually rising from the bed of leaves will do away with a great deal of syringing, but after a spell of morning sunshine, necessitating the airing of the house for an hour or so, a good general damping down at closing time will be beneficial. When the heat is derived exclusively from the hot-water pipes damping must be done more frequently, but it must not be too freely indulged in at this the worst time in the whole year for forcing. If the borders were watered at the start they will hardly yet require further supplies; but if there is any doubt in the matter, test them in two or three places, and thoroughly moisten them, should they be found to want it, with water at a temperature of 85° to 90°. See that the coverings on outer borders are in an effective condition, so that if snow or heavy rains fall the water will run off and not chill the soil. If a regular succession is needed prepare another house for starting by the 1st of January. In many instances this will be the first house, particularly if several houses of late Grapes are grown. When this is so, and a Grape room in which to keep the fruit is provided, the supply can be kept up until the spring or until the early Grapes are ripe in the middle of May or first week in June.

**LATE GRAPES.**—If these are thoroughly ripe, and if the Grape room has been prepared for their reception as advised, they may be cut and bottled at any time within the next fortnight or three weeks. This will afford the Vines great relief and also give them a much longer period of rest. Late Vines experience little of this in places where the Grapes have to hang on the Vines as long as possible; hence the necessity for providing a Grape room wherever they are grown in any quantity. When the bottling is completed, prune the Vines if all the leaves are off them, and apply styptic to the wounds if they are subject to bleeding in the spring. The cleaning of the house may well be left for some future occasion, when outdoor work is suspended through inclement weather. On the other hand, if it is necessary to keep the Grapes on the Vines, great care is now needed. The bunches should be looked over at least once a week, which will keep them pretty free from decaying bruises. Robins are often troublesome about this time of the year if they gain an entrance to the houses, and they soon spoil a few bunches of Grapes if let alone. A strip of old fish-net thrown over the ventilators will exclude them. Make use of just enough fire-heat to keep the air in circulation when the ventilators can be opened but little. Keep the house dry and admit plenty of air whenever the state of the weather will allow. If the Vines are casting their leaves, gather them up daily.

**POT FIGS.**—The buds on the November-started trees will now be breaking, when the temperature may be advanced to 60° at night and 65° by day, with a rise of 10° more with sun-heat. As the leaves push out and develop, the syringe must be used more freely, and for the same reason a greater amount of damping down will be required to keep the atmosphere in a humid condition. Add more leaves to the bed as required, and pay great attention to this matter if they are depended on entirely for affording bottom-heat, which should not exceed 75°. Afford the surface roots a top-dressing of rich compost consisting of loam, bone-meal, and a little spent Mushroom manure, and adopt the same means for holding it

in place as advised for pot Vines. Once the trees get into full growth the roots need ample supplies of tepid water, and stop the shoots at the fourth, fifth, or sixth leaf, according to space at command for the development of foliage. A. W.

## ORCHARD AND FRUIT GARDEN.

### TRAINING THE FIG.

THE Fig would lend itself readily to almost any style of training if required, but as a rule it is generally grown either in the form of a bush for pot work, or fan-trained for covering roof trellises and back walls. Taking

#### BUSH TREES

first, special attention must be devoted to them from the time they are shifted from the cutting pots until the trees are fully formed, which will take two seasons. In the first place, cuttings should be made of short-jointed, well-ripened pieces of wood. These should be inserted singly in 4-inch pots filled with a sandy compost, and January and February are the two best months for their propagation. Bottom heat, such as is afforded by a fermenting bed in a forcing house, facilitates the rooting process, but they are best not plunged until the base of the cutting has had time to callus somewhat. When the pots become well filled with roots, lift and stand them on the surface of the bed for a few days, and then shift them into 7-inch pots. When the young trees start growing freely, pinch out the point of the shoot, which will encourage the formation of side growths. These as they lengthen out should be gradually tied down into a nearly horizontal position, which will leave the centres of the trees open. Pinch these shoots when about 9 inches long, and if kept growing in plenty of heat and moisture, fresh breaks will soon result from this stopping, and a good foundation will thus be secured. No further shifting will be needed the first season, but the following year they should be shifted into 11-inch or 12-inch pots, according to the size of the trees. This is best done as soon as growth becomes general and new roots are being formed. If the wood has been well ripened, no pruning will be required before starting them, but if at all soft and sappy, cut back the shoots to a sound bud. This will result in more growths being made than will be required, but a selection can be made from the best of these, pulling the others off or pinching them back. Care must be taken to regulate growth, pinching back all shoots inclined to grow away in advance of the others, and endeavour to obtain well-balanced heads not too full of wood. Have the wood thoroughly ripe by the autumn, and then a good crop of fruit can be secured the following spring. When the trees come into bearing, growth will be less vigorous, and in course of time they will become furnished with short stubby growths which are most fruitful. The trees would bear, if allowed to do so, while in 7-inch or 8-inch pots, but they would be longer in attaining full size. When good-sized bushes are desired in as short a time as possible it is better to delay their fruiting for a season, and encourage them to make all the growth they can instead. However, when a large collection of Figs is grown, trees in pots of the size referred to are useful for forming the front row. Turning next to

#### FAN-TRAINED TREES,

propagation for these is the same as for bushes. When the cuttings are rooted they may be planted out at once, but I prefer to pot them

on into 7-inch pots and plant them out after they have made from three to five shoots. To accomplish this, the point of the shoot should be pinched out as soon as the roots push into the new compost. This generally results in from three to five breaks being made, and instead of training them out as advised for bush trees insert a stake on either side of the young tree next the rim of the pot. Then place from two to three stakes at the back of the tree diagonal fashion and secure the ends to the upright stakes, thus forming a kind of improvised trellis for training the young shoots to in the same way that nurserymen train espaliers. When these shoots are about a foot long stop them, when others will in turn be formed, and sufficient in number to furnish the tree with future main branches. Planting may be done as soon as these lateral shoots are growing freely, and the same care will be needed as with bush trees to keep all growths inclined to be gross-habited stopped, and thus ensure a greater regularity of growth. No pruning whatever should be necessary the first two seasons if stopping and re-stopping have proper attention during the growing period, and the use of the knife will thus be obviated. The aim of the grower should be to get the trellis covered in as short a time as possible, and this is easily done once the main branches have been secured and trained out. A good extent of trellising can be covered the second year after planting, with good management, when the trees may be allowed to bear. When established, the pruning should be done much in the same way as with Peach trees, thinning out the wood if too much has been laid in, only in the case of the Fig the bearing wood must be left at a much wider distance apart. To obviate the necessity for much pruning the bearing wood should not be laid in too close together, and leave it full length if only one crop of fruit is desired. If two crops are to be taken, pinch the point out of every other shoot at the fifth or sixth leaf, and these will furnish fruit to succeed that borne by the wood of the preceding year's growth. Until the trees come into full bearing, a little root-pruning each winter will check any tendency towards gross growth.

There is another way of training the Fig that should be mentioned before closing this note, which is done in the following manner: If the house is a lean-to, having a trellis under the roof, instead of planting the trees at the front and training them upwards, plant them against the back wall, and when they reach the top bring them downwards. In this case fewer branches are required until the roof trellis is reached. Very good examples of this kind of training are to be seen at Gunnersbury Park and Eastnor Castle, and I have a large old tree trained in the same way. The wood, through having to grow downwards, is always short-jointed, it becomes thoroughly ripened, and is exceedingly fruitful; in fact, it is marvellous the crops of fruit that trees will bear when trained in this way. A. W.

**A new Pear.**—A new late Pear which promises well is *Le Lectier*, a very fine fruit. It appears to be a prolific variety, as young trees fruit very freely indeed. In my case the fruit had to be thinned, and this in a season Pears were none too plentiful. Its season with me is from now to February, though I am aware it is catalogued as a January fruit. My trees were on a south wall, in a light, much drained soil, and all the kinds are much earlier this season than usual. The fruit is large, melting, and for a late Pear of excellent quality. I have it only in cordon form—I mean fruiting trees—and it does well. I am planting it as a bush or pyramid for later supplies, and

probably in this way I may get superior flavour. —G. WYTHES.

**Apple Blenheim Orange as a bush.**—Few will question the value of this old favourite, as its good qualities are well known. Unfortunately, all cannot grow it, as if in standard form (the best for cropping) it takes some years before it becomes profitable, and many do not care to wait so long for a crop. A good return may be secured in a short time if this variety is grown as a bush on the Paradise stock. Grown thus it bears freely in a young state, and frequently produces splendid fruits, which are highly coloured and of a fine shape. I would not advise growing it as a pyramid or in any shape needing severe cutting back, as this does not conduce to fruiting. In bush form and allowed ample freedom, merely thinning out crowded wood, it bears freely and in a short time after planting. If grown as a pyramid it is too spreading to form a good tree and does not like severe pruning. In planting it is well to avoid manure. I find liquid manure during the growing season of great value, as it assists in finishing the crop and builds up fruiting wood for another season. —G. WYTHES.

**Pear Glou Morceau.**—In many gardens this Pear is not always first-rate as regards quality, but in a warm soil it is really good, especially after a hot summer. In the Thames valley, on a light gravel soil of no great depth, Glou Morceau is one of the best winter Pears. In such I get fine fruit and the quality is rich. The tree rarely fails to crop, doing well in any form. I would not advise anyone planting this variety in exposed positions or in badly drained land. As we have none too many good Pears in December, Glou Morceau is well worth growing for mid-winter supplies. My trees are on the Quince. The fruit from a few trees I had on the Pear was so poor in quality that they were not worth growing. On the Pear stock there is no lack of fruit, but it is too small and of poor quality. —G. W. S.

—This is one of our best winter Pears, and although in some places it is not of first-rate flavour, it must be classed amongst the most reliable. Its large size and fine appearance place it in the first rank of Pears for Christmas and onwards. It varies considerably in flavour according to the soil and situation in which it grows. On a cold, wet soil with a bad aspect it is often worthless from a dessert point of view, while on a soil of the opposite character it is frequently delicious. I had a large tree under my charge for eleven years. It grew in a light soil on a south wall on the Pear stock, and during those eleven years it scarcely ever missed a crop. I never had a badly flavoured fruit from this tree, the fruit being handsome and always of a russet appearance, which I have observed denotes the best flavour in this and most other fruits. It requires a warm situation to bring out its fine qualities. I have a tree growing in this garden on a warm wall above the roof of a low glass house, and this last year it gave me several dozen beautiful fruit, while on a wall with a cooler aspect Glou Morceau was indifferent in flavour. This Pear can be grown as an open bush tree, and in some soils it is satisfactory. In a garden where I once was there was a fine tree in this form, and I have seen from one to two bushels of well-developed, highly-flavoured Pears from it. —DORSET.

**Muscat of Alexandria and other Grapes.**—Although I have the highest respect for Mr. Iggulden's opinions and experience as a Grape grower, yet I must venture to contest his statement that Muscat of Alexandria is so delicate that it quickly becomes discoloured and is practically unsaleable, or at least unrepresentable, after it has been carried a little way or exposed for a short time. If that be so in his experience, how was it that the Muscat Grapes shown at the Crystal Palace last autumn were as good in appearance when the show was over as when first staged, enabling some of them to be exhibited elsewhere with success? Is this delicate character

thus ascribed to the berries borne out in the experience of other growers, and especially of exhibitors? All Grapes, white or black, need care in handling and in transit as well as in exposure, but I have never before heard of Muscat of Alexandria being so tender. Whether correct or not, the fact remains that even if somewhat more difficult to grow than most other whites, it is so delicious and generally excellent a Grape that no other white can compare with it. New white Grapes that are not one whit better than other inferior whites that have been raised are no gain whatever. When we can get a white Grape, that has the fine quality of the Muscat and the general excellence of the Black Hamburg, then we may have something to rejoice over. Till then the Muscat of Alexandria remains by far the best white Grape in cultivation. With respect to the flavour of Gros Colman, few growers will, I think, agree with Mr. Iggulden in holding that it is better flavoured than Black Alicante; also that the berries of the latter are mere bags of sugar and water. Gros Colman has the merit of being an easily grown Grape and producing the largest of berries, but it is one of the most difficult of all to properly colour. Its merit lies in the size of the berries and their fine appearance on the table. That may be with many an important recommendation, just as they like to see size in all fruits, irrespective of flavour.—A. D.

**Morello Cherries and stocks.**—In many gardens there is a difficulty with the Morello owing to loss of branches by canker and gumming, and in cases where it fails it is advantageous to get trees worked on different stocks. I found I did much better by having the trees on the Mahaleb. I am aware the use of this stock is greater than formerly, but in many cases I have traced losses, owing to the trees being worked on other stocks. In this country in cold clay or wet soils the stock named fails at times, but much may be done to make the soil suitable for the stock. In gardens where the Morello fails I have with advantage grown the Kentish Red. This will grow where the Morello fails, and the fruit is not inferior in quality. The Kentish Red grows freely in exposed places in cold soils and makes a free growth, but the foliage is small. The fruits are red, but if allowed to hang become dark coloured and acid, and are much liked for cooking. This variety makes an excellent pyramid or bush on the Mahaleb stock and soon attains a fruiting state. Independent of the question of stock is the way the trees are pruned. I fear pruning is often accountable for loss of trees. Some bush trees of the Morello that I planted nine years ago have not shown the least sign of gumming or canker, and they have had little pruning, only a little thinning out and stopping in the growing season. The trees in question were planted at the outset merely as an experiment. It is important that these bush trees be on the stock named. Slovenly worked trees should be avoided, as Cherries are the worst trees to gum at the union.—S. M.

**Grape Gros Colman.**—As a slight addition to Mr. Iggulden's excellent article on the above Grape, an article, by the way, which all, whether market or private growers, are likely to agree with, I should like to note the result of an inspection of a market-place not far from here where Grapes are well done, and where, from a very small beginning, the annual output must now be quite 15 tons. I was aware that the owner had a liking for Alicante, Lady Downe's, and Gros Maroc, and that circumstances had enabled him to try these as well as many others, but found house after house devoted to nothing but Gros Colman, and that a new range some 200 yards long was planted solely with this variety. I have seen rather larger bunches and berries, but for a fine even crop and splendid finish they could not well be beaten. A few Vines of Muscat of Alexandria and Cannon Hall in a warm house were carrying some good crops, the latter especially showing fine, well-finished berries, and I made the remark, "If you can do this Grape as well as this on a small scale, surely a house or two of it would pay well." The answer was de-

ciative. "I have tried nearly all Grapes, but nothing has yet been raised to touch Colman as a market Grape." Naturally a higher price is obtainable for the Muscats, but a comparison of the weights per rod, the firing and trouble of keeping, left the balance with Colman. So far as the other late black varieties were concerned, Lady Downe's was quite discarded, only a few Maroc remained, and the Alicante were half condemned. It has been a bad keeping season for Grapes unless facilities were to hand to maintain a dry warmth all through day and night, and in this matter Alicante and Lady Downe's are with me a bit better than Colman, but at the market-place noted the latter was said to keep plump and sound quite as long as any variety. As, however, most varieties vary as to their perfect development on different soils, so their keeping qualities are naturally influenced. Take the case of Alicante, that receives a deservedly high character from "J. C. B." on page 469. At its best and considering the ease with which it can be grown, it is a very valuable Grape with firm, sweet flesh. Try it, however, in another place and you get little more than a tough skin and water.—E. BURRELL, *Clarmont, Surrey.*

#### APPLE RIBSTON PIPPIN ON WALLS.

It would be worth while, even in the most favoured districts, to grow a few trees of this on walls if only to get some fruit of a different

*Apple Ribston Pippin on a wall facing west.  
From a photograph sent by Mr. W. Burstow,  
Florence Road, Brighton.*

character from that on espalier, standard or other trees. Unfortunately, the tree is prone to canker, and those who recommend planting it largely appear to forget that this Apple, though one of the finest, is one of the most capricious kinds as to soil and situation we have. In spite of all the care that can be bestowed on it, it is sure sooner or later to fall a victim to canker. Provided, however, there is a free outlet for surplus water and the soil is fairly warm and good, we imagine anyone may succeed in growing the Ribston to perfection. Double grafting, using as a stock a strong growing variety like Warner's King, is undoubtedly

effective. While advocating the growing of Ribston Pippin for home use, we fear that for market it is too uncertain. The trees may bloom very freely, but often only a moderate crop follows.

Mr. W. J. Burstow, 30, Florence Road, Brighton, who sent the photograph from which the illustration was prepared, says:—

The photograph I sent you was taken on August 30, and is of a Ribston Pippin cordon. It is growing on a wall facing west and is planted in a narrow border at the side of a lawn and has ordinary garden flowers in front.

#### WINTER GRAPES.

MR. IGGULDEN'S estimate of Gros Colman (p. 448) is certainly a commendable one, and when the high quality of those he has grown this year is taken into account, I think many would be found to support his views and envy the crop and conditions for producing it. It is a problem that has never been satisfactorily solved why perfect Grapes of this and other reputedly bad doers should be obtained in one garden and yet in another, under apparently better surroundings and provisions made for their growth, they completely defy all attempts at successful culture. There is no doubt but that the uncertainty of the Gros Colman to grow and colour satisfactorily is largely conducive to the bad reputation it bears. At the same time, were it as easily managed as the Alicante, it would be much more favourably reported on. I have known some cases where its condition year after year was so unsatisfactory, that it was cut out in despair and its place filled with other less fastidious varieties. This has reference to private gardens. Market growers who take less trouble in the construction of their borders, or make no border at all, invariably secure better results with this particular kind than many private growers, who go to the opposite extreme and provide nothing but the best material procurable to make their borders with. There appears to me to be some element needful for this particular Vine, or what should explain the reason why, when all others in a mixed house should do well, the Gros Colman languishes?

For this reason I should support Mr. Iggulden's views in the matter of a trial of Grapes at Chiswick. A trial would be no more conclusive at Chiswick than it would be in any other vineyard, nor would it furnish any particular lesson to the grower who had stubborn Vines and soil to deal with in his own garden. I presume Mr. Iggulden means dealing strictly with winter Grapes when he advises the weeding out of all such popular sorts as Alicante, Gros Maroc, Mrs. Pince, Mrs. Pearson, Golden Queen, Lady Hutt, and Alnwick Seedling. From an educational and exhibition point of view he will not meet with unanimous support in discarding these entirely at the expense of Gros Colman and Lady Downe's. It may be good advice to the market grower where this is needed, but in the private garden many owners take an interest in the growth and diversity of their crops, and to those who possess such an interest, surely no one would venture to deny them the pleasures variety affords.

Muscat of Alexandria stands absolutely without a rival, and it is unfortunate that from a mixed house it so frequently proves the reverse of satisfactory. If Golden Queen can be as easily grown as Alicante, it certainly deserves to be encouraged. In the winter, and indeed at any other period, black and white Grapes in separate dishes on the dinner-table are often desirable, and Mrs. Pearson or Golden Queen

would form an agreeable change to the Muscat of Alexandria.

"A. D." says Gros Colman is tolerated because of the size of its berries and weight it produces to the market grower, and for flavour ranks among the lowest. This may be true as regards the grower for market, but do not the quantities of that particular kind grown annually prove at the same time that it is favourably accepted by the consuming public—their patrons? It may be taken for certain that those who buy their Grapes like a combination of two qualities—good appearance and good flavour. In well-finished Colman this may be claimed sufficient, at any rate, to justify the purchase by the consumer, and this fact stimulates the market man to provide what to him appears to be just what his customers appreciate. If this were not so, Gros Colman would not have so large a sale in these advanced times. W. S.

**Apple Graham.**—I knew an Apple under this name when living in South Lincolnshire, but have not since met with it anywhere else. On looking through the fruit tree catalogues issued by the leading firms, I find it quoted in one only. It appears to be synonymous with Deux Ans. It is a valuable late kitchen Apple, as I have had fruits of it in excellent condition as late as May. The fruits grew from medium to large and were very regularly formed. The colour of the skin was a clear green with a faint flush on the sunny side, but on the cold clayey loam of South Lincolnshire the fruits could not be expected to put on a great deal of colour. It is very hardy and very prolific, the trees that I remember being generally heavily laden. For growing as a pyramid it is not suitable, as its habit is too spreading, but it makes a fine bush. It could be planted in the colder parts of the country on account of its hardiness and free-cropping proclivities.—A. W.

**Apple Striped Beaufin.**—This is a handsome Apple, and one worthy of extended cultivation. It is by no means a new kind, as it has been in cultivation for more than 100 years. It is more often met with growing as a standard in an orchard than as a garden tree, and I came across a tree of it a short time ago which, to judge by its appearance, could not be less than sixty years old. This, I think, is really the best way to grow it, as bush trees are a long time coming into bearing, the necessary restriction in this case seeming to retard instead of forward fruitfulness. No doubt if it could be allowed plenty of space to extend it might bear well when properly established as a bush. It would, therefore, be a good plan to make an allowance for this when planting if it is not convenient to grow it as a standard. This Apple should be in every collection, not only for the sake of its size and handsome appearance, but because of its good keeping qualities.—A. W.

**Strawberries.**—The best Strawberries grown here in light sandy soil are King of the Earlies, Vicomtesse H. de Thury, Royal Sovereign, President, Gunton Park, Eleanora, and Latest of All, ripening in the order named. Noble is a wonderful cropper and does well in this light soil, but the flavour is poor compared with that of the other varieties. My practice is to make new beds every fourth year on ground that has been heavily manured and deeply trenched for early Peas, which are cleared off and the Strawberries planted without digging the ground. I lay the runners into pieces of turf about 3 inches square and sink them down level with the soil, which prevents them drying up so much, and transplant as soon as they are well rooted, ramming them in as firmly as possible. I plant from the middle to the end of August, and never fail to get a good crop the next season. I make a new bed of King of the Earlies annually in a warm, sheltered quarter, planting the runners 1 foot apart. By so doing I

am able to gather fruit nearly a fortnight before the general crop comes in.—T. TYLER, *Grange, Warcham.*

## PARK AND WOODLAND.

### THE PROTECTION OF FORESTS.\*

THE evils most to be dreaded from the clearing of wooded heights are great risings of rivers and inundations, the reason being that forests exercise a regulating influence upon the flow of water. A rainfall on a bare slope meets with no obstacle to its rapid descent, and when the fall is abundant, as in storms, the mischief is very great, as the water rushing down with violence ploughs up the land, carries off the loam, which there is nothing to hold, and drags along with it pebbles and stones into the valleys below. Such torrents flood the low lands and leave the ascents dry and arid, but where the slopes are covered with wood such terrible effects of storms are not to be feared: the rain falls upon the trees and reaches the soil but slowly, the interlacing branches breaking the violence of the fall. The water drops through the interstices of the foliage as through a sieve; in part it runs along the branches on its way to the soil, where it meets with a carpet of Mosses and dead leafage, which act like a sponge, and instead of forming channels in the earth it is absorbed by it. The lower slopes retain only as much of the rain-water as is necessary to refresh them, and their pastures are always verdant, and the regions that are lowest are protected from inundation; the waters percolating through the soil reappear in the form of springs and the rising of the rivers is not to be dreaded.

The destruction of forests has been the cause of much mischief in a large area of the Rhone valley, especially in the departments of the Basses-Alpes and the Hautes-Alpes. The mountains throughout this region were formerly clothed with magnificent forests which have been little by little almost entirely destroyed, and this country, which was formerly fresh and rich in meadow lands, fertile and prosperous, has become an arid, dry, unproductive, uninhabitable desert. If the department of the Basses-Alpes still retains some shreds of its ancient forests, on the other hand, in the south and south-west there is no wood left, and almost all the loamy soil has disappeared at the same time. In the department of the Hautes-Alpes the whole of Dévoluy, the environs of Gap, the country which is between Gap and Embrun, is a spectacle of ruin and desolation—mountains denuded of grass and the bare rock seen everywhere. Owing to the want of sward or of roots to hold the soil, the torrents drag along with them periodically a considerable amount of mud into the plains, overthrowing everything in their way. The mountains have lost all their fertility; the springs have been dried up and the streams have all been turned into torrents. The number of these torrents has become for these departments the worst of all scourges. Dry during a part of the year, they form large beds full of detritus torn from the sides of the mountains, but in the rainy season, or after a storm, they are changed into rivers of muddy water which inundate the valleys and sometimes overwhelm whole villages. The terror which they inspire in the Hautes-Alpes is apparent in the names they bear. Thus there are the torrents Malaise, Malfosse, Malcombe, Malpas, Malatret, &c. Some bear the name Rabioux (mad);

\* Extract from an article by Gustave Regelsperger in *La Nouvelle Revue*.

several others that of Bramafam (howl-hunger), names that sound quite Dantesque, and savour of the "Inferno." The terror they inspire is quite justified. The Durance, for instance, which is the principal torrent in the region, and of which the flow is from 30 cubic yards to 40 cubic yards a second at low water, has been known to flow at the rate of 10,000 cubic yards in the greatest of its overflows. Its water is charged with mud, and sometimes has the aspect of a quagmire. In August, 1868, it was ascertained to contain mud at the rate of over a hundredweight to the cubic yard. Every year the Durance carries with it not less than 11,000,000 cubic yards of soil. As for the Rhone, it carries off every year to the sea 21,000,000 cubic yards of soil and detritus from the Alps. The whole of Camargue, extending to 65,000 hectares (160,550 acres), is formed of deposits of soil, mud, and slime, called in the locality the "flesh of the mountain." This vast alluvial plain goes on increasing in extent, to the detriment of the soil invaded; the delta encroaches annually on the Mediterranean at the rate of 50 yards or thereabouts. On the same sea-coast the river Var, according to the estimate of engineers, annually carries off 9,000,000 cubic yards of soil and detritus.

Here, it seems to us, are facts enough to dispense with giving other examples of the disasters that accompany the destruction of forests. But this is not all. It remains to be seen what becomes of the population of the devastated regions. The pastures being insufficient for the maintenance of their flocks, the herdsmen descend from the mountains and seek for subsistence elsewhere. Alike the cultivation of the soil has become impossible, because, on the one hand, the fields are threatened by the torrents and inundations, and, on the other, because the moisture is not retained by the soil, and at intervals drought parches up the plantations. The ruined populace seek a distant refuge from this desolate and infertile soil and the land is depopulated. "In these regions," says a writer, "the natural harmony of the terrestrial organisation is disturbed, the providential conditions of human life are annulled and destroyed. Man in ruining the forests ruins his own race; he commits suicide." And it is not only by emigration that the land loses its population, but the loss is partly to be sought in the deplorable hygienic conditions influencing the birth rate. Every census since 1871 reveals this same fact of the decrease of the population in the deforested departments. By the term deforested departments may be understood those thirty which are subject to the enactments of the law of 4th April, 1882, affecting the restoration and conservation of mountain lands. Between 1886 and 1891 these departments have been deprived of 89,682 souls in excess of the birth rate; whereas the fifty-seven other departments show an increase of 213,921 inhabitants. In 1892 the population of France underwent a total loss of 20,041 inhabitants, but the diminution was nine times greater in the thirty deforested departments than in the fifty-seven others. Deforestation, therefore, being proved to be the cause of depopulation in thirty departments is become a question of political hygiene of the highest importance. It is no new discovery of depopulation resulting from deforestation. Dalmatia, for example, which contained 2,000,000 inhabitants before its acquisition by the Venetians in the 15th century, being deforested by the latter in the interests of their navy, at the present day can boast of little over 500,000. Thus we see justified the saying of Chateaubriand: "The forests

preceded the peoples, the peoples go after them. Where the forest is, there is the fatherland."

Long ago farmers, engineers, and statesmen lifted up their voices in warning, but unfortunately they were not listened to. In 1840, Surell, an engineer, published a work on these alpine torrents, in which he showed that the primary cause of the formation, as well as of the enlargement, of torrents was to be sought in the deforestation of their basins. In 1846, on a report by the economist Blanqui to the Academy of Sciences on the deplorable condition of the French Alps, the Government seriously concerned itself with the reforestation of mountains. The first law on the subject was enacted in 1860 after the disastrous floods of 1856, but the resistance which it met with led to a new enactment in 1864, which authorised the substitution of turf-laying for reforestation. Finally, an enactment, dated April 4, 1882, placed the reforestation of mountain lands in the department of public works. The aim of this law is to prevent the washing away of the soil. This is in a direct ratio to the steepness of the slopes and the amount of water which is susceptible of being given off in the form of torrents. The first thing, therefore, to be done is the suppression of existing torrents and their conversion into harmless and useful streams; and the second is to prevent the undermining of the soil and formation of new torrents, or the re-suscitation of extinct torrents. These results are obtained by reforestation.

About 1,200,000 hectares (some 3,000,000 acres) are the extent of the mountainous regions of France, which thirty years ago were still wooded, and now no longer so, thanks to human activity. A third of this surface is now set apart for public works in course of execution at the public expense. Of the remainder, 70,000 hectares have been planted with trees, and 230,000 are represented by pasture lands capable of being restored, which leaves 500,000 hectares as the extent still to be dealt with. The work which remains to be done is therefore considerable. Under the enactment of 1882 the State is authorised to make subventions to proprietors as aids to replanting denuded mountain lands. These subventions, unfortunately, have been insufficient.

## STOVE AND GREENHOUSE.

### CHAMÆROPS FORTUNEI IN HANTS.

I CANNOT say when the Chamærops here figured was planted, but it has stood a number of years without any protection. The aspect is east or south-east on terrace, and planted about 20 feet from the house, by which it is a good deal sheltered. It is 23 feet from ground to tip of centre leaf, and was very beautiful when in bloom at the latter end of May and June with its numerous racemes or branches of drooping golden yellow flowers. H. H.

**Acacia urophylla.**—Nearly the whole of the greenhouse Acacias flower during the spring months, but there are a few exceptions, as the singular *A. platyptera* is usually studded with its golden blossoms during October or November. Following on the heels of this comes the more uncommon *A. urophylla*, known also as *A. smilacifolia*. This latter name is derived from the great resemblance between the phyllodes of this *Acacia* and the leaves of some species of *Smilax*. Like the majority of the Acacias, the flower-heads of this are globular, and in colour pale creamy yellow. Though decidedly less showy than many of

the occupants of our greenhouses even at this season, *A. urophylla* nevertheless affords a pleasing variety.—H. P.

**Nerine Manselli.**—Earlier in the season we have many beautiful species or varieties of *Nerine* in bloom, including the brilliant *N. Fothergilli*, and even now with the advent of December they are not quite over, for *N. Manselli* and *N. undulata* are still in flower. *N. Manselli* is by far the more showy of the two; the flowers, which are borne in good-sized heads, are of a coral-pink when first opened, after which they deepen in colour a little. The segments of this are broad, thus forming a full flower. *N. Manselli* is of hybrid origin and was raised, I believe, by Mr. O'Brien when with Messrs. Henderson. In growing *Nerines*, thorough drainage must be given, and a compost consisting principally of good yellow loam (lightened when necessary with sand) should be used, as this will keep fresh and sweet for years, thus obviating frequent disturbance of the roots, which is apt to hinder the flowering of these bulbous plants. Failures in their culture may be traced to this, or to the fact, sometimes overlooked, that their period of growth is during the winter months, when by some they are kept dry, which is the worst possible treatment they

*Chamærops Fortunei* (*C. excelsa*) in the gardens at Efford Park, Lymington.

can then receive. A good light position in the greenhouse, where the leaves will develop without becoming drawn, is the best place for these *Nerines* in the winter.—H. P.

**Camellia Sasanqua.**—This pretty little *Camellia*, represented though very sparingly in our gardens by several forms, is, under similar conditions to *C. japonica*, flowering freely, being thus much earlier in bloom than its larger relative. It is certainly a very useful flowering shrub for the greenhouse, and the fact that it is almost hardy is another point in its favour. *Camellia Sasanqua* is one of the many plants that, though introduced years ago, had almost dropped out of cultivation. Beside the varieties with single and semi-double flowers of different tints, there is one in which the leaves are marked with white, and when in good condition this is certainly a pretty variegated-leaved shrub. *C. Sasanqua* and its several forms are usually propagated by grafting, but I find that the comparatively slender shoots of this kind strike root much more readily if put in as cuttings than those of its more vigorous relative, *C. japonica*.—H. P.

## THE PERUVIAN HELIOTROPE AND THE GIANT HELIOTROPES (LEMOINE).

I do not suppose there are many more popular plants, or which produce flowers whose perfume stands higher in general estimation than the Peruvian *Heliotrope*. The perfume is, in fact, exquisitely fine, and has been compared with reason to the aroma of the *Vanilla* fruit. Indeed, so close is the resemblance between the two perfumes that it is very frequent to hear people say, "I have a *Vanilla* plant," when all the time it is a *Heliotrope* they possess. Delicate though it is, this perfume is so subtle that, breathed for a length of time in a close room, it produces the sensations of a mild intoxication. The plant itself is elegant in its carriage, and its gracefulness is such that it is well adapted for growing in pots for market. Ever since it was first brought from Peru in 1757, it has been used in the adornment of conservatories and gardens, where its bloom remains with us until the approach of the first frosts. In the open air under Parisian skies its stems and branches are cut down by the first autumn frosts, but in the conservatory its vitality is such that it attains to a great size. By sowing the seeds of *H. peruvianum* some varieties have been obtained which differ from the type in having more ample foliage, and in the wealth, the size, and the colour of the flowers. In some of the varieties, too, the perfume of the flowers is more penetrating even than that of the type. The colour which predominates in all the varieties of *H. peruvianum* is a violet more or less pronounced, but some varieties bear white blooms. Sometimes the leaves, the stems, and the branches bear the imprint of the greater or less intensity of colour of the flowers. Thus the varieties which have the flowers of a deep violet have the branches and foliage equally pronounced in colour.

The giant *Heliotropes* (Lemoine) were scarcely known ten years ago. They owe their existence to crossing the finest varieties of *H. peruvianum* and *H. incanum*. This latter is a Brazilian species introduced to Europe by William Bull, of London, and differs considerably from *H. peruvianum* in stature and general character. It is of some height, and possesses large, vigorous branches and leaves covered with down. The leaves are a grey green in colour, and the flowers bluish and insignificant; it is not very ornamental. M. Victor Lemoine and Son, of Nancy, conceived the idea of crossing some of the finest varieties of *H. peruvianum* with *H. incanum*, with the result that they obtained some hybrids, which they set aside and multiplied for some years. They soon found that the plants were unfitted for cultivation in pots, and gradually they gave up the varieties named and limited their efforts to the multiplication from seed of all the varieties without distinction. The plants they obtained in this way are truly remarkable; they vary in stature from 15 inches to 3 feet. The inflorescences are borne on vigorous branches in the form of corymbs, a mass of flowers on the same level sometimes as much as 15½ inches in diameter.

Notwithstanding the inequality in height which is met with sometimes in plants of the same sowing, the general effect of these plants, whether in baskets or in beds in the sun, is really magnificent. The colours of the flowers are not too varied, and blue, rose-lilac, pearl grey, metallic blue, and sometimes but not frequently rose, are the ones most commonly met with in plants produced from seed.—J. FOUSSAT, in *Le Jardin*.

**Azalea calyciflora.**—If gently forced year after year this pretty little *Azalea* acquires quite an early flowering habit, so that it may without any trouble be had in bloom by the latter part of November. *A. calyciflora* derives its name from the enlarged calyx segments, which are of a bright salmon-red with a distinct orange shade, the same as the rest of the flower; hence in this kind the blooms are of quite a hose-in-hose formation. Although this same feature occurs in *A. amena*, it is wanting in *A. obtusa*, whose flowers

are quite single, though in colour they are much in the way of those of *A. calycellora*. There is a distinct variety of *A. obtusa*, in which the blooms are pure white, or occasionally striped with red. *A. amena* is well known both as a shrub in the open ground and as one for flowering under glass, where it can be had as early in the season as those previously mentioned. A variety of this—Caldwelli—has blossoms as large again as those of the normal form. These smaller-flowered Azaleas are all remarkably free blooming, and apart from their individual beauty they afford a pleasing change from the different varieties of the Indian section. All the Azaleas of this group are far more pleasing when struck from cuttings and allowed to assume their natural shape of much-branched bushes than when grafted on to a naked stem, as is so often done.—T.

**Malmaison Carnations.**—"J. C. B." will be interested to learn that several of the large houses of the above to which I referred in a recent issue were exclusively given up to these plants all the year round. For some time the plants were a success, but eventually the disease overtook them wholesale. These plants were never taken outside, and prior to this I suggested in one instance sulphuring the plants before removal from the house, and thus endeavouring to kill any disease germs that might be about. In many cases the plants were grown on into good-sized pots, and when layering became a necessity this was carried out on the side beds under glass. I mention this to show that with every precaution that could be thought of no cure was effected, nor was the disease in any degree lessened. From repeated trials, however, I am convinced that in certain low-lying districts no treatment will keep the plants long healthy. Some splendid plants purposely purchased in Guernsey for a fresh trial, apparently absolutely clean and healthy, were potted and placed in a cool, airy house at once. In less than two months these plants were badly diseased, yet they had never been watered overhead and only twice at the root, it being late autumn before the disease was rampant.—E. J.

**Arranging plants.**—It is surprising what a lot of money is spent upon elaborate stages and benches in conservatories and show houses generally that would have been much better left alone. A very large percentage of the plants we grow for flowering or for the sake of their foliage looks much nicer when viewed from above than when they are on a level with the eye. There are many Palms and large Ferns, it is true, that require to have their heads high to catch the outline of the stems and fronds, but as often as not the trouble with these is to keep them away from the glass, and it is a simple matter to raise any individual plants that need it, and hide whatever is used for supports with dwarfier subjects. In the *Chrysanthemum* season, for instance, scores of gardeners have wished their stages were movable, and in a greater or less degree the same thing occurs all the year round. On a flat floor beautiful little groups of various plants may be made; the outline of each may be varied and any favourite idea of arrangement carried out, but with a straight rectangular stage for a start there is often little chance for artistic display, and more often than not visitors can see principally the lower part of the flower or the back of fine-foliaged plants, as the case may be. Stages are of course necessary in the growing quarters, but where we have to show the plants they do usually more harm than good.—H.

#### SHORT NOTES.—STOVE & GREENHOUSE.

**Rhynchospermum jasminoides.**—This is a useful old greenhouse plant for growing up pillars, &c. The pure white blooms are well adapted for filling small vases, or bunching in the same way as Violets, as they are very sweet scented and last a long time in water. Some twenty-five years ago this plant was largely grown.—DORSET.

**Geranium Lady Plymouth.**—This is one of the best sweet scented-leaved forms, and a most useful kind when grown in pots to stand in vases in rooms

during the winter. When grown in pots through the summer, exposed in the open, and well fed, it is a most valuable plant in winter. I have some nice plants now (December) grown in this way.—DORSET.

#### THE FRUIT TRADE.\*

I PURPOSE contrasting the fruit trade at the present day with what it was in the memory of many of us forty or fifty years ago. The chief cause that has led to its development has been railway and steamship communication. Fifty years ago the only supply was home-grown and of limited extent, the carriage from a distance to any of the local centres being difficult and expensive. The importation of foreign fruit, with the exception of Oranges and Nuts, was also on a reduced scale, irregular and uncertain. Occasionally a few hundred barrels were sent from America in sailing vessels by private individuals, and the trade in fresh produce, with the exception of a few Pears grown in Normandy and Brittany, was exceedingly small. The prices that had to be paid for fruit put it out of the reach of all but the well-to-do, except in the months of June, July, August, and September, when our home fruits were found in all the markets in the immediate vicinity of the centres of production. I am quite safe in saying that during eight months of the year fruit to the multitude was practically an unattainable luxury, except when Oranges happened to be plentiful. The districts whence Oranges came to this market were St. Michaels and Lisbon. They were sent in sailing ships, which were at the mercy of the winds, and it was no uncommon occurrence for the London market to be without Oranges for two or three weeks. I can well remember often seeing a fleet of ten or twelve sailing vessels moored outside the wharf at London Bridge. Since that time the south of Spain has taken to growing Oranges, and I can call to mind the first few boxes of Valencia's that arrived in Covent Garden Market. They were packed and owned by Robt. McAndrews and Co., who were then the great people in the St. Michael trade. In the first season certainly not more than 200 cases came to Great Britain, and in contrast with this, I may mention that last year the growth in the province of Valencia alone exceeded three and a half million cases. The cultivation has increased to such an extent, that a box of Oranges can now be bought in the months of November, December, and January at a price not exceeding 6s. f.o.b. Valencia, and throughout the season they are being sold here in Great Britain at as low a price as in the towns of Spain where they are produced. Oranges are now being grown in a new district, the province of Murcia; they promise to surpass in quantity, as they certainly do in quality, those of the province of Valencia. The Canaries also are in the field, and whereas six or seven years ago a supply of 200 or 300 boxes during the season was all that was produced, I hear on good authority that last year 50000 boxes were shipped, and that this year the output is more than double. These Oranges, which are of exceptional quality, will have to compete with those from Jamaica, Florida, and California. Florida Oranges occupy a pre-eminent position both in America and here. The frost some seven years ago nearly killed all the trees, and this will be the first season that there has been any crop to speak of. As regards California, the fruit is cultivated there with the greatest

\* Paper read by Mr. M. J. Garcia (of Garcia, Jacobs and Co., London, and Simons, Jacobs and Co., Glasgow) before the Horticultural Club on Tuesday, December 14.

care under the most favourable conditions, and it is only a question of time for it to supplant all the rest grown in America. St. Michaels Oranges, on the other hand, have deteriorated, so much so, that all the trees have been cut down and Pine-apples planted instead. Palestine and Mexico are also now in the field with Oranges, and it is probable that the growth in Jaffa will attain such large proportions as to form a serious opposition to the best fruit that comes from either America or Spain. Efforts have been made to introduce Jamaican fruit, but up to the present with very disastrous results, the loss of one company alone being at least £34,000. The money, however, has not been thrown away, as great experience has been gained, and hopes are yet entertained of the mother country being able to assist in the consumption of the fruit of one of her colonies that has suffered most severely through the failure of sugar not being remunerative. As regards Pines, they are in St. Michaels grown under glass, and are of exceptional quality and size. The average weight is from 2 lbs. to 8 lbs. They are nearly all of the Smooth-leaved Cayenne variety, and I am quite within the mark when I state that there are brought to London each year between 400,000 and 500,000 Pines. These, on account of their size and quality, have entirely supplanted the English growth. Canada is fully alive to the consumption of foreign fruit in England, and the Canadian Government have organised a department for the development of the trade. Cool chambers have been fitted up in the regular steamship lines to London, Liverpool, Bristol, and Glasgow, and the consignments that have arrived this season lead us to hope, now that America is practically closed to British fruit, that we shall be able to assist Canada by being customers for all kinds of her produce. Turning now to

#### ENGLISH FRUIT.

the production fifty years ago was very small, except in the months of June, July, August and September. Hot-house Grapes commenced at about 30s. per lb., and the lowest price, unless in unusual circumstances, was 2s. per lb. The month of November brought us to the end of English hot-house Grapes, and I can well remember when my grandfather, who lived in the Poultry, in Cheapside, had an order for Grapes for the Lord Mayor's dinner, the only person that could supply them was Mr. Crawshaw, of Colney Hatch, and this gentleman used to allow 50 lbs. to be cut specially for this purpose. I have myself sold common Lisbon black Grapes in March at 30s. a lb. The only others that were then obtainable were a few from Almeria, and of these the supply was limited, the average quantity being about 30,000 to 40,000 barrels, and the price 20s. to 60s. a barrel. At the present time the average supply of this one variety is about half a million barrels, and they realise from 8s. to 20s. The cultivation of Grapes and Tomatoes under glass is a matter that you are better acquainted with than I am; but if the amount of care given to this particular branch had been devoted to the growth of Apples and Pears in England, I cannot help thinking that the trade in the latter would be much more profitable than it is to-day. French fruit, with the exception of Pears, was almost unknown fifty years ago, but now the demand is so great, that the cultivation in the south, where Cherries and Green Gages are grown, has been increased solely on account of the consumption in Great Britain. The quantity consumed in Great Britain is extraordinary, and although prices may seem dear, the freight in France is so high as almost to preclude anyone,

with the exception of the French railway companies, from making a profit. The French Government, which has the monopoly of the railway system, throws all sorts of obstacles in the way of the carriage of fruit by fast French trains; and although these are no quicker than our ordinary luggage trains, the freight is higher than any of our railway companies charge for conveyance of similar goods by express. All fruit that reaches us from the south of France is charged at the rate of 1½d. to 1¾d. per lb. Chiefly English capital is now used in the development of this trade, and the largest firm in France, when desirous of turning their business into a limited liability company, had to come to England to obtain the capital necessary. I have left to the last the consideration of the enormous strides made in the

#### AMERICAN APPLE TRADE.

The result to the farmers in America always depends on the crop we have in the United Kingdom, and every year they are as anxious to obtain information as to the outlook here as we are to learn of the prospects on the other side. The business, which commenced by the shipment of a few hundred barrels fifty years ago, has now assumed gigantic proportions. In 1880 there were about 1¼ million barrels shipped from America; for the next eight years the number varied from 81,000 to 800,000, while last year, when the crop was beyond all precedent, over 3,000,000 barrels were sent to Great Britain. This season the crop in general is poor throughout America. In the States the carriage of fruit is evidently much less expensive than here. The bulk that is now arriving is being shipped 2000 miles west of New York at a cost per barrel that certainly does not exceed 15s. to 16s., everything included. If England is to compete with foreign countries, she will have to adopt methods similar to those in use in the country which has made a speciality of the growth of produce for foreign markets. California has certainly set an example as regards trouble taken in the growth of fruit and in the development of the trade, and there are one or two facts which have come to my knowledge from reliable people which I may venture to place before you. Fruit-growing in America is a very important business, and the Government spares no pains in acquiring all possible information on the subject, distributing it in pamphlet form broadcast to all those who are directly or indirectly interested in agriculture. Fruit trees in California, as well as throughout America, are planted at a distance of 24 feet apart, and it has been ascertained from many years' experience that the trees bear more fruit and of better quality in this way than if planted closer. Except during the first few years, no grass or other vegetation is allowed to grow between the trees, and all that Nature and science can do is brought to bear on their development. Some Californian gentlemen have devoted themselves to the culture of fruit in other countries, and one of the most influential has established himself in Cape Colony, 250,000 trees having been sent there four years ago, and this year some of the first produce will reach England. They have decided to send not only to their own, but also to the English markets, and they hope that in a few years, Pears, Plums and Apples, equal to the best grown in California, will be shipped to arrive here during the months of April, May, and June. On one farm alone 90,000 fruit trees were planted last year.

I certainly think that, as regards the production of Apples in England, the nurserymen are

to some extent to blame for advocating the growth of new sorts, for, as I have already said, the old kinds of good eating quality sell well, while, on the other hand, many of the new varieties are difficult to dispose of and less profitable. The same system that exists in America should be followed here, namely, particular attention should be paid to the cultivation of well-known varieties, so that dealers here will be able during the season to depend on a good supply of particular sorts, such as King of the Pippins, Blenheim, Cox's Orange Pippin and others equally appreciated by the British public. Although the production of English soft fruit has increased in proportion to the population, foreign has not caused it to depreciate in value as thirty to forty years ago. Cherries, Plums, Currants, &c., in plentiful seasons were sold at lower prices than under similar conditions at the present day. Thirty-five years since Bigarreau Cherries were sold as low as 5s. to 7s. per bushel of 48 lbs., a figure hardly ever experienced in the present day, while 2d. per lb. for Black Currants was considered a high price.

## SOCIETIES AND EXHIBITIONS.

### ROYAL HORTICULTURAL SOCIETY.

DECEMBER 14.

THIS, the last meeting of the current year, was a remarkably good one, the display of flowering plants, if not of the most extensive character, being a brilliant one. The weather, too, had its share in rendering the meeting brighter and more cheerful than the recent gatherings have been. The attendance was good and the committees were well represented. The greater part of the work fell upon the Orchid committee, as the following list of awards will indicate, the immediate work of the floral committee being light, and that of the fruit and vegetable committee not of a laborious character. The competition for the "Veitch" flavour prizes for Pears and Apples was very keenly contested, the best known sorts for flavour still holding their own.

Of Orchids, the meeting was almost a record one in respect to hybrid Calanthes, in which the prevailing affinity to that grand and useful hybrid *C. Veitchi* was singularly noticeable. The colours of these newer forms were very rich, making quite a show of themselves. Most of these were from the Burford Lodge collection. The major portion of these examples, it was noted, was grown in loam. *Cypripediums* were present in quantity, notably the many fine forms of *Cypripedium insigne* amongst the species, and *C. Leeanum* of the hybrids. Hybrids of other genera were also notably in evidence, more especially in Messrs. Veitch's collection. The groups of *Poinsettias* and *Begonia Gloire de Sceaux* from Isleworth call for special notice, and so does the group of late-flowering *Chrysanthemums* from Groombridge. These all being excellent examples of seasonable decorative plants, some idea could be formed of what can be done for the Christmas supply. Cut *Chrysanthemums* from Ryecroft were present in good numbers, affording useful information as regards the best late kinds. The floral committee, as will be noted, only recommended one award of merit at this meeting, but that in itself was a most worthy one, bearing evidence of what may be accomplished by persistent efforts in the field of hybridisation. The fruit committee had a highly creditable exhibit of Apples from across the border and another from the west country, whilst from Farnham came a splendid exhibit of Selected Conqueror Tomato, these being ideal fruits for kitchen use at this season.

#### Orchid Committee.

A first-class certificate was awarded to—*CALANTHE HARRISI*, a distinct and lovely hybrid. The sepals and petals are pure white, of

fine form and substance, the lip upwards of 1½ inches across, very round, and without the usual keel at the base, pure white with the exception of a little yellow on the disc. It is the result of crossing *C. vestita Turneri* with *C. Veitchi*, and was raised by the late Dr. Harris. From Mr. J. T. Bennett-Poë.

Awards of merit were given to the following:—

*TRICHOPILO BREVIS*.—This is a lovely form, the sepals and petals rich brown, mottled and tipped with bright yellow, the large lip pure white, becoming suffused with yellow in the centre, which deepens at the base. A fine plant with two flowers was exhibited by Sir F. Wigan, Clare Lawn, East Sheen.

*LÆLIA BRISSEI* is the result of crossing *L. harpophylla* and *L. purpurata*. It partakes of the habit and general characteristics of *L. harpophylla*. The sepals and petals are white, suffused with yellow, the lip white on the front lobe with some purple in the centre; the side lobes pure white, with pale yellow at the base. From Mr. J. Douglas, Great Bookham.

*LÆLIA ANCEPS MRS. DE B. CRAWSHAY*.—A grand form of the dark section of this well-known species, the sepals and petals being of fine form and substance, the front lobe of the lip very dark. From Mr. De B. Crawshay.

*LÆLIA PRÆSTANS SUPERBA*.—In this the sepals and petals are of fine form and substance, deep rose in colour, the front lobe of the lip rich crimson-purple with a white spot on the disc, the throat rose, shading to yellow at the base. From Mr. R. W. Richards.

*LÆLIA RUBESCENS*.—In this, better known as *L. acuminata*, the sepals and petals are pale rose, the lip deep rose in front, shading to white in the centre, the side lobes rose, shading to maroon at the base. The flowers are produced on erect spikes 18 in. or more in length. From Sir T. Lawrence and Mr. W. C. Walker.

*CALANTHE SANGUINARIA*.—One of the darkest forms we have seen, the sepals and petals deep red with a little white at the tips of the lower sepals; the lip is similar in colour to the petals and has a deep red blotch at the disc. From Sir T. Lawrence.

*CALANTHE BURFORDIENSIS*.—A grand dark, free-flowering variety, the result of crossing *C. Veitchi* and *C. sanguinaria*. It is a desirable variety, combining both in shape and colour the two parents. From Sir T. Lawrence.

*CALANTHE VEITCHI SPLENDENS*.—A lovely form of this well-known Orchid. It has a compact habit with the free-flowering qualities of the type. From Sir T. Lawrence.

*LÆLIA LINDLEYANO - ELEGANS*.—This is a remarkable combination, being the result of a cross between the natural hybrid *Brassio-Lælia Lindleyana* and *Lælio-Cattleya elegans*. The sepals and petals are greenish-white suffused with rose at the base, the lip rich crimson-purple in front, becoming lighter at the base, the side lobes white shading to purple at the base. The flowers are produced on a raceme 15 inches in length. From Sir T. Lawrence.

*CYPRIPEDIUM ESON VAR. GIGANTEUM (C. insigne × C. Druryi)*.—This is a lovely hybrid in which both species are combined. The dorsal sepal is white at the top, shading to green and thickly spotted with brown on the lower half, the broad petals greenish yellow, suffused with brown, having a few spots at the base; the lip is very broad, yellow, heavily suffused with brown, the whole being highly polished. It is a remarkably bold flower. From Messrs. J. Veitch and Sons.

Messrs. J. Veitch and Sons sent a choice, but interesting group, prominent in this being two fine plants of the secondary hybrid *Cattleya leucoglossa (C. Fausta × C. Loddigesi)*: the sepals and petals pale rose, the lip lighter than the sepals, heavily veined on the front lobe with purple and much crisped on the edges, the side lobes creamy white, shading to yellow at the base, lined with purple at the base. It is a free-flowering and desirable variety. *C. Mantini* and *Lælio-Cattleya Pallas* were also well represented. Amongst the *Cypripediums*, the most prominent were good forms of *C. Adrastus*, numerous fine forms of

C. Lecanum, a grand variety of C. Niobe, and a finely-flowered C. Sedeni candidulum. A silver Flora medal was awarded. Messrs. H. Low and Co. were awarded a silver Banksian medal for a choice and interesting group consisting of finely-flowered *Lælia anceps*, good varieties of *Cattleya Percivaliana*, a nice plant of *Cymbidium Winnianum*, *Dendrobium splendidissimum*, and a finely-flowered *D. Cassiope*. Amongst the numerous *Cypripediums* were a fine form of C. *Miosa*, C. *insigne* Laura Kimball, C. *Pitcherianum* (Williams' var.), C. *Sallieri* Hyceanum, and grand forms of C. *Lecanum*. *Angracum sesquipedale* and *Cycloches Lowi*, a pretty variety with a large bright rose lip, were also included. Messrs. B. S. Williams and Son sent a large group, consisting principally of finely-flowered *Cypripediums*, several finely-flowered *Calanthe Veitchii alba*, good forms of *Lycaste Skinneri*, finely-flowered *Oncidium*s and *Zygopetalum*s in variety. A silver Banksian medal was awarded. Messrs. F. Sander and Co. sent a group consisting of hybrid *Calanthes*, which had a pleasing effect arranged with *Dracena Godseffiana*. Messrs. Paul and Son, The Old Nurseries, Cheshunt, sent ten made-up baskets of *Cypripediums* in such varieties as C. *Spicerianum*, C. *Harrisianum*, C. *Ashburtonæ*, and various forms of C. *insigne*.

Sir T. Lawrence sent a large and interesting group consisting principally of *Calanthes* in variety, the most striking amongst them being the delicate rose-coloured C. *Victoria Regina*. C. *versicolor*, white with a pink centre, was also attractive. Amongst the other species of *Orchids* were fine forms of *Masdevallia irrorata*, *Miltonia Endresi*, a finely-flowered plant of *Platyclinis uncinata* and numerous fine hybrid *Cypripediums*. A silver-gilt Flora medal was awarded. Mr. W. C. Walker sent a grand variety of *Lælia alba bellii* with fourteen flowers on the spike. Sir F. Wigan sent *Cypripedium insigne* (Wigan's variety), a distinct form of the montanum section. Mr. C. J. Lucas, Warnham Court, sent *Lælia anceps Schrederiana*, a distinct form in the way of L. a. *Amesiana*. Mr. M. S. Cook, Kingston Hill, sent two good forms of *Oncidium crispum*. Mr. W. Cobb, Dulcote, Tunbridge Wells, sent *Cypripedium J. Howes* with four flowers and a form of C. *Lecanum*. Mr. T. McMeekin sent *Cypripedium insigne* (Falkland Park variety) and C. Mrs. G. Botterill (C. *Lathamianum* × C. *Savageanum superbum*). Mr. F. W. Moore, Glasnevin, sent *Cypripedium insigne*, a good form and a yellow variety of that species in the way of C. *insigne Ernesti*, *Vanda lamellata Boxalli*, *Maxillaria punctata*, M. *mirabilis* and *Oncidium saltabundum*, for which a botanical certificate was awarded.

#### Floral Committee.

An award of merit was made in favour of

**BEGONIA WINTER CHEEK** (winter-flowering tuberous section), the name chosen for which could not have been more appropriate. The plants bore a profusion of flowers, each from 2½ inches to 3 inches across, these possessing great substance and singularly persistent qualities as contrasted with the majority of the summer flowering section. The colour is a bright rosy carmine, the flowers semi-double, the trusses large and almost erect with the additional advantage of stout foot-stalks. It is of similar habit to B. *Julius*, to which the same award was made at the last meeting, and, like that hybrid, is the result of crossing B. *socotrana* with a tuberous variety. From Messrs. J. Veitch and Sons, Royal Exotic Nursery, King's Road, Chelsea.

Mr. H. J. Jones, Rycroft Nurseries, Lewisham, staged an exhibit of cut *Chrysanthemums* similar to that shown by him at the last meeting, but on a much smaller scale. The blooms were of excellent quality and in very fresh condition. Some of the best varieties shown were *Oceana*, *Geo. Seward*, *Golden Gate*, *Mme. Carnot*, and *Khama*. The arrangement was carried out with great taste (silver Flora medal). Mr. J. W. Temple, Groombridge (gardener, Mr. F. Cubberly) sent a large group of *Chrysanthemums* in pots, all the plants being in excellent condition.

Considering the lateness of the season, the blooms were of good size and colour and very freely produced (silver Flora medal). Messrs. Cannell and Sons, Swanley, Kent, staged a large collection of cut zonal *Pelargoniums* arranged in bunches, with a background of Fern, making a gorgeous bank of colour. The most striking of the newer varieties were Lord Tennyson, with brilliant rose-pink flowers of good size; Dryden, vivid salmon, shading to white, and having smaller flowers; Lord Reay, deep purple and crimson, very rich; Crabbe, soft but bright salmon-pink; Shelley, vivid crimson; Comtesse de Morella, a pretty scarlet and white; Mrs. W. Partridge, light and delicately shaded salmon-pink; Mr. W. E. Corden, bright scarlet; and Duchess of Marlborough, rose-pink and white (silver Banksian medal). Messrs. Hugh Low and Co., Enfield, sent *Cyclamens* and their new *Carnation* Winter Scarlet. The *Cyclamens* were good, bushy plants, with large and handsome blooms thrown well above the foliage. The dark crimson and white varieties were the best. Messrs. Cutbush and Son were awarded a silver Banksian medal for a collection of double *Primulas*, the varieties shown being Princess, white, faintly tinged with lilac, and Marchioness of Exeter, rose-pink. The plants were somewhat straggling and thin in growth, but the flowers were pretty and freely produced (silver Banksian medal). A group of *Poinsettias*, excellently grown and with good full heads of bracts, was shown by Mr. A. Pears, Spring Grove, Isleworth (gardener, Mr. Farr). The foliage was particularly fresh and clean. From the same exhibitor came a group of very handsome plants of *Begonia Gloire de Sceaux*. The delicate pink blossoms, freely produced among the rich and glossy foliage, had a very pleasing effect. For these two groups a silver Banksian medal was awarded.

#### Fruit Committee.

Awards of merit were given to—

**PEAR PRESIDENT BARABE**.—This is a medium-sized fruit, turbinate in shape, skin yellow, much covered with russet, stalk short and thick, and flesh melting. It is a delicious mid-winter Pear and a valuable addition at this season. From Mr. Allan, gardener to Lord Suffield, Gunton Park Garden, Norwich.

**CELERY SUTTON'S SOLID WHITE**.—This was grown at the society's gardens, Chiswick, from seed sent by Messrs. Sutton, Reading. It is a beautiful medium-sized Celery, very solid, remarkably sweet, and free of pith. Messrs. Sutton and Sons, Reading.

Messrs. Berwick, Sidmouth, Devon, staged fifty-six dishes of Apples notable for their splendid colour, the dessert fruits being very fine and splendidly coloured. The cooking varieties were in a few instances past their best. Hornead's Pearmain, Ribston, Cox's Orange, Tyler's Kernel, Stone's, Alfriston, Lady Henniker, Cellini, Bismarck, Golden Noble, and Newton Wonder were the best (silver Knightian medal). Mr. Day, Galloway House, Carlisle, N.B., sent some sixteen dishes of Apples. The Apples were excellent for the locality. Of the kitchen kinds, Lane's Prince Albert, Warner's King, Bramley's Seedling, Mère de Ménage, Peasgood's Nonsuch, Golden Noble, and Blenheim were excellent, while of the dessert kinds the best were King of the Pippins, Mannington Pearmain, Fearn's Pippin, and James Grieve. Mr. Day also showed a handsome dish of Onion Ailsa Craig from seed sown on February 25 of the present year (silver Banksian medal). Mr. Mortimer, Swiss Nursery, Farnham, staged twelve large boxes of *Corqueor* Tomato, excellent fruits for mid-December, well meriting the silver Banksian medal awarded. Sir Trevor Lawrence (gardener, Mr. Bain) sent grand roots of *Celeriac* Smooth Prague, called in France *Geant de Prague*. This is a very large, smooth root of great excellence, and well worth extended culture in this country. A small yellow-topped variety was also shown named *a Feuille Panachee*, useful for salads, as the tops can be utilised and need no blanching. *Couve Tren-*

*chuda*, or *Seakale Cabbage*, was also sent. This was very fine. Caroons were shown by Miss Breton. Celery Jubilee Red, a cut-leaved variety, from Mr. Outram, Fulham, S.W., is very distinct, and Cucumber All the Year Round came from Mr. O. Thomas, Royal Gardens, Frogmore. Celery Victoria Pink came from Mr. T. Cross, Bury St. Edmunds. This the committee wished to be tried at Chiswick.

The Veitch prizes for flavour brought out a strong competition, no less than twenty dishes of Apples and fourteen dishes of Pears being shown. The first prize for Pears went to Mr. Allan, Gunton Park, for President Barabe, the new variety, given an award of merit, Mr. Wythes, Syon House, Brentford, being second with Winter Nelis, also of excellent flavour. Few fruits are superior to this in December, but it lacks size. The other varieties shown were *Josephine de Malines*, *Nouvelle Fulvie*, *Bourré Buisson*, and *Glou Moreceau*. For Apples, Mr. Herrin, Dropmore, was first with nice fruits of Adams' Pearmain, and Mr. Ross, Welford Park, Newbury, second with Cockle Pippin, the other varieties shown being Ribston, Cox's Orange, Blenheim Orange, Claygate Pearmain, Fearn's, Lemon, and King of the Pippins.

#### NATIONAL CHRYSANTHEMUM SOCIETY.

The floral committee of this society held their last meeting of the present season on Monday afternoon last at 3 o'clock. On this occasion there was not a single exhibit of *Chrysanthemums*, this experience being almost unique, if not absolutely so, in the history of the society. A flower-pot, provisionally patented, was submitted for adjudication, having a narrow and shallow channel formed in the rim of the pot. The object of the channel was stated to prevent earwigs getting to the plants, but it was generally considered to be quite inadequate for the purpose. During very hot weather the channel of water would quickly dry up, necessitating constant refilling. The question of certifying varieties as suitable for market was raised, and led to a somewhat animated discussion. A motion was proposed and seconded that "no variety be awarded a first-class certificate or be commended as a market variety." It was contended that the rule regarding decorative sorts should also apply in this case, also that the fact of a plant being certificated as a market variety was rarely stated in the trade catalogues; consequently growers throughout the country were often misled in supposing such sorts to be those suitable for exhibition. An amendment was ultimately proposed and carried that "no certificate be granted to a variety for market purposes unless a plant of such variety be submitted to show its habit of growth and its free-flowering qualities." A resolution was moved altering the number of blooms to be submitted at future meetings to two, instead of three as formerly, but this was, however, lost. It was also decided not to meet on Mondays, November 28 and December 12, 1898, as previously notified in the horticultural press, as it was thought there would be quite sufficient meetings without these two. Each of the foregoing resolutions has to be confirmed by the general committee, who meet on Monday evening next.

A vote of thanks to Mr. Bevan for his conduct in the chair during the past season was unanimously carried.

**The weather in West Herts.**—A very warm week for the time of year, the temperature in shade rising on three consecutive days above 50°, and on one night never falling lower than 43°. At 2 feet deep the ground is at the present time 1° warmer, and at 1 foot deep 3° warmer than the December averages for these depths. Rain has already fallen this month to the depth of 2½ inches, which is nearly the average measurement for the whole of December, and greater than the rainfall of the two previous months taken together. The wind has been as a rule unusually

high, and during the night preceding the 11th the mean velocity for the hour ending 6 a.m. reached 20 miles—direction, W. During the past week the sun shone brightly for altogether about thirteen hours, which may be regarded as a good record for the middle of December.—E. M., *Berkhamsted*.

## NOTES OF THE WEEK.

**Nepenthes Amesiana.**—A splendid example of this is now in fine condition in the collection at Kew, where a well-grown plant is carrying some two dozen of the bold, bandsofely marked pitchers.

**Meconopsis nepalensis.**—The largest rosettes of this species are even now very attractive, as they nestle close to the surface of the soil. Where several large plants are in a group in the rock garden, the leaves with the recent rain lingering on them like drops of silver are very pretty.

**Pelargonium Duchess of Marlborough.**—This is a capital variety for winter flowering where such things can be grown with success, which, of course, is not in all localities. The blossoms are large and finely formed, white, with a suffusion of pink, which deepens towards the centre.

**Cyclamen persicum.**—A well-grown batch of the giganteum strain of Cyclamens may now be seen flowering in the greenhouse at Kew. The group is made up of much variety of colour, from the purest white to the richest crimson. The latter shade is singularly effective, and beside the lighter shades distinctly striking.

**Cissus discolor in bloom.**—Flowering examples of this well-known stove climber were among the exhibits of interest at the Drill Hall this week. The specimens came from the garden of Mr. W. C. Walker, Percy Lodge, Winchmore Hill. The blossoms are of a creamy yellow hue, and in this instance situated on the young shoots near the extremity.

**Tacca cristata.**—Quite recently at Kew we noted a plant of this curious species bearing about eight scapes and many of its curious flowers. It is doubtless a very interesting plant from a botanical point of view, and attractive also in bloom owing to the curiously formed flowers. These are of a reddish-purple hue, and with their appendages more curious than beautiful.

**Injury to fruit trees.**—Messrs. Saltmarsh, of Chelmsford, send us some specimens of the shoots of Apples, Plums, and Cherries which were injured by the great storm of June 24 last. The Pear trees are doing their best to get better, but in some cases the injury was so severe that it led to canker. If the trees had been struck with heavy shot they could hardly have been more injured.

**Rhododendron Queen Victoria.**—For winter-blooming this is a really beautiful kind, being charming in its colour and free and continuous in its flowering. It is also of a distinct apricot tone, and in this way somewhat exceptional, while the well-formed trusses are also compact and full. Like the white Princess Alexandra, it is a fairly good grower, and large bushes remain a long time in perfection.

**Codiaeum (Croton) Van Oosterzeel.**—A coloured plate of this plant was published in *l'Illustration Horticole* (Linden), vol. xxx., 1883. It is said to have been dedicated to M. Van Oosterzee, director of the zoological section at Batavia Botanic Garden. I suppose this is the same plant as the one referred to in *THE GARDEN* of December 11, page 467, but spelt C. Van (Ersted). Where does this spelling come from and which is the true one?—J. SALTER, *Neuilly-sur-Seine*.

**Escallonia montevidensis.**—This shrub generally flowers so late in the season that the large panicles of white flowers are partly destroyed by frost. The absence of frost, however, this autumn has been in favour of this plant, and flowering at a season when but few other shrubs are in bloom makes it doubly valuable. Like most other Escallonias, it thrives well in this moist, mild climate, and is easily propagated from half-ripened wood in sandy soil in a cold frame.—W. O., *Fota*.

**Azalea Deutsche Perle.**—As an early white variety this has for years been valued for forcing, and, seeing it is to be had in full bloom in Novem-

ber, it is extremely useful. For such very early forcing, however, the more established plants are best, particularly those that were gently forced a year ago, and were thus afforded an opportunity of making early growth. Some fine naturally grown bushes of this kind are now laden with the large snow-white blossoms, and with Chrysanthemums on the wane are most effective in the conservatory, where greenery largely prevails.

**Lælia anceps Amesiana.**—This is a lovely form of the dark section of this species, the sepals deep rose, shading to white at the base, the petals very broad and of fine substance, bright rose, heavily suffused with a darker shade at the apex. The front lobe of the lip is a rich velvety crimson, with a blotch of bright yellow across the base, the side lobes deep rose-purple, shading to yellow at the base, where it becomes thickly veined with bright brown-purple. It is a most distinct and desirable variety. A fine form was recently exhibited at the Drill Hall by Mr. F. W. Moore, Glasnevin Botanic Gardens.

**Begonia Winter Cheer.**—It is now quite easy to foresee that before many years are past our winter-flowering plants will be enriched by a group of Begonias almost equal to those of summer. Winter Cheer, which obtained the award of merit on Tuesday from the Royal Horticultural Society, is the result of crossing *B. socotrana* with a tuberous-rooted kind, the former being the seed parent. In the hybrid the pollen parent holds undoubted sway; indeed, apart from the fact of its flowering at this time of year, the new-comer has nothing in common with *B. socotrana*, but leans rather to the tall-growing, free-flowering tuberous Begonia of nearly two decades ago. The present winter-flowering kind is therefore not an ally of the tuberous Begonia of to-day, but has the taller and more branching character of the older kinds, yet considerably larger in its blossoms and more freely flowered.

**Carnation La Neige.**—One of the best winter-flowering Carnations is *La Neige*, a shapely, sweet-scented, pure white variety with a good constitution. Good plants of it raised from cuttings only last March are now flowering freely here in a cool conservatory. From these I have been cutting flowers for the past two months and there are as yet no signs of exhaustion. The flowers are hardly large enough to please those who want their Carnations as big as Malmaisons, but are about the size of an average border variety. The habit is excellent, as the plants branch freely without stopping, so there is no need for the very early striking which is necessary to produce flowers in early winter on many of the Tree Carnations. Plenty of grass is made and quite big cuttings strike very freely. This fine Carnation came to me with a first-class reputation from Mr. Crawford, late of Coddington Hall, and it has in every way sustained the good character it then received.—J. C. TALLACK.

**Sycamores injured.**—I notice in walking through a wood composed chiefly of Sycamores that the bark of nearly all has been ringed round, or almost round, to the width of about an inch. In the case of old trees these bare bands appear on the young branches, but in young trees of from 20 feet to 30 feet high the trunk itself is ringed round at intervals. As many as fifteen of these rings can be counted on one tree. I can think of nothing but squirrels which could reach so high. Can any of your correspondents tell me whether squirrels are known to be fond of the Sycamore bark, and whether this is likely to be their work? I can see no mark on any other kind of tree, and I should be sorry to destroy the squirrels unless quite sure of their guilt.—E. B. SWETENHAM.

**Grouping Chrysanthemums.**—At a local flower show the schedule says, "Group of Chrysanthemums, disbudded, to occupy 40 feet, arranged for effect in half-circle." What I desire to know is, what are the points that the judges give most credit for in awarding the prizes? Are the points (1) size of blooms, (2) new varieties,

or (3) the general effect of the group as to harmony of colours? Further, should the plants be so arranged that the whole group slants downward gradually from the back to the front of the half-circle (the back being against the wall of the room), or should they be arranged somewhat unevenly as to height? and further, should the blooms be close together, or so arranged as not to touch each other? My reason for asking is, my gardener arranged his rather close together and gradually sloping from back to front, the general effect being very good, but the first prize was awarded to a group more loosely arranged and in which the whole of the blooms were larger.—EXHIBITOR.

**White Jerusalem Artichokes diseased.**—In reply to Mr. Wythes, I may say I do not know which variety of the above it is I grow, but the stock was first purchased some years back under the name of New White. The majority of the tubers are more shapely than those of the old purple, but as among the round ones are found many elongated tubers on the same plant, I cannot consider that the shape is a correct indication as to the variety. Since penning my last note the disease has spread wholesale to the tubers, many of which have become absolutely rotten throughout and are simply masses of pulp. I enclose a few of the least affected tubers for your inspection, together with some pieces of stem and tuber-bearing thongs, which show the fungus plainly. In the portions of stem I have wrapped some large black nodules of the fungus itself in an advanced stage; these were found attached to the stems, both inside and outside, and you will be able by their aid to judge of the virulence of the attack. I have now lifted and stored all the seemingly sound tubers and hope to save the stock, in which case I shall plant on a different site next year. A fact perhaps stranger than that of the attack itself is that the old purple variety growing side by side with the white one is absolutely unaffected. As such a visitation of disease appears to be uncommon, it is to be hoped that no more will be seen of it, but I am doubtful if we shall be able to get rid of it at once, as thousands of spores must have ripened and been scattered about the ground.—J. C. TALLACK.

\*\* The Jerusalem Artichokes you sent are attacked, as far as I can judge from the present state of the fungus, by *Sclerotinia sclerotiorum*, which is one of the forms of the fungus known as *Peziza sclerotiorum*. The small black masses that you found are the sclerotia. These will hibernate, and in the spring will give rise to the *Peziza* form, which will produce spores which germinate and develop into long threads which permeate the tissues of the plants they attack, giving off a fluid that dissolves the cell walls of their host. It is said to be one of the worst enemies of cultivated plants. I should be very careful to remove every trace of the infested crop and burn it, and plant an entirely different crop next season on the ground, but I would not plant Potatoes there.—G. S. S.

## OBITUARY.

JAMES CASEY.

It is with sincere regret that we have to inform you of the sudden and unexpected death of Mr. James Casey, which occurred on the 8th inst., from the result of a chill contracted the previous week. The deceased, whose age was fifty-one, had been with us about thirty-four years, and latterly has represented us as a traveller in England, Scotland, and Ireland, where he was thoroughly well known and respected.

HUGH LOW & Co.

**Names of plants.**—*Spring Hill*.—1, yes; your Chrysanthemum is Viviani Morel from a terminal bud; 2, the Dendrobium often behaves as you say. This may be taken off and started on its own account.—T. S.—Box smashed to pieces. Please send fresh specimens.—N. Bond.—*Muhlenbeckia complexa*.—F. B.—*Eccremocarpus scaber*.

## ORCHARD AND FRUIT GARDEN.

### FRUIT TREES FROM SEEDS.

SUGGESTIONS have been from time to time made in THE GARDEN as to the advisability of raising more fruit trees, especially stone fruits, from seed. This might certainly, and with advantage, be more practised in private gardens than it is, as the results obtained are often very good; there is always a chance of obtaining something which will add to the list of the very best fruits, and added to this is the advantage of having such trees on their own roots. Of course this would interfere but little, if at all, with the production of trees for commercial purposes by the usual methods of grafting and budding, as it is only by these means that we can perpetuate varieties of tried merit, and in the case of Apples and Pears the stocks now used, leave very little to be desired, but with such stone fruits as Apricots and Peaches, the results of budding on such stocks as are usually selected, and which are not even closely allied by Nature to the scions they carry, are far from satisfactory. The trouble given by sucker growths from these stocks is well known and not easily dealt with, for, do what one will, the huge bunches of Plum or other growths will persist in coming to the surface in an effort to establish a more direct communication between root and branch. More especially is this the case as the trees get older and less able to bear the diversion of sap thus occasioned. This suckering in the Mussel Plum makes it an ideal nurseryman's stock, as it can be raised in large quantities and quickly by suckers, which perpetuate the fault even more than seedlings of the same thing do. Many years ago, Knight in "The Horticultural Society's Transactions" pointed out the inadvisability of using this stock for the Moor Park Apricot, and advised instead the Apricot seedling stock. This advice is just as good to-day as it was when written, and might be extended to include all Apricots, for though

the one mentioned is more delicate and more given to branch-dying than most Apricots, the injurious effects of an unnatural stock are felt by them all. Speaking generally, it will hardly be denied that Apricot culture is not so satisfactory in this country at the present time as it once was, and though a change of our climate is generally blamed for this, it may well be that the use of bad, but easily raised stocks has had its share in bringing about the degeneration. As Peaches and Apricots come into bearing more quickly from the seed than do any other fruit trees, they are peculiarly suitable for trial on their own roots. I have raised and fruited Peaches in four years from the stone, and this without any special effort in the way of nursing them under glass. At the age mentioned the trees are still young enough to be used as stocks for others in the event of the fruits not proving worthy of cultivation, but my experience goes to prove that both seedling Peaches and Apricots which have been raised from good varieties are generally equal to the parent. I know at the present time where there is a wall some 50 yards in length covered entirely with seedling Apricots which are growing where they were sown; these are all really good varieties, and one amongst them bears the finest Apricots I have seen anywhere in the district. Some few years ago two of these trees fell, as Apricots will, into bad health, and had they been worked trees there would have been nothing for it but to root them out. Instead of this they were cut down almost to the ground, since which they have again filled their allotted space, and appear to be as healthy and vigorous as ever. A similar case which occurred here this year was that of a home-raised Peach tree seven years old. An accident last winter deprived this tree of its entire head and 3 feet of stem, but a new head was formed from a single bud. The newly-formed stem measures already 3 inches in circumference at the base, and the whole growth shows that the Peach tree on its own roots is vigorous and well suited for stocks even if it fails as a good

fruiting variety. The one in question is a seedling from the old Raymakers, and is a worthy descendant of that fine late variety, being a healthy grower, free bearing, fruit of good size and quality, highly coloured, and, although later than any other variety grown here on outside walls, it is juicy and never woolly.

It has been suggested that in raising these stone fruits the plants should be raised and grown for the first year under glass. With this I do not agree, as the seeds germinate better when sown at the foot of outside walls and kept uniformly damp; and as there will be a percentage of weakly growers in every batch raised under any conditions, it is well to find these out and get rid of them at once instead of nursing such weaklings through their early stages, only to find out their delicate nature after a year of such nursing. I have always found that the majority of such seedlings became sufficiently ripened to withstand any wintry weather in their first year, and it is a tolerably well recognised fact that most plants hardly enough to resist an ordinary winter at any time are hardiest when young. It has been stated that where Peach trees are grown on their own roots, or where they have been used as stocks, they are very subject to the "yellows," but this has not been my experience, and well-grown trees are very seldom troubled with that complaint in this country.

Seedling Apples and Pears are slower in fruiting and much less certain as to quality than are the fruits I have already mentioned; still, there are but very few private gardens where room could not be found for raising a few, and the young trees make good stocks for others if they do not themselves prove worthy of perpetuation. Nurserymen who want to clear their stock quickly cannot afford to enter into this work, but that fact should not deter those who have the opportunity from trying to make the world the richer for their labours in this way. Mediocrity among fruits is plentiful enough, but there is still plenty of room for more sterling varieties. J. C. TALLACK.

## ORANGES FOR CHRISTMAS.

For the past few weeks the neighbourhood of the Floral Hall, Covent Garden, has been beset with the traffickers in the yellow fruit to an unprecedented degree. Time was when Pudding Lane held the monopoly of the market in the luscious imports from Spain and Portugal, and the merchants whose warehouses lie thickly scattered about the Monument, encroaching even upon the foundation land arches of London Bridge, still exercise a commanding influence upon the trade; but with the expansion of the Duke of Bedford's accommodation the opportunities have been afforded for developing sales by auction in the west central district also.

From these centres London is supplied with "green," as distinguished from "dry," fruit, and many provincial cities also draw upon the vast supplies which are unladen in the Thames. But, in addition, there are steamers plying from Valencia direct to Bristol, Hull, Liverpool, and Manchester, via the Ship Canal. And so many have been the cargoes received, that when the time comes to complete the December returns it will, it is expected, be found that 1897 has been a "record" year in the Orange trade. An enormous quantity of this fruit had, up to the end of November, been imported, the total, reckoned in bushels, for the eleven months approaching very closely seven millions, of the value of nearly £1,800,000. Taking corresponding periods of the past three years, our Orange bill for 1897 exceeds by the round sum of £325,000 the amount paid last year, and is, roughly, £150,000 above what we disbursed for Oranges in 1895. The supply of Lemons also has very largely increased.

Of the lasting popularity of the Orange there can be no manner of doubt. It is one of those fruits which we cannot very well produce ourselves, though in the last century it was commonly grown in conservatories, and as long since as 400 years ago the Carews of Beddington, in Surrey, cultivated Orange trees in their garden, sheltering them in the winter, and there they remained until destroyed by the great frost of 1739-40. It is on record that the first Oranges brought to this country came from Spain as early as the year 1290. They were called the Poma d'Orange, and were of the bitter, or what dealers call the sour variety, such as are to-day used for medicinal preparations, the expression of essential oils and almost exclusively for the making of marmalade. To-day we are by no means dependent on Spain, though in sweet Oranges Valencia and Denias still lead the way. Denias especially have been very popular with buyers, who are well aware that their rich golden colour appeals to a large public. The quality, too, has been remarkably good, whereas some of the Valencias, though expected to improve in later shipments, were rather below the average, but, nevertheless, arrived in good condition. Both Denia and Valencia Oranges are packed in cases containing from 200 to 1000, and it is a point of some interest that a section of the wholesale trade is entering into a new departure by the supply of unbroken packages of picked fruit to the public direct, thus saving the intermediary profit of the retailer. This new business has originated at Covent Garden. The dealers are not doing more, however, in breaking through old-fashioned trade customs than what the large suburban stores and grocers, who buy in Pudding Lane at public auction, have done for some time. These tradesmen place the middle-class public on an equality with the working class, who are supplied by costermongers regularly frequenting the Monument sale room, bidding at first hand for the lots they fancy.

Some kinds of Oranges rarely find their way to the street barrows, which, in the nineteenth century, have replaced the Orange hawkers of Nell Gwynne's day. Jaffas are sweet, but their colour is paler than that of the Spanish fruit, which by some people is regarded as a disadvantage. They are not so pale, however, as the well-grown, very sweet Teneriffe Orange, which may be seen in shops, and they are not, perhaps, quite so handsome as the curious Californian Navel

Orange, not yet in great quantity. The shapely Jaffas, however, are in considerable demand, and in certain circles they displace the Valencias, Denias, and Mureias. They are in cases holding from eighty to 160, slightly larger than the Canary Islands packages. What is known as the Seville Orange is a bitter one. It has been cultivated without intermission in abundant groves around the city, which gave to it its name when the Moorish conquerors first planted the Orange tree in Andalusia. "Sours" also come to us from Malaga and from Palermo. Mandarin Oranges, in boxes of twenty-five, fifty, or seventy-two, from Valencia, are especially in favour at this season, and the masses appear to be very partial to the luscious pulp. Moreover, not much time is lost in peeling a Mandarin Orange, as the rind readily separates from the flesh.

The money which is being paid for the extra supplies of Oranges and Lemons probably would, in a more favourable season, have been spent in Apples. So far as this year has gone, this country has given for imported Apples about a quarter of a million less than it did twelve months ago, though the total does not compare unfavourably with that of 1895. The loss is chiefly borne by America, Canada and Nova Scotia. From them we have the extremely popular Newtown Pippins, which, in their first qualities, make better prices than the Nova Scotian Ribstons and the ruddy-checked King Pippins. Then we have the Blenheim Orange, the Baldwin, Northern Spy, and Ben Davis, with other varieties, but the first three named are the favourites. France and Holland contribute a small Apple supply. Trade is brisker, prices are advancing, and the market is looking much brighter. It is too early to talk about Tasmania, but California is an important source. The late large consignments of Pears—shipped upon improved methods—are bound to have some influence on the French packers. Pears are still in the shops, but they are not a Christmas fruit. It is otherwise with Grapes. They can always be had. We spend about half a million annually in foreign Grapes, and they are cheaper every year. At all events, the quantities increase in a greater ratio than the price. Grapes are not a thing we leave entirely to the foreigner, for the home and Scotch growers do well with the best hot-house kinds, and Guernsey, too, sends us Hamburgs, Muscats, Gros Colman, and Alicante in neat little handled baskets holding from 5 lb. to 8 lb. The white Grape so popular with the costermongers is the Almeria, which is despatched in neat 65 lb. barrels from Spain, but the cheapest Grape of all just now is the Belgian.

Bananas belong to those fruits originally introduced as luxuries, which have become almost necessities. They are being sent from the Canaries green, and they ripen here, the colouring making a difference in value of from 2s. to 4s. per bunch. Salesmen judge them by the number of rings—seven to ten to a bunch—which, in corkscrew fashion, wind round the stem, carrying from fifty to 120 fruits. Pine-apples are arriving from St. Michael's, in the Azores, five to eleven in a case, with the green tops carefully preserved, for they enhance the value. A considerable export in these takes place to the Continent. Unless Teneriffe egg or apple-shaped Tomatoes be classed as a fruit, the Christmas list is exhausted, though, of course, under the category of seasonable dessert are grouped Dates and all sorts of Nuts, the best Chestnuts coming from Italy, closely approached, however, by the Spanish, the cheapest being the French. France is sending kiln-dried Walnuts from Bordeaux, and Walnut kernels; Italy and Spain supply small Nuts and Peanuts; and when Cocoa-nuts reach us from the British West Indies they are to be reckoned by hundreds of thousands.—*Daily Telegraph*.

**Pear Passe Crassane.**—This is a peculiar variety, and though a few growers get fruits with first-rate quality a great many fail. Doubtless where this variety succeeds it is one of the finest late Pears known. I have seen splendid fruit in a

cool house, but with me, even on a south-west wall, it does not make a good growth. I have seen younger trees doing well. These were double worked, and treated thus it is more reliable. The fruits are medium-sized, green, covered with russet, flesh melting. The best fruits I ever saw of this variety were from old trees planted on a low west wall, the stems being drawn into a cool house. Passe Crassane is worth growing for supplies early in the year where a warm corner can be given the trees, or, what is better, a glass case.—S. H.

**Apple Mannington Pearmain.**—This is one of the best dessert Apples we have if quality is considered, and it generally does well in most soils. It is not large, and is in season from Christmas to February. The fruits are medium sized, conical, and of a greenish yellow colour, skin streaked with russet. It may be kept well into March if gathered late and given a cool store. It makes a good bush or pyramid on the Paradise stock, but the latest fruits are obtained from the standards. The fruit at the late season noted is really excellent from the trees grown on the natural stock. At the great Apple Congress it held its own, no less than forty dishes being staged in 1883. I have since that date grown it as a cordon, but it is not so prolific. I prefer it as advised above.—G. W.

**Apple Court Pendu Plat.**—This is a valuable winter Apple, and one that should find favour for its late keeping, as it comes in when Cox's Orange is past. This variety is easily recognised by its flat appearance, open eye, greenish russet skin streaked with red on the sunny side, and its firm, sweet flesh. The trees fruit regularly if not too hard pruned. It does well in pyramid or bush form, and I have seen excellent crops on standard trees in the southern parts of the country. This variety often escapes late spring frosts, as it is one of the latest of all to flower, and thus a crop is more regularly ensured. Few varieties equal this for late supplies, as it may be had good in the spring, but it must be left as long as possible to prevent shrivelling. I have had good fruits in May, but its season is from February to April.—G. W.

**Pear President Barabe.**—That a distinctly new Pear should at once gain an award of merit and the first prize in the Veitch competition for flavour, and so late in the year as December 14, is indeed a matter for satisfaction. This is, I believe, the first novelty in both Apples and Pears the flavour competitions have brought forth. It is some reward, and it is hoped more novelties may presently crop up. A Pear that is so good in the middle of December, and would be, doubtless, in ordinary seasons good into January, is a valuable acquisition, especially that when put into competition for flavour with Winter Nelis and Glou Morceau it should have taken first place. We are now fast getting through with Pears of any merit. Josephine de Malines was poor in quality, though pleasant in flesh. Winter Nelis was at the recent meeting richly flavoured. Glou Morceau was melting and delicious, yet not, in the judges' estimation, giving the high flavour of President Barabe or Winter Nelis.—A. D.

**A new white Grape.**—I am perfectly content to leave to the judgment of Grape growers of a few years hence the question as to whether the members of the Royal Horticultural Society fruit committee who voted an award of merit to the Marchioness of Downshire Grape were wise in their decision. When it is remembered that so many Grapes getting similar awards have during the past twenty years or so been put into commerce, and white Grapes especially, not one of which can now be classed as other than very second-rate, is it not fair to ask for greater caution in the matter henceforth when any variety of doubtful quality is presented to the committee as new? It does not seem too much to ask that any new Grape should first pass the ordeal of a trial at Chiswick ere it is put into commerce. The raiser would not suffer by waiting another year or

two, but would rather gain were any seedling variety to come out of such a trial well. An award of merit to a Grape enhances its pecuniary value immensely, but does not in the least enhance its fruiting value, and the result is that purchasers are in the end, as they have so often been over certificated Grapes in the past, greatly disappointed.—A. D.

**The Veitch prizes for flavour.**—It is evident that something is wanting in the arrangements which govern these competitions, for their practical value up to this time, especially among Apples, has been very little. We want no further proof as to what are the best two or three varieties, and the constant recurrence of these prizewinners keeps the others from attaining their true place in any prospective tabulated list. I have suggested before that a maximum number of times any variety should be placed first should be fixed, and as each variety attained this maximum it should be debarred from future competition and placed on the list in its proper order. This method would greatly enhance the value of the tabulated report suggested by "A. D.," only, to further the scheme, I would suggest the removal of the clause that now prevents any one grower from winning more than once with the same variety, for the reason that one or two growers might possess a first-rate new variety which has not been widely distributed, and which under existing conditions could not possibly take its proper place in the list. Such restrictions are right enough in showing under ordinary conditions, but in these competitions the one object should be to get at the best fruits wherever and by whomsoever grown. I do not agree with "A. D.'s" suggestion that any variety winning two years in succession should be withdrawn; it would be much better to fix a number of times each should win, for under "A. D.'s" conditions an Apple with a very short season would be placed on an equality with others which are available for use over a long season, and which should be of greater value accordingly.—J. C. TALLACK.

#### THE CHERRY UNDER GLASS.

CHERRIES are not grown nearly so frequently under glass as they might be, especially in gardens where there is a large demand for fruit in variety for the dessert. This is a pity, because there is no difficulty in their culture, neither do they require a great deal of heat. They are not only less difficult to grow, but they require much less warmth than many other subjects that find a home in our hothouses. A Cherry house is a most useful addition to the glass-houses in any garden, and as these can now be constructed at such a cheap rate, it is a wonder that they are not more often met with. Indoors the fruits are secure from insects and birds—their natural enemies—and when fully ripe the fruit will, under good management, keep in excellent condition for some time. In some places Cherries are forced so that ripe fruit may be had in April and May. To do this, two or three compartments or houses must be set apart for them, that is, if a regular succession is required. The first house would then have to be started about the middle of November, the second in January, and the third allowed to come on naturally in the month of March, merely excluding frost should such a necessity arise. If not required so early in the season, two houses would suffice, starting the one in January and allowing the other to come on in a natural manner, as before stated. In some cases the fruits are not required until the usual time for them to ripen outdoors, and in this case one house would be sufficient, and it should be of considerable size if there is a large demand for Cherries. The trees in all three instances may be planted out, but for early forcing they are undoubtedly best grown in pots or tubs. They are then portable

and can be turned outdoors during the summer months to perfect growth and to plump up their buds, also to undergo the necessary period of rest. When grown in pots or tubs and liberally treated, the trees are available for forcing for a good many years. When they begin to exhibit signs of exhaustion, it is an easy matter to prepare for such a contingency by potting up a fresh lot of trees to take their places.

Trees of suitable size can be purchased at a cheap rate at any of the nurseries where fruit-tree growing is made a speciality. After these have had one or two seasons in which to become established, they are then ready for forcing. Until required for forcing they may stand outdoors altogether, only the precaution should be taken to either plunge the pots during the winter or otherwise pack some non-conducting material round and over the tops of the pots. This not only protects the pots from injury, but it prevents the balls of soil from becoming frozen into a solid mass. As early in the autumn as possible is the best time for potting, and if required merely to form a reserve, two-year-old trees will suffice. Trees four and five years old should be purchased ready established in pots to make a start with, as, no matter how well the lifting and potting may be done, it would be folly to attempt to force recently potted trees. They must at the least have one season in which to get re-established after lifting, and those who are thinking of building a house for Cherries should bear this in mind and make preparations accordingly. For planting out, cordons budded or grafted on the Mahaleb stock are the best. These may be single, double or treble-stemmed, just as may be preferred, and if the house is a lean-to or a span, plant them at the front and train them up under the roof. In the case of a lean-to, a three-quarter or a hip-roofed span, the back walls may also be utilised for growing cordons against. In the meantime, or until the trees grow up and cover the roof trellis, the body of the house may be filled with pot trees, thus making the utmost use of space which would otherwise be wasted. A great number of cordon trees could be accommodated in a house from 30 feet to 40 feet long, and a selection of varieties can be made so that it would contain early, midseason and late varieties if only one house is to be devoted to their culture. If three houses are set apart for Cherries, the earliest varieties should be planted in the first, the midseason in the second, and the latest in the third or last house. Regarding

#### COMPOST

for Cherries, this must not be too rich, otherwise the trees will make gross growth, which necessitates a great deal of stopping and hard pruning, with resultant gumming. The selection of compost will depend a great deal upon circumstances, as in some localities the soil is eminently suited to the growth of the Cherry, and in others it is the reverse. A sandy rather than a heavy loam is best suited to its requirements; therefore loams inclining to be heavy should be made porous by the addition of lime rubble broken small, and very light sandy loams should be corrected by adding sufficient dry pounded marl or clay to make them of the right consistency. To loam which is naturally poor, add bone-meal and half-inch bones, half a hundredweight of each to each ton of soil. For pot trees place a handful or so of half-inch bones over the crocks instead of mixing them with the soil. Avoid farmyard manure, as it only promotes rank growth, which brings gumming in its train, and if manure is required at all, use bones in the forms previously men-

tioned. Pay the same amount of attention when constructing the borders as for Peaches and Vines if the subsoil is clayey and damp. If the subsoil consists of gravel or sand, the laying of a concrete floor would of course be unnecessary, but under any other conditions it is far the wisest course to concrete, and avoid future trouble. Good drainage must also be provided, and the border itself must be made firm by treading and beating the materials as the work of construction goes on. Planting is best deferred, whenever possible, until the soil in the borders has had time to settle down, and even then an allowance for shrinkage should be made by not planting the trees too deeply. For pot or tub culture make the soil as firm as possible by ramming it with a blunt-ended potting stick. Borders need not be constructed of the full width at the outset, but may be made from 3 feet to 4 feet in width, and added to each or every other year as may be deemed necessary, or according to the rate of progress made by the trees.

#### VARIETIES.

The following are the names of twenty varieties of Cherries suitable for growing under glass: Early Rivers, Early Red Bigarreau, Bigarreau de Schreken, Belle d'Orleans, Empress Eugénie, Knight's Black, Black Tartarian, Black Eagle, Elton, Governor Wood, May Duke, Royal Duke, Reine Hortense, Nouvelle Royale, Emperor Francis, Archduke, Bigarreau Napoleon, St. Margaret's, Bigarreau de Hedelfingen, and Late Duke. A. W.

**Apple Cox's Orange Pippin.**—I have tried this in all sorts of ways, and in no way is it so satisfactory as in that of a dwarf bush or naturally grown spreading tree. If I were starting a new fruit garden I should have a large proportion of the bush trees of this kind, for it very rarely fails to crop and the fruit always commands a good price. The great thing is to give it good liberal culture and thin the fruit rather severely. I have formed good-sized trees by re-grafting strong growing kinds with a large number of grafts, and then letting them grow with very little pruning. When once the trees commence to fruit, they will make but little wood growth afterwards.—J. G., Gosport.

**Plum Coe's Golden Drop.**—In many parts of the country this Plum gives a good return when others fail. This should be borne in mind by intending planters. I do not say it is one of our heaviest croppers, but it bears a fair crop in most years, and this in connection with its quality, size, and appearance should make it a favourite. I noticed good crops of this variety in the north on walls, and in the far north it well repays for a south-west wall. Few varieties do better in a case or cool house than this, and for pots it is excellent, as it makes a compact, fruitful growth and bears splendid fruits. The fruits keep weeks after being gathered, and if left hanging on the trees in a cool house are like a sweetmeat.—G. W. S.

**Pear Zephirin Greigoire.**—This is a small fruit, and doubtless will not find favour with many on that account. This year my fruits are larger than usual and of excellent quality. It is worth a place where high quality is studied, as the fruits are delicious and not unlike a Passe Colmar in appearance. The flesh is very juicy, rich, and free of grittiness. My best fruits are produced on bush and pyramid trees. It forms a natural pyramid with little pruning and bears freely. I find it does best on the Pear stock, though this does not apply in all soils, as in the south I have noticed excellent results on the Quince. Being a compact grower it does not run to wood on the natural stock, like some varieties. Its season is Christmas, a period we have none too many good Pears.—S. H.

## CHRYSANTHEMUMS.

## DECORATIVE CHRYSANTHEMUMS.

In the production of large exhibition blooms the equally useful and certainly indispensable decorative section seems somewhat neglected. It is the early and late varieties in this section that meet with the largest consideration. Those sorts that might be termed midseason invoke no enthusiasm when associated with the giant flowers. This, however, is not altogether as it would be, but it is true in many cases.

The value of the early Chrysanthemums this year was greatly lessened by the mildness of the autumn, keeping up such a wealth of outdoor flowers and this continued all too late for the welfare of a great many growers. The same conditions have told unfavourably on the late section, especially those intended for Christmas and the early months of the new year. Niveum, one of the most popular late kinds, in many cases is over some time before that date, and the same might be said of Lady Lawrence and Golden Gem, other favourites for the same period. I know of nothing more useful than a good batch of well-bloomed plants of Niveum at Christmas, and it is undoubtedly a variety that has come to stay. Mrs. H. Weeks is another beautiful white kind well adapted for growing in bush form, though its habit is somewhat tall. This would vary no doubt in some seasons and under different treatment. Grown under the adverse conditions common to private gardens, a great contrast is observable in the plants compared to those flowered in the light and airy structures of the market men. L. Canning, once so highly valued for late cutting and furnishing, has lost favour from its indifferent growth and consequent poor flowering characters. I have overcome these objections by retaining the plants and growing them a second year instead of striking so many cuttings and throwing the year-old plants away. Under this treatment I have a good batch of well-flowered, healthy plants that will give plenty of material for the house at Christmas and during January. A portion of the stock must needs be raised from cuttings, so as to have these older stools for potting on, and for convenience the young plants are grown in 8-inch pots, which allow of their being reduced after flowering, placed in 6-inch, and finally transferred into 10-inch pots to flower again. This last size is large enough for L. Canning under any conditions, and the treatment to which the plants are subjected answers my purpose. Those of your readers who have failed with it as yearling plants may do well to give this plan a trial, if only in a small way. The red sport just announced will be an acquisition if it retains the same characters as its parent, and the colour is a decided one; but is not a rather unusual break from a white flower even in Chrysanthemums? This is the first sport I have heard of from L. Canning, and its counterpart in a good yellow shade would be invaluable. Golden Gate is a fine decorative sort, though, like others in the late section, this has come early this year. This is no doubt attributable to the mildness of the autumn and the many warm, sunny days of November. E. G. Hill, too, usually a January sort, is in full flower almost a month too soon, which is also true of Leon Frache, Boule d'Or, Mme. Felix Perrin, Boule de Neige, and New Year's Gift, the last a very nice white, having stiff stalks that carry the flowers erect. Mme. Felix Perrin is a very pretty pink variety, recommended as a superior rival to Leon Frache, and so it has proved, though the latter has cer-

tainly been a victim to the mildness of the autumn and is not so deep in colour as in former years. Phœbus has been very nice, and Cecil Wray bloomed most abundantly, but will be discarded because of the failure to carry its flowers erect. Drooping blossoms convey the impression that they are stale when this is far from being the case. W. H. Lincoln still claims a good position, and Golden Star, a bright yellow single, is very pretty and a good keeper. Amos Perry, E. Dobree, and M. C. Molin have not proved so useful as in the past and will be discarded.

In the early section Lady Selborne still maintains its high position, but the yellow form has certainly lost favour on account of its weak constitution. The Desgrange sports, too, have some dangerously close rivals, yet it will be a long time before they will be generally discarded. Lady Fitzwygram, unless disbudded freely, is very poor, and the same may be said of Queen of the Earlies. With me the former did much better planted outdoors, and I have decided to discontinue pot culture. Rycroft Glory is a gem for pots or as a cut flower, so bright, free, and dwarf. Source d'Or and its yellow form are without rivals in their respective colours, but Wm. Holmes I do not care for, its colour compared with that of Source d'Or, and which flowers at about the same time, being very dull. Among incurved varieties Globe d'Or is very effective, and I have also seen Major Bonaffon producing very fine sprays of golden flowers. Mlle. Marechaux is a good late white, though not often seen, and to see this at its best it should be treated the same as advised for L. Canning. There are many others of the Japanese section suitable for growing in bush form, and no doubt among the newer ones distributed so freely every season others will be found to supersede many that are popular at the present time. White, yellow, and red varieties seem to be the favourites, though other shades find favour to some extent, not so much perhaps for market as for private demands. Possibly other correspondents may be able to name some of the newer kinds that are well adapted to bush treatment, producing freely flowers of a popular shade of colour, and at the same time carrying the blooms on stiff though not necessarily stout footstalks. W. S.

Wills.

**Chrysanthemum Mme. Rozain.**—The flowers of this sort incurve, the florets being very thick and lasting. As a late-flowering variety it is about the best of its colour, a nice shade of pink. Curiously in one place it is met with growing as freely as any kind, and another cultivator may find some difficulty with it. Probably over-feeding has much to do with failures. The variety forms a capital bush plant and has fine foliage.—H.

**Chrysanthemum Tuxedo.**—This variety has been cultivated a considerable number of years, yet it is not at all common. As a late-flowering bronze kind it is of exceptional merit. The habit is somewhat tall, but the plant may be headed back freely in the early part of the season. Its blooms are produced on long footstalks, and they last of good colour right through the dull portion of winter. Few varieties equal it in this respect, and it is a sort that should find general favour.—H. S.

**Chrysanthemum Niveum.**—This pure white variety is excellent for conservatory decoration when in the condition lately noted at Bramley Park, Guildford. One stout stick is placed in each pot, and the main stems are looped loosely to it. The plants having been topped when young have several branches, and these are allowed to produce flowers without any further disbudding. The result is a wealth of blooms in

varying sizes borne on the side shoots as well as the points of the stouter stems. The specimens in question being of large size, a particularly fine effect is obtained. Niveum being an exceptionally good late kind, the flowers will last fresh up to Christmas.—H. S.

**Chrysanthemum Mme. Edmond Roger.**—A few years ago Florenee Davis attracted a good deal of attention owing to the peculiar sea-green tint that suffused the otherwise white blossom. Owing to differences in cultivation, some flowers had this distinct shade much more pronounced than others, but when at its best this variety was—at least, in the opinion of some—regarded as one of the most desirable of Chrysanthemums. After that there was a good deal of fuss concerning a green Chrysanthemum, which proved, however, to be but a poor thing. In the variety Mme. Edmond Roger we have what promises to be a very beautiful kind, whose peculiar greenish tint eclipses even that of Florence Davis. It is at present not much grown, but another season it should be far more plentiful. The raising of new Chrysanthemums is, however, so much over-done that they cannot all be fairly tested, and many are doubtless passed over that would on further acquaintance become very popular.—T.

**Single Chrysanthemums at the Aquarium.**—In your report of the recent Chrysanthemum show at this place some fine singles are mentioned as being too formally set up. That was my own opinion, for the flowers were as flatly and unevenly shown as could be. Seeing that these singles are so appreciated for their lightness, grace, and elegance, it may be worth while suggesting that judges be empowered to base awards in the single classes partly on style of setting up. If still shown in tubes in threes, the flowers should be more elevated, and the back bloom in each bunch be placed rather above the other two. Some day, perhaps, we may see a class for six blooms of a variety shown in vases. The more such informally arranged classes are introduced into shows the better are they liked by visitors, many of whom are less attracted by the huge blooms on the show-boards, and are far more entranced with any decorative effects in which the Chrysanthemum plays the major part. These bunch classes, however, are very charming, and it is a pity they are not more seen at smaller shows. Too much space is still devoted to the Chrysanthemum as a purely show flower, and much too little to its beauty for decoration.—A. D.

## SHORT NOTES.—CHRYSANTHEMUMS.

**Chrysanthemum Mrs. James Carter,** sometimes called Thistle, is a pretty variety when seen as a huge bush plant. The colour is very light yellow. It has small individual blooms, these being composed of light hair-like florets. In a mass they are striking, and the sprays are most delicate in a cut state.—S.

**Chrysanthemum Major Bonaffon.**—This is a first-rate late sort, the colour a soft, bright shade of yellow. The florets, which are of good substance, incurve with just enough regularity to be informal and light. The growth of the plant is sturdy. In America it is highly esteemed as a market variety, and were its qualities better known it would be equally valued in this country.—S.

**Chrysanthemum King of the Plumes.**—This variety deserves extended culture. As its name implies, it bears flowers of a light feathery character. These are rich yellow. The growth is free and naturally branching. It should not be disbudded, then each branch sends up a quantity of medium-sized blossoms that last well into the winter. In fact, it is regarded as a late-flowering kind and one valuable for cutting.—H.

**Chrysanthemum W. H. Lincoln.**—For a late supply of yellow blooms I doubt if there is any sort to equal this old one. Mr. Paddon, the gardener at Bramley Park, grows it splendidly. About two dozen specimens, each from 2 feet to 3 feet through, form a fine mass of colour. The stems of this kind are so stiff that little training is needed, and the flower-stems are equally firm, holding the blooms well up from the foliage.—H.

## FLOWER GARDEN.

## THE HARDY SPECIES OF CLEMATIS.

When Bentham and Hooker published the first volume of the "Genera Plantarum," in 1862, they estimated the number of species of Clematis at 100. Since that time the genus has been added to by discoveries of new species in several parts of the world, and there are now probably about 150 species known. Of these,

garden value it is the hardy species almost exclusively that possess any importance; there is, in fact, only one greenhouse Clematis—the New Zealand *C. indivisa*—that is held in any great esteem by gardeners. But among hardy climbers there is no group of plants that equals the Clematises in variety and number, or even in beauty if we exclude the climbing Roses. Such popularity as the genus now enjoys may be said to date from the introduction of *C. lanuginosa* from China by Robert Fortune in

observations that have recently been made in these columns respecting the wild Roses (THE GARDEN, November 13, 1897, p. 384) apply with equal force to this genus. Whilst none of the species of Clematis can vie with the best varieties of the garden race in mere showiness, they possess a charm and sweetness of their own as well as an exceptional interest to all lovers of hardy plants. There is, happily, in these days a reviving interest in the original types of garden races of plants which in the striving after size and showiness of flower were in danger of being forgotten.

The species of Clematis vary in habit from herbaceous plants little more than 1 foot high to woody climbers with stems 50 feet or more in length. The leaves are always in pairs at each joint, and although occasionally simple, are more frequently compound, consisting of three, five, seven, nine or more leaflets. Most of the climbing species support themselves by means of the leaf-stalks, which curl round twigs or other slender objects near. The leading features of the Clematis flower are too well known for it to be necessary to dwell upon them long. It possesses no true petals, but in their place a coloured calyx consisting of usually four, but sometimes as many as eight sepals. The species belonging to the *Atragene* section (once kept generically distinct) differ from the true Clematis in having between the sepals and the central tuft of stamens one or more rows of petal-like organs which may either be considered petals or abortive stamens. In the more showy species the flower is flat or nearly so and the sepals spreading, but in numerous species it is bell-shaped or pitcher-like, the sepals contracting towards the top into a neck, but with the points spreading and more or less recurved. The seed-vessels, which are numerous and one-seeded, are each terminated by a long and often feathery tail, which gives to the heads of fruit that characteristic appearance of which so familiar an example is furnished by our British *C. Vitalba* in autumn.

The Clematises like an open loamy soil, which should always be fairly rich, and in the case of the largest-flowered kinds even very rich in vegetable humus and fertilising material. All of them appear to succeed best in a chalky soil, and in gardens naturally devoid of chalk or lime it is advisable to supply it. A thorough annual mulching with rotted manure given about November is of great benefit, especially where the soil does not naturally retain its fertility long. Such pruning as may be necessary for these wild types (and it is chiefly a question of the space to be covered) should be done in February. The stronger growers stand pruning well, and if they grow up their supports too high and form a thick heavy tangle at the top, they may safely be cut hard back. The weaker ones rarely need pruning at all. The Clematises may be used to cover walls, rootwork, mounds, arbours, pergolas, &c., and in the open, where no other support is available, rough Oak branches may be used for them, either singly or several set together to form a pyramid.

The following is a list of the species and more noteworthy hybrids dealt with in the present paper. I have roughly classified them, but the grouping must not be taken as necessarily indicating a natural relationship between the species brought together. Such often does exist, but I have arranged them more with a view to the characters obvious to the cultivator than to those upon which the scientific classification of the genus is founded. The nomenclature followed is that of the Kew "Hand-list of Hardy Trees and Shrubs," and for the complete synonymy that work should be consulted.

The sweet-scented Virgin's Bower (*C. Flammula*). From a photograph by Miss Willmott. (See p. 500.)

by far the larger number come from the cool and warm temperate regions, a few only being found in the torrid zone. Not many genera of plants are more widely spread over the globe; Northern Asia possesses the largest number of species, and following that region in importance comes North America, but the Clematises are also plentifully represented in South America, Europe, and the Australasian region. Less numerous they occur in North and South Africa, Java, &c. From the standpoint of

1851, and the intercrossing of it a few years later with other species, which resulted in the advent of *C. Jackmani* and the numerous progeny it represents. Among the hybridisers and cultivators of Clematises, the names of Jackman, Cripps, Noble, Anderson-Henry, Simon-Louis, and, latterly, Smith, of Worcester, hold the foremost places. In the present paper, however, I propose to deal more especially with the original wild types of Clematis, which have in late years been somewhat neglected. The

## HERBACEOUS.

Douglasi.	Fremonti.
Heracleafolia (tubu- losa).	Integrifolia.
„ var. Davidiana.	Ochroleuca.
Recta (erecta).	Stans.

## WOODY DECIDUOUS CLIMBERS.

(I.—With panicles of numerous white or yellowish flowers.)

Apiifolia.	Brevicaudata.
Connata.	Flammula.
Ligusticifolia.	Paniculata.
Virginiana.	Vitalba.

(II.—With solitary, closed or pitcher-shaped flowers.)

Ethusifolia.	Campaniflora.
Coccinea.	Crispa.
Fusca.	Piteheri.
Viorna.	„ var. lasiostylis.

(III.—With large and, except in montana, solitary flowers, the sepals fully or partially expanded.)

Alpina.	Aromatica.
Florida.	Hendersoni.
Jackmani.	Languinosa.
Montana.	Orientalis.
Patens.	Robertsiana.
Verticillaris.	Viticella.

## EVERGREEN CLIMBERS.

Calycina.	Cirrhosa.
-----------	-----------

**C. ETHUSIFOLIA.**—This is a Chinese species, and has been found by several collectors in the neighbourhood of Pekin; from there, however, it extends eastwards to the Amur River, in Manchuria. It is a graceful climber, with slender grooved stems and branches. The leaves are bi- or tri-pinnately divided, the ultimate segments (in the type) being very narrow and irregularly toothed. The flowers have no bright colour to recommend them, but they are abundantly produced and extremely graceful. They are borne singly on stiff, erect peduncles, but are themselves pendulous. Each one is from half an inch to three-quarters of an inch long, somewhat bell-shaped or even tubular, the sepals being yellowish white, and having their tips recurved shortly. Like most of the Clematides, this species varies a good deal in shape of leaf, and one form has been considered distinct enough to receive the varietal name of *latisetata* (*Botanical Magazine*, t. 6542). In this variety (which was found by Dr. Bushell near Pekin, and by other collectors near the Amur and Ussuri Rivers) the ultimate divisions of the leaf, instead of being narrow and linear, are as broad as they are long, about 1 inch in length, and unevenly toothed and lobed.

**C. ALPINA.**—A very pretty species belonging to the *Atragene* section, and flowering in spring. It extends over a wide area, reaching from the mountains of Central and Southern Europe to Siberia, and eastwards as far as North China. The stems are very slender, with prominent joints, which become more and more swollen with age, whence are produced both flowers and leaves from the same bud. The flowers are nodding, the four large sepals being blue with a whitish margin, or sometimes almost entirely white (var. *alba*). The *Atragene* section differs from the ordinary Clematis in the flowers having petal-like organs. In this species they number about a dozen and are small and dull white. The flower is 2 inches to 2½ inches across. This species has been figured under the names of *Atragene austriaca* and *A. sibirica*, but both names are now sunk under *C. alpina*, the Siberian form being the one with white flowers and called var. *alba*.

**C. APIIFOLIA.**—A vigorous climbing species with ternate leaves, growing perhaps 10 feet high, the panicles of flowers produced in August and September. The flowers are each about three-quarters of an inch across and dull white. A native of Japan and China. Closely allied to *C. apiifolia* is *C. brevi-*

*caudata*, the only difference between them, indeed, that I have been able to fix on being the pinnate or biternate leaves of *C. brevicaudata*. Both were originally described by De Candolle, and both are included in Forbes' and Hensley's "Index Floræ Sinensis," so presumably they are distinct. They belong to the group which comprises *C. Vitalba*, *C. virginiana*, &c.

**C. AROMATICA.**—There appears to be some doubt as to whether this is a garden hybrid or a wild plant; if the latter, its native country is not known. It is certainly closely allied to *C. Viticella*, and if it be a hybrid, that species must be one of the parents. In nurseries and gardens it is often grown as *C. cerulea odorata*. It is a slender plant, growing 6 feet or 7 feet high, the leaves consisting of three to seven ovate, untoothed leaflets. The flowers are solitary and terminal and from 1½ inches to 2 inches in diameter, the narrow reflexed sepals of a rich purplish blue. The great charm of this plant is in the sweet, delicate, and slightly aromatic odour of its flowers, which are very freely borne during late summer and early autumn.

**C. CAMPANIFLORA.**—Although this has rather small flowers it is very distinct. The flowers are bell-shaped, each about 1 inch in diameter, with the pointed tips of the sepals recurved. The colour is a pale violet or almost white. This charming species is a native of Spain and Portugal, and will climb 10 feet to 15 feet high. The flowers are very freely borne, and against the deep green, often finely-divided foliage they are very effective.

**C. CALYCINA** (*C. balearica* of Richard).—Although this species can be grown outside in the southern and milder parts of Britain, it is far from being as hardy as the majority of the Clematides here dealt with are. It is a native of Minorca and Corsica, but was introduced to this country from Paris by Thouin, who sent it to Kew in 1783. It is evergreen, and has dark brown, angled stems. During the winter the foliage acquires a fine bronzy hue. The flower is 1½ inches across and of a yellowish white, stained inside with oblong, irregular, reddish-purple spots. It flowers as early as December, and continues more or less in bloom up to March. In the London district it ought to have the shelter of a wall to get it to flower well, although at Kew it has been grown in the open without any particular shelter for many years. It is not a common plant, but is well worthy of the notice of gardeners, especially in the south-western counties and similarly mild districts. It was cultivated sixty years ago at Abbotshury, in Dorsetshire, and may possibly be still grown in that garden, where so many tender shrubs thrive in an extraordinary manner. From its near ally—*C. cirrhosa*—it differs in its narrower and more divided foliage.

**C. CIRRHOSA** (*C. balearica* of Persoon).—Nearly allied to *C. calycina*, this species has been much confused with it, owing to both of them having been called *balearica*. *C. cirrhosa*, however, if it comes from the Balearic Islands at all, is not confined to them, but is a native also of various parts of Spain, and, crossing the Mediterranean, is found also in the neighbourhood of Algiers and on the mountains of the Atlas range. The first recorded discovery of the species was in Andalusia by Clusius. Philip Miller cultivated it in the Apothecaries' Garden at Chelsea, and observes that it endured the winters there for forty years, but it is more tender than most of the Clematides here mentioned, and should have the protection of a wall. It is evergreen. The flowers are dull white or cream coloured, downy outside, smooth within, and about 1½ inches in diameter. In South Europe it is said to climb over big trees, but it grows only some 8 feet or 10 feet high in these colder latitudes.

**C. COCCINEA** (*C. texensis*).—This is nearly allied to *C. Viorna*, and was at one time regarded as no more than a variety of that species. From it, however, *C. coccinea* is easily distinguished by its red (usually scarlet) flowers and glaucous foliage. As a garden plant it is also superior. Its stems grow some

6 feet to 10 feet high, and as a rule in this country die back to the ground in winter. It is a native of Texas, and, as may be judged from its habitat, is not so hardy as *C. Viorna*. The flowers are borne singly on a peduncle 5 inches or 6 inches long, and the colour varies from rosy carmine to scarlet; they are swollen at the base, but narrow towards the top, where, however, the tips of the four sepals are recurved. These sepals are very thick and somewhat leathery and about 1¼ inches long. The species was discovered by Mr. Buckley in Texas in 1859, and was introduced to England some nine years later, but it appears to have been noticed by Dr. Lindheimer in the same State in 1850. A larger-flowered variety is known as var. *major*. Quite recently this species has come into notice as the parent of a pretty race of hybrid Clematides sent out by Mr. G. Jackman, of Woking, which have been shown at the Drill Hall meetings. Herr Max Leichtlin some years ago raised a hybrid between it and *C. lanuginosa*, and M. Morel also has crossed it with *C. Piteheri*.

**C. CONNATA.**—This species, at present very uncommon, is a native of Northern India, being found on the Himalayas between Hazara and Sikkim at 4000 feet to 10,000 feet altitude. It is a climber with stout woody stems; the leaflets (of which there are three or five on each leaf) are 3 inches to 5 inches long, coarsely toothed, or sometimes more or less three-lobed. The flowers are bell-shaped and appear during autumn. The sepals are of a clear light yellow, and have the pointed tips recurved. Each flower is about one inch long, and is followed by silvery-grey plumose fruits.

**C. CRISPA.**—Many of the Clematides show a great tendency to vary, but none perhaps more than this; the consequence is that the nomenclature connected with the species has been very perplexing. In London's time the names *crispa*, *cordata*, and *cylindrica* were all considered to represent different species, and Lindley in his *Botanical Register* devoted three or four pages to an attempt (and not a very successful one) to establish the identity of each. In these latter days the difficulty has been overcome by the simple and effective process of lumping the whole of them under the name *crispa*, and anyone who studies the figures will admit it is the only rational one. *C. crispa* consequently applies to a number of plants alike in all essential characters, but differing in the shape of the leaves and in the size and colour of the flower. The leaf consists of three, five, or more leaflets, which vary in outline, and are sometimes undivided, sometimes three or five-lobed. The calyx is cylindrical or bell-shaped, and from 1 inch to 2 inches long, the upper part of each sepal spreading. The colour is purple margined with white, or in some forms pale lilac. The flowers are fragrant and appear in June, continuing up to autumn. Some of the forms are bright in colour and pretty, but others are amongst the least effective of the shrubby Clematides, the thick, heavy sepals being of a dull purple. A native of the eastern United States.

**C. DOUGLASSI.**—A species hailing from the west of the Rocky Mountains, and discovered by David Douglas, after whom it is named. It is at present scarcely known in English gardens. In general habit it agrees with *C. integrifolia*, *Fremonti*, &c., but instead of having simple, has deeply divided leaves. The flower is solitary on a short terminal stalk and is bell-shaped, 1 inch long, the sepals being recurved at the tips and of an intense purple inside, paler without.

**C. FLAMMULA.**—Although not a native of Britain, this species has been in cultivation here for over 300 years, and is mentioned in Gerard's "Herbal." It is found wild in Central and Southern Europe. A vigorous grower, it is still not so robust and rampant as *C. Vitalba*. Its leaves are of a rich dark green and remain fresh till well into the winter. The flowers are small (half-inch to three-quarters of an inch across) and appear in late summer and autumn on numerous axillary and terminal panicles. They are of a clearer creamy-white than those of *C. Vitalba*, and have a more

decided and Hawthorn-like fragrance. The fruit is white and feathery. This is a very variable species, especially in the size and shape of the leaflets and in the flower panicles, some of which are large and with numerous blossoms, whilst in other forms the panicles are comparatively few-flowered and scarcely branched at all.

*C. FLORIDA*.—Like *C. lanuginosa*, *C. patens* and *C. viticella*, this species is the type of a garden race of Clematis, only much less numerous and important than any of the others. It is a slender

*C. FREMONTI*.—In the Western United States of North America this species may be said to represent the *C. oehroleuca* of the Eastern States, but whilst the latter has been cultivated here since 1767, *C. Fremonti* is a comparatively recent introduction. Its herbaceous stems are from 1 foot to 2 feet high, rarely branched, and carry numerous undivided leathery leaves, 3 inches or 4 inches long, without stalks; the margins are entire or nearly so. The flowers are terminal and drooping, the thick, purple, lanceolate sepals

very thick, brown wool, and the sepals themselves are of a reddish brown colour and also very downy. The flower (which appears in July) is bell-shaped and upwards of 1 inch long, with the points of the four sepals recurved. The fruit forms a thick globular head, 1 inch across, of very plumose tails. Its habitat extends from the north of Asiatic Russia to the Amur region and the Sachalin and Kurile Islands. It was first discovered by Turczaninow in Kamtschatka.

*C. HENDERSONI* (*C. Eriostemon*).—This is considered to be a hybrid between *C. viticella* and *C. integrifolia*, and was raised in 1835 by Mr. Henderson, nurseryman at that time at Pine-apple Place, St. John's Wood, but apparently no record of its origin was kept. The inference as to its parentage has been made because of the resemblance its stems and general habit bear to those of *C. viticella*, whilst its flowers and leaflets follow those of *C. integrifolia*. The plant grows to a height of 8 feet or 10 feet. The flowers are 2½ inches or so across and of a deep bluish purple; the four sepals are spreading, but reflexed at the tips. The flowers appear from June to September and have a faint, sweet perfume.

*C. HERACLEEFOLIA* (*C. tubulosa*).—This species may be taken as the type of a group of herbaceous or slightly woody Clematises found in China and Japan, &c., and of which, according to Forbes and Hemsley, the plants known as *Davidiana*, *Hookeri*, *stans*, *Lavalléi*, and *Savatieri* can only be considered as varieties. Specimens representing the extremes of the group are distinct enough from each other, but they are so linked together by intermediate forms, that it is impossible to draw a separating line between them. The typical *C. heracleefolia* as represented at Kew is a dwarf, sturdy plant under 2 feet high, with large leaves and short-stalked corymbs of flowers of a Hyacinth-like shape and of a purplish blue colour. Much superior to it as a garden plant is the variety *Davidiana*, which often ranks as a species (*C. Davidiana*). Its stems are about 4 feet long, but are rarely strong enough to stand erect without support. The leaves are often of striking dimensions, some of the largest leaflets measuring 6 inches in length by nearly as much in width, and thus the largest of any of the cultivated Clematises. They are coarsely toothed. The flowers are produced in dense heads, borne on long stalks and accompanied by two or more bract-like leaves, but they also frequently appear in short, closely packed clusters right in the axils of the leaves. Each flower is three-quarters of an inch long, the points of the sepals reflexed and resembling a Hyacinth blossom; the colour is a bright lavender-blue. This variety was introduced to France a little over thirty years ago by the Abbé David, who had discovered it in the north of China. It is a useful and an ornamental plant, flowering during September and October, and well worth growing in any mixed herbaceous border.

*C. INTEGRIFOLIA*.—Over 300 years have passed since this species was introduced to Britain; it is, therefore, one of the oldest Clematises in cultivation. It is herbaceous, 2 feet to 3 feet high, its erect stems furnished with leaves 2 inches to 4 inches long and stalkless, or nearly so. The flower is solitary on its stalk, but several of them are produced from the top of the stem and from the axils of the uppermost leaves. The flowers are blue, pendent; the sepals about 1 inch long. It is a European species, and flowers from June to August.

*C. JACKMANI*.—This plant originated in the nursery of Messrs. G. Jackman and Son at Woking, being a hybrid between *C. lanuginosa* and *C. Hendersoni*. The cross was made in the summer of 1858, and seeds from it germinated in 1860, and the plants flowered two years later. A theory was afterwards started by Lavallé in his Monograph of the large-flowered Clematises that the *C. Jackmani* so-called was not a hybrid at all, but a Japanese species—*C. hakonensis* of Franchet and Savatier. The positive evidence, however, of Mr. G. Jackman (*Gardeners' Chronicle*, Feb. 23, 1884) and that of the late Thomas Moore, an authority on the garden Clematis, were sufficient

The yellow Virgin's Bower (*C. orientalis*). From a photograph sent by Miss Maurice Perkins, Schenectady, New York. (See p. 502.)

climber, with stems growing 9 feet to 12 feet long, with very variously divided leaves. The flowers are each 2 inches to 4 inches across, flat and fully expanded, the five or six sepals being of a creamy white and the tuft of stamens purple. It is a native of Japan, and was first made known by Thunberg, but is said to have been introduced by Dr. Fothergill about 1776. There is a double-flowered variety and others with violet or bluish-tinted flowers.

being an inch long with recurved lips. The tails of the fruits are downy when young rather than feathery. The species, which extends from Missouri and Kansas to the mountains of Colorado, was discovered by Fremont.

*C. FUSCA*.—A sub-shrubby or nearly herbaceous species, with decumbent rather than naturally climbing stems. When given support, however, it grows 6 feet or 8 feet high. The flowers are solitary on short stalks, covered with a short,

to dispel the idea. Among the numerous hybrid Clematises that have since been raised, the old *C. Jackmani* holds a high place. Its flowers are 5 inches to 6 inches across, and the sepals (four to six in number) are of a deep velvety violet-purple, making it one of the showiest of all hardy climbers that flower during summer and autumn.

*C. LANUGINOSA*.—Among the many plants upon whose introduction to cultivation the fame of Robert Fortune will rest, few have held a more important place in the horticulture of the latter half of the nineteenth century than this Clematis. It was discovered by Fortune in China, near Ningpo, in 1850, and again by Hancock in the same neighbourhood in 1877. As these are the only recorded instances of its being found wild by European collectors, it is probably a plant with a restricted distribution. It grows only some 5 feet or 6 feet high, and is one of the dwarfiest of the climbing species. The leaves are either simple or consist of three leaflets, which are heart-shaped and covered beneath with the greyish wool to which the specific name refers. The flowers are the largest of any of the true wild types, measuring 6 inches across (considerably more, of course, in the selected hybrids and varieties produced under cultivation), and the sepals (usually about six) are flat and overlapping and of a pale lavender colour. It is to this species more than to any other that the popularity and beauty of the garden varieties of Clematis are due. All the finest varieties in cultivation (including *Jackmani* and its section) contain more or less of the blood of *C. lanuginosa*, and the flowers range in colour from pure white to deep rich purple. Its natural flowering time is from July to October.

*C. LIGUSTICIFOLIA*.—Although nearly allied and very similar to *C. virginiana*, this species may at once be distinguished by the leaves consisting of five leaflets instead of three. Each leaflet is 1½ inches to 3 inches long, three-lobed or very coarsely toothed. The flowers (male and female ones of which are borne on separate plants) appear in axillary or terminal panicles and are white, three-quarters of an inch across, and on the female plants are followed by seed vessels that have pubescent tails 1 inch to 2 inches long. The variety *californica* is distinguished by its smaller, tomentose leaves. It is one of many examples that occur in the North American flora where a widely-spread species is found to be glabrous on the eastern side of the continent, but tomentose or even woolly on the drier and hotter western side. This species will climb to a height of 30 feet.

*C. MONTANA*.—This is one of the most beautiful of all the Clematises, and one which every garden should possess. It flowers during May, and when covered with its white flowers is one of the loveliest of all hardy climbers. It is a native of the Himalaya, and was first brought to Britain by Lady Amherst in 1831. It is quite hardy in the southern parts of the kingdom, and may frequently be seen covering walls to a height of 15 feet or 20 feet. The flower appears singly on a stalk 6 inches long, but several flowers are produced from one leaf axil; the sepals are pure white, and the whole flower, which bears a strong resemblance to a white *Anemone*, measures 1½ inches to 2 inches in diameter. The species has been called *C. anemone-flora*.

*C. OCHROLEUCA*.—A herbaceous species related to *C. Fremontii*, but confined to the eastern side of North America, whilst the other is as purely western. Its stems are 1 foot to 2 feet high, its leaves silky beneath, especially when young. The flower is solitary, terminal, the sepals yellow outside, cream-coloured within. From *C. Fremontii* this species is distinguished by the tails of the fruit being distinctly plumose. It was said by Asa Gray to be rare in a wild state.

*C. ORIENTALIS* (*C. graveolens*, *C. flava*).—A vigorous climber, which grows 12 feet or 15 feet high. The leaves are thin in texture and of a pale and rather glaucous green. It flowers abundantly during August and September, the four sepals being of a yellow colour, tinged with green, and the whole flower measuring about

1½ inches across. There is a sweet, but not very strong fragrance. The fruit heads are rendered very handsome by the tail (1 inch long and covered with silky hairs) that is attached to each seed vessel. The species has a wide distribution, and is found in various parts of Northern Asia; it extends from Persia through North India (where on the Himalayas it reaches altitudes of 12,000 feet) to Manchuria. According to Loudon it was introduced in 1731.

*C. PANICULATA*.—In Britain, this species, although growing freely, has not yet proved of any great value as a flowering plant; this is due probably to the little sunshine our climate affords as compared with the United States, for across the Atlantic it is described as perhaps the most beautiful of all the Clematises. It is a native of China and Japan, and was originally discovered and named by Thunberg, who lived in Japan 120 years ago. It is only lately, however, that it has appeared in cultivation, although, being mentioned by Loudon as a variety of *C. flammula*, it may possibly have been in cultivation at an earlier date, for it is quite a common plant in Japan. It is a very vigorous climber, growing to a height of 30 feet or more. The leaf consists of three or five leaflets, which vary from 1 inch to 4½ inches in length, and are dark green, smooth and glabrous. The flowers are borne in axillary and terminal panicles, and each 1 inch to 1½ inches across, with a charming Hawthorn-like fragrance, the four sepals being of a rather dull white. It is perfectly hardy at Kew and flowers during September, but with nothing like the profusion that makes it so beautiful a climber in America. By planting it against a sunny wall its best qualities would perhaps be brought out. If it flowered with half the freedom of the American specimens it would be worth its room.

*C. PATENS*.—Next to *C. lanuginosa*, this is perhaps the most important of the wild types of Clematis. Even less is known of it in a wild state, but it is certainly a native of Japan (having been found on the island of Nippon), and possibly of China also. It was introduced from the former country about sixty years ago by Siebold, who obtained it in the gardens near Yokohama, where it had, no doubt, been long in cultivation. It is a taller grower and has more slender stems than *C. lanuginosa*, the leaves consisting of three or five divisions that are smaller and narrower than those of its fellow species. The sepals are from six to eight in number, narrow in the form originally introduced, and of a delicate mauve colour, but the varieties subsequently obtained from it under cultivation have flowers much larger, the colours varying from white to deep violet and blue. Its value as one of the parent species of the garden Clematis is due not only to its beauty, but more especially to its flowering as early as May and June, and thus lengthening the season considerably.

*C. PITCHERI*.—Apparently this is a variable species, for there are at Kew three or four forms easily distinguishable, but unmistakably belonging to the one species. The leaves are usually made up of three pairs of leaflets, the petiole ending in a midrib. The flowers are terminal on the main shoots and pitcher-shaped, being broad and swollen at the base, narrow at the centre where the sepals press closely round the bunch of stamens, but have the tips expanded and recurved. The largest flowers are 1 inch long and three-quarters of an inch wide at the swollen base, of a purplish blue outside, and in the typical form the recurved tips of the sepals are yellowish. The fruits are borne in a closely packed bunch, each one narrowing at the top into a twisted tail, 1 inch long, which is not feathery, but covered with a short close tomentum. The fruits are of a reddish purple colour. The species is a native of Colorado and other Western United States, and is sometimes known as *C. coloradensis*. It is a pretty and distinct plant, and with us is about 9 feet high at present, but will probably grow taller. It has been confounded with *C. coccinea*, through the latter being figured in the *Revue*

*Horticole* as *C. Pitcheri*. *C. coccinea* is, of course, to be distinguished by its red, never purple, flowers.

*C. P. LASTOSTYLIS*.—In this variety the sepals have but little of the yellow colour seen in the type, the recurved portion of the sepals being of a deep purplish blue. The fruits, too, are larger and of a richer red colour.

*C. RECTA* (or *C. erecta*).—This is one of the best herbaceous species, its tufted stems growing about 3 feet high and producing from June to August numerous flowers on a large, branching, terminal corymb. They are white, sweetly scented, and each about 1 inch across. The species has been grown in Britain for over 300 years, and is a native of South and Eastern Europe. A handsome double-flowered variety (*flore-pleno*) was sent out by Mons. Lemoine a quarter of a century or more ago.

*C. ROBERTSIANA*.—One of the most recently discovered of the Clematises, this is not yet, so far as I know, in cultivation in this country. It was discovered by Dr. Aitchison in the Kurram Valley in June, 1879, and was subsequently described in the *Journal of the Linnean Society*, vol. xviii. There is every probability of its being hardy in this country, as it occurs at altitudes of 10,000 feet to 11,000 feet on the mountains of Afghanistan, &c. The flower occurs singly on an erect peduncle, but is itself nodding, the sepals being of a pale lemon-yellow, and the whole flower 3 inches to 5 inches in diameter. The large flowers and their unusual colour make its introduction very desirable; botanically also it is of interest as affording a connecting link between Clematis proper and the section *Atragene*. The flowers have none of the petals or antherless staminodes of the *Atragene* group, but otherwise, both in flower and foliage, the species bears a great resemblance to *C. (Atragene) alpina*.

*C. STANS*.—This is one of the group to which *C. heracleaefolia* (*C. tubulosa*) and its variety *Davidiana* belong, and under that species it is sometimes placed as a variety. It is convenient, however, to regard it as a species, especially as it has been figured as such in the *Botanical Magazine*, t. 6810. It is a herbaceous plant, growing with us 4 feet or 5 feet high, with dark green pubescent leaves, the separate divisions of which are roundish, toothed, and more or less three-lobed. The flowers are not borne in such dense heads as in *L'Abbé David's Clematis*, but often in a somewhat verticillate manner on a large terminal panicle, frequently also in clusters close in the leaf axils. Each flower is about three-quarters of an inch long, pale blue, and of the hyacinth-like form common to this group of Clematis. This is one of the least showy of Clematises, but is worth growing for its striking foliage and free growth. Its late flowering (September and October) is also a point in its favour. A native of Japan.

*C. VERTICILLARIS* (*Atragene americana*).—At an earlier date, when the Clematises and *Atragenes* were kept separate, this was known as *A. americana*, under which name most of the published figures have appeared. It is a climber with woody stems 8 feet to 10 feet high or more. In spring a pair of leaves is developed at each of the opposite buds on the stem, thus giving the appearance of a verticillate arrangement of four leaves—hence the specific name. The flowers appear on one-flowered peduncles, and are of a bluish purple and from 2 inches to 3 inches in diameter. The tails of the fruit are plumose. The species appears to have first been raised by Messrs. Loddiges in 1797. According to Dr. Asa Gray, it is a native of the rocky places in mountainous districts in Maine, Western New England, Virginia, Wisconsin, &c. It has in late years been much neglected and is now a rare plant in English gardens.

*C. VIORNA* (the Leather Flower).—Although this is one of the oldest of the American Clematises in cultivation (having been introduced in 1730), it is not a common plant, being, indeed, one of the least attractive in the genus. It is not very vigorous in habit, although growing 8 feet or 10 feet high. The flower is pitcher-shaped and solitary on a long stalk, and the four sepals are

each 1 inch long, very thick and leathery, with the tips usually recurved. The colour is a dull reddish purple, sometimes greenish outside and whitish or greenish yellow inside. It flowers from June to August. A native of the Eastern United States.

**C. VIRGINIANA.**—This is the common Virgin's Bower of the United States and Canada, and may be regarded as the New World representative of our *C. Vitalba*. Its leaves have three—*C. Vitalba* has usually five—ovate, pointed leaflets, which are somewhat heart-shaped at the base and have the margins coarsely toothed and lobed. The flowers are borne in flat panicles, the sepals being spreading, thin, and dull white. It is a common and widely spread plant in Eastern North America, extending from Canada to the Southern United States. It may often be found to bear either male or female flowers exclusively. It was introduced in 1767, and although hardy enough, is not in Britain so strong and woody a grower as our native Traveller's Joy.

**C. VITALBA** (Traveller's Joy, or Old Man's Beard).—There is no climber native to Britain that gives so near an approach to tropical luxuriance of vegetation as this. In ordinary positions it grows 20 feet to 30 feet high, and, according to London, as much as 50 feet to 100 feet high in sheltered or very favoured situations. It is one of the best plants for covering unsightly buildings or mounds, as well as for forming covered ways, arbours, &c. It grows so luxuriantly, that even in winter when destitute of foliage its naked stems are sufficient to prevent an appearance of bareness, and the greater light its deciduous habit admits is often an advantage during our long sunless winters. The panicles are axillary and bear numerous dull white flowers, three-quarters of an inch or so across, with a faint odour resembling that of Almonds. It is, perhaps, most beautiful when covered with its white fruits, the seeds having long feathery tails whose silvery grey colour gave rise to the name of Old Man's Beard. The French name of *Herbe aux Gueux* (Beggars' Plant) arose through that fraternity using the acrid juice of the plant to produce ulcerous wounds of the flesh as a means of arousing pity. The commonest name, that of Traveller's Joy, carries a pleasanter suggestion with it, and apparently originated with Gerard, who says this Clematis is "esteemed for pleasure by reason of the goodly shadow which it makes with its thick bushing and clyming, as also for the beauty of the flowers and the pleasant sent or savour of the same. . . . and because of its decking and adorning waies and hedges where people travel thereupon have I named it Traveller's Joy."

**C. VITICELLA.**—This is the type of one of the leading races of garden Clematis, and is also one of the original species from which the Jackmani group originated. It is a native of Europe, and is known to have been in cultivation in England as long ago as 1569. It is a climber, growing from 8 feet to 12 feet high. It blossoms during July, August, and September, its abundant flowers measuring  $1\frac{1}{2}$  inches to 2 inches in diameter, the four sepals blue, purple, or rosy purple, and the fruits have only short tails, which are devoid of the plumose covering so often seen in this genus. There are now numerous varieties of the species superior to it in size of flower, and offering also a variety of shades. The most distinct in habit is var. *nana*, which grows little more than 1 yard high, and is rather a bush than a climber. It was raised in Paris by Mons. Carrière. Both the single and double forms of this species were grown by Gerard, who says "they grow in my garden and flourish exceedingly." W. J. BEAN.

*Arborum, Ker.*

**Campanula persicifolia.**—This Campanula, especially its white form, is, as indicated by Mr. Arnott (p. 402), of the greatest value for indoor decoration. Even in the hottest weather the old single white lasts in water for many days without showing signs of deterioration, while its double

variety is even more enduring. The newer introduction, *C. p. alba grandiflora*, as far as I have seen, bears out your correspondent's description as having petals of a flimsier texture. Possibly a cross with *C. latifolia* or *C. grandis* may have been instrumental in impairing the substance of the petals, which in the old *C. persicifolia* are thick and almost of a parchment-like consistence; whereas those of *C. latifolia* and *C. grandis*, both most attractive garden plants, are of so unsubstantial a nature, that the flower-spikes are of little value for cutting. *C. persicifolia* and its varieties succeed well in heavy loam in this neighbourhood.—S. W. F., *Torquay*.

#### Mesembryanthemums in the garden.

The illustration and note on *Mesembryanthemum roseum* (p. 439) remind one of the brilliant effect afforded by these flowers where they really succeed. Light soil and a sunny situation seem best suited to their requirements. In my own garden, which lies low, and the soil of which is heavy and damp, *Mesembryanthemums* refuse to bloom, while at Kingswear, on the banks of the river Dart, where the soil is light, they flower most abundantly and are a glorious sight during the summer. There, many varieties are grown, from the brightest vermilion, ranging through crimson, rose, orange, and flesh-coloured to white. Most of them have proved hardy, but the large *Mesembryanthemum* alluded to by Mr. Woodall has been killed back on one or two occasions. At Alibotsbury Castle rock garden, overlooking the Chesil Beach, a large number of *Mesembryanthemums* are grown and succeed remarkably, and one of the features of the Isles of Scilly in the summer is formed by the gorgeous breadths of colour produced by these vividly tinted flowers.—S. W. F., *Torquay*.

**Herbaceous Lobelias.**—It was with great pleasure that I read "R.'s" note on the above (page 441), more than confirming, as it did, my theory expressed on pages 362 and 463, that the hardness of these plants depends rather upon some quality in the soil than upon the temperature to which they are exposed. From the reminiscence of a winter spent in Suffolk in my boyhood, I have no doubt that in the coldest part of that county during the severe winter of 1894-95 the Lobelias had almost as trying an ordeal as they would have experienced anywhere in England, yet, without the slightest protection, they came through it uninjured and flowered profusely the same season. This appears to me to be proof positive that severe and long-continued cold will not kill them, while in my case excessive damp has no injurious effect upon their constitution. It seems, therefore, that growers who fail to winter these plants in the open will, for the future, have to ascribe their ill-success to some other cause than excess of cold or moisture. Whilst I had only cultivated these Lobelias in South Devon, the theory that I had formed was unavoidably wanting in authority, but now that it is borne out from the coldest part of Suffolk I have little doubt but that it is correct.—S. W. F., *Torquay*.

**Tigridias.**—When planted in light soil in sheltered nooks of the south-western counties these Mexican bulbs may be allowed to remain in the ground during the winter. Where this method of culture is followed it is always safer to mulch the bed with cocoa-nut fibre or ashes. In heavy, damp soils the bulbs should be lifted annually in November, hung up in bunches by their foliage, like Gladioli, and when dry stored in sand. "D.'s" experience (p. 400) as to the deterioration of stored bulbs is not an uncommon one, but the plan advocated is the best that can be suggested. If purchasing for planting, it is well to delay this till the end of March, and to inform the firm from which the supply is being procured that large, plump bulbs must be sent or none at all. The commencement of April is the best time for planting. Light soil is the best suited for Tigridia culture, and, until a few months ago, I should have added, dry. Last August, however, I saw many wonderful clumps of *Tigridia grandiflora* over 2 feet in height with blossoms exceeding 7 inches in diameter, growing close to the margin

of a sheet of ornamental water. The position evidently suited them, for I never saw more vigorous specimens. In my former garden, twelve miles from where I now write, Tigridias lived in the light soil winter after winter without the slightest protection, but I was never able to preserve the herbaceous Lobelias. In my present garden, where the soil is heavy and damp, the Lobelias, unprotected in the open ground, have withstood 20' of frost with impunity, but Tigridias left in the ground never appear again. Such losses and their compensating gains indicate the advisability of each one being the compiler of his own "index expurgatorius," a subject which was the theme of a lengthy correspondence during the past spring.—S. W. F., *Torquay*.

#### FLOWER GARDEN NOTES.

**MULCHING.**—I have often called attention to the advisability of a winter mulch for all herbaceous borders, and although in some soils and situations the practice would not seem to be necessary, there is no mistake about the value of it when dealing with a soil that is naturally light and dry. I refer to the subject at the present time because conditions point to the necessity of getting it on as soon as possible. In any lifting operations that have taken place this autumn, whether of ordinary trees and shrubs, fruit trees or herbaceous plants, the dry nature of the soil is very apparent, and unless we get some heavy winter rains to compensate for the long spell of dry weather, flower borders are hardly likely to be seen at their best in 1898, especially if the spring and early summer prove hot and dry. To prevent, therefore, the drying out of such borders as far as possible, a heap of fairly good manure has already been well broken up, and this will go on the borders with the first spell of frost, or at any time when the wheeling can be carried out under favourable conditions. For all small autumn-planted things, peat moss manure will be substituted for the coarser compost, whilst for those things where the mulch takes the form of a slight winter protection rather than a stimulant, or as an aid to retain moisture, I use as far as procurable the foliage of *Taxodium distichum*. It is a capital preservative and a clinging material, that is, if a coating of say 3 inches is put on. It lies close together without blowing about.

**SOME DIFFICULTIES AND DISAPPOINTMENTS.**—Whilst the note on page 441 is interesting as a testimony to the hardness of *Lobelia cardinalis*, it increases the difficulty as to the conditions essential for the plants to winter safely outside, because the alternative suggested in the matter of soil is not responsible for the necessity of housing. Instead of a rather heavy moist soil my plants are in a dry sandy loam, and, like "R.," I have never experienced any loss or indeed the slightest sign of the plants going to the bad. They always get their winter mulching, but for several seasons this has not been put on with any idea of protection, but, as stated earlier in these notes, to retain moisture and as a slight stimulant. That the plants do thoroughly well is shown by the fact that when there is reason to lift and divide for the purpose of increasing the stock either in autumn or spring, a perfectly dense mass of healthy roots is always found. Would the cause of winter failures arise from some agent in the soil that is responsible for root-destruction and a consequent weakening of the plants? Again, the difference in Carnations coming safely through the winter is even more marked, because correspondence has shown that, given nearly similar soil and climatic conditions both as to temperatures and the prevalence of fog, the loss in one case is practically *nil*, and in another it would be so heavy as to necessitate potting up layers and keeping them under cover. In a bulb catalogue recently to hand I read in connection with Daffodils that "they will do in any soil." This is not so, at least if, as one infers from the context, the writer is thinking about naturalisation without any idea of altering the soil. There are soils in which Daffodils may exist, but doing well is quite another

matter; they degenerate alike in the size and quality of the flowers and the strength of the grass and any sign of reproduction is practically absent. A very little matter will often make all the difference. An instance is to hand in the pleasure grounds here where the soil is apparently of the same nature all throughout, a peaty sand running out into pure sand at depths varying from 6 inches to 12 inches below the surface. In some places Daffodils are a failure, in others fairly successful—that is, as good as one can expect. The difference is to be found, not in the varying depths of soil, but in the nature of the sand. Where this is light and dry and runs easily through the fingers naturalisation is a failure, but where it is on the moist side at a depth of 6 inches, and there is just a suspicion of clinging ever so lightly to the hand when compressed, the results are fairly good. Again, given a soil that is naturally of the above description, and even after a lot of making is light and dry, considerable discrimination must be used in dealing with plants that are recommended to be tried on warm dry borders. There are certain things, like Achilleas, Iberis, the various forms of Thymus, alpine Phloxes and others, that may be planted in such positions and in a soil of this nature with the certainty that they will do well, but there are others, (*Zauschneria* and *Dracocephalum* are two species that are suggested) that are not at home, but are seen to much better advantage where there is a greater depth of better soil. Writing of some disappointments reminds me to thank Mr. Arnott for his note on *Bocconia carnea*, and to suggest the great advantage if all who have an opportunity of growing new things would give the benefit of their experience. It should lead to observations that would give us an insight as to the requirements of things not as yet common on hardy plant borders alike in the matter of soil and situation, and also how best to plant them so as to harmonise well with their surroundings.

Claremont.

E. BURRELL.

### ANTHOLYZA PANICULATA.

THERE are many South African plants of striking beauty in the garden, and it is a matter for regret that the hardiness of a considerable number must be looked upon with suspicion. We have only to point to the *Gladioli*, the *Montbretias* and a few other well-known bulbous plants to show what value is possessed by these flowers. The hardiness of very few is admitted; that of more is doubtful; and a greater number can only be recognised as plants which cannot be trusted to endure the hardships of our winters and must be lifted in autumn for replanting in spring. There is an increasing desire to find among these members of the *Iris* and *Amaryllis* families some of recognised hardiness which would give us a welcome change from the crowd of composite flowers we have then in bloom. The *Montbretias* are invaluable, but there is a likelihood of there being too much sameness among them and they give but little variety of form. The *Antholyzas*, and especially *A. paniculata*, may thus well be brought more prominently before the public as sharing the beauty of the *Montbretia*, with a distinct appearance of their own which will be their passport into many gardens.

Some of the catalogues—especially those from Holland, where the winters are more severe than ours—have helped to arouse doubt in the minds of some regarding the hardiness of this *Antholyza*. It is often marked as requiring protection in winter. This is an obstacle to many growers of hardy flowers, who know from experience that this winter protection is often forgotten until it is too late. Frost has entered and stolen the steed before the door was locked. Yet I venture to think from personal observation that the panicked *Antholyza* is in many gardens as hardy as a number of

flowers about which no doubt exists in the minds of their owners. As "The English Flower Garden" says of the genus, "they are hardy in a warm, sheltered border well drained, in rich sandy loam," and in even less carefully selected places will often give much satisfaction by the way in which they thrive. As far north as Stirlingshire I have seen *A. paniculata* not only thriving, but increasing into great clumps with noble leaves and a profusion of spikes of flower, and this, too, in borders neither warm nor sheltered. The *Antholyza* is a fine plant even when out of bloom unless when at rest for the winter. The great, ribbed and plaited *Iris*-like leaves are very handsome. As a fine-foliaged plant alone it may well claim a place from its sub-tropical appearance, and when its tall flower-spikes come into full beauty in autumn it looks distinct from anything else in bloom at the time.

We are told that the name *Antholyza* is derived from the words *anthos*, a flower, and *lyssa*, rage, in reference to the opening of the flowers which resemble the mouth of an enraged animal. One cannot quarrel with the fancy of the namer of the plant. A look at the curiously shaped red flowers reminds us of Ruskin's remarks on the form of flowers in "The Queen of the Air," where, in Lecture ii., 87, he says: "Then the spirit of these *Draconidae* seems to pass more or less into other flowers, whose forms are properly pure vases . . . it touches . . . the *Iris*, and it points into a *Gladiolus*." The *Antholyza* looks as if it had received a double share of this spirit, so dragon or at least beast-like are its flowers. The dense spikes are many-flowered, and the bright red or red-yellow flowers are well elevated above the leaves.

This *Antholyza* comes from Natal, where it was first collected by Gerard, and is described by Klatt in "Linnaea," xxxv., 379. The corm is large and globose; the leaves are described as being each from 1½ feet to 2 feet long, but this is considerably below the height in many gardens. The stem, which is branched, is from 3 feet to 4 feet in length.

With regard to cultivation, it will be safe to adopt, as a general rule, the spirit of the paragraph quoted from "The English Flower Garden," but it also grows well in some gardens in rather heavy soil. I have also seen it grown with fine effect and in capital condition in the rock garden. It should be planted in late autumn about 6 inches deep. In course of time it may become crowded and require lifting. Should this be necessary, the smaller corms can be separated and the larger replanted together.

In his "Handbook of the Irideae" Mr. Baker describes nine species of *Antholyza* as being Cape species, as distinguished from those from Tropical Africa. It yet remains to be seen if there are many others as suitable for the outdoor garden as permanent plants. The others named by Mr. Baker are *spicata*, *fucata*, *æthiopica*, *intermedia*, *caffra*, *quadrangularis*, *Cunonia*, and *saccata*. Of these I have a few under observation here, but the only one named in the "Hand-list of Herbaceous Plants" as grown at Kew is that under notice. It at all events can be confidently recommended to the admirer of uncommon garden flowers.

*Cursethorn, Dumfries, N.B.* S. ARNOTT.

**Lily of the Valley fruiting.**—The correspondence which has appeared on this subject leads me to ask if any of THE GARDEN readers have observed any difference in this respect between the Dutch and the Berlin types of the Lily of the Valley. I have had the former in this garden for more than thirteen years and it has never fruited,

nor have I seen it in fruit elsewhere. A clump of Berlin crowns planted out a few years ago has, however, fruited annually, although there was apparently nothing in soil or position to account for the difference. This may be merely accidental, but others may be able to say something more definite on the point.—S. ARNOTT, *Cursethorn, Dumfries, N.B.*

**Seedling Carnations.**—There is no doubt but that it pays well to sow seeds of choice strains under glass, sowing in April. Last year I sowed in broad pans and stood them in a gentle warmth. The result was far better germination than would have resulted if seed had been sown outdoors. The seedlings were hardened off in a cold frame, and I had them lifted and shaken out of the soil and carried some distance to plant out into a long border early in June. One watering when planted sufficed to keep them alive. Every plant grew, and but the other day, having to replant the border, which is very open and exposed, I lifted all the plants, now very strong and well branched, with good balls of soil attached to the roots, had the border redug, and then the Carnations were replanted, letting them well down so as to bury the stems. I have every hope that, the air being dry and active and the soil porous, these plants will escape harm from wet or cold, and will bloom finely during the summer. To have obtained so many plants from seed is indeed satisfactory. If but a score out of the number are really good, and each one enables half a dozen layers to be made, how cheaply is a good class stock of Carnations secured. Some seed sown outdoors at the end of April came very thinly, due, perhaps, to the dryness which prevailed. Whilst the first stock gave two-thirds germination, the latter gave but one-third.—A. D.

## GARDEN FLORA.

### PLATE 1150.

#### HIBISCUS SYRIACUS.

(WITH A COLOURED PLATE OF H. S. VAR. TOTUS ALBUS, ETC. \*)

As has been the case with many another long-cultivated plant, the true native country of this *Hibiscus* was for many years merely guessed at. Being mentioned by Gerard as a garden shrub of his time, it has consequently been in cultivation in Britain for 300 years at least, but as lately as 1852 Lindley and Paxton, in the *Magazine of Botany*, stated that its native country was unknown to them. The specific name would imply it to be indigenous to Syria, and Loudon says it is native of that country and Carniola, but although common as a cultivated shrub in that and other parts of the East, there is no evidence of its really being a native of Syria. We now know it to be indigenous to China, and to be spread widely over that country both as a wild and as a cultivated shrub. Dr. Henry has collected it wild in localities as far apart as the central provinces and the island of Formosa. It may also be a native of India, but present evidence points to China as the centre from which it originally spread. Both in China and Japan it has long been used as a hedge plant, and in Japan its fibrous bark is said to make good twine and ropes. A common name for this shrub in nurseries and gardens is *Althea frutex*. This name, which has long been in use, was given to it, says Loudon, because of the resemblance its flowers bear to those of *Althea rosea*, the Hollyhock. Philip Miller in his dictionary calls it the Syrian *Ketmie*.

In the south of England it is perfectly hardy,

\* Drawn for THE GARDEN at Gravetye Manor, Sussex, by H. G. Moon. Lithographed and printed by J. L. Gollart.

much hardier than it was evidently thought to be in the earlier days. Parkinson, 250 years ago, put it down as somewhat tender, and advised that it should "not be suffered to remain uncovered in winter." But it is only one of many instances of a similar nature—the common *Aucuba* began its career in Britain as a stove plant. It is a deciduous bushy shrub with erect branches, and in this country is rarely more than 6 feet to 8 feet high, although Fortune, during his first visit to China, saw plants in the gardens there as much as 12 feet high. On the young wood the bark is green, but on the old wood it becomes light brown or greyish. The leaves vary much in size according to the vigour of the plants and mode of culture, but they are usually 2 inches to 4 inches long. The flowers in the single-flowered varieties are of

albus they are wholly white, as the name infers, and distinct on that account. There is now quite a host of named varieties offered by nurserymen; among them, as being of approved merit (although by no means the only ones), the following may be mentioned: *Azureus plenus*, *albus plenus*, *coelestis*, *Duchesse de Brabant*, *ardens*, *anemonellorus*, *violaceus plenus*, *amplissimus*, *Leopoldi*, *carneus plenus*, *amaranthinus*, *Pompon rouge*.

*Hibiscus syriacus* and its varieties flower in August and September. Where it succeeds well it is undoubtedly one of the most beautiful of autumn-flowering hardy shrubs. For it to be seen at its best a fine sunny September is necessary. It sometimes fails to flower satisfactorily through having been planted in positions where the wood does not thoroughly

This *Hibiscus* is the only hardy shrubby species in that extensive genus (150 species), and in the Mallow family is the one of chief importance among hardy shrubs. Several annual species and herbaceous perennials have at various times been in cultivation, but scarcely one of them has proved of sufficient value to retain its place.

W. J. BEAN.

## THE WEEK'S WORK.

### KITCHEN GARDEN.

At last we have had a touch of frost, which appears to have been general, not much, certainly, but sufficient to leave its mark on all tender crops and put those on the alert who have commenced forcing choice vegetables in pits and frames. It will have necessitated covering the lights at sunset with a double thickness of mats or a thick layer of straw or Bracken. When the forcing of different things has to be done by the aid of portable frames and fermenting material, it is no small gain to select a snug corner of the garden sheltered from searching winds, but exposed to as much sun as possible. The old-fashioned forcing ground, surrounded with a high hedge or fence, has been supplanted by the cheap forcing houses, efficiently heated with hot water. For many reasons the old-fashioned manure frames are not to be despised, as sufficient warmth was created and growth was less likely to feel the sudden changes of weather or the effects of searching wind. The forcing house of course is indispensable in small places where there is not a quantity of stable litter and leaves to be obtained. Such material, however, where at command can hardly be put to a better purpose, and its use in this way prepares it for the dressing of vacant ground later on. It is not only necessary to select a warm corner in which to make up the beds, but one, if possible, out of sight, where the leaves and litter can be carted to. The larger the quantity collected the longer will it last in a warm condition, and frames planted with *Asparagus* roots, *Radishes*, *Carrots* and the like would still be in a suitable condition months hence, when these crops are cleared out to receive *Potatoes*, *French Beans*, *dwarf Peas* and the earliest batch of *Turnips*. Another advantage of selecting such a position is the fact that the longest litter can be utilised at night as a covering, and may be used to any thickness without the annoyance of having it blown about and making the rest of the garden untidy; moreover, it proves cheaper than buying mats where a number of frames has to be covered. The mats too often entail a lot of trouble in keeping them secure during rough nights. A bed of tan forms a capital hotbed, and proves a good substitute for manure and leaves, and is sometimes more easily obtained than the latter. Owing, however, to the shortness of the material it is only fit for filling up brick pits. If it is thoroughly moist and well trodden together it will give off a steady warmth for months after, and prove most suitable for early *Rhubarb*, *Seakale*, or *Asparagus*.

**COLD FRAMES.**—A good range of these is very necessary in which to protect winter salad, *Parsley*, *Cauliflowers*, and other things. Such plants, however, are naturally hardy and resent anything approaching eodding, the lights really only being used to ward off inclement weather. When badly ventilated, with no warmth beneath to expel damp, such things as *Lettuce* and *Endive* are liable to rot off at the collar; therefore the lights should be drawn off for a few hours daily whenever the weather is mild and dry. With *Parsley* the lights should not be used at all unless very severe frost or snow is expected, or it will soon take on a sickly colour and die off. Of course, outside gatherings of this should be made as long as possible, saving that which is in the frames until spring, as it often proves scarcer after the trying winds of March, and before it is possible to have spring-sown plants in

Flower of *Hibiscus syriacus*.

the character common to the Mallow family, the five free petals forming a wide trumpet-mouthed corolla, usually  $2\frac{1}{2}$  inches to 3 inches (sometimes 4 inches) across. Many of the cultivated varieties have double flowers, and there are both single and double forms whose flowers are white, red, blue-purple, variegated or striped with white and red, &c. Besides these variations in the flower there are others in the leaf, and forms are in cultivation whose foliage is variegated with white or yellow. One of the varieties here figured, *totus albus*, is perhaps the best with single white flowers. It was raised on the Continent and first appeared in English nurseries about a quarter of a century ago. Nearly all the varieties of this species of *Hibiscus* have the bases of the petals coloured with some shade of red, but in the variety *totus*

ripen. Shady and ill-drained situations must be avoided, for although hardy enough, it is a sun and warmth-loving shrub. In the northern and colder parts of Britain, where autumn sets in earlier, it ought to be planted against a wall for the protection and better development of the flowers and for the more thorough ripening of the wood. Like most of the Mallow family, this is a vigorous and free-rooting plant, and it should be given a deep, open, and fairly rich soil. Propagation is effected by layering or by putting in cuttings of nearly ripened wood in autumn under a bell-glass in a cold frame. Rarer sorts, if necessary, can be grafted on the commoner ones; the stock being practically identical with the scion, worked plants are not so objectionable as are most trees and shrubs propagated in that manner.

any quantity or size, than during the most severe frost. There is always a demand for Parsley, and it is very annoying to the gardener when not able to produce it; therefore, if not already done, a frame of some kind should be placed over a nice sturdy batch, it being better to cover young plants which are not too crowded than what may at present look a finer bed. When too thick, the foliage soon turns yellow or damps off, and there is a dearth in spring. It is better to place a frame over established plants than to lift and replant them. If replanting has to be resorted to, a fork or spade should be driven well into the soil round each plant and care used in lifting and conveying them to the frame, as it is somewhat difficult to lift the roots with a good quantity of soil attached, without which the plants receive a check, the foliage flags, and months often elapse before new leaves form. Autumn-sown seed of both Peas and Broad Beans will now be pushing through the soil, and some means must be employed to protect the seedlings from birds. It is generally in the early morning that the most mischief is done, especially by pheasants and pigeons, which often play sad havoc at this season, as the young growth is very tempting. Strips of rabbit netting placed over the rows are a good preventive. Should wet weather set in, dry fine soil from the potting shed should be used to mould the young plants up. This will protect the tender growth from cutting winds as well as severe frosts. A few dustings of fine dry ashes occasionally will also check frost striking through the surface soil as well as ward off slugs. A sprinkling of dry wood ashes over the rows when frost threatens prevents its action being so severely felt, while a few bushy twigs placed on either side will also tend to keep the plants safe until the worst of the winter is past. Radishes and sa'ad growing at the foot of a south wall can be easily protected by leaning broad boards against the wall, or branches of Fir or Yew will shield them somewhat during severe weather.

The frost has been sufficiently severe in most gardens to cut down the foliage of Globe Artichokes. Before mulching the crowns with litter or Bracken, a few shovelfuls of ashes should be applied if the ground is of a cold, wet nature. This may prevent them decaying, which is not unusual in some districts, as stagnant moisture often proves more disastrous to the centres of the plants than several degrees of dry frost.

R. PARKER.

#### HARDY FRUIT GARDEN.

PEACHES.—There are various opinions as to the time that these should be pruned, trained, and nailed. Some advocate its being done in mid-winter; others defer it until the last moment, or just as the buds are about to burst, while some loosen the trees from the wall at this time of the year, and tie the branches temporarily to stakes let into the alleys. This is done with the idea of retarding the trees, and they are not fastened back to the wall again until the forward condition of the buds will admit of no further delay. All three methods are good, and the best course to pursue is to adopt that which has been proved by experience to answer best in each individual case. I adopt the first mentioned, and as a rule the training and nailing of the trees are finished by the end of the year. I have adopted this policy for several years past, and have never regretted doing so, as I invariably secure good results in the shape of heavy crops of fruit. When the trees are to be left until late winter or early spring, as in the second case, there is no reason why the pruning of the trees should not be done now. This would simplify matters greatly, as there would then be nothing but the training and nailing to do. In the third case, what pruning is required should be done before the trees are loosened from the wall, as it can then be easily seen what shoots can be cut away and which left. Pruning of Peaches should not be required to the same extent as needed for other fruit trees, for if well managed it simply means thinning out

the wood where too much was left in the trees at the autumn pruning. Preference should always be given in this case to the best ripened and well-budded shoots, cutting out the more immature and those sparsely budded. Apply the same rule to neglected trees, or where far too much wood has been retained, and when cutting back a shoot see that the cut is made at a wood-bud. When pruning is completed, whatever cleansing the trees may require is best done before they are trained out afresh, or before they are loosened from the wall. Brown scale if present will require a strong solution of some insecticide to kill it, but ways and means for coping with these foes have been recently referred to. If nothing but fly has infested the trees during the past season, they may be washed several times with soapsuds by those who feel nervous about using the more efficacious remedies. When the trees are to be released from the walls for a considerable time, the required number of stakes of a sufficient length should first be let into the alleys. They should be nearly as high as the wall, and stand some 2 feet or 3 feet away from it. When all is in readiness the branches should be loosened and tied to them, not in bundles, but in loosely extended order. When tied in bundles the object in view is partly defeated, as the buds on the wood situated inside are apt to start growing prematurely as a result of being so confined and protected.

APPLES AND PEARS.—When these are grown in the form of bushes or pyramids they may be pruned as soon as convenient after the wall trees are finished. The amount of pruning required depends in a great measure on the care and attention the trees receive during the summer and autumn. Where summer pruning is systematically carried out, the present pruning consists in merely shortening back the wood which was then stopped to three or four buds. This must be done, otherwise the spurs would grow to an inordinate length. There are, however, exceptions to this rule, and that is in the case of those varieties which are prone to produce fruit-buds at the extremities of their shoots. Notable examples are Potts' Seedling and Beauty of Bath among Apples, and Marie Louise and Souvenir du Congrès among Pears. There are also many others, but those quoted will suffice to put young beginners on their guard. These shoots vary in length from 6 inches to a foot, and should be left for one season. After they have fruited, these shoots may be spurred back the following autumn. Another matter which should be looked after is crowding of the branches. A judicious thinning is always beneficial when this has been allowed to take place. In very bad cases thinning is best spread over two or three seasons, as wholesale amputation of branches is a mistake. The wounds, too, should always be painted over afterwards, this preventing decay from setting in. A well-trained and properly developed tree should have its branches so disposed that sunlight and air can readily reach all parts, and each branch should be like a cordon trained tree, well clothed with spurs from base to tip. This is where a tree trained in bush form is infinitely superior in my opinion to one trained as a pyramid, as in the latter case the tree must have a leader, while in the former it can be dispensed with and the centre of the tree kept open. Young trees, therefore, must have attention in the way of training until their branches become set. Pyramids will require a stake to train the leader to, and this should be long enough to serve for two or three seasons. Bushes, on the other hand, do not always require a centre stake, and then only to draw a branch or branches which may perhaps be inclined to grow down too much into a more upright position. The outer branches in both cases may be trained by simply driving in half a dozen or as many more stakes as may be required all round the tree, securing the branches to them by lengths of twine. A good-sized loop should be formed where the twine encircles the branch, and put a shred or a piece of old indiarubber hose between it and the bark.

The branch can then be pulled down to the desired position, and fasten the lower end of the twine to the stake. Leave the leaders one-third, two-thirds, or nearly full length, according to the ripeness of the wood and the necessity of the case.

PLUMS AND CHERRIES.—The pruning of these should be done at the same time as the preceding. The former will require the same amount of attention if they have been summer-pruned; if not, spur back all shoots emanating from spurs to four buds. The trees have this season set a profusion of fruit-buds, and in the process of shortening back spur growths great numbers of them have had to be sacrificed, but enough and to spare remain. The branches of Plum trees may be left a trifle closer than for Pears for instance, but avoid anything approaching crowding. Leave a young shoot here and there in old-established trees to form future main branches, which will in time allow for the removal of the more decrepit ones. As regards the training and pruning of young trees, proceed as advised for Apples and Pears. Morello and Kentish Cherries may be thinned out if necessary, but no spurring-in must be done, as they both bear fruit on the wood made during the previous year. The less the knife is used the better, as all necessary thinning and stopping can easily be performed during the summer months. The same remark is also applicable to the dessert kinds, as this in a great measure averts disappointment from losses through gumming. A. W.

## TREES AND SHRUBS.

### TREES AND SHRUBS CERTIFICATED DURING 1897.

DURING the year 1897 a considerable number of trees and shrubs have been submitted to the floral committee of the Royal Horticultural Society, and of them nineteen have received either first-class certificates or awards of merit, being an increase of two over last year, more than double that of 1895, when only nine subjects were thus honoured, while in 1894 the number was no less than thirty. This list of nineteen does not include Roses, Tree Peonies, or Clematises, as they scarcely come under the heading of ordinary trees and shrubs. No less than three conifers with yellow-tinted foliage occur in the list, and to each of them a first-class certificate was awarded. Many of the plants are well-tried subjects, and can be obtained from most nurserymen. Hibiscus syriacus and its numerous varieties have been long known as a very desirable class of flowering shrubs, especially valuable from the fact that they bloom towards the end of July and in August when most outdoor shrubs are over. Not one, however, has been recognised by the Royal Horticultural Society till this year, when on July 27 two varieties, celestis and Painted Lady, were given awards of merit.

The following is the list of trees and shrubs that received awards during 1897:—

COTONEASTER HORIZONTALIS.—This is one of the most recently introduced of the Cotoneasters, having been first sent by the Abbé Armand David in 1885. It is remarkable for the peculiar arrangement of the branches, which are flat, frond-like, and disposed almost horizontally. The leaves are small and very dark green, while, in common with the minor twigs, they are arranged in a regular manner. It is especially effective during the autumn, as the berries, which are about the size of those of the other small Cotoneasters, are far brighter than any of them, being of a rich vermilion tint, which is very conspicuous against the deep green of the foliage. As autumn advances many of the leaves change to various shades of scarlet, and remain in this stage for

some time before they drop. It is more thoroughly deciduous than the other low-growing Cotoneasters, but if untouched by birds or mice the berries are retained for some time after the leaves drop. From the peculiarly stiff, flat style of growth it must be planted on a sloping bank or on large bold arrangements of rockwork, while, though seldom seen treated as a wall plant, it is very effective grown in this way, and berries as a rule more freely than in the open. This Cotoneaster was awarded a first-class certificate on March 9.

**CORYLOPSIS SPICATA.**—This pretty shrub, which was introduced from Japan in 1861, is a near ally of the Witch Hazels, and, like them, flowers during the early months of the year. It forms a freely-branched bush, clothed with pale green leaves, a good deal like those of some form of Hazel. The flowers, which are borne in drooping racemes, appear before the foliage. The individual blooms are small and of a pale yellow colour, but they are almost hidden by the large greenish yellow bracts. When the flowers are first expanded the bright red anthers are very conspicuous. *Corylopsis spicata* flowers freely when little more than a yard high, but Mr. H. J. Veitch during his travels in Japan mentions a bush of it in the neighbourhood of Tokio which was about 10 feet in height. An award of merit was given this *Corylopsis* on March 9.

**MORUS ALBA PENDULA.**—This is a weeping variety of the white Mulberry, and in order to show its pendulous characters to the best advantage it should be grafted on to upright stems of the ordinary form. It is fairly well known and can be obtained from most of our tree and shrub nurserymen. There are many other forms of the white Mulberry, it being more variable than the common kind. The weeping form here noted received an award of merit on April 27.

**RHODODENDRON PINK PEARL.**—This *Rhododendron*, upon which was bestowed an award of merit on May 11, is apparently one of the hybrids of *R. Fortunei*, of which we have now a considerable number in our gardens. It is a particularly fine form, the flowers, which are very large, being of a soft rosy pink, with darker spots at the base of the upper segment.

**SYRINGA SENATEUR VOLLAND.**—This is one of the many double-flowered Lilacs raised by M. Lemoine, of Nancy, several of which have been before this acknowledged by the Royal Horticultural Society. As these double forms do not differ greatly from each other, we have, I think, quite enough varieties in our gardens. The flowers of *Senateur Volland* are very double, purple in the bud state, and pale lilac when expanded. An award of merit was given it on May 11.

**RHODODENDRON MME. MOSER.**—This, which was sent by M. Moser, of Versailles, is one of the hardy *Rhododendrons* of the ponticum group. The flowers of this are of a rich deep crimson and semi-double, with crisped petals. Varieties of this section with double blossoms are but few, and *Mme. Moser* is a particularly good type, the colour being rich and the plant dwarf and free flowering—that is, judging by the specimen which was exhibited at the Temple show.

**AZALEA FREYA.**—Several varieties of hardy Azaleas with double blossoms have made their appearance of late years, and this is one of the same section. The trusses of this are large and bold, while the flowers are of a distinct and pretty shade of salmon-pink.

**AZALEA RIBERA.**—Another of the same class, but the flowers of this are bluish-white in the interior and tinged with pink outside. These two Azaleas and the *Rhododendron* immediately preceding received awards of merit at the Temple show on May 26.

**CEDRUS ATLANTICA AUREA.**—This golden-leaved form of the Atlas Cedar is of a good decided tint, and widely removed from either the typical kind or its glaucous-leaved variety. On June 15 a first-class certificate was awarded this Cedar, it being the first of three coloured-leaved conifers that received the same acknowledgment during the year.

**ESCALLONIA LANGLEYENSIS.**—A very pretty hybrid form of *Escallonia*, obtained from E. Philippiana, crossed with the pollen of *E. macrantha sanguinea*. The small dark green leaves and the free-branched habit of the plant partake more of the character of *E. Philippiana*. The open bell-shaped flowers, pink, with a deeper centre, are borne in small trusses on almost every little twig. An award of merit was given this on June 15.

**THUJA GIGANTEA AUREA.**—There are several forms of *Thuja gigantea* (Lobbi of gardens), and this newest one bids fair to become very popular with those that are fond of golden-leaved conifers. In this variety the young growth is of a rich golden hue, which changes in the second season to the normal tint. A well-coloured example was shown on June 29, when a first-class certificate was awarded it.

**PLATANUS OCCIDENTALIS ARGENTEO-VARIEGATA.**—Under this name was shown a Plane the young leaves of which were almost of a uniform creamy white, but as they became older were marked in a very irregular manner with white and different shades of green. As exhibited on July 13 the plant was very pretty and received a first-class certificate, but variegated-leaved trees in general are seldom satisfactory. This variety of the Plane appears to differ little, if at all, from one noted elsewhere under the name of *P. o. Suttneri*.

**VERONICA LA SEDUISANTE.**—Though hardy only in the more favoured districts of this country, the *Veronicas* are very ornamental, free-flowering shrubs, of which we have seen several new varieties within the last few years. *La Seduisante* is certainly one of the best of its class, the long spikes of blossoms being borne in great profusion. The colour of the flower is a beautiful rich purple, while the leaves are shaded with bronze.

**HIBISCUS SYRIACUS CELESTIS.**—This hardy *Hibiscus*, which has now been grown for some years, is, I believe, of French origin. It is certainly very distinct and pretty, the large single blossoms being of a kind of dark lavender-blue with a purplish-crimson centre.

**HIBISCUS SYRIACUS PAINTED LADY.**—The flowers of this are bluish-white with a maroon blotch at the base of each petal, forming a most decided contrast. An additional value is attached to these varieties of *Hibiscus*, as they flower towards the end of July and in August, when outdoor shrubs in bloom are not numerous.

**RETINOSPORA OBTUSA SULPHUREA.**—The whole of the shoots of this variety are tipped with soft sulphur-yellow, while the mature foliage is pale green. It is a pretty and distinct variety of this variable Japanese conifer, and received a first-class certificate on September 21.

**VERONICA SILVER STAR.**—This, the second *Veronica* to win distinction this season, is a pretty little variegated shrub. In the young leaves the variegation is of a creamy tint, but it ultimately becomes silvery white. The plant is of a dwarf, compact habit and will doubtless be useful for decoration. It received an award of merit on October 12.

**NANDINA DOMESTICA.**—In Japan this is largely grown for its ornamental qualities, but it is generally believed to have been introduced from China. It is nearly related to the *Barberries*, and forms a somewhat upright, sparsely branched bush. Towards autumn the leaves become flushed with red, and it was in this stage that an award of merit was given to it on October 12. The small whitish flowers, which are borne in somewhat elongated panicles, are in themselves not at all showy, but they are succeeded by berries about the size of Peas, which are of a bright shining red when ripe. In this stage the plant is particularly ornamental, but as a rule it does not berry freely here. It does, however, in Japan, where the cut sprays are largely used for indoor decoration. This *Nandina* is hardy only in especially favoured districts, and is consequently but seldom met with. T.

**Cotoneaster rotundifolia.**—This shrub as seen at Kew merits a passing note owing to its

particularly bright red berries, which in tint surpass those of any of its immediate relatives. Whether less appreciated by the birds than others I do not know, but the berries of *C. rotundifolia* are untouched, while those of all the others are nearly cleared off. A fine bold clump of this *Cotoneaster* is just now a very striking feature.—T.

**Erica mediterranea hybrida.**—In the collection of *Ericas* at Kew this *Heath* stands out as particularly valuable from the fact that it is now in full flower, and, judging by its previous behaviour, it will continue for some weeks yet. It forms a dense rounded tuft about a foot high, while the flowers, which are borne in erect spikes, are pink, with the dark-coloured anthers just protruding through the mouth of the corolla. Whatever be the origin of this *Heath*, it is certainly widely removed from the typical *E. mediterranea*. It deserves a place in any collection owing to its winter-flowering qualities.—T.

**Wellingtonias seeding.**—An experience gained from the solitary specimen trees of this has not furnished opportunities for observing whether the *Wellingtonia* seeds freely or rarely in this country. In pleasure grounds where avenues of them are planted it may be no uncommon occurrence to find seed-cones develop, and to me, and probably to many other readers of THE GARDEN, it would be interesting to learn what are the conditions in which *Wellingtonias* are known to produce seed-cones. In the grounds here are several trees in varying ages, only one of which has any tendency to seed, and this has not been observed until the present year. The tree under notice is not so large as the others, though it certainly is the best shaped and healthy. The largest has a girth of 17 feet at 3 feet from the ground-line, while the other one has probably not more than half the diameter of stem. In this case even there is no freedom in seed-production, perhaps not more than half a dozen, and I shall be curious to know if the seed will ripen. The fact of their being small and not very conspicuous may account for some lack of knowledge in the matter. At the present time many observers might, without critically examining the higher branches, fail to detect the green cones.—W. S., *Rood Ashton, Wilts.*

## ORCHIDS.

### NOTES ON ORCHIDS.

For a winter display few plants equal the beautiful *Dendrobium Phalaenopsis*. Thanks to the efforts of collectors, we have now plenty of it in cultivation, and in many collections of moderate size only this fine species is represented by hundreds of plants. Nothing can be more showy, yet refined, than its magnificent racemes, the colours more varied than those of any other *Dendrobie*. *Calanthes*, too, are now very fine, many of the choice hybrids as well as the usual *C. vestita* and *C. Veitchi* in their varied forms delighting the eye by their bright tints and delicate texture. The earlier plants of *Dendrobium nobile*, *D. anreum*, and *D. Wardianum* are also beginning to be interesting, though the principal display of these is not yet. *Zygopetalum Mackayi* is a useful old plant, and there are even now many *Oncidiums* and *Miltonias* left of the autumn-flowering kinds. *Lælia autumnalis*, *L. anceps*, and *L. acuminata* in variety have done well this sunny autumn and are showy and bright. *Cypripediums*, of course, are legion, and the cool house is beginning to look very gay with *Odotoglossum crispum* and a few similar kinds. The brilliant *Sophranitis grandiflora*, the showy section of *Masdevallias*, and a few chance sprays of *Mesospindium* and *Cochlidia* form an effective contrast with the snowy white *Masdevallia tovarensis*, a pretty and especially useful garden Orchid. *Vandas* of the tricolor and nearly related species have a few spikes still left, and the spikes on the charming *Saccolabium giganteum* are beginning to lengthen out.

Not much can be done just now in the way of repotting, but a good deal may be done towards the health of the plants by constant and timely attention to cleanliness as the term is applied in its varied senses. The roof-glass, for one thing, should be kept clean both inside and out, and all spare time is well spent in sponging the foliage of any plants where there is a suspicion of insects. A considerable drop in the outside temperature may be expected now at any time, and everything should be in readiness to prepare for it. Because we have wanted little fire-heat as yet is no reason why flues should be left choked with soot. Any night, dull and heavy as it may appear at sundown, may change to severe frost before morning, and this shows the necessity of growers being always on the alert. One can hardly go wrong at this time of year in keeping a little warmth on the pipes even in the cool house and allowing a plentiful supply of fresh air. We are ready then for whatever comes, and the air currents are doing good, no matter what the weather may be. In the metropolitan fog area perhaps it is best not to allow much air while the fogs are on, but this bane of the Orchid grower will insinuate itself no matter what is done to prevent it. Growers in a pure air have a great advantage over those near London, for fog in a pure country atmosphere, though it may be unpleasant, does no harm, not being laden with the sulphurous fumes from thousands of chimneys. Damping at this season must be gone about with caution, and though far from recommending a harsh or dry atmosphere, I should certainly feel safer with any house of epiphytal Orchids a little on the dry side than the other way. Moisture in summer when the sun is bright and quickening in its effects is a very different thing to moisture now, when every day we have more than we want of it outside. Especial care is necessary with such sensitive plants as the Moth Orchids. Any change, however slight, is felt more by these than by the usual run of pseudo-bulbous kinds, and though such vigorous-growing species as *Phalenopsis amabilis*, *P. Schilleriana* and such like may get along under rather unsuitable conditions, there are many of the smaller-growing section and even of the Luddemaniana types that will not stand it. It is easy enough to say keep up a nicely-balanced temperature. Some one who has tried may say, "How is it to be done?" But it is quite impossible to give a detailed description of what is necessary, circumstances varying so much that no two cases are exactly alike. One point is actually necessary in all, and that is to keep up the night temperature of the house. None of the *Phalenopsids*, even when at rest, need a lower temperature than 60°, and this figure must not be much exceeded from now onwards until February or March. Quite different are the *Dendrobes* from the same neighbourhood. One and all of the deciduous kinds are better now for a low cool night temperature, and any house where they get plenty of light and air and a night temperature of 45° to 50° will suit them admirably. Watering at the root now requires care; few plants are taking much, and many may be kept quite dry, the atmospheric moisture being ample to keep them in good condition. Nearly all *Cattleyas* and many *Laelias* are taking much less. The *L. pumila* section being in flower needs a little moisture at the root, and so do most of the large-growing kinds, but even here for a month or two the drier side is the safer. Little alteration is needed in the temperatures given last month, but in every case it is better to allow a slight drop on very cold nights than to unduly press the fire-heat.

**Cypripedium insigne Sanderæ at Cheltenham.**—This rare and beautiful Orchid is at present in flower in Mr. Cypher's nursery. I was much struck with its distinctness. It seems to possess all the good characters of the old *insigne*. The flowers are of the same size and form, and the leaves also are similar, but the colour of the flower is a clear, rich pale yellow that makes it attractive and conspicuous in a house where other

*Cypripediums* in great variety are grown. I am sure when one meets with such a desirable flower as this new *Cypripedium* is proving itself to be, it is to be regretted that choice Orchids cannot be multiplied as quickly and grown as freely as our soft-wooded plants.—M.

**Cymbidium Traceyanum.**—A distinct form of this lovely *Cymbidium* has recently flowered in the collection of Mr. T. McMeekin at Falkland Park, South Norwood. The plant carried a raceme of twelve flowers. The sepals and petals were lacking in substance when compared with many other forms of this species, and the colour was also much lighter. They were of a pale greenish yellow, heavily spotted and lined with reddish brown. The front lobe of the lip is creamy

it requires a liberal amount of moisture at the roots during the growing season. It is liable to attacks of red spider if grown where the position is at all dry.—H. J. C.

**Cattleya dolosa.**—This pretty plant should be more grown, for though the flowers lack the size of and make less show than those of the labiate section of varieties, the delicately tinted little blossoms never fail to excite admiration. It has been described as a variety of *C. Walkeriana*, but it is quite distinct as a garden plant, no matter how nearly related botanically. For one thing, it always flowers upon the top of the growth between the leaves and not from a secondary growth, as in the species named. The flowers, each about 4 inches across, are a pretty

*Clematis Mont Blanc.* From a photograph sent by Mr. C. Metcalf, Halifax. (See p. 499.)

white, spotted with light brown; the ground colour of the side lobes also white, lined with the brown of the front lobe. *C. Traceyanum* first flowered in Mr. H. A. Tracey's nursery at Twickenham, and was exhibited at the Royal Horticultural Society's meeting in December, 1890, when it received a F.C.C. Several other plants have since flowered, though none are equal to the original in point of size and substance of the blooms. Its habitat is practically unknown. It is a plant of vigorous constitution, and should be grown in an intermediate temperature. The compost should consist of good fibrous peat and loam, with a liberal sprinkling of rough sand or finely broken crocks to keep the material free, as

soft rose varying a little in intensity, the lip having a yellow disc and a bright marginal blotch of deep purple. The plant is not a strong grower, and succeeds best either in small baskets or pans, or wired to pieces of Tree Fern stem. The natural roughness of the latter material suits it well, but if grown in pans use a thin compost only, consisting of peat and Moss in equal proportions over good drainage. Disturbance is dangerous with these small growers and should not be more frequent than can be helped. This *Cattleya* flowers upon the newly-formed bulbs without resting, and should therefore be kept moist until the blooms are past, removing these as soon as open from small or weak plants. It is a native

of Minas Geraes, and was introduced in 1872. Importations since have not been very frequent, but it is a plant well worth seeking for.

**Cattleya Walkeriana.**—This I have noticed in flower this week. The blossoms are each about 4 inches across, the sepals and petals recurving and soft rose in colour; the lip has a yellow centre and a bright purple blotch in front. The flowers are produced on few-flowered spikes, not from the top of the pseudo-bulb, as is usual in the genus, but from a kind of spurious growth that springs from the base of this. The plant does best in shallow pans or baskets suspended near the roof in the Cattleya house, and the habit of the species must be kept in mind when preparing these and the compost. A large body of material is about the worst thing possible for it. *C. Walkeriana* is not exactly a robust plant, and care should be taken that it does not over-flower itself. Because the growth that produces the flower-spike dwindles away when the blossoms are past is no reason why the strain of flowering is not felt just as severely as with other kinds. When the plants are strong and healthy, flowering does not, of course, harm them in the least. *C. Walkeriana* is a native of Brazil, where it was discovered about 1840 by Gardner.—R.

**Odontoglossum constrictum.**—This is a modest-looking little Odontoglot, very variable in colour and markings, and very free-flowering. The blossoms are pleasantly fragrant and last well in good condition if not sprinkled with water or bruised. The scapes bear a large number of flowers each about 2 inches across, all the segments being narrow, pale yellow with reddish-brown spots, except the lip, which is usually white with fewer and larger spots of rosy-red. It should be grown in small pans suspended from the roof or in pots, but the semi-drooping spikes look well in the former position. Not only this, but the free circulation of air in such positions tends to health and vigour in the plants. Not more than an inch of compost is necessary, but this should be of the best quality obtainable, brown fibrous peat and freshly-gathered Sphagnum Moss being mixed with crocks and charcoal. Pot the plants firmly in autumn, and keep on the dry side until roots are forming. After this all through the year they must be kept moist, the house wherein they are grown being heavily shaded and freely ventilated. It is a native of La Guayra and Caracas, whence it was introduced in 1843, and first flowered in Mr. Rucker's collection. A very similar plant is *O. Sanderianum* from the same locality.

**Lælia Perrini.**—The flowers of this fine old Lælia are very bright and useful, though not so large as some others in the genus. It produces its flowers from the apex of the young growth after the manner of the autumn-blooming Cattleyas, and each spike bears three or four flowers about 5 inches across. In the typical form the sepals and petals are a bright rosy lilac, the lip similar in ground colour, with purple and yellow markings. It is not a species that delights in much compost; nice specimens may be grown in pots about 6 inches across filled to within 1½ inches of the top with clean crocks. For compost use good peat and Moss, with plenty of crocks and charcoal. The plants, when newly imported, are often very dirty and covered with insects, and this of course must be rectified before placing them among clean, healthy plants. Choose a light position at the cool end of the Cattleya house and encourage the plants to grow freely during the spring and summer, but after flowering keep them dormant until the next spring. The atmosphere may be kept moist the whole year round, but it is not exactly a thirsty subject at the roots. *L. Perrini* is a native of Rio de Janeiro, occurring rather high up on the mountains. The date of its introduction was about 183

**Sophronitis grandiflora.**—Once again the beautiful showy blossoms of this Orchid are open, and by their bright effective tints lighten up the

flowering house considerably. It is really surprising the amount of blossom that small plants of this species go on producing year after year without any apparent harm, and not only this, but carrying them on the plant for weeks on end. A pretty flower is *S. grandiflora* in spite of its somewhat flat shape. The plants are not difficult of cultivation when once a suitable place is found for them, and this will not be in quite the coolest house, but in such a position as the warm section of *Odontoglossums* thrives in. I like them best suspended from the roof, both on account of their liking for plenty of air and also because of the light reaching every part of the plant at all seasons of the year. Under these conditions the plants get solid and of that bronzed appearance that is always the result of health and fore-runner of a bounteous bloom. They are not very strong-rooting plants, so only a thin compost is needed. *Sophronitis grandiflora* is a native of the Organ Mountains, in Brazil, and it must be very plentiful there, scores of large importations having been made since Gardner first sent it to Messrs. Loddiges, of Hackney, about 1840.—H.

#### CYMBIDIUM GIGANTEUM.

THE flowers of this species are now open, and it makes a nice show, especially on large, healthy plants. The leaves are long, sword-shaped, deep green with paler veins, and the pseudo-bulbs are large, oval, with the leaf sheaths clasping them at the base. *C. giganteum* is a very easily grown species, and, like all the large members of the genus, likes a substantial compost. I am aware some growers use manures of various kinds rather freely, but I grow it in equal parts of peat fibre, chopped Sphagnum Moss, and loam, with a liberal addition of large broken crocks or potter's ballast, and have no reason to be dissatisfied with the result. The time when feeding with manures seems to be necessary is when the plants are too large to be shifted into larger pots, yet are pot-bound. It becomes a question then of feeding or else of breaking up the specimens, and when well suited it is remarkable how quickly these plants outgrow their receptacles. A piece I imported about five years ago was then placed in a pot about 10 in. across. It is now in one 18 inches, and has grown out over the sides in all directions, so that next time a shift is given it will need a much larger one. It is not often possible to remove much of the old material, as this is usually so firmly entwined with roots that the latter cannot be interfered with. In such cases a good shift must be given and the material made firm with a potting-stick. The plant noted above is growing in a cool shady fernery, a class of structure that suits *Cymbidiums* much better than a very warm Orchid house. In the latter the plants are sure to be overrun with insects, and the bud-dropping, so troublesome in this and nearly related kinds, is almost unknown in a cool house. For years I was troubled with this in *C. Lowianum*, but since I have adopted a cooler régime I have had no trouble. The worst insect enemy to *Cymbidium giganteum* is a small white scale that clings very closely to the leaves. This should be kept in check by frequent syringing, and wherever the plants are thoroughly clean, use every endeavour to keep them so, for it is a troublesome job to get rid of it once they are badly overrun. Frequent light dampings or spraying overhead are beneficial to the plants, especially when the weather is hot and dry, and at this time a shady position should always be afforded. *C. giganteum* was discovered in Northern India by Dr. Wallich, who introduced it in 1837. R.

**Epidendrum Brassavolæ.**—This is a very distinct and pretty species, the flowers, as denoted by the specific name, resembling somewhat those of a *Brassavola*. It has greenish or straw-coloured sepals and petals, the lip trowel-shaped, pale purple in front, with a yellow-striped throat. The pseudo-bulbs each bear a pair of dark green leaves, from between which the flower-spikes

issue, each spike carrying about half a dozen. It does well in the Cattleya house in medium-sized pots, and likes plenty of moisture while making its growth. It is a native of Chiriqui and was sent home by Mr. G. Ure Skinner. It first flowered in this country in 1867.

**Barkeria Barkeriola.**—Although a small-growing plant, this bears fine racemes when in good condition. These are drooping and contain about five or six flowers, each upwards of 1½ inches across. The sepals, petals, and lip are white, with a suffusion of lilac or soft purple, and the latter has a much deeper purple blotch in front. This *Barkeria* does well suspended from the roof in a cool, moist, yet fairly light house, where it has plenty of air about it all the year round, with only a little compost about the roots. It is a native of Mexico, and was introduced by Messrs. Sander in 1884.

**Odontoglossum pulchellum.**—This pretty plant I noted in flower a day or two since for the first time this season. The spikes grow a foot or more high, and the upper portion is clothed with the chaste little white blossoms, each with a bright golden-yellow centre. A more easily grown *Odontoglot* does not in all probability exist, as it will thrive in many places where none of the crispum or similar type will do. A cool, moist atmosphere all the year round, plenty of water at the root while growing, and a shady position suit it best. The roots are somewhat larger than in some others, consequently the compost must be very rough and open.

**Pilularia fragrans.**—This resembles no other flower so much as the white *Dipladenia boliviensis*, the flat lip with its dense yellow eye being very beautiful. The growth is peculiar, the bulbs having a flattened appearance, and both these and the foliage have a similar shade of dark green. *P. fragrans* when strong and healthy roots with comparative freedom in a rough mixture of peat and Moss, but I know of few Orchids more difficult to induce to root freely again when once they have got into a bad condition. This shows the necessity for good drainage, an open compost, careful watering and timely attention to top-dressing before the old material gets sour.—R.

**Cypripedium Sedeni.**—This is one of the oldest hybrids, but difficult to beat as a garden Orchid, its delicate, yet showy blossoms being produced nearly the whole year round. In the typical plant these are rosy white on the dorsal sepal, the lip deeper in colour, but there are many named varieties. It is a very easily grown kind and will thrive and flower with the greatest freedom in an intermediate Orchid house or fernery, liking a fairly light position without being exposed to the sun. It grows freely in a compost of equal parts of peat fibre, loam and Sphagnum Moss, and may be repotted early in the new year if this is needed.

**Lælia autumnalis atro-rubens.**—This is a richly-tinted and beautiful variety, the flowers of a bright purplish crimson, larger and broader in the segments than the type. It was introduced by Messrs. Backhouse in 1879, and, like the typical plant, delights in a cool, yet moist and well-ventilated house all the year round. It may be in an almost unshaded position, this tending to a firm growth that is bound to be satisfactory at flowering time, and during active growth the plants require a very abundant supply of moisture. While at rest they may be kept perfectly dry for a few weeks with advantage. It is best grown on trellised blocks or in baskets, with a thin compost of peat and Moss over good drainage.

**Epidendrum Cooperianum.**—Although for some reason this section of *Epidendrum* finds little favour with Orchid growers, few plants are prettier when the room they take up and their easy culture are considered. *E. Cooperianum* is not particularly showy, but the contrast of the rosy lip against the olive-tinted sepals is very good, while the habit of the plant and the disposition of the racemes are elegant. It usually grows about a couple of feet in height, the stems being covered

towards the upper part with deep green leaves. To grow it well, a fairly large pot and a rough, open mixture of peat fibre, Sphagnum Moss, and charcoal are necessary. The plants should not be disturbed oftener than really necessary, but it is better to repot than allow a sour and water-logged condition of the compost. Remove everything of this character when taking the plants out of their old pots and drain the new ones thoroughly. Pot firmly, with a very slight rise to the centre only for strong plants, weaker ones being elevated a little more. Grow them as rapidly as possible consistent with a firm growth, and allow plenty of sunlight towards the latter end of the season. Avoid watering them heavily overhead, but light sprinklings are very beneficial in hot weather. It does best under Cattleya house treatment, being a native of Brazil, whence it was introduced in 1865.

## STOVE AND GREENHOUSE.

### PLANTS THAT FORCE WELL.

WHEN the Chrysanthemums and Geraniums are past there is always a demand for spring flowers of various kinds, and in order that there may be no blanks it will be necessary to introduce the plants into heat now. The requirements of places so differ that it would be impossible to lay down any rules as to what are the best things to force, but, as a rule, flowers with strong scent are not so much in request; those, however, having a light, graceful habit, bright in appearance, and producing an abundance of bloom are the most useful. Many of our hardy shrubs will force well, and the same can also be said of some of the early flowering herbaceous plants, and those who have to supply a quantity of cut flowers would do well to grow a batch of such things as the following. The Dornicums in ordinary seasons will bloom freely enough in the open ground in March, but if grown in clumps specially for forcing they may be potted up in October and stood in a cold frame until required. If introduced into a gentle heat in December they may be had in bloom from January onward till those in the open ground flower. The old *D. caucasicum* is the most common and flowers the earliest, but *Clusii* and *plantagineum excelsum* are the two best, the flowers being larger and the stems longer. *Aquilegias* when well grown in pots look very handsome. *A. cœrulea* and *glandulosa* are particularly fine, and may easily be had in flower in February. These plants will not stand much forcing; therefore to have them in bloom early they must be brought on gradually. Plants strong enough for this purpose may be grown from seed sown as soon as it is ripe either in the open ground or in boxes. When large enough to handle, the seedlings should be pricked out into a cold frame where they can be protected through the winter, when if planted out on a light, rich piece of ground they may be lifted and potted the following October. *Dielytra spectabilis* is so well known that it needs no description. Many, however, fail to grow it to perfection on account of applying too much fire-heat. As a pot plant it is charming, and for cutting there are few things more beautiful, as the leaves as well as the flowers have such a graceful appearance. The plants intended for forcing should be potted up as soon as the foliage has died down and protected under beds of ashes till required.

Turning to the shrubs that are useful for this purpose, we find even a greater number to choose from. In the first place, we have *Spirea confusa*, with its pretty little clusters of Hawthorn-like flowers. This species only re-

quires a very gentle heat to induce the flowers to expand, for being naturally very early in bloom too much warmth would cause the buds to go blind. Where there is much room decoration in early spring this is one of the most lovely plants possible for that purpose. The flowers are borne in small clusters along the preceding year's growths, which are very slender, and therefore hang gracefully in great profusion. Another companion is the double-flowering Cherry.

*Staphylea colehica* is also a good shrub to force, its graceful spikes being produced in great profusion with the most gentle forcing. There are several varieties of *Dentzia*, all of which force easily and bloom most profusely. They are easily grown from cuttings and layers, so that no place need be without them. Amyg-

tionation than *Hydrangea Thomas Hogg*. Cuttings of this inserted in a cold frame in July will, if potted up as soon as they have rooted, flower well early in the season. I have often had plants treated thus in full bloom early in March. They can be introduced into heat as required, when they will make nice, useful stuff; the flowers, being white, are always in request. There are many other shrubs that are useful for forcing, such as the Ghent *Azaleas*, *Azalea mollis*, some of the alpine *Rhododendrons*, *Kalmias*, *Andromedas*, &c.

H. C. P.

*Hymenocallis caribæa*.—This handsome species has been flowering well of late in the great Palm house in the Royal Gardens, Kew, a large example having produced several scapes,

The erect *Clematis* (*C. recta*). From a photograph sent by Miss Willmott, Warley Place. (See p. 499.)

dalus and *Prunus* are also two shrubs that expand their flowers with but little forcing. They are useful for decoration, but are of no value for cutting. There are also several varieties of *Syringa*, notably *Charles the Tenth*. This fine variety when well grown produces fine clusters of bloom, which last for some time in perfection if kept in the conservatory. The same may be said of the *Guelder Rose* and *Philadelphus coronarius*, both of which make nice pot plants when in a small state. The flowers of the latter are, however, too strong scented to suit most people, particularly when used for room decoration. But of all the flowering shrubs none are more worthy of cul-

with the usual array of pretty flowers. The chief beauty of several species of this genus, apart from their characteristic grace and elegance, is the prettily formed membranous cup within the segments. In some instances this is exceedingly chaste and beautiful, glistening in the satiny, almost transparent whiteness. Some species also are delightfully fragrant, thus adding another charm to these valuable stove bulbous plants.

*Justicia carnea*.—I remember some thirty years ago this plant was much grown. The old plants were cut back about July, and placed in a warm pit to break. Then they were shaken out, potted, and returned to the pit. As the days shortened they were placed in a vinery just started, and here they gave an enormous amount

of bloom in the months of February and March. Another simple way to grow this plant is to strike the cuttings in March or April. When strong enough take out the tops. When the pots are full of roots in July, put the plants into 5-inch or 6-inch pots, growing them on in a warm frame. When the weather is too cold for them to remain here, place them in a warm house with a temperature of about 50° to 55° at night, and here they will bloom during the dull autumn months. I have them now (December 3) in bloom grown in this way.—DORSET.

**Tacsonia exoniensis.**—There are few more suitable plants for climbing over the roofs of large houses and filling the space quickly than this Tacsonia. In a long glazed corridor here, where it is too draughty for Lapagerias, I planted a small piece three years ago, and it has made wonderful progress. Since June it has not been without flowers, and there are scores of buds to open now; they are, in fact, produced at every joint. Like the Passion Flower, it thrives in almost any description of soil, and to obtain the best results it should be allowed to ramble unchecked as far as possible. A few of the more rampant shoots must, of course, be cut out where they have filled their stations, but if there is room for these to hang down a yard or more from the glass the effect is much finer than if kept tied in closely. Propagation is easily effected by cuttings, seeds, or layers. Cuttings of young wood root freely in sandy soil under a bell-glass or in a propagating pit. Pot on until the plants have made a yard or two in length, and then plant in their permanent positions, giving rather a large but well-drained border if possible.—R.

## KITCHEN GARDEN.

### FORCING FRENCH BEANS.

THE forcing of French Beans from November to January is not profitable; indeed, I have never been able to get sufficient pods to pay for room occupied, as though I have got a fair set, the pods refused to swell, turned yellow, and finally dropped. Of course, in brighter localities there may be greater success. These remarks would more concern what may be termed autumn supplies, as plants from seed sown now will come in for early spring use, and with lengthening days and more light there is less difficulty in securing a crop. I endeavour to get Beans as early as possible in the new year, and for this reason sow early in December. This cannot be advised if cost is considered, as the crop is none too plentiful; still, French Beans in February are a welcome addition. The plants at this dull period of the year are none too strong, and the only gain is earliness. For reliable supplies January sowings are quite early enough, and I will briefly describe the forcing from January to June and note the value of those kinds which do best. For what may be termed early supplies I would advise small pots. I find it advisable to grow the earlier lots in small pots, as there are few roots, these decaying if overwatered or given insufficient heat. Six-inch pots are useful, and I do not exceed 7-inch for the earlier lots. Many sow too many seeds in a pot. It may be necessary to sow liberally, but in no case should thinning be overlooked, as too many plants cause weakness, and they have a tendency to decay at the base just above the surface. Three to five plants in the size of pot named are ample. I prefer the smaller number, as these will then be stronger and yield more pods than crowded plants. Many persons adopt the old method of half filling the pots when sowing, filling up the remaining portion when growth is fairly active or before the plants come into

flower. I do not advise it, as I have noticed the added soil is not filled with roots. The new soil causes the stems to decay. I advise filling up the pots to within 2 inches of the top at time of sowing, relying on liquid manure later in preference to giving top-dressings of soil or decayed manure. I have seen many failures with giving hard forced Beans excess of manure in their early stages. The plants occupy the soil so short a time, say six to nine weeks, that there is not time to absorb the rich food given. After sowing, much depends on how the plants are treated. I have had failures with January sowings; they may have had too much moisture at the start, which is fatal, or have been too long in germinating. Another evil is too old or imperfectly ripened seed. For the earliest supplies, new seed and that ripened early in the summer is the best. I always sow at the end of April to get the best seed for hard forcing. Rapid germination is a great gain, and in potting, if the soil is light, ram firmly, this causing the plants to get a strong root-hold, and they do not dry so quickly or suffer from red spider. I place the plants over the hot-water pipes till the beans push through the soil and then stand on shelves or stages close to the glass and water very carefully; indeed, no water is needed from time of sowing till the plants are a few inches high if the soil is fairly moist. The temperature may range from 60° to 70° by day, 10° lower at night, and the house or pits will need to be fairly dry. In fine weather damping over early in the day with the syringe will do good, but the plants should be dry by sunset and not damped over when in flower. For first supplies very little food will be needed. Weak liquid I find best after the flowers have set. From early January-sown plants there will be gatherings till the end of February and early March. An early variety is best—Syon House, still an excellent early Bean, Ne Plus Ultra or the larger Early Favourite.

We now come to the most important crop—that sown in February and March. Larger pots may be used or they may be planted out. For February sowing I still advise the early quick growers. For years I found Mohawk a reliable variety. At this date 8-inch pots are a useful size. The seeds will germinate more quickly, the plants are stronger and need more moisture. It is well to use bottom-heat to get a rapid growth. For beds I usually sow in 3-inch pots and make the bed at time of sowing. By the time the plants are ready the soil is warmed through and in condition for planting. A bottom-heat of 80° and a liberal top heat are needed. To save time in March or April many sow thinly in boxes and lift the plants direct into the beds when a few inches high, and with care it is a good plan. Another plan is to sow in their growing quarters when the soil is warm, and when a few inches above the soil to thin to the distance required. Beds have much in their favour if near the glass, as more than one crop can be taken from the same plants, as if they are clean after the first crop is cleared, the surface dressed with rich food such as bone-meal or spent mushroom manure and the plants stopped, they make new growth and produce a second crop much sooner than new plants from seed. For April sowings, or indeed when March is well advanced, there is no need to study variety, as now any kind will grow freely, and, if wished, larger pots may be used and a greater depth of soil given plants in beds. Sow every fortnight in pots from March to the end of April, but at longer intervals for beds.

The best variety if size and quality are needed is the Canadian Wonder. There is more than

one variety of this excellent Bean. The true one gives a very large pod and is exceedingly prolific. I have seen this variety give three crops. Canadian Wonder treated too well runs to leaf growth. This is why I have not advocated planting out in cold frames for latest supplies. If planted out the soil should not be too rich or too deep and the plants not too thick. Mohawk is always reliable, also Negro Longpod and Long Sword. For large houses where there is head room, anyone may with advantage sow the newer variety or climbing French Bean. This, with a few sticks, gives a wonderful crop of splendid pods. I do not advise it for forcing, but for latest supplies grown in pots it does well. It is more at home planted out and stopped at 3 feet from the soil. This variety, if sown the last week in March or early in April, will give a good supply just before the earliest plants in the open borders turn in. G. WYTHES.

**Autumn Giant Cauliflower.**—I doubt if ever there was a more favourable season for this splendid vegetable, for up to the present heads are being cut in the open fields by waggon-loads, every one fit for exhibition, and so solid that each one weighs several pounds; in fact, the general complaint has been that they are far too large. A few days since I saw a quantity of heads cut quite large enough for any purpose. The plants had never been transplanted from the seed-bed, but merely thinned out to a foot apart by pulling away the smallest ones.—J. G., *Gosport*.

**Lettuce-leaved Endive.**—This new Endive I have grown this year, and find it valuable for winter salads. It is doubtless a type of the Large-leaved Batavian, one of the best winter Endives grown, as it is hardy and of excellent quality. The variety in question has large leaves, with solid hearts, and it blanches freely with little heat if in a dark place. Unlike the curled varieties, it does not decay, but is crisp and sweet. Some persons like the Endives for boiling in the same way as Spinach. Of course, for that purpose blanching is not necessary. The above, owing to its size and fine shape, is a splendid variety for autumn supplies. I find it does not run to seed for a long time and is very hardy. For winter use the above variety will be found valuable, as it will give a supply when Lettuce is scarce.—W. B.

**Salsafy Giant.**—This is a new introduction, and certainly an excellent one. It is quite distinct from the old type, as it is larger and of better flavour. I am not an admirer of vegetables on account of mere size, but in the old variety the roots are small and in many gardens much forked and difficult to clean or prepare for table. I find the new Giant excellent as regards size, and the roots being thicker, longer, and less forked are a welcome addition to our winter vegetables. For years I have treated this plant different to other roots. It is not well to lift early; indeed, in well-drained land it winters in its growing quarters with a few ashes or litter over the crowns in severe weather. In wet land the roots decay. In such cases late lifting and a cool store are advisable, with plenty of soil or sand between each layer of roots to keep them from shrivelling. When sowing, too rich land must be avoided, as manures cause the roots to fork badly.—G. WYTHES.

**Tomato Conqueror in winter.**—Those who saw the large collection of this variety at a recent meeting of the Royal Horticultural Society could not fail to notice its excellence, and though I have seen better coloured fruits, no fault could be found with the size or quality. I am aware this variety does not find favour with private growers in many places on account of the fruits being uneven and rather flat, but in a measure this may be avoided. I know it is difficult to get the fruits free of the objections noted. Some of the fruits will be-

come corrugated, but this matters little at this season, as they are mostly used for cooking. My object in sending this note is to point out the value of Conqueror as a winter Tomato. Of course there is no lack of home-grown Tomatoes in December, but this variety ripening now will keep longer than many others, and this is a great gain. The fruits of Conqueror do not split or decay at the stem so readily as some of the better shaped kinds. As regards its cropping I know of none better. In the north this is a great favourite for open-air culture. For mid-winter crops plants raised in June will set fruits later than most kinds, and what is so valuable to the large grower is that it sets well into the autumn with scarcely any fertilising. For forcing, Conqueror will hold its own. Doubtless much of its value as a winter Tomato is on account of its free setting. The fruits are drier than those of the Perfection type, but little inferior in quality if season is taken into consideration. For many years I grew Conqueror on account of its earliness and free setting, but there are newer early kinds which now find more favour and are of better shape. Conference is nearly as early and is excellent, and Frogmore Selected is a grand forcer, with fine flavour, and, like Conference, very prolific.—S. H.

**Keeping Onions.**—My Onions are keeping very badly this year, though apparently well ripened when harvested, and although they were perfectly dry, some are already beginning to grow out. White Spanish is largely relied on here, and it is keeping better than any other kind, the bulbs being of medium size with small necks. They are stored in a small lean-to shed with no protection but that of the tiled roof, and last year they were many times frozen quite hard. This does no harm, in fact I believe had the weather been colder the bulbs would have been in better condition now. James' Keeping is a capital Onion when obtained true, but this season I have been growing a large soft variety not unlike Giant Rocca in place of it, thanks to badly selected seed. Autumn-sown plants are looking much better than last year, and with reasonable exemption from bolting these should be an early and useful crop. But these cannot be relied on much before May, and as Onions are a daily necessity in the kitchen it is important that everything possible is done to ensure their keeping well. A free circulation of air and thin storage are important, and the cooler and drier the store the longer the bulbs keep in good order. But even more important it is to get the bulbs thoroughly ripened before storing and quite dry, otherwise, with every care, they will not be satisfactory.—R.

**Good Celery.**—There is no lack of varieties of Celery, and at this season one can soon distinguish any special merit in this vegetable. It is surprising how Celeries differ in the same soils and under the same treatment. Sufficient moisture is an important detail, and one that is often overlooked at the most important period of growth—July to September, as plants at all starved never have the sweet, nutty flavour of those not checked in any way. I am aware there can be excess of food in the way of rank liquid manure, as I have seen many plants ruined by sewage being employed at a season the roots were dry and very few perfect plants were found. Many think that Celery cannot have too much food, but it is wrong, as in many cases such Celery is thick at the base, makes a woody, thickened growth, and soon bolts. I like the medium-sized varieties, not because they are of superior flavour, as a well-grown large kind is quite as good. For table the medium-sized roots are better, as they are more readily cleaned and need less cutting. On the other hand, the large roots keep well if grown specially for late supplies. I find the red Celeries the best flavoured after the new year is in, and there is little doubt that the red kinds are the best keepers. With so many kinds to select from growers of small quantities do not know which is best, but they may get a fair idea from the notes on the different varieties by large growers. I know one large grower who only has two varieties. For market

it may not be important to study quality if size is obtained. He grows those for which there is the greatest demand. Some of the larger Celeries are not at all inferior to the smaller kinds in quality if well grown from the start.—L. W.

**Wintering garden roots.**—Where Beets, not the hardest of roots, are found to preserve their flavour and freshness best in the soil during the winter, and that is generally the case if the soil be fairly porous, it is good practice to lift each other row, and store the roots in dry sand or ashes on their sides in a cool shed, and then carefully earth up the remaining rows, drawing the leaves erect, and covering up the crowns fully 6 inches deep with soil. So covered, Beets will stand much hard weather admirably. There can be no doubt but that roots so kept show the highest flavour when cooked. Parsnips also seem to keep much the best in the soil if it be not too holding or retentive of moisture. They, too, may be earthed up in the same way, and Turnips in drills are much safer for such soil protection. Large Carrots may be best out of the ground, as they are so liable to split with moisture, but the late summer or July sowing does well left in the ground, needing a slight covering of litter or Fern when hard weather comes. Celeries can also be kept fresh and from harm by well earthing up. In some gardens it is found an excellent plan to lift all the roots from the open quarters and to lay them in thickly underneath overhanging trees, as these furnish much protection from frost. A good coating of dry leaves over the roots keeps them safe, and the roots are found to be very fresh and juicy. Too often roots are stored in cellars or places where the atmosphere is close and warm.—A. D.

#### BETROOT IN WINTER.

My experience with Beetroot coincides with that of "G. W." (page 452) as regards its hardness. Although it is convenient to store a few for immediate use under cover, the bulk is better left outdoors. My plan for several years past has been to lift the roots in autumn, laying them in shallow beds on a border near the path, from which they may be drawn as required for use. This is done by simply opening a small trench at one end with the spade, deep enough to lay in the roots, over which the soil removed for the next row is placed, leaving the foliage unbroken. With the roots wholly covered with soil they remain sound and firm for several months, and are thus quite free from the objectionable shrivelling which occurs when placed in dry root stores. Nothing could be more simple, economical, or satisfactory. In the event of severe weather, a covering of leaves, and over these just sufficient straw litter to prevent them being disturbed by the wind, is all that is necessary. By stacking them in an open shed in layers of roots and moist soil alternating, I have had firm roots in July the following year, but it is not everywhere that shed room is so convenient to hand. The advantages, however, of such accommodation are great when long spells of bad weather, particularly frost and snow, set in. Large roots, without doubt, are most unprofitable, and, apart from their inferior cooking qualities, they are a source of complaint from the cook, because of the inconvenience of their great size. Poor and firm soil and late sowing are the best provisions for giving all-round satisfaction, but too often early sowing is resorted to in small gardens. With the early Globe-shaped varieties now available there is not the same necessity for late-stored Beets, because it is such an easy matter to connect the two seasons in the matter of supply. For very late use they should be stored in a cool position under the shade of trees or a north wall. W. S.

Wills.

**Potato Syon House Prolific.**—This is likely to be one of the most useful varieties in existence, judging by results recently noted at Livermere. From a couple of dozen sets there seemed to be a remarkably large heap, and when the quality of

the new-comer is taken into consideration, its value is at once apparent. The tubers were very regular in size, of capital shape, with hardly any perceptible eye. The skin is slightly rough and the flesh white, while its flavour is also excellent. Anyone on the look-out for a good variety should certainly give this a trial.

**Jerusalem Artichokes.**—Judging by a sample I saw very recently grown by a gardener at Surliton, it seems evident that much may be done to improve the outline of the tubers of this vegetable if the most shapely be constantly selected. The samples shown me a few weeks since were smooth and good in form. The grower said that he had already selected for successional planting any tubers that showed the bad protuberance in less pronounced form, and in the tubers I saw this protuberance was scarcely in evidence. Possibly the white-skinned form owes its greater relative smoothness of outline to a rather less robust habit.—A. D.

**Cabbage Sutton's Earliest.**—This is a very useful variety either for spring or autumn use, as nice heads may be cut in about four months from the time of sowing. After a hard winter, when the plants are badly cut up and supplies are likely to be none too plentiful, this variety may be sown in boxes under glass, pricked out and planted on a warm, early border, when it soon turns in and helps materially with the autumn plants. If required to stand the winter, it must not be sown before September, and planted out when ready on firm ground. So treated it has proved very useful, and in seasons when Ellam's Early has run, this has been quite free from bolting.—R.

**Large Carrots.**—Other than for show, I fail to see the utility of having Carrots so large as often seen, and even for exhibition they should not have preference over medium roots with less core and of better quality. A new Carrot—or, at least, a little-known one—I have recently seen measured 2½ feet in length and from 10 inches to 15 inches round. These huge vegetables are not so great favourites as many imagine; in fact, of late years I am pleased to note there is more demand for quality. Most growers know that the best roots are those grown quickly. Tomatoes if extra large find less favour, and Brussels Sprouts also may be grown too coarse. To obtain large roots a much longer period of growth is needed, and when lifted, such roots do not keep so well as smaller ones.—M. E.

**White Jerusalem Artichoke.**—Having grown the white Artichoke for several years without any trace of disease, I was surprised to learn from Mr. Tallack's note (p. 403) that his tubers were attacked. Mr. Wythes, too, imparts information (p. 452) to me previously unknown, namely, that there are three distinct kinds. The stock I have is of medium size, much more even in outline than the old purple sort, clear in colour, and very prolific. A variety, however, that would produce roots 9 inches to 12 inches in length would seem to me to deserve to be better known, notwithstanding, as Mr. Wythes points out, the superior qualities of the smaller kind. Artichokes in many gardens are not given very good quarters or attention, because they are not highly appreciated by many consumers. This happens more frequently in small than in large gardens, and the information given by Mr. Tallack will certainly not be very pleasant reading to those having a good demand to meet throughout the winter and spring months. Was not the original English grown white-skinned Artichoke a sport from the coloured form? I was under the impression, perhaps from unreliable evidence, it was so.—W. S., Wills.

**Early Broccoli.**—Doubtless many growers lack abundance of Broccoli after the Autumn Protecting is over. This is a splendid autumn vegetable, and I have tried to get it in quantity from now till February, but so far have not succeeded, as when sown for late supplies, with a fine, warm autumn it turns in before Christmas. I have tried others, and several appear good

for the season named, but as only a small trial has been given, it is too early to write of their merits. We have Snow's Winter White, a good old variety recommended for mid-winter supplies, but it is not reliable, so far as the supply is concerned, as of late years I have cut this variety from December to March and it varies greatly in quality and shape. For many years Snow's Winter White was the best winter variety grown. If sown in April it usually turned in in December in warm gardens. In northern localities it was well to sow earlier than date named. I fear the true stock is almost lost, as of late it appears much altered, being coarser and later. A variety which came in very early last year called Improved White Sprouting was much liked. This was very free and produced small heads in abundance. Favourite is a very fine Broccoli for February and early March, but a dwarf form to give a supply in succession to the Self-Protecting would be a great boon to growers. I note dwarf, as I find these are the most reliable in our variable winters. I find there is most demand for good Broccoli at the season named, as the supplies of other good things are on the wane.—S. M.

SOCIETIES AND EXHIBITIONS.

NATIONAL DAHLIA SOCIETY.

THE annual meeting was held on Tuesday, December 14, 1897, at the Hotel Windsor, the president, Mr. T. W. Girdlestone, in the chair. The past year has been a very successful one for the society; there has been a considerable accession of members, the income has correspondingly increased, and a substantial balance remains in hand. It is worthy of remark that over 75 per cent. of the annual income is disbursed in prizes at the Dahlia show at the Crystal Palace. The extent of the exhibition of September last surpassed that of previous years. Increased exhibits of all types of Dahlias were staged, singles alone excepted. The quality was also better, and left little to be desired in the majority of the classes. The great national celebration of the year was represented by a special decorative class of large size to illustrate the great development of the Dahlia during the reign of Her Majesty. New classes had been added to the schedule for vase-decoration and for new members respectively. These were all successful, and will be continued next year. The large increase in the number of entries in some of the Cactus classes for amateurs is indicative of the extent to which the culture of this section is being taken up. Still more rapid advances may be anticipated in the future.

The committee deeply regret the loss by death of Dr. Hogg, a distinguished vice-president of the society. The Dean of Rochester and Sir E. Saunders become patrons of the society, whilst the Duchess of Sutherland, Countess of Pembroke, Viscountess Sherbrooke, and Lady Penzance have become patronesses. Mr. T. Pendered, president of the Wellingborough Dahlia Society, was elected a vice-president in the room of the late Dr. Hogg.

Classes have been provided in 1898 for twenty-four blooms of Cactus varieties, distinct, in the nurserymen's section, and for eighteen blooms, distinct, of shows or fancies, or intermixed, in the amateur section. An open class for a shower bouquet of Cactus Dahlias has also been added. Mr. F. W. Fellowes kindly offered a silver cup for the best Dahlia bloom in the show.

The list of Cactus Dahlias was revised for the coming year, and now stands as follows:—

- |                     |                  |
|---------------------|------------------|
| Alfred Vasey        | Cycle            |

**Royal Horticultural Society and Victoria medal.**—At a meeting of council held on December 14 it was decided to issue a diploma to all the recipients of the Victoria medal of honour. It was also unanimously resolved: "That in the event of any recipient violating the conditions on which the Victoria medal of honour was bestowed, by using it for advertising or for the promotion of trade interests in any other way, the name of such offender shall be struck off the list."

**National Chrysanthemum Society.**—The general committee of this society held a meeting on Monday last at Anderton's Hotel, Mr. T. W. Sanders in the chair, and there was a full attendance of members. The secretary announced that the floral committee meetings already fixed for November 28 and December 12, 1898, would not be held. Letters were read from Messrs. Addison and Moorman resigning their posts on the floral and general committees, the latter gentleman being requested to reconsider his decision. A discussion arose on the recommendation of the schedule sub-committee that a new class for twelve vases of specimen blooms of Japanese varieties, distinct, each vase to contain five blooms standing a foot above the top of the vase with no foliage on the stems, but foliage to be on separate stems be made, the prizes to be as follows: £20, £15, £10, and £5. It was also announced that the president, Sir Edwin Saunders, had offered to give a special prize of the value of £15. The Royal Aquarium Company also offered to supply the prizes in the class for twenty-four Japanese, distinct, amounting to the sum of £30 and being divided as follows: First prize, £8 and a gold medal; second prize, £6; third prize, £5; fourth prize, £4; and a fifth prize of £2. A list of other special prizes was also read out. After a somewhat lengthy discussion, the report of the schedule sub-committee as regards all the shows was adopted. The judges nominated for the various shows were then duly elected, with reserves in each case. New members were elected and the Dundee Chrysanthemum Society was admitted in affiliation.

**Magnolia Yulan fruiting.**—Not long ago I noticed on a large tree of Magnolia conspicua some red knobs about the size of a Cherry, with a tassel of about an inch long hanging out near the base. On being gathered they were found to contain a scarlet seed. The best one contained a seed which was plump and of good size. Can you tell me if it is a very unusual thing for the tree to fruit in England, and if the seeds are of any use?—FRANCES C. C. KENNARD, *Shopryke House, Chichester.*

\* \* It is unusual for this to fruit in England. We have asked several people who possess large specimens, and they tell us they have never seen any seed. We believe it fruits in France. Have any readers of THE GARDEN seen it fruiting in England?—ED.

**The weather in West Herts.**—On the 16th the reading in shade was 56°, which is the highest shade temperature recorded here in December for nine years. Since then, however, there has been a rapid fall in temperature, and on the 21st the mercury at no time rose above 37°. The nights were mostly warm for the time of year, the exposed thermometer never showing more than 7° of frost. At 2 feet deep the ground is still 2° warmer than is seasonable, but at 1 foot deep the

reading is now slightly below the average for this depth. Some rain fell on three days during the week, but the amounts measured proved very small. Throughout the last three days the wind has come almost exclusively from some easterly point of the compass. On the 15th nearly six hours of bright sunshine were recorded, but, on the other hand, the last four days have been altogether sunless.—E. M., *Berkhamsted.*

NOTES OF THE WEEK.

**Late Rosea.**—So late as the 16th of the present month, capital blooms of two well-known Roses were noted in a garden having no special facility for their culture. The kinds were Dupuy Jamain and Souvenir de la Malmaison, and in each instance they were represented by good flowers.

**Banksian Rose.**—I send you a spray of yellow Banksian Rose, one of several gathered in a garden near here on December 18. To make up the bouquet there were Neapolitan Violets and *Lonicera Standishi*, an unusual assortment from the open border so near Christmas.—T. H. ARCHER-HIND, *Coombeishacre, South Devon.*

**Primula Princess** is one of the finest of the double varieties of *P. sinensis*, and as such by no means easy of culture. At the same time, the large handsome blossoms are of considerable service during the winter, particularly in those gardens where a large or continuous supply of button-hole flowers is needed. In these respects the variety of colour found in the group is also of service.

**Pelargonium Niagara.**—Possibly among the white-flowered zonals this variety is unequalled either in the form, size or purity of its flowers. In all these respects the variety appears to be well-nigh perfection—so far, indeed, as the present-day florists have arranged such a standard of merit or excellence. Of precisely the opposite shade is a kind bearing the name Owen Thomas, a very fine crimson, with a small, yet conspicuous white eye.

**Brownea coccinea.**—Though possessing a somewhat straggling habit of growth, there is something exceptionally brilliant and striking in the compact trusses of brilliant orange-scarlet flowers as now seen on a large example in the Palm house at Kew. Flowering much earlier in the year would doubtless give a decided increase of its richly-coloured heads, when the tree would be indeed attractive.

**Aralia Sieboldi in North Wales.**—This plant has been greatly admired during the short days of November and December. It is growing here in company with Rhododendrons, and the dark glossy foliage shows the branching spikes of silvery flowers to great advantage. It has been planted over twenty-five years, and is now 9 feet through the centre and 7 feet high. It is growing in light stony soil fairly well exposed to the sun.—W. COATES, *Gorddino, N. Wales.*

**Plumbago rosea.**—At any season of the year this is a beautiful plant, more so at the present time when flowering subjects are rather scarce. There is also much to admire in a growth that is not in the least degree formal, and which is more than ever pleasing when freely studded with its charming rose-pink sprays. During winter the flowering is not so abundant, but its lovely colour renders it most attractive and welcome now, even though the sprays are but sparsely produced.

**Begonia Gloire de Sceaux.**—This is a most valuable kind for winter flowering alike in the handsome foliage as well as the pretty heads of blossoms. The plant would indeed be worth attention for its effective foliage alone. Like many others of its tribe, this kind is useful in small or large plants, forming in the latter really grand specimens. At the last meeting of the Royal Horticultural Society a nice lot of plants was staged, and mixed with useful Palms made a very pleasing group.

**Chrysanthemum Golden Dart.**—This pleasing late Japanese kind is largely grown at Syon by Mr. Wythes for its late flowering. Not only is it a naturally late kind, but it is also reliable

and opens its blossoms well even in bad weather. Some of the so-called late-flowering varieties are very liable to give blind shoots only, which is most disappointing after spending a season growing the plants. So really valuable has the above proved this year at Syon, that Mr. Wythes is increasing his stock for another year.

**Roman Hyacinths.**—Of the beauty and value of Roman Hyacinths we were reminded the other day by a really splendid group in one of the houses at Syon House, and, much as one admires them in the ordinary way, their value is enhanced when seen in bold effective masses. Good culture was evident in fine spikes and foliage also. Too frequently in the early batches the foliage is sacrificed to a considerable degree by undue forcing or the endeavour to rush them too quickly into bloom. Mr. Wythes evidently approves of giving a little more time and is amply repaid by the excellent results that ensue.

**Cypripedium insigne at Syon House.**—At the present time there is a splendid lot of the above in full bloom, fine plants in medium-sized pots. It is doubtful if in general usefulness this old kind in its best forms is surpassed by many of the more recent novelties. The length of time the flowers remain fresh either on or off the plants is remarkable, while its easy culture readily commends it to all. All the summer long the whole of this kind with some few others are relegated to pits and frames in the open, a course of treatment which has been adopted by Mr. Wythes for some years with excellent results. Now that the plants are flowering profusely they make a fine display in a long lean-to structure. Such well-known varieties of *C. insigne* as *Maulei* and *violaceum* are also in flower, the latter very distinct and finely marked. As seen here this well-known plant constitutes a most valuable midwinter Orchid, at once free flowering, reliable, and easy of cultivation.

**Iris stylosa alba.**—In more than one position at Kew just now this ever welcome winter kind is flowering profusely, many spikes already past and gone. There yet remains, however, quite a large number of spikes to keep up a succession of blossoms for some time. One item which strikes one is the variability both of foliage and flower in the Kew examples. In the typical species the foliage possesses considerable variety, while the flowers vary from pale to deep in their pleasing shades. The white kind above mentioned has quite broad leaves, while a form known

as *I. s. speciosa* has very narrow leaf blades and quite dwarf tufts. The examples now in flower are all of good size, and with their crowns closely packed against the wall appear quite content. The plants are equally happy, however, in any position, affording protection from very keen, biting winds that damage the points of the leaves and appear also to check the flowering. Doubtless the examples at Kew have received material assistance not merely from the wall, but also from the mild season.

## PUBLIC GARDENS.

**A park for Ventnor.**—The trustees of the estate of Mrs. Evans, the owner of Loftly Downrise, above Ventnor, one spot of which is the highest point of land in the Isle of Wight, have intimated that it is Mrs. Evans's intention to make the town a present of the Downs for the use and recreation of the public for ever. The Downs comprise several hundred acres, and the summit commands a wide range of view over the whole island and parts of Hampshire and Sussex.—*Times*.

**New open space in the East of London.** The Parks and Open Spaces Committee of the London County Council propose to acquire in Grace Street, Bromley, in the East of London, a plot of land, an acre and a half in extent, which shall be laid out as an open space for the enjoyment of the inhabitants of the locality. The purchase money is fixed at £6000; £1700 will be required for laying-out and boundary fencing, and the space will involve an annual charge of £250 for maintenance.

**Ham Common.**—Ham Common, Surrey, as to which there has been a good deal of litigation between the villagers and the Dysart Trustees, is about to be placed in the hands of a board of conservators, a memorial to that effect having been presented to the Board of Agriculture. In response to this appeal, the Board of Agriculture have, under the Metropolitan Commons Acts, 1866 and 1878, issued a draft scheme for the future management of the common. The scheme provides that the common shall be managed by a body of conservators, who shall have full power to preserve the common for the use of the public, to enclose portions of it for cricket

grounds, to prevent encroachments, to frame bye-laws, and to enforce penalties for infringement of them.

**Churchyard Bottom Wood.**—The Parks and Open Spaces Committee of the London County Council in a report which they have just issued state that at the latter part of the year 1895 they had before them an application from the Hornsey Urban District Council for a contribution of £5000 towards the purchase-money required for the acquisition of Churchyard Bottom Wood. At that time the Council could not legally make the contribution. Since then authority had been given by Parliament by the Highgate Woods Preservation Act, 1897, for the Council to assist in securing this land as a place of public recreation. They had been urged by the Commons Preservation Society, the Kyrle Society, the Metropolitan Public Gardens Association, and many residents in the district to recommend the Council to make a contribution of money towards acquiring the land, and, after mature consideration, they were of opinion that the Council should assist in the preservation of this desirable open space. It was true that the wood was outside the county of London, but it was so near as to be readily accessible to the inhabitants of the northern districts. And it was right that they should draw attention to the fact that, owing to the rapidity with which the area of the county was being covered with houses, it was already practically impossible to provide any more large open spaces in the central, northern, or eastern districts, except by the purchase of property at enormous cost; and it therefore seemed to them advisable that the Council should join with the other public bodies in preserving this wood for the public benefit. The committee recommend a contribution by the Council of £2500.

**A query about Moss Roses.**—I notice as many as over forty Moss Roses in one list alone. Will any of your readers kindly tell me how it is we never, or rarely, see Moss Roses in good condition in the ordinary garden; also if there are any among the many Moss Roses that are really worth growing, and if they are best on their own roots?—R. U. S.

**Name of fruit.**—*Warnley*.—Apple *Reinette du Canada*.
