WATER, WATER, EVERYWHERE.

The Theory of Water Finding by the Divining Rod: its History, Method, Utility and Practice. By B. Tompkins, W.F., author of the "Theory of Water Finding." Second and enlarged edition, with illustrations. Pp. ix + 127. Copyright and all rights reserved. (Published by the author, B. Tompkins, Expert Water Finder, Chippenham, Wilts, 1899.)

BOTH the subject and the method of treatment of the Theory of Water Finding by the Divining Rod, by Mr. B. Tompkins, W.F., are so unlike what are usually met with by those gentlemen whom you, Mr. Editor, honour by a request for a review, and there are such risks of becoming involved in a sort of fourth-dimensional conflict or of giving offence, that I feel the case is one in which the reviewer should write in the first person, and sign his name. Neither the editorial we nor the security of anonymity would, in my opinion, be appropriate.

Mr. Tompkins is a thorough enthusiast; he has discovered that he possesses a power denied to most mortals, and this he practises, so we read in his book, to the great advantage of dwellers mostly in the West of England, in Wales and in South Africa. Evidence of this is given at once in a list, covering seven pages, of patrons, many with handles to one or other end of their names, and of public bodies for whom Mr. Tompkins has found Springs of Running Water.

The divining rod has been known from ancient times, and we are told has been practised for "the tracing of boundaries, murderers, mines, metals, minerals, and hidden sources of water" (mostly things beginning with an "M," as in Alice). "The scientific name given to the art is Rhabomancy."

"The rod is regarded as a symbol of authority, and is often referred to as such in Holy Scripture, and employed in schools. There are, I find, some 130 references to a 'rod,' staff or sceptre as a symbol of power or authority."

Three instances are given in which Moses used a rod with great effect, and Aaron's rod budded. We need not, therefore, be surprised at the success of the Diviner or present Professional Expert Water-Finder.

Mr. Tompkins goes at some length and detail into his own early history and experiences, for which he gives the following excellent reason:—

"My object in giving a detailed account of genealogy and career is to show that the suppositions made by so many persons, that the Water-Finder is some supernatural being, of a low class, possessing a supernatural power, inherited from a race which existed before the flood mentioned in the sixth chapter of Genesis, caused by the amalgamation of these people, resulting in their possessing occult arts, and from these sprung the Water-Finder, are incorrect and most absurd, absolutely without foundation, they being drowned by the Flood; and further there exists no evidence of a supernatural power, which my readers will see later on."

Here is the account of Mr. Tompkins' discovery of his power of water-finding.

"Quite alone and in the month of February 1886, one who was destined to become a philanthropist of some repute, and play an important part in the affairs of life, steps forth quite unconscious of these thoughts being in his mind, or that they were really in existence as regard to his future prospects. Like a nest within a nest . . . I lifted my eyes and saw the trees and hedges just showing signs of life; in one I saw a white thorn twig . . . I held this rod by both prongs in both hands, so—" (here is a picture) "gripping it tightly so that it should not move, and commenced to walk in an upright position, with the apex of the twig downward and some distance from the ground. This was in an orchard where there were no signs of water existing or wells near, or any indication that water could be found at one place more than another. After walking a distance of 80 yards or so, I suddenly felt a running or creeping sensation come into my feet, up my legs and back and down my arms which caused me to look to see what had happened. I noticed the rod began to rise in my hands; I gripped it still tighter to prevent it, and kept walking; still I found the sensation get stronger and stronger, and that I was being led in a zigzag course, the twig at the same time exercising a great determination to turn up. So strong had this influence become that I was powerless to keep it down, and eventually after proceeding some distance further it attained a vertical position, and revolved over and over. So great was this sudden and unexpected pressure or influence on me that I fainted and became very ill. . . ."

I may add for the benefit of those interested that Mr. Tompkins recovered, and is now able to undertake Water-Finding with no other ill results than considerable fatigue.

Of course, people whose reasoning powers have chiefly been developed in the school or the laboratory find a great difficulty in understanding how this power of water-finding can be explained, and Mr. Tompkins makes the following observation, with which few will disagree :—

"The refusal of its acceptance (the gift of water-finding) by some is because scientists have not yet been able to fully explain the marvels, or apparent marvels, in connection therewith, as, if an occurrence that has not been explained by scientific methods, must necessarily be a fraud."

However, this difficulty need not now trouble the public any more because Mr. Tompkins has given a very convincing explanation, which is much more obvious when pointed out than a great deal that is to be found even in these columns or in ordinary scientific books. This is Mr. Tompkins' explanation :—

"It is a well-known scientific fact that water is a generator of electricity, whether in passing through earth in its natural state or any artificial means employed, creates or produces this power through the various fissures or strata through which it passes. The Expert, medium, or Water-Finder, being, as I have previously stated, of a sensitive nature or organism, the moment he passes over or comes across these currents, becomes the receiving instrument for the time being, and there is no question but that the means used (viz. the Divining-Rod) becomes for the time being a part of the Diviner as an indicator in so far as are the hands of a clock, watch, weather-glass, steam-gauge, or the automatic weighing engine and scales seen so frequently in public places of resort."

Then follow two or three pages, too long to copy, and in which the argument would be lost if only extracts were given, but so novel as to be well worth reading, in which Mr. Tompkins proves conclusively, to himself, that electricity or a magnetic influence really does the work. One sentence is beautifully clear:

"The rod immediately points in the direction in which the current flows up to a certain spot, when the rod rises to its full height, and because it cannot go higher than a vertical position it revolves over and over again."

It is interesting to follow the scientific method of elimination made use of by Mr. Tompkins when he is finding other things than water. As already explained, the rod will find all manner of things, but a difficulty must be felt in discriminating. This is how it is done. If you are looking for gold and the rod rises, you then put gold in both hands, when the rod will at once fail to indicate anything if it rose for gold, but it will still rise if it rose for water or silver, or murderers, or boundaries, or things other than gold. The same is true for silver. We can only infer that the murderer can be discriminated by putting a murderer in each hand, but this is not stated. At any rate, Mr. Tompkins proves the gold story by explaining how he found a sovereign under the floor when the Bath and West of England Show visited Gloucester.

While on the scientific explanation of the action of the divining rod, it may be worth while to refer to an article by Mr. John Wallis Mulcaster, late Fellow of the Royal Astronomical Society, and late Member of the London Mathematical Society, quoted by Mr. Tompkins. This gives a good many more details in the proof of the electrical relationship of the divining rod than Mr. Tompkins employed in his more general type of reasoning. He begins :

"All minerals and water, more or less, emit an effluvia, composed of minute particles or physical atoms, of the substance they represent." . . . (Then follows an explanation of the reason why the depth can be judged). . . . "On arrival at the surface of the earth, those minute particles of metal, &c., having a tendency to ascend in vertical lines, the superincumbent air has also a tendency to press them down, whilst the particles are continuously driven forward by those that follow them. Now the divining rod being composed of a porous and fibrous substance, it follows through the natural order of things, that the physical atoms or minute particles of metal being driven up and down by opposing vertical forces, enter the interstices of the light porous wood, which gives them an easy passage."

This, of course, explains why the rod gets parallel to the ascending atoms so clearly that the non-scientific countryman would understand it as well as and perhaps even better than a trained physicist. Mr. Mulcaster goes on to show why it is only running water that will act on the twig, stagnant water being no good, but he has not explained why stagnant metals work. I do not feel equal to the task of supplying the omission with confidence, but on the whole it seems most likely that it has to do with "the natural order of things." Mr. Mulcaster is well aware in conclusion that in his lengthened remarks he has exploded certain ideas hitherto held on this subject for generations, and that the "electro-corpuscle" theory provides the explanation of the so-called mysterious action of the divining rod.

Perhaps enough has been written to give a fair idea of the style and scientific merit of Mr. Tompkins' book. The subject, however, should not be dismissed here. There is no question but that a large number of people of every class, except, perhaps, the purely logical, if there is such a class, are firmly persuaded that the Professional Expert Water-Finder with his Divining Rod can and does find water where ordinary folk, including geologists, fail; and what is more, that in quite a limited locality will, where sinking has failed to produce useful results, make their examination, find no water where failure has resulted, yet within a few yards assert that abundant water is to be found, which is verified on trial. Mr. Tompkins says the subject must be approached with an open mind, and he refers occasionally to X-rays and spiritualists. I hope in the following observations that I shall appear to have done so with a mind sufficiently open, but not gaping open so wide as to be practically turned inside out, a state which at any rate is conducive to sport when chasing spooks guarded by impostors.

Mr. Tompkins, who in many respects appears to be a very able exponent of the Diviner's Gift (not Art) explains how in walking over the ground he feels a sensation, a faculty possessed by only very few people, when he comes to the neighbourhood of running water, and that this sensation gets stronger as he approaches the "Head of the Spring," so that without any stick at all he could be guided to the best place for sinking for water. Further, that the sensation enables him to judge the depth as well as the quantity of water which is to be obtained. The twig serves as a kind of indicator; it is not absolutely essential, but he prefers to go to work in the recognised way; he believes "using a rod is the most successful and satisfactory to the public." So he cuts a forked stick of white thorn or hazel, as he finds these woods best. Ash is too sensitive, oak too sluggish, so the depth is over- or under-rated with these woods, while willow is too soft, so that it turns too easily and becomes useless. The depth of the water is estimated from the

"action or velocity of the rod and the amount of pressure upon the body . . . the yield by the strength and number of strata or streams which converge to the Spring Head. . . . The principle of its action is as a steam gauge on a boiler or engine, indicating the amount of pressure of the steam."

Mr. Tompkins apparently is convinced of the certainty of the method, for he says

"I should like to mention the fact that I have never had an engagement in which I have not found a spring if one existed."

Mr. Tompkins cites X-rays as an instance where a genuine physical agent exists where only a few years ago such action would have been considered impossible by scientific men; why, therefore, should there not be an emanation or "an effluvia" from the running water which might be detected by a sensitive person? I will make Mr. Tompkins a present of another analogy even more to the point. Gravitation, which on a large scale is of the most stupendous importance, so much so that even chemical energy sinks into insignificance by comparison, is yet so feeble when exerted between moderate quantities of matter that it could never have been discovered in the laboratory, and even now, with all our delicate instruments, is not provided against as a disturbing factor. By specially refined means, however, it can be detected and measured in the laboratory. Why should there not be an influence rising vertically from running water which we cannot detect in the laboratory, but which a few sensitive people might feel? We know that quite ordinary people can detect and be greatly affected by the difference in the air of two neighbouring places—one bracing, one relaxing—which cannot be directly traced to a chemical or physical cause. Again, it is maintained that there are people who are instantly aware if a cat is in the room, even though no one in the room may have seen or heard it, and who cannot remain unless the poor beast is removed. I am not referring to those who only find this out after they have seen the cat; that is merely an excess of affectation which should have been spanked out of them when they were young. The first sort, if they really exist, are certainly incredibly sensitive and are far more worthy of being considered supernatural beings than even Mr. Tompkins, if we may judge him by his book. It is hardly logical, therefore, to assert that a specially sensitive person cannot possibly be affected by the existence of water near or below him, but it is very difficult to see by what process the emanation is constrained to move vertically. Any one would have expected that if the "Spring Head" were, say, 50 feet down, there would be a greater effect upon the diviner at, say, 10 feet away from the vertical, but upon the ground, than exactly over it, and, say, 20 feet above the ground; but no, for Mr. Beaven, of Hereford, in a letter quoted, states that Mr. Tompkins in one case located a spring when on the top of a monument, while in another case he actually

"had to climb to the top of a haystack to locate the exact spot where a downward shaft would disclose the spring."

Again Mr. Tompkins on one occasion, much to the surprise of the owner, found indications of water crossing under a lawn where as a fact a water-pipe had been laid. Do the effluvia escape through the metal, or did Mr. Tompkins feel the presence of the metal itself? One of Mr. Tompkins' strongest arguments is that he adopts the professional custom of the water-finder, which is "No water, no pay," even though, to use his own words,

"to-day his name stands boldly before the British Public—in fact absolutely alone—as the only discoverer and guarantor of the 'Head of the Spring.'"

There seem really to be two questions: (1) Can the water-finder by his sensations, whether with or without a divining rod, indicate the position and yield of a hidden spring without employing any knowledge of geological conditions or experience as to the lie and appearance of the land? (2) if so, has the divining-rod anything to do with his success? Of course, if he succeeds in consequence of mere reasoning based upon geological knowledge or experience, while none the less useful to the public, he is, as far as divining is concerned, a fraud.

Reasoning beings would require very strong evidence to be absolutely satisfied that the first question can be answered in the affirmative. Yet a gentleman known to me personally, with mechanical and scientific ability and plenty of common sense, is persuaded from what he has seen that a water-finder (in this case not Mr. Tompkins) can locate hidden water, and that he does so by feeling a sensation. This water-finder asserts freely that the divining-rod has nothing to do with the business at all. This gentleman's son, formerly a student at the Royal School of Mines, now a professional engineer, in whose ability and honesty I have absolute faith, went round with the water-finder, and noticed that he, too, was cognisant of some sensation when the water-finder found indications of water. Mr. Tompkins quotes, and I suppose correctly quotes, a letter from the Chairman of the Quarter Sessions for Herefordshire to the *County Council Times*, in which he states that out of curiosity he went round with a water-diviner and found that he could use the rod successfully himself. While he has no occasion to do this professionally, he now uses it to discover leaks in the embankment of a large piece of water on his estate caused by rats or rabbits which he could not easily find otherwise. Scores of examples might be given.

As I have stated, it does not seem a logical position to take up to say that the gift as distinct from the art is impossible, even though we may require a better quality rather than quantity of evidence than is available to be satisfied as to its reality. But the gift, if it exists, is not sufficiently dramatic to impress the public. It is here, to my mind, that the rod comes in. The forked twig, held as it is, can be made to rise, fall or rotate by an almost imperceptible movement of the hands, possibly after a time unintentionally on the part of the water-diviner, and the public is impressed. For the same reason it may be well to find that water can only be met with in some inconvenient position, such as under a haystack or the cellar of the house, or the corner arch of a large granary. Ignorant and credulous people will have much more faith in you if you put them to a little inconvenience.

If the water-finders would leave it here, there could be no cause of complaint, provided, of course, that they succeed where geologically trained people fail. But when they put forward preposterous "scientific explanations" such as I have extracted, it makes it very difficult not to come to the almost inevitable conclusion that the water-finder has no case, and that the surcharging of his fees by auditors is necessary for the protection of public bodies. Perhaps among the 130 references in the Bible to the rod, staff or sceptre already referred to is this, "a whip for the horse, a bridle for the ass, and a rod for the fool's back."

C. V. BOYS.

HISTORY OF THE ART OF EXPERIMENTING.

Geschichte der Physikalischen Experimentierkunst. Von Dr. E. Gerland und Dr. F. Traumüller. Pp. 427. (Leipzig: Wilhelm Engelmann, 1899.)

THIS work, illustrated by more than four hundred woodcuts, gives a most interesting account of the apparatus used and of the investigations made by scientific inventors from the earliest times at which records exist down to the invention of Morse's printing telegraph in 1843.

One of the most interesting things that appears on the face of this history is the great mechanical ingenuity of many of the inventors of ancient times, as, for example, Hero of Alexandra, who invented a penny-in-the-slot machine, and the almost entire absence of any attempt to carry out what we would now call an experimental investigation. The experimental investigation of natural phenomena is extraordinarily modern, and the looking for mere rules of sequence in the phenomena rather than transcendental souls, spirits, effluvia, and such like efficient causes, is still more modern. This history covers a period of some four thousand years; but experimental science of the modern type is not more than three hundred years old. It is only amongst scientific men that the nature of experimental inquiry has been appreciated for as long as three hundred years. The well-educated man has not appreciated its nature for more than fifty years, and it is only within the last few years that in Britain the characteristic nature of experimental science has been at all generally understood. Even now a person is considered well educated who does not understand how to learn from experiment and observation to regulate his life. As a consequence, many so-called well-educated persons make awful fools of themselves.

In addition to the history of the subject, there are in connection with each period interesting *résumés* of its peculiarities, and of how it was an advance on its predecessors and yet did not attain to the position of subsequent workers. For example, attention is called to the way in which Gilbert, though in many ways imbued with the modern spirit of experimental inquiry, was still so dominated by the notion that magnets were possessed with some sort of soul or spirit that he cannot be rightly classed amongst the moderns, but is a sort of connecting link between them and mediæval superstitions.

There are two interesting questions that are not solved. One concerns the connection between Archimedes' observation in his bath, the method he employed to discover the amount of alloy in King Hero's crown, and the principle he enunciates in his writings as to the loss of weight of bodies immersed in a liquid. There seems no doubt from the description of the experiments he made (by observing the rise of water in a vessel when gold and silver were immersed in it) that he did not use weighings at all in his determination of the alloy in the crown. It would be interesting to know how he then discovered the amount of loss of weight of a body immersed in a liquid. What set him on observing this? The question is the more interesting in that most of the scientific workers of that age seem to have confined themselves to solving practical difficulties in the way of carrying out some project they had in hand, and were not at all imbued with the modern spirit of experimental research. The other question that needs elucidation is as to the observation of the Florentine Academicians that water could penetrate gold. This experiment used to be very commonly quoted to prove the ultimate porosity of solids, but it does not seem to have been repeated, and there are very grave doubts as to the genuineness of this penetration. It seems much more likely that the gold cracked, and that the Florentines did not observe this.

It has several times happened that all the necessary principles involved in subsequent inventions have been discovered, and attempts made to apply them long before the inventions were brought into actual use. In most cases it seems to have been the want of means or of push of the inventor that prevented him from getting his invention into use. There is a generally received notion that this want of success has been usually due to want of practical ability to get over difficulties that arise in actual use. This seems to have been true to only a very small degree. A very remarkable instance of an old invention coming into use is that of heat engines. Hero of Alexandria invented several forms of heat engine, including that latest development of steam engines a turbo-motor; yet it was only during last century that any serious use was made of them, unless imposing on the worshippers in Egyptian temples can be called a serious use. The rate of evolution of the steam engine has been most remarkable. Invented by Hero, it languished in an amœboid condition for many centuries, and then within two hundred years it developed into its present highly organised family of many genera and species. If a future geologist were to exhume the remains of steam engines, and were to have some means of determining the ages that elapsed between Hero's engines and that of Savery, and from these data were to evolve a chronology of the recent developments, he could hardly avoid concluding that it took at least a million years to develop the engines of a modern steamship from Savery's engine. Many other forms of engine have been proposed. Huygens' gunpowder engine is a natural parent of gas engines, and it seems possible that some smokeless explosive might be used for driving motor-cars; for though the fuel would be heavy the mechanism might be simple, and the opportunity for varying the work done at each stroke very considerable, so that its adaptability to the circumstances of motor-car propulsion would be great.

The work is so full of interesting matter that it would be hopeless, in a short review, to call attention to the tenth part of its contents. Accounts of Egyptian, Greek, Roman and Alexandrian inventions are followed by accounts of those of the Byzantines, Arabians and of the Middle Ages. Science progressed slowly in these dark ages. Ten pages suffice for the whole of the inventions of Europe for this thousand years. While the energies of mankind were divided between fasting and praying for others, and fighting and preying on others, there was but little time or opportunity for the study of nature. With the sixteenth century the tide of evolution of the means of studying nature had begun strongly to flow. At first rising slowly it has in this last century come like the bore on the Amazon, almost overwhelming us with the rapidity of its development.

G. F. F. G.

OUR BOOK SHELF.

The Diseases of Children. By G. Elder and J. S. Fowler. Pp. xii + 391. (London: C. Griffin and Co., Ltd., 1899.)

FEW things show more clearly the advance made in the practice of medicine within the last thirty years than the way in which the diseases of children are now regarded as compared with the place assigned to them a generation or so ago.

It was thought then that to attend to the common ailments of women and children, those of children especially, was work that scarcely demanded the preparation of a complete medical curriculum. Even a professor of medicine at one of the leading universities had the courage within living memory to say publicly that a two years' course would be quite enough for successful practice "among women and children."

Nowadays all this has changed. It is universally recognised that the physiology and the ailments of men are not a whit more intricate than those of women, and that both are simpler than those of children. To treat young children successfully requires, not only all the training and knowledge every good practitioner ought to posess, but important additions. Some of these additions, moreover, are natural gifts which cannot be acquired by any amount of training or patience. To be able to read a child's nature easily is as much a gift as a fine ear for music. Some men and women have it, and many more are completely without it. To succeed as specialists in children's ailments it is essential not to be without it.

The work before us is intended mainly for students, and one of its aims is to show them how and what to observe. A large part of the book is concerned with the physiology of growth, of nutrition and of the nervous system. Many of the illustrations are specially good.

The sections devoted to the study of diseases of the various systems, digestive, circulatory, &c., suffer from the condensation necessary in a work of this size. It is a hopeless business to try to make pemmican attractive. But, on the other hand, pemmican has its uses, and a book small enough to be carried to the bedside in a hospital ward will often help a student more, for a time, than larger and more interesting works could do. These he will read later and with a mind more ready to appreciate them.

Fowler and Elder's manual will not displace Ashby and Wright's on the same subject, but it is a sound and trustworthy guide in a difficult department of medical practice.

Analyses Électrolytiques. By Ad. Minet. Pp. 170 (Paris: Gauthier-Villars, Masson et Cie, 1899.)

THIS handy volume, which appears as one of the "Encyclopédie scientifique des Aide-Mémoire," affords another indication of the continually increasing application of electricity to chemical analysis. About a third of the book is devoted to the description of apparatus used in electro-chemical analysis and to general considerations of a practical and theoretical nature. The latter contain certain inaccuracies which indicate that the author is not conversant with the advances made during the last decade, in regard to our knowledge of the nature of salt solutions on the basis of the theory of electrolytic dissociation.

The second and third chapters deal respectively with the analysis of metalloids and with the quantitative determination of the metals when present in solutions free from other metals. The fourth chapter treats of the separation and determination of the metals in a mixture; while the last is devoted to a few technical applications, such as the analysis of industrial copper, of bronzes, and of brass.

The practical portion of the book is clearly written; but on account of the lack of details in the case of a considerable number of the analyses, the book can scarcely be recommended to electro-chemical students for use in the laboratory.

Essais des Huiles Essentielles. By Henri Labbé, Ingénieur-Chimiste. Pp. 187. (Paris: Masson et Cie.)

THIS neat little volume, which forms part of the "Encyclopédie scientifique des Aide-Mémoire," published under the direction of M. Leauté, is intended as an introduction to the analysis of essential oils, substances which, according to the author, are very liable to adulteration.

The directions given for analysis are too general and brief to be of real utility to the practical analyst, but the properties of the pure products, compiled from Schimmel and Co.'s publications and from other trustworthy sources, are carefully tabulated, so that the book will at least be serviceable for purposes of reference.

Chemistry for Organised Schools of Science. By S. Parrish, B.Sc., A.R.C.S. With Introduction by Dr. D. Forsyth. Pp. xiv + 262. (London: Macmillan and Co., Ltd., 1899.)

THE course of experimental work described in this volume is designed for students in Schools of Science of the Department of Science and Art during their first two years of study. It is the outcome of experience, and represents the work which pupils from thirteen to fifteen years of age can do and understand. Following the reformed plan of teaching chemistry, the course begins with simple chemical manipulations, weighing, solutions, distillation, the preparation of common gases, composition of water and air, formation of salts, carbon and its oxides and a few organic compounds. In the second year's course easy quantitative experiments are given, and attention is paid to the laws of chemical combination, symbols, formulæ, &c. The halogens, sulphur and its compounds, the estimation of volume, are among other subjects dealt with. The test-tubing exercises, which once formed the chief part of the work of the student of elementary chemistry, are omitted altogether; and in their place we have a rationally constructed course of work, in which the intimate relation between chemistry and physics is brought out. The pupil who is fortunate enough to receive instruction on these lines will be placed in the receptive intellectual attitude which should be the aim of all scientific education.

Natural and Artificial Methods of Ventilation. Pp. 66 + xvi. (London: Robert Boyle and Son, Ltd., 1899.)

THERE is a considerable difference of opinion among experts as to the most satisfactory system of ventilation. The system by which fresh, warm air is forced into rooms at the top while foul air escapes at the bottom has been introduced into a number of buildings; but the compilers of the present volume give extracts and diagrams from papers and reports to show that this method is wrong in principle, and inefficient in practice. It is held that the heating of a building should always be separate and distinct from that of the air supply, and that the only satisfactory means of ventilation is obtained by extracting the vitiated air near the ceilings of rooms, and admitting the fresh air at lower levels. This "natural" system has been successfully introduced by Messrs. Boyle into several public buildings.

Man, the Microcosm. Part I. The Nature of Man. By Leonard Hall, M.A. Pp. 82. (London: Williams and Norgate, 1899.)

DEFINING a monad as any living organism which consists of only one cell, the author's thesis is that man is a community of monads, each of which is a conscious being, and that "human consciousness must consist of the combined and co-ordinated consciousness of the individual monads." The theory is used to explain many facts concerning the nature of man as an individual and as a member of a social community.

The Reliquary and Illustrated Archaeologist. Edited by J. Romilly Allen. New Series. Vol. v. Pp. 288. (London: Bemrose and Sons, Ltd., 1899.)

MANY articles and notes of interest to all students of archæology are contained in this new volume, comprising the four quarterly numbers issued during the present year. The numerous illustrations of places and objects of archæological significance add to the attractiveness of a volume which appeals to every one interested in antiquities.

LETTERS TO THE EDITOR.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

Botany and the Indian Forest Department.

IN the issue of NATURE of this date I find the second part of Sir G. King's presidential address of Section K, Botany, delivered at the Dover meeting of the British Association. At the end of that address Sir G. King has made a strong attack on the Indian Forest Department, and on the teaching of botany at Coopers Hill College. He maintains that the forest officers trained in this country go out to India with an insufficient knowledge of systematic botany, and that they, on arrival in India, are not encouraged to familiarise themselves with the contents of the forests under their charge.

These assertions are in some respects not in accordance with the facts of the case, and in others they show that Sir G. King, in spite of his long Indian experience, has failed to grasp the real issues. I trust you will permit me to substantiate these two points.

To begin with, Sir G. King puts the cart before the horse. If, as he maintains, the ordinary forest officer educated in England now arrives in India without sufficient knowledge to enable him to recognise from their botanical characters the most well-marked Indian trees, it is chiefly due to the fact that it is now a days almost impossible to secure a botanical teacher in this country who can impart the necessary knowledge to the students. Sir G. King feels this himself, hence his lamentations, at the end of his address, over the decay of the study of systematic botany in Britain. I feel sure that Sir W. Thiselton-Dyer will bear me out when I state that no botanical teacher has been appointed to Coopers Hill College except with his, and latterly also with Dr. D. H. Scott's, advice. They have been good enough to recommend to us the gentlemen whom they considered most suitable for our requirements, but, alas! not one of them, though all were excellent and even famous botanists in other respects, was a systematic botanist in the sense demanded by Sir G. King. Hence I must turn round upon him and say: "Provide well-equipped systematic botanists, and we shall be only too glad to have one of them." In other words, the main difficulty lies with the botanists of the present age, and not with the Forest Department.

On the other hand, we are not free from blame. Until the year 1890 botany was a compulsory subject in our entrance examination, but in that year it was, against my advice, made an optional subject. This, I believe, was due to the influence of the headmasters of our great public schools, who desired to pass their pupils straight into the service, without being obliged to teach special subjects, such as botany. I do not desire to discuss the general question here involved, but I do wish to state that the action in the direction just indicated was decidedly injurious to our special requirements. I am happy to say that during the last year botany has once more been placed amongst those subjects which every candidate for entrance into the forest branch of Coopers Hill College will have to take up.

As for myself, I may state that, ever since I started the forest branch of this College in 1885, I have constantly urged our botanical teachers to extend the study of systematic botany at the expense of other branches, such as physiology. But what with young men trained on the ordinary lines of our public schools, and with teachers with a decided leaning to branches of botany other than systematic, it has been a hard struggle. The otherwise excellent teachers of botany, whom we have had so far, did their best to take up systematic botany on the lines required by us; but that is a branch not learned in a day, and the first two of our botanists left us, for better appointments than we could offer, when they had fallen in with our requirement.

And yet I think Sir G. King goes too far when he states that the ordinary forest officer educated in England is unable to recognise from their botanical characters the most well-marked Indian trees. Cases like this do, no doubt, occur; but I am sure that Sir G. King's assertion does not hold good in the case of many of the men who have been sent to India. Indeed, several of them have developed a decided leaning towards systematic botany. At the same time, the task is, in a great part of India, far more difficult than would appear from Sir G. King's words. I should like to know what he understands by "the most well-marked Indian trees." There are some 4000 different species of trees and woody shrubs in Burma, and about half that number in Bengal-Assam. If Sir G. King expects our forest officers on arrival in the country to recognise even a moderate fraction of these species, then he aims at impossibilities, and his enthusiasm for systematic botany has carried him far beyond reasonable limits. To do what he requires demands a thoroughly trained botanical specialist; and even such a one would require many years to become acquainted with the trees, shrubs and herbs (as demanded by Sir G. King) of an Indian jungle in Burma, Bengal and many other parts of India. For such things the ordinary Indian forest officer has no time.

The statement made by Sir G. King, that the young forest officer on arrival in India is not encouraged to familiarise himself with the contents of the forests under his charge, is not in accordance with the facts of the case. On the contrary, it is made the first duty of the young officer, apart from the study of the language of the people. Sir G. King himself enumerates fourteen forest officers who, during the last thirty years, have done good botanical work. Of these, five have made important contributions to the systematic botany of India. Of the other nine, one was trained at Coopers Hill. Considering that all the men sent out from Coopers Hill are as yet young, and that to my certain knowledge several of them are likely to become botanists, I think Sir G. King's strictures are not justified. Unfortunately, he looks at the matter entirely from the enthusiastic botanist's point of view.

The Government of India does not wish every Indian forest officer to be a botanist. It is desirable that every now and then one of them should take up the subject as a speciality, but it would be disastrous if all took that line. I have no hesitation in saying that as soon as a forest officer takes up botany as a speciality he is, rare cases excepted, likely to become an indifferent forest officer. The ordinary officer of that class has no time for special botanical study.

Forestry is perhaps not a science in itself, but an industry based upon various branches of science, amongst which botany, geology and entomology are the most important. The forest officer cannot be an expert in each of these. To demand such a thing would be just as unreasonable as to demand that a medical man should be an expert in chemistry. The one is as impossible as the other; to become either takes practically a life-time. With the enormous growth of the several branches of science a very minute specialisation has become an absolute necessity, since only a very small fraction of men can be classed as geniuses, while the rest must be rated at the average capacity of the human race. The student of one branch must depend on the work of students in other branches. Thus the forester, instead of being the assistant of the botanist (as Sir G. King seems inclined to demand), must rely on the professional botanist for all the finer and more intricate problems of botany. All he requires is to acquire a sufficient knowledge of botany, so that he may utilise what the professional botanist tells him. For more he has no time, because he has to attend to quite another class of business. The Indian forest officer is an estate manager on a large scale; he must manage his estates in such a manner that they yield the largest possible amount of useful produce with the least possible outlay. For that end his time is taken up by sylvicultural and administrative duties, leaving but little of it for the special study of any of the branches of science upon which systematic forest management is based.

No doubt many of the pioneers of Indian forestry were botanists, but by no means all. Take, for instance, the protection of the forests against fire, a matter to which Sir G. King gives prominence. He himself states that Lieutenant (now General) Michael was the first who was successful in this direction in Madras. I may add that, as far as Central and Northern India are concerned, Colonel Pearson was the first to introduce successful fire conservancy. And yet neither of these two gentlemen will, I feel sure, claim to be a great botanist.

Sir D. Brandis, to whom, as Sir G. King points out, we owe, for the most part, the organisation of the Indian Forest Department, no doubt was a botanist; but he brought about that organisation, not as a botanist, but as an able forester and administrator of extraordinary energy.

Botany is a branch of science the study of which is most fascinating; but the faculties which produce a great botanist do not necessarily include those which are required to produce a great administrator; and herein lies the difficulty, in so far as the Indian Forest Department is concerned. I could point out more than one botanist who occupied the post of the head of the Forest Department in a province, and who could not possibly be counted amongst the successful forest administrators of India. In nearly all these cases so much time was given to botany that little—or, at any rate, not enough—time remained for the proper administration of the extensive Government forest estates which supply the people of the country with the necessary forest produce, and over and above yield now an annual net revenue of a million pounds. These results would be most seriously imperilled if our Indian forest officers were to take the line which Sir G. King recommends to them.

Dark Lightning Flashes.

As an amateur photographer of cloud-scenes, I have taken the image of the setting sun surrounded by clouds on many occasions. I never remember developing a plate in which the image was reversed after an ordinary rapid exposure. Lightning flashes, one would think, ought to be still more rarely reversed, if the chemical reactions of the salts in the gelatine film are solely responsible for the phenomenon; yet dark lightning flashes are not infrequently visible in the developed plates of a thunderstorm.

Dr. Lockyer's interesting photographs (vol. lx., p. 570) of dark flashes with bright cores suggest to my mind another interpretation. A lightning flash (and, for the matter of that, an electric spark) is doubtless a complex phenomenon. A disruptive discharge of high tensional electricity through the atmosphere represents, I take it, a core of rarefied (because incandescent) gases surrounded by an envelope of compressed air. Mr. C. V. Boys has shown (NATURE, vol. xlvii. p. 420) that "a wave or shell of compressed air gives rise to an image on the plate in which there is a dark line and a light line within it. Similarly, a wave of rarefaction must produce a light line with a dark line within it." Surely we have then in the lightning flash itself, when rightly illumined, the necessary data for the production of an image—a bright line edged with two dark lines, as represented in Dr. Lockyer's photographs. In such cases the advantages of a diffused illumination of the background of the scape are obvious. Possibly Mr. S. Bidwell's interpretation of the double flash is the correct one.

Hove, October 21. W. AINSLIE HOLLIS.

IT seems to me difficult to compare the photographic brightness of the disc of the setting sun with a brilliant flash of lightning. For my part I consider that lightning flashes give us every chance of obtaining photographic reversals, for they can be photographed at very close distances, amounting to a few hundred yards, while the rays from the sun's disc when near the horizon must pass through a long range of dense atmosphere which cuts off the most actinic and therefore photographic rays.

With regard to the second portion of Mr. Hollis' letter, the illustration in my article (NATURE, vol. lx. p. 573, Fig. 6) disproves rather than proves his suggestion in my estimation. If, as he assumes, the core may be considered the actual spark, and the outer portion the image of the wave or shell of compressed air, then, as the latter is not so luminous as the core, it ought to be best visible by reason of contrast against a bright background. A glance at Fig. 6 shows that this is not the case, for at C the core exists practically alone with an illuminated background, while without the background at A and B it is most developed.

I cannot convince myself that the large dark flash is a double one. A close examination of the negative strengthens the view that it is single, and the general appearance of the ramifications endorses it. WILLIAM J. S. LOCKYER.

A Gutta-percha Plant.

IN your issue of October 19 you report a communication made to the French Academy of Sciences by Messrs. Dybowski and C. Fron regarding the cultivation of *Eucommia ulmoïdes*, a plant said by them to contain gutta-percha. I am naturally much interested in the possibility of this interesting tree, the "Tu chung" of the Chinese, becoming of economic importance, as some years ago I investigated the bark and leaves of this plant with regard to the peculiar cells containing a rubber-like substance (*Trans. Linnean Society*, 1892, vol. iii., part 7).

Gutta-percha and caoutchouc behave very similarly towards many solvents; but the fact that the contents of these cells were dissolved or partially dissolved by turpentine at ordinary temperatures, whereas gutta-percha is only soluble in hot turpentine, led me to the conclusion that the contents of these cells were caoutchouc. This substance is much more frequently met with in the laticiferous cells than gutta-percha, which is almost restricted to the natural order Sapotaceæ. Eucommia will therefore, I think, be found to be a rubber, and not a gutta-percha yielding plant.

But in either case it is obvious that, with the opening up of China, this plant may become of great economic importance if, as seems probable from the investigations of Dybowski and Fron, it is easily cultivated and propagated.

Halo Round a Shadow.

ON a winter morning some years ago I was driving in a dog-cart from the Lizard across the Goonhilly Downs whilst a dense mist or cloud was matted down on the ground.

Our heads were in bright sunshine, which formed a coloured halo round the shadow of each of our heads on the mist as we travelled on. Half an hour later the mist was more diffused, and we saw a white mist bow in the sky. HOWARD FOX.

Falmouth, October 28.

ON THE DISTRIBUTION OF THE VARIOUS CHEMICAL GROUPS OF STARS.[1]

II.

THE results so far referred to have regard to the stars with dark lines in their spectra, but besides these there are many so-called bright-line stars.

I should state that there has necessarily been a change of front in our views with regard to these bright-line stars since they were first classified with nebulæ by Pickering and myself.

The nebulæ are separated from stars by the fact that in their case we have to deal with bright lines, that is to say, we are dealing with radiation phenomena, and not with absorption phenomena, as in the case of the stars so far considered; and in the first instance it was imagined that the bright-line stars were, from the chemical point of view, practically nebulæ, although they appeared as stars, because the brightest condensations of them were so limited or so far away that they gave a star-like appearance in the telescope.

Since that first grouping of bright-line stars, by the work chiefly of the American astronomers it has been found that in a large number of cases *they have also dark lines in their spectra*, and that being so we must classify them by their dark lines instead of by their bright ones; and the bright-line stars thus considered chiefly generality to only two degrees, and the greatest departure, the greatest galactic latitude, was something within nine degrees. That was the story in 1891. Two years afterwards Campbell, another distinguished American astronomer, also interested himself in this question of the bright-line stars, and he discussed them, his catalogue containing fifty-five as opposed to Pickering's thirty-three. He found also that they were collected almost exclusively in the Milky Way, and that outside the Milky Way practically none had ever been observed. The importance of this result I will indicate by and by, but in the meantime I can throw on the screen a very useful map which Campbell prepared. The central line of that map represents the galactic zone, the plane of the Milky Way, and he marks along it the different galactic longitudes, showing above and below the plane just a few degrees of galactic latitude north and south, sufficient to enable him to plot upon it all the bright-line stars which he discussed. The diagram shows that all these bright-line stars really are close to the central plane of the Milky Way. Only one out of the fifty-five is more than nine degrees from it, and this lies in a projecting spur, so that we cannot really say that that is out of the Milky Way. It is remarkable that these bright-line stars are not equally distributed along the Milky Way. They are chiefly condensed in two opposite regions, and there is one region in which they are markedly absent. The glass globe will

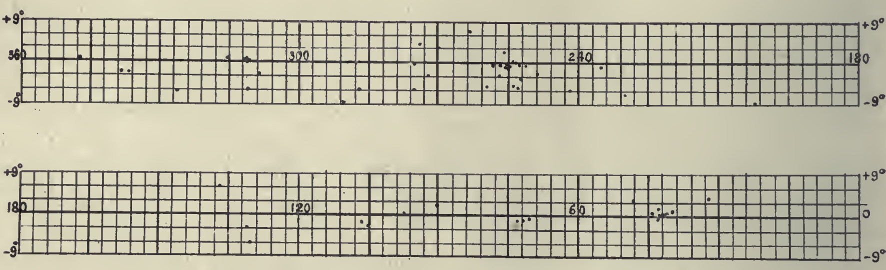

FIG. 3.—Distribution of the Wolf-Rayet stars in the Milky Way.

turn out to be gaseous stars, *with a difference.* What is that difference? It is this, I think: in the case of the bright-line stars we are dealing with the condensations of the most disturbed nebulæ in the heavens; together with the light which we get from the nucleus of that nebula which appears as a star and can be spectroscopically classified with the other dark-line stars, inasmuch as the surrounding vapours close to the star produce absorption, and therefore give us dark lines; other parts of the nebulæ, probably those further afield, give us bright lines which mix with the dark ones. Therefore we get both bright lines and dark lines under these conditions. So far as the result goes up to the present moment, it looks as we have now to consider that these bright-line stars, instead of being nebulæ merely, are gaseous stars at a very high temperature, in consequence of the fact that the nebula which is surrounding them, which is falling upon them, is increasing the temperature of the central mass by the change of *vis viva* into heat. Pickering,[2] in his discussion of these stars, had thirty-three to deal with, and he found that there was a wonderful tendency among these to group themselves along the Milky Way; that very few of them, in fact, lay outside its central plane; that is to say, the galactic latitude, as it is called, the distance in degrees from the plane was limited in the

show how the matter stands, I think, rather conveniently. We have the Milky Way represented by red tape. The secondary Milky Way, which starts from it at one point of the heavens and meets it again, is also indicated. Dark wafers mark the galactic longitudes and latitudes of the bright-line stars. We find that these stars begin just before the doubling commences. They go on, and are sometimes very numerous, and they end just after the doubling ends; and we notice there is a long range of the Milky Way where it is single in which there is absolutely no bright-line star at all. It looks, therefore, very much as if there is a something connected with this doubling of the Milky Way which produces the conditions which generate these bright-line stars.

By the labours of Dunér, Pickering, McClean and Campbell, we are beginning to get very definite notions as to the distribution of the various chemically different stars in relation to the Milky Way. How about the nebulæ from the point of view of chemical distribution? Here we are in difficulties.

I have already stated that with regard to the general question of the nebulæ it is impossible to speak with certainty, because at present there has not been sufficient time and there has not been a sufficient number of observers at work to classify the thousands of "nebulæ" which we now know of into those which give us the gaseous spectrum, and those which are entirely different, apparently, in their constitution, and only give us what is called a continuous spectrum; but still we can go a

[1] A Lecture to Working Men, delivered at the Museum of Practical Geology, on April 10, by Prof. Sir Norman Lockyer, K.C.B., F.R.S. (Continued from vol. lx., p. 620.)

[2] *Astr. Nach.*, No. 2025.

little way in this direction by means of some figures which I have noted. The point is to see whether there is any difference in the distribution of those nebulæ, which are undoubtedly masses of gas, and give us the so-called nebulous spectrum, and those other nebulæ about which at present we know very little, but give us so-called continuous spectra. It is clear that on this point, undoubtedly at some future time, even if we cannot do it now, a great deal will be learned. The table I give brings the results up to the year 1894. If we take the region near the Milky Way, the region bounded by 10° galactic latitude north and south, and consider the planetary nebulæ distinguished by bright-line spectra, we find that there are forty-two; but if we deal with those which are further than 10° from the Milky Way, that number drops to five. If we take other nebulæ, not necessarily planetary, but gaseous like planetary nebulæ, inasmuch as they give us a spectrum of bright lines, we find that there are twenty-two in or near the Milky Way, and only six outside. If we take the so-called nebulæ known to have continuous spectra, which need not be nebulæ at all—we only imagine them to be nebulæ because they are so far away that we cannot get a really true account of them—we find that the conditions are absolutely reversed. There are only fourteen of them in the plane of the Milky Way, but there are forty-three lying outside it; so that the percentage within 10° of the Milky Way comes out to be eighty-four in the case of the planetary and the other nebulæ which give us bright lines, and in nebulæ with continuous spectra only 25. Therefore we get an absolute identity of result with regard to the bright-line stars and the other objects which give us bright-line spectra.

There is another class of bodies of extreme interest. In fact, to some they are more interesting than all the other stars in the heavens put together (because they are "new stars"); each new star being supposed to be a new creation, so that for this reason everybody is very much agog to find out what they are like. When we come to examine these so-called new stars we find that they also are almost absolutely limited to the Milky Way, as shown in the table which gives the number of new stars, so-called, which have been observed in historic times. It begins at 134 years before Christ, and it ends last year. The number of stars thus reported as new stars is thirty-one, and of these only three have been seen outside the Milky Way. The glass globe will show in a convenient way what the facts are with regard to the new stars. The bright line stars being distinguished by dark wafers, the new stars are shown by white wafers. We notice that where we get practically the greatest number of dark wafers we get a considerable number of white ones. That means that these new stars take their origin in the same part of space as that occupied by the bright-line stars, and it is also interesting to point out that the void which I indicated where the Milky Way is single, where there were no bright-line stars, is equally true for the new stars; only one new star has been recorded in this region.

As I have said, a great deal of interest has been attached by many people to the question of the new stars, for the reason that whenever a new star appeared in a part of the heavens where no star was seen before, it was imagined that something miraculous and wonderful had happened. That was justifiable while we were ignorant, but recent work has shown, I think almost to a certainty, that the real genesis of a new star is simply this. We have near the Milky Way a great number of nebulæ, planetary or otherwise; we have more planetary nebulæ near the Milky Way than in any other part of the heavens; the nebulous patches also observed in it may include streams of meteorites rushing about under the influence of gravity; the origin of a new star is due to the circumstance that one of these unchronicled nebulæ suddenly finds itself invaded by one of these streams of meteorites. There is a clash. These meteorites we know enter our own atmosphere at the rate of thirty-three miles a second, and we may therefore be justified in assuming that any meteoritic stream in space, even in the Milky Way, would not be going very much more slowly. If we get this rapidly-moving stream passing through a nebula, which is supposed to be a mass of meteorites more or less at rest, of course we must get collisions; of course, also, we shall get heat, and therefore light. When the stream has passed through the nebula the luminosity will dim and ultimately, attention having been called by this cataclysm to that particular part of space, we shall find that there is a

FIG. 4.—The Milky Way, where double in relation to the Equator and Gould's belt of stars, showing that the bright-line stars (dark wafers) and new stars (white wafers) are limited to the Milky Way.

nebula there. This has always been so; and therefore in the case of new stars we must always expect to get indications of the existence of two bodies, the intruder and the body intruded upon.

We must also expect, if we are dealing with small particles of meteoritic dust, that the action will be very quick, and that the war will be soon over. All this really agrees with the facts. I will, just in order to point my remarks, show what happened in the case of the new star we were fortunate enough to have the opportunity of observing in the northern hemisphere not very long ago, the new star in the constellation Auriga. We have in the diagram the stars in the region in question; a black arrow indicates a dark space in the heavens where there is no star. The next drawing shows the same stars and the same region of the heavens; but we observe that in the centre is a star, which is the new star. In the spectrum of it we obtained undoubted indications of the fact that we were dealing with two different masses of matter; for the reason that if you take the chief spectral lines marked G, *h*, H and K, that is to say, the lines of hydrogen and of calcium, we find both bright lines and dark lines, which being interpreted means that hydrogen and calcium were both giving out light and stopping light. We cannot imagine that the *same* particles of calcium and of hydrogen were both giving out light and stopping light; there must have been different particles of hydrogen and calcium giving light and different particles of hydrogen and calcium stopping light; and if we look at the photograph carefully we find that the bright lines and the dark lines are side by side, and we know that that means a change of wave-length in consequence of movement, and we also know from the change of wave-length indicated that the differential velocity of the particles which gave us the bright hydrogen and calcium, and the dark hydrogen and calcium, must have been something like 500 miles a second. In that way we obtained indisputable proof that we were really dealing with two perfectly different series of particles moving in opposite directions, and that that was the reason we got that sudden illumination in the heavens which as suddenly died out until finally a nebula previously undiscovered was found to occupy the place. The nebula is really not the result, the nebula was the cause, but we did not know of its existence until our special attention had been drawn to that part of the heavens.

So much then for the first statement of facts relating to the distribution of the various star groups and nebular groups in the most general form. The next question is, Can we say anything about the distances of these gaseous stars, bright line stars, and other types? The way in which an astronomer attempts to determine the different distances which the stars occupy in relation to the earth may really be very well grasped, I think, by considering what happens to one when travelling in a railway train. If the train is going fairly quickly, and we look at the near objects, we find that they appear to rush by so rapidly that they tire the eye, and one naturally looks at the objects which are more distant; the more distant the object we look at is the more slowly it appears to move, and the less the eye is fatigued. Now, suppose that instead of the train rushing through the country and passing the objects which we regard under these different conditions, the different objects are rushing past us at rest. Then, obviously, those things which appear to be moving most quickly will be those nearest, and the more distant objects, just because they are distant, will appear to move more slowly; that is to say, we shall get what is called a large "proper motion"—in the case of the objects nearest to us—and a small "proper motion"—in the case of the bodies which are further away.

This question has been attacked with regard to the stars in magnificent fashion by a great number of astronomers. A photograph will show in a diagrammatic form the very various rates of proper motion which have been assigned by careful observation to a very great number of the stars. In the chart the amount of proper motion of the various stars is indicated by the lengths of the lines which proceed from them, and the direction in which the various stars appear to be moving is also indicated by the direction which these lines take. Some of the lines are extremely long; they seem to stretch over a large part of the sky. Of course the scale is an exaggerated one, but it is the *relative* motion that we have chiefly to deal with, and we find that on the same scale in some cases the lines are extremely short; so that the diagram tells us that the amount of proper motion is apt to vary very considerably. We have large proper motions and small proper motions among the stars.

It was Mr. Monck who was the first to show in 1892[1] that the gaseous stars had the smallest proper motion; that is to say, that the hottest stars were further away from us than the cooler ones. That is a good, definite statement, and one which everybody can understand. He next found that the proto-metallic stars—that is to say, the stars not so hot as the gaseous ones, but hotter than the metallic ones—had the next smaller proper motion. This, of course, indicates that the metallic stars are the nearest to us unless proper motion does not depend upon distance, but rather upon a greater average velocity in space. It has been shown, however, by considering the sun's movement in space, that this view probably may be neglected. The first discussion of proper motion then went to show, roughly, that the hotter a star is the further away from us it is; and it made out a fair case for the conclusion that the sun forms one of a group or cluster of stars in which the predominating type of spectrum is similar to its own.

Kapteyn carried the inquiry a stage further.[2] Working upon the idea that stars with the greatest proper motion are on the average the nearest, the part of the proper motion due to the sun's translation in space he considered must depend strictly upon the distance, and he determined this by resolving the observed proper motion along a great circle passing through the point of space towards which the sun is moving, which is called the apex of the sun's way, and reducing to a point 90° from the apex. His results were practically the same as those obtained by taking the individual proper motions. He also found that stars with the greatest proper motion are mainly metallic, and have no regard at all to the Milky Way; that stars with the smallest and no observable proper motion are gaseous and proto-metallic, including a few metallic ones which have collected in the galactic plane. In this he agrees with the prior observations to which I have drawn attention. In the table which I now give the mean proper motion is shown.

Relation between Spectra and Proper Motions of Stars (Kapteyn).

Mean proper motion.	Gaseous and proto-metallic stars.	Metallic stars.	Metallic flutings.	Ratio, metallic to gaseous.
″ 1·39	3	51	—	17·0
0·52	12	66	1	5·5
0·35	14	66	—	4·7
0·24	34	124	—	3·6
0·18	35	67	3	1·9
Inappreciable	79	35	1	0·44

The table deals with something over a second, which may be looked upon as a great proper motion, down to the tenth of a second, which may be regarded as a small one;

1 "Astronomy and Astro-Physics," xviii., 2, p. 876.
2 Amsterdam Academy of Science, 1893.

and we find that the gaseous and proto-metallic stars increase in number as the proper motion decreases. We find also the ratio of the metallic to the gaseous and the proto-metallic. We begin with a ratio of 17, and end with something like a ratio of half, so that the results may be considered to be pretty definite. These results were obtained by Kapteyn with 591 stars which were common to Stumpe's catalogue of proper motions and the Draper catalogue dealing with spectra. The general result may, therefore, be stated that at the nearest distance the metallic stars are seventeen times more numerous than gaseous stars, and at the greatest distance they are not half the number. Here again the question arises, how far the intrinsic brightness of these bodies, in relation to their distance from us and the possible greater or less extinction of light in space, has to be taken into consideration. That is a problem which will require a considerable amount of work in the future. It is rather remarkable that if we take the stars with very great proper motion, very much greater than the average, we find with regard to four that three of them are undoubtedly metallic, but it is possible that the star 1830 Groombridge, which is always looked upon as the star which beats the record in velocity seeing that it would travel from London to Pekin in about two minutes, is not a metallic star.[1]

We are now in a position to make a general summary of the stellar distribution not only in relation to chemistry, but in relation to distance. Taking the chemistry as the basis, we can see what happens to the gaseous, proto-metallic stars and so on, with regard not only to their proper motions, but in regard to the Milky Way.

Summary of Stellar Distribution.

Group.	Proper motion.	Relation to Milky Way.
Gaseous stars	Smallest [2] (Monck)... ...	Condensed in Milky Way (Pickering and McClean)
Proto-metallic	Intermediate (Monck) ...	Brighter ones not notably condensed in Milky Way (McClean) Tend to collect in Milky Way, more especially the fainter stars (Pickering)
Metallic ...	Div. 1. Greatest (Kapteyn)	Not condensed in Milky Way (Pickering and McClean)
	Div. 2. Small (Kapteyn)	Collected in Milky Way (Kapteyn)
Mixed flutings	?	?
Carbon ...	?	?

The gaseous stars, which we have seen have the smallest proper motion, are condensed in the Milky Way. The proto-metallic stars, which have but intermediate proper motion, are notably condensed in the Milky Way according to McClean, and tend to collect in the Milky Way more especially with the fainter stars according to Pickering. When we come to deal with the metallic stars, we find that there is no special condensation in the Milky Way. The greater number are not condensed in the Milky Way.

That being so, then, we may take a still further general view. We find that the bright-line stars, the new stars, are almost exclusively in the Milky Way and are far away from us; that the gaseous stars are chiefly in the Milky Way and are far away from us; that the proto-metallic stars are not so confined to the Milky Way, and they are not so far away from us. But when we come to the metallic stars and the carbon stars they have not much obvious connection with the Milky Way, and they are close to us. Unfortunately, with regard to the metallic fluting stars the information is not certain, so that it is best not to say anything about it. Mr. McClean has dealt with a very small number, and he shows that they, like Dunér's stars, the carbon stars, have very little relation to the Milky Way. We thus obtain a tremendous separation between the hot stars with their great distance and the cooler stars with their smaller distance.

But we can go further. As the stars become hot in consequence of meteoritic collisions, we should expect to find nebulous conditions following suit; seeing that nebulæ are masses of meteorites, we should expect to find especially the gaseous nebulæ and results depending upon their presence in the region where the hottest stars exist.

The planetary nebulæ consist of streams of meteorites moving generally in spirals or in circular paths. There is no very great disturbance. We get a bright line spectrum from them, and we know they are practically limited to the Milky Way. We have found that the bright-line stars are limited to the Milky Way; they are simply stars involved in nebulæ. There again we get a connection between the Milky Way and nebulæ. The new stars are due to fixed nebulæ driven into by moving nebulæ, and they are also limited practically to the Milky Way; there again we have the nebulous touch. A piece of work which has not been done, but which badly wants doing, is to see whether those nebulous regions which Sir William Herschel was the first to chronicle have or have not a strict relation with the Milky Way. I have, in fact, made a preliminary inquiry into this matter, and it suggests that these nebulosities are most profusely distributed in the vicinity of the Milky Way just as is the case with the gaseous nebulæ.

(*To be continued.*)

[1] These stars are—

1830 Groombridge ...	...	7·04 ″ ...	Gaseous or proto-metallic.
Σ 2758... ...	... ..	5·196 ...	Metallic.
Σ 578... ...	... ...	4·049 ...	Probably metallic.

[2] Kapteyn finds small proper motions for gaseous and proto-metallic stars, but does not separate them into two groups.

SOME REMARKS ON RADIATION PHENOMENA IN A MAGNETIC FIELD.[1]

IN many articles which have recently appeared concerning the work which has been done in the study of radiation phenomena in a magnetic field, I find that, from the historical point of view, there are some statements which are not quite correct, and to which I now desire to attract attention. This appears to me desirable, as it is much easier, and much better, to test and correct errors of statement at the outset than after a lapse of time.

In the first place, it has been very generally accepted that the quartet form which occurs in the magnetic effect was first observed by M. Cornu; but on reference to the enclosed paper (*Trans. Roy. Dublin Society*, vol. vi., series ii., p. 385, read December 22, 1897), you will see that the quartet form,[2] the sextet, and other variations of the magnetic triplet were not only observed, but were photographed and exhibited to an audience in Dublin in the latter end of the year 1897. On the other hand, it was not until the following year (1898) that M. Cornu (working quite independently) announced in the *Comptes rendus* that he had observed the quartet form. Now the *Comptes rendus* being a weekly journal which is widely read, lends itself admirably to the rapid diffusion and circulation of new results, whereas the scientific *Transactions* of a local learned society are slow in appearing and little read or known outside their immediate place of publication. For this reason, the observations of M. Cornu became generally known, while mine remained unknown outside Dublin.

It is true, however, that I endeavoured to have them

[1] These remarks were addressed to Sir Norman Lockyer in the course of a correspondence, and have been thought of sufficient interest for publication.

[2] The quartets are clearly shown, as well as the triplet form, in the plate attached to the paper, and reproduced from the photographs shown at the meeting when the paper was read.

FIG. 1.

FIG. 2.—Zinc.

FIG. 3.—Zinc and Cadmium.

EXPLANATION OF PLATE.

In the accompanying plate, Fig. 1 shows the effect produced on the violet line of cadmium 4678. At the top, *a*, we have the line photographed with the magnet unexcited, that is, in the free field. Underneath this, at *b*, the same line is photographed with the magnet excited, but the field is not strong enough to resolve it into its three constituents. It accordingly appears to be merely broadened by the magnetic field. A Nicol's prism was then introduced into the path of the light and the line photographed in the same magnetic field, with the result shown at *d*, where the middle is seen to be removed from the affected line, so that it appears as a doublet. The nicol was then turned through a right angle, and the line again photographed in the same field. The result is shown at *c*, which proves that the sides of the broadened line have been cut off, while the middle has been allowed to pass. This agrees with the supposition that the magnetic field resolves the line into a triplet, but does not absolutely prove it.

The further resolution necessary to prove this point is shown in Figs. 2 and 3. In Fig. 2, a photograph of the zinc lines 4811, 4722 and 4680 is shown, and it will be observed that 4680 shows as a pure triplet, while the others do not. Fig. 3 is a photograph in a still stronger field taken from a spark passing between two electrodes, one of cadmium and one of zinc, so that the lines of cadmium and zinc are obtained simultaneously under precisely the same circumstances. It will be seen that the lines most affected are 4678 of cadmium and 4680 of zinc, and these both show as pure triplets, while the lines 4722 and 4800 show as quartets.

made generally known through the medium of the widely circulated journal NATURE, for on November 19, 1897, I sent photographic negatives to the office of NATURE for reproduction in that journal. These negatives showed the quartets as well as the pure sharp triplets and the diffuse triplets[1] which occur in the spectra of cadmium and zinc. They were produced by me in the end of October 1897, and were, I believe, the first photographic record of the actual magnetic tripling and quadrupling of the spectral lines. These negatives, however, were not considered suitable for reproduction in NATURE (see letter to NATURE, p. 173, December 23, 1897), but were subsequently enlarged and reproduced with great clearness in the *Philosophical Magazine* (April 1898).

In my letter to NATURE accompanying the negatives I did not dwell on the quartet form, as I did not wish to commit myself, or persuade others, to the belief that the quartet was really a magnetic quartet, *i.e.* produced exclusively by the magnetic field. It was quite open to belief at that time that the quartet form might be produced from the triplet by other mechanical causes, for example by reversal of the central line of the triplet, or in other ways, as noticed in my paper mentioned above. After prolonged effort I proved beyond all doubt that these variations of the triplet type (the quartet, &c.) are true magnetic perturbations, and are not due to any other cause; but this required *to be proved*, and for this purpose a very strong magnetic field was necessary.

With this field I found, as already announced in NATURE, that the quartet form becomes resolved into a sextet by the splitting up of the side lines into doublets. It is, therefore, not really a quartet after all, but a sextet.

With regard to other points, namely, the fact that the magnetic effect does not conform to the law deduced by the simple theory (viz. that $\delta\lambda \propto \lambda^2$), and the surmise that some such law might hold for groups of lines, a reference to my first paper, already mentioned (*Trans. Roy. Dub. Soc.*, December 22, 1897), will show both these points clearly emphasised there. On p. 387 I state that while some lines were converted into triplets "others photograph as doublets, or weak middled, greatly broadened lines, having the appearance of quartets; while on the other hand many lines appear to be simply broadened in the same magnetic field, and *others seem to be scarcely influenced in the same magnetic field.*" Thus the effect appeared to be lawless for the spectral lines taken as a whole in any one substance; but I go on to say that "perhaps it might be possible to group the spectral lines of each substance into sets, so that some law of wave-length might apply to the lines of each set."

At this early date I was already seeking for some such law, and I had before the close of 1897 proved that the law, whatever it might be, was *not the same* as that which governs the pressural shift of the spectral lines studied by Messrs. Humphreys and Mohler (see *Proc. Roy. Soc.* of London, January 1898).

My search has resulted in the discovery of a general law which has so far proved to be in complete agreement with all the observed facts.

With regard to the spectrum of iron, you will observe in my note in the *Proc. Roy. Soc.*, January 1898, that I was at that early date of opinion that the spectrum of iron exhibited no peculiarities of its own in the magnetic field. I examined iron early because I thought that by reason of its magnetic properties its spectral lines might show some decided peculiarities (but iron is not magnetic above 700° C., therefore my hopes were not very decided). On the whole I still adhere to that opinion, for although the spectral lines of iron show a variety of effect, yet these effects are the same in character or in kind as those which are observed in other substances. This and other matters I have already treated of fully elsewhere (*Phil. Mag.* and NATURE).

The accompanying illustrations (Figs. 1, 2, 3) have been reproduced from the plate given in the memoir read before the Royal Dublin Society on December 22, 1897. They show that the quartets were observed and photographed by the author certainly before that date.

THOMAS PRESTON.

[1] Really nonets as subsequently determined.

NOTES.

DR. JANSSEN, director of the Meudon Observatory, has issued a circular in which he announces that the success of last year's observations of the Leonid meteors from a balloon has led to arrangements being made to repeat the experiment during the forthcoming shower. Last year, a number of these meteors were observed from a balloon above Paris, though the city itself was at the time enveloped in a thick fog. It is important that numerous observations of the Leonid meteors should be made from as many places as possible; and as balloons render observers independent of cloudy skies, they are evidently of great advantage upon occasions such as that to which astronomers are looking forward. We are informed that two balloon ascents are to take place near St. Denis. The first ascent will be made on the night of November 14–15, with the *Aerostat*, and the second, on the following night, with the *Centaure*. Two seats in each balloon will be at the disposal of Dr. Janssen, who will nominate observers to occupy them, without distinction of nationality. The names of the observers will be announced at the next meeting of the French Astronomical Society, on November 8.

THE opening meeting of the new session of the Institution of Electrical Engineers will take place on Thursday, November 16, when the premiums awarded for papers read or published during the session 1898–99 will be presented, and the president, Prof. Silvanus P. Thompson, F.R.S., will deliver his inaugural address.

A SERIES of monthly lantern lectures has been arranged by the Royal Photographic Society. The first lecture will take place on Tuesday, November 7, when Mr. J. J. Vezey will describe "Some Mediæval Towns of Germany," illustrated with slides by Commander C. E. Gladstone, R.N.

THE death of Mr. Grant Allen, at the age of fifty-one removes one of the most popular of scientific authors whose writings have induced many readers to watch the workings of animate nature. His first scientific work, on "Physiological Aesthetics," was published in 1877, and was followed, in chronological order, by "The Colour Sense," "The Evolutionist at Large," "Vignettes from Nature," "Colours of Flowers," "Colin Clout's Calendar," "Flowers and their Pedigrees," "Charles Darwin," "Science in Arcady," "The Evolution of the Idea of God," &c. In addition, Mr. Allen contributed numerous articles on natural history topics to periodical literature. All his scientific articles and books are attractively composed, and they have been the means of imparting much popular instruction to general readers.

AMONG the privileges which the Hampstead Astronomical and Scientific Society is able to offer its members is the use of a reflecting telescope of 10½-inch mirror, which is erected in a small observatory on the East Heath, by permission of the London County Council. Interest in practical astronomy is aroused by this means, and the instructive lectures given at the meetings of the Society direct attention to facts and things terrestrial as well as celestial. A course of five lectures on astronomy will be given by Mr. P. E. Vizard in connection with the Society on Monday evenings, commencing on November 20. Mr. Vizard will also lecture on November 10, on the subject of the "November Meteors." A popular interest in, and practical study of, various branches of science is encouraged by the Society, and it is to be hoped that residents of Hampstead are actively supporting its efforts.

THE new session of the Royal Geographical Society will commence on Monday, November 13, when the president, Sir Clements Markham, will give a short opening address, to be followed by a paper by Mr. W. Rickmer Rickmers on his "Travels in Bokhara." The paper at the following meeting, November 27, will be by Mr. Vaughan Cornish on "Desert Sand Dunes." At the December meeting, Colonel Sir John Farquharson will probably give an "Account of the Past Twelve Years' Work of the Ordnance Survey," from the directorship of which he has recently retired. Other papers expected to be given during the session are: "An Ascent of Mount Kenya," by Mr. H. J. Mackinder; "The Work of the Yermak Ice-Breaker in the Spitsbergen Seas," by Admiral Makaroff; "Travels in Central Asia," by Captain H. H. P. Deasy; "Travels in the Region of Lake Rudolf and the Sobat River," by Captain Wellby; "Travels in Abyssinia," by Mr. H. Weld Blundell; and "Anthropogeography of British New Guinea," by Prof. Haddon.

THE *Journal* of the Society of Arts states that artificial paving stones are being successfully produced in Germany. The demand in all larger cities is said to be so good, and the expense attached to their production under former methods is so large, that any improvements on the older systems, whether in saving money or in producing a better stone, will be welcomed by almost all countries. The newest process in Germany is to mix coal-tar with sulphur and warm thoroughly; to the resulting semi-liquid mass chlorate of lime is added. After cooling, the mass is broken into small pieces, and mixed with glass or blast-furnace glass slag. This powder is then subjected to a pressure of 200 atmospheres, and reduced to the form or forms wanted. The resistance to wear and tear in use is fully half as great as that of Swedish granite. Thus it commends itself through durability equal to that of many stone roads, resistance to changes of temperature, roughness of surface—giving horses a good foothold—and, finally, non-transmission of sound. Inasmuch as the joinings are very small, dirt is avoided, and cleaning is very easy.

THE Institution of Mechanical Engineers commenced a series of monthly meetings on Friday last, when a paper was read by Mr. W. Ingham on the incrustation of iron pipes at the Torquay water works. The water supply is obtained from a tributary of the River Teign, which rises in the granite hills on a western spur of Dartmoor. The water is conveyed by two cast-iron mains to Torquay, one of them, laid in 1858, ten inches in diameter. At the time the pipes were laid, no one thought that the pure water from the Dartmoor hills would cause much deleterious action upon them. It was, therefore, with considerable surprise that at the end of eight years the delivering power of the mains was found to be reduced to 51 per cent. of their full discharging capacity. A scraper was designed, several years ago, to clean the pipes, and it is now regularly used. The scraper is pushed forward by the pressure of water acting upon pistons a little less in diameter than the diameter of the pipe. As it moves, the knives press outwards against the inside of the pipe and remove projecting nodules. The movement of the scraper through the pipes can be easily followed, when the mains are about three feet deep, by the rumbling noise it makes. The speed varies, of course, and is on the average about $2\frac{1}{2}$ miles per hour, but a speed of as much as $7\frac{1}{2}$ miles per hour can be obtained for about three-quarters of a mile on one part of the line. After scraping in 1898, the delivery was increased from 586 to 708 gallons per minute, and similar results have been recorded for many years.

WATER engineers have to give very serious consideration to the subject of incrustations upon their mains. The deposit varies, of course, according to the nature of the water conveyed. When the water is derived from wells sunk in the chalk, the coating on the pipes is of pure calcium carbonate, which forms a desirable interior surface from one point of view, if not from the other of reduction of pipe area. Mr. W. Ingham states in his paper to the Institution of Mechanical Engineers that, speaking generally, it may be laid down with a fair approximation to the truth that well waters have not as great an action on pipes as those from upland gathering grounds, but where the water is soft the corrosive action will be greater. Filtered water has also a less corrosive power than unfiltered water. Whatever protective covering is applied to pipes, soft waters will cause rusting within a few years of being laid. At Torquay six years is the outside limit when this commences, so every precaution is taken to see that the pipes are well coated. Mr. Ingham remarks that though much has been done to get a satisfactory coating to pipes, there is still considerable room for improvement, and it is hardly necessary to point out that a fortune awaits the man who can invent something that will withstand the action of soft waters.

THERE seems to be some doubt as to the genuineness of a photograph which has been exhibited at the Royal Photographic Society (picture No. 357), as we gather from a letter published by Lieut.-General Tennant (*The British Journal of Photography*, October 13). Although the writer of this note has not seen the said picture, and therefore cannot describe it, General Tennant refers to it as "a very fine picture of clouds, but I am at a loss to understand how it can have been put forward as being like an eclipse of the sun." He states further that "high in the sky there appears a bright disc partly hiding a dark one surrounded by a bright halo . . . it is as though the bright sun were passing in front of the dark surface of the moon." General Tennant, at the time of writing his letter, stated that he was quite certain that it did not represent any phase of a solar eclipse either at Quetta (the place where the photograph was taken) or elsewhere; but in a more recent communication to the same journal (October 20) he is led to alter his opinion after seeing a photograph of the sun passing behind a church spire, saying that the peculiar appearance may possibly be the result of reversion. The latter opinion of General Tennant is no doubt the correct explanation of the abnormal appearance of the photograph in question, but the photographer of picture No. 357 may be glad to learn that a similar photograph was obtained at Sir Norman Lockyer's camp at Viziadrug, India, during the same eclipse. The camera used was a folding kodak, taking pictures 5 by 4 inches, and the exposures, four in all, were made by a blue-jacket. Each exposure lasted fifteen seconds, but, during the last, totality ended before the given time of exposure was concluded. This photograph shows the small crescent of the sun that appeared from behind the moon as black, while the disc of the moon is not black (as it appeared in the other three photographs), but nearly white, the density being just sufficient to differentiate between the corona and the moon's limb. This photograph is seemingly the same as No. 357, mentioned above, and its peculiarity is due, without doubt, to a reversal caused by the extreme brilliance of the uncovered portion of the sun.

THE photographic process of preparing textile designs, invented by Mr. Jan Szczepanik, was referred to by Prof. R. Beaumont in his opening address at the Yorkshire College, and is described in *Pearson's Magazine*. Prof. Beaumont has personally examined the invention, and has seen designs worked out by the new process in the premises of the Szczepanik Company at Paris. The object of the photographic appliances of Szczepanik is to take the artistic sketch, and, without any modification of the same, to enlarge it to scale, to transfer it on to ruled paper or point paper, and mark it with the thousands and millions of dots arranged in the proper orders for the development of the several parts of the pattern, in the weaves necessary for giving to each suitable precision of character when woven. Prof. Beaumont considers that the apparatus of Szczepanik is capable of producing designs in which there is considerable diversity of woven detail, so that it is purely a question of whether the designs thus obtained are legible for all practical purposes. There must of course be limitations to its utility, as there are to all automatic and mechanical appliances. Yet if it can be employed in accelerating the process of designing large patterns, it should have the serious attention of all who desire the further development of the weaving industries.

FROM a note in the *Journal* of the Society of Arts, it appears that there is reason to believe that in the near future mercury will be one of the most valuable of the numerous metallic products of New South Wales. Native quicksilver was found so far back as 1841 in the Cudgegong River, an auriferous stream, which flows through a portion of the western goldfields of the Colony. Cinnabar had previously been found in the same locality. Though efforts were made by the Rev. W. B. Clark to stimulate systematic research for the metal and its ores, little or nothing was done until later years, when cinnabar was found at several places, the richest deposits being discovered near Yulgilbar, in the Clarence River district, about four years ago. The Government geologist has inspected the workings in this locality, and has definitely ascertained the existence of three parallel lodes, which improve as they go down. Machinery is being erected, and a preliminary testing of about one thousand tons of ore will be made. Should the results prove satisfactory the New South Wales quicksilver trade will become revolutionised, as the poorest assays show the ore to be richer than those of the American and Spanish mines. They will also encourage the search for other cinnabar deposits, which, there is every reason for believing, are more numerous and richer than generally assumed. The value of the discovery in connection with the Colonial gold-mining industry can hardly be over-estimated. It simply means that the work of gold production will become enormously stimulated, thereby greatly increasing the already large auriferous output of the Colony.

THE summary of the *Weekly Weather Report* for the September quarter of the thirty-four years, 1866 to 1899, recently issued by the Meteorological Council, shows that mean temperature for both wheat-producing and grazing districts was 2° above the average. The only variations from these values were in the east and west of Scotland, where the excess was only 1°, and in the south and south-west of England, where the excess amounted to 3°. The general mean of the rainfall for the quarter was 2 inches below the average in both the above-mentioned districts; the principal variations were in the north and east of Scotland, where there was an excess of 1 inch, and in the south-west of England, where the deficiency amounted to 4 inches. Reckoning from January 1, the differences from the averages are less marked; in the east of Scotland, the north-west of England and south of Ireland, the excess amounts to about 2 inches, while in the east and south of England the deficiency amounts to 2·7 and 3·5 inches respectively.

DR. E. S. FATIGATI, of Madrid, has sent us a copy of an interesting pamphlet in which he deals with the representations of plants and animals, agricultural operations, and other natural objects and activities found in very old Spanish tombs, in cloisters of the eleventh and thirteenth centuries, corbels of churches, and choir stalls of the fifteenth century. It appears that the leaves, bunches of grapes, and tendrils of the vine, which were used as decorations during the classic period, are also found in the oldest Spanish sculpture of the sixth and seventh centuries. The animal world is well represented. The swan, the gallinaceous birds, the dog, and the lion make up the fauna of the little Asturian churches of the ninth century. In the magnificent cloister of Silos (eleventh century) the indigenous species are found by the side of those of oriental and northern origin. In the capitals of the cloister of Fawagona (beginning of the thirteenth century) are reproduced in stone two snakes devouring a frog, just as they may be seen doing every day in the ponds of the country. In addition, representations are found of the fight of a hunter with a bear of the Pyrenees, the capture of a hare by an eagle, and many others of the same kind. The pictures of nature with its beings and their struggle for life appear reflected in numerous monuments. From these and many other facts given in the pamphlet it seems that the Spanish sculptures of the Middle Ages have not an exclusive symbolic character, and that in those days Spain was not so separated from nature as many have supposed.

MR. JOHN BRILL, writing in the volume of *Proceedings* of the London Mathematical Society just issued, discusses the complete system of multilinear differential covariants of a single Pfaffian expression and of a set of such expressions. An account of the bilinear covariant of a Pfaffian expression is given by Forsyth; this covariant involves the first set of Pfaffians belonging to the given expression, from which latter it is derived by a differential operation. A repetition of this method upon the covariant itself merely produces an expression which vanishes identically. Mr. Brill shows how, by making use alternately of algebraic and differential methods of derivation, a series of covariants of the given expression can be produced which involve the various orders of derived functions associated with the expression. It is to be noted that the places at which differential operations occur are those which mark the passing from one group of cases into the next in the case of a set of equations obtained by equating the Pfaffian expressions severally to zero. Furthermore, the more general derived functions introduced by Mr. Brill play a similar part in regard to these latter covariants to that which the derived functions of a single expression play in reference to its covariants. One of the main difficulties of the subject is the extraordinary complication of the notation.

AN important paper on the development of the carapace of the Chelonia is contributed by Dr. A. Goette to the last number (vol. lxvi., part 3) of the *Zeitschrift für Wissenschaftliche Zoologie*, in the course of which the disputed question as to the relationship of the leathery turtles (Athecata) to the carapaced chelonians (Testudinata) is discussed. If the views put forward by Dr. Goette are correct, they will profoundly modify the generally accepted views as to the relations of the Athecata and Testudinata—more especially the late Dr. Baur's theory as to the former being a specialised group with a degenerate type of carapace.

IN the August number of the *Transactions* of the Connecticut Academy Mr. W. G. Vanhame records some recent experiment in regard to the fertilisation and development of the Planarians. From the ease with which these creatures can be kept in captivity and the number of eggs laid, observations on the development of the group would appear easy, but difficulties have been met with by previous observers, in consequence of which there are discrepancies and uncertainties in regard to many points. The unusually good preparations obtained by the author have enabled him to throw much new light on some of these disputed points. The eggs are laid in clusters or sheets containing from one to two dozens, arranged in a single layer and closely attached together with a white, mucus-like secretion, which is at first very sticky, although it subsequently hardens, Although hermaphrodite, Planarians reproduce by cross-fertilisation. For the details of the author's observations, reference must be made to the original paper.

IN Prof. Verrill's report on the Ophiuroids collected during the Bahama Expedition of 1893 (*Bulletin from Iowa Laboratory*, vol. v., No. 1), the chief general interest centres round the observations connected with the protective resemblances developed by the feather-stars of the Bahamas. According to the author, "most of these species with long, coiled arms, adapted for clinging to the branches of gorgonian corals, are adapted for imitating closely, in various ways, the forms and colours of the corals on which they live. This must afford them a considerable degree of protection against predaceous fishes, in addition to the direct protection due to the stinging powers of the corals themselves, which is sufficient to cause most fishes to avoid them." Many fishes, it is added, have, however, in all probability become immune against coral-stings, and feed on hydroid polyps; and the author argues that if this be so, the additional protection afforded the feather-stars by their resemblance to the gorgonias would be obvious. But, unless the feather-stars form a specially tempting *bonne-bouche* and are liable to be picked off separately, the obviousness of this does not seem quite clear, since feather-stars and gorgonias would be both consumed together by the fish.

THE importance now attached to preparing skins of small mammals for study purposes according to a uniform plan fully justifies the appearance of a paper on the subject by G. S. Miller in the *Bulletin* of the U.S. Museum (No. 39). A list of instruments and material required, as well as the details of manipulation, are given; and a plate illustrates the appearance of the finished specimens.

THE November number of *Science Gossip* is particularly full of interesting articles. Major B. M. Skinner gives a short account of the valley of the Tochi river which he explored during the North-west Frontier campaign; and an account of the foraminifera collected by him from the rocks in Waziristan is given by Mr. Arthur Earland. The limestones fall naturally into two divisions, (1) alveoline, (2) nummulitic, and the article is illustrated by photographs of rock-sections of both of these types.

A SERIES of observations on the "focal depth," or as it is sometimes called the penetrating power, of microscopic objectives is given by Mr. Leon E. Ryther in the *Journal of Applied Microscopy* for September. By plotting the magnifying powers of various combinations as abscissæ and the corresponding focal depths as ordinates, a curve is obtained approximating to an equilateral hyperbola indicating that in the author's experiments the focal depth varied inversely with the magnifying power.

J. ERIKSSON reprints from the *Annales des Sciences Naturelles* a translation of an important paper, which appeared originally in Swedish, on the brown rust of cereals. He proposes to split up into six species the well-known parasitic fungus *Puccinia rubigo-vera*, only one of which species is at present known in the æcidiospore stage. Of the six species described, the first and second only are of great importance in agriculture, the first being very destructive to rye, and the second being apparently the only parasitic fungus which causes rust on wheat in Europe, the United States or Australia. The paper concludes with some practical suggestions for farmers.

THE mineral resources of the Province of New Brunswick form the subject of Part M of the tenth volume of the annual report of the Geological Survey of Canada (1899). The subject is dealt with by Dr. L. W. Bailey. At the outset he remarks that if we except building-stones, gypsum, limestone, brick-clays, and other materials applicable to building purposes, there are but four substances that have been the basis of anything like extended or successful mining operations. These are coal, iron, manganese and albertite, and of these coal only is at the present time being worked. There are, however, large tracts that are still covered with unbroken forest, and consequently are but little known. They comprise rocks whose geological age and character suggest that they may be productive of useful minerals.

A PROGRAMME of lectures received from the Hull Scientific and Field Naturalists' Club shows that the Club is actively engaged in creating and fostering a love of natural knowledge within its sphere of influence.

DURING this month the following popular science lectures will be delivered on Tuesday evenings, at the Royal Victoria Hall:—November 7, Mr. L. Fletcher, F.R.S., on "The Fall of Stars from the Sky"; November 14, Mr. W. J. Pope, on "The Uses of Distillation"; November 21, Dr. J. W. Waghorn on "Bad-Contacts: their application to telephones and wireless telegraphy"; November 28, Mr. Michael Sadler on "A Brother of the Birds" (St. Francis of Assisi).

THE *London Quarterly Review* (Charles H. Kelly) publishes a long article by "A Field Naturalist," in which Darwin's observations and experiments on cowslips and primroses are discussed, and the conclusion is arrived at that the evidence brought forward by him is insufficient to establish the theory that cross-fertilisation is necessary to the full fertility of flowers. "On the contrary," says the reviewer, "we are of opinion that the primrose gives strong confirmatory evidence to Axell's view, that under natural and equal conditions, self-fertilisation of flowers is both the legitimate fertilisation and the most productive."

A NATURAL consequence of the scientific activity of the Liverpool Marine Biology Committee is the preparation of a series of memoirs, edited by Prof. Herdman, on typical British marine plants and animals. Each memoir will be concerned with one type, and the forms selected for description will chiefly be common Irish Sea animals and plants, of which no adequate account already exists in text-books. Three of the memoirs will appear before the end of this year, namely, Ascidia, by Prof. Herdman; Cockle, by J. Johnstone; and Echinus, by H. C. Chadwick. Others will follow in rapid succession, and the complete series of special studies promises to be of value to all marine biologists.

THE additions to the Zoological Society's Gardens during the past week include a Sooty Mangabey (*Cercocebus fuliginosus*) from West Africa, presented by the Rev. A. Clutterbuck; a Young Leopard (*Felis pardus*) from East Africa, presented by Captain J. L. Stanistreet; a Greater Vasa Parrakeet (*Coracopsis vasa*) from Madagascar, presented by Mr. C. Hunt; a Corn Crake (*Crex pratensis*), British, presented by Mr. Collingwood Ingram; a Ring-hals Snake (*Sepedon haemachetes*) from South Africa, presented by Mr. J. E. Matcham; two Red-footed Lemurs (*Lemur rufipes*, ♂ ♀) from Madagascar, an Ichneumon (*Bdeogale*, sp. inc.) from Africa, a Westerman's Eclectus (*Eclectus westermani*) from Moluccas, two Black-tailed Godwits (*Limosa aegocephala*), European; ten Salt-water Terrapins (*Malacoclemmys terrapin*) from North America, deposited; four Common Squirrels (*Sciurus vulgaris*), European, purchased.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN NOVEMBER :—

November 6. 0h. Conjunction of Saturn with the moon, ♄ 1° 1′ N.
11. Saturn. Outer minor axis of outer ring = 16″·11.
12. 11h. 11m. to 11h. 29m. Occultation of κ Piscium (mag. 5) by the moon.
12. 20h. Jupiter in conjunction with the sun.
14–16. Expected brilliant return of the Leonid meteoric shower.
15. Venus. Illuminated portion of disc = 0·966.
15. Mars. Illuminated portion of disc = 0·991.
16. 4h. Mercury at greatest eastern elongation (22° 18′).
17. 10h. 21m. to 11h. 29m. Occultation of A^1 Tauri (mag. 4·5) by the moon.
19. 6h. 10m. to 7h. 1m. Occultation of Neptune by the moon.
19. 10h. 32m. Minimum of Algol (β Persei).
22. 7h. 21m. Minimum of Algol (β Persei).
25. 14h. 11m. to 15h. 21m. Occultation of 55 Leonis (mag. 6) by the moon.

HOLMES' COMET (1899 *d*).

Ephemeris for 12h. Greenwich Mean Time.

	15	12	27
	29	5	43

NEW VARIABLE STAR.—In the *Astronomical Journal*, No. 470, Mr. R. T. A. Innes, of the Cape Observatory, gives the individual results of his observations leading to the detection of a new variable. Its position is :—

$$\text{C.P.D.} - 54°{\cdot}6634 \begin{cases} \text{R.A.} = 15\text{h. } 32\text{m. } 42\text{s.} \\ \text{Decl.} = \ -54° 54'{\cdot}4 \end{cases} (1875).$$

The star was first suspected of variability by Prof. J. C. Kapteyn, who furnished a list of possible variables to the Cape Observatory in December 1896. Mr. Innes, from a discussion of the *fifty-eight* observations he records, finds the period to be about 12·68 days, the variation of magnitude being from 8·7 to 9·3. The fall to, and rise from, minimum seem to be very sharp ; but notwithstanding this similarity to the Algol type, it is not considered likely to belong to that class. The colour of the star is distinctly red.

GEOGRAPHY AT THE BRITISH ASSOCIATION

THE Dover meeting was characterised by the unusual quantity of solid work in physical geography and mainly in oceanography, including polar research, which was brought before the Section. Travel papers were less numerous than usual, though certainly of no inferior type, and the use of the lantern to illustrate nearly every communication added both to the interest and the value of the expositions. The hall was ill-situated and not well adapted for the purpose it was called upon to serve, and this unfortunate environment, not any falling off in the quality of the papers, accounted for the remarkably small audiences, which were the subject of general remark.

The address of the President, Sir John Murray, contained a summary of existing knowledge as to the ocean floor, and concluded with indications as to the direction in which advance during the immediate future is to be looked for. In this respect Sir John Murray gave prominence to the improved prospects for Antarctic research, and emphasised the importance of the forthcoming expeditions aiming at scientific completeness in their work. In seconding the vote of thanks for the address, Sir Michael Foster, the President of the Association, spoke of the interest which the Royal Society as well as the Royal Geographical Society felt in Antarctic exploration, and of the determination of both Societies to make the best possible use of the funds which might be placed at their disposal for the complete scientific study of the south polar area.

ARCTIC PAPERS.

The most recent results of Arctic exploration were described by three explorers who had attacked the problem in very different ways. Admiral Makaroff, of the Russian navy, gave an account of the trial trip of the great Russian ice-breaker *Yermak*, a vessel recently constructed at Armstrong's works on the Tyne for service in the Baltic during winter and in the Kara Sea in summer. The vessel is built of steel, the plates being very heavy and the ribs and cross-girders of very great strength arranged to meet the thrust of ice from all sides. She is built with two hulls, one within the other, is minutely subdivided into water-tight compartments, and fitted with an elaborate system of tanks and steam-pumps which enable the trim of the vessel to be altered very rapidly. Thus the vessel may be depressed at bow or stern, or canted to port or starboard by pumping water from one set of tanks to another. The displacement of the vessel fully equipped is 8000 tons, and her engines have power by acting on three propellers at the stern to drive her at the rate of 14 knots. A fourth propeller at the bow, intended to drive away the broken ice by the currents it generates, was found useful only in light ice, but of no value in breaking ice of great thickness. The trial-trip, which Admiral Makaroff described with many illustrations from photographs, demonstrated the power of the ship to break away through ice as much as 14 feet thick, not so much by smashing the ice as by determining the direction of cracks by which the mass is split. A cinematograph picture was obtained of the *Yermak* forcing her way through the thickest of the Arctic pack-ice north of Spitsbergen, but Admiral Makaroff regretted that the film could not be developed in time for exhibition at the meeting. During the trip the ice was not only broken to make way for the ship, but studied minutely. The powerful derricks with which the vessel is fitted made it possible to capsize large blocks of ice so as to study the parts normally under water, and also to hoist on deck masses of many tons weight, to be studied as to temperature by the insertion of thermometers to different depths, and as to chemical composition, melting point, &c. Admiral Makaroff is convinced of the perfect suitability of strong steel ships for polar research ; and in reply to an inquiry as to whether he hoped to reach the North Pole in the *Yermak*, said that he only wished he might be allowed to try. There was a long discussion on the paper, in which the value of this new method of mastering the ice was generally recognised.

Mr. W. S. Bruce, who had just returned from a voyage to Spitsbergen in the Prince of Monaco's yacht, *Princesse Alice*, gave an account of the physical and biological conditions of the Barents Sea, founded on that cruise and on a voyage last year in Mr. Andrew Coats' yacht *Blencathra*. Only two of the many current floats thrown overboard by the *Blencathra* had as yet been recovered.

Mr. Walter Wellman, in an address on his recent journey to

Wilczekland, dwelt upon the motives and methods of Arctic exploration, advocating the "dash for the pole" as the only practical method of attaining the highest latitude in the short time available during the brief season available for travelling in the Far North. He recounted the incidents of his attempt in 1898-99, which was unsuccessful on account of a serious accident which befel him when camping on an iceflow which was broken up by a sudden pressure.

ANTARCTIC PAPERS.

The records of recent work in the Antarctic were of no less interest, and the display of slides from Antarctic photographs was unique, none of them having been shown in public before.

A short account of the cruise of Sir George Newnes' yacht *Southern Cross*, with Mr. Borchgrevink and his party on board, from Hobart to Cape Adare, was communicated by Dr. H. R. Mill, and illustrated by a few pictures of the Antarctic ice and of the landing at Cape Adare. The *Southern Cross* left Hobart on December 19, reached 50° S. on the 23rd. The first ice was met with on the 30th in 61° 56′ S., and 159° E., and on January 1, 1899, she was practically stopped by the pack in 63° 40′. Every effort was made to proceed southward and eastward, but with small result, as on January 31 the position was only 66° 46′ S. and 165° 28′ E. She then commenced to work northward and eastward to escape from the pack, which she did on February 12 in 65° 43′ S., and then it was found easy to cross the pack to the southward in longitude 173° E., the ship anchoring off the beach at Cape Adare on February 17. Tempestuous weather was experienced, the wind at the most southerly part of the voyage blowing usually from easterly and southerly quarters, and the vessel being more than once in danger of driving ashore. Stores were landed, huts erected, and the *Southern Cross* finally left Mr. Borchgrevink with nine companions and seventy-five dogs on the shore of what he believed to be the Antarctic continent on February 28, 1899.

M. H. Arçtowski, the oceanographer and meteorologist of the *Belgica*, gave a brief account of the voyage and the wintering of the Belgian expedition in the Antarctic ice-pack south-west of Cape Horn. He showed a number of photographs of the newly explored land, and concluded by expressing his views as to the further work required in Antarctic exploration as follows:—

At the present day it is impossible to consider the land alone; the whole Antarctic area exhibits phenomena which remain very imperfectly known, such as the great questions of atmospheric circulation, climate, circumpolar oceanography and magnetic conditions. Hence Antarctic explorations must be conducted in three ways:—

(1) A system of fixed stations arranged between the edge of the continents and the zone of ice. These stations should be supplied with all necessary magnetic and meteorological instruments, and continue at work simultaneously for one year at least.

(2) During the same year two polar expeditions should set out on opposite sides towards the South Pole. This would require two vessels strong enough to withstand the pack, and equipped for wintering.

(3) Finally a circumpolar expedition, planned to follow the edge of the pack right round, and specially equipped for oceanographical and zoological work. This expedition would also survey the accessible parts of the Antarctic coast.

Such a system of exploration must necessarily be the work of several nations. Weyprecht's idea should be revived and followed. Antarctic exploration must be conducted systematically, and it ought to be international. A series of circumpolar stations, where comparable and simultaneous observations are carried on, would make the results of the British and German Antarctic expeditions remarkably complete, and vastly enhance their value.

A polygon of stations should unite South America and the Antarctic lands. The path of the cyclonic storms passes to the south of Cape Horn, and—at least during part of the year—to the north of Palmer Land. The polygon should include stations on the east and west coasts of Graham Land, and one of the South Shetland Islands, on South Orkney and on one of the Sandwich Islands, together with stations at Cape Pillar, Cape Virgins, Cape Horn, Staten Island and the Falklands. With such a system of observation it would be possible to determine exactly the track of every cyclone crossing the polygon of stations. This is a matter of very great practical importance. These cyclones seem to travel in the general direction of the upper winds from west to east, and they seem to follow the outline of Alexander, Graham and Palmer Lands, but how and why this is so we cannot tell as yet. Between South America and the Antarctic land there is a belt of low pressure which seems to encircle the Antarctic region where there is apparently a permanent anticyclone; but observations are wanting to determine the associated conditions of atmospheric circulation.

It seems scarcely necessary to insist on the advantages which two other polygons of stations would present, one to the south of the Indian Ocean, the other between New Zealand and Victoria Land. The second polygon would be formed by the islands of Prince Edward, Crozet, Kerguelen and a station on Enderby Land. The third polygon would include the Balleny, Macquarie and Auckland Islands. This would be a particularly interesting polygon on account of its comparative proximity to the magnetic pole.

The two vessels designed to winter in the pack should approach along the meridians of 145° W. and 35° E. Imprisoned in the pack as the *Belgica* was, these vessels would be able to carry on oceanographical and zoological work, and also to collect magnetic and meteorological observations, thus adding two stations near the pole to the various polygons. From the meteorological point of view it would be extremely interesting for these vessels to reach high latitudes, for the region near the pole will probably differ greatly from the northern edge of the Antarctic lands in everything regarding atmospheric pressure, wind and storms.

As to the circumpolar expedition, the vessel intended for this purpose should be quite independent of those which penetrate the pack. The region is too great to admit of the whole voyage being completed in one season—three would probably be necessary. It is not easy to indicate the route which should be followed, for everything depends on circumstances. Still, it may be observed that—in summer at least—easterly winds predominate near the edge of the south polar pack, and therefore it would be advantageous to proceed from east to west.

Mr. J. Y. Buchanan, F.R.S., treated of the physical and chemical work required for an Antarctic expedition, and pointed out that the principal object at the outset of the expedition should be to push energetically southwards, and effect a landing in the most suitable place in the highest possible southern latitude, and there establish the principal station. The locality should be chosen where the ship, or one of the ships, would find safe winter quarters. As the principal object is to establish the expedition as advantageously as possible on land, no time should be spent unnecessarily at sea. For this reason magnetic observations at sea should not be contemplated. They take up an enormous amount of time, and besides, if they are to be of any use, the distribution of iron in the ship has to be arranged under such restrictions as to interfere materially with the usefulness of the ship in other directions. On land, the magnetic observations would occupy a first place, also pendulum observations for the determination of the intensity of gravity and tidal observations. It has been the general experience of Antarctic navigators that the heavy pack-ice is met with at a considerable distance from land, and between it and the land there is comparatively open water. The ice which would cover this water in winter would probably loosen earlier than the heavy pack, and the ship, if wintering inside, might be able to move much earlier than it would be possible for her to pass the pack; and this would be an additional advantage of finding winter quarters for the ship.

Perhaps the most important work to be done is to obtain a complete meteorological record during the whole of the sojourn of the expedition in Antarctic regions, whether at sea or on land. At present, any view as to the meteorological conditions on the Antarctic land may be held, because we have no facts by which to regulate our speculations. The expedition should be fully supplied with instruments for this purpose, and especially with self-recording instruments. As the station must necessarily be on land, and not on ice, geological observations will be made as a matter of course.

What distinguishes the Antarctic regions above everything is the development of ice as a geological feature, whether it is met with at sea as icebergs, or on land as glaciers, or a continuous covering. It is almost certain that any station on land will be within easy reach of a glacier, and means should be taken to establish marks as early as possible which will enable its motion to be observed before darkness sets in and after the sun reappears.

The Greenland glaciers appear to move about three times as fast as the Swiss ones. Do the Antarctic ones move faster still? In Spitsbergen the glacier streams sometimes take very large proportions. How does it stand with the Antarctic ones in this respect? The "grain" of the Spitsbergen glaciers does not seem to be larger than that of the principal Swiss glaciers. The Antarctic land ice must be dissected with a view to the determination of the size and the articulation of the grain. It is, therefore, of the first importance that the chemist and physicist should have spent some time, both in summer and in winter, examining for himself the conditions of one of the Swiss glaciers. This is quite as necessary for him as having spent a certain time in a chemical or a physical laboratory.

The papers on Antarctic exploration gave rise to an animated discussion. Prof. Rücker, speaking of the requirements for magnetic work, expressed his preference for observations on board a wooden ship cruising round the Antarctic, to the concentration of observations on a few fixed stations; although he allowed that excellent results could be obtained from fixed stations if they were numerous enough, and not established upon magnetic rocks: series of well-distributed stations being more important than a position in high southern latitudes or equipment with apparatus of remarkable delicacy. Major Darwin observed that such differences of opinion as had been expressed regarding the work to be attempted in Antarctic exploration arose simply from the want of funds to provide for the complete representation of all departments; and he indicated two guiding principles. (1) If a special Antarctic ship is to be built, it should spend the whole of the available time in the Antarctic regions proper. (2) The greatest unknown feature should be selected for study; that is, the Antarctic continent. For any kind of south polar expedition it is of the utmost importance to select the scientific staff with the greatest possible care. Mr. George Murray said that he had been carefully studying the question of the cost of ships, and had come to the conclusion that for two well-equipped vessels, each with an adequate scientific staff, a sum of 150,000*l.* would certainly be required. Dr. Koettlitz laid stress on the importance of expert supervision in the preparation of all the tinned foods of an expedition. Sir John Murray, in summing up the discussion, said it was plain that for a proper study of the Antarctic regions two ships would be required, one specially designed for magnetic work and for penetrating the ice, the other equipped for circumpolar oceanographical observations.

OCEANOGRAPHICAL PAPERS.

Dr. Gerhard Schott, of the Hamburg Marine Observatory, the oceanographer of the German deep-sea expedition, gave an account of the chief results of the voyage of the *Valdivia*, illustrated by many photographs, including some fine pictures of tabular and peaked Antarctic icebergs. The expedition, sent out at the expense of the German Government, was practically a circumnavigation of Africa, though in wide curves including the invasion of the Antarctic region to the edge of the pack-ice off Enderby Land. Apart from the exploration of the edge of the southern ice and the rediscovery of Bouvet Island, the cruise was of great geographical importance on account of the exact oceanographical study of the whole of the tropical Indian Ocean for the first time. The oceanographical results include deep-sea soundings carried out with two different machines, one the Sigsbee, of American manufacture, which acted remarkably well, even in very stormy weather.

The utilisation of an electromotor for winding up the wire was a new and very successful application much to be commended, especially for polar work, when steam-pipes are apt to freeze. The most important soundings were those made between Capetown and Bouvet Island, thence southward to the edge of the ice, and eastwards along the margin of the pack, and thence north to Kerguelen. This region had previously been almost unknown. During this part of the trip great attention was paid to ice-conditions, the ice being distinguished into *Drift-ice*, consisting of low fragmentary masses, often obviously portions broken off glaciers; *Pack-ice*, greenish stratified masses of frozen sea-water; and *Icebergs*, which in the east near Bouvet Island were rugged, much waterworn, and had obviously come from a distance; while in the east, near Enderby Land, they were tabular in form, quite fresh and unworn: their height was usually from 100 to 180 feet. The meteorological conditions were also studied throughout the cruise with great care.

Mr. H. N. Dickson discussed the observations of temperature of water and air round the British Islands. The mean monthly and annual temperatures of the surface waters of the sea during the period 1880-97 are shown for sixty-five stations distributed round the coasts of England, Scotland and Ireland. The average for the year at the entrance to the English Channel is nearly 54° F., it falls as the Channel narrows to 52° between the Start and Cape la Hogue, and remains steady to beyond the Straits of Dover, at least as far as the East Goodwin light-vessel. On the south-west coast of Ireland the annual mean is about 52°, falling to 51° in St. George's Channel, and 50° in the Irish Sea. A slow fall from 52° to 50° takes place on the west coast of Ireland until the N.W. corner is reached. The mean of 49° persists along the north coast of Ireland to the North Channel, and along the whole of the west coast of Scotland to Stornoway. On the east coast temperature falls very quickly, as soon as we get out of range of the Straits of Dover, to 50° off Suffolk and Norfolk, and then there is a gradual fall northwards, to 48° off the coast of Northumberland, 47½° off Aberdeenshire, and 47° at the Orkneys and Shetlands. The effect of the tidal streams in mixing the waters is exceedingly well marked. The annual minimum of temperature rarely occurs in March, most frequently in January, especially at stations open to the Atlantic. The annual maximum occurs almost everywhere in August.

Mean temperatures of the surface water are compared with the forty-year averages for the air, recently published by Buchan. A comparison shows that the mean annual difference has hitherto been somewhat over-estimated, especially on the western coast; in no case is the mean excess of sea over air greater than 2° F. The maximum difference occurs everywhere in November and December, and is greatest on the south coast of England between Portland Bill and the Straits of Dover.

Mr. Dickson also contributed a paper on the temperature and salinity of the surface water of the North Atlantic during 1896 and 1897. The completed series of forty-eight monthly charts of surface temperature and salinity, the mode of construction of which was described in a paper read before the Section last year, was exhibited, and along with it maps showing the departures from the mean distribution of air pressure and temperature during the same period. A number of new features in the movements of surface waters were disclosed, notably in connection with the distribution of polar waters from the western Atlantic.

Dr. H. R. Mill suggested a system of terminology for the forms of sub-oceanic relief. He said that the fact that the forms of the ocean floor cannot be seen, but only felt out by soundings, makes their study one of peculiar difficulty. Some distinguished authorities believe that our present knowledge of the deep sea is too slight to justify any systematic terminology. Meanwhile each investigator introduces a set of names of his own, for the most part based on analogies with land forms visible to the eye. It is obvious that there are two great classes of forms, elevations above and depressions below the general level of the ocean floor; but the question is how many subdivisions of each can be recognised as distinctive and deserving of generic names. The following general scheme of terminology is put forward tentatively, premising that no attempt be made to localise any precise type of form unless a considerable number of soundings exist to define it:—

Depression—The general term for any hollow of the ocean floor. *Basin*—A relatively wide depression, with comparatively gently sloping sides. *Caldron*—A relatively wide depression, with comparatively steeply sloping sides. *Furrow*—A relatively narrow depression with comparatively gently sloping sides. *Trough*—A relatively narrow depression with comparatively steeply sloping sides. *Wall*—Any submarine slope comparable in steepness to a precipice on land. *Floor*—Any very gentle submarine slope or nearly level surface. *Elevation*—Any inequality above the general level of the ocean floor. *Rise*—A relatively narrow elevation. *Bank*—A relatively wide elevation. *Shoal*—An elevation coming within five fathoms of the surface, so as to be a danger to shipping. *Shelf*—A nearly horizontal bank attached to the land and bordered seaward by a much more abrupt downward slope.

Mr. C. W. Andrews, in a paper on the relation of Christmas Island to the neighbouring lands, referred to the peculiarities of the geology and biology of the island, and traced the resemblances which seemed to associate it with the Cocos-Keeling group on one side and Java on the other. The occurrence of earthworms in Christmas Island was an anomaly in the biology of oceanic islands, and difficult to explain.

Sir John Murray and Mr. Robert Irvine discussed the distribution of albuminoid matter and saline ammonia in sea-water; and Sir John Murray with Mr. F. P. Pullar exhibited and described the sounding-machine they employed in their bathymetrical survey of the fresh-water lakes of Scotland, and gave an account of the configuration of the beds of the lakes of the Loch Katrine group. The authors expressed their intention of extending the work to the other lakes in Scotland, although they felt that it was rather for the nation than for individuals to carry out work of the kind.

OTHER PAPERS.

Colonel Sir John Farquharson, late Director General of the Ordnance Survey, gave an account of the progress of the work of that department during the last twelve years, and exhibited a number of illustrative diagrams and specimen maps. He said that during the twelve years (1887-99) there have been probably more changes made in the character of the work done by the Survey than in any other equal period of its history; and, as regards the areas covered by its operations, they have been largely in excess of the areas covered during any previous equal period. This is, of course, due to the fact that revisions have now largely taken the place of original surveys. The most important advances made were:—

The progress (to completion in 1890) of the original cadastral survey of England and Wales, including the 6-inch surveys of uncultivated districts. The progress made on re-surveys for the larger scales of various counties of England and Scotland which had been originally surveyed for the 6-inch scale only; and the progress made on the revision of the original cadastral surveys of England and Scotland, whether on the 25-inch or 6-inch scale. The progress made on the re-survey of Ireland for the $\frac{1}{2500}$ or 25-inch scale. The progress made on the completion of the original new series engraved 1-inch maps of Great Britain and Ireland, both in outline and with hills. The progress made on the revision of the new series of 1-inch engraved outline maps of Great Britain and Ireland, and the commencement of the issue for Scotland and the North of England (and for Ireland ultimately) of the same revised 1-inch map with hills in brown by double printing. The progress made with coloured 1-inch maps of the South of England. The progress made with maps on scales smaller than 1 inch to a mile.

A short account was given of the nature, causes, and results of the changes made since 1887 in the system of carrying out the survey, some of which were due to the reports of committees, or suggestions from the general public, while others have been necessitated by the changes which have taken place in the character of the work done by the Department.

The Ordnance Survey Department, in 1887, published town maps at the cost of the State, on the scales of 10 feet ($\frac{1}{500}$) and 5 feet ($\frac{1}{1056}$) to a mile. It does so no longer. The reason for this change was stated. The sales of the Ordnance Survey maps were in 1887 in the hands of the Stationery Office; they are now in the hands of the Ordnance Survey Department itself. The reasons for and results of this change were stated.

Some remarks were also made as to the organisation and superintendence of the department and of its work; as to the use made of the Ordnance Survey maps by other departments of the State and by the public generally; and as to the important work which still remains to be done by the Ordnance Survey.

Mr. Vaughan Cornish described the sand-dunes bordering the delta of the Nile dealing with the ripples, sand-dunes, and dune-tracts in turn.

Ripples.—The author had previously measured twelve wind-formed ripples in the blown sea sand on the Dorset coast. The average ratio of length to height was L/H = 18·4. The least height was ·06 inch, and the greatest ·34 inch. These measurements were, for the most part, of one or two individual ripples. Mr. E. A. Floyer measured six of the largest kind of ripples on the El Arish route, and obtained L/H = 17·7 with H from 6 to 10·6 inches. The author measured thirty-seven *consecutive* ripples to leeward of a sand-dune near Ismailia. The ripples had an average height of 1·43 inches, and the average L/H was 16·57. The appearance of these was intermediate between that of ripples where accumulation is rapid (which never grow large), and the large and nearly symmetrical ripples (? analogous to sastrugi), as much as 11 feet in wave-length, the formation of which is apparently accompanied by a considerable lowering of the general level.

Dunes.—A tract of a few hundred acres of small, but true, dunes (not ripples) on a sandy foreland, exposed during the fall of the Nile, afforded an opportunity for similar measurements.

Higher and lower dunes succeeded one another, and, viewed transversely, the ridges were strongly undulating. Nevertheless, a line having been marked out in the up-and-down-wind direction, the *average* L/H for twenty-four consecutive dunes was found to be 18·04, average height 20 inches. Another set of measurements taken near the same line on the succeeding day gave L/H = 17·89 for twenty-three consecutive dunes. Apparently the ridges are formed of the nearly uniform (L/H = 18) shape, and lateral inequalities are subsequently developed in the manner explained in the *Geographical Journal*, June 1898, pp. 637–9, but these do not affect the *average* L/H. The author hopes to make similar measurements of trains of larger dunes.

The straight, slipping lee cliff of dunes is caused by the undercutting of the eddy. In the dunes near Ismailia a progressive development of the profile form was observed. At first both windward and lee slopes are very gentle, and the highest point is near the middle. The summit apparently moves to leeward, and the lee slope becomes steeper; a slipping cliff is formed on the upper part of the lee slope. This pushes back towards the summit, and the windward slope grows steeper. Finally, windward and average leeward slope become of nearly equal steepness, and the top of the cliff coincides with the summit of the dune.

Dune Tracts.—The condition for formation of a dune tract in a sandy district is that the rate of travel of the sand should be locally diminished without a corresponding diminution in the supply of sand. The persistence of such a condition may cause a stationary dune massif without fixation.

In the sandy district visited by the author the formation of a dune tract or dune massif appears to be chiefly determined by the presence of ground moisture, which gives coherence to the sand. Thus the boundaries of these massifs frequently appear inexplicable when an explanation is sought in the wind. Within the bounds of the massif, however, the modelling of the surface is explicable by the action of the winds. In the neighbourhood of Helwan, wind erosion of limestone and other rocks is very active over areas where there are no dunes. An examination of the wind-formed detritus showed a quantity of sand-sized particles sufficient for the formation of dunes; and the explanation of their non-formation seems to be that the sand-sized particles are too small a *proportion* of the whole. According to this line of reasoning, dunes will only be formed where dust formation proceeds slowly, for if dust be produced rapidly the proportion of sand-sized particles remains low.

Travel papers, for the most part accompanied by graphic illustrations, were contributed by Mrs. W. R. Rickmers on the rarely visited region of Eastern Bokhara, by Mr. W. R. Rickmers on the Karch-Chal mountains in Transcaucasia, by Dr. H. O. Forbes on the island of Sokotra, by Mr. O. H. Howarth on the province of Oaxaca in Mexico, by Dr. A. C. Haddon on some geographical results of the recent Cambridge anthropological expedition to the Malay Archipelago and New Guinea, and by Captain Wellby on a remarkable journey through the western borderlands of Abyssinia. Mr. E. Heawood contributed a paper on the date of the discovery of Australia, in which he brought forward evidence for discrediting the rumours of the discovering of Australia in the fifteenth century or the early part of the sixteenth.

The eighth report of the Committee on the Climatology of Tropical Africa was presented, giving records from forty stations.

MECHANICS AT THE BRITISH ASSOCIATION.

MEETING under the presidency of Sir William White, Chief Constructor of the Navy, naturally the papers which came before the Section dealt mainly with marine engineering, canal and harbour works, and allied subjects.

Owing to the energy of the President a very complete programme was secured; and the papers read and discussed were certainly considerably above the average. The attendance at the sectional meetings was also much better than usual.

On the opening day, after the presidential address, a paper by Messrs. Coode and Matthews on the Admiralty harbour works at Dover was submitted to the Section. It was taken early in the programme in order that the engineers present at the meeting who naturally wished to carefully inspect the magnificent works now in progress at Dover, which will render that port one of the finest in the kingdom, should hear beforehand an account of what it is intended to do from the engineers responsible for the design. In the discussion the difficulties which have been brought about by the more rapid advance of the Commercial Harbour Pier, as compared with the extension of the Admiralty Pier, were much in evidence; but this, after all, is only a question of a more or less ephemeral character, and it is a pity that the discussion did not turn more upon the merits of the particular plan which has been adopted in the construction of this great harbour. It is noteworthy that the general scheme of the present plan differs but little from previous proposals; only that additional deep-water space has been obtained.

If the sanguine expectations of the people of Dover are in any way fulfilled, Dover on the completion of these works will prove a formidable rival to Southamption; before, however, any such rivalry can become serious, Dover must be provided with a railway service on an entirely different scale from that now supplying the wants of the town. The service is inadequate; it is frequently unpunctual, and contrasts most unfavourably with the splendid service which the South-Western Company have organised between Southampton and London.

The other paper taken on the opening day was one descriptive of a process for rendering wood non-flammable. Specimens of wood treated by this process were exhibited, and a practical demonstration of its non-flammability was given at the meeting. The President mentioned in the discussion that the Admiralty have not been satisfied with other people's experiments; they have themselves experimented on wood treated in this way, and have satisfied themselves that the process is a successful and valuable one. It is, however, not only in ships of war, but also in passenger steamers and in the gigantic modern hotels that the use of non-flammable wood will have its application, in spite of the extra cost of the finished wood when treated by this process.

On Friday a paper prepared by Sir Charles Hartley, descriptive of the engineering works of the Suez Canal, was read by Sir John Wolfe Barry in the absence of the author. This paper was one of the greatest interest, giving a complete history of the engineering features of the canal, of the enormous growth of the traffic through the canal, and of the gradual steps which have been taken to provide for that increased traffic, both by widening and deepening the original cutting. How great a change has been brought about in the time of transit by the use of the electric light for enabling night passages to be made can only be realised by a study of the figures given by the author as to the present time of transit compared with what it was ten years ago.

The second paper on Friday was the one that proved, perhaps, the most attractive of all on the programme of the Section. It was a short paper by Mr. Parsons, with details of the fast cross Channel and Atlantic liners which he proposes should be driven by his steam turbines. Models of the proposed vessels were shown, and a working model of a set of steam turbines to show how simple it was to run astern.

Considering how frequently the wildest statements are made as to the possible speed of mail steamers and smaller fast passenger boats, it is noteworthy that Mr. Parsons proposes quite moderate speeds in his liners and cross-Channel steamers. This paper was made more interesting from the figures which the President had given, in his address to the Section, on the question of the relation of power to speed and displacement.

The President had shown conclusively how impossible it was to apply results deduced from small vessels to large vessels; and his calculations as to the enormous power required to drive one of the large vessels at high speeds show that we have little hope of obtaining such speeds with present conditions.

Mr. Parsons in his paper fixed the speed of his cross-Channel boat at thirty knots, and although the boat is only to have a 1000 tons displacement, it will require 18,000 horse-power to maintain that speed. He did indeed hint at an express-Channel steamer which should attain a speed of forty knots, but only at the expenditure of 50,000 horse-power: figures which are likely to damp the enthusiasm of any ship-owner or ship-builder. His Atlantic liner was to have a displacement of 18,000 tons and a speed of twenty-six knots, with an indicated horse-power of 38,000.

The paper which followed Mr. Parsons' was an extremely interesting and valuable one by Mr. Mark Robinson, on the Niclausse water-tube boiler. It came as a natural corollary to Mr. Parsons' paper, because Mr. Parsons had stated in his communication that his proposed steamers would be fitted with the water-tube type of boilers. The interest which has been aroused, and the controversy which has arisen over the introduction of water-tube boilers into the Royal Navy also made this paper one of considerable importance. The author only described fully the particular type of boiler with which he was most familiar, namely, the Niclausse; but the general conclusions and the general results apply equally to all boilers of this type.

Mr. Robinson pointed out in his paper that the Niclausse boiler as now made in this country, or rather as it will be constructed in this country when the plans now being made are completed, is very different from the Niclausse boiler which was fitted into one of the ships of the navy some years ago.

For reasons which are quite satisfactory the Admiralty have not yet been able to satisfactorily test these Niclausse boilers; and now in view of the great changes in the mechanical details of this type of water-tube boiler, interest in the results of their tests will be more or less discounted.

There is no doubt that this boiler will be one of the most satisfactory in its mechanical details of all the water-tube type, and will have a great future, both for sea-going purposes and on land as well.

One set of figures given by the author to show the advantage of the extremely short time required for removing and replacing a tube or tubes is worth quoting. In one instance the boilers were blown down, three tubes removed and replaced by others, and pressure got up again in thirty-five minutes from the time the operation started.

The concluding paper on Friday was one by Captain Lloyd, describing a method which has been developed at Elswick for discharging torpedoes below water from the broadside of a ship when steaming at a high speed. The problem, a most difficult one in all its mechanical details, has been successfully surmounted, and a considerable number of these submerged tubes have been already fitted, and a large number are in the process of fitting at the present time. The paper was, of course, a highly technical one; but the admirable diagrams which had been prepared rendered it easy to follow the working of the mechanism from the firing of the cordite charge to the exit of the torpedo from the tube.

Saturday was fixed by the authorities as the day upon which the French Association would pay their official visit to the British Association, and the paper which was read before the Section, reinforced by a considerable number of French engineers, was one by a distinguished French engineer, M. Alby, describing the construction and erection of the Alexander III. bridge over the Seine in Paris. This bridge forms part of the Great Exhibition of 1900, and is situated on the line of the Great Avenue which will connect the Champs Elysée with the Esplanade des Invalides. Æsthetical considerations, therefore, have played a most important part in the design which has been adopted. A low-arch form of bridge was the only acceptable one, and the great horizontal thrust produced by such a type of arch has given the engineer a very anxious task in the design of his abutments. A full description of the bridge was given, and of the costly but necessary temporary structure or travelling bridge, as the author termed it, by means of which the erection of the bridge proper has been carried out. During next year engineers will have an opportunity, when visiting the Exhibition, of admiring the beauty and harmony of the design, and the skill with which the great difficulties met with have been overcome.

Monday, as usual the electric day, was not in this instance productive of anything very striking. Perhaps the most interesting communication was one by Mr. Cowper-Coles on some recent applications of electro-metallurgy to mechanical engineering. The author described a very beautiful process for the electrolytic manufacture of projectors for search lights for naval and military operations. A projector made by this process was exhibited to the meeting, and figures were given to show that the fine coating of palladium used protects the silver-faced projector from any injury owing to the intense heat of the arc-light, the pure silver face being found to tarnish very rapidly in consequence of the intensity of the heat.

Some brief notes by Mr. A. Siemens on electrical machinery on board ship were interesting because they gave the President the opportunity of refuting the common notion that we are behindhand in the application of electricity to ammunition hoists and other purposes in our navy. The President pointed out that in matters of this kind the opinions and the wishes of those who have to work the appliances must be taken into account.

The concluding day was devoted to several papers of extreme interest. The business was begun with the consideration of a paper by Mr. Thornycroft on recent experiences with steam on common roads. After dealing with the impediment to progress due to the Locomotives on Highways Act of 1896, and making suggestions as to the steps which should be taken to remove these obstacles in future legislation, the author gave an extremely valuable *résumé* of his own work in this field of mechanical science. He described the different types he has built since 1896, and the chief changes in the mechanical details which experience has convinced him to be necessary. He has built vehicles both for heavy goods traffic and for passenger traffic, and has adopted a method of chainless transmission in his most recent type. The author in conclusion pointed out that, after all, in motor work a good deal depended upon the care and intelligence of the driver employed.

A paper by Mr. Edward Case, who, we regret to say, died only a few days after the paper had been read, descriptive of the Dymchurch sea-wall and the reclamation of the Romney marshes, was next taken. These reclamation works are of great antiquity; in modern times the erection of high groynes for the protection of the wall brought about that which they were expected to prevent, namely, the undermining of the wall. Mr. Case decided, when he took over control in 1890, to adopt an entirely different system, and since 1894 a number of low groynes have been run out; the result of which has been to raise the level of the fore-shore as much as 8 feet at the east end of the wall. These groynes have been constructed in such a way that they can be gradually raised as the level of the beach gets higher, at a very trivial expense and with very little difficulty.

The Section meeting was, as has been stated before, an extremely successful one: the quality of the papers being high, the discussions good, and the attendance throughout thoroughly satisfactory. There can be no doubt that a great deal of this was due to the energy and the interest taken by the President in the work of the proceedings. It is too often forgotten by Presidents of Sections that the success of any particular Section is almost entirely in the hands of its President.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—The 204th meeting of the Junior Scientific Club was held in the University Museum on Friday, October 20. Mr. Hartley (Balliol) read an interesting paper on the history of the discovery of the law of isomorphism.—Owing to the length of important private business Mr. Gibson (Ch. Ch.) was unable to read his paper on the retention of food by plant soils, as announced.—The following are the officers for the ensuing term:—J. T. Mance (Balliol), pres. H. E. Stapleton (St. John's), chem. sec. C. H. Barber (non-coll.), biol. sec. F. W. A. Fleischmann (Magd.), treasurer. F. W. Charlton (Merton), editor.

The examiners have notified to the Vice-Chancellor that they recommend for election to the Burdett Coutts scholarship, which is of the annual value of about 115*l.* and tenable for two years, Mr. J. B. Scrivenor, Commoner of Hertford College. They also recommend that Rev. E. C. Spicer, Commoner of New College, be appointed an extra scholar, to retain his scholarship for one year.

CAMBRIDGE.—St. John's College has once more shown its appreciation of scientific merit by electing to fellowships Mr. J. J. Lister, University Demonstrator of Comparative Anatomy, and Mr. A. C. Seward, University Lecturer in Botany. Mr. Lister, who has done important work on the *Foraminifera* and other groups, is a nephew of the President of the Royal Society, and son of Mr. Arthur Lister, who was last year elected a Fellow of the Society. Mr. Seward is a Fellow of the Royal and Geological Societies, and has attained a high position as an authority on fossil plants. The first volume of his treatise on this subject was reviewed in NATURE (December 15, 1898). He has held the Harkness Studentship in Palæontology, and gained the Sedgwick Geological Prize in 1892. Both gentlemen are Masters of Arts of the College of some years' standing, and have been elected out of the ordinary course.

Mr. J. L. Tuckett, Fellow of Trinity College, has been appointed an additional Demonstrator of Physiology by Sir M. Foster.

Prof. G. Sims Woodhead has been elected to a Fellowship at Trinity Hall.

THE details of the reorganisation of the Education Department and the transference of its duties to the new Board of Education are under consideration by a departmental committee; and the committee of the City and Guilds of London Institute have signified their willingness to give any help which may be needed to secure the proper recognition of technological teaching in the arrangements about to be made. Reference to this matter is made in the report of the examinations department of the Institute issued a few days ago. It is remarked that, having regard to the Institute's close connection with technical teaching in all parts of the country, no organisation of education can meet existing requirements which does not take into consideration the educational work now under the immediate direction of the Institute. The report further states that the committee fully recognise how desirable it is to avoid, as far as possible, any overlapping in the organisation of the classes and examinations directed respectively by the Science and Art Department and by the Institute; and they are of opinion that, with the view to the due encouragement of practical instruction in the technology of the different trades in which artizans are employed, the teaching of technology should be placed on the same basis, with respect to State aid, as that of science or art.

MR. A. E. BRISCOE, the principal of the West Ham Municipal Institute, sends a few particulars of the loss caused by the disastrous fire which occurred a few days ago. The whole of the upper floor of the building, including the chemical, art and women's departments, the engineering and physical lecture theatres, the drawing office and the engineering laboratories have been completely gutted. The chemical and art departments are the greatest sufferers, but there is not much to choose between them and what has happened to the others. The electrical and physical laboratories were flooded by the water, and a great many expensive instruments have been damaged by water; but the galvanometers and some of the other expensive things were on shelves covered by dust-covers, so that they have escaped damage. The expensive machinery in the engine and dynamo laboratories and in the engineer's workshop has not suffered by fire, but, of course, tons of water have fallen upon it, and a very great amount of damage has been done. The institute was covered by insurance to the extent of 47,000*l.*, and it is believed the total damage will not reach this amount. Of course, nothing can compensate for the large amount of work that has been done by the staff in the equipment of the institute, and will now have to be done all over again. Though the borough is not a rich one, it is satisfactory to know that the institute will be rebuilt and probably enlarged, as the classes were already too great for the accommodation. The fire commenced in the advanced chemical laboratory, but the origin is absolutely unknown. The building had not been used for thirty-six hours prior to the outbreak.

SCIENTIFIC SERIALS.

Symons's Monthly Meteorological Magazine, October.—Meteorological extremes. II. Temperature. Mr. Symons has collected a large amount of useful information upon this subject from all trustworthy sources. For yearly mean temperatures preference is naturally given to Dr. Buchan's isothermic charts published in the *Challenger* volume, "The Circulation of the Atmosphere." The highest yearly isotherms are 85°, and these occur only in three localities, the largest covering a portion of Central Africa, bounded on the north by latitude 18° N. Two smaller areas exist, one in Central India and the other in the northern portion of South Australia, respectively in latitude 15° N. and 15° S. The absolute range of the shade temperature in the northern hemisphere, and probably in the world, is 217°·8, depending on the absolute maximum of 127°·4 in Algeria, July 17, 1879, and the absolute minimum of −90°·4 at Verchoiansk, Siberia, January 15, 1885. The hottest region is on the south-western coast of Persia, where the thermometer has been known not to fall lower than 100°, night or day, for orty consecutive days during July and August, and often to reach 128° in the afternoon. Among the highest shade temperatures we may mention one at night during the Italian occupation of Massowah, when the thermometer is said to have recorded 122°. Temperatures above 120° are occasionally met with in India; 121°·5 was recorded at Dera-Ishmail-Khan (lat. 32° N.) in 1882, and 126°·0 at Bhag (lat. 29° N.) in 1859. At Wilcannia on the Darling River, New South Wales, shade temperatures varying from 107° to 129° were recorded on each day from January 1 to 24 in 1896. Among the low temperatures (in addition to the extremes mentioned above) we may quote −63°·1 at Poplar River, North America, in January 1885. During the intense frost in Scotland on December 4, 1879, −16° was reported from Kelso and −23° from Blackadder, in Berwickshire. The extremes in or near London for 104 years were 97°·1 in July 1881, and 4° in December 1796 and January 1841.

THE *Journal of the Royal Microscopical Society* for October contains a short paper (with plate) by Mr. James Yate Johnson on some sponges belonging to the Clionidæ obtained at Madeira, in which three new genera are established, named *Acca*, *Nisella* and *Scantilla*. In the section on microscopy is a description of an old compass microscope taken from a German work on the microscope by Martin Frobenius Ledermüller (1763), called Russwurm's "Universal Microscope," which appears to have been a combination of compass and tube microscope in an unusual number of forms; also a description of "Adams' Compendious Pocket Microscope" (1771), which more nearly conforms to the microscopes of the present day than any of those which preceded it. In the section on technique several new pigments are described, also two new methods for orienting small objects.

Bollettino della Società Sismologica Italiana, vol. v., Nos. 2, 3. 1899–1900.—Vertical component microseismograph, description and results, by G. Vicentini and G. Pacher. A reprint of a paper already noticed in NATURE.—Supplementary considerations with regard to the Umbria-Marches earthquake of December 18, 1897, by A. Issel.—The earthquake in the Parma-Reggio district of the Appennines during the night of March 4–5, 1898, by C. Agamennone. The shock was felt over an acre of about 70,000 sq. km., and was also recorded by horizontal pendulums at Strassburg and Shide; the velocity of the earth-waves will be considered in another paper.—The Hereford earthquake of December 17, 1896, by C. Davison. A summary (in English) of the writer's report on this earthquake.—Notices of the earthquakes recorded in Italy, February 5 to April 23, 1898; the most important being those of Asia Minor on February 5, Cividade (Udine) on February 20 and April 12, Reggio and Parma on March 4, Ferrara on March 9, and distant earthquakes on February 18 and April 15 and 23.

SOCIETIES AND ACADEMIES.

Physical Society, October 27.—Prof. W. E. Ayrton, F.R.S., Vice-President, in the chair.—Dr. S. W. Richardson read a paper on the magnetic properties of the alloys of iron and aluminium. Observations were made upon four alloys containing respectively 3·64, 5·44, 9·89 and 18·47 per cent. of aluminium. The alloys were used in the form of anchor rings, and were wound with primary and secondary coils separated by asbestos paper. The temperatures used ranged from −83° C. to 900° C. The low temperatures were produced by the rapid evaporation of ether surrounded either by ice and salt or by carbon dioxide snow. The high temperatures were obtained either electrically or by gas muffles. In both cases the actual temperatures were deduced from the resistance of the secondary, which was made of platinum wire and wound next the metal. The author employed Maxwell's null method of measuring mutual induction, increasing the sensitiveness by the introduction of a secohmmeter making about three revolutions per second. In order to test the accuracy of the method some of the experiments were repeated with a ballistic galvanometer in the ordinary way, and the agreement obtained between the results in the two cases was well within the limits of experimental error. The chief conclusions to be drawn from the experiments may be summed up as follows: (1) The alloys behave magnetically as though they consisted of two distinct media superposed. (2) The general roundness of the curves and their lack of abruptness near the critical point seems to indicate that the alloys are heterogeneous in structure. (3) The permeability decreases with rise of temperature near the critical point until a minimum value is reached, when further rise of temperature produces very slight diminution, if any, in the permeability. (4) The experiments suggest that the maximum value of the permeability for an alloy containing 10 per cent. of aluminium is reached at about −90° C. (5) An alloy containing 18·47 per cent. of aluminium has a critical point at about 25° C., and gives no indication of temperature hysteresis. This alloy probably has a maximum permeability much below −90° C. The author has found that at high temperatures there is a second maximum on the induction curve. This maximum becomes less and less noticeable as the field is increased.—The Secretary read a note from Prof. Barrett on the electric and magnetic properties of aluminium and other steels. The first part of the note dealt with the electrical conductivity of various alloys, and discussed the effect of composition and annealing upon the value of the conductivity. The second part of the note referred to magnetic effects. The most remarkable effect produced by aluminium on iron is the reduction of the hysteresis loss. The permeability of nickel steels is shown to be very much influenced by annealing. It is found that the addition of a small quantity of tungsten to iron hardly affects the maximum induction, yet increases the retentivity and coercive force. The experiments show that the best steel for making permanent magnets is one containing 7½ per cent. of tungsten. The magnetometric method was employed throughout. Prof. S. P. Thompson drew attention to the wide range of temperature over which the author had conducted his experiments, and also to the small number of alloys used. He said a very much finer connection between the properties could be obtained from the examination of more alloys, and expressed his interest in the existence of the second maximum on the induction curve. He would like to know how the percentage composition of the alloys had been determined. Turning to Prof. Barrett's note, Prof. Thompson referred to the difference in the breadths of the hysteresis curves for aluminium and chromium alloys. Mr. Appleyard asked for information upon the permanence of the curves. Dr. Richardson, in replying, said the compositions were determined by analyses made after the experiments had been performed. It was proposed to carry on the research upon a series of aluminium alloys which he had obtained. The Chairman expressed his special interest in the agreement which the author had obtained between the ballistic method and the null method of Maxwell increased in sensitiveness by the secohmmeter.—Mr. Addenbrooke exhibited a model illustrating a number of the actions in the flow of an electric current. The model consisted of a spiral of steel wire in the form of a closed circuit. Inside the spiral was placed a wire which was supposed to be carrying the current, and which directed the motion of the spiral. A rotational movement given to one part of the spiral was transmitted by the wire, and produced a rotational movement at another part of the spiral. The resiliency of the spring represents capacity, and the torque electromotive force. Self-induction can be represented by weighting the spring. Prof. Everett expressed his interest in the way that the correspondence between the propagation and rotation agreed with that between the direction of a current and the direction of the magnetic force. Prof. S. P. Thompson agreed that many analogies could be worked out by the model, but gave one or two examples to show that erroneous conclusions might be drawn by pushing the analogy too far.—Mr. W. Watson repeated some experiments with the Wehnelt interrupter devised by Prof. Lecher. The experiments showed in a clear and striking manner the fact that subsequent sparks tend to pass through the portion of air heated by the first one. In the first experiments motion of the heated air was caused by differences in density, and in the later experiments by allowing the sparks to take place in a strong electromagnetic field. The continuous rotation of the spark in a given field proved the unidirectional nature of the discharge. In reply to Mr. Blakesley, Mr. Watson said he used the word "ionised" in his explanations to express simply the fact that the air had been rendered a conductor by the passage of the spark. The Chairman referred to one of the first experiments performed. In this experiment the electrodes consisted of two copper wires in a vertical plane, slightly inclined to one another and nearest together at their lowest points. On switching on the current the spark passed between the lowest points; but as the ionised air ascended so did the most conducting path, and consequently the spark worked its way to the top of the electrodes. Here the heated air passed away and the spark returned to the lowest point to rise again. The Chairman thought that these effects might be due to the magnetic forces produced by the circuit itself. That similar effects in the arc light were due to this cause had been proved many years ago. Mr. Watson repeated some of the experiments under new conditions, and proved that the explanation of the phenomena was not to be found in the tendency of the circuit to enlarge itself owing to magnetic forces. Mr. Boys pointed out that the relation of the heating effect to the current, which was small in the arc light, was very large in the case of the spark discharges used, and therefore the movement of the spark in the latter case was practically determined by the heating effect in consequence of the relatively small importance of the electromagnetic effect. Prof. S. P. Thompson remarked that similar effects could be produced by an alternating current working an ordinary induction coil. —The Society then adjourned until November 10, when the meeting will be held in the Central Technical Institute.

PARIS.

Academy of Sciences, October 23.—M. van Tieghem in the chair.—On the simultaneous occurrence of phenomena of oxidation and hydration at the expense of organic substances under the influence of free oxygen and light, by M. Berthelot. Experiments were carried out on the slow oxidation of ether in presence of water and air, or of hydrogen peroxide. Practically no oxidation of moist ether takes place in the dark, either with air or hydrogen peroxide. After five months' exposure to light in a sealed tube, the air remaining over the ether contained no trace of free oxygen, but some aldehyde, acetic acid, and alcohol were found in the ether. A little methane is formed at the same time. Two chemical reactions are thus shown to go on together, a hydration and an oxidation. The author considers that similar reactions go on in nature, such substances as the sugars and carbohydrates, glycerides, &c., undergoing simultaneous hydration and oxidation.—Equilibrium of a vessel carrying liquid, by M. Appell. The author has shown in a previous paper on the same subject that the determination of the positions of equilibrium of a vessel with a liquid cargo may be reduced to the determination of the smallest value of the distance between two parallel planes tangential to two given surfaces. The problem is now simplified to finding the shortest distance of a fixed point to a tangent plane to one surface.—Observations on a note by M. Blondel, relating to the reaction of induction in alternators, by M. A. Potier.—On certain remarkable surfaces of the fourth order, by M. G. Humbert.—On the determination of the coefficient of solubility of liquids, by MM. A. Aignan and E. Dugas. In a previous paper by the authors it is shown how to determine the coefficients of reciprocal solubility of two non-miscible liquids when no contraction takes place. In the present paper, expressions are developed in which this restriction is removed, and the results are applied to experiments on mixtures of aniline and water, and amyl alcohol and water.—On merogonic impregnation and its results, by M. Yves Delage. The results published by the author a year ago showing the possibility of producing an embryo from a portion of an egg not containing a nucleus have now been extended. The fertilisation of non-nucleated ovular cytoplasm is not limited to the echinoderms. It is found in some molluscs, and in the annelid *Lanice conchylega*. Since it can no longer be looked upon as a biological curiosity, but is a process which may be generalised, the author proposes to give it the name of merogony.—The affinities and the property of absorption or arrest of vascular endothelium, by M. Henri Stassano. It is shown that it is the affinity of the vascular endothelium for mercury which is the cause of the predominance of this poison in the organs containing the most blood. This endothelium also appears to act in the same way with other poisons, such as strychnine and curare.—Death by the electric discharge, by MM. J. L. Prevost and F. Battelli. From a series of experiments on dogs, rabbits and guinea-pigs, the authors conclude that the fatal effects of the electric shock are proportional to the energy of the discharge, and are not proportional to the quantity of electricity passing.—The grafting of some monocotyledons upon themselves, by M. Lucien Daniel. After many unsuccessful attempts, it has been found possible to graft a part of a monocotyledon (Vanilla and *Philodendron*) upon itself. The success depends largely upon the extent of the surfaces in contact.—*La graisse*, a bacterial disease of the haricot, by M. Delacroix. The disease is probably identical with that recently described by M. E. F. Smith as affecting the haricot in the United States, and the bacillus from which is named *Bacillus phaseoli*. No curative treatment of the living plant would appear to be possible.—Observations relating to the deposit of certain calcareous travertins, by M. Stanislaus Meunier.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 2.

LINNEAN SOCIETY, at 8.—On the Proliferous State of the Awn of Nepal Barley: Rev. Prof. Henslow.—On the Hyobranchial Skeleton and Larynx of the New Aglossal Toad, *Hymenochirus Boettgeri*: Dr. W. G. Ridewood.—On the Eye-spot and Cilium in *Euglena viridis*: Harold Wager.

CHEMICAL SOCIETY, at 8.—The Theory of Saponification: J. Lewkowitsch. —The Action of Dilute Nitric Acid on Oleic and Elaidic Acids: F. G. Edmed.—Tetrazoline: Siegfried Ruhemann and H. E. Stapleton.—On Ethylic Dibromobutanetetracarboxylate and the Synthesis of Tetrahydrofurfuran-$\alpha\alpha'$-dicarboxylic Acid: Dr. Bevan Lean.—(1) Camphoroxime. Part III. Behaviour of Camphoroxime towards Potassium Hypobromite; (2) Optical Influence of an Unsaturated Linkage on certain Derivatives of Bornylamine: Dr. M. O. Forster.

CAMERA CLUB, at 8.15.—Scenery in the Canary Islands: T. C. Porter.

TUESDAY, NOVEMBER 7.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Address by the President, Sir Douglas Fox, and presentation of Prizes.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—Notes on the Ethnology of Tribes met with during progress of the Juba Expedition of 1897–99: Lieut.-Colonel J. R. L. Macdonald, R.E.

THURSDAY, NOVEMBER 9.

MATHEMATICAL SOCIETY, at 8.—Certain Correspondences between Spaces of n Dimensions: Dr. E. O. Lovett.—On the Form of Lines of Force near a Point of Equilibrium; The Reduction of Conics and Quadrics to their Principal Axes by the Weierstrassian Method of reducing Quadratic Forms; and on the Reduction of a Linear Substitution to a Canonical Form; with some Applications to Linear Differential Equations and Quadratic Forms: T. J. I. Bromwich.—On Ampère's Equation $Rr+2Ss+Tt+U(rt-S^2)=V$: Prof. A. C. Dixon.—The Abstract Group isomorphic with the Symmetric Group on k Letters: Dr. L. E. Dickson.

FRIDAY, NOVEMBER 10.

ROYAL ASTRONOMICAL SOCIETY, at 8.

CONTENTS. PAGE

THURSDAY, NOVEMBER 9, 1899.

THE GEOLOGY OF THE SOUTHERN UPLANDS OF SCOTLAND.

The Silurian Rocks of Britain. Vol. I. Scotland. By B. N. Peach, F.R.S., and J. Horne, F.R.S.E.; with Petrological Chapters and Notes by J. J. H. Teall, M.A., F.R.S. Pp. xviii + 749; plates xxvii, and a coloured map. (Memoirs of the Geological Survey of the United Kingdom, 1899.)

THE student of historical geology, in his endeavour to obtain a comprehensive view of the sequence of events in a particular area, is too frequently conscious that he is gazing at a distorted picture. It is probably beyond the power of any one person to gather together the tangled mass of detail, and by a process of anamorphosis, to illustrate the geology of even a single country in such a manner that while the proportions of the whole work are harmonious, every important detail is also presented with conspicuous clearness. But that which is too much for one person may be carried out by a band of workers under the direction of one chief; and fortunately we in Britain, the mother-country of stratigraphical geology, not only possess this band, but know that it is actually engaged in the accomplishment of the desired work.

It is now some years since the first volume of a series of memoirs devoted to a detailed study of the various great groups of the British stratigraphical rock-column was issued by H.M. Geological Survey. This series, when complete, will place within reach of the geologist a history of the British strata, of which we cannot overestimate the value. The Jurassic rocks of Britain have already been described in two volumes: one, by Mr. Fox-Strangways, treating of the Jurassic rocks of Yorkshire; the other, by Mr. H. B. Woodward, describing those of the other British areas. Another volume, by Mr. Clement Reid, is devoted to the Pliocene strata, and we are now presented with the first volume of the series in which the British Silurian rocks will be described, the particular volume under consideration containing an account of the Silurian rocks of Scotland.

The most important area of Silurian rocks in Scotland is developed in the Southern Uplands, and to consideration of this area the present volume is essentially confined. It is noted, however, that igneous rocks and radiolarian cherts have been detected along the southern border of the Eastern Highlands; and in this connection it is interesting to note that Hugh Miller in his "Rambles of a Geologist" records, on the authority of Dr. Emslie, the occurrence of graptolites in a slate quarry at Gamrie Head, near Banff.

In glancing at the memoir by Messrs. Peach, Horne and Teall, we are at once struck with the fact that the great bulk of the contents consists of records of fresh observations. The amount of work which the authors have performed in the field and the laboratory is surprising even to the general reader, still more so to any one who from some knowledge of the area is cognisant of its extraordinary complexity.

Great as the amount of new work recorded in this volume undoubtedly is, the authors took up their study of the region subsequently to its description by a number of other geologists, of whom the illustrious Hutton was the first, while Prof. Lapworth, as is well known, reduced the stratigraphy of the area to order in several masterly papers appearing in the *Quarterly Journal of the Geological Society*, the *Geological Magazine*, and the *Annals and Magazine of Natural History*. The importance of Prof. Lapworth's work is acknowledged in the volume under notice, in the fullest manner, both in the chapter devoted to the history of previous researches in the south of Scotland and in those which treat of the geology of the region in detail.

Though Lapworth led the way to appreciation of the complicated nature of the geology, the authors of the memoir have not only verified his conclusions, but added a great deal of confirmatory matter, and have furthermore made a series of discoveries which throw light upon questions of prime importance to geologists.

Among the discoveries which are of general interest as shedding light upon geological matters of widespread importance, we may notice the discovery of Arenig graptolitic mudstones, radiolarian cherts and contemporaneous volcanic rocks over very wide tracts of country in the Southern Uplands and South-eastern Highlands; the detection of the occurrence of further volcanic outbursts in Llandeilo and Caradoc times; the evidences of the lateral variations in the sediments of different ages indicating a source of supply of terrigenous sediment to the north-west of the area, and of the gradual encroachment of the coarser sediments to the south-east, in the later periods of Silurian times; the definition of a Downtonian period between Ludlow and Old Red Sandstone times, and the description of the rocks of this period; and the discovery of a remarkable fauna of fishes in these Downtonian strata, which has been described by Dr. Traquair. The above discoveries are mainly due to Messrs. Peach and Horne, who, like Lapworth, have chiefly utilised the graptolites as a means of comparing the strata of different localities, though they have also obtained much assistance from the persistent cherts, which, as shown many years ago by Dr. G. J. Hinde, were largely formed by the accumulation of tests of radiolaria. The writers appear to adopt the suggestion that these radiolarian cherts are deep-water deposits, though, in consideration of the evidence which they adduce in support of the existence of a tract of land at no great distance to the north-west, it seems doubtful whether the cherts are strictly comparable with the abyssal radiolarian oozes of modern oceans. Mr. Teall gives a petrographical account of the remarkable volcanic rocks associated with the radiolarian cherts, and of the contemporaneous volcanic rocks of higher strata; also a description of the intrusive rocks of the Girvan and Galloway district, with details of the nature of the metamorphism impressed upon the rocks surrounding the irruptive igneous masses. One exceedingly significant suggestion is made to the effect that the coarsely crystalline plutonic rocks were consolidated beneath a small thickness of overlying rock-cover, though it is stated that the evidence for this is imperfect.

The results of the palæontological investigations are summarised in lists of fossils, occupying about fifty pages at the end of the work; these, and the detailed lists of fossils appearing throughout the book, will be of the utmost value to the stratigraphical palæontologist.

The form in which the book is presented to the reader is excellent, and the work is well illustrated. In addition to the numerous diagrams and sections illustrative of the geology of the area, which are scattered through the memoir, there are seventeen plates reproduced from photographs illustrating the appearance of some of the sediments, including the radiolarian cherts, and especially of the volcanic rocks, both lavas and fragmental accumulations; in connection with the lavas, we may particularly note the illustrations of the remarkable rocks with "pillow-form" structure which are associated with the radiolarian cherts. Of the remaining plates, eight represent microscopic sections of various rocks, while two are devoted to illustrations of characteristic graptolites. In addition to these plates, there is a well-coloured geological map of the area, on the scale of ten miles to the inch.

The third chapter of the book, in which the authors give a general description of the Silurian rocks of the Southern Uplands, will be read by all geologists; the detailed descriptions in the other chapters will be largely utilised by those who visit the region; and, if we mistake not, these visitors will in future become very numerous, attracted to the district owing to the publication of a memoir upon a region of exceptional complexity but also of exceptional interest—a memoir which will at once take its place as a classic in geological literature. J. E. M.

THE PHILOSOPHY OF ATOMIC THEORIES.

Essai critique sur l'Hypothèse des Atomes dans la Science contemporaine. Par Arthur Hannequin, Professeur à la Faculté des Lettres de l'Université de Lyon. Second edition. Pp. 457. (Paris: Alcan, 1899.)

PROF. HANNEQUIN attempts, in the first of the two books into which his work is divided, by a discussion of the first principles of mathematical knowledge and a study of the progress of physical and chemical science, to establish at once the necessity and the contradictions of atomism; in the second book it is sought to reconcile the contradictions by an appeal to metaphysics.

According to M. Hannequin it is by a necessity of its nature that human science reduces all to the atom as it has already reduced all to motion—the need to render intelligible all that falls under the intuition of the senses or all phenomena. Our mind can only take hold of or comprehend what comes from itself, it only knows fully what it creates. Thus science in the measure of its rigour and certainty is a creation of our mind. The science *par excellence*, the science derived entirely from the mind is the science of number. Physical atomism is not imposed on science by reality, but by our method and by the nature of our knowledge. It does not necessarily imply the real discontinuity of matter; it implies only that we make it discontinuous in order to comprehend it. It has its origin in the universal use of number.

"The atom is found at the end of all analysis as the product of the struggle of quantity against magnitude, of unity and number against the multiplicity and continuity of space and time."

In Chapter i. of the first book M. Hannequin discusses the question whether pure geometry itself involves the notion of quantity, and therefore of number, and concludes that it does. Amalytical geometry more obviously does so, and the author discusses at some length what is involved in the process of differentiation. Infinitesimal analysis appears to him to lead the mind necessarily to postulate in every geometrical object indivisible elements. On the other hand he concludes that all attempts, such as that of Cantor, which is criticised at some length, to express continuity by means of number must fail.

The analysis which gives us the concept of the geometrical element would not of itself, according to M. Hannequin, have given us that of the atom, had not our mind demanded the mathematical explanation of nature.

With mechanics our mathematics approaches as closely as it can phenomena and reality. In Chapter ii., on "Atomism and Mechanics," the author sets out to show that our ideas of motion lead us straight to the discontinuity of matter. His treatment of the fundamental notions of mechanics, of motion, force, mass, is interesting but not always convincing. For instance, it scarcely seems legitimate to make the first law self-evident by saying that when a body is in a state of uniform rectilinear motion or is at rest, one has the right to affirm by definition that it persists in an identical state, and that to no change corresponds no cause; on the other hand, to every definite variation of velocity or to every acceleration must correspond a definite cause which we call a force.

The hypotheses of centres of force, such as that of Boscowich, are condemned by Hannequin on what appear to be inadequate grounds. Vortex rings meet with no better fate.

When we come to "kinetic atomism" the necessity of postulating atoms becomes more apparent than the author has thus far succeeded in making it, and at the same time contradictions also appear. The difficulties of kinetic atomism as brought out by M. Hannequin are twofold. In the first place, we have the contradiction between the indivisibility of the atom and its perfect elasticity. In the second place, the number of atoms can neither be infinite nor finite. It is apparently atomism of the most thorough-going kind that is here considered, action at a distance being excluded and gravitational energy being taken as kinetic; otherwise there is no difficulty in holding the number of atoms to be finite.

In Chapter iii., on atomism and nature, the author attempts to show that the particular sciences of nature arrive at atoms of different and decreasing orders.

The chemical atom is first considered; the laws of definite and multiple proportions, and the methods of determining the relative masses of the atoms with the aid of Avogadro's and Dulong and Petit's laws being discussed. The possibility of the existence within the chemical atoms of smaller primordial atoms is next treated with reference to Prout's hypothesis and the facts of thermal chemistry and chemical affinity.

From the facts of optics we deduce the existence of an æthereal medium, which according to Fresnel's view is discontinuous. (A good account is given in this section of the struggle between the corpuscular and undulatory theories.) The dispersion of light as interpreted by Cauchy lends support to the discontinuity of the medium.

Unfortunately, the luminiferous æther cannot be made to explain gravitation. The author discusses some of the theories of gravitation, such as that of Lesage. Moreover, the elastic æther which transmits light cannot account for electro-magnetic actions. Prof. Hannequin also finds difficulties in the electro-magnetic theory of light; these appear to rest, however, not on any impossibility of accounting for optical phenomena on the electro-magnetic theory, but on the irreconcilable differences in the properties of the æther as originally invented to explain light and those of the electro-magnetic æther.

In this way we arrive at a multiplicity of irreconcilable æthers as well as a multiplicity of irreconcilable atoms.

The necessity and the contradictions of atomistic explanations of nature having thus been brought out, the author concludes his first book as follows:—

"Why should atomism be found everywhere in modern science to such an extent that it is, as it were, its vital principle, if its contradictions were final, and if they had not their last reason in the very substance of a reality which only appears to us under the obscure veils of space and time, but which perhaps will reveal its law to him who will seek it above extension and duration, or in a word above the appearances which science analyses?"

We are thus led to the purely metaphysical part of the work, which it would be out of place to attempt to discuss here. The final chapter, however, sums up the conclusions arrived at. Science will never attain to the indivisible towards which she seems to be incessantly marching; if she did reach it, she would be unable to explain nature by means of it. Our difficulties vanish if we render to the atom its true sense—the element, definite but always complex, with a minimum of extension in space and a minimum also of dynamical attributes. And instead of seeing in it the real individual stripped of all activity and of all quality, all that we ought to see in it is the work of the mind pursuing in space the reduction without end of phenomena which, though pure appearances, are appearances which have their basis in reality.

There can be no question of the interest and importance of a philosophical examination of the foundations of science such as M. Hannequin has attempted.

He has, we think, exaggerated the inconsistencies of the "atoms" postulated for different purposes. So long as we do not imagine that we have ever to deal with absolute indivisible structureless atoms the contradictions do not exist. Most of us would agree with M. Hannequin as to the barrenness of any system of absolute atomism.

There is no reference in the book to any of the more direct methods in which matter is proved to have a discontinuous structure, and by which an estimate is obtained of the size of the molecules; such methods as are described in Lord Kelvin's lecture on the size of atoms (Popular Lectures and Addresses). This is surely a serious omission.

OUR BOOK SHELF.

Elements of Physics. By Henry Crew. Pp. xiv + 347. (London: Macmillan and Co., Ltd. New York: The Macmillan Company, 1899.)

THE writer of this review possesses a collection of text-books of physics written during the first half of this century, all the volumes put together occupying a length of about six feet on his book shelves. He sometimes wonders where a future collector would find the space for all the text-books written now, when professors who have not written their own text-books are beginning to be rare curiosities. The proportion of books, however, that possess any originality has not increased, and may be put down, roughly speaking, as one in ten. The rest may be good because they have been inspired by good books, but there is a dreary similarity between them.

It would be ungracious to make these remarks while reviewing one of the average class of productions, and it must therefore at once be stated that Mr. Crew's volume cannot help striking the reader at once as having been the result of a good deal of thought, both in wording and arrangement. The book is very elementary. I think it is customary in this country to enter somewhat more fully into many parts of the subject, even in a first course. On the other hand, it treats of several matters which it is customary to omit, and it is on this point that we wish specially to commend the volume.

I note with great satisfaction a general chapter on waves, before the special consideration of sound waves is entered upon, also the introduction—at an early stage—of the wave theory of light. The great amount of time which, owing to examination requirements, we are forced—often against our will—to devote to geometrical optics, would much more usefully be spent in explaining (as the writer seems to do) the elements of diffraction and interference.

It is, further, a satisfaction to see frequent allusions to the phenomena of every-day life, and this feature might have been still further extended by including, for instance, some reference to the principal meteorological phenomena. No doubt very often the most common occurrences are most difficult to explain, and it may be impossible to give to elementary students a satisfactory explanation of, *e.g.*, the rainbow or the blue colour of the sky. But unless the attempt be made the students generally carry away the impression that what they learn in the lecture room belongs to a different part of their existence from what they can see and observe outside the college buildings. The book begins with mechanical and kinematical principles, including among other matters the consideration of harmonic oscillation and a well-considered chapter on the properties of matter.

Altogether it forms an admirable introduction to the study of physics. The only criticisms I should like to make, refer to some of the illustrations; but as the book only suffers to a slight extent from the prevailing epidemic of bad illustration caused by the spreading microbe of cheap processes of reproduction, we must be satisfied and say no more about it. ARTHUR SCHUSTER.

A Laboratory Outline of General Chemistry. By Alexander Smith. Pp. 88. (Chicago: Kent Chemical Laboratory of the University of Chicago, 1899.)

THIS book comes with a strong claim to attention. I is an untrammelled attempt to lay down a course of practical chemistry in an educational and scientific spirit, and the author's introduction sounds a pleasing note.

Much thought, care, and experience are embodied in the work, and though no claim to originality of material is made there are a good many things included that are fresh to books on practical chemistry The author makes some very just remarks on the difficult question of the correlation of lecture and laboratory work, and it is to be remarked that the efficacy of the course he lays down must depend very largely on the adjustment to it of lecture and tutorial instruction. How successfully this difficulty has been met in the University of Chicago we have not the means of judging. The book as it stands leaves the reader under the necessity of constructing in imagination the whole course of lectures or preferably "conferences" to which it is essentially related, and it is hardly likely to be put in use by English teachers unless they are prepared to recast their oral teaching to suit it.

The particular order in which the topics of general chemistry are to be treated, the particular points to be elucidated by the student's own experiments, are matters which may afford room for endless choice, but after that, in the point of method, there is a clearer right and wrong to choose between. We believe that some chemists may take exception to Dr. Smith's order and choice of topics, but his method of bringing them before the student will probably meet with general approval. He strives throughout to cultivate the investigator's attitude of mind, bearing in mind however that it is impracticable for the laboratory training of a chemist to be wholly carried out on this plan. The text is interspersed with question marks and with parenthetical injunctions to the student to interpret and correlate his facts.

The exercises are all drawn from inorganic and physical chemistry, and include an elementary study of the cardinal points of theory. We can well believe that this course of practical work, combined with properly conducted class meetings, will furnish a much more effectual introduction to the study of chemistry than students ordinarily obtain in Universities, where the continuous expository lecture to junior classes, unlimited in size and containing all sorts and conditions of students, is still the customary, if not the inevitable, method of procedure. A. S.

Ueber den Habitus der Coniferen. Von Dr. A. H. Burt. Pp. 86. (Tübingen: Verlag von Franz Pietzcker, 1899.)

THIS inaugural dissertation is mainly concerned with an analysis of the forms exhibited by the different groups of conifers. Following Vöchtung, the author recognises two principal types—the monocormic and polycormic respectively. The former is characterised by the presence of a decided main axis, the lateral axes being dominated by its growth; the common spruce fir is an example of a monocormic conifer. Polycormic forms are met with in cypresses and junipers, in which the lateral branches are not all reduced to subordinate and graduated positions; whilst in the cedars, forms are met with which combine the characters of both of the principal types.

Elaborate tables of measurements of the relative lengths of main and lateral shoots, and of the angles made by them, are given in the text, and clearly bring out the factors on which the shapes of conifers depend.

Beasts: Thumb-nail Studies in Pets. By Wardlaw Kennedy. Pp. xvi + 152. (London: Macmillan and Co., Ltd., 1899.)

THE spirit of a true naturalist prevails throughout this book. The author records his experiences with a number of uncommon animal pets, among which were a young crocodile, a python, an armadillo, and a mongoose. His observations are of real scientific interest, and his humorous descriptions are pleasant to read as well as instructive. Though natural history cannot be learnt from books, the boy who reads the essays in this volume will be encouraged to observe the habits of animals for himself, and will thus learn to depend upon the evidence of his senses rather than to trust upon second-hand information. The book would be an acceptable Christmas present for any boy interested in natural history.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Next Week's Leonid Shower.

THE anticipated return of the great Leonid shower within a few days is looked forward to with so much interest that it appears desirable to examine what data we possess for forming a forecast in relation to it.

In a paper on the perturbations of the Leonids, which is published in the *Proceedings* of the Royal Society for March 2, 1899, we gave the perturbations which have during the last thirty-three years affected those meteors which are situated near a particular station in the stream, namely the station through which the earth passed in 1866 and of which Adams had computed the orbit. It will be convenient to speak of this position in the immensely long stream of ortho-Leonids as station A.

By these calculations it was ascertained that this portion of the stream has been subjected to an unusual amount of perturbation during the revolution which has occupied the last thirty-three and a quarter years; so much so, that the advance of the node, upon which the epoch of the coming shower largely depends, has during this revolution been of more than three and a half times its average amount. Its having had this exceptional value has been caused by unusually close approaches of the great planets Jupiter and Saturn to the meteors during this revolution.

Another effect of these abnormal perturbations has been to shift the position of the ellipse in which station A moves in a direction perpendicular to the earth's path, so that the point in which it pierces the plane of the ecliptic will, on the 15th of the present month, lie inside the earth's orbit at a distance from it of 0·0141 of the earth's mean distance from the sun. This would be a sufficiently large displacement to carry the stream entirely clear of the earth, if it were a mere cylindrical stream; in which case we should have no great shower this year. But we have satisfied ourselves, by an examination made by one of us into the dynamical conditions which prevailed when the Leonids were drawn by the planet Uranus into the solar system, that the stream is not thread-like but strap-shaped, so that its intersection with the plane of the ecliptic is an oval of some sort—probably a long oval—of which the longer axis originally lay nearly perpendicular to the earth's path. On account of this oval form of the section of the stream, the earth is likely to receive one of the great showers this year, notwithstanding the fact that the situation in the stream through which the earth passed in 1866, will on its return pass at some distance from the earth.

If the longer axis of the oval now lay perpendicular to the earth's path, the most probable epoch for the middle of the shower of this year would be 1899 November 15d. 18h., which epoch we offered with careful reservations in the paper which is above cited. A further examination, however, has shown us that perturbations have been acting on this oval ever since the Leonids became members of the solar system, tending very slowly to rotate its major axis in a retrograde direction through an angle which will ultimately become nearly a right angle. The data at our disposal do not enable us to compute how far this retrogade shift has carried the axis in the seventeen centuries during which perturbating forces have been acting upon it. Under these circumstances we must have recourse to observation to ascertain the amount of the shift. A laborious attempt to estimate it in this way has furnished 52° as the angle of shift, which would indicate that the epoch for the shower of this year is as much as twenty-two hours earlier than 1899 November 15d. 18h., that is it would bring it back to 1899 November 14d. 20h.; but we do not attach any value to this particular determination, inasmuch as the data which are as yet at our disposal are too uncertain for us to rely on them. What appears tolerably certain is that *some* shift of the position of the oval section of the stream has taken place, and that the middle of the shower is accordingly likely to come earlier than 1899 November 15d. 18h., probably some hours earlier, and possibly a considerable number of hours. Under these circumstances it appears desirable that a watch shall be maintained in the atter part of the night between the 14th and 15th, as well as throughout the night between the 15th and 16th of this month, beginning the watch at 10.30 p.m. Before that hour observations cannot be made, the radiant point of the Leonids being below our horizon.

A computation of the perturbations of two other stations in the stream, in which we have made use of Dr. Berberich's results to supplement our own, has established a fact which we had anticipated, viz. that different parts of the immensely long ortho-stream have been so variously affected by perturbations that the stream cannot now be a uniform one evenly extended along a portion of its elliptic orbit. We must accordingly recognise that it is more or less sinuous, and that, moreover, the distribution of meteors along it is uneven. All such circumstances introduce further elements of uncertainty into any attempt which we may make to form a forecast.

On account of the abnormal amount of the perturbations within the last thirty-three years, the method by which the prediction was made in 1866 is not sufficient on the present occasion. It was based on the average amount of the shift of the node. If employed on this occasion, it would assign for the shower of this year the epoch 1899 November 14d. 12h., which is almost certainly too early.

London, November 4. G. JOHNSTONE STONEY.
A. M. W. DOWNING.

Undercurrents.

I AM much obliged to Admiral Makaroff for so courteously answering my queries in my letter to NATURE in the number for August 3, p. 316; and I regret that having mislaid my copy of his book, the "Vitiaz," I have not been before able to reply. On now studying his observations in the Strait of Bab-el-Mandeb, and his remarks in his letter (NATURE, October 5, p. 544), I fear I cannot any more share his opinions than I did before.

My point is that it is not sufficient to ascertain that there is a difference of specific gravity either between the surface water or either side of a strait, or between the surface and lower strata of water in a strait, to be able to come to the conclusion that such difference is the primary cause of surface and undercurrents in opposite directions. It has been shown by experiment that such differences give rise to a slow interchange of water, and to this extent I am of course prepared to agree that differences of specific gravity cause opposing currents; but the currents we are dealing with are of a vastly different character and strength.

I have already pointed out that my observations in the Dardanelles and Bosporus in 1872 showed that the currents did not always run in the normal directions, and that their variations were traceable to the varying winds; and to that I have nothing to add.

On looking at Admiral Makaroff's density observations in the Strait of Bab-el-Mandeb, I see that the specific gravity varied from 1·0279 at the surface to 1·0292 at 200 metres, while the surface waters of the Red Sea itself and of the Arabian Sea near Sokotra are given as 1·0300 and 1·0279 respectively.

In saying that "here are none of the differences of specific gravity demanded by Admiral Makaroff's hypothesis," I was referring to the great contrast between the difference in the densities of the Black Sea and Mediterranean, viz. ·017, and those of the Arabian Sea and Red Sea, viz. ·002, and never thought for a moment that the very small variation in density in the latter case could be held capable of setting up currents of 1½ knots in opposite directions at surface and bottom, as found by "Stork's" observations in the N.E. monsoon.

No observations have yet been made on the undercurrent in Bab-el-Mandeb in the S.W. monsoon; but the surface current is known to run in the contrary direction to what it does in the N.E. monsoon, *i.e.* again with the wind, or *out* of the Red Sea, and I should be much surprised to find that the undercurrent does not also run in the contrary direction, probably with much greater strength than the surface current, because the great evaporation of the sea has also to be made up.

Absolute proof of the causes of such phenomena as these under discussion comes slowly, and only after laborious observation; but I certainly think that the work of the last twenty-five years has tended to show that the influence of density as compared with wind is insignificant. W. J. L. WHARTON.

Florys, Wimbledon Park, November 4.

"Anlage" and "Rudiment."

SOME months ago Prof. Herrick, who is in charge of the department of Neurology in the "Dictionary of Philosophy and Psychology," which I am editing (now in the press of Macmillan and Co.), addressed a circular to various authorities asking their opinion on certain matters of terminology. The results were collated and discussed by Prof. Herrick in the *Journ. of Comp. Neurology*, vii. 3–4, 1898. Among the matters in question was the English equivalent of the German term *Anlage*. Prof. Herrick came to the conclusion that *Proton* and *Rudiment* were more available than any other words suggested (ruling out the use in English of *Anlage* with its German inflexion).

It now happens that the French and Italian committees, who are recommending equivalents, in their respective languages, for the terms in the Dictionary, make reports which I think are of importance. Prof. Delage, of Paris, for the French committee, recommends *rudiment*, and, as it happens, Prof. Morselli, of Genoa, sends in *rudimento* as the preferred Italian term. This agreement—and to say this is my aim in writing—affords a strong argument for the adoption of *Rudiment* in English. It is evident that it would be of immediate and very great advantage—for example, to translators from any one of these languages into any other—if *Rudiment* were made the common rendering of *Anlage* in the three other languages of modern science. The other great advantage would be that we already have the adjective form, *rudimentary*, in use.

Furthermore, the psychologists may use the same term for the German *psychologische Anlage* which has crept into recent German discussions. In English, biologists and psychologists will then have the common term *rudiment* with a well-understood signification. I am recommending this to the committee on terminology of the American Psychological Association, of which I happen to be secretary. J. MARK BALDWIN.

Oxford, October 22.

Interference Curves depending on Perspective.

CLOSELY allied to the halo round an observer's shadow (referred to in Mr. S. Newcomb's letter in NATURE, October 5) are a number of phenomena due to perspective, which may be seen every day by any one who is on the look out for them.

Among these may be mentioned the dark waves which seem to accompany a traveller when he looks through two series of upright palings which lie parallel to each other and his course; also the patterns like the grain of wood which appear when two superposed sheets of gauze are held against the light.

As these and the like appearances have not, as far as I know, hitherto been looked at from a mathematical point of view except in one instance,[1] the three following examples, which are typical but simple, may be of interest:—

(1) Interference rings due to parallel lines on a spherical surface, and their shadow or reflection on a plane or in a plane mirror.

Let a small part of a sphere of radius r be ruled with equidistant parallel lines, the distance between the lines being small compared with r. Let the convex surface of the sphere touch a plane mirror, and let surface be viewed from a distant point, the line joining the distant point, and the point of contact making an angle i, with the normal to the plane.

Taking the plane containing the point of view and the normal through the point of contact as the plane of reference, let a be the angle between the plane containing a line and its reflection and the plane of reference. Let θ be the angle which a point on the spherical surface distant ρ from the normal through the point of contact subtends at the centre of the sphere (so that $r \sin\theta = \rho$), and ϕ the angle which ρ makes with the plane of reference.

It is plain that where, from the point of observation, any part of any line hides the reflection either of itself or any other line, the field will look brighter in that direction than where the line and the reflection are both visible, and the condition which must be fulfilled in order that one line may hide the reflection of another n lines off is (neglecting second order quantities) that the distance between the hidden reflection and the line reflected (that is, twice the distance of the line from the reflector) multiplied by tan i should be equal to n times the projection of a on the plane of reference, or in symbols,

$$2r(1-\cos\theta)\tan i = \frac{na}{\cos a},$$

[1] Lord Rayleigh's "Theory and Manufacture of Diffraction Gratings" (*Phil. Mag.*, 1876).

since this equation does not contain ϕ, ρ is constant whatever the value of ϕ may be; hence the bright parts of the field are circular rings surrounding point of contact of the plane and spherical surface.

The radii of the dark rings can be deduced from the relation

$$2r(1-\cos\theta)\tan i=\frac{2n-1}{2}\,\frac{a}{\cos\alpha};$$

and from these equations it is easily shown that for the bright rings

$$\rho=\sqrt{\frac{ran}{\tan i\cos\alpha}},$$

and for dark rings

$$\rho=\sqrt{\frac{\frac{2n-1}{2}ra}{\tan i\cos\alpha}}.$$

This may be compared with the corresponding values for Newton's rings.

In both cases the radii of the bright and dark rings vary as the square roots of the even and odd numbers, and as the square root of the radius of the sphere and the wave length (which is analogous to a in the present case), but here the likeness ceases.

The rings here considered diminish as i increases, and increase as α diminishes.

Of course, in Newton's rings there is nothing which answers to the angle α.

The easiest way of examining these rings is to mould a small circle of wire gauze to form part of a sphere (which can readily be done by pressing it with a ball against any yielding substance) and laying it, convex surface downwards, on a piece of looking glass.

In general two sets of rings will be seen, one due to the wires of the warp, and the other of the woof of the gauze.

When the eye, however, looks parallel to one set of wires, the rings of that set are all infinite, and only the set due to the wires at right angles to the line of sight are visible.

If the gauze is made to turn slowly on the point of contact, both series appears, one growing, and the other diminishing, which are exactly superposed when $\alpha = 45°$.

A curious effect may be observed when a thick plate of glass is placed between the gauze and the looking glass.

The rings in this case become coloured, showing blue on their inner, and red on the outer margins of the dark bands.

The explanation is obvious, for the pencils of white light entering through the meshes of the gauze are dispersed on entering the glass, and in the neighbourhood of the dark rings only part of the dispersed pencils are cut off on their second passage through the gauze, so that the light which reaches the eye is coloured.

If t is the thickness of the glass plate, the greatest colour effect is obtained when $t=b\mu/2d\mu\tan r$, where b is the diameter of the wire and r the angle of refraction in the glass.

When the glass plate is used, of course the smallest visible ring is not that for which $n=1$, but it is unnecessary here to enter on the alteration in the formula for ρ caused by putting $2r(1-\cos\theta)+t)$ for $2r(1-\cos\theta)$.

(2) Interference rings caused by two series of straight lines, radiating at equal angles, from two centres in the same or parallel planes.

Let there be n lines in each series, then the angle between successive lines in each series is $2\pi/n$.

Let the lines of the first series be numbered 1, 2, 3 . . . p . . . n and those of the second $1'$, $2'$, $3'$ . . . q' . . . n, and let the line 1 be parallel to the line $1'$. Then the angle made by any line p of the first series with another q' of the second is $(p-q)2\pi/n$, hence the intersections of all pairs of lines for which $(p-q)$ is the same will lie on a circle passing through the two centres and having this segmental angle.

When the distance between the centres is a, the radius of the circle is

$$\rho=a\operatorname{cosec}2\pi(p-q)/n$$

if both centres are in the same plane, or

$$(a+b\sin i)\operatorname{cosec}2\pi(p-q)/n$$

if in different planes, where a = distance between the normals to the planes through the centres, b the distance between the planes, and i the angle made by the line of sight with the normal.

The loci of the intersections appear brighter than any other part of the field of view, hence the intersections of the two series show as a family of bright and dark circles which all pass through the two centres, and whose radii are as the cosecants of the multiples of $\frac{2\pi}{n}$.

This is shown in Fig. 1.

A pair of wheels of a carriage, one viewed through the other, show the phenomenon very well, especially when the wheels are turning fast enough to make the individual spokes indistinct.

Under favourable circumstances as to light and background, the appearance of the rings, contracting and expanding as the angle of view changes, is very striking.

(3) Interference curves from two series of straight lines, one radiating and the other parallel.

From a point P in the axis of Y let radiating lines be drawn to cut the axis of X at equal intervals a, and at a, $2a$, $3a$, &c., let lines be drawn parallel to Y.

Then, if the distance of P from the origin is h, to determine the coordinates of the intersection of the nth parallel line with the $n+p$th radiating line, we have, since $x=na$,

$$\frac{h-y}{h}(n+p)\,a=na,$$

hence

$$\frac{y}{h}(n+p)=p.$$

The locus, therefore, obtained by giving the value 0, 1, 2 . . ∞ to n will be a series of points on a rectangular hyperbola passing through P with its centre at $y=0$ $x=-pa$.

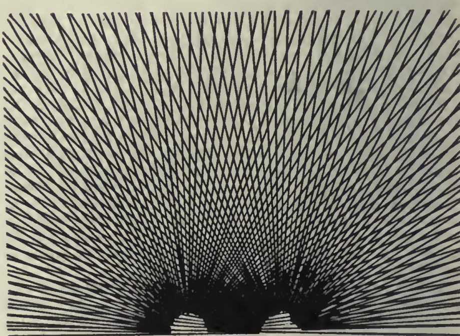

FIG. 1.

Thus the field of view will show a family of hyperbolæ (one for each value of p), all passing through P, the parameters being $\sqrt{pha}$.

In the same way, for the intersections of the nth parallel with the $2n+p$th radiating line we have

$$\frac{y}{n}(2n+p)=p,$$

which indicates a second family of hyperbolæ, the coordinates of the centres being $\frac{h}{2}$ and $-\frac{p}{2}$.

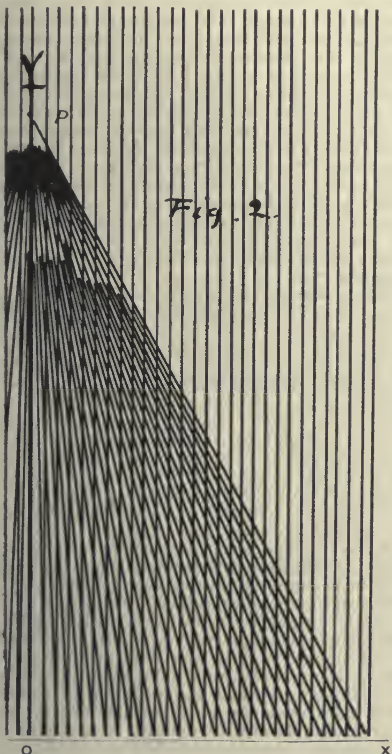
Similar families are formed by the intersection of the nth parallel, with the $3n+p$th . . . $4n+p$th . . . &c., radiating lines, the corresponding centres being $y=\frac{2h}{3}$, . . . $\frac{3h}{4}$, &c. and $x=-\frac{p}{3}$, $-\frac{p}{4}$, &c.

It will be readily seen that the dark and bright bands formed by the interfering lines follow the short diagonals of the quadrilaterals into which the two series of lines divide the field, and that for the bands to be conspicuous, there should be a great difference in the length of the two diagonals, and only a small difference in the length of the sides of the quadrilaterals.

For this reason only a part of each hyperbolic family is recognisable.

In Fig. 2 the first two families are both well seen in parts, and some of the curves of the third family can be recognised.

We may, if we choose, consider the radiating lines as the perspective view of a series of parallel lines in a plane inclined to X Y.



We then have the case of a row of vertical railings and their shadows on the ground.

In passing a line of such railings when the sun is low, the curves, which appear to travel with the observer, may often be noticed. A. MALLOCK.

The Indian Forest Service.

I AM very glad to see Prof. Schlich's defence of the Indian Forest Service in NATURE of November 2. I have myself been very closely connected with forest administration in the Bombay Presidency from 1871 to 1894. I may say that I have seen the Department there grow up from little better than chaos into a well-organised corps of spirited and well-trained officers; and there is not one word in Prof. Schlich's letter that I cannot heartily support.

Botanists can hardly be too abundant in India; but if we want good systematic botanists there, we must call them by that name, and either train them specially to that science, or get men so trained in the market.

It is to me surprising that the Indian forest officers have done so much botanical work as they have, to say nothing of the services of several of them to zoology; and it must be remembered that their appointments are even now won at a considerable cost in toil and money, that their pay is not high, and that their duties involve at least as much hard work of body and mind, as much hardship, and as much risk, as those of any other service in India.

Forestry is not all botany. It may, perhaps, be best defined as the "proper management of hardy life upon large areas." And the man who does that best is the best forester. We have a great many who do it well, and amongst these there will always be some to whom systematic botany is labour of love. But to insist upon any great general proficiency in one of the many subjects that a forester must study, will simply injure the general efficiency of the forest corps; and probably fail in the case of the favoured subject. W. F. SINCLAIR.

November 3.

Peripatus in the Malay Peninsula.

IN a recent issue of NATURE (October 19) the interesting fact is mentioned of the discovery by the Skeat Expedition of several specimens of Peripatus in the Malay Peninsula. Will you allow me to remark that in 1886 I described in the Notes from the Leyden Museum a specimen of Peripatus from East Sumatra, found among a lot of insects collected by Mr. Hekmeyer, of our Indian Medical Service. As it was the first specimen recorded from the Oriental region, Prof. Sedgwick, in his elaborate monograph of the genus Peripatus, considered the Sumatra species to be somewhat doubtful. The specimens, however, found by Mr. Evans in Kalantan appear to correspond so well with our specimen, as well in the number of pairs of feet (24) as in the colour, that I think a more detailed account will prove the identity of the animals found on both sides of the Malaka Strait. R. HORST.

Leyden Museum of Natural History, October 30.

A Wooden Ball of Unknown Origin.

ON the shore of the island of Hadod, latitude 68° 40′ about, in Vesteraalin, north of Lofoten, there was found, probably in the autumn of 1897, a wooden ball, 4½ centimetres in diameter, covered by a thin layer of gum. The ball is of fine workmanship, and just able to float in the water. Circles are engraved upon four parts, and form small rhumbs over the whole surface; and on two places there is engraved with Latin Majuscles the name *Melfort*. Perhaps some of your readers can say from whence this ball has come. I am writing to the man who has the ball now, to ask him to send it to me. H. MOHN.

Det Norske Meteorologiske Institut, Kristiania, October 30.

Large Nicol Prisms.

IN the account of Dr. Spottiswoode's physical apparatus, lately given to the Royal Institution, there are allusions to several large Nicol prisms said to have been made by Mr. Ladd and by Messrs. Sisley and Spiller. Although it is no doubt the trade custom to mention only the names of opticians who sell pieces of apparatus, and not of any of those whom they employ to make them, I still venture to hope that in this case, where skill and labour of a very special kind were required, the name of the actual maker of the above-mentioned prisms may not be forgotten. I would therefore respectfully ask permission to give a few particulars as to size, &c., of some of the larger Nicol prisms which I have myself made from blocks of Iceland spar within the last thirty years.

(1) In 1873 Dr. Spottiswoode bought a very fine block of spar from Mr. Tulinius, of Copenhagen (who then owned and worked the spar quarry at Eskifiördkr in Iceland). Out of this, which was absolutely flawless, I made a Nicol prism having a clear field of 3⅜ inches diameter, the length of each side being 12 inches.

(2) In 1874 I made a second prism from the same block of spar just mentioned, and also a third from another piece of spar bought by Dr. Spottiswoode. Both of these prisms had a clear field of 3½ inches, the length of the sides being 11½ inches. These are now at the Royal Institution.

(3) In 1875 I made a Nicol prism for Mr. Frank Crisp, of 3½ inches field and 11½ inches in length, which he used in a polariscope in conjunction with the first one mentioned above, which he had acquired from Dr. Spottiswoode. These Mr. Crisp sold, and are now in England.

(4) In 1876 I made two more large prisms for Dr. Spottiswoode, one of 3-inch and the other of 2½-inch field, as spar was

even then beginning to get scarce. These are now at the Royal Institution.

In all these prisms the end faces were the natural crystal faces, only smoothed and polished; and the plane of section made an angle of 87° 30′ with them, or 21° 30′ with the length-axis of the prism.

In none of them was Canada balsam used as the cement (I have not used it for this purpose for thirty years past), but a special material. C. D. AHRENS.

Swiss Cottage, King's Road, Upper Teddington,
October 13.

AN ENGLISH STATION FOR BOTANICAL RESEARCH IN THE TROPICS (CEYLON).

THE Royal Botanic Gardens of Ceylon, under the direction of Thwaites and Trimen, to go no further back, have long been known as one of the most important centres of scientific work in systematic and economic botany. Thanks to the British Association for the Advancement of Science, a small room next to the director's office was fitted up as a laboratory, in which have worked many botanists, chiefly English. Among those who have worked in Ceylon during the last decade may be mentioned Profs. Bower, Farmer, Goebel and Potter, and Messrs. Freeman, Keeble, Pearson, Parkin, and others. During the last two years the laboratory has been very much overcrowded, being used by the staff of the gardens as well as by visiting botanists. With the commencement this year of a new research laboratory, now being erected by the Department of Public Works, and to be completed probably before the end of the year, this difficulty will be overcome, and there will be ample room for several workers from abroad in addition to the members of the staff. This being so, it may not be amiss to give at this time an account of the facilities now available in Ceylon for research in the tropics. While the laboratory is primarily intended for botanical research, there is no intention of excluding workers in other lines so long as there is room for them, though of course money cannot be spent in providing special apparatus for their work.

The Royal Botanic Gardens form a department of the public service in Ceylon, under a director. The head-quarters of the department are at Peradeniya, near Kandy, where the principal garden was established in 1821 by Moon. There are now smaller branch gardens in four other places in different climatic regions of the island. A brief account of these may be of interest.

The original Peradeniya garden lies within the municipality of Kandy, about four miles from the centre of the town. It may be reached by driving in a carriage or rickshaw, or by trains which run at intervals to a station near the garden. The roads here, as almost everywhere in the island, are excellent for cycling. The garden has an area of about 150 acres, and lies in a very beautiful situation, in a loop of the Mahaweli river, and in very mountainous country. Its elevation above sea is about 1550 feet, so that it has a much more pleasant climate than the low country. During the day the difference is but little, but the nights are very much colder than in Colombo, so that refreshing sleep can always be had; indeed, during most of the year a blanket is necessary. The mean annual temperature is 76° F., that of the hottest months (March and April) being 79°, that of the coldest (January and June) 74–75°. The highest shade temperatures ever reached are not excessive, rarely exceeding 90°, and in the present laboratory the highest in the last two years has been 82°, the lowest 65°. Work can thus be carried on with as little discomfort as in any European laboratory. The annual rainfall is about 90 inches, but owing to the great violence of tropical rain the number of rainy hours or days is very much less than in England. The number of days with rain averages 170 per annum, and it rarely rains more than four hours on any one day. Rain in the morning is also rare. The weather of the year depends on the monsoons. In the end of May the south-west monsoon begins to blow, and there is much wind and rain, the weather gradually becoming finer through the months of June and July. August and September and the first half of October are delightful months. In October the north-east monsoon begins, and until Christmas it is very wet. In January begins the "dry season," and during the next two or three months there is less rain than at any other time of year, and the weather becomes gradually very hot, though until April the nights are cold. March and April are the only really unpleasantly warm months in the year. The best time on the whole to visit Peradeniya is from October to March, but from July onwards is very nice, the objection to travelling at this time from Europe being the heat in the Red Sea, which, however, is much less formidable than is usually supposed in these days of swift boats and ice chambers.

The garden contains a splendid collection of tropical plants, and, being arranged like an English park, with wide spaces of lawn, the specimens are easily seen and photographed. In the centre lie the buildings of the museum, library, herbarium and laboratory, close together. The museum is chiefly devoted to the economic products of Ceylon, and contains a very good and interesting collection. The herbarium consists primarily of Ceylon plants; but there is also a general tropical herbarium, and a herbarium of the plants contained in the gardens. In the same building is the library, which contains about two thousand books and papers. There is an excellent collection of books relating to economic and systematic botany, and recently a large number of works on the other branches of botany have been added; a considerable number of journals is also received regularly, including such periodicals as the *Annals of Botany*, *Botanical Gazette*, *Botanische Zeitung*, *Flora*, &c.

The laboratory lies a few yards to the north of the herbarium (a plan is given on p. 33). It consists of a one-story bungalow of brick on a stone foundation, and with cement floor and tiled roof. The length of the building runs approximately east and west, and on the north and south sides there are no verandahs. At the east end is a verandah 8 feet wide, the ends of which are built up so as to form—one a lavatory, the other a dark room for photographic work, fitted with sink, &c. At the west end is also a verandah of the same size, not built up in any way.

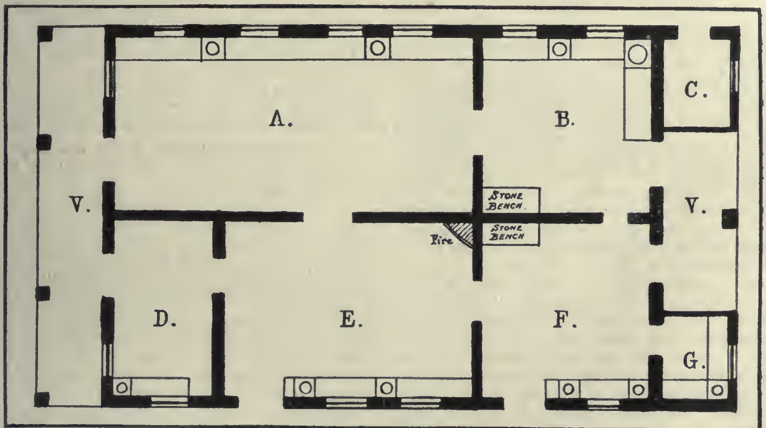
The building has six entrances, provided with French windows, two at each end and two on the south side. The other windows stand above the ground, and open outwards. There are doors leading from each room into all the adjacent rooms, so that free ventilation can be obtained, and at the same time any room can be completely shut up if required to prevent draughts without interference with the accessibility of the others.

The principal room, the general microscopic and morphological laboratory, lies to the north-west, and is 36 feet long and 18 feet wide. It has four working windows facing north, each with table, shelves, sink, &c., and two other windows facing into the west verandah, which can also be used as microscoping windows if required. The central part of the room will contain larger tables for microtome and other apparatus, and writing table.

To the east of this room is the smaller room devoted to physiological and pharmacological investigations. Leading out of this room is a French window, which gives access to the little eastern verandah, which may be used for cultivation experiments, &c. This room has two good working windows facing north, besides the French window. It is provided with three sinks and a large stone bench. South of the physiological is the chemical laboratory, of the same size and construction, and with the dark room opening out of it. West of the chemical laboratory is the economic, a large room 26 feet by 18 feet, with two good working windows, one French window, and a fireplace. This room is intended for experiments in the preparation, &c., of economic products, such as rubber, fibres, &c. Lastly, in the south-west corner of the building, is a small private laboratory for the director or for work requiring special privacy from interruption. This room is 18 feet by 10 feet, with one working window on the south side, and another looking into the western verandah.

The whole laboratory is well supplied with water from a pipe running round it, and starting from a cistern in the museum, at a height of about 15 feet above the laboratory. Gas unfortunately is not at present available, but of course there is no need for artificial light, the day in this country always lasting until 6 p.m.

When ordinarily filled, therefore, the laboratory can accommodate eleven workers, and at a pinch room can be made for four more. For persons working at systematic botany there is accommodation in the herbarium.



Plan of the new Laboratory, Royal Botanic Gardens, Peradeniya. A, General laboratory; B, Physiological laboratory; C, Lavatory; D, Private laboratory; E, Economic laboratory; F, Chemical laboratory; G, Dark room; V, Verandahs. Scale 1/16 inch to 1 foot.

Of the eleven places, the present staff and workers living in the colony will use five or perhaps six, so that there is room now available for five or six workers from Europe and elsewhere. The value to a botanist of a period spent in the tropics can scarcely be overrated, and with the accommodation now afforded at Peradeniya and in Java, the ease and comparative cheapness of the journey, and of living and travelling in Ceylon, there is no reason why many more should not visit and work in a tropical station than have so far done so.

The neighbourhood of Peradeniya is very beautiful; it is mostly cultivated in rice, tea, coco-nuts, fruit, &c., but there are some interesting pieces of wild vegetation within easy reach, and many fine pieces of forest, &c., can be reached within a short time by rail or road. The river below the gardens contains most of the known Ceylon species of that very remarkable order the Podostemaceæ. Kandy is within easy reach, and contains several good hotels, a good English club, tennis, croquet, cricket and football clubs, &c.; and there is a considerable society of English people in the town and suburbs. Colombo can be reached in four, Nuwara Eliya in five, hours by rail. The trains are comfortable, and provided with refreshment and sleeping cars.

For a few economic and other plants the climate of Peradeniya is somewhat too cold at night for complete success, and for trial of these and for the supply of the needs of the populous low-country of the south-west of the island, a second botanic and experimental garden is maintained at Henaratgoda, on the main line of railway, seventeen miles from Colombo. It lies only about twenty feet above the sea, in a very uniform steamy climate, with a mean temperature of about 82° F. The garden comprises forty acres, about twelve of which are still covered with jungle, forming an interesting feature in the garden. There is a very fair collection of plants in this garden, especially economic, including the original rubber trees sent to the East through the agency of Kew Gardens and the Government of India. *Helminthostachys zeylanica* is abundant in the district, and many interesting plants can be seen in paddy fields and elsewhere. There is a rest-house close to the railway station, a mile from the garden, and the garden contains a small laboratory with two working places.

A third garden is maintained at Hakgala, about six miles from the chief sanatorium of Ceylon, Nuwara Eliya. The garden occupies an extremely beautiful situation on the side of Hakgala Mountain, with an extensive view over a wide expanse of mountain country. It comprises about 550 acres of land, only about thirty-five of which are in cultivation, the rest being untouched natural country, some covered with jungle, some being grass land (pătănă, as it is locally called). The vegetation in the district all around here is very interesting, having been but little interfered with by cultivation in any way, and that only in a few spots. The interesting Horton Plains are eighteen miles from Hakgala, through wild country. There is a rest-house at the Plains, which lie 7200 feet above sea-level. The flora of these up-country regions is of great interest to a botanist. Many European genera are here represented, such as buttercups, violets, valerian, brambles, &c. Lycopods, Selaginella, Psilotum, &c., are very common. Many interesting biological features exhibit themselves in this vegetation.

The garden at Hakgala lies at 5600 feet above sea-level, and has a comparatively cold climate, with a mean annual temperature of 61° F. Frost never occurs, though it is frequent at slightly higher elevations, such as Nuwara Eliya (6200 feet). There is, unfortunately, no accommodation for visitors at present nearer than Nuwara Eliya, six miles away; but it is hoped to erect a small laboratory in the garden, with a small living room attached, where workers may live and sleep.

A fourth garden is kept up at Badulla, the capital of the Uva province, at an elevation of 2200 feet, on the eastern side of the mountains. The chief botanical interest of this district lies in its somewhat drier climate, so that it has much more pătănă land than the western side of the mountains, and in the fact that its dry season comes, not in the north-east but in the south-west monsoon, so that the periodicity of the vegetation is different. Fruit, which at Peradeniya ripens in March and April, ripens at Badulla in August, and so on.

Yet another garden is maintained at the ancient capital of the island, the famous "buried city" of Anuradhapura, the capital of the north-central province. This lies in the middle of the dry country, which makes up about three-fifths of the island, and has an Indian climate, with rain almost confined to the last three months of the year, and drought during the remainder, including the south-west monsoon. The flora of this district is therefore, as might be expected, very different from that of the rainy south-western and central provinces.

The island can show, within an area of rather less than that of Ireland, a most remarkable range of climate and flora, rendering it very interesting to the traveller and naturalist; in this respect it is unrivalled in the tropics. The working botanist or student has, further, the great advantage of having at his hand the excellent flora prepared by Dr. Trimen, and finished after his death by Sir Joseph Hooker. There are doubtless many new species still to be found in the eastern and south-western districts, as well as many unrecorded species; but the student who does not desire to specialise in this department of botany will be grateful for the useful flora, which renders the identification of his collections, or of the plants he may be experimenting with, a matter of comparative ease. The vascular cryptogams and many of the mosses have been identified, but there is much to be done at the lower forms of vegetation.

Peradeniya is easily reached from any part of the world, Colombo being one of the greatest ports of call. Direct lines of steamers run to Europe, China, Japan, Java, Queensland, Adelaide, Melbourne and Sydney, Mauritius, South Africa, and all Indian ports. Madras may be reached in thirty-eight hours by boat and rail. To England there is a very large choice of steamers. The favourite lines with Ceylon people are perhaps the Bibby and the Norddeutscher Lloyd, but the P. and O., the Orient, Messageries Maritimes, British India, and many others, are much used. The first-named is the cheapest of the large English lines, but is first-class only. First-class returns to Colombo, available for six months, are from 70*l.* to 90*l.* Second-class, which is very comfortable on the largest lines, is from 50*l.* to 60*l.* A few pounds are necessary on the voyage for tips, sports, trips on shore, &c. Banking accounts may be opened in Kandy, and money easily remitted to and from Europe. The value of the rupee is now 1*s.* 4*d.*, and seems likely to remain at that figure.

Very little is necessary in the way of outfit. Drill and khaki clothes can be bought here for less than half their price in England; also topees (sun-hats). At Kandy the usual dress is similar to that worn in England in summer; at Nuwara Eliya it is colder, and tweed suits are often worn. All articles of clothing can be bought here, and usually as cheaply as, or more so than, in Europe.

The usual division of the day is as follows: Rising at daylight, a light early tea of eggs and toast is taken about 6.15, after which a walk in the garden is pleasant, commencing laboratory work at 7.30, and continuing till 11, which is the breakfast hour. After breakfast follows a rest indoors, but not sleep, and work may be resumed at about 1.30 for a couple of hours or so. After tea the remaining two hours of light are given to tennis, cycling, and other forms of exercise, followed by a bath, and dinner at 7 or 7.30. The evening is devoted to amusement.

Travelling in Ceylon is easy in all but the most out-of-the way or sparsely populated parts. Railways and good roads intersect the greater part of the island, and there are coach services to a great number of places not served by the railways. Rest-houses or Government inns are found in all towns that have no hotels, and at intervals of 14 miles along all main roads. The average cost of living while on tour may be put down as about Rs. 7 or 8 per diem exclusive of fares by rail or coach. Steamers run round the island, calling at all the chief ports.

There is at present no rest-house or hotel at Peradeniya itself, and visitors must live in Kandy, where arrangements have been made with some of the hotels to board persons working in the laboratory at from Rs. 5 to Rs. 7 per day. There is a convenient service of trains, but the most satisfactory way is to cycle in and out. The road is in excellent order, and the distance from the furthest hotel under five miles. It is hoped that accommodation may be provided at Peradeniya itself before long.

Assuming that six months are spent from starting to date of arrival back in Europe, the cost of the trip should not much exceed 185*l.*, made up thus:

Fare (first return)	£85
Twenty weeks' board	66
Travelling	20
Sundry	12 to 20
	£191

This might be much reduced by economy, and by travelling second-class from Europe, and the proportionate cost would of course be less if the visit were of longer duration. If much travelling is to be done in the island the amount shown above will have to be increased, the 20*l.* being allowed for four weeks only. By very close economy and reduction of travelling, and by travelling second-class, the total might be reduced to perhaps 140*l.*

Trustworthy information about Ceylon may be obtained in various books. The most interesting are Sir E. Tennent's "Ceylon," which is now out of print; and to a botanist, Trimen's paper "On the Flora of Ceylon as affected by Climate," in the *Journal of Botany* for 1886. Ferguson's Handbook and Directory contains a vast mass of information and statistics, and his "Ceylon in 1893" is also of interest.

Intending visitors should communicate some time in advance with the director, mentioning what line of work they propose to take up, and any special facilities they may require.

JOHN C. WILLIS.

THE STOCKHOLM INTERNATIONAL FISHERIES CONFERENCE.

THE International Conference, which met in Stockholm from June 15 to June 23 last, and had for its object the arrangement of a scheme for the exploration of the northern seas in the interests of fisheries, has now issued its report. The Conference assembled at the invitation of the Government of Sweden, and official representatives attended on behalf of the Governments of Germany, Denmark, Great Britain, Norway, Holland, Russia and Sweden.

The formal resolutions unanimously passed by the delegates—Messrs. Archer, Cleve, Drechsel, Ekman, von Grimm, Heincke, Hensen, Herwig, Hjort, Hoek, Knudsen, Krümmel, Lehmkuhl, Lundberg, Murray, Nansen, Petersen, Pettersson, D'Arcy Thompson, Trybom, Åkerman—were as follows:—

Considering that a rational exploitation of the sea should rest as far as possible on scientific inquiry, and considering that international co-operation is the best way of arriving at satisfactory results in this direction, especially if in the execution of the investigations it be kept constantly in view that their primary object is to promote and improve the fisheries through international agreements, this International Conference resolves to recommend to the States concerned the following scheme of investigations, which should be carried out for a period of at least five years.

Programme for the hydrographical and biological work in the Northern parts of the Atlantic Ocean, the North Sea, the Baltic and adjoining Seas.

A.—THE HYDROGRAPHICAL WORK.

I. The hydrographical researches shall have for their object: the distinction of the different water-strata, according to their geographical distribution, their depths, their temperature, salinity, gas-contents, plankton and currents, in order to find the fundamental principles, not only for the determination of the external conditions of the useful marine animals, but also for weather-forecasts for extended periods in the interests of agriculture.

II. As the hydrographical conditions are subject to seasonal changes, and as these strongly influence the distribution and life-conditions of useful marine animals and the state of the weather and other general meteorological conditions, it is desirable that the observations should be made so far as possible simultaneously in the four typical months, February, May, August and November, at definite points along the same determined lines.

III. The observations referred to in II. would consist of:—

(*a*) Observations of temperature, humidity and pressure of the air every two hours; self-registering instruments for interpolation, and Assmann's aspirator should be used.

Opportunities should be afforded to the meteorological offices to make on board the ships physical observations on the higher levels of the atmosphere by means of kites.

The other meteorological observations are to be carried out according to the methods adopted by the meteorological offices of the nations represented.

The observations, meteorological as well as hydrographical, made on board the special steamers at the time of the survey in the typical months, are to be immediately worked out under the supervision of the central bureau (see C) for publication in a bulletin, wherein the conditions of the sea and the atmosphere are to be represented by tables and synoptical charts in cooperation with the meteorological institutes of the nations represented.

(*b*) The temperature of the surface water shall be taken every two hours, or, when necessary, more frequently. It is desirable that self-registering apparatus should be used for interpolation.

Observations on the vertical distribution of the temperature are to be taken at the points mentioned in II., and should be taken regularly at intervals of 0, 5, 10, 15, 20, 30, 40, 50, 75, 100, 150, 200, 250, 300, 400 metres, and so on; but all *critical* parts of the curve must be determined by extra-readings.

The bottom-temperature is to be investigated with all possible care.

(*c*) At every point and from every depth where the temperature is observed, a sample of water shall be collected for the determination of its salinity and density.

By *salinity* is to be understood the total weight in grammes of the solid matter dissolved in 1000 grammes of water.

By *density* is to be understood the weight in grammes[1] of one cubic centimetre of water of the temperature *in situ* $t°$, *i.e.* the specific gravity *in situ* referred to pure water of $+4°$C. $\left(=S\frac{t°}{4°}\right)$.

For orientation, preliminary determination of the salinity should be made on board ship with expedient instruments, but the exact determination of the salinity and density of all samples shall take place in a laboratory for scientific work.

(*d*) At certain depths of the points mentioned in II., and elsewhere on the surface, water samples should be collected for analysis of the gas-constituents (oxygen, nitrogen and carbonic acid).

[1] Units of weight are here used instead of mass-units.

IV. For measurement of depth the *unit* to be adopted is the metre, together with which the depth may be also recorded in English fathoms.

Geographical points are to be referred to the longitude of Greenwich, and horizontal distances are to be expressed in sea-miles (=1852 metres).

Thermometers to be used for the determination of the surface-temperature may be either centigrade or Fahrenheit, but for publication all numbers are to be reduced to centigrade.

In the centigrade thermometers the distance between two degree-marks should be at least 5 mm. and the degree divided at least in two parts; the Fahrenheit thermometer to be divided in a corresponding manner.

The use of Pettersson's insulated water-bottle is recommended for moderate depths, and the thermometers used for this apparatus should have a space at least 10 mm. between the marks of one degree, and the degree should be divided in ten parts.

For greater depths of the ocean Negretti-Zambra's or other thermometers of a similar type should be used.

The glass to be used for the thermometers as well as the thermometers should be tested and approved by the central bureau (see C, *a*).

For the determination of salinity and density either chemical or physical methods may be adopted, provided that the salinity can be determined with an accuracy of $0{,}_{05}$ in a thousand parts (and the density up to $0{,}_{00004}$).

The determination of these constants can be founded either upon chemical analysis of the halogen by weighing or titration; or upon physical determination of the specific gravity by means of hydrostatical balance pycnometers and hydrometers, provided that measures be taken to exclude disturbances arising from thermal effects, capillarity, viscosity, &c.

The chemical analysis shall be controlled by physical methods, and the physical determinations by chemical analysis in the following manner:—

From every collection of samples examined at least three shall be selected and sent to the central bureau. *Standard samples* shall be sent in return.[1]

The *specific gravity* is to be represented in the tables by the formula $S\left(\frac{0°}{4°}\right)$.

V. Samples for gas analysis are to be collected each time in a pair of sterilised vacuum tubes.

It is desirable that the existing tables of absorption of nitrogen and oxygen should be revised.

VI. Qualitative plankton-observations should be made every six hours by pumping through a silk net (N: r 18) for the space of fifteen minutes, and at the same time a sample of water (III. *c*) should be taken.

At the points mentioned in II. samples for quantitative analysis are to be collected according to the method of Prof. Hensen at different depths depending on the hydrographical circumstances.

Petersen's modification of Hensen's net is recommended.

Observations on transparency and colour of the water should be made at the points mentioned in II.

Opportunities should be afforded to bacteriological institutions to carry out investigations in the ocean.

VII. Observations on currents and tides should be carried out as frequently as the circumstances allow.

The currents should be examined, when possible, by direct current-meters and by surface and intermediate floats and by bottom-rollers.

The ship should be anchored occasionally in order to make frequent observations during a complete period of tide.

VIII. It is desirable that a chart should be prepared of the bottom of the seas examined, showing the nature of the sea-bottom.

The description of the deposits is to be carried out on a definite plan, to be afterwards settled (see Appendix III.).

IX. The normal observations are to be carried out along the

[1] By *standard* water shall be understood samples of filtered sea-water, the physical and chemical properties of which are known with all possible accuracy by analysis, and statements of which are sent to the different laboratories, together with samples.

In respect to halogen the ordinary water-samples have to be compared with the standard water by analytical methods.

lines provisionally drawn on the annexed chart, where *R* denotes the Russian, *F* the Finnish, *S* the Swedish, *G* the German, *Da* the Danish, *Du* the Dutch, *N* the Norwegian, and *B* the British lines.

The special points are to be decided by the respective nations, and when once chosen the subsequent observations are to be repeated at the same points.

The particular instructions for the stations will be given by the respective nations, and the communications as to the extent and the nature of the observations shall take place through the central bureau (see C, *a* and *e*).

X. It is desirable, in carrying out these investigations, to make use of regular liners, light-ships, &c., and coast stations for the purpose of taking temperature-observations and collecting samples of sea-water and plankton.

These observations are to be taken not only in the typical months, but also during the intervening periods.

abundance, and average size of economic fishes, and the causes of the same.

II. (*a*) Experimental fishings *on* the known fishing grounds during the time of the fishery, as well as *outside* these areas and seasons.

(*b*) Preparation of uniform statistics of the experimental catches, with particulars of the number, species, size, weight and condition of the fish; for example, as done on board the *Garland* by the Scottish Fishery Board.

(*c*) The uniform use of appropriate apparatus for the experimental capture of the different species and sizes of fish.

(*d*) The experimental marking and liberation of fish, for instance, of plaice, on as large a scale as possible and over extensive areas; for example, as carried out by Dr. C. G. Joh. Petersen and Dr. T. W. Fulton (Reports of the Danish Biological Station and the Fishery Board for Scotland) and others (see Appendix IV.).

Division of Areas for Investigations in connection with Fisheries.

B.—The Biological Work.

I. (*a*) Determination of the topographical and bathymetrical distribution of eggs and larvæ of marine economic fishes; for example, by quantitative methods, such as those of Hensen, and with special reference to the most important species, such as plaice, cod and haddock, herring, &c. (see Appendix I.).

(*b*) Continued investigation of the life-history and conditions of life of young fishes of economic species in their post-larva stages and till they reach maturity, with special reference to their local distribution.

(*c*) Systematic observation of mature marketable fishes with reference to their local varieties and migrations, their conditions of life, nourishment (as, for instance, by investigation of the contents of the stomach), and natural enemies; also observations on the occurrence and nature of fish food at the bottom, the surface and intermediate waters down to depths of at least 600 metres (see Appendix I.).

(*d*) Determination of periodic variations in the occurrence,

III. (*a*) It is desirable to collect uniform statistics of the number, weight and value of the fish landed, of the means of capture, and of the persons engaged in the industry; for example, as in the General Reports of the Scottish Fishery Board.

(*b*) It is desirable to collect material for the preparation of maps, showing the fishing grounds and the kinds of fishing here practised (*cf.* A. VIII.).

C.—Organisation of a Central Bureau.

I. The Conference recommends that there should be for the international hydrographical and biological researches of the seas an international Council with a central bureau, furnished with a laboratory (see Appendix II.). The central bureau will be:—

(*a*) To give uniform directions for the hydrographical and biological researches in accordance with the resolutions drawn up in the programme of the present Conference, or in accordance with such modifications as may be introduced later with the consent of the States represented.

(*b*) To control the apparatus and to insure uniformity of methods.

(*c*) To undertake such particular work as may be entrusted to it by the participating Governments.

(*d*) To publish periodical reports and papers which may prove useful in carrying out the co-operative work.

(*e*) To decide the graphic representations, scales, signs and colours to be used in the charts for the purpose of obtaining uniformity in the publications.

(*f*) To make, in connection with the investigations, application to the telegraph administrations for the purpose of obtaining determinations from time to time of the changes in the resistance of the cables which cross the areas in any direction.

II. (*a*) The permanent international Council should consist of commissioners elected by the Governments interested. Each Government may appoint two commissioners who may be represented at meetings by substitutes.

(*b*) The Council elects its president and vice-president, and appoints all officials connected with the central bureau. Should the general secretary represent hydrographical sciences, his principal assistant should represent the biological sciences, or *vice versâ*.

(*c*) The Council shall draw up its own order of proceedings.

(*d*) The expenses of the central office are approximately estimated at 4800*l*. (96,000 marks) yearly.

(*e*) The place of the central bureau, to be decided by the Governments concerned, shall at the same time be the residence of the general secretary, and should be conveniently situated for hydrographical and biological researches.

(*f*) It will be for the Governments concerned to decide among themselves the share to be borne by each.

Scheme for the Expenditure of the Central Bureau.

	£
(1) General Secretary	750
(2) Principal Assistant	500
(3) President, for incidental expenses other than travelling expenses	200
(4) Vice-President, for incidental expenses other than travelling expenses	100
(5) Office, laboratory, scientific and technical assistants, draughtsmen, clerks, servants, postage, telegrams and similar expenses	2250
(6) Travelling expenses	300
Note: Travelling expenses of commissioners attending meetings of the Council shall be borne by their respective Governments.	
(7) Printing	500
(8) Incidental expenses	200
	£4800

D.—It is desirable that these investigations should begin May 1, 1901.

E.—The Conference declares that it is of the greatest importance, both for high sea fisheries and for the weather forecasts for long periods, that the Faröe Islands and Iceland should be included in the European telegraph system as soon as possible.

F.—The relation between the quantity of halogen contained in the water and the density of the water shall be carefully investigated by an experimental revision of the tables compiled by Knudsen (Ingolf Exp. ii. 37). The tables compiled by Makaroff, Krümmel and others for the relation of specific gravity to density and salinity are likewise in urgent need of experimental revision.

It is proposed to undertake these investigations in the technical institute at Copenhagen under the direction of a committee consisting of Sir John Murray, Messrs. Knudsen, Pettersson, Nansen, Krümmel, H. N. Dickson, and Makaroff. The means for carrying out these works are to be requested from such learned societies as have funds for such purposes.

G.—The Conference recommends that these resolutions be brought by the nations concerned to the knowledge of the Governments of France and Belgium.

H.—In case the resolutions of the Conference should be accepted by the States, it is anticipated that some length of time will elapse before the organisation of the central bureau is completed. In the meantime the Governments may wish to possess an organisation in connection with this Conference which may be useful in constituting the Council and the central bureau.

The members of the third committee—Åkerman, Drechsel, Von Grimm, Herwig, Hoek, J. Murray, Nansen, Pettersson—hereby offer their services for this purpose.

Appendix I. is on the quantitative estimation of pelagic fish-eggs and larvæ, by Prof. Hensen; Appendix II., on the Central Laboratory, by Prof. Nansen; Appendix III., on plankton investigations, by Profs. Cleve and Pettersson; and Appendix IV., on the marking of fishes in the waters of the region of the Baltic and the North Sea, by Dr. Trybom.

NOTES.

ONE of the most transcendent sights that it is given to man to witness is due next week. Those who saw the "falling stars" of 1866 readily acknowledge that there is no other phenomenon which is equal to it in majesty and enthralling beauty; and although comparisons are always odious, and generally misleading, some have held that the 1866 display was far more striking than a total eclipse of the sun. It is to be hoped, therefore, that the sky will be clear during the early mornings of next week. It appears from a communication of Messrs. Johnstone Stoney and Downing, which appears in another column, that it is not yet known whether the densest part of the meteors will be encountered on the morning of the 15th or during the next night. It is to be regretted that bright moonlight will certainly prevent the shower from being seen with the same effect as in 1866, ir it should happen before the morning hours.

CERTAINLY not for many years has there been so much anxiety, either expressed or silently borne, as since some days ago, when the wire joining Ladysmith and civilisation was broken. Not only have the relatives of the 10,000 Britons beleaguered there been anxious, but all who take interest in the severe struggle which is now going on. It has been a matter o. general surprise that in a campaign in which the cutting of telegraph wires was the first thing to be expected, and the investment of several isolated garrisons for a time was to be taken for granted, Marconi apparatus was not installed as a matter of course. We do not share this surprise; science, and especially the latest developments of science, are the last things to interest our Government and the Government Departments; they do not believe in science, they care to know very little about it, and the scientific spirit is absent from too many ot their plans and doings. Hence we have now to be thankful that they have reached the level of the pigeon post, which has been the only official means, and that on the part of one or two birds, to keep us in touch with our beleaguered forces. It is stated that even the Commander in Chief, Lord Wolseley, has expressed some surprise that the so-called "Intelligence Department" ot the Army allowed the Ladysmith force to go to the front with mountain guns against a Boer force which they should have known might be armed with Schneider-Canet cannons of large calibre; and it would seem that probably a terrible disaster has been prevented, not by our Intelligence Department, not by the outfit of our Army, but by the apparently accidental arrival of naval guns and *personnel* at the last moment. Why is there not a Scientific Committee to do what it can in advising the military authorities? If they could do nothing, nobody would be the worse, but they might be able to do much to the nation's advantage.

AT the anniversary meeting of the Royal Society on November 30, the following Fellows will be recommended by the President and Council of the Royal Society for election into the Council for the year 1900. The names of new members are printed in italics:—President: Lord Lister. Treasurer: Alfred Bray Kempe. Secretaries: Sir Michael Foster, K.C.B., Prof. Arthur William Rücker. Foreign Secretary: *Dr. Thomas Edward Thorpe.* Other members of the Council: *Horace T. Brown,* Captain Ettrick William Creak, R.N., Prof. James Dewar, *Prof. Edwin Bailey Elliott, Dr. Hans Friedrich Gadow,* Prof. William Dobinson Halliburton, Prof. William Abbott Herdman, *Sir John Murray, K.C.B.,* Sir Andrew Noble, K.C.B., *Prof. Arnold William Reinold,* Dr. George Johnstone Stoney, *George James Symons, J. J. H. Teall,* Prof. Joseph John Thomson, *Prof. Edward Burnett Tylor, Sir Samuel Wilks, Bart.*

The gold medal of the Highland and Agricultural Society of Scotland has been awarded to Prof. Cossar Ewart in recognition of his intercrossing and other experiments. Seeing that the Scottish Agricultural Society has a reserve fund of well nigh 100,000*l.*, and that there was a clear profit of over 4000*l.* at the last show—the show at which Prof. Ewart's zebra hybrids attracted so much attention—it is a matter of some surprise that the directors of the Society have not ere this voted a substantial sum in aid of the extremely costly experiments which for some years have been steadily carried on in the vicinity of Edinburgh.

Dr. W. H. Corfield, professor of hygiene and public health in University College, London, has been appointed to the newly-created post of consulting sanitary adviser to Her Majesty's Office of Works, for the Royal Palaces and Public Buildings in charge of the Department.

At the recent annual meeting of the Royal Academy of Medicine in Ireland, the following distinguished men of science were elected honorary Fellows of the Academy: Sir J. Burdon-Sanderson, Bart., F.R.S.; Prof. Howard Kelly, Baltimore; Prof. Koch, Berlin; Prof. Kocher, Bern; Prof. Th. Leber, Heidelberg; Sir W. MacCormac, Bart., K.C.V.O., London; Prof. Martin, Berlin; Prof. Nothnagel, Vienna; Prof. Osler, Baltimore; and Sir W. Turner, F.R.S., Edinburgh.

An egg of *Aepyornis maximus*, measuring nearly a yard in circumference, was sold at Mr. J. C. Stevens's auction rooms on Tuesday, the price realised being forty-two guineas.

We regret to see the announcement of the death of Dr. Edward Orton, the distinguished geologist, and president of the American Association for the Advancement of Science.

Six public lectures on "England in South Africa," illustrated by maps and lantern slides, will be given at the Imperial Institute on Thursday evenings during this month and next, by Mr. Basil Worsfold. The first lecture will be delivered this evening.

We learn from *Science* that Mr. J. B. Hatcher, and his assistant Mr. O. A. Peterson, have returned from their third exploration of Patagonia, where they were sent by the Geological Department of Princeton University. Very extensive collections have been made of both vertebrate and invertebrate fossils of Patagonia, and much material illustrating the zoology and botany of that region has been obtained.

The leases of the auriferous deposits of the north-western shore of the Sea of Okhotsk, in Siberia, recently discovered and explored by a special commission sent into the region referred to by the Russian Imperial Government, are to be put up for auction at St. Petersburg in February 1900. The conditions of the leases may be seen on application at the Intelligence Branch of the Commercial Department of the Board of Trade.

It is stated by the *Daily News* that Prof. Starr, of Chicago, who for many years has made a study of the ethnographical aspects of the interior of Mexico, has presented his valuable collection of objects, gathered during various expeditions into the heart of Mexico, to the Folk Lore Society, and the latter have, through the medium of their president, Mr. E. Sidney Hartland, offered to place the collection on permanent deposit in the Museum of Archæology and Ethnology at Cambridge.

The new session of the Society of Arts will be opened on November 15 with an address from the chairman of the Council, Sir John Wolfe Barry, K.C.B., F.R.S. In it it is probable that he will develop the subject of his address last year, "London Communications," and will make some suggestions as to the practical means of carrying his proposals into effect. The first paper after the opening meeting will be by Mr. D. E. Hutchins, who will draw attention to the want in this country of measures for the proper conservation of woods and forests. At the next meeting Mr. Allan Wyon will give a paper, principally of an antiquarian nature, on the Great Seals of England. At the other meetings before Christmas it is probable that Mr. Joseph Cash will describe the substitutes which have recently been introduced to replace silk, and the methods of their production. Mr. F. G. Aflalo will draw attention to the necessity for some legislation to restrict sea anglers from catching immature and undersized fish; and Mr. H. Bloomfield Bare will describe and illustrate the methods, which have recently achieved considerable success in America, of teaching drawing by the use of the blackboard, both hands being employed. Mr. H. H. Cunynghame, who has devoted a great deal of attention to the subject, will give a course of Cantor Lectures before Christmas on the art of enamelling. It is intended to demonstrate practically the whole process of enamel-making during the course. The Juvenile Lectures will be by Mr. Herbert Jackson, of King's College, who will lecture on phosphorescence.

An important article on Mangabeira rubber appears in the current number of the *Kew Bulletin*. Partly in consequence of an improvement in the purity of the rubber, the price has recently advanced and the price of the best sorts is not much less than that obtained for Para rubber. The chief centres for export of Mangabeira rubber are Bahia and Pernambuco. Although but little is known so far of the cultivation of Mangabeira, it may be said that there is a considerable probability of its becoming an important tree in rubber-culture. The apparently easy accommodation of the tree to soil and climate, its early and considerable yield, together with the fact that even under the rough treatment of the Indians it preserves its fruitfulness, and also the facility with which it can be cultivated, promise a future. And, taking a wide view of its possibilities, from its presence in the red coffee-growing soils of the west of the Province of São Paulo, it appears suitable for the red earths of the German colonies of Africa, Usambara and Togoland alike, such, for instance, as occur at Misahöhe in the latter Colony. For these soils it promises to be considerably better suited than the Ceara rubber plant and the Para rubbers, and will probably give better results than *Castilloa*, than which it is more hardy, earlier maturing, and smaller.

The information at present available on the subject of injurious insects in India forests is brought together in an illustrated pamphlet (pp. 152) by Mr. E. P. Stebbing, which has been issued from the office of the superintendent of Government printing, Calcutta. Locusts and white ants or termites are among the most destructive pests of the insect kingdom. The former invades the fertile plains of India from its home in the sandy deserts of Rajputana, Sind, and the Punjab, and in the line it takes not a green leaf or shoot is left either in the forest or field. It is pointed out that as the life-history of the pest readily proves that forests and moisture are its greatest enemies, the reclamation of arid sandy areas by means of plantations would tend to check its multiplication. As to the white ant, though it is a most unwelcome intruder in any building, it renders service to man in the forest by rapidly converting fallen branches, dead trees and decaying wood of all kinds into mud, each particle of wood eaten being replaced by earth. Where termites are numerous, the insects only feed on the outer dead portions of the bark of the trees, and do no damage to healthy trees. The instinct of these insects is marvellous. Mr. Stebbing states that he has often noticed that should a tree have a dead branch on its trunk, no matter at what elevation, an earthen gallery is run up by the white ants, and the branch attacked, the decaying wood being replaced by soil, which soon falls to the ground.

A NOTE on a new departure which has been made in connection with the artificial hatching of salmon in Norway appears in the *Journal* of the Society of Arts. Formerly the young fry were allowed to escape as soon as they began to require food, and, therefore, when in a very delicate and defenceless condition. They are now retained in captivity, and fed four times a day upon the raw liver of slaughtered animals, until the autumn, after the system which obtains in America. According to Consul Nelson, of Bergen, the results of the first year's experiment at the Government hatchery on the Drammen were satisfactory; on 280,000 ova treated, the loss was only 2 per cent., and in the middle of October about 211,000 fry were turned out, while the percentage of loss has been still further reduced of late years. A belief is prevalent among the coast fishermen that salmon and sea-trout spawn successfully in salt water, and in this connection a series of experiments were conducted under proper supervision, from which it appeared that (1) roe taken from salmon captured in a river, or from sea-trout which have remained until the spawning time in sea water, cannot be successfully developed in salt water, and (2) salmon and sea-trout roe impregnated in fresh water may be hatched out in brackish water containing a small percentage of salt up to eight or nine per mille—that is to say, rather less than one-third of the salt contained in the sea water on the Norwegian coast.

FEW people are aware that a number of European rivers which were once almost destitute of fish are now well stocked with species propagated from fry obtained from America. An idea of the extent of the operations of the U.S. Fish Commission, by which this change has been brought about, may be obtained from an article in the *Scientific American*. About ten years ago young fry of American landlocked salmon were shipped to Scotland, and since then they have multiplied rapidly, much to the detriment of the Scotch fish. A shipment of American black bass fry was made to France for stocking the rivers and streams, and, like the American salmon in Scotch waters, they have flourished so marvellously that to-day they are quite common articles of diet at the French hotels and restaurants. The French streams, since the introduction of the American bass, have doubled in their productive value, and there is every reason for the French anglers to be grateful to the U.S. Fish Commission for stocking their waters with a new species of food fish. Other varieties of fish have been shipped to France and elsewhere for scientific experiments. The American rock bass has been introduced into several English streams, and the American brook trout is to-day in flourishing condition in the clear, cold streams of Russia and other northern countries of Europe. The waters of Switzerland abound with many American common river and brook fish, which make the angling there superior to anything in the past. It is even reported that the fine American muskalonge has found a satisfactory home in the Rhine and Danube rivers.

WE have received the Report of the Meteorological Commission of the Cape of Good Hope for the year 1898, a folio Blue Book of 168 pages, containing valuable results of meteorological observations made under the direction of the Commission, which has been collecting systematic information since the year 1861. The system now embraces two stations of the first order, 54 of the second order (barometric stations), 17 thermometric stations and 370 rainfall stations. These include observations made in the South African Republic, the Orange Free State, and at various other stations outside Cape Colony. The most noteworthy feature of the present Report is the inclusion of returns from the splendidly equipped station established by the De Beers' Company at Kenilworth, near Kimberley, at which hourly observations have been made during the whole year. It is believed that this is the only station of its kind, not only in South Africa, but in the whole African continent. An interesting ocean-current bottle notice was found on the coast, about latitude 34° 2′ south, and longitude 20° 47′ east. It was thrown from the *Blengfell* in latitude 39° 58′ south, and longitude 23° 22′ east, and had taken two years one hundred and thirty days in travelling 4° 56′ north and 35′ east, having evidently been caught in the Agulhas current. Among other useful information, the Report contains notes on the weather of each month and the whole year, drawn up by the Secretary, with a series of diagrams giving the mean monthly rainfall over the whole Colony, with the percentage differences from the means for ten years (1885–94).

THE Report on the administration of the Meteorological Department of the Government of India in 1898–99, which has just been issued, is divided into two parts: (1) a general account of the more important work of the department, and (2) details of administration. The total number of stations (including four first-class observatories) amounted to 174, and the number of rainfall stations from which monthly statements have been published was 2280. Seismographs have been established at three suitable observatories, and a brief list of the earthquake shocks is now given in the *Monthly Weather Review*; a full account of the work done is promised in the next year's Report. Some important observations of the direction and velocity of the upper clouds have been made, and the results will be published in due course. The seasonal forecasts, based on the snowfall of the mountain districts, show only a moderate agreement with the actual weather experienced, but storm warnings appear to have been carried out very satisfactorily, timely warning being given of all the more important storms which visited the Indian coasts; the opinions of the warnings of floods are also generally satisfactory. The Department is greatly assisted in its useful work by the liberality of the Eastern Telegraph Company, and the Indo-European Telegraph Department, for the concession of free telegrams from Aden and Persia.

IN the Bradshaw Lecture, delivered before the Royal College of Physicians of London on November 2, and published in the *Lancet*, Dr. A. Foxwell points out that the first result of exercise is an increase in the rate and depth of the respirations—that is, of the respiratory exchange. The respiratory quotient, CO_2/O_2, is not increased, but if anything diminished: in other words, the tissues are as rich (or richer) in oxygen during exercise as during rest. This necessitates a great increase in the absorption of oxygen at this time; for it has been shown that a man gives off ten times as much carbonic acid when on the treadmill as he does when asleep. But it is a remarkable fact that arm work, per unit of work done, requires a greater absorption of oxygen than climbing, and climbing than walking on the level. If the amount of oxygen absorbed during sleep per minute be 100 grams, then in a minute's walking at three miles an hour on the level it would be 500 grams; in climbing a yard high 5000 grams, and in doing the same amount of kilogram metres by turning a wheel (arm work) 7000 grams. Such an enormous increase in the absorption of oxygen and giving out of carbonic acid must seriously strain the resources of the organs concerned. Dr. Foxwell considers that the lungs and the right ventricle of the heart bear the brunt of the extra labour involved in short strenuous exertions.

IN the *Physical Review* for September, Messrs. W. O. Atwater and E. B. Rosa give the first part of a paper describing a new respiration calorimeter and certain experiments made with it on the conservation of energy in the human body. The apparatus described has been devised and the methods of experimenting have been elaborated for use in inquiries bearing (1) on the question as to whether the principle of conservation of energy holds good in the living organism, and (2) assuming this law to be true, on the acquisition of more definite knowledge of the ways in which the body is nourished and of the values and uses of food. We would suggest that in experiments upon the living organism, the second law of thermodynamics opens up a much more interesting field of study than the first law. It has been suggested that vital processes afford the most likely region in which to seek for the existence of Maxwell's "demons," and should their non-existence be established, information as to the relative efficiency of the human individual as compared with a perfectly reversible thermodynamic engine is much to be desired.

THE Soulanges Canal, which has recently been opened for traffic, completes the scheme for providing a 14-feet water-way from the Great Lakes to Montreal, in place of 9-feet, which previously had been the ruling depth for the navigation. It is considered that owing to the increased size of the vessels which will now be able to reach Montreal from the Great Lakes, the price of conveyance of wheat and other products of the North-west will be so reduced as to lead to the diversion of the principal part of the traffic which now finds its way to this country through America by the Erie Canal and New York. The St. Lawrence has been dredged and deepened below Montreal, so that large ocean-going vessels navigate the river up to that city, which has become the head both of the ocean and inland navigation. The Soulanges takes the place of the old Beauharnois Canal, it being found less costly to construct an entirely new water-way over this length than to widen and deepen the old one. The new canal connects Lake Francis with the Ottawa River. The fall in this length is 82 feet, which is overcome by four locks, this descent forming about half the total fall between Lake Ontario and the St. Lawrence. Electricity is used for lighting the locks and for operating the machinery for opening and closing the gates and sluices. The canal has cost 1,000,000*l.*; the total sum expended by the Dominion on the improved water-ways amounting to nearly 8,000,000*l.*

THE current number of Petermann's *Mittheilungen* contains a valuable paper on the fundamental lines of structure of the Eastern Alps, by Dr. C. Diener. An examination of the new material collected during the last few years leads the author to the opinion that the old division of the Eastern Alps into three zones, one crystalline and two limestone zones, is inadequate: the division is rather into five zones, which radiate eastward. The "Flysch" zone forms part of a tectonic unit running to north-eastern Switzerland and the western Alps, next comes the northern limestone zone, and then the central zone, which is made up of a number of different parts. The fourth zone is the "Drauzug" of Suess, and the fifth the southern limestone zone.

THE Smithsonian Institution has just issued a reprint of two old papers, by Dr. Otis T. Mason, on the Latimer Collection of Antiquities from Porto Rico, and on the Guesde Collection from Pointe-à-pître, Guadeloupe. There seems to be some doubt whether the wonderful examples of stone carvings were the work of Caribs or of their more peaceful neighbours; the evidence seems rather to point in favour of the former view. At Porto Rico are found mammiform stones which consist of a human or animal image associated with a conical projection; there are also found so-called "collars." These are slender ringed stones shaped something like a horse-collar; they average about seventeen inches long and twelve inches wide. They are beautifully worked and usually decorated with elaborately carved panels; the significance of these two groups of objects is unknown. Those interested in aboriginal stone-work should consult these papers, which have numerous illustrations; those in the second paper are in that queer dotted American style in which even contour lines are usually omitted. The wonderful results that can be obtained by savages without metal tools are here well demonstrated.

WE have received the parts of the Brazilian journal *Lavoura* for May, July and August 1899. They include articles on imported insect-pests, the Soja bean, agriculture, and various other observations, mostly illustrated, principally of local agricultural interest.

THE seventh edition of Foster and Langley's well-known "Course of Elementary Practical Physiology and Histology" (Macmillan) differs in several respects from preceding editions. Most of the lessons have been rewritten, a few have been added, and the lesson on the dissection of the rabbit and dog has been omitted. Dr. L. E. Shore has revised and rewritten the portions of the book dealing with chemical physiology, and with the physiology of muscle and nerve, and his name appears with Dr. Langley's, on the title-page, as joint editor of the new edition. The volume will doubtless be as widely used and appreciated in the future as it has been for more than twenty years.

WE have received from Mr. C. L. Wragge, chief of the Weather Bureau, Brisbane, a set of weather charts of Australasia for January 1898. The isobars are extended seawards over the Great Australian Bight and to New Zealand. These curves are to a great extent problematical, as indicated by the broken lines, and even over the land they appear to have been drawn from insufficient data in the western and north-western districts; the charts are also too much after date to be of general interest. We should prefer to see charts drawn by each Colony separately, from its own materials, and published within reasonable time after date.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*, ♂) from India, presented by Mr. Charles Dallas; a Vulpine Phalanger (*Trichosurus vulpecula*) from Australia, presented by Mr. D. Woosman; a Shag (*Phalacrocorax graculus*), European, presented by Mr. E. S. Montague; a Herring Gull (*Larus argentatus*), two Glaucous Gulls (*Larus glaucus*), European, presented by Mr. H. J. Pearson; seven Cape Scorpions (*Opisthopthalmus capensis*) from South Africa, presented by Dr. W. F. Purcell; a Cardinal Eclectus (*Eclectus cardinalis*) (habitat?), a Grand Eclectus (*Eclectus roratus*) from Moluccas, a Mealy Amazon (*Chrysotis farinosa*) from South America, four Blanding's Terrapins (*Emys blandingi*), five Prickly Trionyx (*Trionyx spinifer*) from North America, deposited; twelve Golden Carp (*Carassius auratus*), European, purchased.

THE COMING METEOR SHOWER.—Much has recently been written respecting the necessary preparations for obtaining photographic record of the Leonids, but hitherto these instructions have only taken into consideration the determination of the position and appearance of the meteor trail. There must be many, however, who are in a position to attempt to obtain a record of the composition of the meteorites. The only additional apparatus will be either a prism or a diffraction grating. After the camera has been focussed, the prism or grating can be very simply attached to the hood of the lens, and the whole then constitutes a small prismatic camera which will give the spectrum of any meteor whose image falls on the plate. A grating is preferable, as the reduction of the spectrum is more easily made, and there is also the advantage that an ordinary picture of the object is obtained in addition to the spectrum. Practically perfect transmission gratings can now be obtained very cheaply of sufficient size to cover the lenses of ordinary cameras. If a prism is used, it should preferably be set at minimum deviation to allow of subsequent comparisons being made.

LONG FOCUS PHOTOGRAPHIC TELESCOPE.—Prof. E. C. Pickering some time ago asked for donations to enable a photographic lens of unusually long focus to be made for the use of the Harvard College Observatory. We hear that now the whole of the necessary amount has been subscribed by anonymous donors, and that a lens of about 12 inches aperture and over 100 feet focal length will probably be ready for trial during the ensuing year.

SECULAR PERTURBATIONS OF VENUS.—Prof. Eric Doolittle, of the Flower Observatory, has completed his investigation of the perturbations of Venus by the computation of those caused by the planet Neptune. The perturbations arising from the six inner planets have been published in the *Astronomical Journal*, Nos. 409, 428, 418, 434, 438 and 465, and the present communication appears in No. 470.

The planetary elements used have been adapted from Dr. G. W. Hill's "New Theory of Jupiter and Saturn."

All the equations are given in tabular form, and the variations arising from the combined action of all the disturbing planets are given in the form of six equations, one for each element.

ENGINEERING PROGRESS AND PROBLEMS.

THE eighty-first session of the Institution of Civil Engineers was opened on Tuesday with an address by the president, Sir Douglas Fox. A general survey of engineering progress during the present century was given in the address, the following being a few of the points to which reference was made:—

British engineers have two chief bodies of competitors to reckon with—the engineers of the great and growing empire of Germany and those of the United States, who have been thoroughly trained in theory and practice, and are proving their ability and courage by the vast works they originate and carry out.

German and other continental engineers are greatly assisted in many ways by paternal Governments, whose officers they generally are, and who lay down valuable regulations, and in many instances establish standards of quality and design.

American engineers are encouraged by the vast demands of a comparatively new country, in which nature exists on a magnificent scale, only equalled by Switzerland and India, and of a rapidly rising civilisation calling loudly for the most recent improvements in locomotion, in building, in lighting, in telephonic and telegraphic communication.

An important matter demanding careful consideration by civil engineers, if not by the Institution itself, is whether competition in the world's race could be facilitated by the establishment, upon sufficient authority, of standard specifications for such materials as steel and cement, and the introduction of standard types for bridgework, roofing and other structures frequently occurring in practice, and for locomotives and rolling stock.

The question of the adoption of the metric system has been ably dealt with by others. I therefore only desire to record my opinion that it is of the utmost importance to the engineers and traders of this empire, that this simple and effective mode of measurement, already in force in almost every other civilised nation, should be introduced here. Having had occasion for many years to work under both systems, I can bear testimony to the great saving of time and of labour effected by the use of the metrical weights and measures, and to the ease with which the system is acquired, even by those trained to use our antiquated and complicated standards. I am strongly of opinion that the two great Anglo-Saxon nations, Great Britain and the United States, must fall into line with the rest of the world in this matter, and it would be a notable and interesting mark of our entry into a new century if, as has already been suggested to our Government, the metric system could be made compulsory as from A.D. 1900. One great obstacle to British designs and manufactures finding their way upon equal terms through the continent of Europe and into the vast empire of China, Japan and elsewhere, would thus be removed, and engineers throughout the world would be thinking and designing upon a basis of like dimensions.

Nothing has more largely contributed to engineering successes of late years than the introduction of cheap steel of good quality and of high tensile strength, both for rails and for plates and rolled sections. Remarkable uniformity of quality has been attained, and, whilst the life of rails has been greatly increased, structures such as the Forth Bridge have been rendered practicable. At the present time mild steel is almost exclusively used for the construction of ships, thus greatly increasing their carrying capacity. Some anxiety is being caused to engineers by the manifest signs in rails and axles of fatigue after considerable wear, and the report of the Board of Trade Committee upon this subject is awaited with much interest.

With reference to this matter and to other questions involving scientific research, the resources of this Institution might, I suggest, be advantageously employed. Large numbers of experiments upon steel and other materials have been made with small specimens, but the testing to destruction of full-sized members of bridges and other structures, and experiments upon the effects of impact and of loads running at high speeds have been generally beyond the limits of private enterprise. As a result comparatively few of such records are available, whilst the value to our members would be very great.

There is no department of engineering which has benefited more by the inventive genius of the century than that of mining. Improved methods of sinking deep shafts, tubbing back water, and winding at high speeds from great depths, have enabled much coal to be opened up. Electricity has been impressed into the service with most beneficial results, not only of economy, but of safety and improved sanitation, and is now largely used for underground haulage, for lighting, for pumping at the face, and, in the shape of telephones, for communication. In dealing with gold and other ores, chemistry, electrolysis and mechanical engineering have combined to reduce cost and waste. Every effort is still necessary on the part of our mining engineers to face the competition, and the labour-saving appliances, not only of Belgium and Germany, but still more of the United States. It is surely to be regretted that it has been found necessary to obtain so large a portion of the mining machinery for our Colonies from our Transatlantic cousins.

It seems probable that liquid air, which can now be produced at a very cheap rate, will prove a most valuable auxiliary for cooling, and thus assist in ventilating mining drifts and railway tunnels. Experiments in this direction are being made in connection with the works of the Simplon Tunnel, which are now in full activity.

The problems now opening up to the civil engineer are of surpassing importance. Trunk railways through Russia, China, Persia, Africa; irrigation works to supply the wants of growing populations; harbours large enough to receive the vessels of the future (already eclipsing the *Great Eastern*, of which the chief shortcoming was that she was before her time); central installations to furnish lighting, power, traction and heating to whole counties; the extension of the telephonic communication—with and without wires; the abolition of the smoke and smell of cities; the replacement of horses by mechanical power in the streets; the increase of the speed of trains to 100 miles per hour; the erection of buildings of great height where land is valuable; the utilisation of waste products, especially the refuse of cities; the improvement of the water-supply; the reclamation of land; the profitable working of deep seams of coal.

These are but some of the branches in which engineering progress in the twentieth century may be expected to develop. They will call with increasing force for engineers sanguine for the future, educated upon a basis of sound scientific attainment, trained in experimental research, and qualified by practical experience—obtained, I trust, by means of that regular course of pupilage under members of the Institution which, in the less favourable circumstances of the past, has nevertheless produced the engineers who have achieved the results to which I have referred.

ANTHROPOLOGY AT THE BRITISH ASSOCIATION.

THE chief point of interest on the first day of the meeting of the Section, apart from the President's address, was a discussion on the rival systems for the identification of criminals of the Bertillon method and that based on finger-prints as propounded by Mr. E. R. Henry and adopted in British India. Mr. Henry, who is the Inspector-General of Police in the Bengal Civil Service, gave a demonstration of his system. The author referred to the importance of fixing human personality so that no efforts made to confuse it subsequently may prove availing. Of this problem the Bertillon system offered first scientific solution. But experience in India has shown that the "Personal Equation" error of measures predominates so much as to vitiate seriously the correctness of the recorded results under that system. Finger-prints, on the other hand, being absolute impressions taken from body under conditions which eliminate error in transcribing or recording, the "Personal Equation" error is reduced to a minimum. Taking the impressions of all ten digits occupies only a fraction of the time required for measuring, while search is more exhaustive and many times more rapid. This new system has been introduced on a most extensive scale throughout British India, and the Legislature has recognised it by passing an Act to amend the law of evidence so as to make relevant the testimony of finger-print experts.

The main difficulty hitherto experienced had been that of providing an effective system of classification. But this difficulty has been overcome. A thin film of printer's ink is spread over a piece of flat tin, and each finger in turn is pressed on the film, and after being thus inked is pressed on paper where a clear, sharp impression is left. Fingers are impressed in their natural order of thumb, index, middle, ring, and little, those of the right hand being above, and the corresponding digit of the left hand below them.

All impressions must be either arches, loops, whorls, or composites—there is a great preponderance of loops and whorls. In primary classification arches are included under loops, and composites under whorls, and therefore, for purposes of primary classification, an impression must be either a loop or whorl. The digits are taken in the following pairs: (1) right thumb and right index; (2) right middle and right ring; (3) right little and left thumb; (4) left index and left middle; (5) left ring and left little finger. Taking first pair and denoting loop by L and whorl by W, we get the following arrangements. Right thumb may be L and right index L; right thumb may be L and right index W; right thumb may be W and right index L; and right thumb may be W and right index W. So there are four, and not more than four, arrangements possible. Similarly, in second pair, there are four such arrangements, which, taken with those of the first pair, yield 16 combinations; taking the third pair we get 64 combinations, and by adding the fourth and fifth pairs, this number rises to 256 and 1024. Now 1024 equals 32 squared; in other words, a cabinet containing 32 sets of 32 pigeon-holes arranged vertically would provide all the locations required. A diagram was shown how this works in practice. But the following rule is very simple. The first of each pair is shown as numerator, the second of each pair as denominator, yielding for the five sets of pairs some such formula as the following: $\frac{L}{W}$; $\frac{W}{L}$; $\frac{L}{L}$; $\frac{W}{W}$; $\frac{L}{W}$. A whorl in the first pair counts 16, in the second pair 8, in the third 4, in the fourth 2, in the fifth 1. No numerical value is given to a loop. Substituting these values in the formula we get $\frac{0}{16}$; $\frac{8}{0}$; $\frac{0}{0}$; $\frac{2}{2}$; $\frac{0}{1} = \frac{10}{19}$. Add 1 to both numerator and denominator and invert the fraction which becomes $\frac{20}{11}$, and this is the primary classification number, and represents that the card containing these impressions will be found on the twentieth pigeon-hole of the eleventh vertical row. The secondary classification required to break up accumulations is equally simple, and the search formula or legend for each card can be prepared rapidly without any key and brings search down to groups of very small volume.

Naturally Dr. Garson argued in support of the French system as taught by him to the English police. He had previously read a paper on the "Personal equation in anthropometry," and had fully described the well-known Bertillon system; he admitted there was always a margin of uncertainty in measurements, but denied that it need be so large as Mr. Henry asserted. He expressed regret that the Indian Government had abandoned the Bertillon system for one based solely on finger-prints.

A paper, also illustrated by lantern slides, was read by Francis Galton on "Finger-prints of young children," in which he demonstrated that clear prints of all ten fingers of a baby would suffice for after-identification by an expert, but by an expert only. Although new ridges may appear in infantile life the type of each pattern persists all through life, and is never doubtful to a practised eye.

The whole of Friday was devoted to samples of the work accomplished by the Cambridge Expedition to Torres Straits and New Guinea. Dr. A. C. Haddon, the organiser and leader of the expedition, led off with a short report on the work done (*cf.* NATURE vol. lx. p. 413), and illustrated with lantern slides the physical character of the inhabitants. A communication on the linguistic results of the expedition, by Mr. Sidney H. Ray, was laid before the Section.

The language of the Eastern tribe of the Straits bears no resemblance to the Melanesian, and but little to the Australian group of languages, while that of the Western tribe is decidedly of the Australian type. Most of the coast languages of the Port Moresby and Hood Bay districts are very closely akin to the languages of the Melanesian Islands, except some, such as the Koitapu, Koiari and Cloudy Bay dialects, which approach the Australian type, but has nothing in common with the Melanesian. Mr. C. S. Myers gave an interesting paper on savage music, based on his observations in Murray Island and Sarawak.

As our modern orchestra admits the noises of drums and cymbals, and our harmony allows chords which in a more classical period were inadmissible, we, in our inquiry into past and primitive music will not refuse to consider certain sounds as musical even though they be noisy. Sympathy should be our sole test of music. In savage life the songs of a tribe are its chief heritage. Certain songs recorded on the phonograph in Murray Island, Torres Straits, are now obsolete, and will probably die out with the old men. Neither there nor in Borneo could any trace of the notes of birds be found in the music. Of the two fundamentally distinct elements in music, rhythm and melody, the one has its basis in bodily movement, the other in the emotional recitative. In Murray Island the drum is beaten to accentuate the words of the old songs, the music being singularly lacking in rhythm; among the North American Indians, on the other hand, rhythm is well developed. The extraordinary complexity of rhythm in certain Malay music was graphically recorded. The Murray Islanders have a wonderfully developed idea of rhythm, as is proved by their being able regularly to continue accurately recorded beats of prescribed rapidity for a considerable period. Many suggestions have been made as to which of the intervals came most naturally to the human voice. The Murray Islanders have no polyphonic music, but in a chorus accompanying the songs of the Kenyah and allied races in Borneo a long-drawn note a fifth below the key-note runs drone-like through the song. A similar interval has been noted in one of the rare examples of polyphonic music found in North America.

Writers have been led to conclude that various peoples employed far smaller intervals than our own, misled apparently by viewing the numerous intervals as if they formed a scale instead of a series of notes from which various scales were derived. In this way travellers have been induced to look for quarter-tone music in uncivilised parts of the world; but the author had no doubt that those quarter-tones, which have been written down as occurring between any two whole (or semi-) tones, merely express a gradual descent in the voice from one of these tones to the other. The insensitiveness of the ear of the Murray islanders to minute differences of interval was estimated by means of tuning-forks. The common incorrect intonation in savage music was alluded to.

Mr. C. G. Seligmann followed with an account of the seclusion of girls at puberty in Mabuiag and other of the Western islands of Torres Straits and also on the mainland at Cape York. The girl is surrounded with bushes in a dark corner of her parents' house, and for months is only allowed to go out at night. The sun may not shine on her; no man may come into the house; ill-luck would befall her father if he saw her; she may not feed herself; and there are other restrictions. Various modifications of the seclusion were described. These observations are of especial interest, as it is a new locality for these interesting customs, the significance of which have been discussed by Frazer in "The Golden Bough." The same author read a paper on some customs of the Otati tribe of North Queensland; and another, illustrated with lantern slides, on the Club Houses and Dubus of British New Guinea. In the Papuan Gulf the club houses of the men are of large size and highly decorated; no women may enter them. Further down the coast their place is taken by platforms, or dubus, the posts of which are generally carved, in some instances probably so as to resemble crocodiles' heads. As a general rule women may not approach the dubu.

The morning's session concluded with a very interesting report on the investigations on comparative psychology made in Torres Straits and New Guinea. Dr. W. H. R. Rivers gave a general account of the work done, with observations on vision, &c. The natives show very considerable variability in character and temperament; they do not appear to be especially susceptible to suggestion, but exhibited very considerable independence of opinion. One hundred and fifty natives of Torres Straits and Kiwai were tested for colour-blindness without finding one case; about eighty members of other races were tested with a similar result, but of eight Lifu islanders three were colour-blind. The names used for colours by the Torres Straits islanders were very fully investigated; there were definite names for red, less definite for yellow, and still less so for green, while a definite name for blue was either absent or borrowed from English. Corresponding to this defect of colour terminology, there appeared to be an actual defect of vision for colours of short wave-length. Numerous observations were made on writing and drawing; the most striking result was the care and correctness with which mirror writing was performed. Unexpected success attended the experiments on the estimation of time. Nearly all the investigations gave some indication of the liability to fatigue and the capability for improvement by practice. Mr. C. S. Myers gave an account of his observations on hearing, smell, taste, reaction-time, &c. Few Murray Islanders surpass a hyper-acute European in auditory acuity, while the majority cannot hear as far. The sense of rhythm is remarkably accurate. There is no reason to believe that they are able to perceive such traces of odour as would be imperceptible to the most sensitive European noses. Experiments were made to determine the appreciation and recognition of the common tastes. The time of simple reaction is probably somewhat shorter than would be that given by a corresponding class of Europeans. The observations of Mr. W. McDougall on the sense of touch showed that the natives have a greater delicacy of discrimination than white men, and at the same time less sensibility to pain.

In the afternoon Dr. Haddon gave a lantern exhibit that lasted for a couple of hours; over one hundred slides were shown, illustrating native handicrafts, customs and mode of life. A number of sacred stones and spots were shown, and their legends narrated. A series of sixteen slides fully illustrated the process of pottery-making at Port Moresby; other slides showed men cutting out canoes with stone adzes at Keapara; raising a pile, and the process of tattooing at Bulaa; and a number of beautiful photographs portrayed the singing games of Papuan children. Most of the photographs exhibited were taken by Mr. A. Wilkin.

Saturday was devoted to archæological papers, and several members of the French Association were present at the session. The most important communications were: one by Mr. A. J. Evans on the occurrence of "Celtic" types of Fibula of the Hallstatt and La Tène periods in Tunisia and Eastern Algeria; the appearance of Celtic types of Fibula among the Numidians finds its complement in the discovery of large hoards of Carthaginian and Numidian coins on the transit line of the amber trade between the Save and the Adriatic. The other, by Mr. G. Coffey, on Irish copper Celts; of these there are eighty-two examples in the Dublin Museum; they are found all over Ireland, and appear to represent a transition from stone to bronze types, and can be arranged in series showing development of form from stone to bronze implements. It would thus appear that, prior to a knowledge of bronze, copper was known and used for cutting implements in Ireland.

Physical anthropology was represented on Monday morning. Mr. J. Gray read a paper, with lantern illustrations, on recent and most excellent ethnographical work in East Aberdeenshire, based on observations on nearly 14,000 children. The maps showed very clearly the penetration up the valleys of an immigrant fair type among a dark population. A very valuable paper, also illustrated by numerous lantern slides, was read by Mr. D. MacIver on recent anthropometrical work in Egypt.

The author gave examples of the ways in which anthropometry may aid archæological investigation, and pointed out the unusually favourable conditions for such anthropometrical work which exist in Egypt. He gave a summary of the series of Egyptian measurements at present available, of the difficulties which have arisen in their interpretation, and of some new methods of publishing measurements specially designed to meet them; these graphic methods were suggested by Flinders-Petrie, and will doubtless prove of value to other investigators.

Details were given of three important series of specimens from Egypt, viz.:

(1) Prehistoric Series; from the excavations of 1898–9.

(2) VI. to XII. Dynasties; from the excavations of 1898.

(3) XII. to XVI. or XVII. Dynasties; from the excavations of 1898–9.

These series were considered (*a*) separately, with the object of ascertaining the race type represented in each; (*b*) in comparison with one another, to show their affinities and differences. The paper concluded with a most instructive and suggestive essay on the light which such comparison throws on Egyptian history.

Prof. A. Macalister followed with notes on a collection of 1000 Egyptian skulls, and exhibited curves compiled from the indices.

In the afternoon Prof. W. M. Flinders-Petrie read a paper on sequences of prehistoric remains. In written history the value of chronology lies almost entirely in its defining the sequence of events; and if the order of changes in a civilisation can be fixed, the reference to a scale of years is but a secondary matter. Hitherto only very vague and general terms, referring to places and not to age, have been used in naming prehistoric remains. But if we possessed a perfect record of an unlimited number of contemporary groups of objects all of which have had a time of invention, popularity, and decay, and the use of which overlap each other, it is clear that with patience it would be possible to arrange all the series of groups in their order of time, and so establish definite sequences among the various objects. If then a sequence can be established, a scale of notation is needed. As a scale of years is impossible, a scale of equal activities is the most reasonable. This may be reached by placing all the available material in order and then dividing it into a scale of equal parts. Such a scale, though not equal in time, will yet give a fair unit for measuring a civilisation. This

Prof. Flinders-Petrie has accomplished for prehistoric Egypt, and his demonstration indicated that his system is an important addition to precision in dealing with undateable archæological remains. A second paper by the same indefatigable and brilliant investigator dealt with early Mediterranean signaries and the sources of the alphabet.

The large series of signs used in Egypt about 2500 B.C. is now shown—by such signs existing as far back as 5000 B.C.—to be independent of the hieroglyphic system or any derivatives of that. Similar signs in Crete show this system to have extended to the Mediterranean by about 2000 B.C.

On looking at the more extended forms of the Greek alphabet found in Karia and Spain, about sixty signs are seen in use, representing about forty-three sounds. Three-quarters of these signs are common to the system found in Egypt and Crete.

The only conclusion at present seems to be that signs were in use from 5000 B.C. onward, and developed by 2500 B.C. to over 100 in Egypt, of which half survived in the fuller alphabets of Karia and Spain. The compression and systematising of these signs was due to twenty-seven of them being adopted for a numerical system by the Phœnicians, and thus the *alpha beta* order was enforced by commerce on all the Mediterranean. This accounts in the only satisfactory way for the confusion of the early Greek alphabets, and is a view forced on us by the prevalence of these same signs long before Phœnician commerce.

On Tuesday Dr. A. C. Haddon read some notes on the Yaraikanna Tribe of Cape York:—

The Yaraikanna are fairly typical Australians in appearance; six men were measured, average height 1·625 m. (5 ft. 4 in.), cephalic index 74·7 (extremes, 72·4–77·7). A lad is initiated by his *mawara*, apparently the men of the clan into which the boy must subsequently marry; he is anointed with "bush-medicine" in the hollow of the thighs, groins, hollow by the clavicles, temples, and back of knees to make him grow—the bull-roarer is swung. In the *Yampa* ceremony the initiates (*langa*) sit behind a screen in front of which is a tall pole, up which a man climbs and catches the food thrown to him by the relatives of the *langa*. Then the bull-roarer is swung and shown to the *langa*; lastly, a front tooth of the *langa* is knocked out, with each blow the name of a "land" belonging to the boy's mother or of her father is mentioned, and the land, the name of which is mentioned when the tooth flies out, is the territory of the lad. Water is next given to the boy, who rinses out his mouth and gently empties his mouth into a palm-leaf water vessel; the clot by its resemblance to some animal or vegetable form determines the *ari* of the lad. The *ari* appears to be analogous to the *manitu* or *okki* (or "individual totem" of Dr. J. G. Frazer) of the North American Indians. After the ceremony the boy is acknowledged to be a man. Other *ari* may be given at any time by men who dream of an animal or plant, which is the *ari* of the first person they meet on awakening. The *Okara* ceremony was alluded to, and various customs, among which may be noted—children must take the "land" or "country" of their mother, a wife must be taken from another country, all who belong to the same place are brothers and sisters.

Mr. W. Crooke discussed the primitive rights of disposal of the dead, as illustrated by survivals in modern India; the points considered were: customs connected with the preservation of the corpse, such as various forms of mummification; platform burial; direct exposure of the dead to beasts of prey; general exposure of the dead; the question of the priority of burial to cremation; transitions from burial to cremation, and *vice versa*: disposal of those dying in a state of taboo; shelf or niche burial; crouched or sitting burial; disinterment of the corpse; jar or urn burial; and dismemberment of the corpse.

A theoretical paper on pre-animistic religion was read by Mr. R. R. Marett, his general thesis being:—

The term religion denotes a state of mind embracing emotional and ideal constituents, whereof the former constitute the universal and constant, the latter the particular and variant element. Self-interpretation in ideal terms on the part of the religious emotion of the savage has found most complete and definite expression in animism, the "belief in spiritual beings." Animism, however, as compared with "supernaturalism," namely, that state of feeling almost uncoloured by ideas which is the primary form taken by man's awe of the supernatural (or extraordinary) is, but as the strongest sapling in a thicket of heterogeneous growths, which, in the struggle for existence, has come to overshadow the rest and give a character to the whole. The vagueness of primitive "supernaturalistic" utterance is illustrated by, *e.g. andriamanitra* (Malagasy), *ngai* (Masai), *mana* (Melanesians), *wakan* (North American Indians), *kalou* (Fijians). A "pre-animistic" validity as manifestations of religion thus attaches to a variety of special observances and cults; and it may therefore be interesting in the case of some of the more important of these to distinguish between the original basis of "supernaturalistic" veneration and the animistic interpretation that as the result of successful competition with other modes of explanatory conception (notably "animatism," namely, the attribution of life and will, but not of soul or spirit, to material objects and forces) is thereon superimposed in accordance with the tendency of the religious consciousness towards doctrinal uniformity.

In the afternoon Colonel R. C. Temple discoursed on the thirty-seven Nats (or Spirits) of the Burmese.

The belief in the Nats, or supernatural beings who interfere in the affairs of mankind, is universal among all the native inhabitants of Burma of every race and religion. Every writer about the Burmese and their customs mentions the Nats. The subject is, however, still but vaguely understood. The Nats are of three distinct kinds: (1) the supernatural beings due to the Buddhist cosmogony; (2) the supernatural beings familiar to the creatures, objects and places with which man is concerned due to the prehistoric animistic beliefs of the people; (3) the supernatural beings who are ghosts and spirits of the notorious dead. Of the many orders of Nats thus created, that of the Thirty-seven Nats is by far the best known among the people. These are the ghosts of the departed royalties of fame, and their connections. About them nothing seems to have been previously published in England, and this paper was a preliminary attempt at an adequate representation of them, and of the history, real or supposed, connected with them during life. The paper was illustrated by a map in order to explain the relative position of the places chiefly connected with the very complicated political history of Burma and its numerous dynasties, so far as these are concerned with the stories related of the Thirty-seven Nats. The paper was further illustrated by a beautiful lantern slide of an image of each of the Thirty-seven Nats from the unique and authentic collection of large carvings of them in teak wood by Burmese artists in the possession of the author.

The most important communication on Wednesday morning was a description of two new methods of anthropological research by Dr. W. H. R. Rivers. He commenced by emphasising the importance of great accuracy in all anthropological investigations. His first exhibit was a contribution to exactitude in recording colours, more especially those of the skin of natives. Lovibond's tintometer proved of great service in matching colours, but it is not very suitable for matching skin-colours; for this a colour-wheel is most suitable, the only objection being that the paper discs are liable to fade, and it is not always certain that any two issues of coloured discs would be of exactly the same tint. By having a large number of discs the original records could be filed for future reference and, if kept in the dark, they would not fade. If permanent and absolutely comparable discs could be produced the colour-wheel would answer all practical purposes. The second was a most important sociological method, and consisted in accurately recording the genealogies of all the individuals of an island or limited community for as far back as the informants can remember. It is necessary to use only the terms of "father," "mother," "wife," "children," "man," "woman," "boy" and "girl." The first two were qualified by "proper" or "true," so as to avoid ambiguity. By asking what A calls B, &c., the names and system of relationship can be obtained with absolute precision. In a totemistic people their totems were also recorded, which yielded evidence as to marriage restrictions. This method also furnishes definite statistics on the size of familes, proportion of sexes, number of early deaths, prevalence of adoption, and various other sociological data which are very difficult to obtain with accuracy by any other method. This method of Dr. Rivers' should be adopted by all investigators, as it is almost impossible to overrate its value.

The rest of the day was devoted to African ethnography. Dr. R. Koettlitz exhibited some interesting ethnographical specimens from Somali, Galla and Shangalla, including some scales and weights of seeds and stones for weighing gold-dust, and the first example of salt-money that has been brought to England. Papers by Lieut.-Colonel J. R. L. Macdonald on the ethnography of the lake region of Uganda, and by Lieut.

H. Pope Hennessy on notes on some West African tribes north of the Benue, were laid before the Section.

The usual reports of various Committees were read at various times, the most voluminous being that of the Ethnographic Survey of Canada. It stated that during the past year the work of the Committee had been extended in important directions. The introduction into the North-west of large bodies of Europeans who were to become permanently incorporated in the population suggested the importance of securing as soon as possible such facts relating to their general ethnology as might seem to establish a suitable basis for the study of these people under the influence of their new environment. Satisfactory arrangements had been made with respect to Russian refugees known as the Doukbohors, and it was probable that similar arrangements might be completed during the coming year with regard to other large bodies of immigrants. The exceptional circumstances in British Columbia, the fact that it was becoming more difficult each year to obtain trustworthy accounts of its people, the rapid disappearance of old customs, dress, and modes of living had seemed sufficient reasons for devoting to their study a much larger share of the resources of the Committee than might otherwise appear justifiable. An appendix contained an account of early Canadian settlers and studies of the Indians of British Columbia. On the whole Section H may be congratulated on the very uniform high excellence of the papers, it probably being one of the very best meetings that the Section has ever had.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—A meeting of the Junior Scientific Club was held in the University Museum on Wednesday, November 1. After private business, Mr. F. C. Lees (Hertford) read a very interesting paper on geysers in action, exhibiting also an excellent working model. A brisk discussion afterwards ensued.—Mr. Gibson (Ch. Ch.) also read his paper on the retention of plant-food in the soil, which had been postponed from the previous meeting.

CAMBRIDGE.—At the annual election on November 6, at St. John's College, the following were elected Fellows: Mr. W. A. Houston, fifth Wrangler 1896 and Smith's Prizeman 1898, Lecturer in Mathematics at University College, Liverpool; Grafton Elliot-Smith, B.A. 1898, M.D. of the University of Sydney. Dr. Elliot-Smith, who entered the University in 1896 as an Advanced Student, has made a number of highly important contributions to the comparative anatomy of the brain, and is one of the assistant-demonstrators of anatomy under Prof. Macalister.

The Council of the Senate propose that, having regard to the extensive and valuable collections procured for the University by the Torres Straits Expedition, a further grant of 100*l.* (making 550*l.* in all) be made from the Worts Travelling Scholars' Fund to Dr. Haddon towards the expenses of the expedition.

Mr. C. Hose, of Borneo, has presented to the Museum of Zoology a fine example of the ourang outan's nest. A collection of skeletons and skulls of the extinct Moriori race, which formerly inhabited the Chatham Islands, has been acquired for the Museum of Anatomy.

Mr. Timothy Holmes has been added to the Medical School Buildings Syndicate. It is understood that the plans for the buildings are in a forward state of preparation.

Mr. F. W. B. Frankland, third Wrangler in 1897, has been elected to a Fellowship at Clare College.

MR. HORACE PLUNKETT, M.P., has been appointed vice-president of the new department of Agriculture and Technical Education for Ireland.

THE educational movement in Wales has afforded an exceptional opportunity of bringing the Principality into the front rank in the matter of scientific education, and it cannot fail to be a matter of regret to well-wishers of the movement to notice indications that the "modern side" of education is not developing to the same extent in Wales as in other countries. In the recent scholarship examination at the University College of North Wales only six science candidates presented themselves, of whom three were not Welsh, while twenty-five candidates intending to qualify in arts entered.

AMONG other agencies by which the Technical Education Committee of the Essex County Council is cultivating scientific knowledge is the County School of Horticulture at Chelmsford, the prospectus of which is before us. The aim of the School is to impart sound elementary instruction in the best methods of cultural treatment, based upon a knowledge of the structure and physiology of plants. The garden attached to the School covers an area of three acres, and is entirely devoted to educational uses. Horticultural and botanical students in Essex are fortunate in possessing an institution in which wisely planned courses of work upon plants can be followed under such good conditions as are available at Chelmsford.

THE purposes for which the Technical Education grant is used in the various counties are shown concisely in a document just published by the County Councils Association. The counties are arranged alphabetically, and under each is given information concerning the work done in regard to (*a*) schools of science and art, (*b*) technical institutes, (*c*) agricultural schools and institutes, (*d*) domestic economy schools and institutes, (*e*) day or other schools or classes giving instruction in agricultural, commercial, domestic, manual or technological subjects. The Returns (which refer to 1897-98) also show the number of scholarships and exhibitions given by each County Council, and the provision made for examination and inspection of classes.

REPORTS received from time to time, referring to the work carried on under the auspices of Technical Education Committees of County Councils, show that in many agricultural counties the committees are gradually building up a system of teaching and experiment which serves much the same purpose as the educational branches of the agricultural experiment stations in the United States and elsewhere. In Somerset, for instance, the committee, of which Mr. C. H. Bothamley is the director, have organised courses of instruction in most branches of agricultural work; and the instructors not only lecture, but visit farms, gardens and orchards for the purpose of giving information and advice, for which no fees are charged, on points, both general and special, arising in agricultural practice, such as the manuring of arable and grass land, the treatment of wire-worm, farm buildings, water supply, and similar matters. On one farm the failure of the mangold crop for the second year in succession was found to be due to an attack of large numbers of a very minute beetle, which Miss Ormerod identified as what is known as the pigmy mangold beetle, an insect which rarely occurs in sufficient numbers to be injurious, and which was in fact first recognised in this country in 1896. It is satisfactory to read that information has been given by several farmers to whom previous visits have been paid, to the effect that favourable results have followed the adoption of the methods suggested by the county instructor. A scheme for the establishment of an experimental farm has been drawn up, and will be put into effect as soon as the Secondary Education Bill is passed. School gardens are already carried on at several places in the county, and with much success. In other sciences, as in agriculture, the Somerset Education Committee appear to be proceeding on the right lines, and good results must attend efforts so wisely directed.

THE U.S. *Experiment Station Record* gives information concerning an extensive system of agricultural education which the Government of Russia is organising. The scheme provides for (1) higher education, furnished by independent agricultural institutes situated in the chief agricultural zones of Russia, and by chairs of agriculture and allied sciences in the universities; (2) agricultural high schools, which are in the nature of technical schools, and schools with courses in agriculture; (3) lower agricultural schools,; and (4) the diffusion of general agricultural information. The schools for the so called lower education include (*a*) secondary agricultural schools, (*b*) primary agricultural schools, (*c*) agricultural classes, and (*d*) practical agricultural courses. These lower schools are to be under the jurisdiction of the minister of agricultural and imperial domains. They are to be maintained at the expense of municipalities, local communities, associations, &c., but may receive a part of their support from the Government. The secondary schools are to be established on Government land, or land donated for that purpose. The other lower agricultural schools may be established on private estates. The secondary schools are open to young men of all conditions who have completed the course in the primary public schools. The diffusion of general agricultural information is to be provided for by the organisation of public readings or lectures on agricultural questions for the benefit of different classes of the population, instruction of the teachers in public schools in agriculture, horticulture, gardening, apiculture, &c., and providing the public schools with small plots of land and means for cultivating the same; also by the teaching of agriculture in the normal schools, and the introduction of supplementary courses in agriculture in the village schools. There are now in Russia three schools for higher agricultural instruction, nine agricultural high schools, eighty-three lower schools, and fifty-nine special courses. Steps have already been taken for the establishment of about fifty additional agricultural schools.

SCIENTIFIC SERIALS.

American Journal of Mathematics, vol. xxi. No. 4, October.—Memoir on the substitution-groups whose degree does not exceed eight, by Dr. G. A. Miller (pp. 287–338), is an exhaustive piece of work, amply furnished with bibliographical notes. The author's aim is to give enough of the general theory of group construction to find all the possible groups whose degree does not exceed eight without any tentative processes. The earliest work that gives considerable attention to substitution-groups is stated to be that by Ruffini, entitled "Teoria generale delle equazioni, in cui si dimostra impossibile la soluzione algebraica delle equazioni generali di grado superiore al quarto" (1799). The author has won his spurs in this field, and the present memoir shows a thorough mastery of his subject. There is a good table of contents appended.—On a class of equations of transformation, by J. Westlund. In this paper the writer discusses those equations whose roots are the $n + 1$ values of

$$y_{\underset{\nu}{\mu}} = \prod_{1,m}^{p} sn^{2\alpha} . \, cn^{\beta} . \, dn^{\gamma} \, (4p\omega/\kappa),$$

where α, β, γ, are any positive or negative integers, and

$$\omega = \frac{4\mu\kappa + 4\nu i\kappa}{n},$$

μ and ν being integers. For the notation reference is made to Weber, "Elliptische Functionen," § 67.—Dr. Wilczynski, in an article entitled "On Linearoid Differential Equations," follows up a previous article in the *Journal* (April 1899). This he looks upon as being a reconnoissance upon a new field of promise. *Linearoid* "suggests" the relation of the present equations to linear differential equations.—Prof. W. H. Metzler contributes a short note on the roots of a determinantal equation. The theorem is similar to one discussed by Dr. T. Muir in vol. xix. (pp. 312–318).—Non-quaternion number-systems containing no skew units, by Dr. Starkweather, opens with a brief statement of a few properties of number-systems in general. Then follows a proof of a statement made by Scheffers (*Math. Ann.* xxxix. 306, 310) as to the possibility, in this special class of number-systems, of a selection of units having certain simple multiplicative properties. He then shows that the units can be chosen so as to give in general a very much simplified form of multiplication table, and a method is given for deriving systems of the type considered in n units from those in $(n-1)$ units. Application of the principles he deduces is made to systems, the degree of whose characteristic equation is two less than the number of units. Other points are discussed, and a table of all the possible non-equivalent orms is given.

VOL. VI. of the *Anales del Museo Nacional de Buenos Aires* contains the following papers:—Contributions to our knowledge of the herpetological fauna of Argentina and the neighbouring countries, by C. Berg; some cases of vegetable teratology, fasciation, proliferation, and synanthy (three plates), by A. Gallardo; species of *Ampullaria* of the Argentine Republic, by H. von Ihering; diagnostics of new South American Diplopoda, by F. Silvestri; new or critical Argentinian fungi (two plates), by C. Spegazzini; observations on Argentinian and other South American Lepidoptera, by C. Berg; brief comparative description of *Lepidocampa* and *Campodea* (two plates), by F. Silvestri; new South American Tenthredinidæ, by F. W. Konow. Of these the fifth only is in Latin, and the last in German; the remainder are in Spanish.

THE numbers of the *Journal of Botany* for October and November are chiefly occupied by papers on descriptive and geographical botany. These are varied by an article, by Mr. E. S. Salmon, on certain peculiar structures found on the peritheces of the parasitic fungus *Phyllactinia corylea*, which appear to have a function in connection with its dissemination. The degeneration of these structures produces mucilage, by which the perithece of the fungus is firmly attached to the leaf of the host-plant.

SOCIETIES AND ACADEMIES.

LONDON.

Entomological Society, October 4.—Mr. G. H. Verrall, President, in the chair.—The President announced the death, at the advanced age of eighty-six years, of M. Hippolyte Lucas, an Honorary Fellow of the Society. He also announced the death of Mr. Samuel Stevens, and in reference thereto said the Society had to deplore the loss of one of its oldest and most highly esteemed Fellows.—Mr. J. J. Walker exhibited a specimen of *Galerita bicolor*, Drury, a North American beetle of the family Carabidæ, said to have been taken many years ago at Doncaster. He also exhibited a remarkable variety of *Vanessa urticae*, L. (*ichnusoides*, De Selys), which was captured in the Isle of Sheppey on August 28.—Mr. B. A. Bower showed dark aberrations of *Boarmia rhomboidaria*, Hb., in which the normal colour of the fore wings is replaced by dark brown, causing the fuscous markings to stand out very prominently.—Mr. C. J. Wainwright exhibited a number of Dipterous insects, including a long series of *Anthrax paniscus*, Rossi, taken in Cornwall at the end of July and beginning of August; a series of *Eumerus ornatus*, Mg., from Herefordshire, and *Eumerus lunulatus*, Mg., from Cornwall; and a specimen of *Mallota eristaloides*, Lœw, taken near Hereford last July.—Mr. H. J. Donisthorpe exhibited specimens of *Dytiscus dimidiatus*, Berg., and *D. circumcinctus*, Ahr., taken last August in Wicken Fen. He also showed eight specimens of *Athous rhombeus*, Oliv., taken last June in the New Forest.—The Rev. F. D. Morice exhibited three female specimens of *Exoneura libanensis*, Friese, taken at Brumana on Mount Lebanon, near Beirut. He commented upon the remarkable distribution of the genus *Exoneura*, Smith, this genus having been hitherto recorded only from Australia.—Mr. G. J. Arrow read a paper on sexual dimorphism in the Rutelid genus *Parastasia*.—Mr. W. L. Distant contributed descriptions of four new species of Cicadidæ, and Mr. Claude Fuller a paper on some species of Western Australian Coccidæ.

Royal Microscopical Society, October 18.—Mr. E. M. Nelson, President, in the chair.—The President called attention to an old microscope by Cary, presented to the Society by Mr. Gleadow. An instrument of the same design was figured in the *Journal* for 1898, p. 474.—Messrs. Watson and Sons exhibited their new school microscope, which was provided with a diagonal rack and pinion coarse adjustment, but no fine adjustment, their idea being to produce a strong well-made instrument at a low price. Dr. Dallinger had seen this instrument, and thought it would admirably answer the purpose for which it was intended; the coarse adjustment was so well made that he had no difficulty in focussing a $\frac{1}{8}''$ objective with it. The President thought the microscope was strongly made and well fitted, and would be found to be a very useful instrument. Messrs. Watson also exhibited a new form of eye-piece, named the "Holoscopic," which was fitted with an adjustment to render it either over- or under-corrected and suitable for use with either achromatic or apochromatic objectives.—Dr. Measures exhibited a microscope for photo-micrography, made by Zeiss, having a new form of fine adjustment which admitted of the arm being made of any length without throwing extra weight upon the fine adjustment screw. Dr. Dallinger considered the way in which the speed of the fine adjustment had been reduced was most ingenious; the motion was extremely slow, being only $\frac{1}{615}''$ for every revolution of the screw. A protest had always been made in the Society against the fine adjustment having to carry much weight, and it was therefore satisfactory to find that this one had to lift only one-fifth of the weight usually put upon the fine adjustment. The President said the application of an endless screw was a novel way of slowing down the fine adjustment; the reduction of weight upon the thread was an important improvement, and the increased length of arm was another good feature.—The President then described a new form of fine adjustment by Reichert, which was shown applied to his Austrian model, exhibited by Mr.

C. Baker; the indicator to this fine adjustment was movable, so that it could be set to zero when required, thus greatly facilitating the reading of the divisions on the head of the screw. The instrument was fitted with the English standard substage, and the axis of the trunnions was placed above the stage to ensure a better balance. Two other microscopes by Reichert were also exhibited, one being a student's without fine adjustment, but fitted with a dissecting loupe as a substage condenser. The President next showed a microscope fitted with his new stepped rackwork coarse adjustment by Messrs. Watson and Sons; there was no "loss of time," though the pinion was pressed but lightly into the rack. The President also exhibited a dissecting stand by Andrew Ross, which was about forty or fifty years old, and was still a thoroughly good working instrument; and though the lenses were not achromatic, they gave very good images.—Mr. C. Lees Curties exhibited some stereoscopic photo-micrographs taken on the Ives principle by Mr. E. R. Turner, who briefly described the method of taking them.—Dr. Hebb said they had received part vi. of Mr. Millett's "Report on the Foraminifera of the Malay Archipelago," which would be taken as read and published in the *Journal*.—Mr. F. Enock gave an extremely interesting account of his observations on the life-history and habits of British trap-door spiders, illustrating the subject with most excellent original lantern views.

MANCHESTER.

Literary and Philosophical Society, October 17.—Prof. Horace Lamb, F.R.S., President, in the chair.—The Secretary read the draft of the address which was recently presented by the Society to Sir G. G. Stokes, Bart., on the occasion of the jubilee of his tenure of the Lucasian Professorship of Mathematics at Cambridge University, and also the reply received thereto.—Prof. Dixon stated that the restoration of Dalton's tomb had been effected under the direction of the committee appointed, and that there remained a balance in hand of about 27*l*. It was hoped to raise this sum to 50*l*., and to form a vested fund which would provide for any future repairs that might be necessary.—The President announced that the Society had had presented to it another relic of Dalton, in the shape of his diploma of honorary membership of the Edinburgh Medical Society, to which he was elected in 1818.—Mr. Thomas Thorp read a paper on diffraction grating films and their application to colour photography, and exhibited an apparatus which showed photographs of objects in their natural colours by the aid of gratings, and without the use of pigments or dyes.—A paper entitled "On the electrical resistance between opposite sides of a quadrilateral, one diameter of which bisects the other at right angles," was read by Dr. Charles H. Lees.

NEW SOUTH WALES.

Royal Society, July 5.—Mr. W. M. Hamlet, President, in the chair.—Suggestions for depicting diagrammatically the character of seasons as regards rainfall, and especially that of drought, by H. Deane. The author called attention to the inadequacy of the ordinary methods of judging of the dryness or otherwise of seasons by using the totals of the rainfall and comparing them with the average. He explained that the proper way of exhibiting the character of any period is by showing diagrammatically the progressive dryness that takes place in the soil after rainfall ceases. This is marked by a descending line, and being from time to time more or less compensated for by falls of rain, these are indicated by rises. The only useful rain to the soil itself is what soaks in and tends to saturate it; all beyond this, although it may be useful for conservation and for keeping up the flow of rivers, is waste so far as the particular ground on which the rain has fallen is concerned. The diagrams exhibited show the effect of this "loss and compensation" system, and the dryness of the years and parts of years given in the series 1883 to 1898, inclusive, are rendered visible and measurable.—The initiation ceremonies of the aborigines of Port Stephens, New South Wales, by W. J. Enright.

August 2.—Mr. W. M. Hamlet, President, in the chair.—On the crystalline camphor of eucalyptus oil (eudesmol) and the natural formation of eucalyptol, by Mr. Henry G. Smith. In August 1897, the author, with Mr. R. T. Baker, announced the discovery of a crystalline camphor or stearoptene in eucalyptus oil. This substance was named *eudesmol*. The present paper deals with the chemistry of this camphor and its relation to eucalyptol. Eudesmol has been found in the oil of many species of eucalyptus, and should be present at certain times of the year in all those eucalyptus oils that are eventually rich in eucalyptol. Eudesmol has a formula $C_{10}H_{16}O$, is isomeric with ordinary camphor, but has the oxygen atom combined in a different manner. It does not appear to be ketonic, and it cannot be reduced by sodium in alcohol or by other methods. It is optically inactive. It forms a dinitro-compound and a dibromide, but does not form a nitrosochloride. It melts at 79–80° when perfectly pure, but has a tendency to form products having a lower melting point. On oxidation with dilute nitric acid, camphoronic acid is formed, but no camphoric acid. A large amount of evidence is brought forward to show eudesmol to be intermediate in the formation of eucalyptol, and that eucalyptol is derived directly from the fraction containing eudesmol if the oil be kept in the crude condition for some time under ascertained conditions. Oxygen is necessary to this alteration. It is shown that the oxygen atom enters the eucalyptol molecule during the formation of eudesmol, and that by the natural alteration of the high boiling fraction of oils containing eudesmol (*E. macrorhyncha*, for instance) eucalyptol is formed. The synthesis by Perkin and Thorpe (*Journ. Chem. Soc.*, 1897, 1169) shows camphoronic acid to be trimethyl tricarballylic acid, as was first suggested by Bredt, and as eucalyptol is derived from eudesmol, and eudesmol forms camphoronic acid, the question is raised whether Brühl's formula for eucalyptol is correct. It is suggested that the oxygen atom in eudesmol is quadrivalent, and that the peculiarity of eucalyptol may be thus accounted for. From the formula suggested for eudesmol camphoronic acid, as trimethyl tricarballylic acid, can be constructed.—Observations on the determination of the intensity of drought, by Mr. G. H. Knibbs. The paper was really a continuation of the subject of Mr. H. Deane's paper, read at a previous meeting. It was shown that if the degree of saturation of ground was taken as the reciprocal of the measure of drought intensity, as suggested by Mr. Deane, then, theoretically, it was determinable. The essential features of Mr. Deane's solution and of the nature of the problem were discussed.—Divisions of some aboriginal tribes, Queensland, by Mr. R. H. Matthews. A short paper dealing with the social organisation of some native tribes of Queensland.

PARIS.

Academy of Sciences, October 30.—M. van Tieghem in the chair.—Remarks on the volume, "Connaissance des Temps pour l'année 1902," by M. Poincaré. This work contains an important improvement as the result of a conference of directors of observatories in England, Germany, America and France. This year the work contains the mean positions of all the stars in Prof. Newcomb's catalogue, the apparent positions of which do not already appear in one of the four official publications.—On the intervention of plants in the formation of calcareous tufa, by M. de Lapparent. The author points out that the results published by M. Stanislas Meunier in the last number of the *Comptes rendus*, concerning the function of mosses and microscopic algæ in the formation of calcareous tufa, were discovered as far back as 1862 by M. Cohn.—On the Giacobini comet, by M. Perrotin. The elements of the comet have been calculated by M. Giacobini, from the observations made in various observatories. The form of the orbit is at present sensibly parabolic. At the time of its discovery the nebula surrounding the nucleus amounted to 1·5 minutes of arc; at the present time this is reduced to 1·0 minute. The nucleus appears to have increased in lustre, being now of about the eleventh magnitude.—Remarks by M. Fouqué on the alterations introduced by M. de Lapparent in the new edition of his "Treatise on Geology."—On the hyperabelian functions, by M. Georges Humbert.—On congruences of normals, by M. E. Goursat.—On the propagation of electric oscillations in dielectric media, by M. Albert Turpain. The author quotes the expressions of Maxwell and of Helmholtz and Duhem for the relations existing between the velocity of light, the velocities of propagation of the Hertzian waves in different media, and the dielectric constants of those media, and shows that the experiments of Arons and Rubens, Cohn and Zeeman, and of Blondlot do not clearly distinguish between the Maxwell and Helmholtz-Duhem hypotheses. The author describes an experiment which he believes to be free from ambiguity, the results of which are in accord with the views of Helmholtz and Duhem.—Transmission of Hertzian waves through liquids, by M. Édouard Branly. The receiver was placed in the centre of a large glass vessel containing the liquid under examination, and measurements were made of the distance to which the exciter had to be removed to produce no effect upon the receiver. Distilled water or spring water possesses a much greater absorptive power for the rays than oil or air, and the effect of sea water was so great that any thickness over 20 cm. was sufficient to completely absorb the radiations, its power of arresting the rays being greater, in fact, than the same thickness of cement.—On Wehnelt's electrolytic interrupter, by M. E. Rothé. The author describes a curious phenomenon produced by varying the resistance of the circuit. For any given interrupter with a fixed potential difference, there appears to be a limiting resistance, such that for all lower resistances a condition of rapidly varying current strength only is possible. For all higher resistances there may be either the same state of affairs, or a steady current, according to the manner in which the current is established.—On the atomic weight of boron, by M. Henri Gautier. Analyses of boron chloride and bromide lead to values for the atomic weight of boron of 11·01 and 11·02 respectively, single determinations varying between 10·98 and 11·04. The chloride and bromide were prepared from the halogen and boron, the latter being prepared by Moissan's method. The author considers that his products were free from dissolved hydrobromic or hydrochloric acids, and that the lower figures obtained by Abrahall (10·84) by the analysis of boron bromide, were due to traces of hydrobromic acid dissolved in the halogen compound.—On the mixed oxyhydrides of fatty and aromatic acids, by H. A. Béhal. The existence of the mixed anhydrides discovered by Gerhardt has been called in question by Rousset, but comparative experiments carried out by the author upon a mixture of benzoic anhydride and acetic anhydride and the mixed acetobenzoic anhydride prepared by Gerhardt's method show that the mixed anhydride really exists, although always containing a little benzoic anhydride as an impurity.—Naphthopurpurin, an oxidation product of naphthazarin, by M. Georges F. Joubert. The analogy between the behaviour of alizarin and naphthazarin is further shown by the ready oxidation of the latter by sulphuric acid and manganese peroxide to naphthopurpurin, or tri-oxy-naphthoquinone.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 9.

MATHEMATICAL SOCIETY, at 8.—Certain Correspondences between Spaces of *n* Dimensions: Dr. E. O Lovett.—On the Form of Lines of Force near a Point of Equilibrium; The Reduction of Conics and Quadrics to their Principal Axes by the Weierstrassian Method of reducing Quadratic Forms; and on the Reduction of a Linear Substitution to a Canonical Form; with some Applications to Linear Differential Equations and Quadratic Forms: T. J. I. Bromwich.—On Ampère's Equation $Rr+2Ss+Tt+U(rt-S^2)=V$: Prof. A. C. Dixon.—The Abstract Group isomorphic with the Symmetric Group on *k* Letters: Dr. L. E. Dickson.—The Fundamental Solutions of the Indeterminate Relation $\lambda x \geqq \mu y$: Major MacMahon, R.A., F.R.S.—Note on Clebsch's Second Method for the Integration of a Pfaffian Equation: J. Brill.

FRIDAY, NOVEMBER 10.

ROYAL ASTRONOMICAL SOCIETY, at 8.—*Papers received*: Observations of Mars, 1898–99: Rev. T. E. R. Phillips.—Observations of Jupiter and his Satellites at Mr. Crossley's Observatory, Bermerside, Halifax, 1898–99: J. Gledhill.—Observations of Nebulæ made at the Chamberlin Observatory, Denver: H. A. Howe.—(1) On the Probable Proper Motion of the Annular Nebula in Lyra; (2) The Exterior Nebulosities of the Pleiades; (3) Diameters of Ceres and Vesta: Prof. E. E. Barnard.—*Papers promised*: Theory of the Figure of the Earth carried to the Second Order of Small Quantities: Prof. G. H. Darwin.—Distribution of Stars Photographed at Oxford for the Astrographic Catalogue: F. A. Bellamy. Variation of Personal Equation with Stellar Magnitude: Prof. H. H. Turner.—Photographic Magnitudes: a Comparison of the Greenwich Astrographic Plates with the Magnitudes of the Bonn Durchmusterung: F. W. Dyson and H. P. Hollis.—Ephemeris for Physical Observations of Jupiter, 1899–1900: A. C. D. Crommelin.

PHYSICAL SOCIETY (Central Technical College, Exhibition Road, South Kensington), at 5.—Contact Electricity: F. S. Spiers.—On the Heat of Formation of Alloys: J. B. Tayler.

MALACOLOGICAL SOCIETY, at 8.—Additions to the List of Marine Shells of South Africa published in 1897, with Descriptions of Seventeen New Species: G. B. Sowerby.—Remarks on a Collection of Helicoid Hand-Shells from Japan and the Loo-Choo Islands: G. K. Gude.—*Metastracon*, a New Slug-like Genus of Dart-bearing Helicidæ: Henry A. Pilsbry.

MONDAY, NOVEMBER 13.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—Opening Address: The President.—Travels in Bokhara: Willy Rickmer Rickmers

TUESDAY, NOVEMBER 14.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Waterloo and City Railway: H. H. Dalrymple-Hay.—The Electrical Equipment of the Waterloo and City Railway: B. M. Jenkin.

MINERALOGICAL SOCIETY, at 8.—Florencite, a New Hydrated Phosphate of Aluminium and Cerium Earths from Brazil: Dr. Hussak and Mr. Prior.—On a New Mineral from Cornwall: Mr. Hutchinson.—Mineralogical Notes: Prof. Miers.—On Various Sulpharsenites of Lead from the Binnenthal: Mr. Solly; with Analyses by Mr. Jackson.—Crystallised Stannite from Bolivia: Mr. Prior and Mr. Spencer.—On the Constitution of the Mineral Arsenates and Phosphates. Part IV. Beudantite: Mr. Hartley.—Petrographical Notes on some Rock Specimens from the Little Island of Trinidad, South Atlantic: Mr. Prior.

WEDNESDAY, NOVEMBER 15.

SOCIETY OF ARTS, at 8.—Opening Address: Sir John Wolfe Barry, K.C.B., F.R.S.

ROYAL METEOROLOGICAL SOCIETY, at 7.30.—The Diurnal Variation of the Barometer in the British Isles: Richard H. Curtis.—Note on Earth Temperature Observations: G. J. Symons.

ROYAL MICROSCOPICAL SOCIETY, at 7.30.—Exhibition of Foraminifera: A. Earland.

ENTOMOLOGICAL SOCIETY, at 8.

THURSDAY, NOVEMBER 16.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: Note on the E.M.F. of the Organ Shock, and on the Electrical Resistance of the Organ in *Malapterurus electricus*: Prof. F. Gotch and G. J. Burch.—On the Formation of the Pelvic Plexus, with especial reference to the Nervus Collector in the genus Mustelus: R. C. Punnett.—On the Least Potential Difference required to produce Discharge through various Gases: Hon. R. J. Strutt.—On the Propagation of Earthquake Motion to Great Distances: R. D. Oldham.—An Experimental Research on some Standards of Light: J. E. Petavel.

LINNEAN SOCIETY, at 8.—The Comparative Anatomy of certain Species of *Encephalartos*, a Genus of the *Cycadaceae*: W. C. Worsdell.—On a Collection of *Brachyura* from Torres Straits: W. T. Calman.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.

CHEMICAL SOCIETY, at 8.—The Chlorine Derivatives of Pyridine. Part IV. Constitution of the Tetrachloropyridines: W. J. Sell and F. W. Dootson.—Contributions to our Knowledge of the Aconite Alkaloids. Part IV. On Japaconite and the Alkaloids of Japanese Aconite: Wyndham R. Dunstan, F.R.S., and H. M. Read.—On the Determination of Transition Temperatures: H. M. Dawson and P. Williams.

FRIDAY, NOVEMBER 17.

ANATOMICAL SOCIETY, at 4.—A Persistent Left Inferior Vena Cava: Stanley Boyd.—Specimen of Sacculated Œsophagus: Miss Stoney.—Child's Skull, showing Parietal Perforations: Prof. A. M. Paterson.—Note on the Morphology of the Biceps Flexor Cruris: Prof. B. C. Windle, F.R.S., and F. G. Parsons.—Lantern Demonstration of certain Points in the Lymphatic System of the Appendix: C. B. Lockwood.

THE CAMBRIDGE NATURAL HISTORY.

The Cambridge Natural History. "Insects. Part II." By David Sharp. Pp. xii + 626. (London: Macmillan and Co., Ltd., 1899.)

THE appearance of the concluding part of Dr. Sharp's treatise on Insects, after an interval of nearly four years since that of its predecessor, is most welcome to all readers who were led by the first part of this work to recognise what a step in advance had been taken in the treatment of the subject.

The present volume has confirmed the opinions we then expressed in these columns on Part i., and again we must record our admiration for the knowledge and industry of the author, and for the attractive manner in which he has set forth his results; for wherever the subject-matter allows, the whole work is most fascinating reading.

As was pointed out in 1896, the chief feature of this work is the extensive use made of modern researches, of a kind not hitherto found in text-books. So far as insect morphology is concerned, one or two other recent works may challenge comparison with the present one, but we know of none that attempts to bring forward so large a bulk of unfamiliar particulars, which in a "natural history" are appropriately of the first importance, about the habits and life-histories of insects. But such topics take space, and a complete history of insects on this large scale can only be condensed, even into the 1100 or more pages of this treatise, either by general compression or by the selection of topics for detailed treatment, to the exclusion, so far as practicable, of others. Dr. Sharp has preferred the latter plan, and has been remarkably concise in dealing with such parts of his subject as are familiar from other accessible text-books, which this work may be said rather to supplement than to supersede.

The treatment of certain portions, particularly of Coleoptera and Lepidoptera, will perhaps come as a disappointment to those students who do not bear in mind the limitations of space that have hampered the author. Preconceived notions of the relative importance of insect-families are not easily got rid of, and it is something of a shock to find, *e.g.*, the Cerambycidæ dismissed with less than four, or the Tineidæ with three pages. It would have been an advantage if the editors could have seen their way to devote still more space to the subject, perhaps by restricting Vol. v. to the insects alone. The association with the Prototracheata and Myriapods, if zoologically orthodox, is not of much practical value.

We think, too, that the omission of certain obscure families, except for a bare mention of their existence, would have been a gain. However much symmetry may require a notice of each of the many families of insects (Dr. Sharp enumerates eighty-five in the Coleoptera alone), such notice is not worth giving unless it can be adequately done, and the accounts, for example, of the Rutelinæ, Ægialitidæ, or Apioceridæ, to select at random, serve no clearly useful purpose.

The present volume deals with the Tubuliferous and Aculeate Hymenoptera, the Coleoptera, Lepidoptera, Diptera, Thysanoptera and Hemiptera. The Aphaniptera are treated as a sub-order of Diptera, and the Strepsiptera and Anoplura are included provisionally with Coleoptera and Hemiptera respectively.

Of these orders, the Hymenoptera, which lend themselves admirably to treatment from a bionomical standpoint, are dealt with in great fulness, the observations of M. Fabre on habits being in particular constantly referred to at length. No less than fifty-three pages are devoted to the ants alone, and, among much that is interesting, attention may be called to the accounts of the Dorylides, of the associations of ants with other insects (chiefly based on Father Wasmann's work, and again dealt with under Coleoptera), and to Mr. Green's drawing, on p. 147, of a worker of *Oecophylla smaragdina* using a larva of the species as a kind of animated gum-bottle for joining together the edges of leaves.

In proportion to their numbers, Coleoptera are the least interesting of insects. Their life-histories are very little known, and with the exception of the singular parasitism and hypermetamorphosis found in the Cantharidæ and their allies, are singularly devoid of noticeable peculiarities. It is not surprising, therefore, that even Dr. Sharp's intimate knowledge of the Order has not prevented him from being "gravelled for lack of matter,' and that this chapter, overweighted as it is with many families, is among the least readable in the work. With the removal of Gyrinidæ from the Hydradephaga, few entomologists will be disposed to disagree; but the grouping of the Clavicorn and Serricorn series of Coleoptera into a single aggregate, to be called Polymorpha, is of questionable value. The new series is admittedly incapable of definition, except by the fact that its components do not belong elsewhere; and to associate into a single congeries of forms such widely different families as, for example, the Staphylinidæ and Buprestidæ, is to abandon classification, so far as a fourth of the Order is concerned.

Dr. Sharp pays a good deal of attention to stridulating organs throughout his work, and describes and figures (we imagine, for the first time) a remarkable modification of the hind legs of Passalid larvæ into paws which scratch a stridulating plate on the middle coxæ. It is hard to imagine why a larva that lives in rotten wood should desire to stridulate, but the practice appears to be common among the Lamellicorns. He does not refer to, and perhaps is not acquainted with, the remarkable asymmetrical structure, probably a sound-producing organ, which Ribaga has described in the abdomen of the bed-bug.

Great advances have been made in recent years in the study of Lepidoptera, chiefly with a view to obtaining sound classificatory points; and the chapter on these insects is noteworthy for the completeness with which it deals with lepidopterous structure and development, especially of the mouth parts (in connection with which attention may be called to the figure illustrating the pupal mandibles of *Micropteryx*, first described by Dr. Chapman in 1883) and of the wings, wing-scales, and coloration. An interesting sense organ of unknown function in the abdomen of *Chrysiridia* is here described for the first time. More might have been said with advantage on Dr. Chapman's researches on lepidopterous pupæ, for, though several times alluded to in the text, no description of them is given. Although incomplete, they have given a great impetus to the study of lepidopterous relationships, and it is not every reader that has time or opportunity for turning them up in the *Transactions* where they appeared.

The system followed in the Heterocera is that given in Sir George Hampson's "Fauna of British India—Moths," but it has the manifest disadvantage that it does not include two or three of the families referred to. On p. 432 the Prodoxidæ are called a family, though they are clearly intended to be included in the family Tineidæ. The use of the same term and ending for an aggregate and its subdivision tends to confusion.

Mention of the Lepidoptera leads naturally to the subject of mimicry. So far as facts are concerned, Dr. Sharp brings forward many interesting examples, among them an unrecorded case of the larva of a British bug, *Nabis lativentris*, which mimics an ant, the resemblance being absent in the imago. On the other hand, no reference is made to some of the astounding and comparatively little known resemblances found among Membracidæ. In a species allied to one, *Heteronotus trinodosus*, which is figured, the prothoracic prolongation takes on the form of the entire body of a Hymenopterous insect, so that the Membracid walks about under a mask, or rather, a false body, of the most deceptive kind.

Dr. Sharp is, however, averse from countenancing any theory of the subject, and his brief account of existing hypotheses is scarcely impartial. In a singular criticism he writes:

"In endeavouring to realise the steps of the process of the development of the resemblance we meet with the difficulty that the amount of resemblance to the model that is assumed to be efficient at one step of the development, and to bring safety, is at the next step supposed to be inefficient and to involve destruction."

This appears either to involve a non-comprehension or to imply a complete negation of the principles of natural selection; we do not know whether the latter is intended.

Of the remaining chapters, that on Diptera is of especial value, on account, not so much of their intrinsic interest, great as that is when once the repugnance to their study has been overcome, as of the help it gives towards obtaining a fair general knowledge of an Order which does not form as a whole the subject of popular monographs, and of which the study is particularly difficult.

In view of the economic importance of Diptera, it is greatly to be regretted that they do not absorb more of the entomological energy that is wasted in investigating trifles that lead to nothing. With Dr. Sharp's account, it is possible at least to make a start.

Economic questions, which would have led the author outside the scope of this work, are seldom referred to. With this necessary exception, it is difficult to find a subject of any importance in entomology that is not, in some place or other, touched on more or less fully, and often in the light of independent observation and research. Very few forms of real interest are omitted; but among them is that of *Dyscritina*, on the life-history of which Mr. E. E. Green has lately thrown light. Though his paper was published since the appearance of Vol. v. of this series, reference might have been made in the short appendix to the present volume to his account of this Forficulid larva, which so singularly modifies our knowledge of the earwigs.

We do not recollect to have before met with the word "exstulpate," which Dr. Sharp is rather fond of using to denote the extruding of an eversible papilla. If it is a latinised form of the German "ausstülpen," it can hardly be considered as an ornament to the English language!

It remains to allude to the illustrations; these are as good as, though relatively fewer than, those in the preceding volume. The figures of *Ornithoptera paradisea*, one of the few butterflies selected for figuring, are not successful. Exquisite as this insect, at least the male, is, it does not look well in a woodcut, and these large blocks look coarse and inappropriate on so small a page.

W. F. H. BLANDFORD.

A COMPREHENSIVE GEOGRAPHY.

The International Geography. By Seventy Authors. Edited by Hugh Robert Mill, D.Sc. Pp. xx + 1098. With 488 illustrations. (London: George Newnes, Ltd., 1899.)

SOME forty years ago geography was the most dreary of subjects in school lessons. Its text-books were as arid as the Sahara, lists of names and compilations of statistics; mere cram, without a single statement or principle which could help the learner to understand the history either of the earth or its inhabitants; useful as exercise for the memory, but baneful in every other respect. All that has been changed. Geography is now taught as illustrative of principles. Like geology, it is an application of a group of the natural sciences to explain a particular problem, the history of the earth; differing however, from that in dwelling more on the superficial aspect—the physiography—of our globe, and less on underlying causes or on the remote past. The volume before us is an example of the new method. Though too large for direct use as a text-book in schools, for it consists in all of over 1100 pages of rather closely-printed type (which ageing eyes will wish thicker), it will filter down to the classes through the teachers. The first part of the work deals with the principles of geography, the more distinctly scientific aspect of the subject, in a series of excellent essays, which treat of the principles and progress of geography, its relation to mathematics, the making of maps, the plan of the earth and the features of its surface, the ocean, atmosphere and climate, the distribution of life, including the races of man, and the political aspect of geography; all these subjects being discussed by very high authorities. Each of the following parts is devoted to one of the great divisions of the earth, treating it first as a whole, and then under its minor natural or political divisions, in a series of separate articles, each of which is contributed by "a specialist or recognised authority of high standing."

To review critically such a book as this demands something like geographical omniscience, to which I have no pretensions; probably the editor himself is about the only really competent person, and he might be not unnaturally suspected of a certain prejudice. So I have tried to look at a few sections from the point of view of personal knowledge, and others from that of ignorance; for in the one case I might test the information, in the other regard the book as a learner. For the former purpose I have read in a carping spirit. Not that I hold it right to do this with a really good book. Horace lays down the true rule, "Ubi plura nitent in carmine non ego paucis offendar maculis"; but I did it, and now give the results to show that the book will stand a test which is almost unjust. A short glossary of rock names and some other geological terms would be a useful addition for the sake of the unlearned. In the course of my reading I have found one misprint, "Apls" for Alps, which is very likely due to that familiar of the printer who should be out of place in a chapel. Editors are not always responsible for press errors. However, here they must be few indeed. In mentioning Suess' idea that sometimes it is rather the ocean which has sunk than the land which has risen, a writer says that the 100-foot beach-line in Western Scotland

"maintains its level, lying on rocks of different ages and hardness, and crosses undisturbed great faults and dislocations."

But if the antiquity of the faults, as is the case here, is much greater than that of the beaches, the last reason is not conclusive, for the mass might be so far welded together as to move as a whole But is the fact itself certain? If it be so, it does away with an objection commonly urged against the marine origin of the parallel roads of Glenroy. At any rate it should have been added that in Norway, not to mention other parts of the northern hemisphere, a beach level often varies in height. Perhaps, also, a little too much prominence is given to the theory of the earth's tetrahedral figure, for it is still on its trial, and apparently fails, as the author admits, to explain every fact. On p. 57 boulder clay is said to be an accumulation left by ice-sheets or in extra-glacial lakes. As not a few persons who have carefully studied the subject maintain that some boulder clay has been deposited in the sea, and have added proofs which have been met only by hypotheses, that view also should have been mentioned as a third possibility. In another aspect of ice-work, one author (p. 258) boldly abandons glacial excavation to account for the origin of the Alpine lakes, and attributes them, rightly as I believe, to crust movements; yet we are told on p. 272 that the lakes of the Alpine foreland are clearly related to the great ice-sheet which once overspread it. We presume this signifies glacial excavation; but, if so, what about the "hinter land"? Again, has it yet been *proved* (see p. 269) that the Scandinavian ice-sheet extended over northern Germany? It is, no doubt, an article of faith with a large school; but as difficulties suggest themselves to a sceptical mind after examining the ground, a less positive statement would have been better. As regards the Alps, it is not a happy phrase to speak of the Finster Aarhorn, Jungfrau, Möneh, Wetterhorn, &c., as

"grouped in one compact mass of snows and rugged peaks *round* the valleys of Lautebrunnen and Grindelwald";

for nothing can be more striking than the apparent ending, of those valleys at the foot of that great mountain wall. We find no mention of the Viso among the Italian Alps, yet no peak is more conspicuous than it from the Piedmontese plain; and the fact that the south-eastern Alps near the Austro-Italian frontier—so remarkable in their scenery—are magnesian limestone is not clearly stated.

The Pelvoux (p. 237) is not over 13,000 feet high, for only two peaks in the Dauphine group, the Ecrins and the Meije, exceed that elevation. To say that "since historic times not the slightest eruption has taken place in Auvergne" assumes a controverted point. In Italy the remarkable group of the Carrara mountains is not distinguished so clearly as it should be from the rest of the Appennines, and to say that Pozzuoli "stands in the midst of vast ruins of the Roman period" is not quite the most accurate of phrases.

Enough however of such criticisms, for they are so trivial as to be hardly worth mention. We only write them down to show how difficult, even if one tries to carp, it is to find any fault. When we come to excellencies their name is legion. With seventy contributors, all of whom have done their work well, it is almost invidious to select, but we may mention Prof. De Lapparent's article on the physical geography of France as no less lucid in statement than powerful in grasp, and those on Natal, the Transvaal and the Orange Free State, by the Right Hon. J. Bryce (which we naturally selected to look at from the standpoint of general ignorance), as singularly clear and informing. The book must have cost Dr. Mill no little toil as editor. Organisation and correspondence in a work like this must have been heavy tasks; and besides these he has himself contributed some excellent articles, and translated wholly or partially those of seventeen contributors. We heartily congratulate him on the final result. He deserves our gratitude for giving us a geography which is at once good in literary form and invaluable for reference, far in advance of any similar work which has been produced in this country. No teacher, indeed no advanced student, can afford to be without it; more than this, it must be on the shelves of every important library, and will be of the greatest use to literary as well as to scientific men, indeed to all who read for the love of culture. T. G. BONNEY.

CHEMISTRY FOR THE PEOPLE.

Einführung in die Chimie in leichtfasslicher Form. Von Prof. Dr. Lassar-Cohn. Pp. xi + 299. (Hamburg and Liepzig: Leopold Voss, 1899.)

THIS book begins with an interesting *apologia.* When the author first took up the work of teaching in Volkshochschulen he lectured to the pupils very much in the same way that he himself had been lectured to in the University during his first semester. He soon came to think, however, that this was a mistake, and that a class of people, meeting in the evening hours for the improvement of their general knowledge, should not be treated like students taking up a professional study. He therefore altered the form of his lectures, and endeavoured to present a more general and expansive view of chemistry, and to impart, as it were, the spirit and stimulus of the science. In like manner he came to the conclusion that ordinary chemical text-books are unsuitable for the pupils of Volkshochschulen, and the present work has been written to fill the void. The case which Prof. Lassar-Cohn endeavours to meet is a somewhat special one. Given an evening class of young men desirous of improving their general education, which is the best way of giving them some notion of chemistry? Prof. Lassar-Cohn answers this question by saying that as a laboratory is a luxury which a Volkshochschule cannot afford, you must content yourself with experimental lectures and present the subject in its broadest and most interesting aspect.

Here again, it would seem, the prejudice of University training makes itself felt, in the notion that a laboratory suitable for teaching the elements of chemistry is necessarily the large and expensively furnished apartment set apart in universities for the professional study of chemistry. This is indeed a common enough belief, one that has led in this country to great extravagance and much futile teaching. It is impossible to believe that Germany would make difficulties about providing the Volkshochschulen with all that is really requisite for teaching, by practical work, the amount of elementary physics and chemistry which should be there attempted. Until this is done, until a properly coordinated course of work in the laboratory and class-room can be arranged, really profitable *teaching* will, in the opinion of the present writer, be impossible.

Whether or not we accept the author's standpoint that lectures are inevitable, we must admit they may be made to open out new vistas of knowledge and supply a stimulus to study, and we cannot hesitate to praise the book before us. Dr. Lassar-Cohn possesses in a high degree the faculty of exposition; he writes in a style which, for force, clearness, and above all, freedom from prolixity, is uncommon enough in German text-books. The matter of the book, too, fully corresponds with the author's intention. It is comprehensive without being encyclopædic, and is supplied with a good deal of human interest. The historical element is not introduced to any great extent, not as much, in fact, as it might well be in such a book. Hardly a great name in the roll of chemists is mentioned, except that of Kekulé. The book begins much in the orthodox way, with an attempt to delimit the frontier between chemistry and physics, and quickly and discreetly passes on to water and hydrogen. After this come the halogens and the hydracids, followed by lucid explanation of the laws of chemical combination and the atomic and molecular theories. The other chief non-metals and their compounds are passed in review, and then half a dozen of the metals are dealt with. Here and there chapters appear dealing with special topics, such as the building up of plants from inorganic substances, the preparation of metals by electrolysis, the classification of the elements. The treatment of these topics is excellent. The author has a lightness of touch which is very agreeable, and very different from the heavy hand of the compiler. This is particularly evident in the treatment of organic chemistry, which is admirably reviewed in some forty pages, and throughout the work there is indeed a pleasant sense of freshness. To those who wish to gain a general idea of the scope of modern chemistry, and who cannot obtain class instruction, this book may be strongly recommended. It has not the popular interest of the author's "Chemistry in Daily Life"; but it has a different object, the aim being to show the philosophy rather than the practical usefulness of the science. It is probable that there is a considerable public to whom the book will be a really valuable acquisition, and with whom it will fulfil its aim of being an introduction to chemistry "in leichtfasslicher Form."

The illustrations, which are fairly numerous, call for a word of criticism. They are exceedingly crude, over-shaded, and often purposeless. The first figure in the book, for example, is an ill-drawn dinner-bell, which is to illustrate the statement that a bell when sounded remains unchanged in substance, and that therefore the science of sound belongs to physics!

In a brief postscript Dr. Lassar-Cohn enters a vigorous protest against the recent decision of the German Chemical Society to tabulate the atomic weights on the basis of $O=16$. He maintains that, to the beginner, it will be quite unintelligible why the lightest atom should have a weight of 1·01—chemical teaching, in fact, will sink back to a half-alchemistic stage if the system of atomic weights, which lies at the foundation of the whole science, is to be a matter for belief rather than for logical reasoning. There seems to be some exaggeration here. Whatever may be said in favour of oxygen being taken as 16 or 15·88, it is surely not a very difficult matter to explain, even to beginners, the practical reasons why *for the time being* 16 has been selected. It may indeed be an advantage if pupils are thereby forced to realise a little more fully than has been usual how atomic weights actually are determined. It must be admitted, however, that the question of $O=16$ *versus* $H=1$ is well worth consideration from the point of view of the chemical teacher.

A. S.

OUR BOOK SHELF.

Laboratory Manual. Experiments to illustrate the Principles of Chemistry. By H. W. Hillyer, Ph.D. Pp. 200. (New York: The Macmillan Company. London: Macmillan and Co., Ltd.)

THIS book is intended as an introduction to chemistry for college students, and is written on the newer (or, as we have heard it termed, the new-fangled) plan. In other words, the student is asked to record what he finds in his experiments, and not told what he should find. The success of this newer method, as of the older one, must depend on much besides the text-book; but if it be assumed that the student is anxious to learn and willing to take trouble, there can be little doubt where the advantage lies.

In addressing the student, the author remarks that "the mere bringing of chemical substances into conditions under which they will react has less utility as a means of culture than most of the manual occupations"—a just if a somewhat "superior" observation—and he proceeds to give general directions which, if only observed, will leave nothing to be desired in the student's attitude of mind. Experience shows, alas! how very difficult it is to get these injunctions observed.

To illustrate the author's method, the following may be cited. "Heat a few pieces of zinc with a strong solution of sodium hydroxide. What gas escapes? What is there in the solution? From your previous experience, what acids will dissolve zinc?" Or again, "To 1 c.c. of silver nitrate solution add a little ammonium chloride solution, and then a solution of some of the salt made above [sodium thiosulphate]. Describe the phenomena, and explain, using equations."

It is obvious that each of these experiments opens up a large subject, and will necessitate reference to a descriptive text-book, and probably to a demonstrator as well. This is, of course, eminently desirable, and there can be little doubt that Dr. Hillyer's book, if properly used, will prove a helpful laboratory manual. It ranges over inorganic chemistry, and the selection of experiments has been carefully directed to bring out the most important facts and principles.

L'Industrie des Matières Colorantes Azoïques. Par George F. Jaubert. Pp. 167. (Paris: Gauthier-Villars.)

IT is over forty years since the late Dr. Peter Griess placed at the disposal of chemists a reaction which has since proved of such importance, both scientifically and technically, that a large literature is now in existence dealing with the class of compounds known as azo- and diazo-compounds. From the industrial side, the most important development has been the manufacture of a group of colouring-matters which are now turned out on a colossal scale, and which are so numerous in individual members, that in the last edition of the "Tabellarische Übersicht" of Schultz and Julius (1897) no less than two hundred and seventy-three distinct technical products of this class were catalogued. The present little work is one of the useful "Aide-Mémoire" series from the "Encyclopédie Scientifique," published under the direction of M. Léauté of the Institute. It is fairly brought down to date, and contains in a handy and portable form a tabular list of the colouring-matters in question, including also the nitro- and azoxy-compounds which find place in technology. The little volume will be found valuable by all engaged in this department of chemical industry.

R. M.

Elementary Practical Mathematics. By Frank Castle, M.I.M.E. Pp. x + 401. (London: Macmillan and Co., Ltd., 1899.)

IN this book the student is carried rapidly through a course of arithmetic, algebra, geometry and trigonometry to some of the simpler problems of mensuration and dynamics. The idea is to bring the desk and paper work of the pupil into closer touch than heretofore with the work of the shop or factory—in other words, to indicate from the very beginning the practical value of mathematical methods.

The purely academic theorem or problem is to be "taboo," or, in the words of the preface, "abstract reasoning is to be relegated to the background, and concrete facts are to form the basis of the student's work." The principle is probably a sound one, but it may be carried too far; and experience alone will decide as to the efficiency of the system embodied in Mr. Castle's book. The student, if not otherwise instructed, will find certain parts very hard to follow. Thus on p. 341, in the discussion on maxima and minima, a differential coefficient is suddenly introduced without a word of explanation or apology. The great brevity, which the limits of the book impose on many of the sections, will also be a serious barrier to their ready intelligibility. As a general rule, the explanations and descriptions are clear and accurate; but we have noticed two statements which, if not absolutely incorrect, are, at any rate, misleading. On p. 23 we read that "the invariable interval of time between two consecutive southings of a star is divided into 24 equal parts, each called an hour." True, but this is not the hour as usually understood and *practically* used; yet there is nothing in the context to indicate the distinction between the sidereal and mean solar hour. The other doubtful statement is on p. 290, where we read: "Any change in the direction or speed of a moving body is produced by force. When a force acts in either of these ways it is said to do work." The "direction of a moving body" is a curious truncated phrase; but the implication that a force always does work when it alters the direction of motion of a moving body is still more curious. Here truly are sinks of waste of solar energy that were never dreamed of in the philosophy of Helmholtz and Kelvin! These blemishes apart, however, there is much to commend in the book. Contracted arithmetical operations are strongly insisted upon. The chapters on logarithms, the slide-rule, orthographic projection and graphical methods, are particularly deserving of praise. The book is beautifully printed, the illustrations are clear and well conceived, and the examples —both in the text and in the exercises—are all of a distinctly practical character.

The New Education. Manual Training: Woodwork. By Richard Wake. Pp. viii + 360. (London: Chapman and Hall, Ltd., 1899.)

MANUAL training, or instruction in the use of tools, may be made of great educational value if care is taken to develop the rational and constructive faculties rather than to produce dexterity in tool manipulation. The author of this volume deals with the subject upon the right lines, and the course described by him will encourage pupils to measure accurately, observe minutely, and work with close attention to details—all of which are desirable attributes to cultivate. A special feature of the course is the effort made to develop the creative faculty in children by inducing them to design for themselves the simple models to be constructed in wood. No attempt is made to describe woodwork of the ornamental character which is often seen in school workshops; each exercise has a purpose, and that purpose is to educate.

The book covers the requirements in manual training for Standards V., VI. and VII. of public elementary schools. It is well illustrated with working drawings and reproductions from photographs showing pupils performing the various operations of woodwork. Teachers of the subject will find the volume helpful and suggestive.

The Naval Pioneers of Australia. By Louis Becke and Walter Jeffery. With illustrations. Pp. xii + 314. (London: John Murray, 1899.)

THIS is a pleasant and accurate compilation for popular reading, based largely on the authoritative documents now being published by the Government of New South Wales. It is, in fact, a short history of the connection of the British navy with Australia. The standpoint is that of political rather than natural history; but many references are made to the large interest taken by Sir Joseph Banks in the beginnings of Australian colonisation. The problems of the first discovery of Australia are scarcely touched on, and the book is in no sense concerned with controversial questions.

Arithmetical Exercises in Chemistry. By Leonard Dobbin, Ph.D. Third Edition. Pp. vi + 52. (Edinburgh: James Thin, 1899.)

PROF. CRUM BROWN, who contributes a preface to this book, points out that it contains clear descriptions of "the principles involved in the calculations required in dealing with chemical changes, and such physical changes as are of special importance to junior students of chemistry." The exercises should be of value in fixing ideas in the minds of students and illustrating the operations of arithmetical chemistry. The ability to make such simple calculations as are here given is essential to a clear understanding of the laws of chemistry.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Coccospheres and Rhabdospheres.

I RECENTLY learned with much surprise from Sir John Murray that the German *Valdivia* expedition failed to discover anywhere in the ocean either Coccospheres or Rhabdospheres. Since the earlier Plankton expedition under Prof. Hensen had also failed to find any of these organisms, a certain amount of doubt has been privately expressed in Germany and elsewhere as to the validity of the results obtained by Mr. V. H. Blackman and myself.

In addition to our Atlantic work (published in *Phil. Trans.*, 1898) on this subject, I may state that, through the agency of Captains Cowie, Leigh and Wright, of the P. and O. Company, we have obtained these organisms from the Indian Ocean.

I have, however, received most welcome confirmation from Mrs. Weber van Bosse, who is with her distinguished husband on board H.M. *Siboga* engaged in the Dutch expedition in Malayan waters. She writes :—"Will you kindly insert a little note in a paper to state that the *Siboga* expedition found *Coccosphaera pelagica* and *C. leptopora* both in the Ceram and Banda Seas? We get them floating in the water with the horizontal cylinder of Hensen. . . . I found also Rhabdoliths, but as yet no Rhabdospheres. I am looking out for them," &c.

November 10. GEORGE MURRAY.

The Stockholm Fisheries Conference.

As the British Government was represented by official delegates at the recent International Fisheries Conference at Stockholm, and took part in its proceedings presumably with the view of undertaking fishery investigations upon a more extended scale in the future than it has previously done, the resolutions of the Conference (see p. 34) are of more than usual interest and importance to marine biologists in this country. For this reason I would ask you to allow me space for some remarks upon them.

The general plan of the investigations proposed by the Conference, both as regards hydrographical and biological work, will, I believe, meet with the approval of all competent judges, though doubtless minor differences of opinion as to details will be found. The researches suggested are a continuation, upon a more extended scale, of those which the various bodies undertaking fishery investigations in this country have been endeavouring to carry out in so far as the limited means at their disposal have permitted, and there can be no doubt that only by the prosecution of such investigations can that accurate knowledge be acquired upon which a rational treatment of fishery questions may be based.

Two points only relating to the schemes of investigation proposed by the Conference call for comment. In the first place, with regard to the value of international co-operation in such investigations it may be pointed out that, in case the scheme should not be carried out in its entirety, such co-operation is of greater importance in the hydrographical than in the biological work, since in the former simultaneous observations made by identical methods over great areas are of primary importance, a condition which does not apply to an equal extent to the latter. This, however, does not affect what is, perhaps, the chief argument in favour of international co-operation, and one which is given a prominent place in the preamble to the resolutions of the Conference, namely, that any attempt to regulate the fisheries of the high seas can only be carried out by international agreement. Whether or not any such international agreement can be regarded as reasonably probable, or whether, if attained, the regulation could be made effective, are certainly questions open to doubt.

In the second place, from the point of view of British fisheries as a whole, the area proposed by the Conference to be covered by the hydrographical investigations should be extended to include the English Channel, the Irish Sea and the western coasts of the British Isles. Even in considering the North Sea fisheries alone such an extension is of importance, since it has been clearly demonstrated that water from the Channel enters the southern part of the North Sea from time to time, and the fauna of this region is known to contain a considerable number of southern forms, which show it to be in reality an extension of the Channel fauna.

In attempting to give effect to the recommendations of the Stockholm Conference, what appears to be the most satisfactory course for the British Government to pursue is to develop and as far as possible coordinate the work of the various organisations already in existence, namely, the Marine Biological Association (either as at present constituted, or with a more intimate connection with the Fisheries Department of the Board of Trade), the Scientific Department of the Scottish Fishery Board, and the Fishery Department of the Royal Dublin Society, at the same time encouraging the formation of local laboratories established by County Councils and other bodies at various points around the coast, such as those of Liverpool (at Port Erin), Piel, Cullercoats and Millport.

For the actual carrying out of the proposed investigations the two essential requirements are (1) a sufficient number of capable naturalists devoting their whole energies to the work, and (2) sea-going steamships efficiently equipped. The various laboratories around the coast would form valuable ports of call or depôts for the vessels engaged in the investigations. The elaborate and expensive organisation of a central bureau and of a central laboratory proposed by the Stockholm Conference appears to me to be a matter of only secondary importance, against which some objections may be made. To coordinate the investigations of the different countries, and to insure such uniformity of method as will make the results of the different observers comparable, an international Council, composed chiefly of the experts actually responsible for carrying out the investigations, and meeting once a year, seems an adequate arrangement.

With an elaborate organisation such as that suggested by the Conference there is a danger that the work of the biological stations would degenerate into the mere taking and recording of routine observations, whilst original work and the development of new methods of research, which are in reality of far greater importance, would receive a check. Good men would certainly not be attracted to work which consisted merely in recording observations taken according to a stereotyped plan dictated by a central bureau. A large amount of individual freedom to the workers is absolutely essential in order to secure the best results from scientific research. For these reasons a more elastic organisation than that of the international central bureau proposed by the Stockholm Conference would seem to be preferable.

The Laboratory, Plymouth. E. J. ALLEN.

Sextant-Telescopes.

I RECENTLY made the attempt to attach one of the prism forms of binocular to a sextant in place of the ordinary telescope, and it seemed that such an adaptation would materially increase the usefulness of the instrument and add to the accuracy of its records. In the sextant which I used there was no provision for rigorous attachment. and only a device of a temporary character could be adopted; but a very slight modification in the construction of the instrument or of the so-called "up and down piece" would overcome this drawback.

I am inclined to believe that very frequently only a plain sight is used in observations at sea, and that in many cases, where some optical power is employed, an ordinary Galilean opera-glass, with a power of about three, is preferred. The telescope usually supplied, which will give a power of from ten to fourteen, has so many drawbacks that its use is not popular, at least in the Mercantile Marine. The field is small, the telescope inverts, and the sextant is obliged to be held at a considerable distance from the body, so that if the framework be not made of aluminium it becomes heavy and burdensome.

The prism opera-glass which I used was made by Messrs. Goerz, of Holborn Circus, and among other advantages over the ordinary form, it gave more light in the field of view, of obvious importance in judging of the position of a dimly illuminated horizon. Also there was a direct view, so that the ordinary methods of observing needed no modification, and the field was sufficiently large to enable the object to be followed with ease. The power was about nine, quite as high probably as could be used on the deck of a ship with advantage; but I imagine it would be preferable in surveying work to use the highest power constructed, which gives a magnification of twelve. Possibly fifteen might be reached with advantage.

Liverpool Observatory. W. E. PLUMMER.

Solution of the Quartic.

PERHAPS the following semi-graphic solution of a quartic equation may be of some interest to your readers.

Suppose the parabola $x^2 - y = 0$ is drawn, once for all, on a sheet of squared paper. Take an equal parabola, and place it with its vertex at the point (a, b) and axis parallel to OX so that its equation, in this position, is

$$(y - a)^2 = x - b.$$

Then the abscissæ of the intersections of the parabolas are the real roots of

$$x^4 - 2ax^2 - x + (a^2 + b) = 0 \quad . \ . \ . \ . \ . \ (1)$$

Now the general quartic is at once reducible to the form

$$x^4 + px^2 + qx + r = 0,$$

and if we put

$$x = -z\sqrt[3]{q},$$

this becomes

$$z^4 + \frac{p}{q^{\frac{2}{3}}}z^2 - z + \frac{r}{q^{\frac{4}{3}}} = 0.$$

This is identical with (1) if

$$a = -\frac{p}{2q^{\frac{2}{3}}},\ b = \frac{4r - p^2}{4q^{\frac{4}{3}}};$$

so we can calculate a, b, then place the movable parabola in position, read off the real values of z, and finally take

$$x = -z\sqrt[3]{q}.$$

Rural Education.

I AM very glad to learn from my friend, Prof. Meldola, that the school of which I previously wrote is so well known. The frequent reference to Bigods as an experiment, and as the first attempt to give a systematic training in science in a purely rural district, led me to imagine that people were not generally aware of Sexey's Trade School. It seemed therefore that some mention of its success might act as an encouragement to others, but obviously the fact that this work has been successfully carried on for some years in Somersetshire in no way detracts from the value of what is now being done in Essex. I may observe too that, while the latter has had to depend mainly upon the generosity of Lady Warwick and the enthusiasm of Prof. Meldola, the former enjoyed certain advantages in the way of endowment.

At Bruton the outlay in capital has amounted to 5140*l.* (cost of site 640*l.*, buildings and equipment 4500*l.*). This sum is made up of grants from the County Council amounting altogether to 1100*l.*, and of 4040*l.* derived from endowment, income account and donations. The County Council Building grants were thus distributed: in 1891 250*l.* for building and equipment, in 1892 450*l.* for a similar purpose, in 1894 250*l.* for new class-rooms and metal work, in 1897 150*l.* for a new physical laboratory, &c.; in all 1100*l.* Nothing under this head has been contributed by the Science and Art Department. Since 1893 a capitation grant of 2*l.* for day scholars and 3*l.* for boarders has been paid by the County Council to all approved schools in Somersetshire. At Sexey's Trade School this amounts to about 225*l.* a year. These grants go towards the salaries of science and technical teachers, and the school is open to inspection by the County Director of Technical Education. The total annual income of the school is about 1200*l.* Since 1894, pupils from the school have obtained 21 out of 36 County Intermediate Scholarships, and 5 out of 11 Senior Scholarships.

The school was opened with fifty pupils in temporary premises in April 1891. At Easter 1892 the new buildings were opened with sixty pupils. The cost of the buildings so far was nearly 3000*l.*, towards which, as stated above, the County Council contributed 700*l.* and the Governors subscribed 120*l.* Some of the classes were registered in connection with the Science and Art Department in the autumn of 1892, and the first examinations were held in May 1893. The school buildings were enlarged in 1897, when two new class-rooms, a metal workshop and gymnasium were erected. In 1895 the new regulations of the Science and Art Department for organised science schools were issued. The school appears to have been working for three years on similar lines to those laid down by the Department, and I am told that the conversion of the school into an "organised science school" was accomplished with practically no change of curriculum or method. The first grant of 260*l.* under the new regulations was received in 1896. Since then the grant has been very high, almost maximum grants for chemistry and physics having been awarded. The grant this year was 385*l.* and the number of pupils presented was fifty-seven. The grants from the Department have been as follows:—1893, 57*l.*; 1894, 104*l.*; 1895, 96*l.*; 1896, 260*l.*; 1897, 384*l.*; 1898, 355*l.*; 1899, 385*l.* To comply with the requirements of the Department, a new physical laboratory and other buildings were provided in 1897, and this year a new museum and additions to the master's residence are being undertaken at a cost of nearly 400*l.*

I regret that I can furnish no information as to the constitution of the Technical Instruction Committee of the Somersetshire County Council, but doubtless these particulars can be ascertained from its annual report. JOHN C. MEDD.

Stratton, near Cirencester, October 29.

I SHOULD like to add to the above interesting statement by Mr. Medd that a rural school of science, which is even more akin to Bigods' than Sexey's Trade School, has been at work for some years at Bakewell in Derbyshire. I referred to this in my address at Bigods in 1898. The resemblance in constitution and function is due to the co-education of boys and girls, and it would add to the value of the present discussion if some information could be given as to the working of the Bakewell school.

R. MELDOLA.

IN addition to Sexey's Trade School, Bruton, the visitors of Sexey's Hospital recently (and in this case also at the instance of Mr. Hobhouse) have established a dual school of the same general type as the Bruton school in the village of Blackford, five or six miles from the nearest railway station, and in the midst of a purely agricultural district. New buildings have been erected at a cost of about 4000*l.*, towards which the County Education Committee has contributed 1000*l.*, in addition to 250*l.* in aid of the equipment of the laboratory and workshop. The Blackford school has been carried on for about one year in unsuitable temporary premises, but nevertheless attracted more than fifty pupils. The new buildings were opened at the end of September by Sir Henry Roscoe. The school has now between seventy and eighty pupils, a considerable proportion being boarders. The school will receive from the County Education Committee an annual grant of at least 120*l.*

C. H. BOTHAMLEY.

County Education Office, Weston-super-Mare, November 2.

Birds Capturing Butterflies.

WITH reference to Mr. O. H. Latter's note in NATURE (September 28, p. 520) on the capture of butterflies by the sedge warbler, it may be of interest to note that Sweet, whose work on keeping warblers in captivity is incorporated with Bechstein's "Cage-birds" in Bohn's edition of that work, recommends a living butterfly as a bait for this very species, and for several other warblers, when it is desired to trap adult birds.

I may mention that not long ago I saw here in Calcutta a common Mynah (*Acridotheres tristis*) with a white butterfly in its bill, which it had no doubt obtained in repose, as the day was dull, and the Mynah is not very expert at catching insects on the wing. I remember also once seeing at Dehra Dun a Dhyal or Magpie-robin (*Copsychus saularis*) take a disabled *Catopsilia* I threw out for it, though I have seen the same bird disregard a specimen flying at no great distance. Evidently the birds wait their opportunity, and, though too wise to waste their energies in the pursuit of these evasive insects on the wing, are always ready to snap them up when they can take them at a disadvantage. In this way it can hardly be expected that attacks by birds on butterflies will be often noticed, unless a naturalist will undertake to watch individual insectivorous birds for whole days at a time.

Similarly, one does not in India see kites and crows pursuing sparrows, though a dead one flung out will be greedily snapped up by either species, and no doubt fledglings perish in numbers by these ever-watchful enemies. F. FINN.

Indian Museum, Calcutta, October 19.

MR. FINN'S letter is interesting as giving support to the opinion that it is when at rest that butterflies are chiefly attacked by birds. The injurics to be noticed on the wings of the insects very frequently are symmetrical on the right and left sides, and can only have been inflicted when the wings were folded in repose. I can only recall one occasion on which I have witnessed a bird attack a butterfly in flight, and then the attempt was unsuccessful. OSWALD H. LATTER.

Charterhouse, Godalming, November 7.

THE EFFECT OF WEATHER ON EVERY-DAY LIFE.[1]

SOME time since, a distinguished member of the Cotton Exchange asked my assistance to solve a problem connected with the variation of prices in "futures." He remarked that these prices varied almost from hour to hour without any apparent cause, such as a knowledge of the state of the crop or of the condition of the American market, which would explain these fluctuations. He was tempted to look for a subjective cause, and thought it might be found in the state of the weather exercising a powerful but unrecognised influence on the dispositions of purchasers and speculators, inducing them to buy or sell as they were alternately swayed by hopefulness or despondency. I was therefore invited to compare the movement of the cotton market with the variations in the weather, with the view of detecting the hidden relation, and was further stimulated to exertion by the assurance that if the origin of the fluctuation could be discovered "wealth beyond the dreams of avarice" would be at my command. Unhappily I failed to trace in the fickle weather the hidden springs that underlie the motives of speculators; and that fortune is still to be made by some one, possessed it may be of greater ingenuity or greater application, and to such an one I present the idea without hope of reward or acknowledgment.

Mr. Dexter's book reminded me of this experience, for he, too, has apparently embarked on an inquiry as difficult, but with a motive more noble, and let us hope with a reward more certain. Mr. Dexter wishes to trace the influence of weather on human conduct in general, and to see how far man's emotional state is affected by meteorological conditions. His reward is the attainment of a degree of Doctor of Philosophy, and the inquiry which he has instituted has apparently been undertaken with a view to meet the requirements of the authorities of Columbia University. One may sincerely hope that Mr. Dexter will have his ambition gratified, for to say that he has not spared himself in the labour of the inquiry is to say little. What is much more to the purpose he has not spared others. Teachers and superintendents of schools, wardens of prisons, superintendents of asylums for the insane, officials of the Weather Bureau and many others have been laid under contribution, by having submitted to them a "questionnaire" to completely satisfy whose interrogations involved not a little labour. Apart from the inconvenience which such a process might cause individuals, we doubt whether the plan adopted is the most trustworthy that could be found. Personal influence rather than climatic conditions is likely to introduce a systematic error into the final result. It is open to question whether the authorities consulted have satisfactorily eliminated the effect of weather from their own systems and mental states. The power of punishment rests with the authorities who have been consulted, and it may happen that those under their care are the victims of an irritability, engendered in the supervisors from causes with which the weather has absolutely no concern. To judge therefore mainly by the infliction of punishments seems of rather doubtful wisdom. This obvious objection has, of course, not escaped the author, and in one place he certainly recognises that the emotional state of the teacher is a not unimportant factor in the result. Indeed, he says, it may be the teacher we are studying more largely even than the pupil. The frankness with which this admission is made is more to be approved than is the reasoning by which it is set aside.

And now we are tempted to record a fact of which Mr. Dexter is entitled to make the fullest use. The temperature is 78°, the sky is cloudy, the wind is east, the velocity about three miles an hour, and under these conditions we find it much easier to present the facts at which Mr. Dexter has arrived than to criticise his results or carp at his methods. We notice that the author has studied, grouped, and commented on no less than fourteen classes of empirical data, embracing more than a quarter of a million separate facts. These fortunately can be grouped under fewer heads than the elaborate method pursued by the author admitted, and we hope we shall do him no injustice by the curtailment. First we have the registration and the behaviour of children in public schools (which we should probably call Board Schools in England) in New York City and at Denver, Colorado, two very widely different climates it will be remarked. Then we have a large amount of information drawn from police reports, which include assault and battery, discipline in penitentiaries, arrests for insanity and reported suicides. To these are added a few more or less fancy matters, in which the numbers involved are necessarily small, such as the clerical errors discovered in the records of certain of the national banks in New York City, maximum strength tests in gymnasia, and lastly "a study in discrimination carried on in the Psychological Laboratory of Columbia University." The discussion, it will be seen, is very wide, and one fact that will strike the reader prominently when he considers the variety of occupations into which the author has thought it judicious to push his investigations is the length to which this kind of inquiry can be carried when once we are bound hand and foot by the demon of statistics. Possibly the weather has no more to do with a clerk's mistakes than has the quantity or the quality of his supper the night before, but given a nicely ruled sheet of paper, and a system of rectangular coordinates, it is impossible to forgo the delight of plotting results to a scale. This is a harmless amusement; but when we begin to draw conclusions and to build theories, we may go as hopelessly astray as did the famous witness who connected the high tides with the building of a steeple. The author endeavours to meet any criticism of this nature in a passage which we may quote at length, to serve both as an example of his style of writing and his method of argument.

"The meteorological conditions are the essential causes of certain general physiological or mental states, some of which seem to be fertile fields for the action of immediate causes which are, from the standpoint of this problem, accidental. To be concrête, on a certain morning Johnny could not have what he wanted for breakfast, and went to school with the sulks, with a consequent disastrous effect upon his deportment. Most certainly the disappointment at home had a causal relation to his demerit, and no excuse from the weather is sought. But if we take the record of 200 Johnnies for 600 different days, and find that on certain days more of them are out of sorts than on other days, we look for a constant con-

[1] "Conduct and the Weather: an inductive study of the mental effects of definite meteorological conditions." By Edwin Grant Dexter, A.M. (New York and London: The Macmillan Co. *Psychological Review* Memoir.)

dition which might be considered in some way the cause. We cannot suppose that bad breakfasts or whippings or the disappointments common to child life would bear this constant relation, so look for it elsewhere. Wherever found it must be considered valid. But it must be some factor which would be a part of the environment of all the children similarly affected. We have sought it in the varying conditions of weather, with what success is shown by the curves which form the basis of our discussion."

These curves or diagrams are not so conclusive as the author seems to think. We have no proof that a legitimate application of the calculus of probabilities has been attempted. We cannot estimate the amount of variation exhibited by particular instances from the general interpolatory curve. In a word we cannot understand how the numerous observations have been combined, so that the unavoidable irregular errors have the least possible effect on the result. Further, these diagrams, or at least some of them, present another difficulty. To take the first figure which exhibits the effect of weather on the deportment, the class and mechanical work of boys and of girls in schools of various towns, and of boys and girls combined, in Colorado. The abscissa line is divided into eight sections of equal length defined by the weather conditions—hot, cold, wind, calm, storm, muggy, cloud and clear. Evidently there is no connection between the several parts—no regular progression in such an abscissa line. We cannot see, therefore, any reason for joining the several points, of which five out of eight are practically zero. But taking the author's interpretation as it stands, which for reasons already given we are quite prepared to do, this is what we learn.

In climates similar to those of New York, deportment and work are considered to be at their best on cold, calm, clear days, irrespective of sex, and at their worst on "muggy" days. In Colorado, calmness of the atmosphere produces a desirable effect on the condition of the pupils, wind exercises the most deplorable influence. Deportment, which apparently plays a great part in these schools, a fact which should rejoice the shade of the late Mr. Turveydrop, is affected by weather conditions, more in the case of boys than girls. This fact is explained by one teacher on the ground that boys are under less disciplinary control than girls. Another adds that girls "are greater adepts, not only at restraining impulses to do mischief, but also in concealing all evidences of it when it is in progress. This may be due to a greater horror on their part of an open reprimand." The cogency of this argument is not manifest, because the consequences of detection are likely to be visited on the boys with greater asperity than is covered by the term "open reprimand." The knowledge that acute punishment can and will follow conviction, should act as a deterrent and suggest methods of concealment that defy the penetration of the teacher.

When we come to discuss the behaviour of children of older growth, we still find the weather capable of exercising a baneful influence on their conduct and self-control, as illustrated by the number of suicides, assaults, and the perpetration of grave crimes. With regard to the morbid tendency disclosed in the mental state that produces the first of these misdemeanours, the author confirms the remark of Morselli and of others, who have considered the statistics of suicide, that an undue proportion take place in May and the spring and summer months of the year. This fact, which is contrary to the commonly received opinion, Mr. Dexter explains as arising not merely from a depleted vitality, produced by the exhausting influence of the cold of winter, but also by the "conscious or unconscious contrast of the recognised low condition of vitality with the exuberance of energy and life in the rejuvenated nature about, making one that is weak feel that the struggle against the resistance to life and progress, in competition with a world so virile, is hopeless." This remark is perhaps more ingenious than convincing, but if any considerable space of time is supposed to elapse between the contemplation and the completion of the act, it seems useless to tabulate the number of suicides with the height of the barometer and the humidity of the atmosphere, quantities that are continually varying.

It is of interest to notice that the number of assaults increases pretty uniformly with the temperature, or it would be more correct to say with an excess of temperature. Given a hot day in the spring or autumn, and our pugnacity rises in an alarming manner, though in the hot days of summer this quarrelsome mood is not so aggressive. The author concludes from the arrangement of his facts that the effects of heat up to a certain limit are vitalising in their tendency, while at the same time irritating; but above that limit, heat is so devitalising in its effects as to leave hardly energy enough to carry on a fight. Sad to relate, the effect of heat upon ladies is greater than on men; and this is shown not only by an increased desire to fight, but also by evident mental unbalancing. Whether one is the consequence of the other, or whether both are to be traced to the greater sensitiveness of women to weather conditions, is too thorny a subject for masculine debate. But the tales that come from penitentiaries and from those who have charge of the insane, alike testify to the irritating effects of increased temperature. In this connection the author thinks that a study of the record of profanity might yield interesting results, but unfortunately he adds "inclination alone will at least get no one into the police court," so that numerical data are wanting to discuss this phase of the weakness of human nature. It would probably be found that the curve would not greatly differ from that of assault, and it would certainly be comforting if we could shift the responsibility of our deviations from rectitude to such an impersonal agent as the weather. In our own ignorance we were rather tempted to attribute these lapses from good conduct to too free an indulgence in alcoholic beverages in the warm weather, but the author with far greater familiarity with the subject traces them to a much deeper source to be found possibly "in the depletion of the cell structure," or "in acceleration of the oxidising processes of life," expressions which we can only hope are as accurate as they are sonorous.

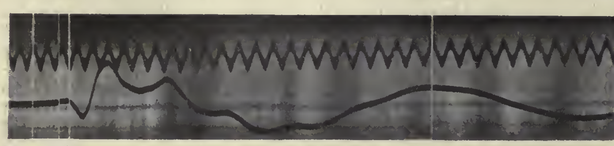
It is no new question to seek the effect of weather upon the moods and impulses of the population, but Mr. Dexter has tapped a new source of inquiry when he asks what are the meteorological conditions which induce clerks in banks, and we presume computers in general, to make mistakes in their work, and to offer up incorrect answers. When the barometer is low, let us forswear computations, but if the humidity be at the same time small, it would be positively immoral to attempt to add up a column of figures. The author explains this by the fact "that the intellectual balance is more disturbed by the increased electrical potential than is the emotional." We are afraid to discuss this proposition, more especially as we have overstepped the limits of space, but we must find room to say that we respect the evident trouble and care which the author has taken in compiling his results, and to ask his pardon if our remarks have appeared too flippant, when applied to a work which he has taken very seriously. Some of his inquiries are not yet complete, but we hope that he will continue them to the end, and leave his results in such a form that a more rigorous discussion may be possible. By "rigorous" is merely meant on recognised mathematical principles, in which one can see easily the relative "weight" which is to be attached to the separate deductions, and the "probable error" that accompanies each.

W. E. P.

VIBRATIONS OF GUN BARRELS.[1]

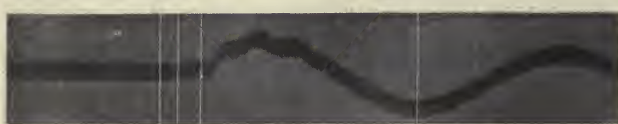
THE authors of this research on the vibrations of gun barrels were induced to make an experimental investigation of the behaviour of rifle barrels, in order to clear up certain difficulties connected with that which is known in ballistics as the *error of departure*. It had been noticed that in shooting with a rifle (whether held loosely, or firmly fixed), that the initial tangent to the trajectory —"die Anfangstangente der Flugbahn"—does not coincide, as would be expected, with the axis of the bore of the barrel, when produced, but is more or less inclined to it at a small angle; this is called *the angle of error of departure*. The authors, working with photo-chronographic methods, determined the movements of the muzzle end of a rifle in a vertical plane, and a vibrational movement of the barrel was detected, and recorded on a moving photographic plate, on the same plate; a trace from a tuning-fork of known period was also formed, so that the position of the muzzle was known at any instant. The rifle used was of the Mauser type M 71.

The collection of photo-chronographic records, twenty-eight in number, show the manner in which a rifle barrel



γ

Fig. 1.



γ

Fig. 2.

Curves showing the vibrations of different parts of a gun barrel after firing. The spot on the bright line marked γ indicates the moment at which the shot left the barrel. Fig. 1 is the vibration curve of a point 1·5 cm. from the mouth, and Fig. 2 of a point 18·5 cm. from the mouth.

vibrates when subjected to the concussion due to an explosive. Figures 6, Plate I., and 7, Plate II., indicate a rapid initial vibration, apparently due to the beginning of the explosion. The records, as a whole, show how an error of departure may be produced. The photographs in some cases are not so clear and defined as those usually produced in physiological research; this is probably due to the beam of light having been cut off by an object of circular section, such as the wire used by the experimentalists. A thin metallic lamina, such as blackened aluminium foil, would have given sharper details. The authors show that the experimental results agree well with figures calculated on the assumption that the rifle barrel is a cylindrical tube.

There is much in the work of Messrs. Cranz and Koch which will be of value to the student of ballistics and to those who design military and other rifles. F. J. J-S.

[1] "Untersuchungen über die Vibration des Gewehrlaufs." Von C. Cranz und K. R. Koch. Pp. 31. Six plates; 13 figures in letterpress. (München: 1899.)

NOTES.

THE Council of the Royal Society has adjudicated the medals for the current year as follows:—The Copley Medal to Lord Rayleigh, F.R.S., for his contributions to physical science; a Royal Medal to Prof. George Francis Fitzgerald, F.R.S., for his contributions to the advancement of physical science, especially in the domains of optics and electricity; a Royal Medal to Prof. William Carmichael McIntosh, F.R.S., for his important monograph on British marine zoology and on the fisheries industries, and on account of his work in establishing a Marine Biological Laboratory at St. Andrews; the Davy Medal to Mr. Edward Schunck, F.R.S., for his investigations on madder, indigo and chlorophyll. Her Majesty the Queen has graciously signified her approval of the award of the Royal Medals.

THE first congress of Russian electricians, organised by the Société Impériale Technique de Russie with the authority of the Ministers of the Interior and Finance, will be held at St. Petersburg on December 27, 1899 (January 8, 1900). The objects of the congress are the promotion of friendly intercourse between electricians, the exhibition of the most recent inventions in electricity and its applications to industry, the discussion of instruction in technical electricity, and other subjects which are concerned with the advancement of electrical science in Russia. The apparatus and machinery, plant, models and inventions, sent by electricians of any nationality, will be exhibited in the rooms of the Imperial Technical Society, Panteleimonskaja 2, St. Petersburg, to which address all communications should be forwarded. Objects intended for the exhibition will be admitted into Russia free of duty, under the condition that they are removed within a month of the close of the exhibition.

PROF. TYLOR writes to call attention to the remarkable activity of anthropological research of late years throughout Austria-Hungary. Students interested in such work may profit much by visiting several districts now of easy access, whether in quest of remains of the Hungarian Copper Age, the caves and burial-places of the Trieste district, the dug-out canoes of the Bosnian fishermen, or the dwindling survivals of ancient patriarchal-communal life in the zadrugas of Croatia. As an example of the activity of the anthropological museums may be mentioned the descriptive catalogue, by Dr. Jankó, of the Biró Ethnographic Collection from New Guinea in the Hungarian National Museum at Buda-Pesth. The first part has been lately published, and is of so excellent quality that it is to be hoped that funds will be forthcoming to complete the work on the same scale.

MR. R. F. MUIRHEAD has been elected president o. the Edinburgh Mathematical Society for the ensuing year.

THE American Geographical Society receives 1000*l.* under the will of the late Mr. C. P. Daly, for the foundation of a medal to be awarded for distinguished services to geography.

THE *Chemist and Druggist* announces that Prof. Moissan has been appointed director of the Laboratory of Practical Chemistry at the Paris Faculty of Sciences.

THOUGH the distance is not less than thirty miles, the sound of the firing at Ladysmith is said to be so plainly heard at Estcourt that the reports of heavy guns (supposed to be the two naval 4·7-inch guns, followed by the bursting of Lyddite shells) can be easily distinguished above those of the Boer 40-pounders and the smaller guns on both sides.

WE learn from *Science* that Mr. R. E. Snodgrass and Mr. A. H. Heller have 'ust returned from a ten months' collecting trip to the Galapagos Islands. The collections are large; birds, fish, and insects and spiders being represented by especially large numbers of specimens. The collections belong to Stanford University, under whose auspices the expedition was made.

As the gravels in the neighbourhood of Chelsea are very rich in rude flint-flakes and the like, many students of archæology and geology may be glad to know that a large vacant space at the corner of Cheyne Walk and Beaufort Street, Chelsea, is shortly to be built upon, and the excavations will probably go down into hitherto undisturbed soil. Mr. W. F. Sinclair calls our attention to the opportunity which the excavations will afford for collecting flint specimens.

BY the death of Mr. William Pamplin, in the ninety-third year of his age, on August 9, English botanists have lost their *doyen*. Mr. Pamplin was an authority on British plants, and especially on their geographical distribution, in the first half of the present century. The "London Catalogue of British Plants" owed much to him. In the year 1827 he published a list of the rarer plants of Battersea and Clapham; and he was elected an Associate of the Linnean Society in 1830. Mr. Pamplin at one time carried on the business of a second-hand bookseller in London, but had lived for many years in great retirement near Bala in North Wales.

THE annual course of Christmas lectures, specially adapted for young people, at the Royal Institution, will this year be delivered by Mr. C. V. Boys, F.R.S. The subject will be "Fluids in Motion and at Rest." The lectures (which will be six in number) will commence on Thursday, December 28, at three o'clock. The remaining lectures will be delivered on December 30, and on January 2, 4, 6, and 9, 1900.

Science announces that Mr. O. F. Cook, of the Division of Botany, U.S. Department of Agriculture, left New York a few days ago for Puerto Rico to make a preliminary examination of the plant products of that island with reference to the introduction of new and useful tropical plants. Mr. Cook is accompanied by Mr. G. N. Collins, of the Department of Agriculture, as photographer, and by Mr. George P. Gall, who is sent by the Smithsonian Institution to collect material for the National Herbarium.

WE learn from the *Cape Times* that Mr. P. L. Sclater, F.R.S., who has lately returned from a visit to South Africa, attended a meeting of the South African Philosophical Society on September 17, and gave an address on the desirability of establishing a Zoological Garden in Capetown. Mr. Sclater showed that the important centres all over the world were taking measures to establish such institutions for instruction and recreation, and urged that Capetown, being the port and capital of what would shortly be an enormous empire, should not be behindhand in the matter. Mr. Sclater's proposals were discussed and well received, and a committee of the Society was appointed to consider the subject and report to a future meeting.

REFERRING to the death of Dr. Edward Orton, professor of geology in the Ohio State University, in the seventieth year of his age, the *American Journal of Science* remarks that while his labours have extended to all branches of geological science, his close watch of the exploitation of petroleum and natural gas, in Ohio and the neighbouring States of Pennsylvania and Indiana, has given him a place of pre-eminence as interpreter of these important geological products. In 1897 Dr. Orton was elected president of the Geological Society of America, and, as president of the American Association for the Advancement of Science, presided at the recent meeting of the Association, in Columbus, in August last. Prof. Orton was a man of broad culture and of influence outside his chosen science. He was for a time president of Antioch College, Yellow Springs, Ohio, and them became president of the Ohio Agricultural and Mechanical College, which has now become the State University. He resigned the presidency and became State geologist in 1882, which position he held up to the present year. Dr. Orton received the degree of Ph.D. from Hamilton College in 1848, and LL.D. from Ohio State University in 1881.

AT the opening meeting of the new session of the Royal Geographical Society on Monday, the president announced that, including the Government grant, the funds at the disposal of the joint committee on Antarctic exploration amounted to 90,000*l.*, but he recalled the fact that the grant which had been promised was made dependent upon another 5000*l.* being raised from other sources. A valuable paper, illustrated by many striking photographs, was read by Mr. W. Rickmer Rickmers, on a journey in the Eastern provinces of Bokhara, with his wife and Dr. von Krafft, now of the Geological Survey of India. Mr. Rickmers established a permanent camp on a tributary of the Yakh-su river, with the object of studying the wonderful mountain system of the "conglomerates" of East Bokhara. The "conglomerates" cover an area of 800 square miles, disposed in a long strip between the rivers Vaksh and Panj, with a strike from north-east to south-west. They show distinct stratification, and Dr. von Krafft ascribes them to the Tertiary period. The stones composing them are chiefly crystalline. The greatest thickness of the formation may be said to be at least 4000 feet. The population of the region is mainly dependent for its livelihood on the gold-washing industry. The yearly gold output of East Bokhara is variously estimated from 20,000*l.* to 30,000*l.*, but this is a mere trifle considering the potentialities of the alluvial deposits. The quantities extracted by the natives in the course of centuries have hardly encroached upon the store, and are as nothing compared with what Europeans could produce in a few years.

As appears from the Report of the Select Committee on the Destruction of Vermin, lately presented to the House of Assembly of the Cape, no less a sum than 27,084*l.* was spent in the various districts of the Colony in the year ending June 30, 1899, in rewards paid for the "destruction of vermin." This large expenditure not unnaturally excited the attention of the Legislative Assembly, who appointed a Select Committee to consider it. The Committee, after taking the evidence of many farmers, land-owners and other persons interested in the subject, have come to the conclusion that it is expedient for the agricultural interest (a predominant factor, it may be remarked, in Cape politics) that the system of giving rewards for the "destruction of vermin" should be continued, but that more care should be exercised in ascertaining that those who claim the rewards are properly entitled to them. The "vermin" in question appear from the evidence to be the Black-backed Jackal (*Canis mesomelas*), the Aard Wolf (*Proteles cristatus*), the Cape Baboon (*Papio porcarius*), and the so called "Lynx" or Roode Cat (*Felis caracal*), all of which are accused of ravaging the farmers' flocks, especially during the lambing season. The Aard Wolf, it is admitted, is not usually carnivorous, but is said to have developed of late years a noxious habit of tearing open the breeding ewes in order to get at the milk in their breasts.

A POSSIBLE substitute for india-rubber and gutta-percha was exhibited and described by Mr. W. F. Reid at the last meeting of the Society of Chemical Industry, under the name of "Velvril." The material appears to be suitable for machine-belting—made by coating cotton canvas with it—waterproofing cloth or canvas, and as a varnish for paint, wood or metal; and so far as its mechanical and protective properties are concerned, it compares favourably with gutta-percha. *The Electrician* is of the opinion that the material at present lacks the flexibility necessary to the core of a submarine cable, and also the strength and elasticity required for a golf ball. Perhaps with improved methods of manufacture these qualities can be given to "Velvril," but until then gutta-percha will hold its own as the most suitable substance for these two purposes.

A FEW years ago the phenomena of "Barisâl Guns," and other similar noises, were discussed at some length in the columns of NATURE. A valuable contribution has recently been made to this interesting subject by Prof. A. Issel, in a paper published in the *Bollettino* of the Italian Seismological Society. The author's chief object is to describe the detonations which were heard at about the time of the Umbria-Marches earthquake of December 18, 1897. These detonations are quite distinct from the sound which generally accompanies an earthquake-shock. They are rather crashes, more or less prolonged, and resemble the boom of thunder or the report of heavy guns at a distance. Sometimes they are isolated; at other times they occur in series, following one another at brief intervals. Generally they begin with a strong blow, which has very often a slightly metallic sound, and then gradually diminish in number and intensity until they cease, but there may be one or more renewals of activity. To many persons the crashes seemed to come from Monte Nerone, where the epicentre of the earthquake was situated. They are frequently heard at other times by the inhabitants of the middle Appennine region, and are known to them by the name of Bomblo. Very often they occur in close connection with earthquakes, and they may be followed immediately by a slight shock or tremor; they are also stronger and more numerous during epochs of maximum seismic activity. Prof. Issel correlates these crashes with those known in other places as Marinas, Mist-Poeffers, &c.; and, as these phenomena are especially characteristic of seismic districts, he regards them for the most part as due to endogenous causes.

ELECTRICITY is rapidly gaining ground as a motive power for harbour and dock works and for traction on canals. In France haulage by electricity has been in use on some of the canals for several years, and, besides being found economical, has been of special value for working the boats through tunnels. The system is now to have a trial in this country, a portion of the Leeds and Liverpool Canal near Wigan being fitted for electric traction; and it is anticipated that, besides other advantages, a saving in the cost of traction of 50 per cent. as compared with horse haulage will be effected. On the Dortmund and Ems Canal in Germany, recently opened for traffic, the cranes and other machinery at the terminal stations, and all the work at the locks connected with the opening and closing of the gates and sluices are to be operated from a central station, where electricity is to be provided by steam power. The haulage along the canal is to be effected by a small electric locomotive running along the tow-path, and obtaining its supply from trolly wires. On the Erie Canal one or more systems have already been tried with partial success. It is now reported that the storage battery system is to be introduced; an electric traction engine will run along the tow-path and haul a canal boat filled with storage batteries of sufficient capacity to furnish current for the traction engine and the boats towed by it. The locks of the North Sea and Baltic Canal, and also the new lock of the Amsterdam Canal at Ymuiden, are both worked by electricity, which is found to have great advantages over hydraulic power in winter when sharp frosts prevail. In this country, at Southampton Docks and other places, cranes are in use worked by electricity.

A THESIS on "The Memory Image and its Qualitative Fidelity," reprinted from the *American Journal of Psychology*, has been received from Dr. I. Madison Bentley. The results of experiments carried on for the special investigation of the visual memory image and its fidelity to an original presentation have led to several conclusions of psychological interest. It appears that discs—grey and coloured—shown and remembered in daylight, tend to grow light in the visual memory, while grey discs shown in a dark chamber display a tendency in the visual image to grow dark during an unilluminated interval. These results indicate that the condition of the retina in respect to stimulation during the memory interval is important for the memory image. Illuminated and unilluminated intervals, where all other conditions are constant, are followed by different judgments with the same memory stimuli. It is therefore concluded that in all experiments with brightness and colour, where a time interval is involved, care should be taken to control the state of the visual organ. It is not improbable that a similar caution would apply to other sense memories. The results also show that memory is not to be regarded as a storehouse of perfectly conserved images, but that the most simple memories are continually exposed to change, and that it is, at times, only by the combination of various memorial resources that retention is made definite and exact.

THE intermittent treatment o. sewage in bacteria coke-beds forms the subject of a second report presented to the London County Council by their chemist. Various investigations were carried out and are here recorded with the object of ascertaining the most effective method of constructing and working the coke-beds, and the data obtained form an interesting contribution to the literature, now considerable, daily accumulating on this method of sewage treatment.

THE reports of the malaria expedition in Italy under the direction of Prof. Koch receive adverse criticism at the hands of Dr. Grassi, writing in the *Atti dei Lincei*, viii. (2), 8. Among the points at issue it would appear that Koch, in the reports referred to, still admitted the possibility of malaria being propagated by *Culex pipiens*, a view long since abandoned by Grassi on circumstantial evidence, which he now summarises in detail. Much of the evidence which led Grassi to attribute the propagation of malaria to Anopheles and not to Culex has been given in previous papers in the same journal.

THE well-known experiment of the early popular text-books on "freezing and boiling water simultaneously" under the exhausted receiver of an air-pump being difficult to perform in practice, Mr. R. W. Quick describes in the *Physical Review* another mode of achieving a similar result. This is a continuation of the experiment commonly described under the heading "water boiled by cold," in which the tightly-corked flask containing the water and steam is cooled, first with iced water, and then with a mixture of solid carbon dioxide and ether, until ice forms as the water boils—or the flask bursts. As Mr. Quick remarks, there must not be sufficient residuum of air in the flask to keep the pressure above 0·46 cm. (the vapour pressure of ice at 0° C.), otherwise no amount of cooling would be effectual in causing boiling and freezing simultaneously.

A PAPER by Prof. Archibald Barr, on "Similar structures and machines," read before the Institution of Engineers and Shipbuilders in Scotland, is appearing in the form of a series of illustrated articles in *Engineering*. The disproportionality between large and small structures required to ensure corresponding strength in supporting weight is illustrated by figures showing the difference in structure between the skeletons of large and small animals, and also by diagrams showing the Britannia and Forth Bridges reduced to the same span.

THE *Proceedings* of the annual meeting of the Indiana Academy of Science, held at Indianapolis at the end of December last, contains quite a number of mathematical papers, foremost among which are Mr. D. A. Rothrock's papers on point invariants for the Lie groups of the plane, and on differential invariants derived from point invariants. To those interested in the geometry of the triangle, Mr. Robert Judson Aley's list of concurrent sets of three lines connected with the triangle will prove a most useful synopsis for purposes of reference; it enumerates eighty-four different concurrences. The same writer communicates a note on a new triangle and some of its properties; while Mr. C. E. Smith, of Indiana University, discusses the geometry of Simson's line. A linear relation between certain of Klein's X-functions and sigma functions of lower division value is given in a note by Mr. John A. Miller.

A FEW years ago Lussana discovered that the electric resistance of aqueous solutions presented certain anomalies in the neighbourhood of the temperature of maximum density, these anomalies being represented by a point of inflection in the curve expressing the relation between the resistance and the temperature. In view of the objections raised against Lussana's work and the intimate relation known to exist between the electric resistance of a fluid and its viscosity, it occurred to Dr. G. Pacher to examine whether any variations analogous to those found by Lussana existed in the coefficient of viscosity of water near the temperature of 4° C. The results of Dr. Pacher's experiments are described in a paper in the *Atti del R. Istituto Veneto*, lviii. (2), pp. 785–814. The coefficient of viscosity was found by observing the efflux of the liquid through a capillary tube, Poiseuille's law being assumed, and the temperature was maintained constant by immersing the tube in a water bath. From the viscosity its temperature-coefficient was calculated and represented graphically by a curve. The conclusions arrived at are as follows: (1) In the neighbourhood of 4° the viscosity of distilled water presents an anomaly indicated by a point of inflection in the curve connecting he viscosity with the temperature; (2) the temperature-coefficient of the viscosity presents a maximum followed by a minimum between the temperatures of 3° and 6°; (3) given the relation between the temperature-coefficient of viscosity and that of electrical resistance, a similar anomaly may be expected to exist in the electrical resistance of distilled water; (4) Lussana's results thus receive indirect confirmation from the present investigation.

A POPULAR account of the possibilities and difficulties of aërial navigation, based upon the scientific experiments made by Langley, Lilienthal, Pilcher, Maxim and others, appears in the current number of the *Fortnightly Review*.

SIR JOHN EVANS's presidential address, on "The Antiquity of Man, with especial reference to the Stone Age in Egypt," delivered at the Birmingham and Midland Institute, has recently been published. It is a brightly written sketch of a vast subject; the more important approximate dates are given, which is a useful feature.

THOSE who are interested in Indian folk-lore must always keep an eye upon the *Journal* of the Asiatic Society of Bengal. The first part of the new volume of the Anthropological Section for this year contains a variety of interesting papers, amongst which may be noted one, by Mr. C. C. Mitra, on folk-lore about birds, and one, by Mr. C. A. Silberrad, on a rain-compelling ceremony which is performed by women.

A COPY of the Report and Transactions of the South-Eastern Union of Scientific Societies, containing an account of the proceedings at the fourth annual Congress held at Rochester in May last, has been received. The Union systematises scientific work among the different societies composing it, and in various ways promotes the interests of science. Next year's Congress will be held at Brighton early in June.

FROM Messrs. Williams and Norgate's very useful "Book Circular" (Scientific Series, No. 72), containing descriptive notes on the contents of recent foreign publications, we obtain the following announcements as to forthcoming scientific works:—"Die Elemente der Entwicklungslehre des Menschen und der Wirbeltiere" is the title of a work by Prof. O. Hertwig, of Berlin, which will shortly be published.—M. Le Dantec, lecturer on embryology at the University of Paris, has written a work entitled "Lamarckiens et Darwiniens," which will be issued very shortly.—"Ueber Reduktionstheilung, Spindelbildung Centrosomen und Cilienbildung im Pflanzenreiche" will be the subject of the sixth part of Prof. E. Strasburger's "Histologische Untersuchungen."—The first part of "Nouveaux éléments de botanique," by Prof. Louis Crié, of Rennes, will soon appear, and the second part will be published in the course of next year. —The fourth edition of Prof. Lapparent's "Traité de Géologie" will be issued in three parts. Of these, the first two will appear almost immediately, and the third will appear in January.

THE difficulty of preparing metallic cæsium is well known. The metal has hitherto been obtained chiefly by the electrolysis of the cyanide mixed with barium cyanide, but the unsatisfactory character of this process is sufficiently shown by the price of the product, which is about twenty-eight shillings a gramme. It has been shown quite recently by Herren Graeffe and Eckhardt that cæsium can be prepared easily and with an almost theoretical yield by the reduction of cæsium carbonate by means of magnesium powder. The mixture is heated in an iron tube through which a slow current of hydrogen passes. The metal distils over, and is collected under melted paraffin. It has a silvery lustre with a slight yellow tint, and remains bright under paraffin. On exposure to air it oxidises rapidly, melts, and finally inflames. In its action on water it resembles potassium. A previous attempt by Winkler to prepare cæsium by reducing the carbonate with magnesium failed, and led that chemist to doubt the statement of Beketoff that the reducibility of the alkaline carbonates increased with increasing atomic weight of the metal. Herren Graeffe and Eckhardt, however, confirm Beketoff's conclusion, and show that cæsium is more easily reducible than rubidium, and rubidium than potassium.

THE additions to the Zoological Society's Gardens during the past week include a Sykes's Monkey (*Cercopithecus albigularis*) from East Africa, presented by Lord Alexander Thynne; a Macaque Monkey (*Macacus cynomolgus*) from India, presented by Mr. W. J. Beard; a Vervet Monkey (*Cercopithecus lalandii*) from South Africa, a Viverrine Phalanger (*Pseudochirus cooki*) from Tasmania, an Agile Wallaby (*Macropus agilis*) from Australia, a Brown Capuchin (*Cebus fatuellus*) from Guiana, a Rufous-necked Wallaby (*Macropus ruficollis*) from New South Wales, three Cardinal Eclectus (*Eclectus cardinalis*) from Amboyna, four Serrated Terrapins (*Chrysemys scripta*), three Prickly Trionyx (*Trionyx spinifer*), four Menobranchs (*Necturus maculatus*), an Amphiuma (*Amphiuma means*) from North America, three Mute Swans (*Cygnus olor*), European, deposited; a Black-backed Jackal (*Canis mesomelas*) from South Africa, two Brazilian Caracaras (*Polyborus brasiliensis*), an Anaconda (*Eunectes murinus*) from South America, purchased; a Spring-Bok (*Gazella euchore*) from South Africa, received in exchange; a Hog Deer (*Cervus porcinus*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE ANDROMEDES.—In respect to the reported observation of Biela's comet, no confirmation of which, however, is yet to hand, it will be well to keep careful watch on the character of the second November display. The maximum is timed to occur from the 23rd to the 27th, the approximate coordinates of the radiant being

R.A. = 1h. 40m.
Decl. = +44°;

that is, a little north-west of γ Andromedæ. The usual characteristic of these meteors is their slow flight, in contrast to the swift Leonids, and this should facilitate photographic impressions of them being obtained.

HOLMES' COMET (1899 *d*).

Ephemeris for 12h. Greenwich Mean Time.

1899.	R.A. h. m. s.	Decl. ° ′ ″
Nov. 16	2 20 25·87	+48 25 43·7
17	19 24·98	19 55·4
18	18 25·68	13 51·5
19	17 28·03	7 32·5
20	16 32·09	48 0 59·3
21	15 37·93	47 54 12·3
22	14 45·60	47 12·4
23	2 13 55·17	+47 40 0·2

OCCULTATION OF NEPTUNE.—On Sunday evening next, November 19, there will be an occultation of Neptune, visible throughout the whole of northern Europe, for the observation of which the following particulars will be useful :—

	Sidereal time. h. m.	Mean time. h. m.	Angle from North point. °	Angle from Vertex. °
Disappearance...	22 4	6 10	95	129
Reappearance...	22 56	7 1	261	299

The angles given will facilitate the adjustment of the moon's image so as to bring the points of "immersion" and "emersion" into the positions of best definition. The "angle from the north point" is the angle subtended at the centre of the moon's disc by the arc extending from the star when in contact to the point of intersection of the moon's limb by a great circle passing through the North Pole; the "angle from the vertex" is the angle subtended by the arc extending from the star to the point of intersection of the limb by a vertical great circle passing through the zenith.

For the convenience of observers south of London it may be mentioned that the limits of latitude for this occultation are 90° N. to 25° N.

"THE HEAVENS AT A GLANCE" (1900).—Mr. Arthur Mee, of Cardiff, has published his annual astronomical calendar, upon which is given a concise tabulation of the more important astronomical constants and events for the coming year. One half of the card constitutes a celestial diary, indicating the favourable dispositions of the various constellations for each month, the sun's declination, phases of the moon, and configuration of the planets, with detailed enumeration of occultations and variable star phenomena. Following this, descriptive notes are given of the prominent features visible on the moon at various stages throughout the lunation; times of elongation, opposition, &c., of the planets throughout the year; a list of the more prominent meteor showers, the eclipses of the year, and several facts concerning variable stars. The whole is printed on a single card, facilitating its being kept within reach for instant reference by the observer's side, and thus specially recommends itself to the amateur who may be unable to spare the time necessary for obtaining the information from the more complete reference works of the observatory. Astronomical time is used throughout, and all the data are for Greenwich, but are applicable with slight corrections to the whole of the British Isles. Not the least important feature is the clear style of arrangement and printing, which will render its use more pleasant under actual working conditions.

THE CONFERENCE OF GERMAN MEN OF SCIENCE AT MUNICH.

THE seventy-first meeting of the Society of German Naturalists and Physicians opened at Munich on September 17, and continued until the 23rd.

A great disaster had just visited the city; the floods which had wrought such havoc throughout the Salzkammergut and South Bavaria culminated their work of destruction in Munich, where the Isar, rising many metres in a few hours, destroyed two of the finest bridges in the capital, inundated the low-lying parts of the town, and threw out of gear the Electric Works and many factories along the banks; many lives were lost.

The Prince Regent bridge, which was entirely destroyed, was the gift of the ruler whose name it bears; the original cost was 1,500,000 marks, and the munificent Prince has undertaken to bear the cost of rebuilding the same.

In spite of the dislocation of all routes of communications, the congress was attended by about 3500 members. The proceedings opened with a gala meeting in the Royal Theatre on Monday, September 18, when the congress was inaugurated by Councillor von Winckel, and the members were welcomed, on behalf of the Prince Regent, by Prince Ludwig Ferdinand, who evinced his interest by attending all subsequent general meetings.

After several other speeches had been delivered, Dr. Fridtjof Nansen ascended the tribune and summarised the scientific results of his Polar Expedition.

Parenthetically, it is interesting to note that three of the most remarkable addresses were delivered by foreigners—Nansen, van t' Hoff and Ramsay—in fluent German.

Nansen showed the typical glacial appearance of the Siberian coast, then described Franz Josef's Land, which is far less extensive than appears on the maps; the land is almost entirely covered with ice, relieved here and there with masses of black basalt rocks, which rest on a seam of clay some 500 feet in thickness.

The Arctic Ocean may be considered as a kind of lagoon separated from the Atlantic by a submarine range of mountains, stretching from Spitsbergen to Greenland; this range is responsible for a curious condition of things. The Arctic Ocean is covered with a layer of brackish water containing a low percentage of salt, and collected from the Siberian rivers and the Bering Strait; below this is Gulf Stream water, containing a normal quantity of salt.

If these two layers of water were mixed, the average temperature would fall, but this average would not be so cold as that of the surface layer of Arctic water; this condition accounts for the enormous formation of ice in the polar region.

The points were all illustrated by photographs, tables and diagrams, and drawings of the diatoms found in the fresh-water lakes, formed by the sun melting the surface of the ice, were shown.

The lecturer was followed by Prof. von Bergmann, who demonstrated the value of radiography in the diagnosis of surgical diseases; and by Prof. Förster, who described the alteration in the face of the heavens from the remotest periods down to the present time.

After these addresses many members adjourned to the Technical College, the whole of which magnificent building had been placed at the disposal of the congress, and where reading and writing rooms, reception and inquiry offices, a restaurant, &c., were to be found.

Here the daily programme was to be obtained, and each member of the congress was presented by the city with an admirable album of views and a "Festschrift."

The Festschrift was a magnificent quarto volume describing the development of Munich under the influence of the natural sciences during the last decades. The first part of the work was devoted to vital statistics and general municipal organisation. A few facts are, however, of general interest and formed the subject of addresses during the congress.

The Electrical Works on the Isar are a most remarkable example of a municipal undertaking; besides the current used for the electric cars, lighting, telegraph and telephone purposes, they supply current to work 172 motors (1329 H.P.), 13,500 incandescent and 329 arc-lights in 91 factories. Besides the Corporation works, there are 317 private installations, of which 69 use gas, 39 water, and 179 steam to supply the motive power.

The population of Munich is 450,000. The cost of lighting the streets (incandescent gas and arc-lights) represented last year, per head of the population, a yearly cost of 1·925 marks; in 1881 the cost was less than half this sum, 0·81 mark per head.

Of the two most prominent industries in Munich, the second, the industrial production of cold, originated in the demands and necessities of the first, the brewing industry.

In 1898 there were 24 breweries, producing 1,540,000 hectolitres of beer. Munich has always been celebrated for its beer, and in the year 1500 possessed 38, in 1618 no less than 69 breweries.

The industry of the production of low temperatures is due to the energy of, and was initiated by, Dr. Carl Linde, who in 1881, with the help of the Polytechnic Society, started the famous works, where successful experiments were carried out with the "high pressure and low temperature system," and with the happy combination of Siemens' alternating principle with the Joule-Thompson "cooling effect," produced by the streaming of gases from high to low pressures. The following are the chief industrial and scientific uses of low temperatures: manufacture of ice in the brewing industry; preservation of meat and alimentary products generally; preservation of anatomical specimens; in the morgues; the arrestation of the development of the silk cocoon; arrestation of the growth of bulbs (making the same independent of their accustomary flowering season); in the testing of meteorological instruments; and in scientific research generally; the preparation of explosives, the fractionation of liquid air, and consequent preparation of mixtures rich in oxygen; the manufacture of ozone.

The Cold Air Storage Installation at Munich is the most complete building of the kind at present erected; the cells are kept constant at 3° C., and the air contains 60–70 per cent. of moisture.

The second general meeting was also held in the Royal Theatre, and the addresses on this occasion were delivered by Prof. Boltzmann (Vienna) on the course of the development of modern physical methods; by Prof. Birch-Hirschfeld on science and therapeutics; and by Prof. Klemperer (Berlin) on Justus von Liebig and medical science.

The last-named speaker showed that Liebig initiated the use of chemical preparations of known composition in the place of those plant infusions of doubtful consistency, which formed the staple drugs of the older physicians. Prof. Klemperer declared that the days were drawing near when such extracts would disappear from pharmacology, and chemistry would be entirely substituted for botany.

In another, less direct, way Liebig was the means of enriching our pharmacopœia, for it is by the method of organic analysis he perfected that the composition of the numerous synthetic remedies of to-day is determined. Chloroform and chloral were discovered by him, and, working in a somewhat different region of thought, Liebig exploded the theory that the warmth of the animal organism was in part due to electricity and the action of the nerves, showing that all animal warmth was produced by the chemical processes continually taking place within the organism.

THE CHEMICAL SECTION.

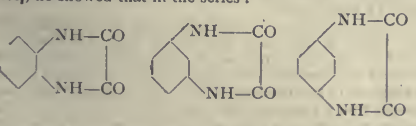
This Section was presided over by Prof. Adolf von Baeyer, Professor of Chemistry at the University of Munich, who welcomed the members of the section, and spoke a few words in memory of Bunsen; the following passage deserves to be quoted:—

"Bunsen's value as a teacher and master lay not so much in the lectures he delivered as in the example he set. He was always working himself, and worked in the presence of his pupils."[1]

Prof. Wislicenus, sen., was elected president for the first day, and won general approval by keeping the speakers strictly to the twenty-minute time limit.

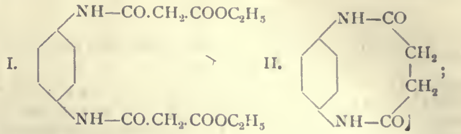
The proceedings were opened by Prof. van t' Hoff (Berlin), who showed that the formation of the Stassfurt salt beds by the evaporation, at 25° C., of a solution of common salt, borates, and calcium and magnesium sulphate and chloride, could be graphically represented on a diagram.

Richard Meyer gave an account of his experiments on the condensation of aromatic diamines with dibasic acids of the oxalic series; he showed that in the series:



the ortho-derivative alone was stable; further, that with malonic ether an amino acid ether (I.) was obtained, but with succinic ether a ring (II.)

[1] This seems an important pronouncement in view of the disputed question of the efficacy of private-research rooms as compared with large laboratories.



the difference being possibly due to the greater length of the succinic acid chain lessening the tension.

Dr. H. Stobbe (Leipsig) described the condensation products of benzaldehyde with succinic ether, and showed that such a body as dibenzal succinic acid

$$\begin{array}{l} C_6H_5.CH=C—COOH \\ \qquad\qquad\quad | \\ C_6H_5.CH=C—COOH \end{array}$$

which yields a colourless anhydride is converted by means of iodine into a stereoisomeric acid giving a bright yellow anhydride.

Dr. Krämer (Berlin) advanced certain views as to the formation of petroleum by the decomposition of diatoms; he found that the wax contained in diatomaceous mud consisted largely of decane.

In the subsequent discussion a geologist pertinently remarked that though it was possible that petroleum was formed to a certain extent in this way, yet much larger quantities must be formed by the decomposition of fish and marine animals generally; in confirmation of the animal origin of petroleum he mentioned the fact that many fossil bivalves contained, on opening, drops of oil; he also suggested that the oil in the Caucasus was formed to some extent by the large number of fish that were killed yearly by passing from the fresh water into the strong brine of the lagoons.

The animal origin of petroleum was acknowledged by all speakers.

J. Tafel followed with a paper on the course of electrolytic reduction. The experiments were carried out with a solution of caffeine, and the rapidity of the reaction measured by the evolution of hydrogen at the kathode as compared with the evolution of hydrogen in a similar cell containing dilute sulphuric acid.

In order to effect reduction Tafel showed that the kathode must be of lead, and, moreover, must be coated by spongy lead, the use of a polished lead pole giving a bad result, immediately rectified by the introduction of a little lead acetate solution. The introduction of copper and the noble metals stopped the reaction, which, in the case of these metals, recovered its normal course; if platinum had been introduced, there was no recovery.

In the discussion Drs. Bodländer, Nernst and Arendt took part, the latter remarking that the anode also should be of lead.

Richard Meyer read a second paper on the thio-derivatives of the di- and tri-phenylmethane series, and the influence on the fluorescence of the substitution of sulphur for oxygen in such bodies as

$$CO\left\langle {C_6H_4 \atop C_6H_4} \right\rangle O \quad CS\left\langle {C_6H_4 \atop C_6H_4} \right\rangle O \quad CO\left\langle {C_6H_4 \atop C_6H_4} \right\rangle S\,;$$

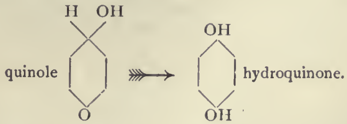
the results were, however, conflicting.

R. Schenck read a paper on the two kinds of dimorphism and their mutual relationship, describing the course of the change (in the case of para-azoanisole) from enantiomorphism to monotropism.

Dr. Bachhold (Frankfort) gave a short account of the work done by bacteria in the disposal of sewage—in one experiment he took mud from the filter-beds in July and found it to contain 14·60 per cent. of fats; on preserving this, moist, in a corked flask till November, he found it contained only 5·82 per cent. of fats; if the mud was previously dried, the percentage, naturally, did not alter.

Prof. Bamberger's (Zürich) address was of especial interest to organic chemists, and was also remarkable in introducing a new expression, which should be welcomed by chemical philologists. He used the expression "torso" to describe the molecular aggregate or residue which had been bereft, so to speak, of its limbs; thus  represents the torso of diethyl-aniline, &c.

In his paper on the mechanism of the passage of hydroxylamines into amidophenoles, he described a new class of bodies, quinoles, which only exist at a low temperature, and pass on warming into more stable isomers; thus he obtained a quinole isomeric with hydroquinone:



Prof. Lieben (Vienna) gave a general review of the properties and formation of the aldoles, introducing a new classification of these bodies, according to the ease with which they lose water—the three classes being thus graphically represented:

$$\overset{\text{I.}}{CH_3\text{—}CH(OH)\text{—}} \qquad \overset{\text{II.}}{R.CH_2.CH(OH)\text{—}} \qquad \overset{\text{III.}}{R_2.CH\text{—}CH(OH)\text{—}}.$$

Aldoles belonging to the first class split off water with difficulty, those belonging to the third class with ease.

Prof. Ramsay's address on "The Newly-discovered Gases" was delivered at a combined meeting of the Chemical and Physical Sections, and, despite the early hour at which it was given, attracted a large audience.

As full accounts of these researches have appeared from time to time in NATURE, it will suffice to state that the lecture was illustrated by Crookes' tubes, containing the gases, and to recall the analogy in the periodic system between the group formed by the new gases and the group formed by the halogens

H = 1	F = 19	Cl = 35·5	Br = 80	I = 127
Helium = 4	Neon = 20	Argon = 40	Krypton = 82	Xenon = 128

The periodic system, indeed, furnished the subject-matter for several papers in the Chemical Section, and, passing over a paper on this subject, which caused much amusement, it is interesting to note the conclusions arrived at by Prof. Brauner in his investigation of the position of the elements of the rarer earths in this system.

He considers that the position indicated by the fourth group and the eighth series must be assigned to a group of three elements.

Cerium 140, Praseodidymium 140·8, Neodidymium 143·6.[1]

This conclusion is based in great measure on the study of the higher oxides. Prof. Brauner considers that the oxides Pr_2O_4 and Nd_2O_4 belong to the oxides of the PbO_2 or ozonic type—that is to say that the metals in these oxides are tetravalent, and the oxides correspond to Ce_2O_4.

At first sight the oxides obtained by precipitation with hydrogen peroxide should belong to the second, H_2O_2, or antozonic type of oxide; Prof. Brauner found that on repeating this experiment at low temperatures the hydrates of true superoxides were formed, possessing the formula Pr_2O_5 and Nd_2O_5, and loosing oxygen with great ease.

Dr. Otto Bleier followed with a paper on "The Vapour Density of Sulphur."

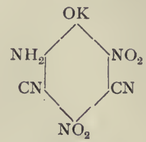
The present methods for the determination of vapour densities cannot be applied with exactitude in experiments performed in order to determine the density of sulphur vapour before the molecules have begun to dissociate.

By a new method, which combines low pressures and low temperatures, Dr. Bleier showed that, though it was impossible to reach a combination of pressure and temperature at which no dissociation of the sulphur molecule had taken place, yet at 214° and at a pressure of 4 m.m. the density of the vapour was 7·88, which corresponds to a molecule containing $7\frac{1}{2}$ atoms; it may therefore be reasonably concluded that the molecule of undissociated sulphur vapour may be represented by S_8, and not by S_6, as given in the text-books.

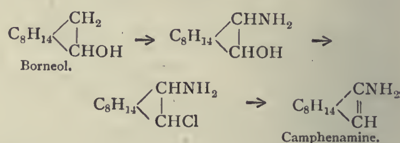
[1] The German expressions Praseodym and Neodym are less cumbersome!

Papers were also read by Dr. Staudenmeier on graphitic acid, and by Prof. S. Ruhemann on the acetylene carboxylic acids.

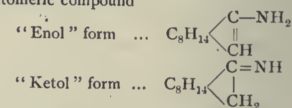
Dr. Nietzki gave the results of investigations undertaken with his pupils on isopurpuric acid, and detailed the grounds on which he assigned to the potassium salt of this acid the formula:



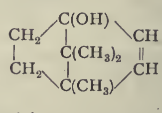
Dr. Dulden gave an account of certain researches in the camphor series. Starting with borneol, he obtained amidoborneol, and converted this body by means of phosphorus pentachloride into a substance which, with potash, split off hydrochloric acid to yield camphenamine:



This body shows a considerable analogy with vinylamine, and is a tautomeric compound



The investigator hopes to convert this base into an isomer of camphor by replacing the NH_2 group by hydroxyl; experiments in this direction have led to the isolation of a substance which appears to possess the formula:



Dr. Brauns (Giessen), in a paper on the different modifications of sulphur, described no less than seven distinct varieties. A paper of considerable interest to English chemists described the researches on colloid metals, conducted by Prof. E. von Meyer and Dr. Lattermann, the first example of a metal in this condition having been discovered by Carey Lea.

Mercury, bismuth, copper and silver were obtained in a colloidal condition by reduction of dilute solutions of their salts by means of sub-salts of tin, and subsequent precipitation of the colloid metals by ammonium citrate. Such solutions contained invariably stannic acid in a colloidal condition, and it seems probable that mercury, copper and bismuth can only exist in this state when combined with stannic acid. Colloidal silver when treated with a halogen yields a colloidal solution of the silver halide; true colloids, such as gelatine, increase greatly the stability of the above solutions, which, on the other hand, are immediately precipitated by electrolytes.

The papers in this section were given in the original lecture theatre which Liebig built and which bears his name, and attracted an audience of 100 to 120 daily; at the British Association the morning devoted to organic chemistry did not attract a tenth of this number. The papers began at 9 a.m. and continued, with a pause of fifteen minutes, up to nearly 1 p.m.; the section resumed at 3 p.m. and sat again till 5.30 p.m.; two and a half days were occupied by the sessions of this section.

Among the chemists attending the meeting were von Baeyer, van 't Hoff, E. Fischer, Curtius, Kahlbaum, Bernsthen, Ramsay, W. H. Perkin, jun., R. Meyer, H. Stobbe, Bamberger, Brauner (Prague), Hantzsch, Lieben, Einhorn, Ostwald, Werner, J. and W. Wislicenus, Soxhlet, Staudenmeier.

OTHER SECTIONS.

In the Physiological Section Prof. Rudolf Cohn (Königsberg) described a new series of his investigations of the nature of the base obtained by the action of hydrochloric acid on albumen.

He obtained a body possessing the formula $(C_6H_{13}N)_2$, and isomeric with and similar to leucinimide, and probably possessing the constitution of dioxydibutyldiethylendiamine. The ease of the formation of such bodies may explain the occurrence of certain bases, such as spermine in the animal organism.

In the Section for Hygiene and Bacteriology an important discussion was inaugurated by Dr. Czaplewski on the method of using formaldehyde (formal, formaline) as a disinfectant.

A remarkable paper was contributed to this section by Dr. Weyl (Berlin) on the sterilisation of water by means of ozone. Water to be sterilised is pumped to the top of a tower and allowed to flow slowly over stones, meeting as it falls a current of air charged with ozone.

In one experiment with Spree water containing 80,000–90,000 micro-organisms per cc., 3000 litres of water were obtained in an hour, containing less than 100 organisms per cc.

This process appears to be also effectual in purifying peat and bog water, the solution of the iron salts of humic acid being decomposed and oxidised, and the brown colour disappearing in consequence.

The method can be advantageously used in connection with filter-beds, by which the floating organic matter is removed from the water before it is treated with ozonised air.

The cost of sterilising an average river water works out at $\frac{1}{4}$*d.* to $\frac{1}{2}$*d.* per 1000 litres; no ozone remains in solution.

In the Physical Section an interesting paper was read by Dr. Carl Linde, on the industrial uses of liquid air.

Prof. Adami's discourse, in the same section, was remarkable for demonstrating the possibility of constructing dynamos and galvanometers at the cost of a few pence, and the power of performing electrical experiments with the simplest materials. It is impossible in an abstract to give any idea of the charm of Prof. Adami's manipulations.

Prof. C. Kahlbaum's (Basle) experiments on the distillation of metals showed that most metals can be distilled in vacuo, vessels of glass or porcelain being used. Very remarkable is the fact that alloys can be fractionated by this method; in one experiment the copper was quantitatively separated from the nickel in a German coin, the nickel remaining in the flask as a silvery regulus, and the copper crystallising in the receiver; such newly-distilled metals resist to a greater degree the action of atmospheric oxygen.

Prof. Ostwald's paper on periodic changes in the rate of reaction was received with some scepticism, and produced a lively discussion. It appeared that pieces of a certain block of metallic chromium, 5 kilograms in weight, and prepared by Dr. Goldschmidt, showed a remarkable property.

When such pieces were placed in dilute hydrochloric acid, the numbers of the bubbles of hydrogen evolved in equal times, and measured in a capillary tube, exhibited a constant variation; thus in equal periods of time two, four, six and eight bubbles appeared respectively, and then the series recommenced with two bubbles. This truly remarkable phenomenon was confirmed by observations reaching over many months.

Unfortunately, this was the only specimen of metallic chromium which could be obtained possessing this curious property.

All the scientific sections were invited to a meeting in the Kailnsaal, where Prof. Chun explained the exhibition of the results of the German Deep Sea Expedition.

These results confirmed in many cases the results obtained on the *Challenger* expedition, especially as to the existence of life at the greatest depth of the Antarctic Ocean.

When the explorers landed at Kerguelen they were immediately surrounded by great flocks of birds, showing no fear, and perching on the shoulder or pecking at the boots of the astonished members of the expedition.

Some of the fish found at depths of 3000 metres, to which depth naturally but little light penetrates, resembled those found in the Lias, representing a period when the atmosphere of the earth was dense, and charged with carbon; these fish were in some cases provided with special means of collecting light, being in possession of enormous eyes occupying nearly the whole side of the head, or supplied with telescopic organs; in other cases they carried their light with them on their heads, in a somewhat similar fashion to the glow-worm.

On Wednesday afternoon and on Saturday no meetings were held, and a large number of excursions were arranged, comprising visits to the lakes and watering-places near Munich, and excursion to the royal palaces and to Ratisbon.

On Thursday a gala-performance of "Lohengrin" was given at the Opera by royal command, for which every member of the Congress received a ticket.

During the whole week the picture galleries and exhibitions were open to the members at a reduced charge, and opportunities of visiting the breweries, ice-works, &c., were afforded.

The accommodation of the guests was in the hands of a special committee, who performed their difficult task to the satisfaction of every one, the prices of the rooms being especially moderate.

The next meeting of the Society will be held in September 1900, at Aachen (Aix-la-Chapelle), and, being easy of access, should attract English men of science. W. T. L.

BOTANY AT THE BRITISH ASSOCIATION.

THE President of the Section (Sir George King) delivered an address in which he gave a comprehensive sketch of the history of Indian botany. Reports were presented by the committees on assimilation in plants and on fertilisation in the Phæophyceæ. In the former investigations—conducted by Dr. F. F. Blackman (Cambridge)—the experimental work dealt with the sources of the carbon dioxide of leaf assimilation, with the respiration of the stem as distinguished from the leaf, with the magnitude of the absorption of carbon dioxide from the soil, and with kindred problems, of which a preliminary account was given by Dr. Blackman at the Bristol meeting. Mr. Lloyd Williams (Bangor) had been engaged during the past year in researches into the cytology and life-history of various members of the Phæophyceæ, including *Dictyota dichotoma*, *Halidrys siliquosa*, *Himanthalia lorea*, *Laminaria saccharina*, *Alaria esculenta* and several species of Fucaceæ.

Mr. Williams contributed a preliminary note on the life-history and cytology of *Halidrys siliquosa*, in which he dealt with the formation and liberation of the sexual cells, the striking phenomena accompanying the act of fertilisation, the segmentation of the spore, together with the cytology of the various processes. In the process of fertilisation the most important points observed were (1) the gyrating, clockwise movement of the antherozoids; (2) the long time taken to effect fertilisation—30–50 minutes as against 3–10 minutes in *Fucus*; (3) the peculiar behaviour of the egg at the moment of fertilisation, its distension and sharp rugged conical projections with beady threads emitted from their apices; (4) the subsequent restoration of the egg to its normal shape and size.

In accordance with the usual custom, Friday afternoon was devoted to a semi-popular lecture, which was this year delivered by Mr. Harold Wager, on the sexuality of the fungi. The lecturer gave an interesting and clear account, illustrated by lantern slides, of the phenomena of sexuality in the various groups of fungi.

An additional value was given to the lecture by the number of new facts dealt with by Mr. Wager; these included some new observations on fertilisation in *Peronospora parasitica* and *Polyphagus Euglenae*.

Miss Ethel Sargant gave a demonstration of vermiform nuclei in the fertilised embryo-sac of *Lilium Martagon* (*vide Proc. Roy. Soc.*, vol. lxv. p. 163, 1899).

Mr. J. C. Willis, Director of the Royal Botanic Garden, Peradeniya, Ceylon, gave an account of the research laboratory and of the facilities afforded to botanists conducting investigations in the Ceylon Gardens.

On Saturday, September 16, Mr. G. Dowker, the local secretary of Section K, whose intimate knowledge of the Kent flora made him an admirable leader, conducted a botanical excursion to Sandwich. Those who were present at the meetings of Section K will learn with sincere regret that Mr. Dowker died suddenly on Friday, September 22. The botanists present at Dover had learned in their short acquaintance with Mr. Dowker to appreciate his kindly nature and the keen interest he took in botanical work.

THALLOPHYTA.

Prof. Marshall Ward gave an account of his recent work on *Onygena equina*, a horn-destroying fungus (*Proc. Roy. Soc.*

vol. lxv., 1899, p. 158). The genus *Onygena* comprises six species, all very imperfectly known, remarkable for their growth on feathers, hair, horn, hoofs, &c., on which their sporocarps appear as drumstick-shaped bodies 5–10 mm. high. A cow's horn thoroughly infested with the mycelium of *O. equina* yielded material for the investigation; the author not only verified what little was known, but was able to cultivate the fungus, to trace its life-history, and to supply some details as to its action on horn. The development of the sporocarps, the structure, germination and biology of the chlamydospores were dealt with; also the details and development of the asci and the germination of the ascospores. Prof. Ward expressed the view that no trace of any morphological structure comparable to sexual organs could be discovered, though many points suggest the alliance of this fungus with Erysipheæ and the Truffles.

Mr. R. H. Biffen (Cambridge) presented an account of *Bulgaria polymorpha* (Wettstein) as a wood-destroying fungus. *Bulgaria polymorpha* is stated by Ludwig to be parasitic on oak. The author has examined its anatomy, and studied it in pure cultures on wood and in food-material. The white early growth soon becomes bright orange; small rounded elevations are afterwards formed, which are incipient reproductive bodies. The action on wood was examined in some detail. The fungus grows better on oak than on pine. The lignified wood-elements are de-lignified. Details as to the reactions in various stages of its destructive action are dealt with in the paper. The author does not regard the fungus as of great importance as a wood-destroying organism in this country.

Mr. A. Howard (Cambridge) described some recent work on a disease of *Tradescantia*.

During the summer it was found that two species of *Tradescantia*, growing in greenhouses, were being attacked by a fungus. Diseased leaves and stems were in many cases found to be covered with long white conidiophores. Pure cultures were made of the parasite, which proved to be a species of *Botryosporium*. Some difficulty was experienced in obtaining this form free from another fungus, a species of *Cladosporium*. It was found in the case of the naturally growing host plants that infection started either on the upper side of the leaf or from the margin. Tangential sections of the upper epidermis of the leaf, when grown in hanging drops, showed in all cases hyphæ on the epidermis, which gave rise to the same species of *Cladosporium* as that mentioned above, occurring as a weed in the *Botryosporium* cultures. The development of this *Cladosporium* was then followed out from a single spore by the hanging-drop method, and infection experiments were made which proved successful.

Prof. Potter (Newcastle) read a paper on a bacterial disease—white rot—of the turnip.

The author found in the early autumn numerous turnips, whose roots, when fully grown, became completely rotten. The rotten portion presents a white glazy appearance, and the tissues are reduced to a soft pulpy condition; the cell-walls are much swollen, faintly stratified, and separate from each other along the middle lamella. The decaying mass is infested with bacteria, but the most careful microscopic search has failed to detect any fungoid hyphæ. The rottenness can be readily introduced into a sound root by inoculation at a wounded surface; from this point the decay spreads rapidly through the root, the leaves gradually turn yellow, and in about fourteen days the entire plant has succumbed. Among the bacteria found in the rotten mass one has been isolated, which, when sown from a pure culture on turnips, under sterile conditions, induces all the characteristic effects of the "white-rot."

The bacterium, which has a single polar flagellum, was described by the author under the name *Pseudomonas destructans*. It occurs in the form of short rods about 3μ long by $\cdot 8\mu$ broad, with one polar flagellum; it rapidly liquefies gelatine, forming circular whitish colonies. The organism is parasitic on turnips, potatoes, carrots, but not on beetroot, forming a cytase.

Mr. Harold Wager gave an account of the phosphorus-containing elements in yeast. By using the method of Macallum for the determination of phosphorus in cells, which consists in the formation of a precipitate by means of a nitric acid solution of ammonium molybdate and subsequent coloration by means of the reducing agent phenylhydrazine hydrochloride, the author has been able to demonstrate that the phosphorus resides in a definite organ of the cell, which has been described as a nucleus by various observers. This affords, therefore, additional evidence in favour of the nuclear nature of the body.

¶ Prof. Ward contributed some notes on methods for use in the culture of algæ. The notes were of the nature of suggestions, the experiments being still in progress; but the author gave an account of the work in hand with a view to interest those engaged in investigations involving the cultivation of algæ.

If agar is swollen in dilute acetic acid, and then washed very thoroughly, it can be used, mixed with the necessary culture fluids, as a convenient medium for the growth of some algæ, as Beyerinck had already observed.

The author has succeeded in separating algæ by the following methods:—

The algæ are shaken up in a sterilised nutritive mineral solution, mixed rapidly with silica jelly, also sterilised, and poured into glass dishes. With species of *Oscillaria* and of *Palmella* the author has observed growth in hanging drops of this silica-jelly medium under high powers.

Another device is as follows:—Shake the algæ up in the nutritive solution and rapidly mix with sterilised plaster of paris and pour into dishes. The fixed algæ grow *in situ* in some cases, but others appear to be too sensitive for such treatment.

Experiments have also been made as follows, with some promise of success:—The algæ are shaken up in the culture medium, and a large quantity of lime-water quickly added. Carbon dioxide gas is then passed rapidly through, and the algæ are thrown down with the precipitate of calcium carbonate; this is poured into dishes as if it were plaster of paris. Perhaps this method could be utilised in the study of calcareous algæ, but with some forms it appears too drastic. One drawback is the difficulty of obviating the use of unsterilised materials.

In illustration of the application of the methods, Prof. Ward described some observations of the growth of *Oscillaria tenerrima* in hanging drops of silica-jelly. The growth of a single filament was followed for more than a week, and the curve showed that growth ceased during the hours of darkness, and was coincident with assimilation during the day. The author also obtained "light-figures" by exposing plates of green algæ, covered with stencil letters, to various intensities of daylight reflected from mirrors. When the light was not too strong, a green letter on a colourless ground was formed, but with intense illumination the exposed algæ were killed, while those in the covered area, illuminated only by diffuse light, were able to grow; the result was a colourless letter on a green ground.

Mr. W. G. Freeman (Royal College of Science) contributed a note on the *Anabaena*-containing roots of some Cycads. The author drew attention to the manner in which the roots occur on various species of Cycads growing in very poor soil in the Royal Botanic Garden, Peradeniya. In most cases a dense coralloid mass of specialised fleshy roots was found encircling the stem; in others—*e.g. Macrozamia Peroffskiana*—normal-looking lateral roots ran horizontally beneath the ground, giving off the special algæ-containing roots at intervals. These primary lateral roots may be apogeotropic for a time, but after bearing the *Anabaena*-containing masses they resume a normal habit and grow downwards.

Mr. E. J. Butler (Queen's College, Cork) communicated a note on a mixed infection in *Abutilon* roots. The roots of seedlings of *Abutilon* hybrids in the plant-houses of Queen's College, Cork, presented tuberoid enlargements due to, at least, two parasites—a Nematode and an Ascomycete. (1) The Nematode is a *Heterodera*, apparently not identical with *H. Schachtii*. All stages of the life-history were worked out by the author. (2) The Ascomycete is a new *Thielavia*, which the author named *T. Hartogii*, differing from *T. basicola* in its more abundant sporidia in each pseudo-sporangium and dark green chlamydospores. (3) A fungus, coexisting with (1) and (2), whose unseptate hyphæ, "cellulose" wall and reproductive bodies recall Peronosporeæ, has been partially studied.

PTERIDOPHYTA.

Prof. Bower read a paper on fern sporangia and spores, in which he gave an account of the results of his recent investigations described at a meeting of the Royal Society on April 20 (*Proc. Roy. Soc.*, vol. lxv. p. 96, 1899). Prof. Bower suggested the following classification of the ferns based on (1) the relative time of appearance of sporangia of the same sorus, (2) certain details of structure of the sporangium and its stalk, (3) the orientation of the sporangia relating to the whole sorus, (4) the potential productiveness of the sporangium as estimated by its spore-mother cells, and the actual spore-output.

Simplices	Marattiaceæ	Eusporangiatæ.

	Hymenophyllaceæ	
	Cyatheaceæ	
	Dicksonieæ	
	Dennstædtineæ	
Mixtæ ...	The bulk of the Polypodiaceæ	

Mr. L. A. Boodle (Jodrell Laboratory, Royal Gardens, Kew) gave an account, illustrated by numerous microphotographs, of his researches into the stem-structure in *Schizaeaceae*, *Gleicheniaceae*, and *Hymenophyllaceae*.

There is a wide difference between the types of stem-structure shown by the different members of the *Schizaeaceae*. *Lygodium* has a stele in which the xylem forms a central solid mass and is surrounded by a continuous ring of phloem, pericycle and endodermis. *Aneimia Phyllitidis* has a ring of separate bundles (or steles); *Mohria* resembles *Aneimia Phyllitidis* in type. Certain species of *Aneimia*, *e.g. A. mexicana*, have in the internodes a complete ring of xylem bounded on the inner and outer side by a ring of phloem, pericycle and endodermis, with a central pith. *Schizaea* has a ring of xylem surrounding a central pith, but no internal phloem or endodermis.

The above four genera, which make up the *Schizaeaceae*, agree in having a stem protoxylem, which is not well marked. *Lygodium*, *Aneimia*, and *Mohria* are exarch; in *Schizaea*, however, the relative position of the protoxylem has not been made out with certainty.

The *Aneimia* type (which corresponds with that of a mature *Polypodium*) may be regarded as the more specialised type among the *Schizaeaceae*, and *Lygodium* (which corresponds in structure with the base of the stem of *Polypodium*) as the more primitive type.

The *Gleicheniaceae* and *Hymenophyllaceae* also include forms with a solid central mass of xylem, but differing in some details from *Lygodium*. *Gleichenia* is mesarch and closely resembles the fossil genus *Heterangium*. In the *Gleicheniaceae* the only advance on the *Lygodium* type is found in *Platyzoma*, in which there is a ring of xylem surrounding a central pith, as in *Schizaea*, but differing from the latter plant in having an inner endodermis.

In the larger species of *Trichomanes* there is a solid xylem-mass, but with a group of parenchyma in connection with the one or two more or less centrally placed protoxylems. In *Hymenophyllum* the corresponding parenchymatous mass is large in proportion to the amount of xylem. In the smallest species of *Trichomanes* the stele of the rhizome takes the form of a collateral bundle. The protoxylem of *Trichomanes spicatum*, unlike the other species examined, resembles that of the *Schizaeaceae*.

The solid stele may be regarded as primitive, the *Aneimia* type being derived from it by the following steps:—

(1) Solid central xylem-mass surrounded by phloem, &c.

(2) Ring of xylem surrounding a central pith.

(3) Ring of xylem with internal phloem, endodermis, and pith.

(4) Ring of separate bundles formed by the breaking up of the above vascular ring, owing to large leaf-gaps.

PHYSIOLOGY.

Sir William Thiselton-Dyer described some experiments of far-reaching importance, made by Prof. Dewar, on the influence of the temperature of liquid hydrogen on the germinative power of seeds. The most important was one in which five kinds of seeds, varying in size and composition, were immersed for six hours in liquid hydrogen. The temperature to which they were cooled was $-453°$ F. below melting ice. They were subsequently sown at Kew, and germinated readily without exception (*vide Proc. Roy. Soc.*, vol. lxv. p. 361, 1899).

The bearing of the experiment on the accepted conception of protoplasm gave rise to some discussion. Protoplasm is conceived to consist of physiological molecules, the properties of which cannot be explained with our present knowledge of either physics or chemistry. They are in a state of constant kinetic energy based upon equally continual metabolic change. But if it is admitted that the latter is impossible at very low temperatures, the former must cease and the evidence of life disappears. The physiological molecule becomes purely static; its energy is wholly potential, and in fact it becomes, as Prof. Casimir De Candolle has pointed out, analogous to an explosive.

Mr. Francis Darwin described some exceedingly interesting investigations on the localisation of the irritability in geotropic organs. The seedlings of *Setaria*, *Sorghum* and some other grasses are remarkable for possessing a hypotcotyl or stalk-like part intercalated between the grain and the cotyledon. Rothert has shown that while the hypocotyl is the motor apparatus, the sensitiveness to light resides in the cotyledon, which transmits a stimulus to the hypocotyl, and this results in curvature. The author showed that the cotyledon is also a sense-organ for gravitation, the stimulus which leads to geotropic curvature being in like manner transmitted to the hypocotyl. If a seedling of *Sorghum* or *Setaria* is fixed by its grain to a support so that the hypocotyl is horizontal, it bends upwards apogeotropically till the cotyledon is vertical; it then ceases to be geotropically stimulated, and no longer transmits an influence to the region of curvature. But if the conditions are reversed, if the seedling is supported by its cotyledon (which is fixed in a horizontal position) while the hypocotyl projects freely, the result is otherwise. The hypocotyl begins to curve upwards just as in the first experiment, but it does not cease to curve when the free end points vertically upwards; the curvature continues indefinitely, so that the hypocotyl curls into a spiral of three or four rings. This can only be explained by the assumption that the geotropic sensitiveness resides in the cotyledon, and that since the cotyledon remains horizontal it continues to be stimulated and transmits a continuous influence to the motor part of the seedling.

On Saturday morning some of the members of the Botanical Section took part in a joint discussion with the Chemical Section on symbiosis. Prof. Marshall Ward introduced the subject by an able account of the meaning and significance of symbiosis, as illustrated by numerous instances of symbiosis and symbiotic fermentations afforded by various vegetable organisms. After describing particular cases of symbiosis, more particularly of symbiotic fermentations, Prof. Ward dealt with the physiology of symbiosis.

Mr. J. Parkin (Cambridge) communicated some isolated observations bearing on the function of latex.

The author has lately returned from a year's sojourn in Ceylon, where he has been acting as scientific assistant to Mr. Willis, the Director of the Royal Botanic Gardens. During his time there he has been principally engaged in investigations on caoutchouc-yielding trees, chiefly *Hevea brasiliensis* (Para Rubber) and *Castilloa elastica*, var. (a Central American rubber-tree). The results of this research are contained in a recently-published circular of the Royal Botanic Gardens, Ceylon, entitled "Caoutchouc or India-rubber," intended primarily for those interested in rubber cultivation.

The author drew attention to some of the observations and experiments recorded in the circular, which, besides their practical value, have a general botanical interest; he also recorded other observations which may throw light on the functions of laticiferous tissue.

The points treated of in the paper were grouped under six sections:—

Section I. dealt with the coagulation of the latex of *Hevea*.

Section II. contained observations and remarks relating to the carbohydrates of latex.

In Section III. reasons were given for thinking that in some caoutchouc trees the latex of the young stems and leaves differs in composition from that of the trunk and main branches. While the latter yield rubber free of stickiness, the former give a somewhat viscous substance with feeble elasticity. Such is the case with *Hevea*, *Castilloa*, *Landolphia Kirkii*, &c.

Section IV. treats of an important fact connected with the tapping of *Hevea* trees—namely, that wounding the bark causes a greater flow of latex from subsequent injuries.

In Section V. a peculiarity in the exudation of latex from the severed base of the petiole of *Hevea brasiliensis* and *Plumiera acutifolia* was described and discussed.

And in Section VI. a special laticiferous system in the immature seed of *Hevea brasiliensis* was described.

The paper concluded with general remarks and suggestions on the origin and functions of laticiferous tissue.

Mr. R. H. Biffen (Cambridge) contributed some notes on india-rubber. Caoutchouc is a constituent of the latex of many plants belonging chiefly to the Euphorbiaceæ, Apocynaceæ and Urticaceæ, that is, of plants characterised by the possession of laticiferous cells as distinct from vessels. Caoutchouc occurs as small particles in latex; if a reagent is added which will cause coagulation, the particles run together in strings and form a moss-like mass of rubber with the watery portions of the latex entangled within it. Two physical processes are now being used. (1) The latex, mixed with water, is strained and churned; the thick cream which rises to the surface is pressed through rollers and converted into rubber. (2) The author's process consists in separating the rubber with a centrifugal apparatus. Details are given in the paper regarding the chemical properties of the different kinds of rubber obtained from *Hevea*, *Castilloa*, *Manihot*, *Ficus*, *Hancornia*, *Kickxia*, *Artocarpus* and *Clusia*. The author also raises some questions of theoretical interest with regard to possible relations between caoutchouc, starch and resin-bodies, and indicates lines for further inquiry.

Flowering Plants, &c.

Mr. J. C. Willis, of Peradeniya, Ceylon, read a paper of exceptional merit, illustrated by numerous lantern slides, on the morphology and life-history of the Indo-Ceylonese Podostemaceæ.

The paper read was an abstract of a forthcoming monograph of the Indian and Ceylon species of this very remarkable order of water plants, in which the various species will be described in detail both morphologically and ecologically. A few typical species were described and their life-history explained, showing the extraordinary modifications which the vegetative system has undergone to suit the needs of life in rising and falling water and in rapid currents. The vegetative organs consist largely of modified roots forming thallus-like bodies, and bearing leafy or floral endogenous shoots, and branching themselves in an exo- or endo-genous manner. The conclusion was drawn that the endo- or exo-genous origin of an organ or a branch is a phenomenon of an adaptive nature in these plants, and to a large extent in others also. The adaptive modifications of the structure, such as the gradual reduction, through a series of forms, of the shoots and leaves, the increased multiplication of the shoots by vegetative budding, the reduction of the number of flowers per shoot, and the change to anemophily, the increased dorsiventrality and other characters, were shown to be rather correlated with the rise and fall of the water than with the velocity of the stream. In conclusion, some of the more general questions of morphology were discussed in the light of the observations made on these plants.

Prof. Douglas Campbell (California) gave a short account of work in progress on the development of the flowers and embryos of various species of Araceæ.

The materials for the author's investigations were collected mostly in Jamaica, and include species of *Dieffenbachia*, *Aglaonema*, *Philodendron* and *Anthurium*. A study was also made of *Lysichiton* of Pacific North America.

A study of the development of the ovule indicates that the primitive form is axial, as in other low monocotyledons; the early development of the embryo-sac follows the ordinary type. Later there is a multiplication of the antipodal cells, and the sac becomes filled with endosperm at an early stage. The ovule is often massive, and there is a marked development of mucilage-secreting hairs upon the funiculus and the base of the nucellus. In all forms so far examined the embryo is destitute of a suspensor, and the cotyledon is very large, sometimes suggesting the scutellum of the grass-embryo.

The forms with a single carpel are probably most primitive and most nearly related to the other low monocotyledons.

Mr. G. Dowker gave a description of the sand dunes between Deal and Sandwich, with remarks on the flora of the district.

The author in this paper gave an account of the formation of the dunes and mud-banks, claiming for them the reclamation of the large tract of sand from the sea, mostly since the Roman occupation of Britain. He referred to the Acts of Parliament passed prohibiting the destruction of the mat grass, which contributed so largely to the preservation of the hills, and lamented that nothing was done to prevent the wholesale gathering of Sea holly by men who ruthlessly destroyed it by taking it away to sell. He recounted his long experience and knowledge of the district, dating back to his schoolboy days with the Rev. J. Layton, a distinguished botanist of Sandwich. He particularised the following rare or characteristic plants as denizens of the hills: *Allium vineale*, *A. compactum*, *Poa bulbosa*, *Hippophae rhamnoides*, *Silene conica*, *Orobanche caryophyllacea*, *Lepidium latifolium*, and on the salt marshes, *Atriplex pedunculata*, *Frankenia levis*, *Aster Tripolium*, and *Polypogon monspeliensis*. The author added a list of over 300 species of flowering plants to be met with in the district.

Miss Dale (Cambridge) presented a paper on intumescences of *Hibiscus vitifolius*.

The plants on which the observations were made were grown, directly or indirectly, from seed from Somaliland. The intumescences, which vary in size and shape, occur on the leaves, stems, green parts of the flower, and on the young fruit. Some are entirely colourless; others are green at the base. On the leaf the intumescences are either purely epidermal or partly subepidermal; and on the stem the outgrowths are more complex and usually larger.

A number of seedlings were planted in separate pots, and allowed to grow under identical conditions. They all developed intumescences, and were all very much alike. When each had about nine or ten leaves, and was beginning to flower, the plants were placed under different conditions, and examined at the end of six weeks.

The experimental evidence points to the conclusion that the intumescences are pathological, and are due neither to insects nor to fungi, but to the direct effects of environment. The formation of outgrowths appears to be caused by excessive moisture combined with a high temperature. If the temperature is low the plants do not appear to have strength to form them. The production of outgrowths seems to be a response on the part of the plant to insufficient transpiration.

Fossil Plants, &c.

Prof. Bertrand (Lille) described the structure of a stem of a ribbed *Sigillaria*. The specimens of *Sigillaria* hitherto described anatomically are species with a smooth bark, but no account has so far been published of the structure of an undoubted *Sigillaria* belonging to the *Rhytidolepis* section. The species described by Prof. Bertrand exhibits external characters recalling those of *Sigillaria elongata*. The primary wood, which forms a continuous ring, agrees with that of the stems previously described as *Diploxylon*; it is enclosed externally by a zone of secondary wood. The primary xylem is characterised by the prominent ridges or points on its external face, the projecting points corresponding with the grooves on the surface of the stem. In the immediate neighbourhood of the origin of a leaf-trace, the small tracheal elements form a median band in the middle of a sinus on the face of the corona. Each leaf-trace passes outwards through a medullary ray of the secondary wood; it consists solely of primary elements. The author compared his specimen with *Sigillaria spinulosa* and with *Diploxylon* stems from Halifax, Oldham and Burntisland. The central cylinder of the ribbed *Sigillaria* differs from that of a Phanerogam in the manner of origin of the leaf-traces, and in the structure and centripetal development of the primary wood.

Prof. F. E. Weiss (Manchester) communicated a paper on a biserial *Halonia* belonging to the genus *Lepidophloios*.

At the Bristol meeting of the British Association, Dr. D. H. Scott exhibited photographs of this *Halonia* from the Hough Hill Colliery, Stalybridge, and pointed out the agreement of its structure with that of *Lepidodendron fuliginosum* of Williamson. Dr. Scott had generously allowed the author to undertake the further examination of the specimen, and this confirmed the identity of the internal structure of the *Halonia* with that of Williamson's *Lepidodendron fuliginosum*.

The same structure is shown also by stems of the ordinary multiseriate Halonias, which, as Kidston and Potonié have shown, belong undoubtedly to the genus *Lepidophloios*. Stems, therefore, showing the structure of *Lepidodendron fuliginosum*, Williamson, should be referred to the genus *Lepidophloios*.

The fruiting branches of this genus, however, termed *Halonia*, or halonial branches, have usually a number of rows of spirally arranged tubercles. The Hough Hill *Halonia* has only two rows of tubercles; hence it would by some palæobotanists be classed as Ulodendroid, but it seems better to call it a "biserial *Halonia*," since the name of Halonia has been reserved by Kidston and others for the fruiting branches of *Lepidophloios*, and also because its elevated tubercles distinguish it from the usually depressed Ulodendroid scars.

The author described two specimens of biserial Halonias showing on the surface *Lepidophloios* leaf-scars, in support of the view that the Hough Hill specimen may be regarded as a fruiting branch of *Lepidophloios*.

Mr. A. C. Seward showed some microphotographs, and gave a brief account of a new genus of Palæozoic plants.

The description of this genus, which represents a new type of Cycadofilices, was founded on a single specimen in the Binney Collection of Coal-measure Plants. The specimen consists of a small piece of stem, unfortunately without the cortical tissues, with the structure of the primary and secondary wood very clearly preserved. A strand of primary xylem, 1·9 cm. in diameter, occupies the axial region; this consists of large iso-diametric or slightly elongated tracheids with multiseriate bordered pits, associated with parenchymatous tissue; the narrow protoxylem elements occur at the margin of the primary stele, which is, therefore, of exarch structure. Surrounding the primary stele there is a broad cylinder of secondary wood exhibiting anatomical features characteristic of Cycadean stems. Leaf-traces, consisting of long tracheids intermixed with parenchyma, are given off from the periphery of the primary strand.

The features of most interest in the anatomy of this stem are (1) the manner of origin and behaviour of the leaf-traces; (2) the exarch structure of the primary xylem; and (3) the structure of the large primary tracheids. The author placed the genus among the Cycadofilices, and compared it with *Heterangium* and other Palæozoic genera, also with *Lygodium* and other recent plants.

Mr. A. C. Seward also gave a *résumé* of his recent work on the Jurassic flora of Britain. The Lower Oolite rocks exposed in the cliff-section between Whitby and a few miles south of Scarborough have long been famous as affording rich collections of fossil plants, which enable us to form a fairly accurate idea of the chief characteristics of the Jurassic flora. Plants from the Yorkshire coast are abundantly represented in most of the English museums as well as in continental collections. The Ferns and Cycadean genera constituted a large proportion of the vegetation, with an abundance of one or two species of *Equisetites* and a few conifers; no trace of undoubted Angiosperms has so far been discovered. The account of the flora includes a description of the more important types, a general comparison of the English species with recent plants, and remarks on the characteristics and distribution of the Lower Oolite floras.

The same author, in conjunction with Miss J. Gowan, gave an account of the morphology and geological history of the maiden-hair tree (*Ginkgo biloba*). The chief points dealt with in the paper may be summarised as follows:—

(1) *Ginkgo bilboa.*—The history of our knowledge of *Ginkgo;* its external features and peculiarities; the variability in form and structure of the leaves; the structure and morphology of the male and female flowers; pollination and fertilisation of the ovule; the development and structure of the embryo; the anatomy of the seedling and adult plant; comparison of *Ginkgo* with other genera, and its place in the plant-kingdom.

(2) *Fossil Ginkgoaceae.*—A general consideration of the evidence available towards an account of the past history of *Ginkgo* and closely allied plants; a comparison of *Ginkgo* with various fossil types from Palæozoic, Mesozoic and Tertiary horizons; the geographical distribution of *Ginkgo* during the Mesozoic and Tertiary epochs.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—The following is the speech delivered on November 9 by the Public Orator, Dr. Sandys, in presenting Prof. Somerville for the complete degree of Master of Arts *honoris causa*.

Agri culturae professorem nostrum primum, auspiciis optimis nuper electum, Universitatis totius nomine libenter salutamus. Salutamus virum, primum per sex annos rei rusticae experientia probatum, deinde per quinquennium scientiae studiis et domi et peregre excultum; virum non modo nomismate non uno honorifice donatum, sed etiam doctoris titulo inter Monacenses summa cum laude ornatum; virum denique et Societati Regiae Edinensi et Societati Linnaeanae Londinensi in perpetuum adscriptum. Olim inter Edinenses primus rei silvestris praeceptor, deinde in Universitate Dunelmensi agri culturae professor primus constitutus, nuper eodem cum titulo e Boreali Britanniae regione ad nos feliciter devectus est. Viri talis auxilio rei rusticae scientia, olim ab ipso Tullio senectutis inter voluptates numerata nunc demum etiam iuventutis nostrae inter studia locum diu sibi debitum sine dubio vindicabit.

Duco ad vos WILLELMUM SOMERVILLE.

Mr. Shelford Bidwell, F.R.S., has been approved for the degree of Doctor of Science.

An Isaac Newton Student in Astronomy and Physical Optics will be elected next term. The studentship is worth 200*l.* a year for three years. Candidates must be Bachelors of Arts who are under the age of twenty-five. Applications are to be sent to the Vice-Chancellor between January 16 and 26, 1900.

Prof. Somerville will give an inaugural lecture on "Some aspects of the bearings of Science and Education on Practical Agriculture" on Friday, November 24, at noon, in the Chemical Theatre.

A report proposing a new scheme for the Mathematical Tripos has been issued to the Senate. Among other changes, it suggests the abolition of the time-honoured "order of merit" in the Tripos list.

BY the will of the late Mr. Cornelius Vanderbilt, of New York, Yale University receives 100,000 dollars, and Vanderbilt University 50,000 dollars.

SIR MICHAEL HICKS BEACH, Chancellor of the Exchequer, spoke on the subject of commercial education at the Mansion House on Friday last. In the course of his remarks he referred to the University of London, and said that the reorganisation offered an opportunity to a "pious founder" to graft upon the University a faculty of commerce in which the study of all subjects belonging to commercial education shall be encouraged. He pointed out that there is no part of the world in which there are greater chances at the present time of pushing our trade and commerce than in the empire of China, and yet there is no civilised part of the world the language and history and customs of which are so absolutely unknown to the vast majority of our people. If it were possible to expend a comparatively small sum in extending a knowledge of these things in connection with a faculty of commerce in the University, more might be done to promote British trade and commerce in China than will ever be done by extracting concessions from the Government of China, many of which, the speaker added, will confer benefit upon nobody except the promoters who try to float them into companies.

THE ninth annual report of the Technical Instruction Committee of the City of Manchester shows that steady progress was made during the year ending last month. The large scale of the operations of the committee may be judged by the fact that the payments made in connection with the Municipal Technical School amounted to 16,796*l.* The expenditure on capital account to meet various charges in respect of the new building was 26,531*l.*, making a total sum of 97,061*l.* expended for this purpose up to last March. The receipts from the Exchequer Contribution Account (Customs and Excise) were 15,567*l.* and the amount raised from the rates was 7585*l.* The new estimates provide a sum of 33,000*l.* for building purposes during the current year in connection with the technical school in course of construction. The total sum now borrowed upon capital account for providing technical schools in Manchester is 140,000*l.* When the new municipal technical school is completed, Manchester will possess one of the finest buildings in the country for carrying on the work of technical education. For the equipment of the building alone a loan of 59,025*l.* has been sanctioned by the Local Government Board. Referring to the subject of secondary education, the committee remark:—"The enactment during the past session of Parliament of a measure establishing a Board of Education cannot but be satisfactory, however much it may fall short of finality, to all those who are sincerely interested in the advance on sound lines of secondary and technical education, since it creates for the first time a real and responsible Minister of Education, and unifies the various branches of education—elementary, secondary and technical—under one controlling authority. It will unquestionably promote the efficient working of the technical schools by the measures which it will take to place the secondary education of the country, now so lamentably deficient, upon a sound and satisfactory basis, without which no technical education worthy of the name can be carried on."

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, November 10.—Ordinary meeting held in the Physical Laboratory of the Central Technical College (by invitation of Prof. Ayrton).—Prof. Lodge, F.R.S., President, in the chair.—Mr. F. S. Spiers read a paper on contact electricity. The object of the paper was to determine, in a more satisfactory manner than has hitherto been attempted, the part played by the medium in the potential difference which arises when two dissimilar metals are put in contact. The first experiments were made with a piece of apparatus used by Profs. Ayrton and Perry about twenty years ago. This apparatus, in which the metals in contact are capable of a rotation of 180° about a vertical axis, and are placed between two vertical inductors connected to a quadrant electrometer, was afterwards considerably improved, and the compensation arrangement of Lord Kelvin was introduced so as to measure the potential differences by a null method. The metals first used were platinum and zinc, but on account of the low melting point of the latter metal it was replaced by aluminium. In order to try and remove the air sheets which cling to the surfaces of the metals, the tube was repeatedly heated and exhausted. The potential difference between the plates was found to gradually fall as this was done. It was proved that this was due to the oxidation of the aluminium, for on cleaning its surface the original effect was again obtained. Attempts were then made to remove the oxygen by displacing it with hydrogen; but after four washings with pure dry gas and at low pressures there was still enough oxygen left to completely oxidise the aluminium. The oxide of aluminium is not decomposed by hydrogen at a bright red heat. It was therefore decided to substitute iron and burn out the oxygen with hydrogen by encasing the lower part of the apparatus in a copper tube, and heating to bright redness with a blowpipe flame. By this means the value of the Volta effect between iron and platinum in an atmosphere of hydrogen was found to be 0·6 of a volt, the platinum being positive to the iron. This result is different both in magnitude and sign to that obtained when air is the medium. The Chairman said he had given the subject of contact electricity some attention during the last fifteen years, and the author had performed a valuable series of experiments which he should have liked to have seen done several years ago. He had always felt that a vacuum would never get rid of the condensed air films. The burning-out process used had provided the most trustworthy results upon the subject. Dr. Lehfeldt pointed out that the action of hydrogen upon ferric oxide was a limited one, and that it was impossible to bring about complete deoxidisation in that manner. At a dull red heat the ratio between the water vapour and oxygen present is about 20 to 1. Prof. Perry expressed his interest in the experiments, but said that they had not affected his opinion upon the nature of the Volta effect. Prof. Armstrong said he was not wholly satisfied with the results, although a substantial approach to a solution had been made. The author had fully realised the difficulties of the experiments, but he had treated the matter as a surface gas effect, and had not guarded against moisture. Gases must be both dirty and moist before chemical action can take place, and we cannot expect to arrive at a solution of the problem until we have removed not only oxygen but dirt and moisture. It is impossible to completely exhaust the apparatus, and a number of molecules must always be left which is more than necessary to produce the Volta effect. Moisture can never be got rid of by exhaustion. The method of Dewar of using liquid oxygen or liquid hydrogen would get rid of gases and water vapour, and in this manner it would be possible to perform experiments which could be regarded as final. If the effect disappeared at low temperatures it might be urged that the temperature was too low for it to be produced. The author must have been dealing with combination effects, for it had been proved that hydrogen alloyed both with platinum and iron at a dull red heat. Mr. Cooper said he would like to see the experiments repeated after precautions had been taken to remove nitrogen from the apparatus. Prof. S. P. Thompson said he had recently taken part in a discussion upon the subject with some earnest followers of the old contact theory. They uphold that the property of metals which determines the potential difference when two are put in contact is as fixed and definite as other physical properties, such as density, and that the potential difference observed in air is approximately the same as the true potential difference. It has been agreed to call the former the apparent potential difference. Prof. Thompson said that according to Pellat the real Volta effect was near to the effect observed in air. In circuits formed of metals there are other electromotive forces of the order of a millionth of a volt. The chemical electromotive forces in a circuit are of the order of a volt. The value of the Volta effect derived from thermodynamical considerations concerning the Peltier effect is much smaller than observed chemical potential differences. If, however, we take into account not only the Peltier effect but also the Thomson effect, we will have other terms entering into the equations which may tend to give a value more nearly equal to a volt. Prof. Thompson said that in observing chemical E.M.F.s the Peltier effects did not come into the question because of their smallness compared with the value of the chemical effect. Prof. Perry pointed out that the Peltier effect was not distinct from the Volta effect, but was simply the differential coefficient of it. The Chairman said that if a circuit containing Peltier effects were treated thermodynamically as if it were a reversible heat engine, we could arrive at an equation connecting the value of the Peltier effects with the rate of change of the whole electromotive force in the circuit with temperature. The electromotive force which changed was not necessarily the Volta effect. Prof. Perry said he thought it was. Prof. Ayrton suggested that an advance might be made in the theoretical side of the question if the Chairman were to put in writing his objections to the statement that the E.M.F. concerned was the true Volta effect. The extent of the Peltier effect proves the variation of the Volta effect with temperature; but because it is small it does not necessarily follow that the Volta effect is small. Where the Volta effect is a maximum or a minimum the Peltier effect vanishes. The experimental work of the paper did not go far enough to convince him of the nature of contact electricity. Before we can hope to prove anything with respect to the two theories, we must be able to get a cyclic change of events; that is to say, we must be able to change our surfaces and media in a perfectly definite manner so as to be able at any time to return to the particular state from which we started. Prof. Everett said that as the variation in the potential difference between two metals in a medium was probably due to slow chemical action which caused the metals to become less and less susceptible, he should expect that changing backwards and forwards from one medium to another would give to the potential difference an oscillatory variation gradually becoming smaller and smaller. The Chairman said he would like to see experiments showing a cyclic effect similar to that mentioned by Prof. Ayrton. The difficulty in these experiments is to avoid chemical action. Chemical action is not necessary to get the Volta effect. The effect would be greatest in dry gas. Moisture tends to reduce the effect, and that is why its presence is unimportant. Prof. Callendar expressed his interest in the surface character of the effect and its independence of the manner in which the plates were touched. Dr. Stansfield suggested gold as a suitable metal to be experimented on because of its non-oxidisability. Mr. Spiers, in replying, referred to Dr. Lehfeldt's assertion that the whole of the oxygen cannot be removed by hydrogen. In his experiments, however, there was very little ferric oxide and a large quantity of hydrogen, and although it was possible that all the oxide was not reduced, still a large portion of it was. The experiments were to be carried on, and attempts would be made to get a cyclic effect.—A paper on the heat of formation of alloys was postponed until the next meeting.

MANCHESTER.

Literary and Philosophical Society, October 31.—Prof. Horace Lamb, F.R.S., President, in the chair.—Dr. Broadbent introduced the subject of the well at Giggleswick, known for the ebb and flow of its water, and asked whether an explanation of what is known locally as the "silver thread" could be offered by any member. The well consists of a stone cistern, at the top and back of which the water enters from the Giggleswick Scars, there being two small outlets about half-way down each side of the tank and opposite each other. Under certain conditions there appears extending through the water, from one outlet to the other, a thread apparently formed of air. Prof. O. Reynolds suggested that the phenomenon might be explained by the inflow producing a circulation of the water having its vortex parallel between the two outlets, the reduction of pressure thus permitting a passage of air from one orifice to the other.—Mr. J. Cosmo Melvill communicated a paper by Mr. Peter

Cameron, entitled "Hymenoptera Orientalia; or, contributions to a knowledge of the Hymenoptera of the Oriental zoological region. Part ix. The Hymenoptera of the Khasia Hills. Second paper."—A paper "On the question of Irish influence on early Icelandic literature, as illustrated by the Irish MSS. in the Bodleian Library," was read by Miss Winifred Faraday (communicated by Mr. F. J. Faraday).

PARIS.

Academy of Sciences, November 6.—M. van Tieghem in the chair.—Researches on the diamines: piperazine, by M. Berthelot. The heats of solution of anhydrous diethylenediamine and its hydrate are given; and also the heats of combustion and formation, and of neutralisation with hydrochloric acid.—On some characters of the diamines deduced from their neutralisation, by M. Berthelot.—Preparation and estimation of glycogen, by M. Armand Gautier. The author had observed that when a slight excess of mercuric acetate is added to an animal or vegetable extract, dilute potassium carbonate solution being added at the same time to keep the liquid neutral, the nitrogenous bodies are nearly wholly precipitated. Liver or muscle is treated with boiling water, and the liquid pressed out on cloth. The neutralised liquid is concentrated by rapid boiling to half its bulk. The exact quantity of mercury solution is then added, the precipitate separated by a centrifugal machine. The clear liquid is acidified with acetic acid and poured into alcohol, when crude glycogen is precipitated. The method is a quantitative one, 1000 grams of fresh human liver giving 20·5 grams of glycogen, and of rabbit's liver 14·0 grams. Glycogen is apparently dissolved by water, but filtration through porcelain shows that the glycogen is not really dissolved, as the whole of the sugar is found on the outside of the filter, pure water only passing through. Its copper reducing power is slightly less than that of anhydrous glucose (97·8 : 100).—On the theory of the hydraulic brake in guns, by M. Vallier.—On the mass of the cubic decimetre of water, by MM. Ch. Fabry, J. Macé de Lepinay and A. Pérot. The authors have shown in previous papers how to measure the dimensions of a quartz cube in terms of a wave-length of light as a unit of length, and now give a method for obtaining, by a photograph of the fringes, the exact deviations of opposite faces from parallelism. These curves, together with the absolute thickness at one point, give the mean thickness corresponding to the pair of faces considered. The results of measurement of the mass of water at 4° C. displaced by this cube show that the mass of 1000 c.c. at 4° is 21·4 mgr. less than 1 kilogram, showing a remarkable agreement with an unpublished result of M. Chappuis (1 kgr. − 24 mgr.) obtained by a different method.—Microphonic registration of the beat of chronometers, by M. Alphonse Berget. The apparatus described, consisting of a small Hughes microphone working a relay, gave clear curves very easily read. The method has the advantage of suppressing the personal error in reading the chronometer, and also renders it possible to apply the method of coincidences with great accuracy to the comparison of a chronometer and a pendulum. It is also possible in this way to make one chronometer govern several pendulum clocks.—On the radio-activity induced by the Becquerel rays, by M. P. Curie and Mme. M. P. Curie. A disc of an inactive substance, placed immediately over a radio-active substance (polonium or radium), acquires the property of emitting Becquerel rays, and rendering air capable of conducting. The activity so induced increases with the time of exposure to the radium, but tends to a limit. Discs of various substances were tried—zinc, aluminium, brass, lead, platinum, bismuth, nickel, paper, barium carbonate, bismuth sulphide—but the effects produced were all of the same magnitude. Experiments were made showing that these results cannot be explained by the assumption of an actual transference of the radio-active material, either as powder or vapour, but that there really exists an induced radio-activity.—Remarks by M. Becquerel on the preceding paper.—On the spectrum of radium, by M. Eug. Demarçay. As the barium chloride gained in radio-activity new rays appeared in the spectrum, which it would appear reasonable to attribute to the radiating element. In the latest specimens prepared by M. and Mme. Curie, besides the spectra of barium, platinum, lead and calcium, were fifteen new lines, the most marked being one $\lambda = 3814·7$, $4683·0$, and a nebulous band having $\lambda = 4627·4$ as a centre.—Electrical reproduction of Savart's figures, obtained by the aid of liquid layers, by M. P. de Heen.—Transformation of styrolene into metastyrolene under the influence of light, by M. Georges Lemoine. A quantitative study of this isomeric change, including the effect of the thickness of liquid layer, nature of the radiations, temperature.—On molybdenum dioxide, by M. Marcel Guichard. Pure MoO_2 can be prepared in several ways, by the action of molybdic anhydride upon ammonium molybdate, by heating ammonium molybdate alone, or by the electrolysis of fused molybdic anhydride, in all cases the final purification from unchanged molybdic anhydride being effected by washing with 10 per cent. soda solution, which gives much better results than the ammonia solution used by previous workers.—On rhamninose, by MM. Charles and Georges Tanret. Xanthorhamninose, which on hydrolysis gives ultimately rhametine, rhamnose and galactose, by careful treatment with very dilute sulphuric acid gives an intermediate sugar, rhamninose, besides galactose and rhamnose. The ferment rhamnose gives better yields of the new sugar, whose composition is $C_{18}H_{32}O_{14}$, its hydrolysis being represented by the equation

$$C_{18}H_{32}O_{114} + 2H_2O = 2C_6H_{12}O_5(\text{rhamnose}) + C_6H_{12}O_6(\text{galactose}).$$

Rhamninose is lævorotatory, $[\alpha]_D = -41°$, and melts with some decomposition at 140°. Its reducing power is one third that of glucose, and it is not fermentable by yeast. With sodium amalgam it gives rhamninite, $C_{18}H_{34}.O_{14}$, from which dulcite and rhamnose are obtained by hydrolysis. Galactonic and mucic acids are produced on oxidation by nitric acid.—Researches on the progressive development of essence of bergamot, by M. Eugène Charabot.—On a new disease of carnations, by M. Louis Mangin.—On the actual state of the volcanoes of Southern Europe, by M. Matteucci.—On the innervation of the pancreas, by MM. E. Wertheimer and L. Lepage.

AMSTERDAM.

Royal Academy of Sciences, September 30.—Prof. Van de Sande Bakhuyzen in the chair.—Prof. Beyerinck, on the production of indigo from woad (*Isatis tinctoria*). The generally accepted opinion that woad contains the glucoside indican is erroneous. The chromogene, present in all growing parts of this plant, is indoxyl C_8H_7NO in the free state. *Polygonum tinctorium* and *Indigofera leptostachya* on the other hand contain indican, which can be split up into indoxyl and sugar by a peculiar enzyme, present in the species, but absent in the woad, by certain bacteria and yeasts and by boiling with acids. The woad, as an "indoxyl plant," when exposed to the vapour of ammonia in a confined atmosphere, at once produces indigo blue, whereas *Indigofera leptost.* and *Polyg. tinct.* as "indican plants" do not become blue by the action of ammonia, the indigo enzyme being destroyed by it. "Indican plants" can, however, be converted into dead "indoxyl plants" when slowly killed by the exclusion of air, which is best performed by complete submersion in mercury. If then exposed to alkaline vapour and extracted with alcohol, which dissolves the chlorophyll pigment, they become dark blue. Indigo plants do not contain a peculiar oxydase, but produce some alkali when slowly dying in the air.—Prof. Bakhuis Roozeboom communicated the results of an inquiry, made by Dr. W. Reinders, concerning the mixture crystals of HgI_2 with $HgBr_2$. The melted mixtures of these substances solidfy into a continuous series of rhombic mixture crystals. No chemical combination takes place. The temperatures of solidification show a minimum at 59 per cent. Mol. $Hg.Br_2$. Below 127° the mixture crystals change from rhombic yellow ones into tetragonal red ones. Moreover, the transition temperature varies within a transition interval, which has been studied down to 0° partly in the optical way, partly through crystallisation of the mixture crystals out of solutions. With due allowance for the composition of the two kinds of coexisting mixture crystals, the fall of the conversion temperature is in accordance with the laws of diluted solutions. Prof. Bakhuis Roozeboom also presented, on behalf of Dr. Ernst Cohen and Dr. C. van Eyk, a paper entitled "The enantiotropy of tin (II.)."—Prof. Lobry de Bruyn presented, on behalf of Mr. H. Bijl and himself, a paper on isodialdane, a substance analogous with cane sugar. (These communications will be inserted in the *Proceedings*.)—The following were further presented for publication in the *Proceedings*: (*a*) by Prof. Bakhuis Roozeboom, on behalf of Dr. Ernst Cohen, a paper entitled, "On a new kind of transition elements (sixth kind)"; (*b*) by Prof. Kamerlingh Onnes, on methods and apparatus employed in the cryogen laboratory," and (1) on behalf of Mr. Fritz Hasenoehrl, "Die Dielektricitäts constante von verflüssigtem

Stickoxydul und Sauerstoff"; (2) on behalf of Dr. W. van Bemmelen, a paper on spasms in the earth's magnetic force. Dr. Van der Stok, correspondent of the Section, showed some seismograms and magnetograms illustrating Mr. Van Bemmelen's paper. Magnetical curves, obtained by means of a self-registering instrument, exhibit oscillations of the same kind as those observed on photographic lines produced by seismographs of various patterns, which oscillations are known as earthquake motions, pulsations and tremors. Seismographs have been in actual use for a few years only, while magnetical curves have been known for a period of about twenty years; the latter may, therefore, be considered more sufficient data for an investigation into these oscillations by statistical methods than the former. Dr. Van Bemmelen has investigated those movements of short duration, which he calls "spasms," and also the oscillations of a well-defined zigzaggy description and longer duration, viz. pulsations. In both phenomena the author has found well-marked diurnal and annual variations, but no connection between their frequency and cosmical causes can be traced. Dr. Van Bemmelen has also tried to investigate these movements by means of a very sensitive bifilar, which inquiry takes a great deal of time and trouble, because it is not possible to make this instrument self-registering, owing to the enlarged time scale and the lack of sensitiveness of the photographic paper. This inquiry by ocular observation has hitherto not yielded any definite results.—(*c*) By Prof Hubrecht, on behalf of Dr. J. F. van Bemmelen, a paper entitled "Results of a comparative inquiry into the palatine orbital and the temporal region of the skull of the monotremata."—(*d*) By Prof. V. A. Julius, on behalf of Dr. A. Smits, a paper entitled "On decreases in the tension of solution vapours at 0°." The previous experiments with the micromanometer on solutions of NaCl, KOH and sugar were repeated, and it was again found that the molecular decrease of vapour tension increased with the concentration. The inquiry was then extended to H_2SO_4, $CuSO_4$ and KNO_3. In the case of H_2SO_4 and $CuSO_4$ the molecular decrease of vapour tension increased with the concentration; while, on the contrary, in the case of KNO_3 the decrease of vapour tension became smaller on the concentration becoming greater.—(*e*) By Prof. Cardinaal, on behalf of Mr. K. Bes, a communication concerning the formation of the ultimate equation.—(*f*) By Prof. Zaayer, on behalf of Prof. W. Einthoven, a paper on the theory of the capillary electrometer. The mechanical friction in the capillary tube and the resistance of the circuit influence both time relations of the capillary electrometer. The amount of either of these influences has been measured. The experiments show that in many capillary electrometers the influence of the resistance of the circuit is far surpassed by that of the mechanical friction. Hermann's theory of the capillary electrometer is rejected.—(*g*) By Prof. Van der Waals, on behalf of Mr. E. H. J. Cunaeus, a paper entitled "Refractivity determination as a method of inquiry into the composition of the coexisting phases in the case of mixtures of acetone and ether." The inquiry comprises, besides the determination, by Lord Rayleigh's method, of the refractivity of some mixtures of H_2 and CO_2, also the determination of the refractivity of the vapour above various mixtures of acetone and ether, in order to derive therefrom the composition of the coexisting liquid and vapour phases with the appertaining pressure.—Prof. Haga showed a negative, obtained by means of Uran-rays, yielded by the "A" preparation from de Haën's manufactory (*Wied. Ann.*, August 1899).

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 16.

ROYAL SOCIETY, at 4.30.—Note on the E.M.F. of the Organ Shock, and on the Electrical Resistance of the Organ in *Malapterurus electricus*: Prof. F. Gotch, F.R.S., and G. J. Burch.—On the Formation of the Pelvic Plexus, with especial reference to the Nervus Collector in the Genus Mustelus: R. C. Punnett.—On the Least Potential Difference required to produce Discharge through various Gases: Hon. R. J. Strutt.—Mathematical Contributions to the Theory of Evolution. VII. On certain Formulæ in the Theory of Correlation, and their Application to the Inheritance of Characters not capable of Quantitative Measurement: Prof. Karl Pearson, F.R.S.—On the Propagation of Earthquake Motion to Great Distances: R. D. Oldham.—An Experimental Research on some Standards of Light: J. E. Petavel.

LINNEAN SOCIETY, at 8.—The Comparative Anatomy of certain Species of *Encephalartos*, a Genus of the *Cycadaceae*: W. C. Worsdell.—On a Collection of *Brachyura* from Torres Straits: W. T. Calman.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.

CHEMICAL SOCIETY, at 8.—The Chlorine Derivatives of Pyridine. Part IV. Constitution of the Tetrachloropyridines: W. J. Sell and F. W. Dootson.—Contributions to our Knowledge of the Aconite Alkaloids. Part IV. On Japaconite and the Alkaloids of Japanese Aconite: Wyndham R. Dunstan, F.R.S., and H. M. Read.—On the Determination of Transition Temperatures: H. M. Dawson and P. Williams.

FRIDAY, NOVEMBER 17.

ANATOMICAL SOCIETY, at 4.—A Persistent Left Inferior Vena Cava: Stanley Boyd.—Specimen of Sacculated Œsophagus: Miss Stoney.—Child's Skull, showing Parietal Perforations: Prof. A. M. Paterson.—Note on the Morphology of the Biceps Flexor Cruris: Prof. B. C. Windle, F.R.S., and F. G. Parsons.—Lantern Demonstration of certain Points in the Lymphatic System of the Appendix: C. B. Lockwood.

EPIDEMIOLOGICAL SOCIETY, at 8.30.—Presidential Address on the Comparative Mortality of English Districts: Dr. Franklin Parsons.

MONDAY, NOVEMBER 20.

SOCIETY OF ARTS, at 8.—Enamelling upon Metals: H. H. Cunynghame.

TUESDAY, NOVEMBER 21.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Papers to be further discussed*: The Waterloo and City Railway: H. H. Dalrymple-Hay.—The Electrical Equipment of the Waterloo and City Railway: Bernard M. Jenkin.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—The Nature of the Arab Jinn illustrated by the Present Beliefs of the People of Marocco: Dr. E. Westermarck.

ROYAL STATISTICAL SOCIETY, at 5.—Notes on the Food Supply of the United Kingdom, Belgium, France and Germany: R. F. Crawford.

WEDNESDAY, NOVEMBER 22.

SOCIETY OF ARTS, at 8.—National Forestry: D. E. Hutchins.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—Openings for Mechanical Engineers in China: The Right Hon. Rear-Admiral Lord Charles Beresford, C.B.

CONTENTS.

THURSDAY, NOVEMBER 23, 1899.

THE APPLICATIONS OF THERMODYNAMICS TO CHEMISTRY.

Traité élémentaire de Mécanique chimique, fondée sur la Thermodynamique. Par P. Duhem. 4 vols. Vol. i. pp. viii + 299; vol. ii. pp. 378; vol. iii. pp. 380; vol. iv. pp. 381. (Paris: Librairie scientifique, A. Hermann, 1897–1899.)

PROF. DUHEM'S treatise on the thermodynamic potential is so well known that little or nothing need be said in introducing another work from the pen of the same writer dealing with thermodynamical considerations.

The study of the laws of combination and dissociation is intimately connected with that of such physical processes as evaporation, liquefaction and solution. To this subject the not over-appropriate title of "chemical mechanics" (*mécanique chimique*) has been given in France. While Berthollet sought an explanation of the fundamental phenomena in the laws of motion combined with the Newtonian hypothesis of molecular attractions and repulsions, Sainte-Claire Deville referred the principles of "chemical mechanics" to thermodynamical considerations, and thanks to the labours of Hortsmann, Moutier, Gibbs, Helmholtz and a large number of other physicists, there has sprung up that wide field of investigation which has given the present book its title of "chemical mechanics founded on thermodynamics," or more briefly, chemical thermodynamics.

It is not with special applications alone that Duhem deals. The greater portion of the first volume and part of the second are occupied with thermodynamics proper, and constitute, to our mind, the best treatise on thermodynamics that we have seen. An introductory section contains a summary of the more important mathematical and dynamical theorems and principles required at the outset, and this should be helpful to students.

In his preface the author calls attention to the great difficulty of giving a perfectly rigorous and logical exposition of the laws of thermodynamics, and claims only to have attained the degree of precision usually adopted in treatises on physics. A comparison of Duhem's work with the heterogeneous mixtures of experimental results, mathematical formulæ and veiled assumptions which commonly have to do duty as text-books on thermodynamics, will show that the author has really advanced a long way in making the subject clear and intelligible. No better illustration of this can be cited than the careful precautions taken to avoid premature assumptions with regard to thermometric scales in the treatment of perfect gases. In these days of widespread education in "general elementary science" such terms as "a perfect gas" and "absolute temperature" bid fair to become by-words; but how many B.Sc.'s either of London or of our provincial universities can give correct definitions of them? If this point were tested, we venture to predict that in the vast majority of cases the first term would be defined by reference to the second, and the second by reference to the first, and if the circular nature of this reasoning were pointed out, the graduate under examination would have to take refuge in considerations respecting molecules, about whose nature and mode of motion he knew nothing. Moreover, apart from Charles's law and the difficulties connected with it, comes the question as to whether or not the definition of a perfect gas is to include Clausius's hypothesis as to the constancy of one (and therefore both) of the specific heats. Here again the question is considered most explicitly.

Another feature of Duhem's treatment is that while the old familiar p, v, t trio receives full consideration, generalised coordinates are introduced from the very outset, and the significance of such coordinates is explained by illustrative examples as far as possible. To one feature, however, we must take exception, and that is the retention in Duhem's equations of the useless E (synonymous with the English J) standing for the "mechanical equivalent of heat," as it was once, and unfortunately often still is, called. This quantity is nothing more or less than the work measure of the specific heat of water at a certain temperature, and the equations of thermodynamics in no way depend on the specific heat of water. The absolute unit of heat is the unit of work, and with this unit E must be replaced by unity. As Prof. Poynting remarked in his address to Section A at Dover, "the real superiority of the work measure of specific heat lies in the fact that it is independent of any particular substance, and there is nothing whatever hypothetical about it."

In this respect the work unit of heat stands on a much more rational footing than the universally adopted dual systems of so-called "absolute units" of electricity and magnetism, which are not independent of the medium, and whose dimensions moreover are incompatible.

As regards Duhem's two chapters on stability, we can only wish they had been before us when first learning thermodynamics, as we should have been saved the trouble of thinking out for ourselves conclusions similar to those here expounded, after vainly attempting to follow the arguments of the text-books and to apply them to a Tripos rider; now the whole matter appears before us in a clearer light than it ever did previously.

The last part (Book ii.) of volume i. deals with false equilibria and explosions. By "false equilibria" (*faux équilibres*) are meant states of equilibrium which can be realised experimentally, although the conditions of equilibrium of conventional—or, as Duhem calls it, "classical"—thermodynamics are not satisfied. They are analogous to the equilibrium of rough bodies in statics, in configurations which, in the absence of friction, would have been impossible. This analogy has led, in Duhem's hands, to the development of an extremely elegant mathematical theory of false equilibria and explosions based on the introduction of a function which the author calls the "friction" (*le frottement*) of the system. This function is entirely distinct from that which represents viscosity, but when it is introduced into the equations of the system, along with the thermodynamic potentials, Clausius's inequality for irreversible cycles $\int dQ/T > O$ is satisfied. In a diagrammatic representation, the line of true equilibrium is bordered on either side by a region of false equilibrium. When the

E

representative point just falls outside this region the conditions required for the occurrence of an explosion admit of a simple geometric interpretation.

In the second volume, Book iii. deals with change of state, dissociation, and the triple point; much of the latter matter will be familiar to those who have read the author's "Thermodynamic Potential." Book iv. deals with the critical point, the principle of James Thomson, Van der Waals's and allied formulæ, and the principle of corresponding states, specific heats of fluids, and adiabatic expansion of vapours. Book v. treats of dissociation in mixtures of perfect gases. In the third volume, Book vi. deals with the thermodynamic potentials of a homogeneous mixture, solution, osmotic pressure, the hypotheses of Van 't Hoff and Arrhenius, and the law of Guldberg and Waage. Book vii. contains a full investigation of the general problem of solution, the chapter dealing with double salts being of much interest, especially the graphical representations. In the fourth volume Book viii. is devoted to the consideration of double mixtures, including the thermodynamic theory of distillation, while an account of Willard Gibbs's theory of the statics of heterogeneous systems in Book ix. concludes the treatise. In this last book the law of phases is established, and the different degrees of variance of a system are considered separately, actual instances of the systems in question being cited. A separate chapter is devoted to the properties of univariant and bivariant systems. As Duhem points out, the whole of this theory is based on "classical" thermodynamics where "friction" is left out of account, as is also capillary action.

The treatise, taken as a whole, shows what vast progress has been made in expressing the laws of mixture, combination, dissociation, and chemical transformation generally, in terms of a single potential function of generalised coordinates, and thus placing chemistry and chemical physics on a similar footing to dynamics. The essentially mathematical treatment is not the least valuable feature of Duhem's work. Thermodynamics is quite as capable of being regarded from a purely mathematical standpoint as dynamics or hydrodynamics, but hitherto its mathematical aspect has not been exhibited so prominently as it ought to be. The inclusion of descriptions of details of experiments would have broken the continuity of the theory, and such details can be far better studied in the original papers to which abundant references are given in footnotes. Indeed, the present work appears to be in many respects a model of what such a treatise ought to be. In any special problem certain hypotheses are first made; these should be clearly pointed out, and attention specially drawn to them. From these hypotheses certain conclusions are drawn by mathematical reasoning, and lastly we have references to the evidence derived from experiment as to the accordance of these conclusions with observed facts. So long as a substance is regarded as a purely mathematical abstraction, it may be defined by any hypotheses whatever as to the form of its thermodynamic functions, and a Thermodynamics based on hypotheses convenient for purposes of calculation would possess the same interest to mathematicians as a Hydrodynamics which ignores viscosity and capillarity or a Geometry of any particular non-Euclidian space. But it would appear that the conclusions *do* largely represent, either exactly or as approximations, the results of experiment; and the subject thus assumes a physical reality.

It is difficult in writing on such a subject as the present to avoid, quite unintentionally, "smuggling" doubtful assumptions into the midst of an argument without declaring their nature. As we all know the late Clerk Maxwell was much addicted to this practice, the gaps in his reasoning having afforded fruitful material for later investigators. When we consider the variety of sources from which the subject-matter of the present treatise has been compiled, we can only congratulate the author on the measure of success he has achieved in admitting only perfectly rigorous deductions based on explicitly stated hypotheses.

We cannot close this work without some reflections as to the relative progress that has been accomplished by the two schools in explaining the properties of matter, the one by means of the thermodynamical potential, and the other by the application of dynamical principles to the individual molecules of bodies. Molecular dynamics has given us equations representing, under certain conditions, the fact that dQ/T is a perfect differential; but there is still a something we have not got to the bottom of in every kinetic theory of matter, as applied to thermodynamics. We have as yet discovered no dynamical theorem of sufficient generality corresponding to the uniqueness of temperature, or establishing the fact that under the most general possible conditions the entropy of a system tends to a maximum. The question—Can the irreversible phenomena of thermodynamics of a body of finite size be accounted for by applying the equations of a conservative and reversible dynamical system to its individual molecules without making *some* special assumptions?—has never been completely answered. To deduce the second law from the equations of the kinetic theory imposes restrictions on the systems to which the conclusion applies where no such restrictions exist in the law itself. Even the very question of applying statistical methods at all to systems of molecules endowed with the property of perpetual motion requires careful consideration, since our statistical theories are so largely based on our experience of every-day phenomena—events by their very nature irreversible. One may thus be led to wonder whether Prof. Duhem's "friction" may possibly involve the existence of some molecular property which prevents molecular motions from being represented by the equations of what in the author's own nomenclature may be styled "classical" dynamics, and which introduces irreversibility into the motions even of individual molecules.

From a mathematical point of view the theory of the thermodynamic potential has attained far greater perfection than any theories based on molecular hypotheses that have been suggested up to the present; whatever the future may bring forth is another question. While thermodynamics originated in this country from the discoveries of Joule, it now hardly receives so much attention from Englishmen as it deserves. Prof. Duhem's treatise, by showing the wide range of phenomena which come under its scope, even omitting (as he does) thermo-electric phenomena and thermo-elasticity, cannot fail to attract students to this fascinating branch of mathematical physics. G. H. BRYAN.

THE CONTINUITY OF THE ERYTHREAN RIFT VALLEY.

Seconda Spedizione Bottego. L'Omo. Viaggio d'Esplorazione nell' Africa Orientale. By L. Vannutelli and C. Citerni. Pp. xvi + 650; 11 plates, 9 maps, and numerous illustrations. (Milano: Hoepli, 1899.)

THE Erythrean Rift Valley has been proved continuous across forty degrees of latitude from the Jordan to the south of Kilima Njaro, except for a possible break of about 250 miles between Lake Rudolf and the basin of the Hawash. Whether the valley is broken in that district depends on the course of the Omo and its relations to the river known as the Nianam, which flows into the northern end of Lake Rudolf. The name Omo was introduced into geography by Léon des Avanchers in 1858, for a river which drains part of the southern slope of Abyssinia, a little to the west of Menelik's capital at Addis Abeba. The river had been known long before, for it is the Zebé of the seventeenth-century Jesuit missionaries. The upper part of its course was described by Ludolf in his "New History of Ethiopia" (1681) from information supplied by the Abba Gregorius. But the lower course of the river was quite unknown. Ludolf believed that it flowed eastward and entered the Indian Ocean near Mombasa.

Bruce in the following century accepted this hypothesis and called the river the "Zebé or Quilimancy," the latter being an old name for the Ozi, a river which is a parasite of the Tana.[1]

But in the present century Frederick Ayrton and Antoine d'Abbadie claimed the Zebé as one of the head-streams of the Nile. This view was supported by Petermann, who held the Zebé to be a tributary of the Sobat, and by Bonala, who believed that it flowed into the Victoria Nyanza, and was therefore the remotest source of the Nile. Harris, McQueen, Schweinfurth and Cecchi on the contrary supported the theory that the Zebé belonged to the Indian ocean drainage, and rendered this view more plausible by identifying the Omo as one of the sources of the Juba. In 1889 and 1890 a fresh explanation was introduced by Teleki and von Höhnel's discovery of Lake Rudolf, and Borelli's descent of the Omo towards that lake, into which native rumour asserted that the river flowed. The work of these travellers seemed to disprove both the old theories; but Dr. Donaldson Smith, after his important journey to Lake Rudolf in 1895-6 again advocated the connection of the Omo and the Juba. What was known of the levels of the three rivers seemed fatal to this idea, and in a review of Donaldson Smith's book in NATURE (July 1, 1897) it was maintained that the Omo and the Juba could not be connected, and that "the Omo must continue as the Nianam and flow into Lake Rudolf."

[1] Bruce is quoted on p. 4 of the present work as having regarded the Zebé as one of the head-streams of the Nile; but that was only the view of some of his editors. Bruce himself did not reach the Zebé; he does not appear to mention it in his narrative, and his map marks it as separated from the Nile tributaries.

In order to settle this long controversy Vittorio Bottego, an explorer well known from his work in the Juba basin in 1891–2, proposed an expedition which was fitted out under the auspices of the Italian Geographical Society. Thanks to the energy of this Society, Bottego started in October 1895 from Barawa on the Somali coast at the head of a powerful caravan of four European officers, 250 natives, 120 camels, and 300 mules.

The expedition left Barawa in October 1895, and marched across Italian Somaliland, along a route parallel to the river known to geographers as the Juba. The authors, however, speak of it as the Fiume Ganana, which being interpreted is the "River River."

The first long halt was at Logh, the principal commercial centre in the Juba valley. After building a fort and a trading station at that town the expedition crossed the "Fiume Ueb" (which also means "River River"), and marched north-westward up the course of the principal tributary of the Juba. The explorers found that this river dwindled rapidly, and long before they reached its head found that it could have no connection with the Omo. Leaving the Juba basin, the expedition carefully explored Lake Abbaia, which it is proposed to call Lagho Regina Margherita, and then proceeded to its main objective the Omo. The river was reached near the point to which Borelli had tracked it from the north. Bottego, after his former expedition, inclined to the view that the Omo was one of the Nile tributaries; but after following the river for some distance westward it suddenly bent southward, became the Nianam of von Höhnel, and entered Lake Rudolf. The Omo problem was settled.

While resting in the food country at the northern end of Lake Rudolf, the expedition mapped its western shores, and collected much fresh information regarding the Reshiat, who are described under the name of the Gheleba. This interesting tribe was first described by von Höhnel. From the facts and figures given by Vannutelli and Citerni it appears probable that the people are Nilotic negroes, allied to the Njempsians, and altered by Galla intermixture.

After mapping the western shores of Lake Rudolf the expedition proceeded up the second river, which von Höhnel had described as entering the northern end of the lake. The existence of this river has, however, been denied. Bottego's party followed the river, which it is proposed to rename the Fiume Maurizio Sacchi, to the north-west; but its course is short, and the expedition climbed the water-shed into one of the tributaries of the Sobat. For this tributary the authors propose to restrict the name of Juba. They followed this river to the north-west until it left the Ethiopian highlands near its junction with the group of rivers that unite to form the Sobat. They traversed the swamps of this region to a point some forty miles from the old Egyptian station of Nassur. Having thus settled the relations of the Sobat-Juba, the expedition returned to the Abyssinian highlands on the home trail. They entered the Sajo country, which is ruled by one of Menelik's governors. Bottego sent a polite request for permission to return to Massowah either across the Amhara province around Lake Tsana, or through Shoa, or by any route which might be suggested. The expedition was invited to visit the

Abyssinian chief at Jellem, where it was received with great state; but two days later Bottego's Abyssinians were invited to desert, and in the night twelve men escaped, taking away two cases of cartridges. At daybreak the Italians found their camp surrounded; they attempted to cut their way to open country, and were attacked. They fought with desperate courage against overwhelming odds. Bottego was killed, Citerni was wounded and captured, and Vannutelli compelled to surrender. Fortunately Major Nerrazzini was then in Addis-Abeba arranging the final details of the peace which had been concluded between Italy and Abyssinia. At his intervention the two officers were promptly released, and they returned to Europe through Addis-Abeba, where they were courteously and sympathetically received by Menelik.

Meanwhile the second part of the expedition had fared as disastrously. Dr. Sacchi had left the main party at Lake Stefanie, and crossed the Borana country, intending to reach Lake Abbaia by a new route. But his party had a fight with a force of Abyssinians a little to the south of that lake. Sacchi was killed, apparently on February 7, 1897. Part of his diaries have been recovered, and they contain many interesting notes on the geology of the country traversed.

In spite, however, of these disasters, the results of the journey were of great importance, and they are admirably summarised in the present volume, which has been written by the two survivors Vannutelli and Citerni. The book is interestingly written; the incidents are graphically related; and the details are sufficiently full to be of great scientific interest. Geographically the main achievement of the expedition was the final solution of the Omo problem, and proof of the unity of the northern and southern parts of the Erythrean Rift Valley. The basins of lakes Stefanie, Abbaia and Zuai connect the well-marked depressions of Lake Rudolf and the Hawash. The atlas that accompanies the volume is not only a complete revision of the geography of the region, but contains extensive new surveys. Ethnographically, the expedition has collected much new information regarding the little-known Somali and Galla clans of the Juba country and of the mixed Nilotic-Hamitic races around the northern part of Lake Rudolf. The zoological collections, in spite of losses, were very large, and have been previously described in a series of reports by specialists, and in the present volume there is a general summary of results by Prof. Gestro.

The geological collections made by the expedition are described by d'Ossat and Millosevich, who from Dr. Sacchi's notes have been able to prepare a geological map of the Omo and Upper Juba. The meteorological records, which seem to have been very carefully taken, are edited and discussed by Dr. Peyra. The present volume is therefore not only a narrative of an adventurous expedition, but a most important contribution to the geography and natural history of Eastern Africa. It not only confirms Bottego's reputation as one of the most daring and successful of Italian African explorers, but shows him to be a man of wide scientific sympathies and attainments. His friends have at least the consolation of knowing that his life has not been laid down in vain. J. W. G.

MODERN SURGERY.

Surgery: a Treatise for Students and Practitioners. By Thos. Pickering Pick, Consulting Surgeon to St. George's Hospital. Pp. xix + 1176. (London: Longmans, Green, and Co., 1899.)

IT is always a matter of satisfaction when a senior member in any profession writes a text-book, for the seniors who have attained to a high position have had unrivalled opportunities of practice which renders their opinions of the greatest value. Mr. Pick is therefore to be highly commended for the completion of his self-imposed task. The book contains, he tells us, the substance of the lectures which he has delivered at St. George's Hospital for fifteen years, and is the outcome of his experience as a hospital surgeon and teacher of surgery for nearly thirty years. It is worthy of comparison with the world-renowned text-book of surgery written by Erichsen, which has hitherto been the most satisfactory of all the English surgical works, and it bears the comparison well, for it is written on very similar lines. Mr. Pick's treatise has the advantage of being an original work, whilst Sir John Erichsen's has been adapted repeatedly to present needs, and however skilfully such adaptations are made they lack somewhat of the savour which first gives a successful book its vogue. Mr. Pick's work, too, is contained in a single volume, whilst Sir John Erichsen's, by a process of incorporation and the requirements of successive editions, has become two bulky volumes.

Mr. Pick has brought his book to a most successful issue. It contains a clear and concise account of modern surgery, not overweighted by detail, and yet sufficiently full to be an accurate guide both to the student and to the medical practitioner who can only afford a single work in each department of his profession. Mr. Pick is old enough to have been educated in the days of suppurative surgery, but his actual practice has been carried out in the modern operating theatre and wards where antiseptic surgery reigns supreme. He is able, therefore, to contrast the old with the new systems, and one of the charms of his book is the skilful manner in which he selects the good points in the practice of the older surgeons and adapts them to the present *régime*.

Where all is good it is difficult to select one article more than another for praise, but the influence of the great surgical school attached to St. George's Hospital is perhaps best marked in the chapter on diseases and injuries of the head; whilst Mr. Pick's acknowledged eminence in connection with the surgical diseases of children, and in fractures and dislocations renders his remarks on these subjects of especial value.

The surgical pathology throughout the work is quite consonant with modern teaching, and such errors as may be present are rather errors of omission than of commission. The recent summer has shown how large a part gnat bites may play in the production of cellulitis amongst the poorer and less healthy inhabitants of towns. There is no mention of ossifying sarcoma of bone, or of Pirrie's fracture; whilst in describing the diatheses or "complexions" it would be more accurate to speak of them as being characteristic of persons predisposed to tubercle rather than of the tuberculous individual.

The sections on actinomycosis and syphilitic disease of joints might be advantageously recast and made somewhat fuller, whilst "tensing" as a synonym for "tighten," and "sorbefacient" for "causing resolution" are certainly as ugly as they are unwarranted.

The book is illustrated by 440 drawings, of which the majority have been executed by Dr. Harvey Goldsmith, some from preparations or drawings in the museum of St. George's Hospital, others from rough sketches made by Mr. Pick himself. The drawings for the most part fulfil their purpose of illustrating the text, but in Fig. 6 the veins appear to be situated external to the skin; whilst the drawings of the mocmain and lever trusses in Fig. 338 are too diagrammatic to be useful.

The book has a good index, and concludes with an appendix containing a description of the various methods of amputation. This appendix might have been rendered additionally serviceable by the introduction of a section upon prothetic appliances. D'A. P.

OUR BOOK SHELF.

Elements of Precise Surveying and Geodesy. By Mansfield Merriman, Professor of Civil Engineering in Lehigh University. Pp. 261. (London: Chapman and Hall, Ltd. New York: Wiley and Sons, 1899.)

THIS book will be useful not only to undergraduates attending Prof. Merriman's classes at the well-known Lehigh University, but to all who may be engaged in carrying out accurate or geodetic surveys. It is clearly written, methodically arranged, and well illustrated; and the problem at the end of each section seems well designed to test the student's knowledge.

In Chapter i. the laborious method of least squares is explained, and the most important processes for the comparison of observations are described. Chapter ii. deals with precise plane triangulation, the measurement of horizontal angles, the adjustment of the angles of a triangle and the computations. Chapter iii. is devoted to base lines, their measurement and reduction to sea-level. A steel tape, from 300 to 500 feet long, is recommended as a convenient apparatus for the measurement of base lines, and instances are given of the excellent results that have been obtained with it in the United States. In its favour are its portability and the moderate cost at which accuracy of measurement can be secured by its use. Chapter iv. contains useful sections on accurate levelling and the adjustment of "a level net." In Chapter v. the field operations necessary for the determination of azimuth, latitude and longitude are well described, and it may be noted that a good sextant is held to be preferable to a transit theodolite for taking altitudes of a star. In Chapter vi. there is a slight sketch of the attempts to determine the form and size of the earth from that of Eratosthenes to the measurement of the Lapland and Peruvian arcs by the French Academy. This is followed by sections on the solution of geodetic problems on the supposition, first, that the earth is a sphere, and then, Chapter vii., that it is an oblate spheroid. In the latter case Clarke's elements of the spheroid are used for the calculations. Chapter viii. deals with projections, including the polyconic projection adopted in the United States; and Chapter ix. is a brief but clear account of the various operations connected with the practical work of geodetic triangulation. In Chapter x. there are short discussions on the figure of the earth considered as a spheroid, an ellipsoid, an ovaloid and a geoid; and in Chapter xi. there are tables sufficient for the solution of the problems given in the volume.

Prof. Merriman's book contains frequent references to the valuable publications of the United States Coast Survey, which are not always easily accessible, and the American meter is used in the tables and calculations. But this does not lessen its value as a treatise on the elements of precise surveying and geodesy that may be profitably used for instructional purposes in this country. C. W. WILSON.

Experimental Science (Physiography: Section I.). By R. A. Gregory and A. T. Simmons, B.Sc. Pp. viii + 332. (London: Macmillan and Co., Ltd., 1899.)

THIS is one of the school books called into existence by the alterations which have been made by the Department of Science and Art in the syllabus for elementary physiography. A clear perception of the needs of both pupils and teachers is evident throughout, and the high standard which the authors have set themselves in previous works of a similar character is thoroughly maintained. The book is so planned that it is well adapted for the new arrangement whereby the subject may be taken in three stages, by candidates for engagement as pupil teachers, and pupil teachers in their first and second years; and it also includes most of the subjects of the Oxford and Cambridge Junior Local examinations in experimental science. Though treating a considerable range of subjects, and keeping examination requirements well in view, the book is by no means sketchy, but indicates very clearly the significance of the progressive series of experiments described. Many of the experiments are suitable for performance by the pupils themselves. The illustrations are both numerous and good.

Tito Nenci. I. Bachi da Seta. 3a edizione con note e aggiunte di Francesco Nenci. Con 47 incisioni e 2 Tavole. Pp. xii+300. (Milano: Hoepli, 1900.)

THIS is a compact little manual which seems to have first appeared in 1883, and has now arrived at its third edition. The portrait of Prof. T. Nenci forms the frontispiece, and the other plate illustrates the ventilation of a silkworm establishment. The text illustrations are good, some of them occupying a whole page. The book is divided into seven parts, dealing with the natural history of the silkworm; the "bacheria," or silkworm-breeding establishment; races and rearing; diseases of the silkworm; degeneracy and regeneration; outlay; properties of silk, &c.; and other silk-producing Lepidoptera. But the book is chiefly intended as a practical manual; and the last chapter gives little more than the names of a few of the best-known silk-producing Saturniidæ, though the cocoons of two of these are illustrated. W. F. K.

Types of British Animals. By F. G. Aflalo. Pp. xx + 290. (London: Sands and Co., 1899.)

THIS well-illustrated and very readable addition to the "Library for Young Naturalists" is likely to become a favourite with boys. Technical terms are reduced to a minimum, though room has been found for necessary explanatory paragraphs. The first eight chapters describe types of British quadrupeds and whales, and are followed by eight chapters on birds. After single chapters on British reptiles and amphibians, with six on British fishes, invertebrate life is considered in the concluding six chapters. Spiders and insects are described by Mr. C. S. Colman. The familiar and chatty style which is adopted throughout will be sure to capture a boy's attention, and eventually set him observing for himself. We hope the author's appeal to his readers to burn their catapults may prove successful, but we have our doubts. The eight full-page plates and thirty-one illustrations by Mr. Caldwell not only add to the attractiveness of the volume, but will prove useful in enabling the reader to recognise living specimens.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Stockholm International Conference on the Exploration of the Sea.

THE publication of a portion of the report of the Stockholm Conference in NATURE of November 9 (p 34) shows, I suppose, that the matter is now open for discussion by scientific men; and it is certainly desirable in that case that marine biologists and others interested in Fisheries investigation should express their opinions on the resolutions, and especially the recommendation, of the delegates. I feel sure that those gentlemen who attended the Conference and took part in drawing up the report will not consider such discussion ungracious, or that we who criticise are in any way wanting in appreciation of their labours. It is because we recognise the great importance which this report, with its series of resolutions, ought to have that we think it worth while to urge that some parts of it should receive careful re-consideration.

Although one may cordially approve of many of the resolutions passed by the delegates, still the report is certainly in some respects a disappointing document; and there is internal evidence to show that this is the result of compromises which were perhaps inevitable, but which have probably led to the omission of what might have been a valuable programme of work.

Last summer, when the arrangements for the Conference were announced, hopes ran high, and it was very naturally and confidently anticipated that the report, when issued, would contain strong recommendations to the Governments concerned involving the use of sufficient boats and men to carry out a definite scheme of biological investigation during a definite period. For surely what we need most at the present time in the interests of more exact fisheries knowledge is the nearest possible approximation to a census of our seas—beginning with the territorial waters. Most fisheries disputes and differences of opinion are due to the absence of such exact knowledge.

If anything approaching a census or a record of trustworthy fisheries statistics had been taken fifty years ago, it would now be invaluable to fisheries inspectors, superintendents and local authorities, as well as to biologists. Our successors will justly reproach us if with our increased knowledge and opportunity we let the twentieth century commence without inaugurating a scheme of practical work which will give us the desired statistics.

The Stockholm report unfortunately says nothing to the point in regard to all this. In place of asking for boats and men, it urges—in the only recommendation of the Conference (" Résolutions textuelles," p. 12, C)—the establishment of a "central bureau," in which the work will apparently in large part be that of a physico-chemical laboratory.

I hope I shall not be misunderstood in this. I do not undervalue the importance of hydrographic work in its connection with the fisheries (and I am only considering it in that connection at present) as carried on of late years, chiefly by the Scandinavians; but it is curious how in this report the obvious, primary, biological investigations are passed lightly over and the secondary physico-chemical work in the central bureau is strongly recommended. Part of the report is called a programme of work, but it contains no definite programme of biological work. I suppose it may be said, all that will be arranged in time at the central bureau, but in the meantime an opportunity is lost. If nothing but an International Committee and a central bureau is asked for, probably that (at most) is all that will be obtained, and *it is not all that is necessary.* In my opinion, what we want at the present time is not conferences, or committees, or a central bureau, so much as boats and men, *and work at sea.*

W. A. HERDMAN.

Croxteth Lodge, Liverpool, November 16.

P.S.—I see Mr. Allen's letter in to-day's NATURE. On the whole he seems to regard the report with more favour than I do; but on most points we are in agreement. It is certainly curious to omit the English Channel and the Irish Sea from an investigation in the interests of the British fisheries.

The Meteors of Biela's Comet.

WITH your permission I should like to call attention to the possibility of a return of the Andromedes meteors on or about November 23. A consideration of the period of the shower, as deduced from all its known returns, had some time back led me to the conclusion that this year was more likely to be favoured with it than last. The fact that it was not seen last year is, as far as it goes, in support of my contention. But, of course, the stream may take less than a year to pass the point of the intersection of the orbits, in which case the earth may very possibly not pass through it at this return of the meteors.

E. C. WILLIS.

South Radwello, Norwich Lodge, Ipswich.

MR. WILLIS's inference that some Bielan meteors may be visible this year seems quite in accordance with the historical facts of the stream. The parent comet was observed between 1772 and 1852, and its mean period from twelve revolutions was 6·71 years. If this also represents its mean orbital time since 1852, perihelion would occur in September 1899. But the last four observed returns from 1826 to 1852 averaged 6·62 years, which would indicate perihelion at the end of January 1899. On the whole it seems highly probable that when the earth crossed the comet's orbit in November 1898 it was too far in advance of the cometary nucleus for any meteoric shower to result. It also appears likely that at the meeting, now imminent, of the earth and cometary orbit, the former will encounter a section of the stream too far in the wake of the comet for it to be very thickly strewn with its material. However, this remains to be seen. The apparition of a fine shower of these meteors on November 23, 1892, sufficiently proves that the period of thirteen years intervening between the rich displays of 1872 and 1885 did not exactly represent two returns of the same part of the meteoric group. In 1872 the earth passed through a section of the stream following the comet, while in 1885 it encountered a part preceding the comet. Intervals of twenty years (equivalent to about three periodical revolutions of the comet) seem favourable to recurrences of the meteoric shower as it was observed in 1798 and 1838 (including two periods of twenty years) and in 1872 and 1892. I think the next brilliant return of the meteors will certainly occur in 1905, and that a minor display is very likely to be visible in 1899. If so, the meteors will appear in the early evening of November 24 next, the longitude of the node being 242°·2.

According to the investigations of Schulhof and Abelmann, the planet Jupiter will greatly disturb this meteoritic stream in about March 1901 and cause a minus displacement of the node to the extent of 6°·2. This means that in 1905 the shower will make its apparition on about November 18.

November 15.

W. F. DENNING.

RECENT DEVELOPMENTS OF WIRELESS TELEGRAPHY.

THE efficiency of the system of wireless telegraphy developed by Mr. Marconi has recently been put to some striking tests, with results which are in every respect satisfactory. During the yacht races for the America Cup, descriptive reports of progress were sent by wireless telegraphy from the *Grande Duchesse*, on which Mr. Marconi had his apparatus installed; and as many as four thousand words were transmitted by this means over distances up to thirty miles in the course of a single afternoon.

The method of sending the reports of the yacht races is described by the *Scientific American* to have been as follows:—"The foremast of the *Grande Duchesse* carried an auxiliary mast of sufficient length to give the desired vertical height of 120 feet to a wire, which reached from a short yard on the mast to the table of the operating room below, on which the sending and receiving apparatus was placed. A similar wire was suspended from the foremast of the Bennett-Mackay cable steamer, which was anchored near the Sandy Hook lightship, the starting and finishing point of the races, and also from a mast at the Navesink Highlands. The cable ship and the Highlands had temporary cable connections with New York.

The *Grande Duchesse* accompanied the yachts over the course, and the momentary details of the race, as observed from her decks, were flashed to the cable ship, from which they were sent over the cable to New York, and thence telegraphed throughout the world."

Before leaving the United States Mr. Marconi gave some demonstrations of his system to naval officers and technical experts appointed to report upon its value in naval warfare. With the instruments he had available, perfect communication was kept up between the cruiser *New York* and the battleship *Massachusetts* when the vessels were thirty-five miles apart; and messages were exchanged over a distance of ten miles with a torpedo boat travelling at full speed.

An even more striking demonstration of the utility of wireless telegraphy was given as we went to press last week. It appears from a letter communicated by Major Flood Page to the *Times*, that when Mr. Marconi left New York he cabled to the office of his company in London that he would speak to the Needles from the steamship *St. Paul* on their arrival in English waters. The vessel was expected to pass the Needles about 10 or 11 o'clock on Wednesday morning, and Major Flood Page arrived there on the previous evening, when all arrangements for communication were made. On Wednesday morning, he writes:

"We sent out our signals over and over again, when, in the most natural and ordinary way, our bell rang. It was 2.45 p.m. 'Is that you, *St. Paul?*' 'Yes.' 'Where are you?' 'Sixty-six nautical miles away.' Need I confess that delight, joy, satisfaction swept away all nervous tension, and in a few minutes we were transcribing, as if it were our daily occupation, four cablegrams for New York, and many telegrams for many parts of England and France, which had been sent fifty, forty-five, forty miles 'wireless,' to be despatched from the Totland Bay Post Office."

Upon the vessel itself a *Transatlantic Times* was printed by the ship's compositor, and the subjoined extract from this novel newspaper is of interest in connection with that given above:

"Through the courtesy of Mr. G. Marconi, the passengers on board the *St. Paul* are accorded a rare privilege—that of receiving news several hours before landing. Mr. Marconi and his assistants have arranged for working the apparatus used in reporting the yacht race in New York, and are now receiving despatches from their station at the Needles. War news from South Africa and home messages from London and Paris are being received. The most important despatches are published on the opposite page. As all know, this is the first time that such a venture as this has been undertaken. A newspaper published at sea with wireless telegraph messages received and printed on a ship going 20 knots an hour! This is the 52nd voyage eastward of the *St. Paul*. There are 375 passengers on board, counting the distinguished and extinguished. The days' runs have been as follows:—November 9, 435; November 10, 436; November 11, 425; November 12, 424; November 13, 431; November 14, 414; November 15, 412; 97 miles to Needles at 12 o'clock, November 15. Bulletins:—1.50 p.m. . . .—. First signal received, 66 miles from Needles. 2.40.—'Was that you, *St. Paul'?* 50 miles from Needles. 2.50.—Hurrah! Welcome home! Where are you? 3.30.—40 miles. Ladysmith, Kimberley, and Mafeking holding out well. No big battle. 15,000 men recently landed. 3.40.—At Ladysmith no more killed. Bombardment at Kimberley effected the destruction of one tin pot. It is felt that period of anxiety and strain is over, and that our turn has come. 4.0.—Sorry to say the U.S.A. cruiser *Charleston* is lost. All hands saved."

In addition to the messages above-mentioned, the *Times* states that passengers availed themselves of the instruments to send greetings to friends in England and America, and when the *St. Paul* was forty miles from shore in one case arrangements were completed by a passenger for a supper party in town upon the night of the arrival of the American Line express at Waterloo Station.

This interesting development of wireless telegraphy solves the problem of the communication of a ship with the shore, so far as ocean-liners are concerned; for there should be no difficulty in installing the necessary apparatus, or in training officers to work it. Now that such results have been obtained, advantage should be taken of the system as a means of communication whenever opportunity affords.

SOME RECENT WORK OF THE MARINE BIOLOGICAL ASSOCIATION.

ONE of the most important tasks which can be undertaken by the staff of a sea-side laboratory is the exact description of the relations between the fauna of the neighbourhood and the external conditions. Excellent anatomical work can be performed, as it is habitually performed in all the various marine stations which now exist, by naturalists who are unable to live continuously at the sea-side. In many cases a short visit to a suitable locality will enable an anatomist, aided by the knowledge and experience of skilled residents, to collect in a short time material for the most complete study of a species from the anatomical point of view. But many complicated problems connected with the breeding of marine animals, and others, equally complex, which arise from even the most superficial study of their distribution, can only be solved by continued observation extending in many cases over years; and such observations can only be conducted by resident naturalists, with the resources of a properly equipped laboratory at their command.

It is well known that officers of the Marine Biological Association have for years been engaged in the study of questions connected with the breeding of fishes and other marine animals. The last number of the Association's *Journal* contains a report of some 180 pages, illustrated by sixteen charts, which shows that Mr. Allen, the Director of the Plymouth Laboratory, is fully alive to the need for continuous and careful study of the way in which the fauna of the neighbourhood is distributed.

The report deals with the strip of sea-bottom which runs from a point just west of the Eddystone Lighthouse to the Start, at a depth of from about 28 to about 35 fathoms.

A careful description of the nature of the sea-bottom throughout this area is given, and a useful suggestion is made as to the possibility of a uniform nomenclature, by which descriptions of the character of a sea-bottom may be made more clearly intelligible than they are at present.

The bottom deposit is washed through a series of sieves, with apertures varying from 15 millimetres to 0·5 mm.; and a distinct name is given to the material which rests upon each of these sieves, if the deposit is washed through them in order. Six kinds of material are thus recognised, from "stones," which will not pass through a sieve with perforations of 15 mm. diameter, to "medium sand" which remains on a sieve with a mesh of 0·5 mm. The material which passes through apertures of 0·5 mm. diameter is separated into two portions by being shaken up in sea-water. Anything which settles in one minute is spoken of as "fine sand," anything which remains in suspension after one minute is spoken of as "silt."

When a deposit has been separated in this way into constituents of different degrees of fineness, the various constituents are dried and weighed, and the weight of each, expressed as a percentage of the total weight of the sample of deposit, is given for each locality.

This method of describing the texture of a sample of the sea-bottom is simple, and not very laborious. The general adoption of such a method would certainly make it easier than it is at present to compare descriptions by various writers.

A short geological account of the various sands and gravels obtained is given by Mr. R. H. Worth, together with a determination of the $CaCO_3$ (which in these deposits is nearly all of organic origin) in deposits of varying degrees of fineness. Several partial analyses of silts are also given.

Mr. Allen clearly appreciates the great importance of the character of the silt, which forms so large a part of the food of many creatures living on the sea-bottom, and it is to be hoped that in course of time he may be able to attempt a systematic survey of the silts in the neighbourhood of Plymouth, so as to tell us not only more about their chemical composition, but more about their physical character, and about the organisms they contain. He has already made an important advance in our knowledge by showing that "coccoliths" occur in shallow water deposits very much more frequently than has hitherto been believed; but many other organisms, such for example as the the various bacteria which exist in these deposits, are likely to be of considerable importance as part of the biological environment; and of these we know practically nothing.

Having given a detailed description of the nature of the sea-bottom at eighteen selected places in the small area dealt with, Mr. Allen gives a complete list of the species obtained at each locality as the result of a number of dredgings, together with an estimate of the relative abundance of the various species. This complicated information has been admirably digested, and it is so tabulated that the reader can see with very little trouble the relation between the abundance of any species and the character of the bottom deposits or of the fauna of adjacent localities.

The work is deliberately limited to a small area, where the conditions of life are tolerably uniform throughout, and statements are made which lead one to hope that this is only a first instalment of a more extended survey.

Every one who cares about the problems of marine zoology will hope that Mr. Allen may be able before very long to publish his promised account of the region between the thirty-fathom line and the shore, so that the relation between the littoral fauna and the fauna he has now described may be determined. As it stands, however, his work is a solid and valuable contribution to a kind of knowledge which must be largely increased before we can hope to understand the bionomics of the sea.

THE OLD RED SANDSTONE OF SHETLAND.

THOUGH abounding in ill-preserved plant remains, the Old Red Sandstone rocks of Shetland have hitherto yielded none of those characteristic fossil fishes which would enable us to compare them with rocks of similar age elsewhere in Scotland. On the general evidence of lithological features and the supposed identity of their respective floras, they have been regarded usually as a northward extension of the "Orcadian" beds of Caithness and the Orkneys. Two years ago Mr. John S. Flett, M.B., B.Sc., of Edinburgh University, was able to report that he had found certain obscure fish remains in Shetland, and, this summer, assisted by a grant from the Royal Society of London to defray the expenses of quarrying, he has succeeded in obtaining a number of undoubted fish-remains from the flag-stones of Brissay, near Lerwick. In this collection, which consists mostly of broken and detached plates, Dr. R. H. Traquair, F.R.S., has recognised fragments of an *Asterolepis* (probably a new species) and of *Holonema*, a fish new to Britain, but occurring in the Chemung (Upper Devonian) of North America. A full description of these will, no doubt, shortly be forthcoming. In the meantime, it seems certain that the fauna of these beds is distinct from any fauna of Old Red age at present known in Britain, and, until more fully investigated, its horizon remains open to question; but Mr. Flett inclines to believe that its real position will turn out to be intermediate between the John-o'-Groat's beds (the highest of the Orcadian series of the Orkneys) and the true Upper Old Red of Moray and Elgin. The genus *Asterolepis*, so characteristic of the Upper Old Red, was shown by him two years ago to occur also in the Thurso beds of the Orkneys, and the general forms of the Shetland flora would indicate a connection with the Orcadian. Nevertheless, the whole aspect of the fauna is Upper Old Red; not one of the commoner Orcadian fishes has been obtained in Shetland. An interesting problem is opened up by these discoveries, to which it is to be hoped further investigations will furnish a definite solution.

SIR J. WILLIAM DAWSON, C.M.G., LL.D., F.R.S., &c.

NEWS has been received of the death of Sir William Dawson, Emeritus Principal and Chancellor of McGill University, Montreal, and the most distinguished of Canadian geologists. He was the son of James Dawson, of Picton, a town on the northern shores of Nova Scotia, where he was born in October 1820.

Coming to this country in early youth he studied at the University of Edinburgh, and gained a knowledge of geology and allied sciences from Robert Jameson, then Regius Professor of Natural History. Returning to his native land, Dawson became Superintendent of Education in Nova Scotia from 1850 to 1853; and later on Professor of Geology and Principal of McGill College and University 1855 to 1893.

On his return to Nova Scotia he directed his attention with the greatest enthusiasm to the study of geology, for as early as 1845 we find him communicating to the Geological Society of London papers on the Coal-formation of the country. To this formation for many years he gave especial study. In company with Sir Charles Lyell he made in 1852 a detailed examination of the fine succession of "fossil forests" of the Coal-period in the cliffs of South Joggins. Together they obtained also the first remains in the Coal-measures of an "air-breathing reptile," named *Dendrerpeton*, which was found in the interior of one of the erect Sigillariæ; a single species of land-shell, *Pupa vetusta*, was found in the same situation.

Zealously pursuing his observations, Dawson was enabled to issue in 1855 his well-known work entitled "Acadian Geology: an account of the Geological Structure and Mineral Resources of Nova Scotia." A third edition of this work was published in 1878.

In 1854 he became a Fellow of the Geological Society of London, and it is noteworthy that all his leading discoveries, before and afterwards, were brought before this Society. His contributions to geological science were many, and though dealing largely with fossil plants, with footprints and impressions of various animals, he also wrote concerning the higher forms of life, and devoted much attention to the phenomena of the Glacial period.

In 1862 Dawson was elected a Fellow of the Royal Society. Two years later his name was rendered familiar to every student of geology by the announcement of the discovery of an organism in the oldest known rocks, the Laurentian of Canada. As early as 1859 Sir William Logan had expressed his opinion that traces of organic structure were to be found in Laurentian limestone; but it was not until 1864 that Dr. Dawson determined by the aid of the microscope that the structure was that of a Foraminifer. He then gave to the "fossil" the name *Eozoon Canadense*, and his opinion was strongly supported by Dr. W. B. Carpenter and Prof. T. Rupert Jones. It is needless here to refer more particularly to the controversy that took place regarding this supposed organism; suffice it to say that for many years the fossil was figured as an organism in most text-books, and was considered to be the oldest evidence of life on the earth. If we turn to Prof. Lapworth's "Intermediate Text-book of Geology, 1899," p. 182, we still find a figure of "Eozoon"; but the author remarks: "the organic nature of *Eozoön* is discredited by most geologists, and the preponderance of scientific opinion has long been in favour of regarding it as a peculiar mineral structure, imitative of the organic." Dawson himself, however, in the *Geological Magazine* for 1895, still boldly upheld the animal nature of Eozoon.

In 1881 the Council of the Geological Society awarded to Dr. Dawson the Lyell Medal, the President (Mr. Etheridge) remarking on the value of his researches on the fossil flora of the Carboniferous and older rocks of Canada. In 1884 Dr. Dawson published a series of articles, and afterwards a small volume, on the geology of Egypt and Syria, but for the most part his original contributions relate to Canadian geology.

In addition to his Acadian Geology, he was author of several other more or less popular volumes, including "Archaia; or Studies of the Cosmogony and Natural History of the Hebrew Scriptures" (1860); "The Story of the Earth and Man" (1873, and many later editions); "The Dawn of Life" (1875); "Fossil Men and their modern Representatives" (1880); "Geological History of Plants" (1888); "Relics of Primeval Life" (1897).

Dr. Dawson was appointed C.M.G. in 1881, and he was knighted in 1884 on the first occasion when the British Association paid a visit to Canada. He was elected President of the Association for the Birmingham meeting in 1886.

He died November 19, in his eightieth year. His son, Dr. G. M. Dawson, C.M.G., F.R.S., is the distinguished and energetic Director of the Geological Survey of Canada.

H. B. W.

THE LEONIDS.

THE following communications have reached us with reference to the Leonid meteors observed last week:—

MR. DENNING'S REPORT.

It may be safely said that no meteoric display was ever so generally looked for and awaited with so much interest as the one which has just occurred. That the character of it should have proved disappointing is to be regretted, and especially so after the previous failures in 1897 and 1898. The astronomical world had been eagerly anticipating the event for many months, and the curiosity of the general public had been excited by articles in the newspapers pointing out, perhaps too confidently, that the meteors would appear in such amazing numbers that the event would form one of the most striking spectacles of a lifetime. Every one therefore sat up to see the shooting stars, but all more or less failed to realise the expectations they had formed. Some people saw nothing, for clouds or fog hid the moon, stars and meteors on the nights of November 14 and 15. Others had a clearer sky and a dazzling moon, but the grand display of meteors was entirely wanting. The constellation of Leo could be distinctly seen as it rose higher in the east, but meteoric stars only shot at intervals from the familiar "sickle." We had expected that the whole firmament would be furrowed with these "Leonids," as it was in 1799, 1833 and 1866; but instead of a heavy bombardment, there was only weak, desultory firing, and when, in the grey dawn of November 16 observers discontinued their vigils, it was with a feeling of regret; moderated, however, by the knowledge that better success might attend similar efforts in 1900 and 1901.

A large number of reports have been received from observers in different parts of the country. Observations were commenced on November 6 by Prof. A. S. Herschel, at Slough, and in three hours he counted twenty-eight meteors after 14h. on that night, but there was no sign of the Leonids. On November 8 he watched for two hours after 13h. 45m., and saw seventeen meteors, but still no indication of radiation from Leo. On the same night Mr. Besley, at Clapham, watched between 10h. 55m. and 13h. 10m., and counted twenty-two meteors, including seven Taurids and possibly two Leonids.

On November 10 further observations were secured by Prof. Herschel and Mr. Besley, as well as by Mr. T. H. Astbury, at Wallingford, and by the writer at Bristol. An aggregate of seventy-two meteors was seen, including perhaps two Leonids; but it is often very difficult to identify true Leonids from the same swift, streak-leaving meteors directed from other radiants in the neighbouring region of sky.

On November 11, in two hours between 14h. 30m. and 16h. 30m., the writer at Bristol noted ten meteors, including two certain Leonids. One of these at 14h. 52m. was a well-observed foreshortened path from $158°+15°$ to $160°+12°$, and would, in combination with the other Leonid, indicate the radiant at $152°+23°$. If this position is correct the radiant would appear to be a stationary one like that of the October Orionids.

On November 12 the sky was much clouded, but on November 13, between 17h. 8m. and 17h. 50m., Mr. J. E. Clark, at South Croydon, saw nine meteors (seven Leonids). At Bristol the S.W. sky was partly clear from 17h. 15m. to 18h., and five meteors (one Leonid) were counted. At Marlborough between 17h. 20m. and 18h. 30m. twenty-one meteors (eighteen Leonids) were seen by Mr. H. Savory. At Cambridge between 17h. and 18h. 25m. twenty-three meteors were counted by Mr. Hinks.

On November 14, Mr. T. H. Astbury, at Wallingford, registered twenty-five Leonids, and saw about a dozen more between 16h. 3m. and 17h. 53m. Sir W. J. Herschel, at Littlemore, Oxford, saw ninety-eight meteors (sixty-six Leonids) during the night. At Yeovil the sky was generally cloudy, but between 17h. and 18h. 30m. six meteors were seen crossing breaks in the clouds. Both at Littlemore and Yeovil a very fine non-Leonid was seen at 17h. 40m. At Worthing, Sussex, between 15h. and 18h. more than 200 Leonids were counted by Mr. A. R. Schulz. At Cambridge four observers watching from 12h. 5m. to 16h. 35m. observed forty-five meteors. At Brighton between 14h. 30m. and 18h. twenty-eight meteors (twenty-four Leonids) were noted by Dr. R. J. Ryle.

On November 15, 16 and 17, further observations were made, but meteors fell in very moderate numbers. They appear, in fact, to have been no more numerous than on mid-November nights in ordinary years when the comet is not far from aphelion.

Reports from foreign stations may possibly modify our present views and show that a fairly bright shower was observed elsewhere and during the daytime in England. But from a few descriptions already to hand from America and various parts of Europe it appears that the meagreness of the display formed a common experience even among observers situated in widely different longitudes.

There is every reason to suppose that though the shower has managed to elude us this year it must confront us next year, and possibly in 1901. It will be remembered that there were rich displays in 1866, 1867 and 1868. The one in 1866 occurred ten months after the parent comet of Tempel had passed through its perihelion (January 11), while the shower of 1868 appeared nearly three years after the return of the comet. The latter object probably reached perihelion last spring (though it was not observed anywhere), and we are clearly entitled to expect from the great extension of the meteor stream visibly encountered from 1866 to 1868 that exhibitions of the finest kind will be presented in the two ensuing years. Whether or not the phenomenon will be favourably perceptible in England is uncertain, but it ought to be seen in one of the two years.

In 1833 there was a magnificent display. In 1866 the earth passed through a section of the orbit three months in advance of the part we encountered in 1833. There was a very rich shower in 1866, but it was nothing like the preceding one. In 1899 the earth intersected a region of the stream six months in advance of that of 1833, and where the meteors are thinly distributed. Everything supports the view that observers will not watch in vain for these meteors in 1900 and 1901.

When we consider the circumstances affecting the visibility of the Leonids, we must readily concede that it will often evade notice at a given place. In England, November nights are rarely clear and clouds may hide the meteors, or the earth may traverse the swarm at some time during the 15 hours in a day when it possibly could be seen, for from 7 a.m. to after 10 p.m. either daylight or an invisible radiant places it beyond reach. But many of us will hope to find compensation for the disappointments of recent years in observing a brilliant return of the meteors in one of the two ensuing years, and certainly before the denser region of the stream gets too far on its outward journey to aphelion.

W. F. Denning.

Cause of the Non-appearance of the Shower.

None of the Leonid meteors are visible until and unless some out of their vast number chance to plunge into our atmosphere and are extinguished after a second or two of intense brilliance. We cannot accordingly follow their motions by observations in the open sky, and can only tell where they are when we can compute where they must be. This has become possible with reference to station A in the stream, that portion through which the earth passed in 1866, and of which Adams determined the osculating ellipse as it existed in that year. Any change either in form or position which it has since undergone has been due to perturbations. The meteors occupying that portion of the stream have nearly completed another revolution since 1866, November 13. The perturbations they have suffered in the latter part of their course have been computed in Germany by Dr. Berberich, and the perturbations over the whole of the revolution have been computed in this country by Dr. Downing and the present writer, with the aid of the skilled computers of the Nautical Almanac, and at the expense of the Royal Society. These more full computations enable us to follow all the motions of this portion of the stream. It will reach its descending node, where it comes nearest to the earth's orbit, on the 27th of next January, and is accordingly at present advancing towards the earth, along an osculating ellipse of which the present form and position can be determined. This has been done, and it has been thus ascertained that the earth passed the descending node of this orbit last Thursday morning at about 6 a.m. In 1866 this orbit intersected the earth's orbit, but unusually intense perturbations have since acted on it, and have so shifted its position that the point when it pierced the plane of the earth's orbit last Thursday, and which we may call point P, lay at a disrance from the earth towards the sun which was 0·0141 of the mean distance of the sun, that is, it lay about five times farther from the earth than the moon is. A subsidiary investigation, which will shortly be published, makes it almost certain that the point P indicated above is situated within the stream which was passing the earth last Thursday. This is the only point in the stream which was passing us last Thursday of which we actually know the position; and it was at the great distance from us which is above stated.

Now comes in another consideration. A separate dynamical investigation into the conditions under which the Leonids were drawn into the solar system by Uranus, has shown that when that planet advanced along his orbit and left them behind, they found themselves moving nearly with the same speed and nearly in the same direction, but not quite. They were in fact scattered over a very small cone of dispersion. This occasioned small differences to exist between the vast elliptic orbits round the sun, upon which they then entered. Some of the meteors found themselves in planes slightly more inclined to the ecliptic than others, some started along ellipses of slightly greater ellipticity, and so on; but all when they had travelled along the inward part of their new elliptic journeys would cross the plane of Uranus's orbit (which is nearly the plane of the earth's orbit) at points which lay along the line of nodes, measured in the plane of Uranus's orbit, a line which nearly coincided with the radius of the earth's orbit, which lay along the line of nodes in the plane of the ecliptic. Hence the stream became a ribbon-shaped stream at its descending node, where the earth encounters it, the width of the ribbon lying very nearly along one of the radii of the earth's orbit. The position of this ribbon has been somewhat altered by the perturbations to which it has been exposed during the seventeen centuries and threequarters which have since elapsed. Its width accordingly no longer lies quite perpendicular to the earth's orbit. We know that the stream has this ribbon shape, but we do not know its width further than that it is considerable, nor do we know where in the width of the ribbon the point P lies whose position we have been able to determine. That we have not had one of the great Leonid showers this year conclusively proves that the part of the width of the ribbon which lies outside the point P has not been able to reach the whole way out to the earth's orbit—a distance of about 1,300,000 miles.

G. Johnstone Stoney.

Greenwich Observations.

The Astronomer Royal reported to the *Times* on the 16th inst., that the preparations made at Greenwich for observing the Leonid meteors were rendered abortive by cloud and fog on the nights of November 14–15 and 15–16. During a short break in the clouds on the morning of the 16th only 16 Leonids were noted (by four observers) in 42 min. from 5h. 34min. to 6h. 16min. A.M. November 16. No photographs could be obtained.

Report from the Solar Physics Observatory.

To take advantage of the meteor shower that was expected at the earlier part of last week, the whole staff of the Solar Physics Observatory took part in a carefully-prepared programme. The observers were divided up as follows: The six-inch Dallmeyer camera for photographing the radiant point, and a siderostat with three small cameras mounted on its polar axis for obtaining spectra were worked by Dr. Lockyer and Mr. Howard Payn, who was a volunteer. Mr. Fowler took charge of an integrating spectroscope and a small visual spectroscope mounted equatorially to examine bright trails. The large 6-inch prismatic camera was used by Mr. Baxandall and Mr. Shackleton on alternate nights, while a 9-inch prismatic reflector and another battery of small cameras was worked by Mr. Butler and Mr. James.

On all the four nights (9 p.m. to 6 a.m.) during which a watch was kept, the weather was very unfavourable, and it was only for short periods of time on Wednesday and Thursday that a glimpse of the sky was at all possible. In fact, fog and cloud seemed to alternate or combine at the expense of a clear sky. To take advantage of a clear sky at some distance from the observatory, such as at Hampstead, several volunteers took up their positions there with advantage. At the observatory itself no photograph of any meteor trail or spectrum was obtained, and it was practically only for a short period on Thursday morning that plates were actually exposed with any prospect of success. Eye observations indicated, however, that if the shower had arrived on Wednesday or Thursday, at least some trace of its presence would have been seen during the period of observation, in spite of the fog, if the display had attained anything like its grandeur of 1866.

Tuesday night was apparently very clear at Hampstead, and one of our keen amateurs reported that between 10 p.m. and 4 a.m. the next morning, there was an absolute dearth of meteors. Another observer on Banstead Downs also saw no signs of the shower, for between 2.28 a.m. and 3 a.m. on the Wednesday morning, he counted only ten meteors, and these might not all have been Leonids. Brighton had a clear sky on the morning of Wednesday, and an observer there who watched between midnight and 4 a.m. saw no evidence of a display but sixteen Leonids and a few sporadic meteors. Several other observers who observed from Hampstead Heath on the Thursday morning early also reported no shower, but simply a meteor or two.

It must be concluded therefore that the expected shower did not arrive, or rather that the earth has not passed through any very dense portion of the swarm. It may be recollected that in the two preceding Novembers the Leonids were conspicuous by their absence, and this may practically be said of the recent display.

In addition to the above reports, the communications printed below have been received :—

Mr. E. C. Willis, of Ipswich, reports as follows :

November 14 :—

Time.	Meteors seen. Leonids.	Others.	Remarks on weather.	
12 5 – 12 45	1	0	Thick mist	Moonlight.
13 0 – 13 20	0	0	Very thick mist	
14 0 – 14 25	1	0	Thick mist	
16 45 – 17 0	10	4	Fine	No moon.
17 0 – 17 15	4	1	Fine, with some cloud	
17 15 – 17 30	8	3	Fine	
17 30 – 17 45	12	6	Fine	
17 50 – 18 5	2	2	Fine, sky much lighter	

November 15.—Observed occasionally from 11h. to 18h. The clouds at times covered the entire sky, while at times they were much broken up. No meteors were seen. The conditions were such that a brilliant shower could not have passed unobserved.

November 16.—Observed from 11.40 till 12.10. The sky was mostly covered with cloud. No meteors were seen.

The following notes by the Rev. Martin Wall, Fort Augustus, N.B., have been received from the Meteorological Office :—

"Great meteor" seen at 8.20 p.m., November 15. Flying with tremendous velocity south-east to north-west. Described, by an engineer, as a mass of flame of between 2 and 3 feet square ; in brilliancy like the arc-light ; leaving a trail of flame in its course, and lighting up the sky with a white light. It was seen by a second person to explode, over hill to north-west.

[N.B.—Indoors, where the electric light was burning, the diffused light of the meteor was distinctly noticeable.]

Two or three Leonid meteors were seen on the night of November 14 (one or two at 2 a.m., and one at 5.45) ; but the 15th and 16th were totally clouded over ; hence photographic preparations were of no avail.

[N.B.—Numerous ordinary meteors were also seen on the 14th.]

NOTES.

THE scientific lessons of the war are crowding upon us. We have already referred to the blunder made by our military authorities, in not sending Marconi apparatus to South Africa among the first equipments. We now learn indeed, after the investment of Ladysmith is drawing to a close, that Marconi apparatus is being sent out. The silence of Ladysmith during the last eventful weeks will point the moral, which is not likely to be forgotten in the future ; and it may well be that in the movements about to take place, in which the Ladysmith and the relieving force should be able to work in concert, the absence of a sure and rapid method of signalling, the absence of the Marconi apparatus, may render this difficult if not impossible. We have been informed on good authority that some time ago the importance of a locomotive search-light in operations of war was strongly represented to the military authorities ; but they would have none of it. Fortunately, however, the naval force in Natal has now provided the army with one. It is certain to do good service.

THERE can be little doubt that the presence of another scientific instrument, the balloon at Ladysmith, has saved the situation. A moment's consideration of what this touch of science can do for us will indicate that the above expression is well grounded. Imagine two identical maps of Ladysmith and its surroundings, including the region dominated by our guns, carefully marked with squares, so that the position of any patch can be exactly defined by the rectangular coordinates shown at the side. A1, A20, &c., X6, Z30, Z40, &c. Imagine one of these in the hands of an officer who knows the ground thoroughly well, in the car of the captive balloon. He telephones the position of the enemy to the officer commanding the artillery down below, who is possessed of an identical map. From this he can at once determine the azimuth and range, and in a few minutes the shell may be fired in the required direction. The telephone of the balloon will inform the gunners how the shell has been dropped, and any directions regarding range can be given. It will therefore be impossible for the rebels, thanks to the balloon, to form in daylight in any large numbers for an attack on the camp, without rendering themselves liable to the searching fire of the guns. May we hope therefore that the balloon will also be used along the chief line of advance? During a calm day it is possible that this scientific instrument may be far more valuable than an army of scouts, though the difficulties attending its working are fully recognised. Seeing then how important scientific instruments are in this struggle, in which millions are freely spent, we return to our question, how is it that there is no scientific committee to advise the Government in such matters, even if only to anticipate scientific applications? and how is it that from the Grand Council of the nation, the Privy Council, men of science are rigorously excluded?

A CONFERENCE of representatives of electric railway and electric tramway enterprises on the one hand, and representatives of the Government interested in the Greenwich and Kew Observatories on the other, was held at the Board of Trade on Wednesday in last week. The object of the conference was to ascertain the best means of dealing with the interference with the delicate instruments in the observatories by the leakage which there is reason to believe will follow from the introduction of large systems of electric traction. After Sir Courtenay Boyle had opened the proceedings, Prof. Rucker and the Astronomer Royal showed that magnetic instruments are seriously affected by the proximity of systems of electric traction ; but Sir Douglas Fox and Major Cardew would not admit that any interference with observatory instruments had at present been proved. As a result, a committee was appointed "to investigate the amount of magnetic disturbance produced in the neighbourhood of electric tramways and railways constructed and worked under the Board of Trade regulations ; and to report as early as possible." The committee consists of Profs. Rucker, Ayrton and Perry, representing the laboratories ; Prof. Kennedy, Mr. H. F. Parshall, Major Cardew and Mr. Brousson, for the electric traction companies ; and Mr. A. P. Trotter for the Board of Trade.

THE Paris correspondent of the *Chemist and Druggist* makes the following announcement :—The Professorship of Inorganic Chemistry at the Paris School of Pharmacy, vacant by the retirement of Prof. Riche, has been given to M. Henri Moissan. The latter's appointment as professor of toxicology at the School, which he already held, was perhaps due more to a very natural desire to attach the brilliant professor to the teaching staff than to poisons being his *forte*. He will now lecture on the subject that has practically been his life study. His first lesson on

Thursday afternoon of last week produced quite a little ovation, M. Moissan being loudly cheered by the large number of students present. He gave a short address on the career of Prof. Riche, and touched on the subject of electro-chemistry.

THE *Cecil Rhodes*—the first iron steamer designed for service on Lake Tanganyika—was launched at Wyvenhoe on Saturday. The steamer is to be employed primarily in laying the wires of the Cape to Cairo telegraph line along the shores of the lake. After the trial trip the boat will be dismantled and taken to pieces for shipment to Chinde, on the East Africa coast, whence she will be taken up the Zambesi and Shiré rivers by the Sharrers Zambesi Traffic Company, thence by native porters through Blantyre to Mpimbo, where she will be again shipped and carried across Lake Nyassa to Karonga, and finally taken overland along the Stephenson road to the south end of Lake Tanganyika, at which point she will be reconstructed and launched for the second time.

PROF. FERDINAND TIEMANN, honorary professor of chemistry in Berlin University, died on November 7.

DR. HENRY HICKS, F.R.S., the distinguished geologist, died on Saturday last, at the age of sixty-two.

THE death is announced, at Southport, of Mr. Alexander McDougall, who was widely known about sixty years ago in connection with the invention of the atmospheric railway, and has been associated since then with a long succession of mechanical and chemical appliances of public utility.

WE regret to see the announcement of the death of Dr. Camara Pestana, chief of the Bacteriological Institute at Lisbon. It was his verdict on specimens sent to him from Oporto for examination that conclusively established the existence of the plague there in August last. Dr. Pestana caught the plague while studying it at Oporto, and his death was due to that disease.

FROM the *Cape Times* we learn with regret that Prof. Francis Guthrie, until the end of last year professor of mathematics in the South African College, died on October 19. Prof. Guthrie was a brother of the late professor of physics at the Royal College of Science, South Kensington. He was born in 1831, and went out to Cape Colony in 1861 as professor of mathematics in the then newly-established Graaff-Reinet College. In 1875 he resigned his appointment at this college, and went to Cape Town. After a brief visit to England in 1876, he was appointed to the chair of mathematics in the South African College, then vacant by the retirement of the Rev. Prof. Childe. This appointment he held for twenty-one years, retiring from it in 1898. The Council of the college marked their appreciation of his long and honourable term of service by according a pension of double the amount to which he was legally entitled. Prof. Guthrie was deeply interested in botany; and he had the advantage of attending the lectures of John Lindley, an English botanist of high reputation. In Graaff-Reinet he gave, outside the college course, a series of public lectures; and on his removal to Cape Town, took up again more assiduously his botanical pursuits. Finally, he undertook, in conjunction with his life-long friend, Mr. Harry Bolus, the enormous task of a revision of the Order of the Heaths, for the next volume of the "Flora Capensis," now in course of preparation at Kew. Into this work he threw himself with all the ardour and enthusiasm of youth, and was engaged upon it up to a short period before his death.

FELLOWS of the Physical Society, and their guests, dined together at the Hotel Cecil on Friday evening, November 17. The president of the society, Prof. O. J. Lodge, took the chair, and the guests included many distinguished men of science.

MR. STEWART CULIN, of the University of Pennsylvania, is preparing a memoir on the late Dr. D. G. Brinton, at the request of the family of the deceased anthropologist. He will be glad to receive letters and other literary materials bearing upon the subject of his memoir.

THE *British Medical Journal* states that Mr. J. W. Stephens and Dr. R. S. Christophers, members of the Royal Society expedition on malaria, have returned home, but they may possibly at a subsequent date proceed to the West Coast of Africa.

As a proof of his cordial sympathy with the cause of bird protection, the Poet Laureate, Mr. Alfred Austin, has written a special poem for the Christmas card which the Society for the Protection of Birds is issuing this year. It is entitled "Peace and Goodwill to the Birds," and is illustrated by a coloured picture of that much persecuted bird the tern, designed for the purpose by Mr. A. Thorburn.

A MONUMENT erected, by public subscription, to the memory of the lamented astronomer, M. Felix Tisserand, late director of the Paris Observatory, was unveiled at Nuits-Saint-Georges on

October 15, in the presence of a distinguished company of men of science. The accompanying illustration of the monument is given in *La Nature* with an account of the inauguration ceremony. Général Bassot, speaking on behalf of the Academy of Sciences, referred to Tisserand's scientific work. M. Poincaré spoke as the representative of the Bureau des Longitudes; M. Baillaud reminded the company of Tisserand's work at Toulouse; M. Callandreau spoke on behalf of the Société Astronomique;

M. Tannery in the name of the École Normale; M. Bigourdan for old pupils; and M. Lœwy, the director of the Paris Observatory, as the representative of the Government and the Observatory. The French delight to honour their men of intellect; but it is not often that a memorial of the kind erected to Tisserand is unveiled in honour of a man who has devoted his life to science in England.

FOUR years ago a scheme was drawn up by the late Dr. E. von Rebeur-Paschwitz for the organisation of the study of earthquakes over the whole globe. He obtained for it the support of all the leading seismologists, but his early death unfortunately delayed its execution. Prof. Gerland, on whom Von Rebeur's mantle has fallen in Germany, continues to support the scheme, and, having secured the approval of the Geographical Congress at Berlin, has issued a pamphlet in which he suggests the foundation of an international seismological society. The objects of the society would be to diffuse as far as possible the study of earthquakes in all countries, and especially in those which do not yet possess seismological stations; to create a methodical organisation of microseismic observations; and to centralise the publication of reports, which would appear in the form of supplements to the *Beiträge zur Geophysik*. It is also proposed that the Society should hold its general meeting conjointly with the International Congress of Geography.

MAJOR S. J. RENNIE describes in the *British Medical Journal* a grave case of snake-bite treated successfully with Calmette's antivenene serum. In concluding his account, he remarks: "That we have in Calmette's antivenene serum a most powerful remedy against the bites of venomous reptiles has been fully proved both in the laboratory, and also, in a few instances, in actual practice. In the year 1896 it fell to my lot to treat the first case in which this serum was used in India, and since then other successful cases have been reported. The case under consideration is, however, of especial interest, in that it proves, first, that no matter how acute the symptoms, or how far advanced the effects of the poison, it is never too late to use the antidote; for, as will have been noted, the boy, in this instance, was, to all intents and purposes, dead at one time; and, secondly, that the "antivenene" will keep for an almost indefinite period, and exposed to all vicissitudes of climate, as I had the serum used in this case in my possession in the plains of India for nearly four years."

THE annual report by the Board of Trade on their proceedings under the Weights and Measures Acts has just been issued as a Parliamentary paper. The report refers to the biennial meeting of the International Committee of Weights and Measures, which was held in Paris in April last, to consider the work undertaken at the bureau of the committee since the year 1897, and also to arrange the future proceedings at the bureau for the years 1899–1901. The committee was attended by representatives from various countries, including Great Britain, and was presided over by the president, Prof. W. Förster, director of the observatory at Berlin. The discussions at the numerous meetings of the committee, and the results of the inquiries by the committee into the administration of the bureau and the scientific investigations undertaken there by the director of the bureau, Dr. J. René-Benoît, have been published under the directions of the committee in the "Procès-Verbaux des Séances de 1899," and also in the "Travaux et Mémoires du Bureau International des Poids et Mesures." The report states that the Board of Trade are in communication with some Government departments with the view of ascertaining how far the metric system of weights and measures might be officially adopted in contracts. The Standards Department have in course of preparation, for the purpose of explaining the principles of the metric system in schools, a set of education models of metric weights, measures, and weighing and measuring instruments similar to those used in trade.

TWO papers, dealing with the construction and equipment of the Waterloo and City Railway, were read at last week's meeting of the Institution of Civil Engineers. The first paper, by Mr. H. H. Dalrymple-Hay, was devoted to a description of the general features of the line, and the methods used in its construction. The new line is one and a half miles long, and, with the exception of a short length at Waterloo, consists of two iron tunnels with a station at each end, approached by stairs and inclines. The method of tunnelling in the London clay and in water-bearing strata was the well-known Greathead system, except in the case of a short length of tunnel which was driven by a new method not requiring the employment of a heading or timbers outside the shield. The average rate of working in the small tunnels was ten feet every twenty-four hours where the tunnels were in the clay. In the larger tunnels at the City Station, which were also in the clay, six feet was completed regularly in the same time. In water-bearing strata, however, the speed varied greatly, depending upon the character of the ground and the depth of ballast and head of water at the face.

THE second paper, referred to above, by Mr. Bernard M. Jenkin, gave an account of the electrical equipment of the line, which is the second underground railway that has been built to be worked electrically. The electric energy is generated at the Power Station, at the Waterloo end of the line, by high-speed engines coupled direct to two-pole dynamos. The energy is transmitted to the trains by feeders connected to an insulated rail, or conductor, placed between the two running rails of the permanent way. Experiments and tests were made on completion of the line to ascertain the time and power taken to drive a train from one station to the other under different conditions and with different limits of speed on the sharp curves. The time in which a train could traverse the whole of the distance from one station to the other depends mainly upon the maximum speed which could be allowed on the sharpest curves. There are some very sharp curves at the bottom of the dip in the line where it passes under the river, and it was originally intended that the speed on these curves should be limited to twenty-four miles an hour. Before the line could be opened it was inspected by the Board of Trade, and Sir Francis Marindin decided to limit the speed round the sharpest curves to fifteen miles an hour instead of twenty-four miles an hour, for which the whole of the electrical equipment of the line was designed. This alteration has had naturally a very great effect on the whole working of the traffic on the line, the brakes having to be applied to the train on the down gradients, as the speed which would be attained by gravity alone would very much exceed the limit of fifteen miles an hour by the time the curves were reached. The switchback principle of working the line cannot, therefore, be adopted as it might otherwise have been with the particular arrangements of gradients and the absence of intermediate stations which is the peculiarity of the line described.

IN the few years that have intervened since the water of Niagara was first turned into the wheel-pit of the Niagara Falls Power Plant, a large number of entirely new industries have sprung up around, or within easy touch of, the power station. That the tendency is for the industries to gravitate to the power rather than the power to be transmitted to the industries is shown in an account given in the *Scientific American*, from which it appears that out of a total of 35,000 horse-power delivered from the station, over three-fourths are consumed in its vicinity, as against less than one-fourth that is transmitted to a distance—the principal long distance transmission being that of 8000 horse-power to Buffalo, for the use of the Cataract Power and Conduit Company. It must not, however, be concluded that long distance transmission will not enter largely into the ultimate utilisation of the energy of Niagara. The remarkable installation recently opened in Southern California, where a transmission of eighty-three miles has been successfully accomplished, suggests that a large part of the 7½ millions of hydraulic horse-power available at Niagara Falls may yet be transformed and transmitted to the large cities of the eastern States. The present indications are, however, that for some time to come transmissions are not likely to be attempted for distances of over 100 miles.

THE success of the Naples Zoological Station in preserving marine animals for the purposes of both exhibition and study is so well known to all interested in museum work, that they will be prepared to welcome the translation by Mr. E. O. Hovey, which has recently appeared in the *Bulletin of the U. S. Museum* (No. 39), of Dr. Salvatore Lo Bianco's memoir on the methods employed in such preservation. It is to Dr. Lo Bianco himself that the exquisite results obtained are chiefly due; and the translator appends the following remarks on the secret of this success. "One reason for the beautiful appearance of the material sent out by the station is that it is properly caught in the first place; another is that, for the most part, the animals are alive when the process of preservation begins. With many forms it is indispensable that they be alive at the beginning of operations; with some it is not so necessary, but with all it is highly desirable. . . . The best methods have been determined for each species by itself, different species of the same genus often requiring different handling. . . . When new species are encountered, the best method of procedure must be determined by experiment." It is interesting to note that the author assigns to alcohol the first place as a preservative medium; adding that although formalin is a very useful liquid for keeping animals temporarily, it is less well suited for their permanent preservation.

LOCAL scientific societies often have a tendency to develop into societies for the promotion of penny readings and popular lectures; but the committees should always bear in mind that though interesting accounts of the scientific work of others may create a desire to know more of the facts of nature, the real value of a local scientific society must be judged by the facilities afforded for original observations, and the use the members make of them. The Preston Scientific Society, to judge by the annual report presented last week, not only encourages interest in science by means of lectures, but in each of its sections systematic studies and individual investigations are organised. A scheme for identifying and recording the flora of Preston and the neighbourhood was drawn up three years ago, and has been actively carried out during the past summer. Much new information has thus been gained, and in regard to the flowering plants it appears that the flora of the district was never so completely known as it is now. Mr. E. Dickson, who has been elected president for the ensuing year, pointed out in his address that this is the kind of work that can usefully be done by a local society, namely the investigation of local facts and phenomena. There is much to be done in the way of working out details of the natural history in every district, and the societies which stimulate activity in the required directions will assist in the advancement of scientific knowledge.

THE *Bulletin* of the Cracow Academy for July contains an important note of a mathematical character by Dr. Ladislaus Natanson on the thermokinetic properties of solutions. The present investigation appears to furnish a thermodynamical interpretation of Van 't Hoff's molecular theories of osmotic pressure.

WE have received the fourth report of the International Commission of Glaciers. The report is entirely devoted to records of glacier measurements made in various parts of the world during 1898; it forms a substantial addition to our knowledge of glacier movements and their periodic variations.

THE new *Bulletin de la Société de Géographie* contains a number of papers of more than average interest. Mr. F. J. Clozel contributes a historical paper on the Ivory Coast; Captain Chanoine writes on the Voulet-Chanoine Mission; Dr. Huguet describes the physical geography of Southern Algeria in a paper illustrated by some rough but suggestive sketches of sand-dunes. There is an account by Dmitri Klementz of travels in Western Mongolia in 1885 and 1897, and the first part of an important paper on the Meteorology of Palestine and Syria, by Father R. P. Zumoffen, S.J.

WE have received parts 1-3 of vol. xxi of the *Transactions and Proceedings* of the Botanical Society of Edinburgh (1897-1899), which contain several interesting articles, especially on the structure and microscopical examination of woods, recent and fossil, viz.:—On the histological structure of fossil woods, by Mr. R. A. Robertson; on a method of injection-staining plant vascular systems; on contact negatives for the comparative study of woods; and on the histology of some fossil woods, by the same writer. Mr. R. Stewart McDougall has a paper on the bacteria of the soil, with special reference to soil inoculation; Mr. R. Turnbull, one on *Apodya lactea*, a fungus belonging to the Saprolegniaceæ; Mr. Percy Groom, one on the fusion of nuclei among plants, and Mr. R. A. Robertson, one on abnormal conjugation in *Spirogyra*.

OUR German contemporary *Globus* is always interesting, and it is a great pity that there is no journal on similar lines in the English language. The following articles in recent numbers are well worth reading: "The Philipponens of Ostpreussen" (vol. lxxvi. No, 12) gives an account of the houses, mode of life, and religious beliefs of a strange Christian sect that was established about 1700 by Philip Pustoswiät. "The Onondaga Indians of New York State, and the Sagas of the foundation of the confederation of the five nations by Hiawatha" (Nos. 13, 14). "Indian and Singhalese Children and their Games" is a welcome addition to a neglected subject; there are several illustrations (Nos. 14, 15). R. Schumacher gives (No. 15) an illustrated ethnographical account of a recent travel among the uncivilised Tschin-huan who live in the high and hard-to-reach mountains of Formosa; the author does not believe that they are an aboriginal population (No. 14). "Folk-lore among the Huzulen" (Nos. 15, 16, 17). Dr. H. Jansen gives (No. 17) a valuable illustrated *résumé* of recent ethnographical, anthropological, and archæological work in Portugal. We would call attention to the illustrations of existing pile dwellings.

MESSRS. WILLIAM WESLEY AND SON have sent us a catalogue of books and pamphlets on modern astronomy, which is a model of clear and orderly arrangement. The catalogue is limited to astronomical literature of the nineteenth century, and includes 2240 titles, arranged under thirty-three heads and subheads. The classification adopted is particularly convenient, and it enables an astronomer to find at once the works in the list bearing upon the branch of celestial science in which he takes special interest.

THE additions to the Zoological Society's Gardens during the past week include a Diana Monkey (*Cercopithecus diana*, ♂) from West Africa, presented by Mr. E. F. Martin; a Spotted Ichneumon (*Herpestes auro-punctatus*) from Busreh, presented by Mr. B. F. Ffinch; two Dusty Ichneumons (*Herpestes pulverulentus*), a Cape Crowned Crane (*Balearica regulorum*) from

South Africa, presented by the Trustees of the South African Museum; two Schalow's Touracous (*Turacus schalowi*), four Cape Turtle Doves (*Turtur capicola*) from South Africa, presented by Mr. W. L. Sclater; a Vulturine Eagle (*Aquila verreauxi*) from South Africa, presented by the Rev. D. Kolbe; a Tawny Eagle (*Aquila noevioides*) from South Africa, presented by Mr. Claude Southey; a White-tailed Gnu (*Connochaetus gnu*, ♂) from South Africa, presented by Mr. C. D. Rudd; two Mandrills (*Cynocephalus mormon*, ♂ ♂), two White-collared Mangabeys (*Cercocebus collaris*, ♂ ♀), a Tantalus Monkey (*Cercopithecus tantalus*, ♂), a Lucan's Crested Eagle (*Lophotriorchis lucani*) from West Africa, a Spring-Bok (*Gazella euchore*, ♂) from South Africa, a White-tailed Ichneumon (*Herpestes albicauda*) from the Atbara River, a Yellow-headed Conure (*Conurus jendaya*) from South-east Brazil, four Lesser Pin-tailed Sand-Grouse (*Pterocles exustus*), a Black-headed Partridge (*Caccabis melanocephala*) from Arabia, deposited; a Roi Rhe-Bok (*Cervicapra fulvo-rufula*, ♂) from Maryland, Schombie Station, Cape Colony, a Gannet (*Sula bassana*), British, purchased.

OUR ASTRONOMICAL COLUMN.

HOLMES' COMET (1899 *d*).

Ephemeris for 12h. Greenwich Mean Time.

During the week the comet passes from the northern part of Ophinchus into Hercules, about 6° east of α Ophinchi.

REFRACTION EFFECT OF COMET SWIFT (1899 I).—Prof. C. D. Perrine, during May and June 1899, made several attempts to determine if any appreciable refraction was caused by the body of Swift's comet on a ray of light passing through it, and contributes his conclusions to the *Astronomische Nachrichten* (Bd. 150, No. 3602). The observations were made with the 36-inch Lick refractor, and consisted of determining accurately the position angle and distance of two stars, (1) when one or both of them were seen enveloped in the mass of the comet; (2) when quite free from the cometary matter. The diameter of the head of the comet was computed to be about 174,000 miles, and the extent of matter traversed by the light from the stars about 163,000 miles. The greatest range of variation in the measured distance of the stars was 0″·26, which the author thinks in all probability accidental, as no systematic variation was detected; so that from these experiments the conclusion is that the mass of a comet causes no appreciable effect of refraction on light passing through it.

PREDOMINANCE OF SPIRAL NEBULÆ.—In the *Astronomische Nachrichten* (Bd. 150, No. 3601), Prof. J. E. Keeler describes the preliminary results of his inquiry into the structure of nebulæ. The discussion is based on photographs obtained with the Crossley reflector of the Lick Observatory, and the author finds that in addition to confirming the spiral structure of the nebulæ catalogued by the Earl of Rosse, so many others possess the same characteristic form that their being put in a special category loses its significance; in fact, any small compact nebula not showing evidence of spiral structure, appears exceptional. He finds gradations leading to the belief that the elongated spindle-shaped nebulæ of Herschel also really belong to this class. The author concludes by stating that if numerous exceptions prove that spirality in nebulæ is not an universal law, it may perhaps be regarded as the usual or normal accompaniment of contraction in cosmical masses, and any departure from it may be explained as the result of special conditions, tending to suspend or weaken causes which are generally in operation.

BULLETIN ASTRONOMIQUE.—The *Bulletin Astronomique* for November 1899 contains an illustrated article by M. Camille Flammarion on the "Eclipses of the Twentieth Century visible at Paris." Forty-three eclipses of the sun will be visible, two of them being total, and thirty-three presented in good positions for observation. The particulars of each are given, with a diagram showing maximum phase. The same author describes the observations of 339 Perseids made at Juvisy from 10–13 August 1899, with illustrations showing the plotted paths. The mean position of the radiant was RA = 3h. 3m.; Decl. +56°.—M. Souleyre concludes his article on the "Distribution of rain on the earth's surface."—M. A. Benoit contributes a very interesting article on "Transneptunian planets," giving particulars respecting a proposed instrumental equipment for a systematic search for such bodies.

THE FITTING OF THE CYCLE TO ITS RIDER.[1]

THE present time is opportune to notice some points in cycle riding which have received our attention during the last three years. Every intelligent rider of a cycle must have at some time compared his powers as a human motor with the motors that drive the motor-cars which he now so frequently meets in the streets. He naturally wishes to study the question of most efficient propulsion, including that of his own mechanical efficiency as a motor driving his cycle. The design of the modern cycle was so far developed by 1896 that a standard type then became the rule, most cycles having a 45-inch wheel base, two wheels of equal diameter 28 inches, cranks 6½ inches long, and a ratio of gear varying between 59 to 80 inches, the sole difference made between cycles intended for tall riders and those for short ones consisting in varying the height of the frame. In 1896 the writers, being urged thereto by Mr. Otto Blathy, the well-known engineer of Budapesth, had their attention called to the necessity of varying the crank length to suit the varying length of leg of the rider. A series of experiments was carried out for cranks up to 9½ inches long, and the results obtained were very remarkable. It may now be taken as admitted that a very large proportion of the riders who have tried cranks of increased length have found great benefit from their use, but although they feel strongly how tangible these advantages are, some difficulty has been felt in satisfactorily explaining them.

All that has been written on cycle riding in the past has been confined to the style of riding which has been gradually elaborated on cycles fitted with the standard 6¼-inch to 6½-inch cranks, but this is little or no assistance to us when we attempt to investigate the subject through wider limits of muscular movement.

When mechanical engineers measure the efficiency of any form of mechanical motor they confine themselves generally to the consideration of the fuel that it consumes, but do not, as a rule, when considering its efficiency, take into consideration the cost of keeping it in repair, or include with it the cost of feeding and maintaining the driver; but the food which is the fuel of the cycle rider has not only to perform the same duties as the fuel of the mechanical motor, but has in addition to supply the nerve waste and repair the muscle waste which answers to the repairs to the mechanical motor, and from the same supply to maintain the brain power of the driver. The food energy of the cyclist has, therefore, to be distributed through three distinct channels: the first in importance is that which is required

[1] Abstract of paper read before the Cycle Engineers Institute at Birmingham, by R. E. Crompton and C. Crompton.

to repair brain waste, and which we hereafter call "Brain Waste"; second, that required to supply the nerve action, which energises the muscles when ordered to do so by the brain, and which we hereafter call "Nerve Waste"; and third, that for the upkeep of the muscles themselves, and which we hereafter call "Muscular Waste." Hitherto writers have, we believe, given too much prominence to the last-named of these. We think that, instead of being the most important of all and taking the largest share of food, it is probably the least important of the three. Dr. E. Turner has shown a method of estimating, with considerable scientific accuracy, the proportions of the food supply required by the above three sources of waste. He has noticed that the proportions of uric and phosphoric acids present in the human urine after exertion give the measure of the brain and nerve wastes relatively to the urea present, which is a measure of the muscle waste. A long series of experiments have made us feel reasonably certain that the nerve waste is practically proportional to the number of times that the nerve centres energise the muscle in order that it may make a stroke; in other words that the nerve waste is proportional to the number of revolutions of the crank shaft of the cycle, and it is doubtless this fact that has led to the craving for high gears, which allow of a reduced number of crank revolutions, as riders have found that by reducing the number of crank revolutions they can economise their nerve waste so as to leave a greater reserve of food energy to supply brain and muscular waste. Our attention was directed to this at a very early stage in our experiments; but we found that a limit was soon reached to the raising of the gear, as if the crank length is kept constant the crank pressure necessary to drive the cycle increases just as the gear is increased, so that a strain is brought on the muscles at times of facing high winds or climbing steep hills, which is greater than the muscles can stand without muscular soreness setting in; in fact, the limit of strain is surpassed, which it will be convenient to call the "elastic limit" of the muscles, and whenever this "elastic limit" is passed for more than a few minutes the muscle is temporarily weakened for the remainder of the day's run; in fact, the repair of that muscle cannot be made until the rider rests and sleeps as well.

We have adopted this term "Elastic Limit" of the muscles because it corresponds very closely to a term well known to mechanical engineers when used to express the extent to which metals may be strained or stretched without taking permanent set; so long as they are subjected to strains within this limit no permanent injury is done to the metal, whereas if it is passed the structure of the metal is altered and becomes weaker and liable to fracture. This process of being strained, even to a small extent above the elastic limit, has been sometimes called the fatigue of metals, and is somewhat analogous to the fatigue of muscles strained above their elastic limit.

We use the term "Pedal Pressure" and symbol "F" to express the pressure in lbs. which the rider must apply at the pedal during the entire revolution of the crank shaft in order to drive his cycle at the required speed. We measure the total resistance or pull of the cycle on the road in lbs., and call it total resistance expressed by our symbol "R," the power exerted by the cyclist, that is, the rate of doing work in foot pounds per minute by the symbol "P," and the work done in foot pounds per hour by the symbol "W." So long as the crank lengths are kept constant, or nearly so, the term geared to 60 or 70, as the case may be, give a sufficiently accurate idea of how far the pedal pressure "F" is influenced by the ratio of revolutions of the crank shaft to that of the driving wheel, but immediately the crank length is varied this term gear leads to confusion. We think a better term is multiple, which we denote by the symbol "M." "M" is the figure by which the angular speed of the feet or pedal is to be multiplied in order to get the lineal speed of the cycle moving along the road, consequently R multiplied by M gives F. We have prepared several tables which give the value of "R" for speeds varying from 5 to 20 miles an hour. It will be seen that "R" consists of three parts, $r1$, $r2$, and $r3$. $r1$ is the mechanical friction of the cycle, $r2$ is the road rolling and tyre resistance; these two first are functions of the weight of the machine and its rider, $r3$, the most important of all, is that due to air resistance. In a second table we have the value of F worked out for various multiples, and in a third table we give the value of F under maximum conditions of hill climbing at a speed of 8 miles an hour. From

M = 6	7·75	9·3	11·1	12·9	14·9	17·05	19·5	21·8	24·5	27·0	29·8	33·1	36·2	39·4	42·9	46·4

TABLE III.—*Values of F in lbs. on Various Hills with Different Values of M at* 8 *miles an hour.*

Hill of	1 in 30	1 in 25	1 in 20	1 in 15	1 in 10
M = 4½	38·160	43·875	52·425	66·645	95·175
M = 5	42·40	48·75	58·25	74·05	105·75
M = 5½	46·640	53·625	64·075	81·455	116·325
M = 6	50·88	58·50	69·90	88·86	126·90

these tables we are able to show that we have to deal with values of F varying from 18 lbs. to 130 lbs. It will be seen that the F required by an average rider using a multiple of 5 when he is maintaining a speed of 12 miles an hour on a calm day will vary between 18 lbs. and a maximum of 106 lbs. when he is climbing hills of 1 in 10 at a reduced speed of 8 miles an hour. These figures are representative as average conditions of the forces which have to be exerted by riders, although it is needless to say that far greater values of F are reached by riders when racing or in hill-climbing competitions.

We have endeavoured to give some approximate value of the elastic limit of muscles, and have made extended experiments to settle this point. In the case of one of the writers, the elastic limit of the quadriceps cruris at the point where soreness is usually felt, *i.e.* just above the knee, appears to be that corresponding to an F of 120 lbs., so that in this case with a multiple of 5, whether the arrangement be 6½-inch cranks, 65 gear, or 9½-inch cranks, 95 gear, a gradient of 1 in 10 can be ridden, and it is probable that this limit can be reached for three or four minutes without causing the muscular soreness. This of course varies greatly with the physical condition of the rider, but it is probable that this elastic limit is a function of the cross section of the muscle, and that the above value may be taken as an average one for men of average physique; with women it is probably somewhat less. It appears certain that the value of the elastic limit is a most important determining factor in designing a cycle to enable a rider to develop his physical powers when cycle riding in the most efficient manner. Once we determine it we can fix on the multiple M, and then, as we desire to keep down the nerve waste by reducing the crank revolutions for a given road speed, we can only do this, as M is a fixed quantity, by increasing the crank length. To what extent can this be done to give the best possible efficiency? The rider's thigh bones and the muscles that work them up and down may be looked upon as levers working on the hip joint as a fixed point, the outer ends being connected to the pedal by the shank bones, ankle joint and foot acting as a rather complicated connecting rod. The effective length of the thigh bone of riders varies between 15 inches for short men and 23 inches for tall men. The length of the standard 6½-inch cranks is therefore 43 per cent. of the length of the thigh bone on short riders, but only 28 per cent. of its length in tall men. In the case of the writers it is about 35 per cent. It was necessary to determine this proportion of the crank length to the thigh-bone length.

Our experiments, extending over three years, show that although we have gradually increased the crank length from 6½ inches to 9½ inches, in other words, from 35 per cent. up to 53 per cent. of the effective length of the thigh bone, we have not yet passed the point of greatest efficiency. Our proposals have of course been severely criticised, mainly by those who have not tried the system, and the following objections have been urged against increased crank length.

(1) Causing loss of power when hill climbing, or when riding against the wind, in fact at any time when the F required is considerable, and that this loss of power is caused by the excessive bending of the knee joint, which in its turn causes knee soreness.

(2) Militates against proper ankle action.

(3) Causing saddle soreness, bad steering, and other troubles.

(4) Causing extra strains on the parts and frame of the cycle.

Dealing with these questions in the above order, we have shown that the main object of increasing the crank length is to reduce the number of revolutions at a given road speed without increasing the value of F, and as it is practically certain that the knee soreness complained of entirely depends on this value of F not being exceeded, the only other way in which knee soreness could be produced is by excessive knee flexure. There are two ways in which this question of knee flexure may be considered. It has been said that when the knee is bent beyond a certain angle the muscles act at a disadvantage, and again that the extra flexure of the joints is the cause of the soreness which riders complain of, and that a rider having an 18-inch thigh bone can actually exert a greater pedal force at the half-stroke of 6½-inch cranks with its corresponding knee angle, than he can with 9 inch cranks and the correspondingly increased angle. We have, however, settled this question by careful experiments made in a testing machine, and we have shown that the knee angle at which the maximum pushing strain can be exerted is that which corresponds to a crank length of 18¾ inches; in other words, that the maximum force of the leg is obtained with a knee flexure far in excess of that required for any possible crank length that could be used on a cycle, so that this question of loss of power from excessive knee flexure is completely disposed of. Fig. 1 shows these results plotted on a curve.

TABLE IV.

Distance between hip-joint and ball of foot in inches	Angle at knee between shank and thigh	Maximum push in lbs.
22	75° 30′	325
23	79 36	370
24	83 31	390
24½	86 0	412
25	87 44	408
26	92 46	385
27	97 32	362
28	102 32	325

What writers mistake for knee soreness caused by excessive flexure is really due to the following cause. Any muscle which is constantly used throughout only a part of its stroke becomes developed and hardened into a condition which Sandow calls "a muscle-bound condition." It becomes shorter as it is never properly stretched out, the tendons which secure it also become shortened, and if this condition is not speedily remedied it becomes permanent. In the hard riding short crank cyclist, this applies to the quadriceps cruris, it being only called upon to work through a part of its stroke. When such a cyclist uses long cranks for the first time, he finds himself unable to properly flex his knee joints on account of this shortening of the quadriceps. The effort of stretching the muscle out to its full stroke causes the knee soreness complained of. There can be no question, however, that long crank riders benefit greatly by the extra knee flexure, compelled by the long cranks, and that this greatly increases their bodily activity and enables them to excel in exercises, such as running, walking, hill climbing and jumping, all of which require flexibility of the knee joint. Sandow points out that the best way to prevent the muscle-bound condition is to work the muscles in pairs throughout their full stroke; consequently, if we desire to develop the quadriceps cruris in a perfect manner to the full length of its stroke, we must also develop the muscles which form the pair to it on the underside of the thigh, *i.e.* the biceps cruris. It occurred to us, therefore, at an early period, that we ought to train these muscles to do their share of the work of propelling the cycle, hence arose what we call the pull stroke. Cyclists who use toe clips, or those who notch the soles of their cycling shoes, so as to get a better grip of their pedals, can use this pull stroke to a small extent; that is to say, they can claw or pull the pedal round

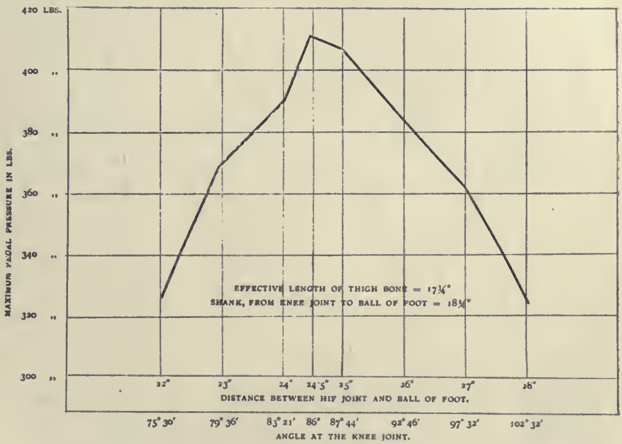

FIG. 1.—Curve showing relation between knee angle and maximum thrust on pedal.

during the lower portion of its circular path; but unless special devices are provided to enable them to draw the pedal upwards throughout a much larger arc, they cannot make use of the pulling muscles in a satisfactory manner. In order to do this we have bent our pedal plates slightly forward, as shown on Fig. 2, and we have prepared shoe plates of a form which enable them to hook into the back plate of the pedal.

It will be seen that our pulling device differs essentially from toe clips, which do not enable the upward pull being made unless the toe is pointing downwards. We find that this militates against good ankling action, and has a tendency to induce cramp in the calf muscles; on the contrary with our pulling device, the calf muscles may be quite inert during the upward stroke, the shank acting merely as a connecting rod in tension. It will be seen that the pull stroke enables us to reduce

FIG. 2.

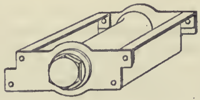

FIG. 3.—Crompton patent pedal.

the minimum pressure on the downward stroke, which is necessary to produce the average pressure F. Our experience of this subject is that it takes a long time to teach these muscles, which are seldom used except by running men, to take up their share of the work of cycle propulsion, and those who begin to use the pull stroke will find that, although it does greatly reduce the pushing strain made by the upper thigh muscles in hill climbing, yet that the thought and attention required to apply it under ordinary conditions of riding is so considerable that they do not persevere in practising it. It is our opinion that it is well worth while for a rider to cultivate the pull stroke. The pulling muscles are large and powerful, their elastic limit is high, it is not easy to overstrain them, and the extra brain waste that is required during the process of teaching these muscles is soon found to be reduced, as by practice these muscles automatically take up their share of the work.

It has been said that increased crank length militates against proper ankle action. The use of ankle action is not generally understood. The moving portion of a man's leg has considerable weight, when it is at the top of the stroke it possesses potential energy which is changed into kinetic energy as the leg descends, when it gets at the bottom of the stroke it stops going downwards and commences to rise, and the kinetic energy due to the downward movement of the leg has to be given up. What becomes of it? If the stopping of the leg is done by the same muscles which lift the leg there is a considerable waste of power, but if towards the lower end of the downward stroke the man begins to flex his calf muscles the velocity of his leg is gradually decreased, the force required to do this not coming from the muscles which move his leg, but from the calf muscles, which take a purchase, not against the saddle, as would be the case if he did not use ankle action, but against the pedal itself, so that the kinetic energy which is taken out of the leg in stopping its descending weight is usefully employed in propelling the cycle, and thus there is a great saving of energy by good ankle action.

If we take curve Fig. 4, the vertical lines of which represent velocity, the velocity downwards being represented by the vertical lines below the base line A B, and the velocities upward by the vertical line above it; if also we take the horizontal line to represent time when travelling with 60 gear and 6-inch cranks at 10·71 miles an hour, M being 5, a complete revolution is made in one second, and the upward and downward velocity of the leg at any moment is shown by the curve. Now rate of acceleration is change of velocity at a given time, and therefore the acceleration at any point is represented by change of velocity in a given time at that point. Suppose the acceleration to remain the same throughout that time as it is at the point P, the curve would describe a tangent to that curve at the point P and the acceleration—that is, the change of velocity divided by the time—would equal the tangent of the angle formed by the tangent of the curve with the base line.

You will notice that up to 90 degrees the tangent increases as the angle increases, therefore the steeper the curve at any point the greater is the acceleration at that point, and the greater the acceleration the greater the rate at which kinetic energy has to be taken out of the leg, and therefore the greater necessity for ankling. If, however, when riding at the same speed we use 9-inch cranks with 90 gear M is still 5, but the curve takes the form of the black line. You will see that the curve is obviously of the same relative shape as the red curve, but it is drawn out lengthways in the proportion of 6 to 9, and therefore the angles which the curve makes with the base line at any point is less than the angle which the red curve makes at a corresponding point. The tangents of the angle of steepness vary as 6 to 9, and the rate at which acceleration is reduced is also as 9 to 6, so that the necessity for careful ankling is in this case reduced in the same proportion, in other words, for equal efficiency long cranks do not require such careful ankling as short ones; although as more time is given in which to carry out such ankling, it is easier for the average rider to acquire it to a sufficient extent.

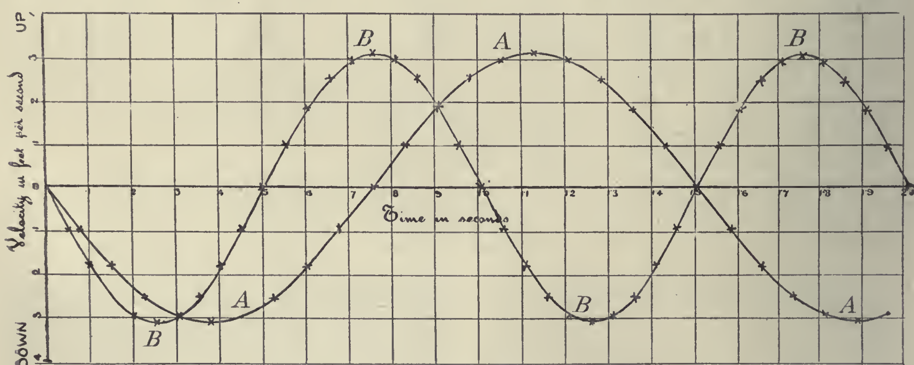

FIG. 4.—Curve B shows vertical velocity of pedal of 6 inch crank, 60 gear } Both at speeds of 10·71 miles per hour.
" A " " " 9 " " 90 "

It is unnecessary to deal at any length with the question of saddle soreness. We cannot find that lengthened cranks have made any notable difference in this respect. Those who were liable to soreness with short cranks have not had this liability increased, but rather decreased by the new system. The position of the saddle has of course to be carefully attended to in riding with the lengthened cranks. As to the bad steering, this is an imaginary fault. We find that a well-designed machine will steer just as well, hands off, with long cranks as with short ones. It is true that the long cranks do introduce some extra strains into the cycle. The cranks themselves have to be carefully designed and made of special material. The use of nickel steel has enabled us to make the long cranks of ample strength, although they weigh very little more than short ones. The strains introduced into the frame are mainly those due to chain pressure, and are not influenced by crank length but entirely by the speed of the chain. The speed of the chain can be increased by enlarging both the sprocket and back pinion wheels. Summarising our results it appears—

(1) That when we talk of designing the cycle to suit any individual rider, so as to develop his powers as a motor to the greatest extent, we have first to consider how we can best economise his nerve waste by enabling him to reduce the number of revolutions and increase the stroke through which his legs can travel. Our experiments have shown us that these conditions are best fulfilled in the great majority of cases by giving to the rider a length of crank equal to half the length of his thigh bone.

(2) That the value of M the multiple, in other words the gear, is then to be determined by the maximum strains which his muscles will stand, and we believe in most cases this corresponds to a pedal pressure F not exceeding 100 lbs. for weak individuals up to 140 lbs. for strong ones.

(3) That the crank length determines the shape of the frame and the length of the wheel base, and that the extra long wheel base necessitated by the long cranks renders the cycle pleasanter to ride and does not materially increase its weight.

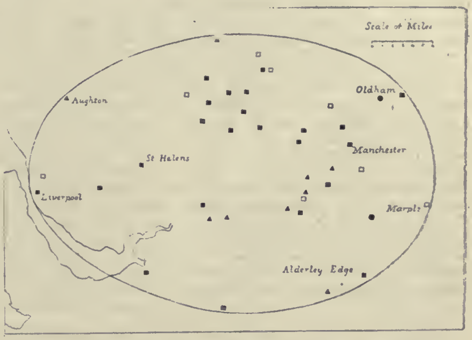
(4) That considering how important it is to reduce the number of crank revolutions in order to economise nerve waste, the cultivation of the pull stroke enables a greater average F to be obtained without straining the muscles beyond their elastic limit, and, consequently, allows of a higher multiple M and a correspondingly reduced number of revolutions. Out of a number of carefully made test runs we have selected the following as representative of the increased efficiency which we have obtained from the use of the lengthened cranks. The elder of us, aged 54, height 5 feet 10 inches, thigh bone 18-inch shank, from knee to ball of foot 21 inches, made a trial in the summer of 1896 with a cycle having $6\frac{1}{2}$-inch cranks, geared to $99\frac{1}{2}$. The total weight of rider and cycle was then 195 lbs., and the surface exposed to the air, including cycle, was $5\frac{1}{2}$ square feet. The maximum distance that could be travelled on a good road with an average wind was 78 miles in ten hours, including rests, or in an actual riding time of $7\frac{1}{4}$ hours. The average foot pounds per minute in this case was 2917. In September 1898 R. E. Crompton made a test on a cycle having cranks 9·1 inches long, geared to 102. The weight of the cycle and rider was, as in the former trial, made up to 195 lbs. The test run was from Kensington Court, London, to Romsey in the New Forest and back; total distance 156 miles, total time 13 hours 28 minutes, riding time 10 hours 54 minutes. The bodily fatigue on this day was no greater than on the 78-mile run in 1896. In this ride the average foot pounds per minute throughout the day was 6650, so that whereas with the old system of short cranks in 1896, R. E. Crompton was able to maintain P at 2917 for $7\frac{1}{4}$ hours, with the new system in 1898 he was able to maintain 6650 for 10 hours 54 minutes; in other words, from a given amount of food or, what is the same thing, a given amount of bodily fatigue, R. E. Crompton was in 1898, on the long-crank machine, able to do three times as much work as he did on the short-crank machine in 1896. Many other similar runs have been made, and other long-crank riders can produce equally satisfactory results.

The theory we have formed as to the nature of bodily fatigue induced by cycle riding, in which we have endeavoured to show the extreme importance of the part played by the brain and nerve systems, and that probably the major portion of the energy of the human body considered as a motor passes through the brain and nerve tissues to energise the muscles, is a matter which merits the careful attention of physiologists. Writers on this subject have hitherto considered the human or animal motor as a heat engine, all the useful energy being obtained by corresponding chemical work done on the muscles. We believe that the greater part of the energy-yielding processes goes on within the brain itself or in the nervous system directly connected with the brain. Many facts observed by cyclists and other athletes when carrying out feats of endurance show that brain and nerve nourishment is to be aimed at rather than the repair of muscle waste, and that certain foods and drinks have to be avoided on account of their action in producing temporary slackness; in fact, on account of their preventing the brain from effectively energising the muscles.

NOTE ON THE DISTANCES TO WHICH EXPLOSIONS ARE FELT AND HEARD.

ST. HELENS being situated in a thickly populated district, the disaster at Messrs. Kurtz's works (belonging to the United Alkali Company) seemed to offer a good opportunity for determining how far a great explosion may be felt and heard. Isolated observations, as will be seen below, have been made on other occasions; but, to feel confidence in the results, we require a fairly continuous series of records extending from near the centre of disturbance to the boundary of the affected area. I therefore wrote letters to all the more important newspapers in the south of Lancashire and north of Cheshire, in request of observations either of the sound or of the movement of windows by the air-waves. In reply to them, I received more than fifty accounts, which, in addition to several which appeared in the local press, gave a total of 61 records from 47 different places.

The immediate cause of the explosion was the firing of one of the vessels used in crystallising the chlorate of potash, the vessels being made of wood lined with lead. It is computed that eighty tons of chlorate exploded. The whole of Messrs. Kurtz's buildings were razed to the ground, and nine out of ten great vitriol chambers on the other side of an adjoining road were destroyed. Within a few hundred yards of the chemical works there are many streets of workmen's cottages; the doors, windows, chimney-stacks of whole rows were dismantled, and, in some cases, the roofs fell in. Within a radius of a mile or so, hardly a window seems to have escaped;[1] but according



to one of my correspondents, who was in the north-west of the town, the damage to windows around him was comparatively slight.

On the accompanying map are shown all the places from which records of the explosion were obtained. A small square denotes a place where the air-wave was strong enough to make windows and doors rattle; if the square is filled in, the sound was also heard. Places where the observation of the sound only is recorded are represented by a circle if the observer was out of doors at the time, and by a triangle if he was inside, or probably inside, a house. A perceptible tremor of the ground, strong enough to be mistaken for an earthquake, was felt at some distance from St. Helens, but how far cannot be definitely ascertained.

It will be seen that the area over which the sound was heard is practically the same as that in which the air-wave was strong enough to make windows rattle. The bounding curve is elliptical in form, $39\frac{1}{2}$ miles in length from east to west, $27\frac{1}{2}$ miles in breadth, and includes an area of about 850 square miles. St. Helens lies close to the longer axis of the curve and nine miles to the west of the centre. Towards the east, the sound was heard at Alderley Edge ($24\frac{1}{2}$ miles from St. Helens) and at Oldham (27 miles). Windows were observed to rattle at Alderley Edge and also at Marple (28 miles). To the west of St. Helens the sound was heard at Liverpool (10 miles) and Aughton (10 miles). I have tried in vain to ascertain the direction of the wind at the time of the explosion at different places

[1] The above particulars are obtained from the account given in the *Manchester Guardian* for May 13.

within the sound-area, but the observation above recorded from the north-west quarter of St. Helens is worthy of notice in connection with the easterly elongation of the area of disturbance.

For the sake of comparison it may be worth while to refer briefly to the results obtained from previous explosions. At the conclusion of Sir John Moore's retreat, a great Spanish powder magazine, containing, it is said, 1500 barrels, was blown up near Corunna. The ground rocked sensibly for miles, and at a distance the shock was felt before the sound was heard (R. Mallet, *Irish Acad. Trans.*, vol. xxi., 1848, pp. 63-64). In the great Erith explosion (October 1, 1864) two barges, a large magazine and a small one blew up in succession. They contained respectively about 9, 33, and 4 tons of gunpowder. Everything within a distance of half a mile—trees, houses, barns—was utterly destroyed, except two haystacks on the south side of the river. Windows were shattered within a radius of at least five miles. The explosion was heard and felt at Teddington (21 miles), Uxbridge (27 miles), and Windsor (32 miles), and the concussion is said to have been felt near Ashford, which is distant about 40 miles (*Times*, October 3-6, 8, 1864). The catastrophe in the Regent's Canal (October 2, 1874) was caused by the explosion of about five tons of gunpowder. The shock and sound were observed as far as Chiselhurst (13 miles), and the vibrations were felt at Aveley (18 miles) and Gravesend (23 miles) (*Times*, October 3, 5, 1874). To effect the removal of the Flood Rock in Hell Gate, New York Harbour, about 130 tons of dynamite, &c., were exploded; and the vibrations were perceived, with the aid of a mercury bath and telescope, at a distance of 183 miles (*Times*, October 12, 1885; Milne's "Seismology," pp. 98-99). Mr. Fox Strangways states that the blasting operations in the Charnwood Forest quarries can be heard at a distance of 18 miles or more (NATURE, vol. liii., 1895, p. 130). The shock caused by the explosion of nearly 50 tons of dynamite at Johannesburg on February 19, 1896, was felt at Krugersdorp (19 miles) and Pretoria (33 miles) (*Standard*, February 21, 22, 1896). The Lagouban naval magazine (near Toulon), which blew up on March 5, 1899, is said to have contained 50,000 kg. of black powder. The country for a radius of nearly two miles was swept almost bare. Houses were razed to the ground, and trees were overturned or bent into the most extraordinary shapes. It is affirmed that the report of the explosion was heard at Nice (84 miles), and even beyond the frontier at Ventimiglia (100 miles); but it is obvious that, in the absence of intermediate records, we cannot place much reliance on these accounts (*Times*, *Daily Chronicle*, *Daily Mail*, *Daily Telegraph*, March 6, 1899).

CHARLES DAVISON.

THE HURTER MEMORIAL LECTURE.

THE memorial lecture established by the Liverpool Section of the Society of Chemical Industry in memory of Dr. Ferdinand Hurter, and which will be given every alternate year, was inaugurated by Prof. G. Lunge, of Zürich, on October 4, before a large and representative gathering at University College, Liverpool. Prof. Lunge's subject was "Impending changes in the general development of industry, and particularly in the alkali industries." After an appreciative review of Hurter's contributions to technical chemistry, in which special reference was made to his remarkable mathematical power and to the manner in which he employed it side by side with the highest branches of chemical science for the investigation and elucidation of technical problems, Prof. Lunge turned to the more immediate subject of his address. In contemplating the general features of chemical industries as carried on to-day, the question of the supply of fuel and of other sources of power was first considered; it was pointed out that the superiority which many countries, notably Great Britain, enjoy in many industries on account of their wealth of coal is limited in time, and that the increasing consumption of coal with a decreased source of supply as the result, must lead to the employment of other sources of energy. The economical use of coal in the blast-furnace, the adoption of closed coke ovens which, in addition to allowing the recovery of by-products, also increase the yield of coke, and recent improvements in the production of gaseous fuel are likely to postpone the time and force of the competition of those other sources of energy of which water-power stands foremost, but such postponement is restricted essentially to certain industries. From a general standpoint the total energy of the fossil fuel of the world is an infinitesimal fraction of the energy which the sun expends daily on the evaporation of water, and which is transformed to a great extent into the kinetic energy of falling water. The transformation of water-power into electrical energy, with its easy and cheap power of transmission, is likely to lead to revolutionary changes in chemical industries, not only in respect to the conditions of manufacture, but also in regard to the centres of production. Countries possessing great water-power will in the future carry on all those manufacturing processes in which electricity is either essential or an advantage, subject to certain limitations regulated by the cost of carriage of both raw materials and products. Prof. Lunge detailed the present position of electrical processes applied to chemical industries, dealing especially with the alkali trade and the manufacture of bleach and chlorate; the next generation will in all probability, in his opinion, obtain its chlorine by electrolytic methods, but the accompanying alkali will not form more than one-eighth or one-tenth of the world's demands. The bulk of the latter must therefore be derived from other sources—these, in Dr. Lunge's opinion, will be the ammonia-soda process and naturally occurring soda. In regarding the future of these industries the modern developments of the manufacture of sulphuric acid by the catalytic process, in which sulphur dioxide and oxygen are passed over platinised asbestos, were discussed; the success of this method, especially for the manufacture of strong acid, is thoroughly established, and the lead chamber is threatened with extinction in consequence. Prof. Lunge pointed out, however, that this old apparatus has still certain claims of efficiency in the manufacture of weak sulphuric acid. Incidentally, in considering the economical use of fuel, Prof. Lunge gave a most interesting description of the Dellwik-Fleischer water-gas process, the efficiency of which he had himself examined with the result that he found that it gave no less than 82 per cent. of the fuel value of the coke against the 45 per cent. of the older processes. The characteristic of the process is the formation of carbon dioxide during the "blow" instead of carbon monoxide, a fact which reduces the time of the blow from 10 minutes to $1\frac{3}{4}$ minutes.

In looking back upon the industry with which Hurter's life-work was associated, Prof. Lunge dwelt upon the fact that the very processes Hurter had helped so ably and successfully were without doubt doomed, if not to complete extinction, still to a most serious crippling. Like other earnest workers, Hurter had but tilled the soil from which others will reap a harvest; and although there is a feeling of sorrow in the thought that so much genius, inventive talent and honest labour had been expended in what seemed now a transient aim, still

Der wer den Besten seiner Zeit genug gethan
Der hat gelebt für alle Zeiten.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr A. Hutchinson, of Pembroke College, has been reappointed Demonstrator in Mineralogy and Assistant-Curator of the Museum of Mineralogy for a term of five years.

Sir Walter Gilbey and Mr. Austin Keen have been appointed additional members of the Board of Agricultural Studies.

Mr. H. Woods, of St. John's College, is to be appointed a University lecturer in Palæozoology. He has hitherto held the post of demonstrator in this subject at the Woodwardian Museum.

The awards of entrance scholarships have been made at the two groups of Colleges, the first comprising Trinity, Clare and Trinity Hall, the second Pembroke, Caius, King's, Jesus, Christ's, St. John's and Emmanuel. One hundred and seventeen scholarships and exhibitions have been given; of these 23 are for mathematics, 28 for natural science, and 49 for classics. The value of these scholarships varies from 80*l*. to 40*l*. a year, that of the exhibitions from 50*l*. to 20*l*. a year.

NEGOTIATIONS have been proceeding with the authorities of Mason College and King Edward's Foundation relative to the provision of a remodelled system of commercial education in Birmingham. It is expected that the charter of the new University for Birmingham will be granted early next year, and that there will be a faculty of commerce in connection therewith.

Speaking at the Birmingham Chamber of Commerce last week, Mr. Neville Chamberlain said they were on the eve of a new departure in the educational life of Birmingham. They were looking forward to the rise of a University which would take up new and special lines, including commercial education. That was a great experiment, and it seemed to him to be the duty of that chamber, as representing the commercial life of Birmingham, to do what it could to ensure the success of the experiment.

SCIENTIFIC SERIALS.

Bulletin of the American Mathematical Society, October.—The number opens with a partial analysis of the papers communicated at the sixth summer meeting of the Society, held at Columbus, Ohio, in August last, by Prof. Holgate.—The President, Prof. Woodward, congratulated the Society on the manifest interest in mathematical study and investigation as evidenced by the large number (twenty-three) of communications presented.—A report on the recent progress in the theory of linear groups is an interesting and thorough report by Dr. L. E. Dickson, which was made before Section A of the American Association for the Advancement of Science at its meeting at Columbus, previous to the above gathering of the Society. It is a supplement to the previous report, drawn up by Dr. G. A. Miller, which appeared in the February (1899) number of the *Bulletin*. The author restricts himself to finite linear groups, and of these he considers first the finite collineation groups and afterwards the linear congruence groups and the more general groups in Galois fields. These reports are very useful to students of the subject.—A few shorter notices (small reviews) follow.—The "Notes" contain many items of interest, but two of them are not quite accurate. For instance, the London Mathematical Society has *not* decided to issue its *Proceedings* in two volumes per annum. The resolution, as stated in the appendix to Volume xxx, says "in future the volumes of *Proceedings* shall contain as nearly four hundred pages as may be found convenient, provided that each volume shall begin with the report of proceedings at a meeting, not necessarily an annual general meeting." This may sometimes result as in the "Notes," but not necessarily so. A statement on p. 40 would lead one to infer that Dr. Graves was professor at Trinity College, Dublin, at the time of his death, and had been so ever since 1843.

American Journal of Science, November.—March weather in the United States, by O. L. Fassig. If the earth's surface were uniform, the normal circulation of air would produce two belts of high pressure at a latitude of about 30° north and south. The presence of continents breaks up these areas. The author shows that the "permanent" high pressure areas have a great determining influence upon weather in its general aspects, and that a considerable advance in forecasting work may be expected to result from their study. The March weather of the United States is determined by the relative extent of three such areas, and the course of the March storms lies along the gap between them.—Some new minerals from the zinc mines at Franklin, N.J., by S. L. Penfield and C. H. Warren. The minerals include "hancockite," which has the general formula of epidote, but having lead and strontium isomorphous with calcium; "glaucochroite," $CaMnSiO_4$, closely allied to monticellite, $CaMgSiO_4$; and its matrix "nasonite," the empirical formula of which is $Pb_6Ca_4Cl_2(Si_2O_7)_3$. The authors also investigate the chemical composition of ganomalite, and show that the acid, $H_6Si_2O_7$, of which nasonite and ganomalite are salts, is intermediate between orthosilicic acid, H_4SiO_4, and metasilicic acid, H_2SiO_3, and may be regarded as their algebraic sum, or as derived from two molecules of the former by abstraction of water.—Action of acetylene on the oxides of copper, by F. A. Gooch and D. Baldwin. While metallic copper may at comparatively high temperatures induce the polymerisation of acetylene, it is an oxidising action which starts at moderately low temperatures the formation of the peculiar "acetylides." Thus it is found that ferric oxide heated in acetylene at temperatures varying from 150° to 360°, according to circumstances, darkens, glows, and gathers with evolution of heat a dark carbonaceous deposit. In the products of such action the content of iron varies from 2·8 to 5·8 per cent. Silver oxide also acts upon acetylene.—A new mode of occurrence of ruby in North Carolina, by J. W. Judd and W. E. Hidden. Corundum occurs in North Carolina in three different forms. In the ordinary schists of the district, long prismatic crystals, usually of grey, pink and blue tints, occur. In the peridotites, crystals are found, some of very great size and of great variety of colour, but seldom or never clear and translucent. In certain garnet-bearing basic rocks at Cowee Creek, small tabular and short prismatic crystals are abundant, and these very frequently exhibit the transparency and colour of true ruby.

Wiedemann's Annalen der Physik und Chemie, No. 10.—Explosions in air, by W. Wolff. The effect of an explosion in air is propagated by a process analogous to the propagation of sound, except in the immediate neighbourhood of the source, where a bodily translation of the air is superadded. But that translation does not extend further than about 25 m. Up to that point the propagation of the wave is more rapid than the propagation of sound.—Glow-light phenomena with high-frequency alternate currents, by H. Ebert. There is a residual effect of the positive charge in the glow-light, which persists for a short time after the glow has ceased. This produces a repulsion between the two electrodes.—Influence of impurities upon a gaseous spectrum, by P. Lewis. The addition of very small quantities of mercury vapour to hydrogen gives rise to the green mercury line, which only disappears at −20 degrees. When oxygen is added to hydrogen in increasing quantities, the maximum of emission is shifted towards lower pressures.—Resistance to projectiles in air, by R. Emden. The resistance offered by air is jointly proportioned to the square of the velocity, v^2, and to another function of the velocity, $f(v)$. The latter quantity is constant up to the point where v becomes the velocity of sound. Then it abruptly increases to about three times its former value, remaining constant at high velocities. The increase is due to the energy expended in producing and maintaining the head wave.—Electric pictures, by L. Fomm. The author produces pictures of sections of different kinds of wood by covering them on one side with tinfoil and on the other with bromide paper, with the film in contact with the wood. A metallic point negatively charged by an influence machine, mounted at 5 cm. from the paper surface, produces a good impression in about half a minute.—The Macfarlane-Moore vacuum vibrator, by J. Elster and H. Geitel. To avoid the sticking of the vacuum interrupter the authors keep it vibrating by a separate interrupter outside the vacuum tube, in unison with the one inside.—A fault in Lippmann's photography, by O. Wiener. There is always a difference of phase between the wave reflected by the gelatine surface and that reflected by the first elementary stratum. The remedy consists either in eliminating the surface reflection altogether, as by immersing the plate in benzol, or in producing a large difference of path, by coating the gelatine with a film of collodion. With a suitable thickness of the latter, very brilliant and true effects are obtained.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, June 15.—"On the Resistance to Torsion of certain forms of Shafting, with special reference to the Effect of Keyways," by L. N. G. Filon, M.A., King's College, Cambridge, Fellow of University College, London.

In this paper solutions of the torsion problem are obtained for cylinders whose cross-sections are bounded by confocal ellipses and hyperbolas. The method employed is that of conjugate functions, suggested by Saint-Venant, Thomson and Tait, Clebsch, Boussinesq and MacDonald, and applied by them to other cases.

The strains and stresses are obtained in the form of infinite series of circular and hyperbolic functions. There are two types of sections specially studied.

The first is bounded by an ellipse and by the two branches of a confocal hyperbola. The solution is worked out numerically for various values of the eccentricity of the ellipse and of the angle between the asymptotes of the hyperbola.

The position of the fail-points, or points of maximum strain and stress, is investigated at length.

It is shown that the maximum stress does not always occur, as is usually assumed, at the point of the boundary nearest to the centre of the section, but that in some cases there are four fail-points symmetrically distributed round the contour, on the broad sides of the section.

An example of this kind has already occurred in Saint-Venant's edition of Navier's "Leçons de Mécanique." This is compared with the present results. The paper also investigates the critical sections when the two cases of four and two fail-points pass into one another. It is shown in particular that when the angle between the asymptotes is less than 73° the greatest stress always occurs at the neck of the section.

The second type of section is bounded by one ellipse and one branch of a confocal hyperbola.

The case in which the confocal hyperbola reduces to a straight slit or thin keyway is specially studied.

For the first type of section this case gives two thin keyways; for the second only one.

The manner in which the reduction of the torsional rigidity, due to cutting such slits into the material, varies with the depth, is very striking. This reduction, which is as great as 23 per cent. when the depth of the keyway is 0·6 (semi-major axis) falls to about 1 per cent. when this depth is 0·12 (semi-major axis). This would account for such keyways not always giving in practice the reduction in torsional rigidity which we should expect from Saint-Venant's results for the circle. Keyways of only moderate depth will affect the torsional rigidity very little.

Finally, the effect on the torsional rigidity of two such equal and opposite slits is shown to be about twice the effect of a single slit.

Chemical Society, November 2.—Dr. W. H. Perkin, Vice-President, in the chair.—The following papers were read: On methods for determining the relative proportions of gaseous chloroform and air in a mixture of the two, and on a method for producing a mixture of air and chloroform in any desired proportion, by A. Vernon Harcourt.—The theory of saponification, by J. Lewkowitsch. It is demonstrated that partially hydrolysed fats contain di- and mono-glycerides, and that the hydrolysis of triglycerides constitutes a bimolecular reaction.—Note on the action of dilute nitric acid upon oleic and elaidic acids, by F. G. Edmed. Dilute nitric acid converts oleic acid quantitatively into elaidic acid.—Formation of tetrazoline, by S. Ruhemann and H. E. Stapleton. A good yield of tetrazoline, $CH\langle{}^{NH.N}_{N.NH}\rangle CH$, is obtained by heating monoformylhydrazide.—Asymmetric optically active nitrogen compounds. Dextro- and lævo-benzylphenylallylmethylammonium iodides and bromides, by W. J. Pope and S. J. Peachey. On heating α-benzylphenylallylmethylammonium iodide with silver dextrocamphorsulphonate and acetone, a mixture of the camphorsulphonates of the dextro- and lævo-quaternary ammonium derivates is obtained. From these salts the corresponding and optically active iodides and bromides may be prepared. It is thus proved that dissolved substances may owe their optical activity to asymmetric nitrogen.—Camphoroxime. Part III. Behaviour of camphoroxime towards potassium hypobromite, by M. O. Forster. Camphoroxime yields, when treated with potassium hypobromite, a nitroso-derivative, $C_{10}H_{16}BrN_2O$, which is converted into a compound of the composition $C_{10}H_{14}BrNO$ by sulphuric acid; on treating either substance with soda, a nitrite, $C_9H_{13}N$, and an amide, $C_9H_{15}NO$, are produced. The latter seems to be campholytic amide.—Optical influence of an unsaturated linkage on certain derivatives of bornylamine, by M. O. Forster.—The interaction of sodium hydroxide and benzaldehyde, by C. A. Kohn and W. Trantom. Electrolytic preparation of induline dyes, by E. C. Szarvasy. On electrolysing a fused mixture of aniline and its hydrochloride, the following substances are formed: induline, anilidoinduline, induline 6 B, and azophenine.—The heat of combination of copper with zinc, by T. J. Baker.—The action of sulphuric acid on fenchone, by J. E. Marsh. 1:2:4-Acetorthoxylene is produced by the action of sulphuric acid upon fenchone.—On glucosides, by H. Ryan.—Note on polyazo-compounds, by R. Meldola and W. A. Williams.—On ethyl dibromobutanetetracarboxylate and the synthesis of tetrahydrofurfuran-αα'-dicarboxylic acid, by B. Lean.—The application of powerful optically active acids to the resolution of externally compensated basic substances. Resolution of tetrahydroquinaldine, by W. J. Pope and S. J. Peachey.—The application of powerful optically active acids to the resolution of feebly basic substances. Resolution of camphoroxime, by W. J. Pope.—The application of powerful optically active acids to the resolution of externally compensated basic substances. Resolution of tetrahydroparatoluquinaldine, by W. J. Pope and E. M. Rich.—Homogeneity of dextrolævo-α-phenethylamine dextrocamphorsulphonate, by W. J. Pope and A. W. Harvey.—The characterisation of racemic liquids, by F. S. Kipping and W. J. Pope.—A method for discriminating between "non-racemic" and "racemic" liquids, by W. J. Pope and S. J. Peachey.—On two hydrated cobalt oxides, green- and buff-coloured, by W. N. Hartley.—A method of separating isomeric xylidines from the commercial product, by W. R. Hodgkinson and L. Limpach.—Action of hydrolytic agents on α-dibromocamphor and the constitution of bromocamphorenic acid, by A. Lapworth.

Entomological Society, November 1.—Mr. G. H. Verrall, President, in the chair.—Mr. J. J. Walker exhibited two living specimens of *Bostrychus cornutus*, Fab., obtained from a wooden stool which was brought from Zanzibar.—On behalf of Mr. W. Purley, of Folkestone, Mr. C. G. Barrett exhibited the following species of Lepidoptera:—*Stigmonota trauniana*, *Lozopera beatricella*, *Peronea cristana*, *Cledeobia angustalis*, *Crambus inquinatellus*, var., *Eudorea dubitalis*, var. *ingratella*, and *Endotricha flammealis*.—Mr. McLachlan showed four examples of *Deilephila lineata*, taken by Mr. E. W. Hainworth at Victor, Colorado, at an elevation of 9000 feet, on July 23, 1899; also an ash-twig which had been girdled by hornets, the observation of this curious fact having been made by Mr. W. C. Boyd, of Cheshunt, from whom he received the twig.—Dr. T. A. Chapman exhibited specimens of *Erebia flavofasciata* taken at Campolungo at an elevation of 7000 feet. He stated that the species occurred only in those places where there was an outcrop of dolomitic strata belonging to the crystalline schists, and was not met with elsewhere at that elevation, nor was it to be found in association with the same strata at lower levels.—Mr. H. J. Elwes exhibited and gave a brief account of a collection of Lepidoptera made by Mrs. Nicholl and himself in a part of Bulgaria which had not previously been visited by entomologists. *Lycaena eroides*, *L. anteros*, *L. zephyrus*, *Melitaea cynthia*, *Erebia gorge*, and *Coenonympha typhon* were a few of several interesting forms to which he directed attention.

Linnean Society, November 2.—Dr. A. Günther, F.R.S., President, in the chair.—Prof. Stewart, F.R.S., exhibited and made remarks on a preparation of the leaves of *Mimosa pudica* showing the diurnal and nocturnal positions. He also exhibited the embryo and egg-cases of *Cestracion Philippi*.—Rev. G. Henslow read a paper on the proliferous state of the awn of Nepal barley. After describing the two varieties *Hordeum coeleste*, vars. *Aegiceras* and *trifurcatum*, he showed that the inverted flower-buds (which constitute the peculiarity of the monstrosity) were different in the two varieties.—Dr. W. G. Ridewood read a paper on the hyobranchial skeleton of the new aglossal toad, *Hymenochirus Boettgeri*. The hyoidean cornua of this animal was shown to be ossified, a fact unique among tailless amphibians.—Mr. Harold Wager read a paper on the eye-spot and flagellum in *Euglena viridis*.

Mathematical Society, November 9.—Lord Kelvin, G.C.V.O., President, in the chair.—The President stated that the Council, as announced at the June meeting, had awarded the De Morgan medal to Prof. W. Burnside, F.R.S. After Major MacMahon, R.A., F.R.S., on behalf of the Council, had stated the grounds of the award, the President presented the medal to Prof. Burnside, who suitably thanked the Council for the honour they had conferred upon him.—The following gentlemen were elected the Council for the ensuing session: President, Lord Kelvin; Vice-Presidents, Prof. Elliott, F.R.S., Lieut.-Colonel Cunningham, R.E., Prof. Lamb, F.R.S.; Treasurer, Dr. J. Larmor, F.R.S.; Secretaries, R. Tucker and Prof. Love, F.R.S.; other members, Prof. Burnside, Dr. Glaisher, F.R.S., Prof. Hill, F.R.S., Dr. Hobson, F.R.S., A. B. Kempe, F.R.S., Dr. F. S. Macaulay, H. M. Macdonald, Major MacMahon and E. T. Whittaker.—Prof. Burnside communicated a short note by Dr. L. E. Dickson on the abstract groups isomorphic with the symmetric group on k letters.—Major MacMahon spoke on the fundamental solutions of the indeterminate relation $\lambda x \geqq \mu y$.—The following papers were read in abstract. Certain correspondences between spaces of n dimensions, by Dr. E. O. Lovett. (1) On the form of lines of force near a point of equilibrium; (2) the reduction of conics and quadrics to their principal axes by the Weierstrassian method of reducing quadratic forms; and (3) on the reduction of a linear substitution to a canonical form; with some applications to linear differential equations and quadratic forms, by T. J. I. Bromwich: (1) on Ampère's equation $Rr + 2Ss + Tt + U(rt - S^2) = V$, and (2) the theory of automorphic functions, by Prof. A. C. Dixon.—Note on Clebsch's second method for the integration of a Pfaffian equation, by J. Brill.

Zoological Society, November 14.—Dr. A. Günther, F.R.S., Vice-President, in the chair.—Mr. Sclater gave an account of his recent journey to the Cape, and made remarks on the animals he had obtained there for the Society's collection. He also called attention to the desirability of the establishment of a Zoological Garden at Capetown.—Mr. A. Smith Woodward read a communication from Señ. F. Ameghino containing some further notes on *Neomylodon listai* (*Grypotherium*). Mr. A. Smith Woodward also exhibited, on behalf of Dr. Moreno, the skull and other specimens of this animal lately discovered in the cave in Southern Patagonia where the original pieces of skin had been obtained, and made remarks on them.—Mr. Lydekker exhibited and made remarks on a remarkably fine head of the swamp-deer (*Cervus duvauceli*), obtained by Major C. B. Wood in the Central Provinces of India.—The Secretary exhibited, on behalf of Mr. C. Pole Carew, some malformed horns of the Sambur Deer (*Cervus aristotelis*), obtained by him in the southern province of Ceylon, and read some notes on them sent by Mrs. Carew.—A communication was read from Mr. F. Vaughan Kirby, containing field-notes on the blue-buck of the Cape Colony (*Cephalophus monticola*).—A communication was read from Mr. R. I. Pocock, containing an account of the collections of Arachnids made by Mr. G. L. Bates in French Congo. To this was added a complete list of the species of the same group represented in the British Museum, and descriptions of the new genera and species.—A communication was read from Mr. Stanley S. Flower containing notes on a second collection of Batrachians made in the Malay Peninsula and Siam from November 1896 to September 1898. Forty-nine species, of which fifteen had not been previously recorded from these countries, were enumerated, and the tadpoles of several of them were described for the first time.—Mr. R. Lydekker read three papers dealing with (1) the specific characters of the Chilian Guemal (*Cariacus chilensis*), which previously, from the absence of good specimens of the animal, had been inaccurately given; (2) the skull of a Shark-toothed Dolphin (*Prosqualodon australis*) from Patagonia, in which he pointed out the characters of distinction between that species and the genus *Squalodon*; (3) the results of recent investigations on the dentition of the Marsupial and Placental Carnivores.—A communication was read from Mr. Ernest Gibson, containing field-notes on the Wood-Cat of Argentina (*Felis geoffroyi*), two specimens of which animal had recently been presented to the Society by Mr. William Brown, of Buenos Aires.

CAMBRIDGE.

Philosophical Society, October 30.—Mr. J. Larmor, President, in the chair.—The following were elected officers for the ensuing year: President, Mr. J. Larmor; vice-presidents, Mr. F. Darwin, Prof. A. R. Forsyth, Dr. W. H. Gaskell; treasurer, Mr. Newall; secretaries, Mr. Baker, Mr. Shipley, Mr. Wilberforce; members of Council, Mr. Harker, Mr. Hutchinson, Prof. Liveing, Mr. Skinner, Mr. Gadow, Mr. Sharp, Prof. J. J. Thomson, Mr. Berry, Sir G. G. Stokes, Mr. Bateson, Mr. Seward, Mr. G. T. Walker.—The following communications were made to the Society: On semi-convergent series, by Mr. W. McF. Orr.—An experiment on the condensation of clouds, by Mr. C. T. R. Wilson. The author gave an experimental demonstration of the production of cloud by the contact of layers of moist air of different temperatures.—On the conductivity of gases from arcs and from incandescent wires, by Mr. J. A. M'Clelland. The first part of this paper contains an account of experiments on the conductivity of gas through which an arc discharge has passed; the second part deals with the conductivity of gas near an incandescent wire. Experiments have been made with an arc between platinum terminals and with an incandescent platinum wire in air, oxygen and carbonic acid gas. The conductivity is shown to be produced by ionisation, and the nature of the carriers, their velocity under an electric force, and other points are investigated. With the arc in air, or oxygen, there is a small excess of positive electricity in the gas taken from the neighbourhood of the arc, and this excess is very great in CO_2; the greater velocity of the negative carriers under electric force causes more of them to be discharged to the terminals of the arc. The velocity of the carriers under electric force is not a constant quantity, but varies with the nature of the arc and the temperature of the incandescent wire. The velocity diminishes as the temperature is raised; this may be caused by the carriers coming from the wire itself or the arc terminals at these higher temperatures, or by the disintegration of the wire or terminals affording material to condense on the carriers already formed in the gas.—On the secondary Röntgen rays, by Mr. J. S. Townsend. This paper contained an account of experiments made with the rays given out when Röntgen rays fall on metals and other bodies. These rays are of two kinds. The first are rapidly absorbed by the air, and at a distance of one centimetre from the radiating body their power of ionising the air is reduced to one-thousandth of its value at the surface. The rays of the second kind are more penetrating, and extend to a distance of several centimetres from the radiating body. They cannot be considered part of the first kind of rays, as these would only have an effect of $\frac{1}{10^{18}}$ of their initial value at a distance of 6 centimetres, which would be too small to detect.

MANCHESTER.

Literary and Philosophical Society, November 14.—Prof. Horace Lamb, F.R.S., President, in the chair.—Mr. W. E. Hoyle exhibited a series of flint implements, &c., from Egypt, forming part of a large collection obtained by Prof. Flinders Petrie during the past winter in excavating about twenty miles of cemetery in the western desert between Hu and Dendereh, and since presented to the Manchester Museum. These belonged to various periods, from prehistoric to Roman. Certain types of knives with very finely notched edges and forked lance-heads are very characteristic of the prehistoric age. One cemetery dates from the Libyan settlements in Egypt at the close of the Middle kingdom, about 2400 B.C. Here the graves were all shallow pits of the form known as "pan graves," in which the bodies were laid in a contracted position, but not all in the same direction. From this were obtained several of the strings of beads exhibited. The shell bracelets are very characteristic of this period. Another large cemetery at Hu began in the sixth dynasty, and contained, besides pottery, a large quantity of beads. One large necklace of five strings was of amethyst, others were of cornelian and garnet, whilst in the other sets were metal beads, which, from their not having corroded, were presumed to have contained a considerable proportion of gold. The collection included a large number of pieces of engraved bone, apparently prepared for inlaying, as well as two beautiful diorite saucers, one circular and the other in the shape of a large *Unio* shell. A block of stone about six inches square, with a circle and two cross-lines on the top, once formed the upper part of a short stone pillar, and is believed to have been a surveyor's mark.

PARIS.

Academy of Sciences, November 13.—M. van Tieghem in the chair.—Observation relating to researches on the diamines, by M. Berthelot. A correction to the paper published on this subject in the last number of the *Comptes rendus*.—The disease attacking carnations at Antibes, by MM. Prillieux and Delacroix. The primary cause of the disease is a fungus, a detailed description of which is given. Artificial cultures could be carried out either on potato or in a drop of nutrient fluid. The species appears to be new, and the provisional name of *Fusarium Dianthi* is given to it.—Researches on acute alcoholism; estimation of alcohol in the blood and tissues, by M. N. Gréhant. The alcohol was introduced into the stomach in measured amounts through a tube, and samples of blood taken at half-hourly intervals were submitted to distillation in vacuo, and the alcohol in the distillaters estimated by the bichromate method of Nicloux. In another experiment the animal was killed, and separate analyses made of the brain, muscles, liver, kidneys and blood. The amounts per 100 grams of material were nearly the same, varying between 0·325 and 0·41 c.c. of alcohol.—On congruences of circles and spheres which intervene in the study of cyclic and orthogonal systems, by M. C. Guichard.—On equations of the second order with fixed critical points, by M. Paul Painlevé.—On the generalisation of expansions in continued fractions given by Gauss and Euler, of the function $(1 \times x)^m$, by M. H. Padé.—A new mode of considering the propagation of luminous vibrations through matter, by M. G. Sagnac.—On the spectrophotometry of the electric light, by M. Fernand Gaud. A comparison between the intensities of different portions of the spectrum of incandescent and arc lights with sunlight was made by decomposing each light by screens of homogeneous colour, and measuring the intensity of the transmitted light with a simple Foucault or Bunsen photometer. The screens were previously carefully examined by Frauenhofer's method, and the wave-length of the light transmitted by the screen exactly determined.—On the atomic weight of the metal in radio-active barium chloride, by Mme. Sklodowska Curie. Fractional crystallisation of barium chloride obtained from uranium minerals gave a salt which concentrated the radio-activity in the least soluble portions. The atomic weight was found to increase with the radio-activity, the maximum value obtained being 145·8 as compared with 137·8 for the inactive barium. These results confirm the original view of the existence of a new element, radium.—On the preparation and properties of the crystallised phosphides of strontium and barium, by M. A. Jaboin. Crystallised strontium phosphide is prepared in a pure state by heating pure strontium phosphate with lamp black in the electric furnace. The phosphide has a dark colour, breaks with a crystalline fracture, and is rapidly attacked by moist air, or by chlorine, at about 30° C. At the temperature of the electric furnace carbon replaces the phosphorus slowly, giving strontium carbide. Barium phosphide is prepared in a similar manner and has corresponding properties.—On the estimation of phosphorus in organic compounds, by M. Ch. Marie. The organic material is destroyed by heating with nitric acid and potassium permanganate, and the phosphoric acid precipitated with molybdate, certain special precautions being necessary.—On some new asymmetric compounds of nitrogen obtained synthetically and possessing rotatory power, by MM. W. J. Pope and S. J. Peachey. α-Benzyl-phenyl-allyl-methylammonium iodide is heated with dextrocamphorosulphonate of silver, the silver iodide filtered off, and the resulting salt recrystallised from a mixture of acetone and ethyl acetate. From the less soluble fractions a dextrorotatory form ($M_D = +208°$) is readily isolated, the more soluble salt ($M_D = -87°$) being lævorotatory. From these salts a dextrorotatory iodide ($\alpha_D = 52°·4$), bromide ($\alpha_D = +68°·6$), and a lævorotatory iodide ($\alpha_D = -51°·4$) and bromide ($\alpha_D = -67°·3$) were obtained. In these compounds the rotatory power is clearly due to the asymmetrical arrangement of the groups round the nitrogen atom.—On the absorption of iodine by plants, by M. P. Bourcet. From a series of analyses of plants grown under identical conditions in soil containing iodides, it was found that certain plants absorb much more iodine than others, some absorbing none at all.—On the morphology and sexual evolution of a parasite of *Hemioniscus balani*, by MM. Maurice Coullery and Félix Mesnil.—On the absorptive power of seeds for moisture, by M. L. Maquenne.—On the origin of the symmetry in crystallised bodies and of polymorphism, by M. Fred Wallerant.—The relations existing between diuretic actions and osmotic properties of the sugars, by MM. E. Hédon and J. Arrous.—On lipase in pathological conditions, by MM. Ch. Achard and A. Clerc.—New experiments relating to the antiphylloxeric disinfection of vine plants, by MM. Georges Couanon, Joseph Michon and E. Salomon.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 23.

THE INHERITANCE OF DEAFNESS.

Marriages of the Deaf in America. By Edward Allen Fay. Pp. 527. (Washington: The Volta Bureau, 1898.)

MR. FAY'S work is an inquiry concerning the results of marriages of the deaf in America, a research originally instituted by Dr. A. Graham Bell among the charges which he committed to the Volta Bureau when he endowed that institution. When Mr. Fay undertook this work—as a labour of love—the resources of the Bureau were placed at his disposal, and he was further helped in his investigations by his Government appointment as a special agent for the collection of statistics relating to the deaf of the United States during the taking of the eleventh census. By these means Mr. Fay was particularly well equipped for his work, and the volume before us is no mean result. Taking as the chief aims of his inquiry the solution of certain questions of interest and importance to the deaf as a class and as individuals, he has sought by all the means in his power to obtain satisfactory replies, and his success will be seen by all who care to give the book a careful study. The questions to be elucidated were as follows:—

(1) Are marriages of deaf persons more liable to result in deaf offspring than ordinary marriages?

(2) Are marriages in which both of the partners are deaf more liable to result in deaf offspring than marriages in which one of the partners is deaf and the other is a hearing person?

(3) Are certain classes of the deaf, however they may marry, more liable than others to have deaf children? If so, how are these classes respectively composed, and what are the conditions that increase or diminish this liability?

(4) Aside from the question of the liability of the offspring to deafness, are marriages in which both of the partners are deaf more likely to result happily than marriages in which one of the partners is deaf and the other a hearing person?

These are questions which have been submitted to considerable discussion both in Europe and America, with the result that the conclusions arrived at have differed widely. Indeed the conclusions have ranged between the dictum of Graham Bell, that "the evidence shows a tendency to the formation of a deaf variety of the human race in America," on the one hand, to that of the Commissioners of the Irish census of 1881, that "it appears evident that the question of deafness and dumbness in parents has no influence in propagating the defect."

Mr. Fay's inquiry commenced in 1889, and the work has continued uninterruptedly since that time. Exhaustive questions were sent out and about, and the replies received were both more numerous and more complete than was anticipated.

It would be beyond the purpose or scope of this review to enter with any detail into the large number of statistics placed before Mr. Fay's readers; suffice it to say that they bear the stamp of having been most carefully collected, tested, and arranged, and may therefore be taken as more trustworthy than statistics are usually found to be. In the tabular statement of marriages details are given of no less than 4471 unions—a fact that will give the reader some idea of the onerous nature of Mr. Fay's task.

It appears that marriages of the deaf are more common in America than in Europe, and they have increased at a high rate of progression during the present century. From the statistics it appears that marriages of deaf persons, one or both of the partners being deaf, are far more liable to result in deaf offspring than ordinary marriages. The proportion of deaf marriages resulting in deaf offspring is 9·7 per cent., and the proportion of deaf children born therefrom is 8·6 per cent. Accurate data as to the proportion of deaf children born of ordinary marriages are not easily obtainable, but that proportion is probably less than 1·10 per cent. On the other hand, marriages of the deaf are far more likely to result in hearing offspring, the proportion of hearing children being 75 per cent.

These results are in accordance with the two laws of heredity: (1) that a physical anomaly tends to be transmitted to the offspring, and (2) that offspring tend to revert to the normal type.

There is a greater liability to deaf offspring of marriages of the congenitally deaf, since congenital or innate characteristics are far more likely to be transmitted than are acquired characteristics.

It appears also that deaf persons having deaf relatives, however they are married, and hearing persons having deaf relatives and married to deaf partners, are very liable to have deaf offspring. Finally, the marriages of the deaf most liable to result in deaf children are those in which the partners are related by consanguinity.

The most important statistics (summed up in a separate table) are those showing the number of marriages of each class of which the results are reported and the number and percentage of each class resulting in deaf children, with the number of children born from marriages of each class, and giving the number and percentage of those deaf. These statistics show the comparative liability to deaf offspring of the several classes of marriages.

As regards the *happiness* of deaf unions, marriages in which both parties are deaf appear to be more likely, other things being equal, to result happily than those in which one of the partners is deaf and the other possesses normal hearing; the proportion of divorces and separations in the former class being 2·5 per cent., in the latter 6·4 per cent. This is easily explainable on the grounds of mutual fellowship and identity of social relations and sympathies which arise from the union of individuals suffering from similar conditions.

An appendix is devoted to illegitimate unions, but the totals of their statistics are too small to furnish any certain basis for trustworthy conclusions.

Mr. Fay has produced a valuable work, and one which should take a prominent place in the literature—necessarily not a very large one—of the subject. From a careful perusal one cannot fail to note the clearness of his statements and the logical way in which he works out his deductions. There is but one thing lacking, and that is the devotion of any special chapter to those diseases of the ear—notably the condition known as middle ear sclerosis—acknowledged to be hereditary, or to the diseases of the throat and nose which are predisposing causes of deficient hearing power. Considering the large percentage of all forms of nasal obstruction existing in the condition of civilisation—a percentage larger, we believe, in America than in Europe—it would be of interest to investigate the influences diseases of the throat and nose exercise upon the marriages of persons suffering therefrom.

In spite of the fact that statistics are always somewhat dry, and the deductions given from those in Mr. Fay's work are put without useless verbiage, the book is a very readable one to those interested in all branches of the subject, and should rank high as a work of reference.

MACLEOD YEARSLEY.

THE LIQUEFACTION OF GASES.

The Rise and Development of the Liquefaction of Gases. By Willett L. Hardin, Ph.D. Pp. viii+250. (New York: The Macmillan Co. London: Macmillan and Co., Ltd., 1899.)

La Liquéfaction des Gaz et ses Applications. By Prof. Julien Lefèvre. Pp. 175. (Paris: Gauthier-Villars et Fils, and Masson et Cie.)

A BOOK should be criticised with reference to the author's professed object in writing it. Dr. Hardin professes to have written for the popular reader, in the popular science style. Regarded from this point of view the work deserves a good deal of praise. It is, in the first place, interesting to read, collecting, as it does, a great many facts connected with the development of low-temperature research, and detailing numerous experiments which are explained with the assistance of copious and clear illustrations. It may therefore be recommended, with the reservations which are made below, to those who, with a very elementary knowledge of physics, desire to learn something of the details of recent progress in a very interesting subject. The recommendation should be all the heartier because the author's style is free from the patriotic brag and boom which disfigure another recent American book on the same subject, and because the right side is taken as to the marvellous industrial revolutions heralded from America as a consequence of later work in this department of science. A further merit in the work is the abundance of exact references to original authorities, for the benefit, as stated in the preface, of those who wish for fuller information.

The fact, however, that the author had the latter object in view emphasises what should be a binding obligation even in books intended solely for popular reading, namely, to take care that such science as is introduced shall be strictly correct; and this obligation Dr. Hardin has fallen short of in a serious degree. On pp. 183-185 he reproduces Edwin J. Houston's suggestions for an apparatus to produce intense refrigeration. The nearest thing to a novelty in these suggestions is the proposal to modify Windhausen's machine by substituting a two-stage compressor for a single-stage one, and so obtaining a higher pressure of sixty atmospheres. He expressly retains Windhausen's system of power expansion in a cylinder doing work on a piston; yet Dr. Hardin says:

"In the apparatus suggested, Houston anticipated the methods which were employed twenty years later in the liquefaction of air by Linde, Hampson and Tripler."

This is inexcusable in one who undertakes to "enable the popular reader to understand the principles involved." The same confusion is repeated much more deliberately later on. On pp. 205-208 the author works out mathematically the formula for the cooling produced by power expansion, $\left(\frac{p}{p_1}\right)^{\frac{k-1}{k}}=\frac{T}{T_1}$, which he calls equation (7). He then says:

"Applying these results to the liquefaction of gases by means of the regenerative coil, it is evident that the expansion of the gas in the tube lowers the temperature by an amount which corresponds to equation (7)."

The formula for power expansion is here applied where we ought to have had Thomson's formula for free expansion, $-\frac{d\theta}{dp} = A\left(\frac{273 \cdot 7}{t}\right)^2$. The title of the section is "Theory of the Self-intensification Method of Refrigeration," and a note, at the foot of the same page, refers us to Joule and Thomson for a more complete discussion, which, however, in the body of the section, instead of being abridged or summarised, is altogether replaced by another analysis. The way in which the book is written gives no reason to suppose that Dr. Hardin is incapable of distinguishing between the very different conditions involved in power-expansion and free expansion, or the very different mathematical analyses appropriate to these two sets of conditions. The only tolerable explanation of such a gross confusion is that it has never come in Dr. Hardin's way to read Thomson's papers on the cooling of gases by free expansion, or to examine intimately the nature of the phenomena involved, and so he has carelessly applied to these phenomena the well-known formula for cooling by power-expansion. This is not the proper way to write a book even for the satisfaction of the interest of the popular reader. These are not the only instances that the author shows of a lack of thorough acquaintance with his subject. If he had studied Mr. Tripler's British patent of 1893, which is put forth as the foundation of his claims as inventor of a form of self-intensive air-liquefier, and had paid attention to the chronology of the subject, Dr. Hardin would perhaps not have felt justified in treating those claims so well as he has done, by describing those parts of Mr. Tripler's apparatus which are not kept secret. On p. 227, the author gives Prof. Dewar's conclusion, that the liquefying points of hydrogen and helium are near together, without giving the subsequent correction.

The style of the writing is occasionally careless and slipshod, and the meaning sometimes undiscoverable. On p. 209 we are told

"the issuing jet experiences a much greater decrease in temperature owing to the greater difference between the initial and final pressures."

This is unintelligible in view of the fact that the difference between the initial and final pressures does not increase, while in case of supply from a cylinder of compressed gas, it actually decreases. On p. 232 we find the sentence: "Below the temperature of zero degrees ice slowly sublimes." Some misprints have escaped correction. On p. 208 the minus sign is omitted between k and 1 in equation (7). On p. 243 the second "i" in the name Lavoisier has been omitted.

If in a new edition such mistakes be corrected, and the latter part of Chapter iv., Section 3, be rewritten, the book will be useful as well as interesting to the class of readers for whom it is chiefly intended.

Prof. Lefèvre's book is very well written and clearly illustrated. Within the narrow limits of 175 pages it contains a considerable amount of correct theory, a very interesting history of the experimental development of gas-liquefaction, some discussion of industrial applications, and a very full list of references to original authorities; and all this with a surprising freedom from the evils of over-compression. The arrangement is not altogether perfect. Prof. Dewar's apparatus figured on pp. 55 and 61 apply the combination of free expansion with counter-current interchange, a method of which there was earlier authenticated invention both in England and Germany. These applications should have been described in Section 35 under the head "Machines à détente sans travail extérieur," and after the invention on which they depend; or, if it was thought advisable to discuss them out of chronological order, their dependence on the combination in that invention should have been clearly brought out. The illustration of Mr. Tripler's apparatus on p. 84 might well have been omitted. The employment of three-stage compressors, with cooling coils between the stages, with purifiers, water-separators, and pressure-gauge, was familiar to pneumatic engineers for years before they were employed by Mr. Tripler in liquefying air; and the vitally important interchanger and expansion valve remain such a mystery that the illustration gives no idea what they are like or whether they differ essentially from the invention of Dr. Linde and Dr. Hampson. On p. 70 the statement that helium was liquefied at the temperature of boiling hydrogen needs correcting in accordance with later results. Chapter ix., on modern commercial refrigerating machines, is very much out of proportion with the rest of the book; a discussion of this subject, which entirely passes by the great American and British developments in this field, might as well be omitted altogether.

A CONTRIBUTION TO ZOO-GEOGRAPHY.

Studien zur Geographie. Von Dr. W. Kobelt. Zweiter Band. Pp. x + 369. (Wiesbaden: Kreidel, 1898.)

IN this, the second part of his "studies," Dr. Kobelt deals at full length with the characteristics of the fauna and to some extent also, of the flora of the "Meridional Sub-region." This region very nearly corresponds to the Mediterranean sub-region of Dr. Wallace; its northern limits are a trifle more extensive, embracing as they do the Crimea and Bessarabia.

As might be expected from the nature of his own zoological studies, the author lays most stress upon the distribution of Mollusca, and gives a series of elaborate and apparently very full tables of species found in the different departments into which he divides the region described in this volume. It must not, however, be inferred from this that other groups of animals are neglected or even treated with indifference.

A great deal is said about the range of the vertebrata of this part of the world in the past as well as in the present, all the orders of that assemblage of animals being taken into consideration. There is one group of terrestrial, aquatic and semi-aquatic invertebrates which are not at all discussed by Dr. Kobelt. This group—that of the earthworms and their allies—might profitably have been dealt with, inasmuch as their range, so far as is known, marks out very well not only the limits of the Palæarctic region (excluding only Japan), but also enables a line to be drawn between the more northern and the Mediterranean portions of the region dealt with by Dr. Kobelt. Inasmuch as a large portion of the meridional region is occupied by the Mediterranean sea, the author is, we think, wise in paying some attention to the fauna of that sea, as well as of other stretches of water included within his area. A special chapter is devoted to the Mediterranean, and the author commences by addressing himself to the problem as to whether that inland sea is really an independent tract or a section of the Atlantic.

The colossal faunistic and structural monographs issued by the Naples Zoological Station, as well as the results of elaborate studies carried on at similar institutions along the coasts of the Mediterranean, have made us well acquainted with the shallow water fauna of that sea. We are less informed as to the pelagic creatures, especially mammals, and about the deep-sea fauna. As to the former, observes the author, "the mammalogist will, with a regretful shrug of the shoulders, confess himself incompetent" to speak with accuracy. So far as we know, the whales are not special to that sea; nor does palæontological evidence hint at the Mediterranean as a centre of origin. Oliver Goldsmith, in his "Animated Nature," pointed out that the Mediterranean dolphin occurred in the Red Sea. He was doubtless right, though the reasoning employed may have been defective, and there is no prevision of the Suez Canal! The sperm whale is found therein, and (if we may regard the sea beast from which Perseus delivered Andromeda as a "monstrous physetere"!) was even known to the ancients. Pliny's Orca was, it appears, rather that "sea should'ring whale" than a gladiator. The dolphin of the Mediterranean has received many names, but there seems to be little doubt that that whale of Greek coins is exactly the same as the dolphin of the coasts of the Atlantic. "As concerns mammals," concludes Dr. Kobelt, "the Mediterranean is an impoverished gulf of the Atlantic Ocean.'

In the characteristics of the Mollusca found, and some other animals, the Mediterranean presents tropical characters which are, partly at least, in reality due to the Suez Canal. Mr. E. A. Smith, of the Natural History Museum, contributed some years since a number of interesting facts to the Zoological Society bearing upon such immigrations. The Mediterranean, as is well known, sinks in places to profoundly abyssal depths; the actually greatest depth appears to be 4400 metres; but here no living organisms have been found. It is purely azoic; the reason for the want of life is, according to the author, the want of oxygen and the abundance of carbonic acid.

There is, in fact, no special deep-sea fauna found in this large tract of water.

Turning to the terrestrial mammalia, the author comes to the conclusion (elaborated in a special and highly interesting chapter) that their range to-day is in thorough agreement with the distribution of land and water. The Mediterranean southwards and the Bosphorus westwards form barriers which divide faunas. This is illustrative of what is apt to be a common error in text-books of zoology. When Mr. Sclater originally divided up the earth into zoological regions, he did not profess to do so for more than the Passerine birds, though his conclusions were shown later by himself and by others to apply to other groups also. They do not, however, in the least apply to various invertebrate groups; and in dogmatically dividing the world into the Sclaterian regions, the writers of some text-books have entirely lost the prime object of such a regional division. The more modern Eutherian mammals are controlled in their range by what are largely existing barriers; the more ancient molluscs show in their distribution the non-existence of such barriers in ancient times. Dr. Kobelt dwells upon the distinctness of northern Africa from Europe so far as concerns its mammalian inhabitants. He is disposed to dismiss the Gibraltar monkey as truly indigenous to that peninsula, though admitting the occurrence of fossil allies in European strata of Pleistocene and Pliocene age.

On the whole, however, we are not certain that Dr. Kobelt has taken so fortunate an instance as he might have done to illustrate the effects of modern barriers in the dispersal of mammals. It is perhaps a little too strong, in the face of the lists which he gives, to state of the Straits of Gibraltar and the narrow passage opposite to Carthage that they are "faunistic boundaries of the first rank." The division between the arctic and the non-arctic parts of the palæarctic region are more easily defined from their mammalian indigenes.

Dr. Kobelt's book is closely packed with solid fact, and there is no more speculation than is necessary to give prominence to such generalisations as appear to him to be the legitimate outcome of his laboriously collected material. This has been amassed from the most diverse sources; and the author by no means disdains the older writers, even the ancients being laid under contribution. We commend the book to the serious student of zoogeography only, for it is emphatically not to be trifled with in an arm-chair.

F. E. B.

A TEXT-BOOK OF HEAT MOTORS.

The Steam Engine and Gas and Oil Engines. By John Perry, D.Sc., F.R.S. Pp. viii + 646. (London: Macmillan and Co., Ltd., 1899.)

THIS is one of the best books which has been published in this country on the steam engine and other heat motors. The method and style is thoroughly characteristic of Prof Perry. Many will no doubt object to the order of arrangement of the various chapters, and will be inclined to think the author has put the cart before the horse; the author will probably reply that the book was not written for the beginner, but for advanced students.

There is something to be said for the plan adopted; if a text-book for students, engaged during the day in practical engine work, is given up in its early chapters almost entirely to the properties of steam and thermodynamic problems, there is great risk that the student will be discouraged and eventually give up the attempt to improve his knowledge of the principles underlying the working of heat motors.

The author's plan is to deal first with the more practical details, in the hope probably that in mastering these the student will find out what he lacks and what he needs of thermodynamics and kindred subjects. Granted this, it is still a little difficult to see that an improvement would not be effected by putting Chapters xv., xviii. and xix. on methods of calculation, on temperature and heat, and on the properties of steam, earlier in the book. This is shown by the necessity of a footnote on p. 99 to explain the way in which the total heat required in evaporating a pound of steam is determined.

Chapter ii. is devoted to description of cylinders, pistons, valves, frames, &c., of what the author calls the commonest form of steam engine, but as the details explained include parts of steam turbines, the title is hardly happy. The illustrations in this chapter are extremely good and complete.

Chapter iii. deals with the value of expansion, and the author points out, as a result of his calculations, that there are limits of economic expansion, and how easily the Willan's law can be deduced from such calculations.

Chapter iv. describes the indicator, its construction and the proper way to use it, and the errors it is liable to. Then, in the following chapter, come a most valuable series of exercises on calculations from indicator cards.

One of the chief merits of the book, apart from the fact that it is so thoroughly up to date in all its information and methods, is the way in which almost every chapter is filled with numerical exercises; any student genuinely working these out for himself cannot fail to become thoroughly master of the main problems confronting the student of heat motors.

In this chapter again (v.) we have a little awkwardness introduced from the particular arrangement adopted by the author. One of the exercises is the drawing of a $\theta\phi$ diagram, and no explanation of this has been given, the reader is referred for explanations to a much later chapter of the book. We fear the student is not likely to start with much knowledge of entropy, and will therefore probably skip these sections.

The next eight chapters are devoted to the mechanical details of valves, governors, air pumps, boilers and their fittings and accessories.

The first fourteen chapters may be said to mainly deal with the mechanical details of engines and boilers; while the rest of the book is devoted to what may be called theory and principle.

In Chapter xvi. the author deals with the cost of production of energy and the efficiency of various types of motors, a most complete and valuable chapter full of good examples. Then come some chapters on temperature and heat, properties of steam, and work, &c., all very thorough and very full of matter for careful thought.

In the chapter on the $\theta\phi$ diagrams, more advanced theory is taken up; and, in fact, there are several chapters here that will be above the average student, and will form good reading for the expert; the facts are marshalled with great skill, and the deductions show that the author is a thorough master of his subject.

The chapters on valve motion problems and inertia of moving parts are good, and the methods adopted to deal with these very difficult problems are as simple as it is possible for them to be.

Though only forty-two pages are devoted to gas and oil engines, the author has managed to get in a great amount of most useful information, and to give all that the general student needs.

The remaining chapters are devoted to certain important thermodynamic problems and to an inquiry into the properties of superheated steam.

Most certainly Prof. Perry has produced a text-book which must be on the shelf of every student of applied thermodynamics, and of every engineer who has to deal with the utilisation of energy. H. B.

OUR BOOK SHELF.

Practical Plane and Solid Geometry for Advanced Students; including Graphic Statics. By J. Harrison, M.I.M.E., and G. A. Baxandall. Pp. xii + 558. (Macmillan and Co., 1889.)

THIS book appears to compare very favourably with most English works of its class. The greater part of it deals with practical solid geometry, including the method of indexed plans; this subject is treated in a much more methodical way than is usually the case, and the authors very properly call attention from time to time to constructions which are of a fundamental character. It is a pity they did not go further, and clearly distinguish throughout the book the worked examples which involve new points of theory from those which merely illustrate general constructions previously given. The directions for making cardboard models ought to be very useful to the student; and the constructions are explained in such a way as to make the reasons for them intelligible. The section on plane geometry is distinctly above the average; in particular, there is a very interesting discussion of the description of an ellipse by means of a paper trammel. Of graphical statics only a brief outline is given; but it is useful enough so far as it goes. There is one error to which attention ought to be drawn: on p. 342 it is stated that the tangent plane to a surface at an anticlastic point cuts the surface in a curve with a double point *where there are two inflexions:* this is not generally the case, and, in fact, the anchor-ring gives an example of the contrary. Here the section is a bicircular quartic which has a real ordinary node when the tangent plane cuts the ring, and is not parallel to the polar axis.

Grundlinien der maritimen Meteorologie. By W. Köppen. Pp. vi + 83. (Hamburg: G. W. Hiemeyer, 1899.)

THIS little work serves two purposes; it is practically a concise elementary meteorology, and a guide for the use of sailors, showing the best routes in the different oceans, with directions for the management of vessels in storms, especially the dangerous West India hurricanes and the typhoons of the China seas. Dr. Köppen has been known for many years as one of the most prominent meteorologists, and having access to the large amount of materials collected by the Deutsche Seewarte, we might expect to find the result of his long experience embodied in a useful and an attractive form. The work meets our expectations in every way; all details which are unnecessary for the object in view have been carefully excluded, while all technical and nautical expressions are fully explained, so that the work, which is specially written for seamen, may be read with interest and advantage by all who are desirous of obtaining a knowledge of maritime meteorology. His treatment of the subject includes the general circulation of the atmosphere, as well as the movements of waves, tides and ocean currents, and the value of the treatise is much enhanced by explanatory figures in the text and by separate charts and diagrams.

Inorganic Chemical Preparations. By Felix Lengfeld. Pp. xviii + 57. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1899.)

THIS is a compact series of instructions for the preparation of typical inorganic compounds, the selection of which seems to have been very judiciously made. References to original literature are given in connection with each preparation. The author takes care to explain "that the manual is merely a laboratory guide, and that unless the work is carefully supervised, it may become purely mechanical, and the course lose half its value." It is, in fact, a series of recipes, and no attempt is made to explain the innumerable difficulties that will confront the inexperienced worker. This is not said by way of complaint; on the contrary, it is the incidental and unexpected difficulties of an operation rather than the plain sailing that give the operator occasion to think, and lead to the close association of the teacher with the mind of the learner.

Mr. Lengfeld purposely refrains from giving a complete list of references to literature, being of opinion that the student should learn to use dictionaries of chemistry. It is doubtful, however, whether the student is able to make a discreet choice from the innumerable references of a dictionary, and we think that the author has rather lost an opportunity in not making his list of references more ample. To those teachers who are introducing more inorganic preparation work into their courses, this book is likely to prove welcome. A. S.

The Utility of Sulphate of Ammonia in Agriculture. By James Muir, M.R.A.C. Pp. 68. (London: Sulphate of Ammonia Committee, 4 Fenchurch Avenue, E.C., 1899.)

THIS is the essay which won the prize lately offered by the Sulphate of Ammonia Committee. Mr. Muir has carefully compiled his little treatise, and made a judicious selection of results of field experiments to illustrate the use of sulphate of ammonia, and to compare its results with those obtained from the use of nitrate of soda. Naturally, the results of the Rothamsted experiments are those most largely drawn upon; Woburn is also quoted from to a considerable extent, and the author considerately always gives references to his authorities. The comparisons between the effects of nitrate of soda and sulphate of ammonia are fully and very fairly drawn, and the farmer should find the essay a great help in deciding which of these nitrogenous manures to apply in any particular case. No doubt the farmer, for whom the essay is chiefly written, will turn to the last three pages, which contain a summary of conclusions and comparisons between the two important nitrogenous manures. This summary is in twenty-seven paragraphs, and but few of these lay themselves open to criticism. We can only suggest that the author might have pointed out more clearly in this summary, paragraph 3, that leguminous plants can, under favourable conditions, make use of free nitrogen; paragraph 7, that nitrogenous manures, and *especially* ammoniacal manures, do not give their bes results unless plenty of ash constituents are present, phosphates as well as potash; paragraph 20, that phosphates are a highly desirable addition in the manuring of barley; and paragraphs 24 and 27, that both phosphates and potash should be used on potatoes and on grass-land when sulphate of ammonia is used to supply nitrogen.

The Committee is to be congratulated on having secured and published a very useful and very justly written essay.

Euclid. Books I.–IV. Edited by Charles Smith and Sophie Bryant. Pp. viii + 288. (London: Macmillan and Co., 1899.)

WITH this book we have another addition to the great number of text-books on the Elements of Geometry. Its chief features seem to be that the editors endeavour to instil into the students the notion that it is the correct reasoning and proof of the propositions which should be mastered, and not so much an exact repetition of the words of the text-book or teacher.

Abbreviations are freely used early in the first book, and these should be adopted generally by beginners, as the reasoning of a proof can be more easily scanned. The editors have in several cases departed from Euclid's solutions and adopted in their stead more modern and simple methods. Included in the text are many examples, both original and selected, from mathematical journals and examination papers. In this form the Elements should be found useful in many schools.

Sylvia in Flowerland. By Linda Gardiner. Pp. 198. (London: Seeley and Co., Ltd., 1899.)

AN attempt is here made to employ the methods of Lewis Carroll in the teaching of botany. In the first chapter the foxglove explains: "This is Leap Year with us (the flowers), and so we have a thirty-first of June," and because the thirty-first of June does not occur every year, it is a day of special favour to humans, who are allowed "to hear with both eyes and ears." Sylvia talks with plant after plant, and is instructed by them in the fascinating mysteries of cross-pollenation and many other interesting questions of plant-life. The jam is sometimes scarcely thick enough to hide the powder; but we have little doubt that the volume will find many appreciative readers.

Magnetism and Electricity. By J. Paley Yorke. Pp. viii + 264. (London: Edward Arnold, 1899.)

MR. YORKE'S object is to provide an introduction to this branch of physics for those students who already possess some acquaintance with general elementary science. His treatment is non-mathematical, and no precise instructions are given for experimental work. It is a little difficult to understand the reason for the interpolation of chapter v., headed "Electricity," between the subjects of magnetism and the study of electric currents, more especially as the subject of electrostatics is resumed in chapter xii. The explanations are clear and simple, and the book should give an intelligent reader sound preliminary conceptions of an important subject.

Field and Folklore. By Harry Lowerison. With a chapter on Folklore by Alfred Nutt. Pp. vii + 77. (London: David Nutt, 1899.)

THE collection of short essays on various aspects of nature-study collected here should do a great deal towards enlisting the sympathy of school teachers in developing a love in their pupils for outdoor observations of animal and plant-life. Mr. Lowerison gives, in an informal way, a series of useful hints as to how to set about observing nature, and what books to consult to find the explanation of observations which are not at first easily understood. Mr. Nutt's chapter describes the scope of folklore and the aims of students of this department of knowledge.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Stockholm Conference on the Exploration of the Sea.

I CANNOT refrain from addressing to you a few words in support of Prof. Herdman's remarks on the outcome of the Stockholm Conference. With marine biology so eminently represented at the meetings, there was ground for an expectation that the report would contain primarily recommendations for work at sea. The representatives of chemical and physical work appear to have known their minds and to have obtained the just recognition of their claims.

Hitherto in biological investigation work has been too exclusively devoted to the food fishes themselves—too little to the food of these fishes—far too little to their biological environment. It will be to many eager students, both of fishery affairs and marine biology, a matter of dismay if nothing more definite results from this Conference. There are, and have been, too many committees, secretaries and bureaus engaged on this subject. As Prof. Herdman says, we want work at sea. To be precise, we want, to begin with, two well-equipped trawlers and the right men in them. If the Stockholm Conference had recommended even one, it would have been a sign of grace. Such boats are not mere scientific instruments—not merely the luxuries afforded by governments in times of prosperity—but sound financial investments in fishery affairs. The Norwegian Government has, I understand, ordered one, admirably devised for marine investigation. GEORGE MURRAY.

November 25.

Bust of Sir George Stokes.

YOU were kind enough to say last June that Mr. Hamo Thornycroft would undertake the production of bronze copies of the presentation bust of Sir George Stokes, about one-third of the size of the original, at a cost of seven guineas each, in case twenty-five were ordered, and that names would be received by Sir William Crookes and myself.

If anybody wants such a copy I hope that he will write to me at once. JOHN PERRY.

Royal College of Science, London, South Kensington, S.W., November 22.

A Geometric Determination of the Median Value of a System of Normal Variants, from two of its Centiles.

A SHORT account appeared in NATURE, October 12, p. 584, of a paper read by me at the British Association, entitled the "Median Estimate," which will appear in the forthcoming Journal of the Association. Its object was to solve a problem of the following kind:—40 per cent. of the members at a meeting vote that a proposed grant should be less than 100*l.*, 80 per cent. vote that it should exceed 500*l.* What is the Median Estimate, supposing the normal law of frequency to hold good? That is to say, What is the sum that one-half of the members would think too little, and the other half too much, and which therefore presents the best compromise between many discordant opinions? I showed that the calculation was exceedingly simple if certain tabular values are used that will be spoken of later. But, on after reflection, it seems to me that further simplification is both desirable and feasible. The problem is representative of a large class of much importance to anthropologists in the field, few of whom appear to be quick at arithmetic or acquainted even with the elements of algebra. They often desire to ascertain the physical characteristics of races who are too timorous or suspicious to be measured individually, but who could easily be dealt with by my method. Suppose it to be a question of strength, as measured by lifting power, and that it has been ascertained that *a per cent.* of them fail to lift a certain bag A of known weight, and that *b per cent.* of them fail to lift another heavier bag B. From these two data, the median strength can be determined by the simple method spoken of above, and not only it but also the distribution of strengths among the people. Having indicated the utility and importance of the general problem, I will proceed to work out the particular case of the voters by the now further simplified method. In Fig. 2 let the base line G represent 100*l*. and let each successive horizontal line above it represent an increment of 100*l*. A dot A is placed on G, at the division 40°, and another dot B is placed on the ordinate at the division 80° at the level of the fourth line above G. Therefore A and B are plotted at their respective places. Join the two dots with a straight line. The place where this line cuts the ordinate at 50°, shows the Median value. The principle on which this exceedingly simple process rests must be explained by beginning with Fig. 1, where an ordinary curve of distribution is drawn about the axis H, with a quartile equal to 1. The

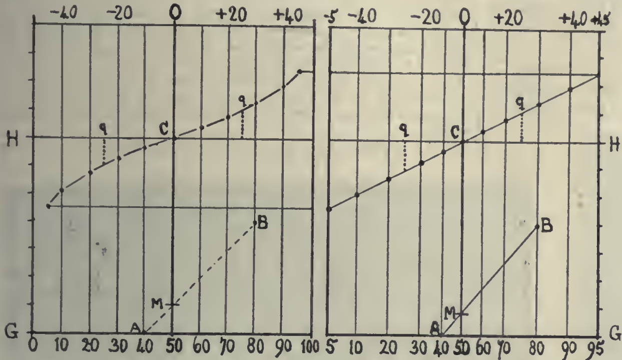

Fig 1. {Limits, 0° & 100°, otherwise, 0° & ±50°.

Fig 2 {Limits 5° to 95° otherwise 0° to ±45°

centiles from the axis to the curve are given in the following small table (see my "Natural Inheritance," Macmillan, 1889) which is reproduced here for convenience.

Centiles to the grades 0° *to* ± 50° (*negative for negative grades, positive for positive grades*).

±	0	1°	2°	3	4	5°	6°	7°	8°	9°
0	0·00	0·04	0·07	0·11	0·15	0·19	0·22	0·26	0·30	0·34
10	0·38	0·41	0·45	0·49	0·53	0·57	0·61	0·65	0·69	0·74
20°	0·78	0 82	0·86	0·91	0·95	1·00	1·05	1·10	1·15	1·20
30°	1·25	1·30	1·36	1·42	1·47	1·54	1·60	1·67	1·74	1·82
40	1·90	1·99	2·08	2·19	2·31	2·44	2·60	2·79	3·05	3·45

The theoretical values for ± 50° are infinitely large.
The curve ceases to be trustworthy outside about ± 45°.

When A and B are plotted on Fig. 1 there can be only one normal curve of frequency whose steepness, as measured by its quartile, allows it to pass through both of them. This curve might be drawn, but by a tedious process of trial and error, to avoid which the arrangement shown in Fig. 2 has been devised, and the troublesome curve is dispensed with. The ordinates in Fig. 1 are so stretched apart or compressed together, laterally, that the curve is changed into a straight line. Let x be any abscissa in Fig. 1, counting from the middle of the axis to the right or left as the case may be, and let y be the corresponding tabular value. Then, as in Fig. 2, draw an abscissa x' of the same *nominal* length as x, but of a real length $= ny$, where $n = 1$ or some more convenient number. Now let p_1, p_2, p_3, &c., be points on the curve in Fig. 1, having the co-ordinates x_1, y_1; x_2, y_2; x_3, y_3, &c., then the corresponding points in Fig. 2 will occupy positions having the co-ordinates of ny_1, y_1; ny_2, y_2; ny_3, y_3, &c. In other words, they will lie in the same straight line. The ordinates of any normal curve are expressed by multiplying the tabular numbers by the quartile of that curve. Let q be the quartile of any given curve, and write n' for nq. Then substituting n' for n in the above, we still find that p_1, p_2, p_3, &c., will lie in the same straight line in Fig. 2. Consequently the proposition is true generally.

Prof. Karl Pearson informs me that various curves representing technological formulæ were similarly translated into straight lines by Lalanne, and discussed by him in a series of papers (1846–1878). He termed the process by which a proper choice of scales enables us to represent a given curve by a straight line, *anamorphic geometry*. Prof. Pearson also tells me that in Lalanne's hands and in those of his followers (Hermann, Vogler, Kapteyn, &c.) this geometry has been of great service in exhibiting engineering and other data in a form suitable for easy reckoning.

A convenient scale for the pocket book may be made on a strip of paper squarely ruled in millimetres, on which the tabular numbers divided by 4 and multiplied by 100 are entered. Its range between ± 45° is consequently $100 \times \frac{1}{4} \times (2 \times 2{\cdot}44) = 122$ millimetres, which is less than 5 inches, or than the length of a half sheet of ordinary notepaper. The scale is to be used for plotting the values of a, b, and m, while the millimetre graduations along the opposite edge of the strip serve for the ordinates A and B. For frequent service, a ruled blank form, like Fig. 2, is quicker in use, and it need not, I think, be larger than half a sheet of foolscap paper, or eight inches wide. This would suffice to show clearly each alternate centile, as about the middle of the form, where the centiles lie closest together, the alternate centiles would be more than one-tenth of an inch apart.

An attempt is made at the bottom of Fig. 1 to exhibit the amount of error that would be produced by a simple interpolation between A and B, but it is better to make the comparison numerically.

Let a and b be the percentage of those who vote, &c., for less than A and B respectively, and let α and β be the tabular numbers *including their signs*, corresponding to a and b, on the scale reckoned from 0° to 100° (and not from 0° to ± 50°). Let m be the unknown median and q the unknown quartile of that curve of normal frequency which passes through the plotted positions of A and B, then

$$m + q\alpha = \mathrm{A} \qquad m + q\beta = \mathrm{B}.$$

Whence, by eliminating q, we have

$$m = \mathrm{A} - \alpha\left\{\frac{\mathrm{B}-\mathrm{A}}{\beta-\alpha}\right\}, \text{ or } = \mathrm{B} - \beta\left\{\frac{\mathrm{B}-\mathrm{A}}{\beta-\alpha}\right\}.$$

The "medians calculated" in the table below are thus derived: The simple interpolations require no explanation. Graduations on the scale 0° to ± 45° are in brackets.

	Values of b			
	(+20°) 70°	(+30°) 80°	(+40°) 90°	(+50°) 95°
$a = 20°$ (−30°)				
Medians calculated	348	300	259	236
Simple interpolation	340	300	271	260
$a = 40°$ (−10°)				
Medians calculated	231	193	167	154
Simple interpolation	233	200	180	173

The interpolated results are, of course, correct when A and B are symmetrically placed, as they are at 20° (−30°), and 80° (+30°). They are most incorrect when either A or B is near to the limits of the curve, and when both are on the same side of its middle point.

When applying the method practically, especially upon some unfamiliar characteristic whose law of frequency is doubtful, the determination of M should be considered as a first approximation, and the process be repeated with two new values A_1 and B_1, the one a little less, and the other a little greater than M. The new result M_1 could be accepted as final.

For perfection of simplicity some method, whether it be graphic or tabular, for converting observed numbers into percentiles, might be printed at the back of the blank form.

FRANCIS GALTON.

On the Cause of Dark Lightning and the Clayden Effect.

I HAVE been criticised in a letter which appeared recently in NATURE for not alluding in my letter on dark lightning to the peculiar photographic reversal known as the Clayden effect. I must confess that at the time of writing my letter I was unaware of this effect, a description of which has only appeared, so far as I know, in one of the photographic journals. Mr. Clayden has certainly explained dark lightning, and it only remains to explain his explanation. As I think that this effect is not generally known, I believe that it may be worth while to devote a few words to the statement of the case before describing the experimental work by which I have determined the factors which play a part in this very curious photographic phenomenon.

Mr. Clayden showed that if a plate which had received an

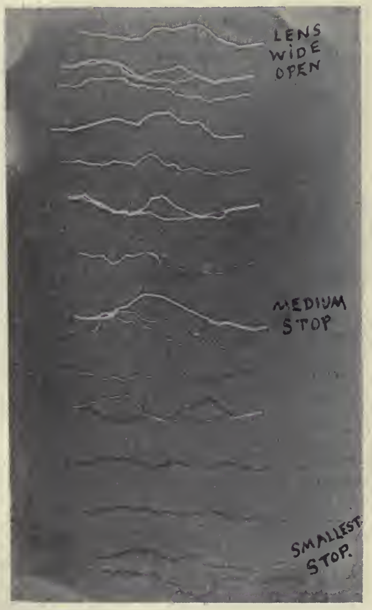

FIG. 1.

impression of a lightning flash or electric spark was subsequently slightly fogged, either by exposing it to diffused light or by leaving the lens of the camera open, the flash on development came out darker than the background. If, however, the plate was fogged before the image of the flash was impressed, it came out brighter than the background, as in the ordinary pictures of lightning. I refer to the appearance in the positive print in each case. This is quite different from ordinary reversal due to the action of a very intense light, for the order in which the lights are applied is a factor, and the phenomenon lies wholly in the region of under-exposure. I repeated Mr. Clayden's experiment, and obtained dark flashes without any difficulty.

The effect cannot, however, be obtained by impressing an image of the filament of an incandescent lamp on a plate, and subsequently fogging the plate. Clearly there is something about the light of the electric spark which is essential to the production of the reversal. It is not intensity, however, for I found that it was impossible to obtain reversed images of bright sparks with the lens wide open.

Fig. 1 shows a series of spark images, some normal, some partly reversed, and others wholly reversed. The sparks are those of a large inductorium with a good-sized Leyden jar in circuit. The sparks were all of equal intensity, but after each discharge the iris diaphragm of the lens was closed a little. It will be seen that the borders of the bright sparks are reversed. In some the image is reversed, with the exception of a narrow thread down the core. The images were impressed in succession on the plate by moving it in the camera. A plate holder was dispensed with, an opening being made in the ground-glass back by removing a strip a few centimetres wide. The plate was held against this opening, and a large number of exposures made in a few moments. Of course, the room was in total darkness. After exposure, the plate was exposed to the light of a candle for a second or two, and then developed.

In this series of pictures it will be seen that the edges of the bright images of the sparks are reversed, the intensity on the border of the image being less than at the core. As the intensity of the spark becomes less and less, the bright central core dwindles down to a mere thread, and eventually disappears, the spark's image being feeble enough to reverse over its entire area.

This explains why the dark lightning flashes are usually

FIG. 2.

ramifications of the main flash. The ramifications are less brilliant discharges and reverse, while the main one is too bright to cause the effect.

The first thing that occurs to one is that it may be some peculiar radiation, which the spark emits, which is wanting in the light coming from other bodies. If a small photographic plate is partly screened by a piece of black paper and illuminated by the light of a small spark at a distance of two or three feet, and a similar plate, screened in the same manner, is illuminated for a moment by candle light of sufficient intensity to produce the same amount of blackening on development, we shall have the means of showing that the spark light differs in its action on the plate from that of the candle. If these two plates, before development, be half-screened in a direction at right angles to the former one, and exposed to the light of the candle for a second or two, the part of the plate which has been illuminated by spark light plus candle light does not become as black on developing as the part which has received candle light alone, whereas the part which has been twice exposed to candle light is blacker than that which has been only exposed once. This shows that the light of the spark does not act in the same way as the light of the candle. Wherein does it differ? It seemed possible that the peculiarity lay in the nature of its radiation. To test this a prism was placed before the lens of the camera, which broke up the image of the spark into a series of spark images of different colour. The plate was exposed to the flashed spectrum of a single spark, then removed from the camera and exposed to the candle light, and developed. If the reversing effect was due to any peculiar radiation or wave-length we should find the reversal at that part of the spectrum where the effective radiation belonged, say in the infra red if the reversing power lay in long waves given out by the spark. It was found that the entire spectrum came out lighter on the negative than the fogged background. A second plate was exposed to the spectrum flash, then slightly fogged, and a second spectrum impressed on it in a different place. On developing, one spectrum came out light and the other dark. Clearly the effect does not depend on wave-length. It then occurred to me that the time-element might enter into the problem. The light of the spark is over in about 1/50000 of a second, and it did not seem impossible that a bright light of exceedingly short duration might act quite differently on a plate from a weaker light of longer duration. This may be tested in a variety of ways. We may open the lens wide, impress the image of a single spark on the plate, and then stop the lens down and superimpose a number of spark images sufficient to make the total exposure the same in each case. This was the first method which I tried. In order to compel the successive sparks to pass over the same path, that their images might be superposed, I shut them up in a capillary tube. With the lens open wide enough to give the maximum reversing action, I passed a single discharge through the capillary. Stopping the lens down to one quarter of its former aperture, four discharges were passed through the tube. The plate was then fogged in the usual manner, and on development the single discharge was reversed, but the composite one was not.

Fig. 2 is from a plate showing this effect. The upper images are those of single discharges through the capillary, with different apertures of the lens; the lower images are those of double or triple discharges through the same tube. The left-hand side of the plate was exposed to the candle light for different amounts of time, by moving the screen over small distances during the exposure. Only the single discharges reverse, though the density of the images on the unfogged portion of the plate is the same.

This was very strong evidence that the duration of the illumination was the important factor. Some years ago I measured the duration of the flash of exploding oxy-hydrogen, finding it to be about 1/12000 of a second. Possibly the flash of such an explosion would duplicate the effect. I exploded several glass bulbs filled with electrolytic gas, but found that the action was the same as that of ordinary light, it being impossible to get any reversal. The flash evidently lasted too long, or there still remained some undiscovered factor.

The difference between the action of spark light and the light of the oxy-hydrogen flash is shown in Fig. 3.[1] Plate "a" shows the effect of the explosion flash. Squares 1 and 2 received the light from an exploding bulb, the rest of the plate being covered. Squares 1 and 3 were then exposed to the light of the candle. Square 1, which has received the light from both sources, is the brightest, that is, the effects are additive, there being no reversal. Plate "b" shows the action of the light from the spark. Squares 1 and 2 were illuminated by the spark light, then squares 2 and 4 were exposed to the candle. In this case, square 4, which was illuminated by the candle, is brighter than square 2, which received both the spark light and candle light. In this case the effects are not additive, there being reversal.

To demonstrate conclusively that the time-factor was the only one, it was necessary to secure an illumination independent of the electric spark, and of as short duration. This was accomplished in the following manner: A disc 30 cms. in diameter was furnished with a radial slit 1 millimetre wide near its periphery, and mounted on the shaft of a high-speed electric motor. A second slit of equal width was arranged close to the rim of the disc, in such a position that the two slits would be in coincidence once in every revolution. This second slit was cut in the wall of a vertical chute, down which a photographic plate could be dropped. By means of a large convex lens of short focus, an image of the crater of an arc-lamp was thrown on the point of coincidence of the slits. The intensity of the illumination transmitted by the slits when in coincidence was almost sufficient to char paper. The motor was now set in motion, and a plate dropped down the chute. On developing this plate, three images of the slit appeared, not at all over-exposed, though the plate was the fastest obtainable, and the intensity of the light while it lasted comparable to that at the focus of a burning glass. By measuring the distance between the images and the vertical distance through which the plate had fallen, it was an easy matter to calculate the speed of rotation, which was found to be sixty revolutions per second, the air friction of the disc preventing higher speed. The duration of the exposure will be the time occupied by the rim in travelling a distance equal to the width of the slit, or 1 mm. This was found to be 1/55000 of a second, about that of the spark. The crucial experiment now remained. A second plate was dropped, and, before development, was exposed to the light of the candle. *The images of the slit were most beautifully reversed*, except at the centre, where the light was too intense. It seems, then, that we are justified in assuming that *the action of an intense light on a plate for a very brief time-interval decreases the sensitiveness of the plate to light*. It is curious to contrast with this effect the fact that exposure to a dim light for a moment or two appears to increase the sensibility by doing the small amount of preliminary work on the molecules, which seems to be necessary before any change can be effected that will respond to the developer.

I am not prepared to say what the nature of the change effected by the flash is. Possibly some one familiar with the theory of sensitive emulsions can answer the question. I have tried using polarised light for the reversing flash, and then fogging one half of the plate with light polarised in the same plane, and the other half with light polarised at right angles to it. As was to be expected, there was no difference in the effects.

R. W. WOOD.

Physical Laboratory of the University of Wisconsin, Madison, Wisconsin, October 20.

[1] The details in this figure, and in two others sent by Prof. Wood, are too indistinct to be reproduced satisfactorily.—ED. NATURE.

Experiments on the Floral Colours.

IN 1837 the illustrious Berzelius wrote: "The red pigment of several kinds of berries has generally been regarded as a blue pigment reddened by an acid. This is not the case with all berries. I have examined the pigment of *Prunus cerasus* and of *Ribes nigrum*, which contain the same pigment, and this is not blue. Probably this has been surmised from the circumstance that the sap of these berries gives a blue precipitate with acetate of lead; but these precipitates are malate and citrate of lead, wherewith the pigment is combined." He found that, after separating these acids from the colouring matter, the latter yields a green and not a blue precipitate with acetate of lead; and, moreover, when to its aqueous solution a little milk of lime is added sufficient to saturate all the free acid, the supernatant liquid is red and not blue, which latter it would be if its natural colour was blue. He arrives at similar conclusions with regard to the red pigment of the autumn leaves of cherry, red currant, &c.

On the other hand, Julius Wiesner, of Vienna, in 1862 and 1872, by a series of experiments, endeavoured to prove that the compounds of anthocyan—*i.e.* the blue and red pigment of flowers, with lead, alkalis, &c.—are always blue, and it is only when anthocyan is present in the cell-sap simultaneously with a substance which is coloured yellow by alkalis, &c., that it passes by the latter body into green, which thus arises as a mixed colour. He found that by completely washing out (as he thought) this latter body from the petals by warm dilute hydrochloric acid, and then immersing them in solutions of lead and iron salts, they became intensely blue; hence he was led to conclude, contrary to Berzelius, that the original and actual colour of anthocyan was blue and not red.

During last summer I have performed a series of experiments on a number of flowers, with a view of settling the question in dispute, as above set forth. In the first place, it was deemed advisable to observe the effect produced in each case by immersing the fresh petal into ether saturated with ammonia. The results were as follows:—(1) Petals which became blue, *e.g.* pæony, pink campion, deep red garden rose, sweet pea, vetch, mallow, balsam, geranium, fuchsia, scarlet rhododendron, crimson flax, blue centaurea; red daisy, periwinkle, lady's smock, became bluish-green. (2) Petals which became green, *e.g.*

anemone, larkspur, violet, willowherb, scarlet tropæolum, red rhododendron, bilberry, flowering currant, scabious, wild thyme, potato, forget-me-not.

The colouring matter was then withdrawn from these and other petals by macerating them for two days in cold methyl alcohol, the solution was poured off, evaporated to dryness, the residue taken up with warm water, and the solution after filtering tested as follows:—(1) One drop HCl or H^3PO^4, followed by several drops of ammonia; (2) solution of acetate of lead followed, or not, by acetic acid; (3) solution of acetate of magnesium. The results are tabulated as follows:—

Name of flower.	Natural colour.	HCl and NH^3.	Acetate of lead.	Acetate of Magnesium.
Pæony	red	deep blue-green	bluish-green	blue-green
Larkspur	blue	green	green	blue
Anemone	red	green	green	—
Violet	violet	nearly blue	green	dark blue
Oriental Poppy ...	scarlet	blue flush	green	green
Campion	pink	blue at neutral point	—	—
Ragged Robin ..	red	blue-green	green (blue, acid)	green (blue, acid)
Garden Rose ...	deep red	blue	bluish-green	green
Dog Rose ...	pink	green	green	green
Pyrus japonica ...	crimson	dark green	bluish-green	—
Clover	red	green	green	green
Vetch	red	blue	blue	—
Vicia sepium ...	red	green	green (blue, acid)	—
Sweet Pea ...	red	blue-green	green (blue, acid)	green
Mallow	red	blue	green (blue, acid)	—
Fuchsia	red	blue	blue-green (blue, acid)	green
Geranium ...	red	blue	red-purple (blue, acid)	red-purple
Flax	crimson	blue	blue	green
Flowering Currant	red	green	green	green
Daisy	red	dark-green	green (blue, acid)	—
Dahlia	deep red	blue	green (blue, acid)	green (blue, acid)
Scabious	blue	green	green (blue, acid)	green
Betony	red	green	green	—
Rhododendron ...	pink	dark green	dark green	deep green
Primula	red	green	green	—
Periwinkle ...	blue	blue-green	green (blue, acid)	—
Foxglove... ...	red	green	green	—
Snapdragon ...	red	green	green	—
Hyacinth... ...	blue	blue flakes	green (blue, acid)	green (blue, acid)
Tulip	red	red-brown	green	deep blue postea
Orchid	red	pure blue	green (blue, acid)	green (violet-blue, acid)

In a few cases the aqueous solution of the pigment, after acidification by HCl, was shaken up with amyl alcohol, and after allowing to separate, the lower acid liquid was withdrawn, and tested with excess of ammonia and of acetate of lead. In this way, rhododendron, red daisy, red tulip, violet, foxglove, *Vicia cracca*, red poppy, gave a brilliant pure blue coloration; while, on the other hand, flowering currant and woundwort gave greens with ammonia, but blue precipitates with acetate of lead. In order, however, to purify the pigment still more thoroughly, its alcoholic or aqueous solution was shaken up at intervals for two days with well-washed hide-powder, and the latter, after filtering off the liquid, was well washed and extracted with very dilute HCl. The bright red liquid thus obtained was treated successively with the aforementioned reagents. The result was extremely interesting; for while flowering currant and rhododendron gave greens, red tulip and purple orchis gave blues. In some cases the Wiesner's experiment was repeated, *i.e.* the fresh petals were warmed with dilute HCl, and the acid quite washed out with water, and the now reddened organs placed into solutions of acetate of lead and acetate of zinc, when rhododendron, flowering currant, violet (in some cells), foxglove, *Vicia cracca* (in some cells), became green; while, on the contrary, *Geranium pratense*, bugle, the rest of the cells of violet, and of *Vicia cracca* became blue. It was evident, therefore, that Wiesner's opinion that anthocyan is invariably blued by alkalis, &c., and never greened, was not confirmed; inasmuch as at least three petals, when treated in the manner he prescribed, were distinctly greened, the presumption being that all yellow intermixture had been obviated.

The general conclusion which I think must needs be drawn from these my experiments is, that there are different stages in the development of the floral pigment. In the lower stages the natural colour is red, whatever the chromogen may be; and so far Berzelius was right. In the higher stages, on the other hand, the natural colour of anthocyan is blue, or rather (at least with some chromogens) it becomes capable of forming blue compounds or lakes with alkalis and certain metallic salts. Moreover, as I have laboured to show elsewhere, chromogens exist which, except under very exceptional conditions and circumstances, are incapable of producing a blue pigment; and these in all stages naturally develop into a red, the brilliancy of which, when contrasted with that of a blue accidentally obtained in an allied species (*e.g.* in flax), unequivocally attests its real, original, and proper character. P. Q. KEEGAN.

The Colour of Flints.

AN examination of the pebbles lying on the beach of the coast of the English Channel shows that while these are principally flints they vary considerably in colour.

The flints derived from the chalk cliffs surrounding this part or the coast, and from which the shingle is generally supposed to be derived, are, so far as my experience goes, invariably black, with a white coating on the exterior.

Only about one-third of the flints on the beaches of such localities as Eastbourne, Hastings, Brighton, Hythe, Folkestone, Dover, &c., or in the large accumulations at Dungeness and at the Chesil Beach are apparently derived from the adjacent chalk cliffs, the remainder being different shades of brown, grey, white and red, the former being the most prevalent. In some cases the outside coating is of a different colour to the interior of the pebble. It follows, then, either that the flints from the chalk undergo some chemical action, either internally or externally, while exposed to the air and salt water of the beach, which changes their colour, or the majority of them must have been derived from inland gravels.

The first theory does not seem feasible, as flints are to be found in raised beaches and other positions, where they have been deposited for long periods, still retaining not only their interior black colour, but also the white coating on the outside.

If these various coloured beach flints are derived from inland gravel beds, they must have been deposited under different conditions from those which now prevail, as there is no action in operation on the south coast which can convey the flints from inland to the sea. The age of some of these shingle beds must, therefore, be much greater than has been generally supposed.

There are isolated pockets of gravel at the top of the chalk cliffs in some places, which fall on to the beach where the cliffs are eroded by the sea; but these are too few in number to account for immense deposits such as those at Dungeness, Pevensey and Chesil.

Failing to obtain any light on this subject from geologists to whom I have mentioned the matter, and whose opinions vary as to the changes flints undergo, I venture to appeal to NATURE for a solution. W. H. WHEELER.

Boston, Lincs., November 27.

THE PROPOSED CHANGES IN THE MATHEMATICAL TRIPOS.

THE Cambridge Board for Mathematics has presented to the Senate a report on the Mathematical Tripos. This report recommends certain changes in the regulations relating to that Tripos. The following note contains an abstract of the proposals made by the Board:—

The schedule of subjects for Part I. of the Tripos has been reduced by the entire omission of some subjects (calculus of variations, elliptic functions, Bessel's functions, hydrodynamics, sound). Other subjects have been limited in extent (*e.g.* rigid dynamics, electricity, optics, astronomy and others). Care has been taken to specifically exclude parts of some subjects. The arrangement of papers is to be entirely changed and no papers are to be exclusively devoted to problems. At the present time particular methods are prohibited in answering the questions set in certain papers ; such general restrictions of methods are no longer to be maintained. A special regulation provides that at least half the questions set throughout the examination shall be of an elementary character.

The Board also proposes to abandon the custom of publishing the list of successful candidates in order of merit, and to follow the method at present adopted in the Classical Tripos. There will be three classes (Wranglers, Senior and Junior Optimes), and each class will consist of three divisions, the names in each division being arranged in alphabetical order.

The proposed changes in Part I. have involved some corresponding changes in Part II. The class-list is to consist of three divisions only, the names in each division being arranged alphabetically ; and it is to be possible for a candidate to obtain a place in the first division in two ways. He may do so (as at present) by showing special proficiency in one section of the schedule of subjects, together with general proficiency in one or more other sections ; or by showing general proficiency over a wider range of subjects.

The Board hopes that these changes will induce more men to take Part I. in their second year ; it is at present possible to do so under a regulation which came into force in 1893, but very few have actually availed themselves of the rule (probably not 1 per cent. of the whole number of candidates since 1892). This is partly due to the fact that 90 per cent. of the candidates cannot cover the whole range of reading in two years, and partly to the natural desire of the more able men to appear in as high a place as possible in the list. By taking the Tripos in their second year, men who intend to study subjects such as physics or engineering will be able to gain a preliminary knowledge of mathematics, with indications as to how to extend their knowledge in any special branch which they may need in their future course. The second year Tripos will be of advantage also to the better mathematical men, who now spend half their third year in revision and in acquiring facility of solving artificial problems. Under the proposed regulations these men will have two years after Part I. (instead of one) in which to become acquainted with the ideas and methods of modern mathematics. This will be of special advantage to men who intend to devote themselves to mathematical research.

It is thought that the abolition of order of merit will assist the aims of the Board by making it possible for the papers to be easier, and by helping to remove artificial problems ; and also by inducing a greater number of men to take the Tripos in the second year of residence. It is further felt by many that the proposed Part I. is not of sufficient extent to even profess to classify the candidates in an exact final order of merit.

On November 23 the proposals of the Board were discussed by the Senate. As might be anticipated, the scheme was criticised at some length, and particularly the proposal to abolish the order of merit. The Board will now revise its suggestions in the light of the criticisms of the Senate, and the Senate will have to vote on the final recommendations of the Board.

It seems that the present Tripos must be modified in some way, as the number of candidates has been steadily falling off in recent years. Though once the largest Tripos in the University, the Mathematical Tripos is now smaller than both the Natural Science and the Classical Tripos. Taking an average of the candidates for the four years 1869–72, we find that, of the resident undergraduates, one in eighteen passed the Mathematical Tripos ; while for the five years 1895–99, the average falls to one in thirty-five (of course, this relates to Part I. only).

THE RESISTANCE OF THE AIR.

THE mportance of determinations of the resistance of the air to moving bodies, in connection with the problem of aërial navigation and numerous other practical applications, has led the Société d'Encouragement pour l'Industrie Nationale to offer a prize for investigations of an essentially experimental nature dealing with the reactions on a surface moving through the air under varying conditions as to form and velocity. One series of experiments with this object has been undertaken by M. l'Abbé Le Dantec, and a second set by M. Canovetti. The following account of these researches is based on the papers communicated by their authors to the *Bulletin* of the Society, and the report on them by M. Barbet.

The method adopted by M. l'Abbé Le Dantec is very simple, and had been used in some previous experiments by him in 1893. It is based on the property that the motion of a falling body is at first accelerated, but the resistance of the air, increasing as the velocity increases, soon balances the weight of the body, and the body thus soon acquires its terminal velocity, and then moves uniformly. The resistance of the air at this velocity is exactly equal to the weight of the falling body.

In the present experiments the surface whose resistance is to be observed slides down a vertical wire, which acts as a guide without introducing perceptible friction. Its weight and area can be easily and accurately measured ; and Le Dantec has now devised an electric recording apparatus, which enables the time of fall to be estimated with equal precision. A band of paper is unrolled by clockwork action, and on this band an electric arrangement records the vibrations of a seconds pendulum. Furthermore, when the falling surface is released, a current is started whereby a toothed wheel is brought into contact with the paper band, and traces on it a dotted line. The surface at the end of its descent comes in contact with a buffer, the current is broken, and the cessation of the dotted line indicates the exact instant at which the surface reached the buffer. The operator can vary the height in such a way that the descent occupies one, two, three or more seconds, and by subtraction the distances traversed in each successive second are obtained.

The experiments were conducted in the chapel of the Conservatoire des Arts et Métiers, the nave of which is of considerable height, and their accuracy is verified by the perfect agreement of the results. Thus several experiments conducted for the purpose of determining the height through which a surface fell in a certain number of seconds agreed to within a centimetre. The chief conclusions are as follows :—

(1) Even feeble air currents such as are produced by persons moving about in the neighbourhood of the apparatus suffice to considerably modify the results, and it is important therefore that the experiments should be conducted in a closed building, which must, however, be sufficiently large for the walls not to materially affect the stream-lines of the air flowing past the moving surface.

(2) A square surface 1 metre square, moving with a velocity of 1 metre per second, experiences a resistance of 81 grammes.

(3) Experiments conducted with three different surfaces, each of 1 square metre in area, but of different forms, viz. circular, square, and of the form of an equilateral triangle, respectively, show that the resistance depends on the form of the surface, and the results accord with the hypothesis that the resistance of a surface of given area is proportional to the length of its contour. This property appears to be new.

(4) For velocities varying within certain limits, the law of proportionality of the resistance to the square of the velocity was verified.

The resistance of the air to a moving surface can also be measured by attaching the surface to a small truck which is allowed to descend an inclined plane under gravity. If there were no resistance to motion the square of the velocity at any point would be equal to twice the product of the vertical height fallen into the acceleration of gravity, but since friction and atmospheric resistance retard the motion, and the latter resistance increases with the velocity, the truck soon acquires its terminal velocity, and in the uniform motion which follows, the total resistance is equal to the weight of the moving body resolved down the plane. By experimenting with the truck alone, the resistance experienced by it can be obtained separately, and by subtraction the portion of the resistance due to the surface under observation is found.

This method forms the basis of M. Canovetti's experiments. Instead, however, of an inclined plane, a copper wire was employed, three millimetres in diameter and 370 metres in length, of which one end was fixed on the side of a hill, and the other on the level ground at its base. This arrangement is similar to that used in many countries where bundles of wood are sent down from the hills by means of a wire. Owing to the wire hanging in a catenary, the lower part of the wire was much less steeply inclined than the upper, the wire even sloping upwards near its lower extremity. For this reason Canovetti did not take into account the last ninety metres of the path.

The mode of suspending the various surfaces by a trolley is shown by the accompanying figures. The wheels of the trolley were provided with ball bearings. In order to determine what part of the resistance was due to the trolley itself, the latter unloaded was allowed to descend a wire at an inclination considerably smaller than that employed when it carried one of the surfaces, the smaller resistance of the unloaded trolley rendering a reduction of the gradient necessary in order that the resistance might be calculated under similar conditions as to velocity. The experiments indicated that the resistance of the trolley alone was proportional to the velocity.

In determining the velocity, Canovetti contented himself with reading on a chronometer the instant of starting the trolley and the instant at which it passed a mast placed 90 metres in front of the stopping point. By dividing the 280 metres traversed by the time occupied between the two readings, the average velocity of descent was obtained, and this average velocity formed the basis of Canovetti's conclusions.

The most interesting of these results are those referring to the relative resistances of circular and rectangular planes, and the effects of attaching a cone or hemisphere to a circular disc forming a bow or stern. Canovetti finds that the resistance of the air on an area of one square metre moving with a velocity of 1 metre per second is 90 grammes for a rectangle and 80 grammes for a circle.

A right cone, whose altitude is 1·5 times the diameter of its base, attached to the rear face of the circle reduces the resistance to 60 grammes.

A hemisphere placed in front of the circle as a prow (Fig. 1) reduces the resistance to 22·5 grammes.

Finally, in a double cone, formed by placing a cone of altitude double the diameter of the base in front of the circle, and a cone of altitude equal to the diameter of the base behind (Fig. 2), the resistance is reduced to 15 grammes, or less than a fifth of the original resistance.

Canovetti made a series of further experiments on solids resembling in form the Chalais balloon by suspending a cone and hemisphere, joined by their bases in a net (Fig. 3). In one of these observations the resistance was equal to 80 grammes. This high resistance was due largely to the net, but also in part to the instability of motion, which caused the whole model to undulate. In proof of this latter influence experiments were separately made on models rigidly attached to and freely suspended from the trolley. By taking a model formed of a cone and hemisphere, and attaching it to the trolley by rigid supports fixed one near the common base and another near

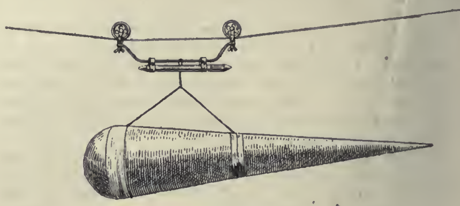

FIG. 1.

the vertex of the cone, a coefficient of resistance equal to one-seventh of that of the corresponding circular disc was obtained.

To sum up, then, Le Dantec's experiments appear to have been conducted with every precaution to secure

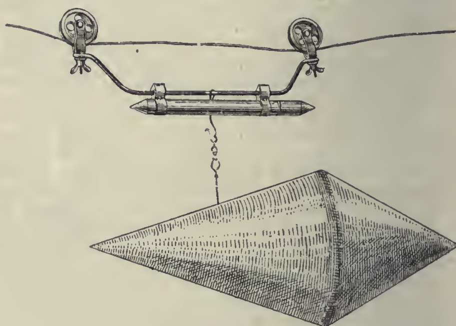

FIG. 2.

accuracy. The coefficient of resistance which he calculates from determinations made in a room from which draughts are carefully excluded must be regarded to some extent as the limiting value of a physical constant ob-

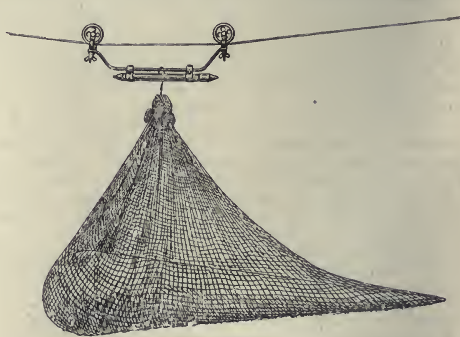

FIG. 3.

tained under conditions which are difficult to realise in practice. We may compare such determinations, *e.g.* with the determination of the weight of a cubic centimetre of absolutely pure water, since in all probability a large volume of air free from all currents and a cubic centimetre of water free from all impurities, are both of them well-nigh equally difficult of realisation. The exact determination of such constants is nevertheless of the greatest scientific interest, and even the difference between their values and those obtained under more normal conditions affords a measure of the allowance that must be made for the discrepancies which exist between theory and practice.

Canovetti's experiments, on the other hand, are essentially of the rough and ready order in several respects. The wire hanging as it does in a catenary, the differences of inclination at different parts of the course render the motion far from uniform over the 280 metres, and the estimated velocities can only be regarded as average velocities in a motion with variable velocity, the details of which have not been fully investigated. A further source of error is due to the sagging of the wire at the point where the trolley rests on it, and the consequent absorption of energy in producing vibrations. It is thus not surprising to find that Canovetti obtains 90 grammes for the resistance of a rectangle where Le Dantec finds 81 grammes; one might not unreasonably have expected a greater discrepancy. Although Canovetti avoided windy days, yet his experiments were conducted in the open air under conditions which might be regarded as normal in ordinary calm weather, and so far as the results bear on the question of the relative efficacies of different forms of balloons and other bodies in overcoming air resistance, they may be regarded as furnishing data of considerable practical value. G. H. BRYAN.

DR. HENRY HICKS, F.R.S.

BRITISH geology suffers a severe loss in the death of Dr. Henry Hicks, a loss which will long be felt on personal as well as scientific grounds. His chief work was in South Wales, among the older Palæozoic formations, whose life-history was previously but little known. He pushed his inquiries into the very oldest pre-Cambrian rocks, both in Wales and Scotland; and then turning from these most ancient records he gave attention to those immediately preceding the present order of things, and pursued with equal ardour the evidences of glaciation in South Wales and Middlesex, the records of old bone-caves, and the remains of mammoth in the Thames Valley. No man had a keener eye for fossils. To him rocks which had for long been deemed unfossiliferous yielded up some evidences of life.

Now and again his enthusiasm led him to draw conclusions and express opinions that were too slenderly supported by evidence, and consequently he was brought perhaps more than any other man of his time into active conflict on the battle-field of geology. No one, however, seemed to enjoy more heartily the animated debates which his own papers so often provoked than Dr. Hicks.

Henry Hicks was born at St. David's, in Pembrokeshire, in 1837, and was educated at the Collegiate and Chapter School in that city. Coming to London to study for the medical profession, he entered Guy's Hospital, and was admitted a Member of the Royal College of Surgeons and a Licentiate of the Society of Apothecaries in 1862. Returning then to his native place he commenced a practice which he continued until 1871, when he removed to Hendon. He now devoted special attention to mental diseases, took the M.D. degree at St. Andrews in 1878, and continued his active and useful medical work until the close of his life.

It was in 1863, while resident at St. David's, that Dr. Hicks' attention was first attracted to geology, and the inspiration came through the late J. W. Salter, then palæontologist to the Geological Survey. In the previous year Salter had himself discovered, for the first time in Britain, remains of the large Trilobite *Paradoxides*, which was then stated to occur in the "Lower Lingula Flags," of St. David's. Dr. Hicks' interest was aroused; he diligently commenced to search for fossils among the old rocks around him, and as he himself has told, the enthusiasm with which every new find was welcomed by Salter, "to whom they were first sent, was in itself a sufficient stimulus for any exertions required." A grant in aid was received from the British Association in 1863, and in the following year Salter was enabled to report at the Bath meeting that the energetic work of Dr. Hicks "has already brought to light more than thirty species of fossils, most of them Trilobites"; and as he elsewhere remarked, these discoveries "made a large addition to the Primordial fauna."

With the help and encouragement thus given by Salter Dr. Hicks pursued his work with unflagging devotion. His first communication to the Geological Society was made in 1865, and dealt with the genus *Anopolenus*; and from that date onwards for some years he contributed a series of most important papers on the stratigraphy and palæontology of the Cambrian and Lower Silurian rocks of South Wales, two or three of the earlier papers in conjunction with Salter or Robert Harkness. These researches led to the establishment of the Menevian group in 1865 by Salter and Hicks for part of the Middle Cambrian division which is characterised by *Paradoxides Davidis* &c.

In 1876 he communicated a more particular account of the pre-Cambrian rocks of Pembrokeshire, and here he came perhaps more into conflict than on any previous occasion. The granitoid rock which he named Dimetian and claimed as pre-Cambrian was regarded by Sir A. Ramsay as metamorphosed Cambrian, and afterwards by Sir A. Geikie as a granite mass intruded into the Cambrian rocks. The Pebidian volcanic series, also regarded as pre-Cambrian by Dr. Hicks, was grouped with the Cambrian by Sir A. Geikie. The evidence for a third and intermediate series named Arvonian by Dr. Hicks was subsequently admitted by him to be inconclusive. In his views concerning the antiquity of the Dimetian, Dr. Hicks was strongly supported by Prof. Bonney, Prof. Hughes and Mr. Thomas Davies. With regard to the Pebidian, it is now recognised that the beds are of the type of the Uriconian of Shropshire, generally classed as pre-Cambrian.

Between 1878 and 1883, Dr. Hicks published a series of papers on the metamorphic and overlying rocks of parts of Ross-shire and Inverness-shire, with petrological notes by Prof. Bonney and Mr. T. Davies.

Since he went to reside at Hendon, Dr. Hicks gave much attention to the local geology, and recorded many facts of interest. In course of time the subject of bone-caves greatly occupied him, and Cae Gwyn Cave in particular was explored in company with Mr. E. B. Luxmoore and others. It was then shown that this Denbighshire cavern was occupied by an early Pleistocene fauna and by man before the deposition of any of the local glacial deposits.

In 1890 Dr. Hicks bent his steps into North Devon, and was much struck with the evidences of folding, faulting and crushing near Ilfracombe. He then for the first time found a *Lingula* in the Morte Slates, and expressed the opinion that these rocks were older than the Devonian. Working zealously in Devonshire, and revisiting South Pembrokeshire for the sake of comparisons, he elaborated his views in 1896 and 1897. He had now succeeded in finding a number of fossils in the Morte Slates and in different localities, but whether these were in part true Silurian fossils as maintained by Dr. Hicks and the Rev. G. F. Whidborne, or wholly Lower Devonian, Dr. Hicks had clearly shown that the succession across North Devon was not continuous and unbroken as had been supposed. The discovery of the fossils was indeed a grand one, and it indicated also that the Morte Slates "vary considerably in different areas, and probably include beds of very different age."

These, his last researches, were carried out with all the enthusiasm of his earlier work, and when first announced to the Geological Society they roused as much opposition. The fact is that when he read the first paper only one *Lingula* had been found in the Morte Slates, and it was felt that the conclusions drawn by the author were not justified. Undaunted, he returned again and again to the field; he reaped a rich harvest where others had altogether failed, and if he did not succeed in demonstrating that Silurian rocks occur in North Devon, he at any rate made manifest that until better preserved fossils are obtained it is not safe to say they are not there.

Dr. Hicks became a Fellow of the Geological Society in 1871; for many years he served on the Council, he was one of the honorary secretaries from 1890-93, and president from February 1896 to February 1898. The Bigsby Medal was awarded to him by the Council in 1883. Dr. Hicks had also been President of the Geologists' Association, 1883 to 1885. He was elected a Fellow of the Royal Society in 1885. In his busy professional life he found geology a "means of recreation and of much intellectual enjoyment"; and until near the close of his life he maintained a youthful energy and vivacity, and looked the picture of health. To his many friends the sad tidings of his death at Hendon on November 18, at the age of sixty-two, came as a surprise, and everywhere raised feelings of the utmost sorrow.

H. B. W.

NOTES.

THE sum of fifteen thousand marks appears in the Budget of the German Imperial Home Office as Germany's contribution towards the preparation of an international catalogue of science.

THE *Electrician* states that a school for wireless telegraphy is being established on one of the Government hulks in Portsmouth harbour.

M. DE COPPET has forwarded to the treasurer of the French Physical Society a cheque for 1000 francs towards meeting the expenses of printing the "Receuil des Constantes Physiques."

AT the annual meeting of the Royal Institution of Cornwall held at Truro on November 21, under the presidency of the Rev. S. Baring-Gould, the Henwood Gold Medal was presented to Mr. Rupert Vallentin for his observations on the fauna of Falmouth, accounts of which are published in the last three numbers of the *Journal* of the Institution.

THE Walsingham Gold Medal of the University of Cambridge has been awarded to Mr. H. H. W. Pearson, Assistant for India in the Kew Herbarium. This medal is obtained by competition in original essays on any branch of biological science. Mr. Pearson's essay was on the botany of the Ceylon Patamas, recently published in the *Journal* of the Linnean Society.

PROF. KARL PEARSON, F.R.S., will deliver a lecture entitled "Matter and Motion" in the chemical theatre of University College, Gower-street, on December 6 at 5 P.M. The members of the Chemical and Physical Society invite the presence of all who are interested in the subject.

THE fourth international congress of psychology will be held at Paris, in connection with the international exhibition, on August 20-25, 1900. It is hoped that all who are interested in the study of psychology in its various aspects will take part in the congress. The general secretary is Dr. Pierre Janet, Rue Barbet-de-Jouy 21, Paris, to which address all communications concerning membership should be sent.

WE regret to learn, from the *Botanisches Centralblatt*, of the death of Prof. P. Knuth, at Kiel, on October 30, in the forty-fifth year of his age, shortly after his return from a long journey. Dr. Knuth had worked on the same lines as the late Dr. Hermann Müller, in collecting an immense amount of information respecting the visits of insects to flowers and their agency in cross-fertilisation. Only last year he published the first and second volumes of his "Handbuch der Blütenbiologie," in which every observation of importance made by himself or others recorded during the last quarter of a century, since the publication of Müller's "Befruchtung der Blumen," is collated. A third volume remained unpublished at the time of his death.

IT appears from a detailed article in *Engineering* that the British display at the Paris International Exhibition next year will be quite unworthy of the manufacturing power of this country. This, we need hardly remark, is a matter for deep regret, especially as our chief competitors are arranging for exhibits on a very large scale. The German display will be of the first magnitude. Thus the German exhibit in the group of appliances and general processes relating to literature, science and art, will be contained in a separate pavilion, the contents of which will be valued between three and four million marks. In the group devoted to decoration of buildings, furniture, &c., the value of exhibits is estimated at 150,000*l.*, and a similar value is set on Germany's electrical exhibits. The value of exhibited general machinery is stated to be 35,000*l.*; agricultural exhibits 20,000*l.*; the naval and military exhibit 30,000*l.*, and so on. The total value of German exhibits is estimated at a million sterling. British industries and science will only be represented by 642 exhibitors. Referring to the inferiority of the representation of Great Britain at the Exhibition in comparison with other countries, *Engineering* remarks: "Manufacturers best know what are their own interests, and they have presumably come forward in such small numbers only after careful consideration. Possibly this apparent indifference is partly due to the remarkable absence of information available about the Exhibition, and partly because of the unsatisfactory arrangement, from an exhibitor's point of view, by which exhibits will be scattered over a large area, instead of being concentrated into a British section. But whatever the causes, we must be prepared to meet our chief competitors in as many thousands as we number hundreds; if manufacturers are then disappointed, they will only have themselves to blame. One reason of our inferiority in numbers is, no doubt, to be found in the antipathy of the British industrial to co-operate in industrial exhibits. He stands alone in this prejudice, and has, of course, to pay the penalty."

THE claims of inorganic chemistry to increased attention have recently been urged in Germany on two important occasions. Addressing the Naturforscher-versammlung at Düsseldorf last year, Prof. van 't Hoff gave a most interesting review of the recent achievements of inorganic chemistry, and made a strong plea for the cultivation of this branch of the science. This plea has been put in a more concrete form at the Göttingen meeting of the German Electrochemical Society. The subject was introduced on this occasion by Prof. W. Hittorf, and the proceedings culminated in a letter addressed to the Minister of Education asking definitely for the establishment of professorships and laboratories for inorganic chemistry.

PROF. HITTORF points out how largely German chemists have deserted inorganic for organic chemistry; how, with the exception of the late Victor Meyer, hardly an organic chemist of the later school has made important contributions to inorganic chemistry; how at the present time only two of the largest Universities and one Hochschule have independent professors of the subject. He urges the cultivation of inorganic chemistry not only in the interests of technology, but from the conviction that the study, especially in relation to electro-chemistry, will give a deeper knowledge of the nature of chemical combination, and so strengthen the foundations of the whole science. He would not in the least deprecate the study of organic chemistry, but maintains that at present inorganic chemistry is in the position of a cinderella.

A NUMEROUS and influential deputation waited upon the Town Council of Edinburgh last week to urge the Corporation to give their influence towards the promotion of the movement for the establishment of a zoological garden in Edinburgh. Prof. Cossar Ewart described the advantages of zoological gardens, and pointed to what was being done to establish and carry on such institutions in the British Isles and elsewhere. Such an establishment in Edinburgh would be very valuable for the advancement of biological science, besides being a constant source of recreation and instruction to the public. Prof. Ewart remarked that though the climate of Edinburgh might not equal that of Dublin, it is better than that of Amsterdam, where there is a flourishing if not a very large zoological garden. The expenditure in Dublin is 3000*l.*, while the income, including a Government grant, is just over 3000*l.* When it is borne in mind that some 10,000*l.* or 12,000*l.* was raised in four days in connection with the recent show of the Highland Society in Edinburgh, the raising of 3000*l.* annually should not prove insuperable. Among other advantages, a zoological garden would prove a very valuable addition to the educational institutions of Edinburgh. The chairman of the School Board of the city, who was a member of the deputation, supported Prof. Ewart in this view, and pointed out that a zoological garden would be particularly valuable in connection with object lessons in natural history. In replying to the deputation, the Lord Provost said that the Corporation could not embark at the present time upon any large capital expenditure, but asked the deputation to consider what the Corporation should do in support of the movement.

IN connection with the subject of the foregoing note, the account of the New York Zoological Park given in *Forest and Stream* is of interest. This establishment was opened on November 8, at South Bronx Park, New York, and is the largest zoological garden in the world. The well-known Zoo of London has an area of 30½ acres; that at Amsterdam of only 25; that of the Société d'Acclimitation at Paris of 50 acres; that at Berlin of 60. In the United States the Philadelphia Zoo occupies 33 acres, the Cincinnati Zoo 36, while the National Zoological Park at Washington, maintained by the U.S. Government, and with an area of 168 acres, has until now been the largest zoological garden in the world. The New York Zoological Park, however, is more than one-half larger, covering 261 acres. The new park belongs to the New York Zoological Society, which was incorporated by a special act of the Legislature with purposes to establish and maintain a zoological garden in the city of New York, to encourage the study of zoology, and to furnish instruction and recreation to the people. As a condition of the grant of South Bronx Park and the maintenance of the collections and the park by the city, the Zoological Society was required to raise 250,000 dollars, of which amount 100,000 dollars was to be in hand before the society entered into occupation of the park. This fund was to be expended in the erection of the necessary buildings and inclosures, and in the purchase of collections, as well as for the general purposes of the society, but as stated, the city was to prepare the ground of the park, to maintain it in good order and to bear the expense of caring for the collections. The 100,000 dollars were raised by the New York Zoological Society, and in July, 1898, ground was broken. Recently the last touches were put on the more important buildings that have been erected. The animals began to arrive a few weeks ago, and the number already received is very large, although, of course, as yet only a beginning has been made.

THE Berlin correspondent of the *British Medical Journal* states that on the occasion of Prof. Rudolph Virchow's jubilee—the fiftieth anniversary of his tenure of office as professor ordinarius—the Senate of the University, with its rector, Prof. Fuchs, at their head, assembled to greet their revered and honoured colleague, and to present an illuminated and illustrated address, the text of which had been written by Prof. Waldeyer. In it Virchow's wonderful many-sidedness, and his achievements as investigator, archæologist, and politician were recounted in glowing terms. Prof. Virchow, who was surrounded by his family and many personal friends, in his reply gave expression to his thanks for the support which he had always met with on the part of the university, and said it was true that his chief feeling had ever been that of "the professor." In cases of conflicting interests he had always chosen the course of "professor." In the evening the Berlin Medical Society did homage to its president (Prof. Virchow) by a graceful little spontaneous ceremony. The presidential chair was wreathed and decorated with flowers and garlands, and the vice-president, Prof. v. Bergmann, greeted Prof. Virchow with a speech full of hearty good feeling, respect and admiration.

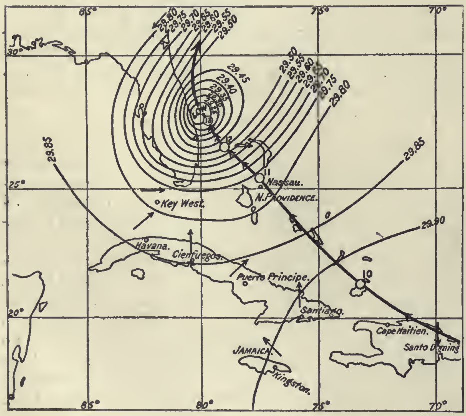
IN a letter to the *Times*, Captain G. Neville, R.N., describes what was apparently the fall of a meteorite, witnessed by him on November 19 from H.M.S. *Dido*, off the Greek coast. He remarks that during a thunderstorm which had lasted all the day "we passed between the islands of Zante and Cephalonia and were about to anchor under the shelter of Cape Clarenza for the night, when there was a sudden flash, a splash in the water about 100 yards from the ship, a report as of a 12-pounder gun being fired, and a little cloud of blue smoke over the spot where the splash had been. It looked exactly as if a shell had struck and exploded, except that there were no fragments flying about." The description suggests that a large meteorite fell in the water, and it would be worth while to attempt to find some of its parts by dredging, and to bring them to the surface.

THE following announcements are made in *Science*:—Dr. Samuel W. Stratton, associate professor of physics in the University of Chicago, has been appointed director of the Bureau of Weights and Measures, United States Coast and Geodetic Survey.—The Rumford Committee of the American Academy of Arts and Sciences has made a grant of five hundred dollars to Prof. E. B. Frost of the Yerkes Observatory, to assist in the construction of a spectrograph especially designed for the measurement of stellar velocities in the line of sight.

THE *Pioneer Mail* states that the Commission appointed to consider the advisability or otherwise of forming an Agricultural Department for Ceylon has reported favourably upon the formation of an agricultural department. It is recommended that the department should be combined with the irrigation department. Further, the Commission has recommended the appointment of four experts to be attached to the department—an entomologist, a cryptogamist, a chemist and a veterinary surgeon. The connection of the Botanical Gardens with the proposed department is not very clear; but it is understood that it will also come under the department, as will the Agricultural School.

REFERRING to the subject of standard time, Prof. Cleveland Abbe remarks in the U.S. *Monthly Weather Review*:—"Our international commercial intercourse will become precise only when we adopt Greenwich dates and Greenwich time throughout the world. This improvement, conducing as it does to the transaction of daily business, will not injure but rather be helpful to meteorology. No one has ever attempted to plot upon an ocean chart the observations of a storm by a hundred vessels at sea, but has found inextricable difficulty with records that are kept by the rules of the ancient navigators; the trouble is with the date of the month and day of the week. The modern navigator and the modern business man will do well to think, speak, and write of Greenwich days and dates only, if he would attain precision in current history."

THE West Indian hurricane of August 7–14 is described by Prof. E. B. Garriott in the *National Geographic Magazine*, from which the accompanying diagram of the storm has been reproduced. During August 7 and 8 the character and extent of the destruction caused in the Leeward Islands, Porto Rico, and Santo Domingo were such as will make the hurricane rank among the historical storms of the West Indies. At San Juan, in Porto Rico, the barometer began to fall at 10 p.m. on August 7, and the lowest recorded reading, 29·23 inches, was



The West Indian Hurricane.

reached at 8·30 a.m. on August 8. The hurricane was strongest at San Juan between 7 and 9 a.m. on August 8, when the wind velocity was calculated by a U.S. Weather Bureau observer at 85 to 90 miles an hour. The rainfall was very heavy, a total of 6·37 inches falling, of which 4·18 inches fell from noon to 8 p.m. on August 8. By prompt action the U.S. Weather Bureau were able to warn many places of the approach of the hurricane centre. Prof. Garriott states that the warnings outran the storm by a period which varied from a few hours at the easternmost Leeward Islands to thirty-six and forty-eight hours at points along the South Atlantic coast and gulf parts of the United States.

THE pilot chart of the North Atlantic ocean for November contains a very useful map of the hurricane tracks during the ten-year period, 1890–99, and the distance travelled by each storm centre during twenty-four hours. With a few exceptions the tracks exhibit the usual features, the motion of the centre in that portion of the track to the southward of latitude 25° being directed towards a point between north and west, and thence moving in a north-easterly direction. The position of this point of recurvature or point of greatest westing is arranged in a tabular form. From this table it is evident that to rely upon the assertion that the storms of a particular month in the West Indies recurve within certain fixed and narrow limits of latitude may lead to serious error at a most critical time. Thus the hurricanes of September, instead of recurving between 27° and 29°, as formerly maintained, may recurve in any latitude from $20^\circ\ 20'$ to $33^\circ\ 30'$ north. Likewise those of October, instead of recurving in latitude 20°—23° north, may continue their north-westerly course until the parallel of 39° is attained.

THE Deutsche Seewarte has published in a quarto volume the results of meteorological observations made on board German ships for the ten-degree square of the North Atlantic comprised between latitude 20°–30° N. and longitude 60°–70° W. This is the seventeenth square, for which the observations have been similarly discussed and published, in the district of the North Atlantic lying between latitude 20° and 50° N., leaving but a small area to complete this very valuable work. It joins on to the nine ten-degree squares lying between latitude 20° N. and 10° S. and longitude 10° to 40° W. discussed and published some time ago by the Meteorological Council, so that shipmasters navigating that part of the ocean have at their disposal a large amount of trustworthy information extending over a considerable number of years. The observations are given in a tabular form for each month, and for each one-degree square, and the results are then combined for each five-degree square. They show the distribution of winds under 16 points of the compass, the prevalence of storms, the mean barometric pressure, air and sea temperature, duration of rainfall and other useful data, and the form adopted allows of the results of future years, or of those obtained by other countries, being added; so that, if desired, comprehensive charts, from accumulated materials, could be constructed without going through the preparatory work *de novo*.

TWO or three months ago reports were published in the daily press of the discovery of an electrical method of giving sight to the blind. It was alleged that Mr. Stiens had succeeded in constructing an electrical apparatus which performed all the functions of the eye and was an efficient substitute for it. Like many other newspaper reports of so-called scientific discoveries, this has proved to be without sound foundation. Mr. G. H. Robertson, who is himself afflicted with blindness, describes in the *Electrician* the results of personal inquiries into the matter with a member of the staff of our contemporary. In spite of several visits to Mr. Stiens, no experimental proof in substantiation of the claims which were put forward on his behalf was obtained, and the conclusion arrived at is that these claims are foundless. Life is so short and crowded with so many important duties that it is impossible to investigate the many sensational statements made by irresponsible interviewers, but we are grateful to any one who will take the trouble to examine some of the rumours which are put forward in the name of science.

IN the *Bulletin* of the French Physical Society, No. 137, is described an ingenious disposition for estimating the duration of Kerr's phenomenon, in which certain dielectric liquids are made to assume the optical properties of double refracting crystals by placing them between the plates of a condenser. The light observed is produced by the spark by which the condenser is discharged, and the time interval between the discharge and the passage of the light through the condenser may be varied by an arrangement of mirrors, whereby the rays may be made to traverse any length of path required. The experimenters, MM. Abraham and Lemoine, find from these investigations that Kerr's phenomenon is reduced to half its original value in the four-hundred-millionth of a second, and becomes insensible in the one-hundred-millionth of a second after the discharge of the condenser. MM. Abraham and Lemoine have also succeeded in showing Kerr's phenomenon for a conducting liquid. The Kerr's condenser, having water between its two armatures, is arranged in the circuit connecting two ordinary condensers in series. On discharging these by the spark used as the source of light the charges liberated instantaneously charge the plates of the Kerr's condenser. For a very small interval of time the water is affected in the same way as a dielectric, and on observing the analyser a brilliant reappearance of light establishes the existence of the phenomenon.

IN the *Bulletin International* of the Cracow Academy, M. P. Rudski continues his papers on the elastic properties of rocks. It would appear that even such rocks as granite cannot be regarded even "grosso modo" as isotropic; but the expression for the elastic potential generally involves five constants. There are no grounds for assuming the separate propagation of dilatational and torsional waves in gneiss, granite and similar rocks; on the contrary, the actual waves are partly torsional and partly dilatational.

THE *Mineralogical Magazine*, vol. xii., No. 56, which has just appeared, contains a description of a new three-circle goniometer designed by Mr. G. F. H. Smith, and intended for comparatively rapid measurements of the geometrical constants of crystals and the indices of their faces. The paper gives a historical account of the one-circle goniometer of Wollaston, the two-circle or "theodolite" goniometer of Miller, and then describes the new instrument, which is a combination of those forms. The great advantage of the combination is that the crystal is adjusted once for all. The measurements may be made in any desired zone, the orientation of which is at once determined. For crystals small enough to be firmly held by wax in all positions, the most convenient arrangement is to give all three motions to the crystal; but, if necessary, the telescope and collimator may have one or more.

THREE noteworthy papers on the cultivation and manufacture of tobacco have recently appeared. One of these publications is Report No. 60 of the U.S. Department of Agriculture, and in it Mr. Milton Whitney and Mr. T. H. Means describe their investigations upon the temperature changes in fermenting tobacco in Florida and Connecticut. The report also comprises a *résumé* of Dr. Oscar Loew's investigations of the cause of fermentation, which throw light upon and explain the observed temperature changes, and the necessity of maintaining a definite amount of moisture in the tobacco during the curing and fermentation. In another paper (Report No. 62), published by the U.S. Department of Agriculture, Mr. Marcus Floyd describes the cultivation of cigar-leaf tobacco in Florida, where striking developments of the tobacco industry have taken place in recent years. The object of collecting information of this kind is to investigate whether the crops produced on the various types of tobacco soils are the best obtainable with the present state of knowledge and skill in manipulation. In this way the Department of Agriculture is making a scientific study of the possibilities of the improvement and extension of an important industry. The third paper mentioned, on the cultivation and manufacture of tobacco, appears in the *Revue Générale des Sciences* for October 30, and is accompanied by a map showing the districts in which tobacco is cultivated in France.

"THE Geology of the Country around Dorchester" is the title of a Memoir (price 1*s.*) just issued by the Geological Survey in explanation of the new series map, No. 328. The Memoir is written by Mr. Clement Reid, and it deals mainly with the chalk, eocene strata and drift. Among the more interesting natural features in the region are the numerous swallow-holes on Puddletown Heath and adjacent tracts. Perhaps the largest is that known as Cull-pepper's Dish, a hollow about one hundred yards long and forty feet deep. Another is known as Hell Pit. Altogether there are some six hundred of these pits, due to the dissolution of the chalk and the subsidence of superincumbent tertiary deposits. Mr. Reid points out that the lower tertiary (Reading) beds consist locally of sands with impersistent beds of clay. The rainfall readily sinks into the porous ground until arrested by one of the clay-bands, and these guide the water in particular directions, whence it descends and dissolves the chalk. The Reading beds and London clay vary considerably from their equivalents elsewhere, the London clay consisting largely of sand and sandy loam. The Bagshot beds furnish evidence of true river-deposits which replace the more estuarine strata of the eastern part of the Hampshire basin. Large pits near Moreton station show (beneath plateau gravel) Bagshot beds comprising current-bedded sand, pipe-clay and gravelly seams containing chalk-flint, Greensand chert, Purbeck limestone, Radiolarian chert, and Schorl-rock. Here, in fact, are found fragments of all the rocks which occur further west in gravels which have been regarded as drift, but which Mr. Reid considers, with good reason, to be of Bagshot age. The accounts which he gives of these and other deposits will be read with interest. Among the latter we may mention the Pliocene formation at Dewlish, the clay-with-flints, plateau gravels, and more recent deposits.

SOME interesting experiments on the rate of multiplication of various yeast cells have been carried out by Dr. D. P. Hoyer, of Vienna, and are published in the *Centralblatt für Bakteriologie*, Part ii., No. 21. The author has determined the time required at different temperatures, 13° C. and 20° C. and 25° C. respectively, by various yeasts to produce a new generation from a parent cell. Thus at 13° C., *S. ellipsoideus I. Hansen* requires nine hours and four minutes, and at 25° C. six hours and twelve minutes; *S. membranae-faciens* at 13° C. seven hours and one minute, and at 25° C. five hours and thirteen minutes to form a new generation. At 6° C. it appears that the majority of the yeasts investigated did not, even after a week, produce a new generation, and the experiments conducted at this temperature were discontinued. The yeasts thus so closely scrutinised were grown on gelatine, and were not more than from three to four days old. Many bacteria have been submitted to similar observations; but until these experiments, made by Dr. Hoyer, were published, scarcely any investigations of this kind, in regard to yeasts, have been recorded.

THE *Bulletin of Miscellaneous Information* (Trinidad) for October contains a fuller diagnosis of the new fungus-parasite of the cacao-plant, *Nectria Bainii*, Mass. It seems, however, still doubtful whether it is the cause of the disease, or simply saprophytic.

IN the number of the *Agricultural Gazette of New South Wales* for October is a very interesting further account, by Mr. J. H. Maiden, of a botanical visit to Mount Kosciusco. The flora presents some Alpine features, but the flowers are not specially large or brilliant. There is an extraordinary predominance of white flowers, almost exactly one-half of those gathered at high altitudes. The flora presents, on the whole, a strong affinity with that of Tasmania. A list of the plants collected is appended.

THE *Journal of the Royal Horticultural Society* for November, besides purely horticultural papers, contains several *résumés* of the present state of our knowledge in various branches of botany:—On the dispersion of seeds, by Prof. Boulger; and on the importance of light and heat to plants; on movements of plant organs; and on fertilisation by insect agency, by the Rev. G. Henslow, read at the meetings of the Society. In the last of these papers, Mr. Henslow sums up strongly against Darwin's dictum that "Nature abhors perpetual self-fertilisation," which, however, he quotes as "Nature abhors self-fertilisation," an assertion never made by Darwin.

THE second volume of Dr. Isaac Roberts' "Photographs of Stars, Star Clusters and Nebulæ" is about to be issued from the publishing office of *Knowledge*. It will contain seventy-two photographs reproduced by the collotype process, in addition to many pages of text. Only a limited number of copies of the work will be available for the public.

A SECOND fully revised edition of "The Physiology of Plants: a Treatise upon the Metabolism and Sources of Energy in Plants," by Dr. W. Pfeffer, professor of botany in the University of Leipzig, translated and edited by Dr. Alfred J. Eward, will be issued immediately from the Clarendon Press.

THE members of the St. Marylebone Natural Science Society apparently derive a large amount of pleasure and instruction from one another, for the report on the meetings held during the present year shows that a number of interesting papers on diverse subjects were read before the Society. Every organisation which creates and fosters a love of natural knowledge furthers the interests of science; therefore, we are glad to know of the activity of the scientific society of St. Marylebone.

THE only ionising inorganic solvents hitherto found in addition to water are nitric acid and liquefied ammonia. In the current number of the *Berichte* Prof. Walden, of Riga, gives a preliminary account of experiments with liquid sulphur dioxide, which shows that this liquid acts to an unsuspected degree as a solvent for inorganic and organic substances. Since it permits of double decompositions, and gives electrolysable solutions, liquid sulphur dioxide must now be reckoned as an ionising solvent. Many substances dissolve in liquid sulphur dioxide with characteristic colours. Thus the iodides of the alkalis and alkylammoniums dissolve with a yellow colour. As an example of double decomposition, the action of potassium iodide on trimethylammonium chloride may be cited. These substances in sulphur dioxide solution give a precipitate of potassium chloride. Ferric chloride and ammonium sulphocyanide give the usual red colour of ferric sulphocyanide. The electrical conductivity of salts in sulphur dioxide solution is not the same in order as that in aqueous solution, nor does the molecular elevation of the boiling point in liquid sulphur dioxide correspond altogether with that found in aqueous solutions. Prof. Walden promises a thorough investigation of the many points of interest raised by this new discovery.

THE additions to the Zoological Society's Gardens during the past week include a Vervet Monkey (*Cercopithecus lalandii*, ♂) from South Africa, presented by Mrs. A. Rousbey; a Persian Gazelle (*Gazella subgutturosa*, ♂), a Chaplain Crow (*Corvus capellanus*) from Persia, presented by Mr. B. T. Ffinch; two Chipping Squirrels (*Tamias striatus*) from North America, presented by Mr. C. M. Stewart; two Snake Fishes (*Polypterus senegalus*) from the River Gambia, presented by Mr. J. S. Budgett; an Indian Antelope (*Antilope cervicapra*, ♂), a Banded Parrakeet (*Paloeornis fasciatus*) from India, a Sooty Phalanger (*Trichosurus fuliginosus*, ♂) from Tasmania, a Fennec Fox (*Canis cerdo*) from North Africa, deposited; two Red-backed Buntings (*Emberiza rutila*) from Japan, purchased.

SPECTROSCOPIC BINARIES.—(1) *α Aurigæ* (*Capella*). Prof. W. W. Campbell, from examination of six spectrum plates of the star obtained with the Mill's spectrograph during 1896–97, finds decisive evidence of its being a spectroscopic binary. The component having a spectrum of the solar type showed velocities of 34, 54, 49 and 3 kilometres per second from 1896, August 31, to 1897, February 4. The spectrum of the second component appears to consist chiefly of Hγ and the more prominent iron lines (*Astro. Physical Journal*, vol. x., p. 177). (2) *α Ursae Minoris* (*Polaris*). Photographs of the spectrum obtained in 1896 showed no decided evidence of variable velocity. Others taken in August 1899 gave such different values, ranging from $-15·2$ to $-9·0$ kilometres per second, that the star was suspected to be a short period variable, and a curve was plotted from additional observations specially made. (*Astro. Physical Journal*, x., p. 180). The 1896 values of the velocity lie altogether out of the recent measures, and this is the reason assigned for suspecting the presence of a disturbing force in the form of a third component. The period of the chief pair is about 3d. 23h. All the observations were made with the Mill's spectrograph on the 36-inch refractor.

In the same number of the *Journal*, p. 184, Prof. E. B. Frost, of the Yerkes Observatory, gives the velocities in the line of sight of this star, obtained from spectrograms taken with the 40-inch refractor. The resulting values quite confirm the short period variation found by Prof. Campbell, and the range in velocity (7 kilometres) is also closely in agreement.

POSITION OF PERTH OBSERVATORY.—Mr. W. E. Cooke, Government Astronomer at the Perth Observatory, Western Australia, has recently, with the co-operation of Sir Charles Todd, of the Adelaide Observatory, determined the latitude and longitude of the station. The latitude was determined by observations of meridian zenith distances of circumpolars, and the final adopted value is

Latitude 31° 57′ 09″·63 S.

The longitude was found by interchanges of clock signals between Perth and Adelaide, the adopted value being

Longitude = 7h. 43m. 21·74s. E.

VARIATIONS IN THE SPECTRUM OF ORION NEBULA.—Prof. Scheiner, in the *Astronomische Nachrichten*, Bd. 150, No. 3593, made some lengthy criticisms of Prof. Keeler's observations of the spectrum of the Orion Nebula, obtained with the Lick telescope. Prof. Keeler's reply is given in No. 3601, and the *Astro. Physical Journal*, vol. x., pp. 164–8, contains both the reply and a translation of Prof. Scheiner's article. The experiment consisted in obtaining two photographs of the nebula, one on an ordinary plate, the other on an isochromatic plate protected by a greenish-yellow screen. The resulting negatives showed considerable differences in the relative intensities of several parts of the nebula. Prof. Scheiner pointed out the doubtful comparison of different types of plates, the possible photographic exaggeration of really minute differences of intensity, and the difficulty of observations of such faint phenomena.

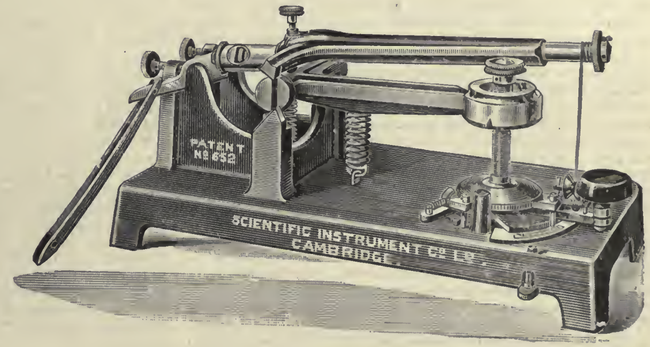
To this Prof. Keeler replies, "That the difference between the plates is not sufficient to explain the irregularities found, as the *star* images on both plates are equally intense; the differences in intensity are measured from point to point on the *same* negative, not from one to the other; the observations are neither difficult or delicate, as the light given by the 36-inch is quite sufficient for the purpose.

A NEW ROCKING MICROTOME.

SERIAL section-cutting has sprung into such prominence during the last fifteen years, and has now become so essential to almost every branch of biological research, that we are apt to forget that we are still using, practically unmodified, one of the earliest invented automatic microtomes. The Rocking Microtome designed by the Cambridge Scientific Instrument Company was first put before the public in 1885, within a short time of the appearance of the very earliest of all automatic microtomes, that designed by Caldwell and Threfall. The simplicity, efficiency and cheapness of the former soon caused it to become both widely known and used by all biologists, and it may be doubted whether any instrument has ever spread so rapidly and deservedly over so wide an area as the familiar "rocker" which is now a characteristic feature in all laboratories in which any branch of biology is taught.

Considering the number of years which the microtome has been in use, and the variety of purposes which it has been made to serve, it is not surprising that several small alterations have been made in it from time to time; none of these, however, have affected the essential features of the rocker, which remains the same instrument to-day that it was years ago.

Recently the Cambridge Instrument Company brought out an enlarged and improved form to obviate what has generally been regarded as the chief defect of the "rocker," viz., the fact that, owing to the principle upon which this instrument is constructed, the cutting surface was of a necessity a curved one. This microtome, however, is too expensive to replace the rocker for which, in spite of its curved cutting surface (a defect of no moment in most work), there was and is still a great demand. The makers have, therefore, set to work to remedy certain minor defects in the rocker, and have, as a result, placed what they consider to be a greatly improved microtome on the market.



The new microtome, as will be seen from the figure, is of much the same form as the old design, and is built upon the same principle, the chief difference being in the bearings of its working parts, and in the addition of one or two new features.

The following advantages are claimed for the new model:—

(1) Increased rigidity.
(2) Impossibility of tearing sections on the upward movement of the object.
(3) Impossibility of cutting thick and thin sections.
(4) Graduated arc for showing the thickness of the sections.
(5) Catch for holding object above the razor edge.
(6) Improved method of fixing the cord.
(7) New object-holder.

Most of these are small but useful additions to the microtome, which by themselves would call for no special comment. The chief features presented by this instrument, and through which it claims more than passing notice, are Nos. 2 and 3 in the above list.

Every one who has had much experience in serial section-cutting will at one time or another, no matter what automatic microtome he was using, have found that the sections were torn or lifted off the edge of the razor, and adhered to the block of paraffin on the upward stroke. It is to obviate this trouble that the modified rocker has appeared.

All possibility of this injury to the section is prevented in this model by the fact that in the upward movement the object cannot touch the razor, since, by means of an additional pawl which at the end of the stroke turns the screw down by four teeth on the notched wheel, the object is drawn backward before the upward movement commences.

This apparatus acts perfectly, but may possibly introduce a new source of damage to the machine, viz., additional wear to the notches on the toothed brass wheel. As one who has used a rocker since its first appearance, I can state that the only serious trouble I ever had with this instrument was due to the wearing down of these teeth; therefore, it seems to me that the addition of a second steel pawl will cause these important structures to wear away more quickly. After all, is the occasional displacement of the section in the upward movement due to a defect in the older microtomes? Or is it not rather due to carelessness on the part of the manipulator, a blunt razor, a paraffin block with imperfectly trimmed edges, and the latter not arranged parallel to the edge of the razor? Personally, I believe the operator is generally to blame, and that it is due to a combination of the above mistakes on his part. But even if it is so, we ought to thank the makers for trying to save us from ourselves, and if the extra pawl will not wear the very important teeth too much, it should prove a very useful addition to the microtome, since even the most careful of us are apt to err at times, and it is very trying to struggle with an object which will not ribbon.

Most of the bearings of the machine are based on a new design, which is said to reduce wear and friction. That at the base of the big screw, as now spherical instead of conical, this is believed to prevent the cutting of thick and thin sections. How far this is a fact time only can tell, but a trial of the instrument with very hard and trying objects gave highly satisfactory results.

The whole instrument is much more rigid than the old form, and the addition of a catch for holding the object above the razor, the improved cord fixer, the graduated scale for showing the thickness of the sections, and the new compact object-holder provided with universal movement, will add much to the utility of the machine. It is to be hoped, however, that the scale will be quite accurate; the divisions on the scale attached to the machine (a rough model only), which has been examined, did not appear quite equal, some giving two and some three teeth.

It may be mentioned that the new microtome will be issued at practically the same price as the old form, and should, with its new additions, prove a boon to all biologists. M. F. W.

CORRESPONDING SOCIETIES OF THE BRITISH ASSOCIATION.

THE meetings of the Conference of Delegates of the Corresponding Societies were held in the Mayor's parlour at the Town Hall, Dover, on September 14 and September 19.

First Meeting.—The Corresponding Societies Committee of the British Association were represented by Rev. T. R. R.

Stebbing (Chairman), Rev. J. O. Bevan, Mr. G. J. Symons, Prof. W. W. Watts, and Mr. T. V. Holmes (Secretary).

A short report, stating that the resolution passed at the Bristol meeting of the conference of delegates on the desirability of securing the co-operation of the coastguard as observers of coast erosion had been favourably received by the Admiralty, and giving copies of the forms issued to the coastguard for the promotion of uniformity in their observations was in the hands of every delegate present, and was taken as read. Then Rev. T. R. R. Stebbing, after alluding to the result of last year's discussion on coast erosion, read a short paper on the living subterranean fauna of Great Britain and Ireland.

The first undoubted mention of an underground crustacean seemed to be that of an amphipod found in London and named by Dr. Leach, of the British Museum, in 1813. Since that time many valuable treatises on the subterranean fauna of various parts of the globe have appeared in many European languages, Polish among others. The English student might be advised to study "The Cave Fauna of North America," by Dr. Packard, published in the *Memoirs* of the National Academy of Sciences, vol. iv., Washington, 1888. Also "The Subterranean Crustacea of New Zealand," by Dr. Charles Chilton, published in the *Transactions* of the Linnean Society of London, 1894. Packard enumerated 308 European cave animals and 102 American. This list of 410 included a few Protozoa, a sponge, two hydras, a few worms, one mollusc, several crustacea and myriapods, numerous arachnids and a host of Coleoptera, the other insects being chiefly Thysanura. The vertebrates consisted of four American fish and one European batrachian, the celebrated *Proteus anguineus*. The known well fauna of Great Britain and Ireland comprised only four species which belong to the amphipoda. These, however, de Rougemont would reduce to a single species. In addition, it may be mentioned that an insect and a copepod have been found in the recesses of coalpits in Scotland and northern England. After noticing the colourlessness and blindness characteristic of subterranean fauna, Mr. Stebbing remarked, in conclusion, that it would be strange should the caverns and wells of Great Britain and Ireland not yield, on investigation, a fauna comparable in some degree to that found in other parts of the world. In this research he hoped that some members of our local scientific societies might take a share.

In answer to a question as to the best way of catching the well shrimp, Mr. Stebbing replied that a good plan was to wait till the well was nearly empty, then let down a bucket and withdraw it as quickly as possible. Sometimes well shrimps were brought up when pumping was going on.

Some discussion then arose, in which Rev. J. O. Bevan, Mr. T. Workman, Mr. Hotblack and Mr. Stebbing took part, as to whether the bats in the Mammoth Cave at Kentucky passed all their time there. The matter could not be absolutely settled, though there seemed to be a presumption against their doing so; Mr. Workman stating that he had not found them in the depths of the cave, though they were in large numbers near the mouth.

SECOND MEETING OF THE CONFERENCE, SEPTEMBER 19.

The Corresponding Societies Committee were represented by Rev. T. R. R. Stebbing (Chairman), Dr. Garson, Mr. G. J. Symons, Prof. W. W. Watts, and Mr. T. V. Holmes (Secretary).

After a long and desultory debate on the best ways of increasing the usefulness of the meetings of the Conference, during which Mr. Stebbing was obliged to leave, and Prof. W. W. Watts became Chairman, Mr. Hugh Blakiston, Secretary of the "National Trust for Places of Historic Interest or Natural Beauty," delivered an address on the aims and work of the Trust.

Section A.—Mr. G. J. Symons stated that the Committee for Seismological Observations was much in need of a home.

Section C.—The Chairman remarked that the Erratic Boulders Committee had presented a report. The Geological Photographs Committee would be glad to receive contributions of photographs. They hoped shortly to be able to publish a selection of typical photographs. Their duplicate collection of prints and slides would be sent to any local society wishing to exhibit them.

Section D.—Rev. T. R. R. Stebbing said that the Secretary of Section D recommended the study of the fauna of wells and caverns to the Corresponding Societies.

Section K.—Mr. H. Wager had to inform the delegates that the Section had appointed a committee to consider the geographical distribution of mosses.

PROGRESS OF AGRICULTURAL CHEMISTRY.[1]

AN important address has been recently delivered by Prof. Maercker, of Halle, to the German Chemical Society (*Ber.* 1897, p. 464), summarising the advances which have been made in agricultural chemistry during the last twenty-five years. Prof. Maercker pointed out that the term Agricultural Chemistry meant more at the present time than the mere application of chemistry to agriculture, as shown by the fact that the agricultural chemist, in his efforts to assist the farmer, was often more concerned with the biological sciences than with chemistry; while, in addition to his purely scientific work, he was required to take account of economic questions of the day possessing special interest to agriculturists. The following account of the most important parts of the address is given under the following heads:—I. Plant-food; II. Soils and Manures; III. Artificial Selection. It is reproduced here by the kind permission of the editor of the *Imperial Institute Journal*.

I. PLANT-FOOD.

In supplying nourishment to plants we must know what substances are necessary, and in what form and quantity they should be provided. Little progress was made in our knowledge of the subject till the quite recent introduction of the method of water-cultures of Sachs, Knoop, and Nobbe and the method of sand-cultures of Hellriegel permitted of the conduct of experiments in pure media, and thus rendered it possible to ascertain not only what substances are essential for plant-life, but also the part played by each substance in the plant cell. Thus we know now that phosphoric acid is essential for the formation of nitrogenous substances in the plant, because the albumens, which are of fundamental importance in the transformations of substances in plants, result from an intermediate phosphoric acid compound, as is indicated by the regular occurrence of lecythin in protoplasm. Again, iron is an essential constituent of chlorophyll and sulphur of albumen, and hence must be supplied to plants. The true function of calcium was for long doubtful; its action is now known to be of a medicinal character, since it serves to neutralise the poisonous oxalic acid, which is always an intermediate product of the oxidation of the carbohydrates. It was formerly thought that calcium fulfilled some important function in the leaves, being chiefly found in the foliage of plants. Since, however, the leaves are also the chief seat of the oxalic acid, this distribution of the calcium is easily explained.

The part played by potassium has only within the last three years been explained by Hellriegel, who, by exact experiments with beet-root showed that the amount of sugar in the beet stands in close relation to the amount of potassium provided for the plant. P. Wagner has made the interesting observation that the potassium may be *partly* replaced by sodium.

The exact value of magnesium to plants is not yet well understood, but it appears to be of importance in the formation of the nitrogenous substances of seeds, as in these considerable quantities of magnesium phosphate occur.

Nitrogen is an indispensable plant-food, for it is an essential constituent of albumen.

In addition to the quantities of mineral substances required by plants to enable them to exhibit a healthy growth, further quantities are found to be essential to satisfy what has been termed, though not very aptly, the "*mineral-hunger*" of the plant. This is best explained by an example. E Wolff found that for the production of 100 parts of oat-plant (dried), ·5 parts of phosphoric acid were necessary, when the remaining mineral substances were supplied in excess to the plant. By other similar experiments he showed that the following quantities of mineral substances were necessary for the production of 100 parts of oat-plant:—

Phosphoric acid	·50 parts
Potash	·80 ,,
Lime	·25 ,,
Magnesia	·20 ,,
Sulphuric acid	·20 ,,
	1·95 parts.

A total of 1·95 parts of mineral substances is therefore *necessary* in the case of the oat-plant. However, there is no oat-plant in nature which contains so little as 1·95 per cent.

[1] Reprinted from the *Kew Bulletin* (No. 144).

The minimum is 3 per cent. The difference, 1·05 per cent., is the measure of the "mineral-hunger" of the plant, and represents the mineral substance which does not perform any special function. This excess of mineral substance may be supplied in the form of some indifferent substance, such as silica. The observation is of considerable interest to the farmer, for it shows that it is not economical to manure crops with pure substances.

II. SOILS AND MANURES.

Having ascertained in general what substances are necessary as plant-food, the agricultural chemist has next to apply this general information to the manuring of soils which are more or less deficient in certain ingredients. It has been found, unfortunately, that the chemical analysis of a soil is of little use as a guide unless accompanied by what may be termed a "mechanical analysis," by which is meant chiefly a determination of the amount of finely-divided constituents present in the soil. It is only the finely-divided earth which presents a sufficiently large surface for the exercise of the solvent action of the water and its dissolved carbonic acid. There is one case, however, in which chemical analysis alone is of the greatest importance, viz. when only traces of some necessary element are present in a soil. Here there is no question of the need for a manure containing this substance.

If, on the other hand, large quantities of an element are present, it does not follow that there is a sufficiency in the soil even when the latter is in a satisfactory state of division, for the substance in question may be present in an insoluble or refractory form. This is commonly the case with nitrogen, which exists in the soil chiefly in the form of a mixture of indefinite nitrogenous substances known as *humus*, or mould. These substances sometimes easily give up their nitrogen to plants, but in other cases are very refractory. The uncertainty as to their action is indeed so great that certain peaty soils are known which consist almost entirely of humus, but contain, nevertheless, an insufficiency of available nitrogen.

Phosphoric acid affords another illustration. The soluble phosphoric acid of the manure is absorbed by the soil as dicalcic phosphate, which is comparatively easily soluble in the soil-water. With time, however, it may change in the soil to the insoluble tricalcium phosphate, or even to iron or aluminium phosphates, which are still less soluble.

In the case of calcium, chemical analysis has been found to be of considerable service in determining what manuring is required, since calcium is chiefly valuable in the form of carbonate or humate, and these are easily estimated in the soil.

Since then the direct method of soil-analysis is an insufficient guide to manuring, it is fortunate that chemists have been able to develop successfully an indirect method. This is the *cultivation method*, by which plants are allowed to grow in the soil under examination, after taking care to provide a sufficiency of all plant-food stuffs except the one, *e.g.* phosphoric acid, whose presence in available form is being tested. The plants are then analysed, and the results compared with the analyses of the same plants grown on soils provided with all the necessary plant-food stuffs. As an important result of the method it has been found that different plants take up very different quantities of the same mineral substances. On this is largely based the system of rotation of crops, where the second crop is so chosen that it chiefly removes the ingredients of the soil which have been left by the preceding crop.

With the aid of the cultivation method it has also been possible to draw up the following table, which represents the relative values of the different nitrogen compounds for plant-food.

Nitrogen of Saltpetre	100
,, ,, Ammonia	85–90
,, ,, Albumen	60

This table may be made use of in determining the nitrogen value of a manure.

The cultivation method may be used for testing the value of manures of all kinds. Thus it was by a few cultivation experiments that Wagner in Darmstadt first showed the very great value for agricultural purposes of the "Thomas" Slag, produced as a bye-product in the manufacture of iron by the basic process of Thomas Gilchrist. The million tons of phosphate meal annually produced in Germany is now wholly utilised by the agriculturist, and its preparation for the farmer has become an important offshoot of the iron industry.

Similarly the demonstration by the cultivation method of the value of potash salts in manures has given an enormous impetus to the potash industry.

Speaking generally, the method gives us complete control over the fertility of a soil in so far as this depends on manuring. One consequence of this has been that our views as to the value of agricultural land have completely changed, for whereas formerly sandy soils were generally considered poor, they are now, by means of a system of intelligently directed manuring, made to give yields which are scarcely inferior to those of the best soils. The beet-sugar industry, which formerly could only be conducted in the best soils, has now been extended with marked success to sandy soils.

III. ARTIFICIAL SELECTION.

It might seem that with a perfect knowledge of the manuring of plants, the need for further investigation would cease, for when we have learned exactly what each plant requires to attain its highest development, we have reached a certain limit. The supply of excessive nourishment is a disadvantage, and only tends to produce sick plants.

There still remains, however, a method by which the fertility of plants may be increased far beyond the limit which nature appears to have fixed. This is the method of artificial selection, which has been applied in Germany on the most approved scientific principles. German agriculture would have long since broken down under the stress of foreign competition had it not been for the perfect technology of its agriculturists. As an example the sugar-beet may be quoted. This plant contained originally but a small amount of sugar, and could only be used as a source of sugar when the price of the latter was very high. With the fall in price came the urgent need for increasing the percentage of sugar in the beet-root. This was effected by utilising the fact that sugar-richness is hereditary, so that by selecting artificially the roots richest in sugar, getting seed from these, planting the seed, again selecting the richest roots, and so on, a race of plants is at length obtained in which a high percentage of sugar is normal.[1] Accordingly the producers of beet-root seed in Germany have erected great laboratories in which the percentage of sugar in the roots is carefully determined. By applying the principle of artificial selection with regard also to the form and size of leaf and the purity of the sap, it has been found possible to improve the roots from year to year, so that now beet-sugar can easily hold its own against cane-sugar, and is indeed cheaper than flour, costing as it does in Germany less than a penny a pound.

Similar success has attended the efforts to increase the crops of different kinds of grain. The improvement in malt-barley has been specially marked.

It has been found that plants which have been highly cultivated by artificial selection easily lose their acquired characters when they are exposed to unfavourable conditions of cultivation; and this has led to many exact investigations, conducted for the most part in Germany, during the last ten years, on the chemistry of plants. The most interesting of these trace the chemical history of nitrogen as it passes from the atmosphere to the soil, then into the substance of plants, and finally back into the atmosphere.

The corresponding cycle for carbon has long been known.

Most plants assimilate nitrogen only in the form of compounds. As, however, the total quantity of nitrogen compounds in the atmosphere is comparatively small, there must be some other source of nitrogen for plants. Now the classical researches of Hellriegel have shown that there is one class of plants, the *Leguminosae*, or nitrogen collectors, which are able to assimilate elementary nitrogen and so to leave a soil in which they have been grown richer in nitrogen compounds. It has been found that the power of acting as nitrogen collectors is always associated with the presence of micro-organisms on the roots, and that the assimilation of the nitrogen is in some way not understood due to the micro-organisms. The recognition of the power of leguminous plants to act as nitrogen collectors is manifestly of great practical importance, for it shows clearly that the best rotation of crops is one in which a leguminous crop is followed by one of nitrogen consumers, *i.e.* plants which cannot assimilate nitrogen directly.

[1] See *Kew Bulletin*, 1897, pp. 317, 318.

Leguminous plants, whether first used as fodder for animals or simply left to decay in the soil, have their albumen changed in the first instance to amides, which under the influence of ammonia-ferments are decomposed with formation of ammonium-carbonate. The saltpetre bacillus then converts the ammonium-carbonate (and probably also amides) into saltpetre, *i.e.* into the best form of nitrogen plant-food.

Unfortunately the whole of the nitrate thus formed is never available for plants, on account of the destructive action of the nitrate-destroying bacilli, which decompose the nitrates with evolution of free nitrogen, and so complete the nitrogen cycle.

The nitrate destroyers are usually present in stable-manure, and cause a deplorable loss to agriculture, amounting in Germany to a sum of several million pounds annually.

Efforts which, as Prof. Maercker assured the German Chemical Society, are likely to meet with success at an early date, are being made to avoid this loss; and for this purpose special bacteriological investigations are now being conducted at many agricultural stations in Germany.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Dr. Langley, F.R.S., has been appointed Chairman of the Examiners for the Natural Sciences Tripos.

Mr. E. A. N. Arber, of Trinity, has been appointed Demonstrator in Palæobotany.

Mr. W. F. Cooper, of Clare, has been nominated to the occupation of the University table in the Naples Zoological Station.

Mr. H. H. W. Pearson, of Gonville and Caius, and Mr. J. Barcroft, Fellow of King's, have been awarded the Walsingham medals for research in botany and in physiology, respectively.

The degree of Master of Surgery was on November 23 conferred on Mr. Timothy Holmes for his distinguished contributions to the art and science of surgery.

Sir Ernest Clarke has been re-appointed Gilbey Lecturer in Agricultural History and Economics for the ensuing year.

Prof. Woodhead, and Drs. Anningson, Collingridge, Notter, and Stevenson, have been appointed Examiners in State Medicine.

Dr. Somerville, Professor of Agriculture, has been elected a Fellow of King's College.

THE Lawrence Scientific School of Harvard University has received a gift of twenty thousand dollars to be used to equip the mining and metallurgical laboratories.

DR. PAUL STAECKEL, assistant professor of mathematics at Kiel, has been appointed professor ordinarius. Dr. J. Traube, privatdocent in physical chemistry at the Berlin Technical High School, has been appointed professor.

THE new leather industries buildings in connection with the Yorkshire College, Leeds, which have been erected by the Skinners' Company of London at a cost of 5000*l.*, were opened on Monday by the Master of the Guild, Mr. J. Colman. In addition to the gift of the buildings the Company has granted an endowment of 250*l.* a year for ten years, thus placing the instruction in the branches connected with the leather industry on a solid foundation.

THE Canadian *Educational Review* announces that Sir W. C. McDonald, of Montreal, whose magnificent gifts to McGill University have made him justly celebrated as a public benefactor to education in Canada, has placed in the hands of Prof. Robertson, Dominion Agricultural Commissioner, sufficient funds to establish for three years technical schools in various centres throughout the Dominion. The nature of the plan is to take one city or town in each province in which to establish regular classes in some of the ordinary schools on one or two days a week, in which scholars between nine and thirteen years of age shall spend a portion of the day in actual work with tools. This will be supplemented whenever desired by more advanced and special evening classes in manual training and technical instruction.

A COPY of the *Magnet*, the magazine of University College, Bristol, has been received. There are several noteworthy articles and items of information in the magazine, not the least interesting being the editorial note on the appointment of Dr. Ryan, professor of engineering, to the principalship of the Woolwich Polytechnic. Dr. Ryan has been at the College for fourteen years, and has devoted his best energies to bringing the engineering department to its present satisfactory position. He would have done much more if the funds at his disposal had permitted him to develop the work of the department; but, unfortunately, the College possesses only a small endowment, and Bristol manufacturers are not so actively interested in the progress of their University College as are many commercial men in Liverpool, Birmingham, and other cities. Leaving this point, attention may be called to an article in the *Magnet* on life in a mediæval university, by Dr. Hastings Rashdall. The description of the ceremonies through which the freshman or bejannus of the middle ages had to pass before he could call himself a student of the university would suggest many comparisons to an ethnologist. It must be remarked that the periodical does not show the signs of active interest in scientific work which are given in the form of notes and articles in some other magazines of the same type.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, November 24.—Prof. G. Carey Foster, F.R.S., Vice-President, in the chair.—A paper on the conductivities of certain heterogeneous media for a steady flux having a potential was read by Dr. C. H. Lees. Two formulæ have already been proposed to express the conductivity of a mixture in terms of the conductivities of its constituents. In the first formula the conductivity is represented as the sum of a number of terms, each one of which is the product of the conductivity of any constituent and the fractional part of the mixture which is made up of that constituent. In the second formula the resistivity of a mixture is expressed in the same way with respect to the resistivities and percentages of its constituents. In general, the first of these suppositions gives results which are above the experimental values, while the second gives results which are below. If we suppose that the mixture is made up of a series of columns of the separate parts stretching normally between two equipotential surfaces, then the conductivity would be accurately represented by the first formula. If, however, we assume that the constituents are arranged in parallel layers, then the second formula would apply. In the present paper the author has attacked the problem two-dimensionally, and has investigated the relation which holds between the conductivities, when the constituents are arranged in the mixture alternately like the squares on a draughts board. Dealing first with two components it is easily shown that the problem reduces itself to finding the form of the equipotential curves and of the stream lines in a square which is divided by a diagonal into two parts of different material. By means of conformal representation Dr. Lees has referred the square under consideration to a kite-shaped quadrilateral with two opposite angles right angles, and the other two so determined by the conductivities of the constituents as to give straight equipotential lines in the two portions of the figure which represent the two materials and which are separated the one from the other by the axis of symmetry. The general relation which exists between the vector co-ordinates in the two systems has been proved by Love to consist of elliptic functions; but near the angular points of the figures a close approximation can be obtained by the use of a simple exponential expression. Taking the known solution to the problem in the case of the kite-shaped quadrilateral, it is easy to calculate the result for the square under consideration. This leads to the conclusion that the conductivity of the square is the geometric mean of the conductivities of the constituents. Allowing the medium to become fine-grained and introducing new materials, it follows at once that the logarithm of the conductivity of a mixture is equal to the sum of a number of terms, each one of which is the product of the logarithm of the conductivity of any constituent and the fractional part of the mixture which is made up of that constituent. By a superposition of fluxes, the author has shown that the above law holds for flows in four directions, and he therefore considers that with the assumed structure the formula represents the conductivity for any flux.—Dr. Lees then read a second paper on the thermal conductivities of mixtures and their constituents.

In this paper the three formulæ considered in the preceding communication are applied to the known experimental results upon the conductivities of mixtures of liquids. The author finds that the least satisfactory formula is the first one, whereas the least unsatisfactory is the logarithmic one. Mr. Appleyard said that it was frequently of importance to be able to determine the resistance of a mixture of gutta-perchas from the known resistances of component parts. He had attempted, without success, to do this by means of the old formulæ, and he would be interested to see whether Dr. Lees' logarithmic formula gave better results. In electrical work Mr. Appleyard pointed out that the nature of the contacts affected the conductivity, the resistance of a sheet of rubber being different when measured between metal plates and mercury sheets. Mr. Campbell said that the difference between the calculated and observed results might be due to the thermoelectric properties of the materials. Lord Rayleigh had observed that the high resistivity of alloys might be due to a back E.M.F. produced by the contact of dissimilar metals. Mr. Campbell said that he had measured the resistances of ferro-nickels both with direct and alternating currents, and found them the same in the two cases. In reply, Dr. Lees said that all his experimental work on conductivity had been carried out with mercury contacts.—The Society then adjourned until December 8, when, by the invitation of Prof. S. P. Thompson, the meeting will be held in the Physical Laboratory of the Finsbury Technical College.

Chemical Society, November 16.—Prof. Thorpe, President, in the chair.—The following papers were read.—The chlorine derivatives of pyridine. Part IV. The constitution of the tetrachloropyridines, by W. J. Sell and F. W. Dootson. The authors have determined the constitutions of the three known and theoretically possible tetrachloropyridines.—Contributions to our knowledge of the aconite alkaloids. Part XV. On japaconitine and the alkaloids of Japanese aconite, by W. R. Dunstan and H. M. Read. The authors show that Japanese aconite, *A. Fischeri* ("Kuza uzu"), contains japaconitine, $C_{21}H_{29}(OMe)_4(OCMe)(OCPh)NO_3$, which, contrary to the views of many investigators, is chemically distinct from aconitine.—The dissociation constants of very weak acids, by J. Walker and W. Cormack. Using a special form of apparatus, the authors have determined the electrical conductivity of solutions of feebly acid substances, such as phenol, hydrogen sulphide and acetic, carbonic, boric and hydrocyanic acids; the behaviour observed is in accordance with Ostwald's dilution law.—Preparation and properties of solid ammonium cyanate, by J. Walker and J. K. Wood. Pure solid ammonium cyanate may be obtained by mixing cooled ethereal solutions of ammonia and cyanic acid; its molecular heat of transformation into solid urea is 49 K, whilst in aqueous solution this constant is 75 K.—Etherification of derivatives of β-naphthol, by W. A. Davis.—On the determination of transition temperatures, by H. M. Dawson and P. Williams. The authors' method of determining transition temperatures depends upon ascertaining the point at which the two branches of the density or electrical conductivity curves at temperatures above and below the transition point, intersect each other.—Constitution of amarine, of its supposed dialkyl- and diacyl-derivatives and of isoamarine, by F. R. Japp and J. Moir. The authors regard amarine as a *cis*-diphenyl compound of the constitution $\left.\begin{matrix}CHPh.NH\\ |\\ CHPh-N\end{matrix}\right\rangle CPh$, Snape's isoamarine being the corresponding *trans*-isomeride; the latter is readily obtainable by fusing amarine with sodium or heating its hydrochloride above the melting point.—The atomic weight of nitrogen, by G. Dean. The ratio Ag : AgCN was found to be 107·93 : 133·962, whence CN = 26·032 and N = 14·031 if C = 12·001.

Mineralogical Society, November 14.—Prof. A. H. Church, F.R.S., President, in the chair.—Dr. E. Hussak and Mr. G. T. Prior gave an account of a new Brazilian mineral, Florencite, a hydrated phosphate of aluminium and cerium earths ($3Al_2O_3.Ce_2O_3.2P_2O_5.6H_2O$), crystallising in the rhombohedral system. The mineral is isomorphous with the recently discovered Hamlinite, to which it is also very similar in chemical composition; the strontium and barium of Hamlinite being replaced in Florencite by cerium earths.—Mr. A. Hutchinson described a new mineral, Stokesite, from Cornwall, of peculiar chemical composition. It is a hydrated silicate of tin and calcium, $CaO.SnO_2.3SiO_2.2H_2O$, and crystallises in the orthorhombic system in forms closely resembling gypsum, from which it is easily distinguished by its much greater hardness.—Mr. R. H. Solly contributed a paper on sulpharsenites of lead from the Binnenthal, and gave descriptions of the crystallographic characters of the rare minerals, Rathite and Jordanite. Analyses made by Mr. H. Jackson gave to Jordanite the ordinary formula, $4PbS.As_2S_3$, and to Rathite the formula, $3PbS.2As_2S_3$.—Mr. L. J. Spencer described complex twinned crystals of Stannite on specimens from Bolivia collected by Sir Martin Conway. The crystals appear to be tetragonal, with crystal element close to that of copper-pyrites. The analysis by Mr. G. T. Prior tends to confirm the usually accepted formula.

Royal Meteorological Society, November 15.—Mr. F. C. Bayard, President, in the chair.—Mr. R. H. Curtis read a paper on the diurnal variation of the barometer in the British Isles. The principal features of a curve exhibiting the diurnal march of barometrical pressure are two minima and two maxima—the first minimum occurring early in the morning and the second in the afternoon, while the first maximum falls in the forenoon and the second not far from ten o'clock in the evening. In the tropics the oscillation may amount to as much as a tenth of an inch, but its amplitude decreases as the latitude increases, and the greatest amplitude in the British Isles amounts to not much more than three-hundredths of an inch. The author discusses the mean hourly readings of the barometer from twenty-five years' observations, 1871–95, at four observatories maintained by the Meteorological Council, viz. Kew, Aberdeen, Falmouth and Valencia. The author is of opinion that the primary cause of the diurnal oscillation of the barometer is solar radiation, and that its amplitude is chiefly determined by the temperature of the lower strata of the atmosphere. The relative magnitudes of the different phases of the barometer oscillation, as observed, depend largely upon the geographical position and physical surroundings of the place of observation, in so far as these are capable of modifying its temperature conditions, and especially the relative distribution of temperature over the regions immediately surrounding it.—Mr. G. J. Symons, F.R.S., described some experimental observations which he made during the hot weather in July with two thermometers one foot below the surface of the ground, with the view of ascertaining (1) the influence of slight shade, (2) the amount of daily range, and (3) the approximate curve of daily fluctuation.

PARIS.

Academy of Sciences, November 20.—M. van Tieghem in the chair.—Note on the Leonids, by M. Lœwy. An account of the results obtained in various French observatories on the Leonid swarm. The results were disappointing. At Paris only thirty-three Leonids were seen on three nights; at Algeria, sixty-five in two nights; at Lyons, forty during three nights; at Toulouse, forty-three. The most favourable conditions for observations appear to have existed at Marseilles, where twenty shooting stars were seen on the night of the 13th, seventy-one on the 14th, and forty-three on the 15th, or 134 in all.—Note on the observations of the shooting stars known as the Leonids, made at the Observatory of Meudon, by M. J. Janssen. In order to prevent the possible interference of clouds or fog with the observations, two balloons were employed, at an altitude of about 200 metres. Full details will be given in a later paper.—On the course of a system of plane waves, laterally indefinite, moving in an isotropic heterogeneous medium, formed of plane parallel layers, by M. J. Boussinesq.—Action of fluorine and hydrofluoric acid upon glass, by M. Henri Moissan. The statement of Louyet, that anhydrous hydrofluoric acid does not attack glass is shown to be based upon a misconception, since although under certain conditions glass maintains its polished surface in contact with hydrofluoric acid, it can be shown to have been attacked by its loss of weight. In the present experiments glass was invariably found to be attacked at the ordinary temperature by gaseous hydrofluoric acid, even although very carefully dried. In the first experiments made with fluorine, a similar effect was observed; but this was afterwards found to be due to the presence of a minute trace of hydrofluoric acid. Pure fluorine, freed from traces of acid by passing through a V-tube cooled in liquid air, may be kept in sealed glass bulbs for weeks without the glass being attacked.—Observations of the Leonid swarm of November 13 to 16, 1899, made at the Observatory of Paris, by M. G. Bigourdan.—Observations of Leonids at the Observatory of Toulouse, by M. Baillaud.—Observation of the Leonid swarm at the Observatory of Meudon, by M. H. Deslandres.—Observations of the new planets (E W) and (E R) made at the Observatory of Algiers with the 31·6 cm. equatorial, by MM. Rambaud and Sy.—Observations of the sun made at the Observatory of Lyons during the second quarter of 1899, by M. J. Guillaume. The results are collected in three tables, showing the number and area of spots, distribution of the spots in latitude, and of the faculæ in latitude.—Contribution to the theory of the function $\zeta(s)$ of Riemann, by M. Edm. Landau.—On systems simultaneously isolated, by M. Andrade.—A new theory of the optical phenomena of the entanglement of ether by matter, by M. G. Sagnac.—On a new binocular lens, by M. Émile Berger.—Chemical effects produced by the Becquerel rays, by M. P. Curie and Mme. Curie. Radio-active barium chloride possesses the property of converting oxygen into ozone. This necessitates an expenditure of energy, and hence is a proof that the radiation represents a continual disengagement of energy.—Reciprocal displacement of metals, by M. Alb. Colson. The disturbing effects of oxygen and occluded gases were eliminated in these experiments by working in a Crookes vacuum. It was found that the reactions

$$Hg_2Cl_2 + 2Ag = 2Hg + 2AgCl$$

and

$$AgS + Hg = HgS + Ag$$

are reversible, the reaction being limited by a definite pressure of mercury vapour for a given temperature.—Action of nitric oxide upon chromic dichlorhydrin, by M. V. Thomas. Nitric oxide combines vigorously with chromyl dichloride, giving an amorphous compound, the results of the analysis of which can be best expressed by $Cr_5Cl_5O_7.2NO_2$.—On a methylene sulphate, by M. Marcel Delépine. By the interaction of dry trioxymethylene and fuming sulphuric acid, a neutral crystallised substance, $CH_2O.SO_3$, is obtained, thermochemical data for which are given.—On a mode of synthesis of parabanic acid, by M. P. Cazeneuve. Oxamide added to boiling phenyl carbonate gives parabanic acid and phenol, the acid being identified by means of its silver salt. The yields do not exceed 5 per cent. of the oxamide employed.—On a new Myxosporidium, *Nosema Stephani*, a parasite of *Flesus passer*, by M. Hagenmuller.—On the cytological phenomena preceding and accompanying the formation of the teleutospore in *Puccinia Liliacearum*, by M. R. Maire.—On the histological modifications produced in stems by the action of *Phytoptus*, by M. Marin Molliard. The chemical action which corresponds to the presence of parasites such as *Phytoptus* determines the formation of a new tissue which differentiates itself at the expense of any cells, independently of what these cells would have become in the ordinary course of development.—On the negative variation of the axial nervous current, by M. Mendelssohn.—The cryoscopy of urine as an aid to diagnosis, by MM. H. Claude and V. Balthazard.—Effect of a diet poor in chlorides upon the treatment of epilepsy by sodium bromide, by MM. Ch. Richet and Ed. Toulouse. The use of sodium bromide in the treatment of epilepsy, although efficacious to a certain extent, leads to other troubles owing to the large doses necessary, 8 to 15 grams per day. By the use of a diet as free as possible from salt, equally good effects were produced with only 2 to 4 grams of sodium bromide daily. The special diet appears to have no effect upon the general nutrition.

DIARY OF SOCIETIES.

THURSDAY, NOVEMBER 30.

ROYAL SOCIETY, at 4.—Anniversary Meeting.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Bridges for Light Railways: L. H. Rugg.

FRIDAY, DECEMBER 1.

GEOLOGISTS' ASSOCIATION, at 8.—The Zones of the White Chalk of the English Coast. I. Kent and Sussex: Dr. A. W. Rowe.—A New Rhætic Section at Bristol: W. H. Wickes.

MONDAY, DECEMBER 4.

SOCIETY OF ARTS, at 8.—Enamelling upon Metals: H. H. Cunynghame.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—The Fireproofing and Preserving of Timber: Sherard Cowper-Coles.

VICTORIA INSTITUTE, at 4.30.—Pictorial Art among the Australian Aborigines: R. H. Mathews.

TUESDAY, DECEMBER 5.

INSTITUTION OF CIVIL ENGINEERS, at 8.—*Paper to be further discussed*: The Waterloo and City Railway, and its Electrical Equipment.——*Paper to be read with a view to discussion*: Combined Refuse-destructors and Power-plants: C. Newton Russell.

WEDNESDAY, DECEMBER 6.

SOCIETY OF ARTS, at 8.—Artificial Silk: Joseph Cash.

GEOLOGICAL SOCIETY, at 8.—On the Occurrence in British Carboniferous Rocks of the Devonian Genus *Palaeoneilo*, with a Description of the Species *Palaeoneilo carbonifer*: Dr. Wheelton Hind.—On the Geology and Fossil Corals and Echinids of Somaliland: Dr. J. W. Gregory.—Note on Drift-gravels at West Wickham, Kent: G. Clinch.

SOCIETY OF PUBLIC ANALYSTS, at 8.—Note on Asafœtida: C. G. Moor.—On some Analyses of Modern Dry Champagne: Dr. P. Schidrowitz and Dr. Otto Rosenheim.—On the Determination of the Iodine Value: Dr. J. J. A. Wijs.—Treacle or Golden Syrup: E. W. T. Jones.—On a Method for Distinguishing between Hops and Quassia: Alfred C. Chapman.

ENTOMOLOGICAL SOCIETY, at 8.

THURSDAY, DECEMBER 7.

ROYAL SOCIETY, at 4.30.—*Probable Papers*: Vapour-density of Bromine at High Temperatures: Dr. E. P. Perman and G. A. S. Atkinson.—Polytremacis and the Ancestry of Helioporidæ: Dr. J. W. Gregory.—Gold Aluminium Alloys: C. T. Heycock, F.R.S., and F. H. Neville, F.R.S.—On the Association Attributes in Statistics; with Examples from the Material of the Childhood Society, &c.: G. U. Yule.—Data for the Problem of Evolution in Man. III. On the Magnitude of certain Coefficients of Correlation in Man, &c.: Prof. Karl Pearson, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Cost of Steam Raising: John Holliday.—Influence of Cheap Fuels on the Cost of Electrical Energy: R. E. Crompton. (Adjourned Discussion.)

LINNEAN SOCIETY, at 8.—On some Vegetable Poisons used for the Capture of Fish by the Australian Aborigines: J. W. Fawcett.—On some New Zealand Schizopoda: G. M. Thomson.—On the Structure of Porites: H. M. Bernard.

CHEMICAL SOCIETY, at 8.—Ballot for the Election of Fellows.—The Oxidation of certain Organic Acids in presence of Iron: H. J. H. Fenton, F.R.S., and H. O. Jones.—The Determination of the Constitution of Fatty Acids, Part II.: Dr. A. W. Crossley and H. R. Le Sueur.—On Sulphates of the Form R'_2SO_4, $2M''SO_4$, especially those of Isometric Crystallisation: F. R. Mallet.

RÖNTGEN SOCIETY, at 8.—Observations on Practical X-Ray Work, with Exhibition of Apparatus and Stereoscopic Skiagrams: Mackenzie Davidson.—Bullet in the Brain: J. Moore.

LYON PLAYFAIR'S LIFE.

Memoirs and Correspondence of Lyon Playfair, First Lord Playfair of St. Andrews, P.C., G.C.B., LL.D., F.R.S. By Wemyss Reid. Pp. xii + 487. (London: Cassell and Co., Ltd., 1899.)

IN writing the life of Lyon Playfair, and editing his autobiography and correspondence, Sir Wemyss Reid has had a congenial task, and this he has accomplished with his usual tact and success. The result is a volume full of interest both for the scientific and for the layman, for Playfair himself truly defines his position as half man of science and half politician, and his biographer has rightly appreciated the remarkable dual part which he played, and the work which in each direction he accomplished:

"The man the story of whose life is to be told in these pages, never rose to that dazzling eminence which justifies the world in describing a human being as supremely 'great.' He did not pretend to the genius which lifts a few men high above their fellows. It cannot be affirmed that he was one of the great figures of his generation. Yet his life, though it was lived without ostentation and without parade, was undoubtedly one of the fullest and most useful lives of his time. It was emphatically a life of work, and of work not for the accumulation of wealth, or for the achievement of fame, but for the acquiring of truth, and for the service of his fellow men."

The most interesting portions of the volume are doubtless those containing Playfair's own description of his life and labours. These, although fragmentary, give a truer picture of the man and his doings than can be attained even by so skilled a biographer as Wemyss Reid. Playfair did not write them with a view to publication, and begins by remarking that if they are ever made public,

"My only apology is that they may form some encouragement to others, who, like myself, have had in early life few friends and no influence, to believe that their future position depends upon themselves and not upon their surroundings."

This is indeed the keynote of the life. The story, told by Playfair in his own way, is one not of adventure but of work. Many a poor Scots lad has done as great things, and risen in the social scale as high as, or higher than, Lyon Playfair, but no one carried out his life's work more devotedly than he.

"To Lyon Playfair the good of his country," truly says his biographer, "was a thing to be pursued not merely in the Senate or on contested fields, but in the laboratory and the council room, in social intercourse and in the humdrum round of daily life. It was something calling not so much for isolated deeds of heroism as for a prudent and unremitting care extending even to the most trivial tasks and incidents."

And he was fortunate in the period over which his life's work extended. In early days he showed his partiality for scientific studies, and especially for chemistry. In 1835 he left the Glasgow University, where Thomas Thomson was the professor, for the Andersonian College, where a younger and more active man—Thomas Graham—occupied the chair. This was a fortunate step, for Graham, himself actively engaged in research, fired Playfair with a desire to do likewise, and sent him to Giessen.

"On presenting myself to Liebig," he says, "I was much struck by his handsome appearance and classically cut face. I mentioned my name and told him that I was a pupil of Graham's, and he laughingly said, 'You might have said that you are the discoverer of iodo-sulphuric acid,' which I had recently described in short papers,"

the titles of which are not, however, to be found in the Royal Society's Catalogue. This introduction and the friendship which followed were the most important events in Playfair's early life. He translated the "Agricultur Chemie," though "my knowledge of German was not good." This candid admission is amusingly borne out in a letter written many years later to his wife, in which he says of a German girl that she speaks English "*schlecht*," but French "*vorläufig*," instead of "geläufig"!

Notwithstanding the above opinion, there is no doubt that Playfair's English translations of Liebig were well done, and that they were the means of introducing him to many men of position and influence in this country, by whom his talents were soon appreciated and whose friendship formed a starting-point in his career.

The story of his introduction to the great Sir Robert Peel is well told, and the results were as unexpected as they were gratifying. The question of sanitary reform then arose, and Playfair was fortunate in being one of the first to be employed in carrying out the battle against dirt and disease, and to his last days he remained what he was in his youth, the most energetic of sanitary reformers.

Then, again, he was fortunate in being a forerunner of the great educational movement which has been one of the chief glories of the nineteenth century. That he was well fitted to be the pioneer of technical instruction was due to his true appreciation not only of the value of pure science as a means of culture, but of the importance of the application of scientific principles to the arts and manufactures.

"Not to teach trades or manufacturing, but the principles, scientific and artistic, which underlie those trades and manufactures,"

was his definition; and that he lived to see these principles carried into effect must have been to him a source of keen satisfaction.

"In the chapter which history devotes to the social progress of our century, Playfair's name must always hold a place of honour."

Early in the year 1851 he was brought into personal and intimate contact with Prince Albert, and soon the confidence of the Prince was gained, so that Playfair from that time forward became his trusted adviser and friend. Although Playfair acted as Gentleman Usher to the Prince Consort, and was afterwards a Lord-in-Waiting upon the Queen, he, as he tells us, was not a courtier in the sense often ascribed to the word. He spoke his mind fully and frankly both when his views were in agreement with, and also when they were opposed to those held by "exalted persons." Of the Prince Consort's character and abilities he had the highest opinion.

"The attachment to his service," he says, "gave me the privilege of being associated with the illustrious

Prince in many of the works which he undertook to promote education, science, and art. . . . In all my future intercourse with the Prince, I never on any occasion saw him animated by a single desire that was not connected with the public weal. . . . Only those who had the honour of his confidence can fully know the purity, ability, and simplicity of his character."

The history of the Great Exhibition of 1851, of the many difficulties satisfactorily surmounted, and of the grand final success, are all graphically told, including the celebrated story of the "Junk Chinaman" dressed up to represent a "yellow jacket" mandarin, and placed in the procession between the Archbishop of Canterbury and the Duke of Wellington! Greater than his services to the Exhibition were those which he bestowed on the appropriation and consolidation of the large funds placed at the disposal of the Royal Commissioners. Without the advice and the business capacity of Playfair this fund, now large and altogether devoted to purposes of science and art, would have been in danger of being frittered away, if not lost. "Nobody but yourself," writes the Prince of Wales to Playfair in 1889, "could have got us out of the serious pecuniary embarrassments in which we found ourselves placed."

"So long as South Kensington continues to exist in its present state, there will be no need to raise any monument to the memory of Lyon Playfair."

The letters and memoir contain interesting descriptions of professorial life at Edinburgh. He does not scruple to dilate on some amusing but not very creditable University squabbles in which he was often called upon to act as arbitrator. Then comes his Parliamentary career in both Houses, the details of which are both interesting and entertaining. How he represented the Universities of Edinburgh and St. Andrews. How he retired from this constituency in consequence of the Government putting Scotch education under a Scotch Secretary. How he was elected for South Leeds, "a working-man's constituency, where he received an almost enthusiastic appreciation, which quickly developed into a feeling of warm confidenec and affection."

As Chairman of Committees in the Commons, he had hard times in consequence of Irish insubordination. But he did yeoman service in speaking out strongly and fearlessly about the follies and the crimes of the Anti-vivisectionists and the Anti-vaccinators. The correspondence which occurs throughout the volume with persons of all ranks is full of interesting matter. The letters to his wife and children, and to the members of the Russell family, show the depth of his feelings, although, as one of his children writes:

"No letter he ever wrote could give an idea of his deep and intense sympathy, of his loving help in any trouble to those dear to him, and even to strangers. I never in the whole of my life have seen him cross or impatient, or known him speak a harsh word to any one."

Then his sense of humour was keen, and his powers as a *raconteur* were of the first order, and not the least interesting portion of the memoirs is that in which these powers are shown by the numerous anecdotes with which the volume abounds. Altogether the book is one which will be found full of interest, as giving a striking picture of a wonderfully full and varied life. H. E. R.

THE GOLD-FIELDS OF ALASKA.

Alaska and the Klondike: a Journey to the New Eldorado, with Hints to the Traveller, and Observations on the Physical History and Geology of the Gold Regions, the Conditions of Working the Klondike Placers, and the Laws governing and regulating Mining in the North-west Territory of Canada. By Angelo Heilprin, F.R.G.S., F.G.S.A. Pp. 315; with 35 plates from photographs, and 3 maps. (New York: D. Appleton and Co. London: C. A. Pearson, 1899.)

THE search for gold still holds something of the romantic glamour which has surrounded it from the earliest days of our civilisation. It is true that modern conditions have enmeshed the winning of gold from vein and banket, reducing it, like diamond-mining, to a systematised industry scarcely more inspiriting to the labourer himself than the mining of coal or ironstone. But placer-deposits still offer a possible chance of sudden riches to the man possessed only of bodily vigour and a few simple uncostly implements, and men's imaginations still take fire whenever the rumour reaches them that the old conventional symbol of wealth is to be had for the digging. And still, as in the ancient days, the greater the difficulties to be overcome, the stronger to the adventurous spirit seems the probability of success. So when, in 1896-7, through an ever-widening circle, was spread the news of rich discoveries of the precious metal in a remote and barely accessible corner of north-western America, thousands were found ready to cast aside their everyday pursuits and make, in the words of the wise Camillo,

"a wild dedication of themselves
To unpathed waters, undream'd shores, most certain
To miseries enough."

To any one knowing anything of the land, the newspaper information which led to the rush seemed strangely inadequate and misleading—a characteristic compound of half-truths, whole truths and untruths, out of which stood the bare fact that placers of unusual richness had been found. What was heedlessly lost sight of in the excitement was that this discovery was not the sudden outcome of a single traverse of a previously unknown Golden Land, but had been attained only at the end of twenty years of persistent exploration, during which, though in the aggregate much gold had been won, the average net individual gain had been rarely more and often less than "day-wages."

As usual, these initial stages (unmentioned in the volume before us) attracted little or no attention from the outside world, for the restless spirits who undertake the hardships of pioneer life in the unbroken wilderness, though perhaps *too* fluent in speech, write no descriptions of their journeyings. Almost everywhere these men penetrate in advance of the "original explorer," who often in his own narrative forgets to mention their presence; but unless some unusual happening brings their doings into prominence, their traces in the land they have traversed are slight. In this instance it was surely a matter for prime consideration that a body of more or less experienced men—in numbers, according to a table published recently in the eighteenth Annual Report of the U.S. Geological Survey (p. 132), rising from 50 in 1882 to 1000 in 1894, and to 1700 in 1896—should for many years have been prospecting up and down the Yukon from its mouth nearly to its sources with only moderate success. This in itself was sufficient to show that the riches of the land were neither unlimited nor easily attained, and that most of the tyros in gold-hunting who made their laborious march in the wake of these men must do so in vain. According to Prof. Heilprin, "probably not less than thirty-five thousand to forty thousand people, possibly even considerably more, have in the short period following the discovery of gold in the Klondike region already passed to or beyond the portals of what has not inaptly been designated the New Eldorado. To some of these a fortune has been born; to many more a hope has been shattered in disappointment."—And how could it be otherwise?

The sudden movement of this great army, made up of units marching independently and without organisation, with self-interest as the only motive, into the heart of a wild land incapable of furnishing more than a very small number with the barest elements of sustenance, dependent therefore for their very existence upon supplies from a base many hundreds of miles away, possesses extreme interest to the student of economics and sociology; and perhaps the chief value of Prof. Heilprin's book is that it contains the record of a certain stage in the transient and unstable conditions which arose under these circumstances. That within the space of a few months this transplanted social mass should with scarcely any disorder have struck root amid novel and arduous surroundings, and by the play of individual interest alone should have found itself provided with all the actual necessaries, and many—indeed, too many—of the luxuries of life (brooms and window-glass being, according to Prof. Heilprin, the chief things lacking) is, in its way, as remarkable an object-lesson as the century has afforded. At no previous period in human history could this have happened, and it is all the more deserving of careful record. The flood of hazily inaccurate or wilfully misleading information from the newspaper press is past; we have reached the second stage at which, as in the volume before us, the underlying facts emerge; and there will follow, no doubt, in the fulness of time, the brightly coloured growth of fiction which imaginative writers will cultivate for our entertainment around the picturesque elements of the movement when its sordid details are forgotten.

As for the actual contents of Prof. Heilprin's book, it aims to place before its reader the impressions of one accustomed to examine critically and record accurately, during a tour to the Klondike by the Upper Yukon route, made under favourable circumstances between the end of July and the middle of October of last year. Prof. Heilprin went in from tide-water at Skaguay by the White Pass to the head of inland navigation on Lake Bennett in a day and a half, and came out, late in the season, by the Chilkoot Pass in one day with comparative ease, and concludes that the difficulties of both trails have been greatly exaggerated.

"To a mountaineer or traveller of ordinary resource neither the White Pass nor Chilkoot Pass will appear other than it actually is—*i.e.* a mountain pass, sufficiently rough and precipitous in places, and presenting no serious obstacle to the passage of man, woman, or child" (pp. 15-16).

But he justly observes that what to a person in his own circumstances seemed easy enough, both in these passes and on the trails of the interior, might wear a very different aspect to the man struggling onward with a load of 60 or 80 lbs. on his back In fact, all through the book we realise that the impressions are those of one travelling in ordinary tourist fashion, light and with sufficiency of means, and that the prospector mentioned on p. 177, "who was moving by slow stages, and without assistance of any kind, an equipment weighing somewhat over 400 lbs." would have another tale to tell.

However, with the completion of the railway in course of construction on the White Pass route, the journey to Dawson City becomes simply a matter of the payment of fares. Already, we learn from the newspapers, the journey from Vancouver to Dawson has been made in so short a time as six days, while from eight to twelve days is now ordinarily the length of the through trip.

From Lake Bennett Prof. Heilprin went by river-boats down the lakes and the Lewes or Upper Yukon River to Dawson in 4½ days, reaching the last-mentioned place on August 6. Here he took quarters in the recently opened "foremost hotel of the land," paying 35 dollars per week for his scantily furnished room, and 25 to 35 dollars per week more for board. He estimated the number of inhabitants of the two-year old city at 16,000, and this sudden concentration of humanity ahead of the resources of the country had, necessarily, curious consequences upon the relative values of merchandise. Thus we read (p. 101), that chickens "earlier in the season had sold for 100 dollars for three," but later "were obtainable at 10 dollars apiece"; eggs were 2½ dollars per dozen; radishes 75 cents a bunch of five pieces, and so on; while at the same time at the auction rooms many articles could be bought for less than the original outside cost (p. 104). But with regard to the enhanced value of food-stuffs, it may be well to mention that the Canadian Geological Surveyors, who were in Dawson during the same summer, state in their report that "it was found quite possible to purchase provisions at retail prices at the stores, for the maintenance of a party, at less than a dollar a day per man (Rep. Geol. Survey of Canada for 1898, p. 62).

That the conditions were peculiarly evanescent, and with the establishment of Dawson City as a distributing centre are not likely to be repeated in the district, should make the fluctuations of the Dawson markets during the last three years an instructive chapter in economics.

One notices at times in Prof. Heilprin's book an unpleasant oblique mode of expression, not uncommon in the literature of forty years ago, but now happily rare. This is especially pronounced in the chapter on the inhabitants of Dawson, as, for example, in the passages describing "Sir ——," "Count C——," the "professor-doctor" and the "Gold Commissioner" (pp. 110—112).

The author notes that the number of blacklegs was surprisingly small, and remarks on "the feeling of security which every one seems to experience and enjoy." This he ascribes in great measure to the efficiency of the Canadian military police, and comments on "a condition so wholly different from that which but a few weeks before dominated the atmosphere of Skaguay and the American side of the trails" (p. 119).

In praising the summer climate of the Klondike Prof. Heilprin waxes enthusiastic—

"From August 6th to September 20th, barring three days of partial rain, and perhaps a fourth of cloudiness and mist, the weather was simply perfection—a genial, steady, mild summer with a temperature rising at its highest to about 80° or 82° F. in the shade. . . . In August . . . the evenings were but little less pleasant than the days, the balmy night air rarely necessitating clothing warmer than that ordinarily worn" (p. 70).

Neither did he personally experience any trouble from mosquitoes. He also thinks that the rigour of the winters has been exaggerated, as "most of the Dawsonites are inclined to make light of the winter's cold, and assure you that, except for head and foot wear, they take little stock in that over-burdening with heavy clothing which outfitters so delight in foisting, as 'absolute necessities,' upon the too credulous tenderfoot" (p. 73).

In short, there appears to be nothing in the region inimical to the permanent residence of civilised man the year round in comparative comfort. Even the agricultural possibilities of the country are spoken of hopefully (p. 83), and Dr. Dawson's previous favourable estimate in this direction is quoted with approval (p. 85).

As to that which to most people constitutes the sole interest of the region—its future possibilities for gold-production—Prof. Heilprin, while writing with somewhat oracular caution, takes on the whole a sanguine view. After describing the conditions and methods of working the placers which differ, in the frozen state of the subsoil and in some other particulars, from any placers hitherto worked on the continent except those of Cassiar in the northern part of British Columbia, and after pointing out that some of the best claims, viz. those of the hillsides and high benches, were located in the early part of 1898, at the time when the incomers had been warned that the region for a hundred miles or so about Dawson had been fully staked and occupied, the author concludes that "many good locations in the Klondike territory are still open, although it may not be easy or possible to say just which they are" (p. 207). This, we fear, will seem rather "thin" guidance to the anxious gold-seeker! The output of the past year Prof. Heilprin estimates to have been "in the neighbourhood of nine or ten million dollars, perhaps more; but that it will be vastly greater in the current year (1899) is certain" (p. 204). Like other investigators of the district, he thinks that capital judiciously expended in hydraulic-mining should yield profitable returns.

A summary of the Canadian laws regulating mining in the Yukon region forms one of the most useful chapters in the book.

The longest chapter is that which deals with the physical history and geology of the Klondike gold-fields (Chapter xi. pp. 212–280), and this is, perhaps, the least satisfactory part of the volume. To the general reader it may indeed be of some service; but to the student of geology or of physiography more adequate sources of information are available, and the chapter contains little that need detain him, especially since though passing mention is made of previous investigators exact references to their works are rarely given. Besides the early scientific descriptions of the Yukon country by Dawson, McConnell, Russell and others, the recently issued report of the Canadian Geological Survey for 1898 includes (pp. 55–62) a concise and practical summary of the geology and conditions of the Klondike gold district by those excellent observers Messrs. R. G. McConnell and J. B. Tyrrell, which gives a clearer view of the structure of the country than the volume before us; and the eighteenth Annual Report of the U.S. Geological Survey (Part iii. pp. 101–391) contains an elaborate memoir on "the Geology of the Yukon Gold District" by Mr. J. E. Spurr, with a particularly interesting preliminary chapter, previously referred to, on "the history and condition of the district to 1897," and a discussion of the drainage peculiarities, by Mr. H. B. Goodrich. To these works, then, rather than to Prof. Heilprin's book, the scientific student should turn for information.

Prof. Heilprin, after much discussion of the subject, comes to the conclusion that "the known facts of the Klondike region, so far as they relate to the primal origin of the gold in the placers, favour the theory of chemical solution and precipitation, as opposed to the generally accepted view of accumulation from disintegrated reefs, bodies or veins" (p. 280).

But his arguments are unconvincing, and his views are neither shared by Spurr for the placers on the American side of the frontier, nor by McConnell and Tyrrell, the latter investigators stating that "the gold in the Klondike has certainly been derived from the rocks of the immediate vicinity" (Rep. Can. Survey, *op. cit.*, p. 60). It is of course evident that during whatever time the rich ground may have remained permanently frozen, no percolation of the supposed solutions can have taken place.

With regard to the auriferous high-level deposits, Prof. Heilprin adopts a view similar to that held by Spurr to account for the high benches of the American side, viz. that they are "evidences of the past existence of large lake-like bodies of water, perhaps even of a vast inland sea" (p. 226). On this supposition he builds various speculations, and thinks that the old shores have formerly been of far greater extent and have yielded by condensation much of the gold of the valley placers. But Messrs. McConnell and Tyrrell offer a more simple and adequate explanation of the phenomena in question, as follows:—

"On Bonanza and Eldorado creeks, and doubtless also on a number of the other creeks that rise in the high land near the Dome, the work of concentration has been greatly expedited by small local glaciers, which, at a period not very remote, have originated at the heads of these creeks, and have filled the bottoms of their valleys through parts at least of their lengths. Thus the Eldorado glacier would appear to have had a greatest thickness of about 200 feet at French Gulch, and to have joined the Bonanza glacier at the Forks, below which both continued on some distance together. The gravel that fills the bottom of the valley from side to side is a typical glacier-wash, having been deposited by the stream which flowed from the face of the glacier. The lower benches on Bonanza Creek were also deposited in a similar way, but the higher so-called benches have been formed either as lateral moraines along the sides of the glacier, or by streams which flowed between the side of the glacier and the bounding slope of the valley" (Rep. Can. Survey, 1898, p. 61).

There are no existing glaciers in the Klondike region, and while the former presence of small local valley-glaciers has been recognised, all the observers are agreed as to the absence of any trace of widespread glaciation. This probably implies that, as in Siberia, the climate throughout the Glacial Period was dry, and that then, as now, heavy precipitation was confined to the vicinity of the coast.

To sum up our impressions of this book, Prof. Heilprin may be complimented on having given us a vivid picture of transient conditions in the Klondike; but, from a physical standpoint, his work can scarcely be taken as a solid contribution to our knowledge of the district.

The numerous excellent reproductions of photographs with which the book is illustrated are for the most part well adapted to show the general character of the scenery and conditions, though now and again a picture is introduced for effect rather than for instruction. The deep yellow binding with its pictured dog-trains, reminiscent of the "yellow press," is not particularly happy. G. W. L.

A NEW TEXT-BOOK ON CHEMISTRY.

Inorganic Chemistry for Advanced Students. By Sir Henry E. Roscoe, F.R.S., and Arthur Harden, Ph.D. Pp. 432. (London: Macmillan and Co., Ltd., 1899.)

THIS book is intended to supplement "Chemistry for Beginners," which was published about six years ago by Sir Henry Roscoe, with the assistance of Mr. J. Lunt. It is not a complete treatise on the elements of inorganic chemistry, but part of a complete treatise. It is intended for students who have already gained a little knowledge of the subject, and those who would use it must first learn something about oxygen, hydrogen, chlorine, carbon, and their simpler compounds, and about many other matters, either from "Chemistry for Beginners" or from some other suitable elementary work.

We suppose that a small text-book is put into the hands of most beginners when they reach the stage at which they need such a book, and that presently, when they are older and more advanced, this small book is changed for one of the larger treatises. Now, at this latter stage a certain amount of confusion and some loss of time are very apt to occur owing to the overlapping of the contents of most elementary and advanced works on chemistry, and to the fact that the majority of young students are not able to skip with discretion. It is evident that this confusion and loss of time might be avoided by the use of two books, such as those which have now been provided by Sir Henry Roscoe and his colleagues, Dr. Harden and Mr. Lunt; and we believe that those who have had much experience in teaching chemistry under school conditions will at once recognise the merits of their method of dealing with the subject in two volumes, one quite elementary, one more advanced, and each the complement of the other.

The present volume, like its predecessor, follows in the main the lines laid down so successfully a generation ago in the familiar "Roscoe's Chemistry." That is to say, the book is intended for students who want to learn the fundamental principles of chemistry, and something about its methods and its data, rather than for those who desire to use the subject as part of a system of mental gymnastics. But though the new book follows lines which have so long been made familiar to us by the previous work of its eminent senior author, it differs from that earlier work in several respects, notably in its somewhat more limited scope, for organic chemistry finds no place between its covers, in the greater attention given to chemical theory, and in the fact that a great number of experiments for the student are described in the text.

The subject-matter of the volume is divided into thirty-nine lessons, the elements treated of being grouped in such a manner that from the beginning the student may be said to be preparing the way for his subsequent study of the periodic system of classification. The chapters on chemical theory are dispersed among the rest. This arrangement may, perhaps, seem open to the objection that the student's reading in certain subjects may be somewhat broken up; but the authors have adopted it, as they tell us in their preface, with the object of relieving him of the tedious task of working without a break through a long series of metals and their compounds. The parts of chemical theory chiefly discussed in these lessons are atomic and molecular weights, equivalents, specific and atomic heats, crystals and isomorphism, valency, the constitution of hydroxides and oxyacids, dissociation, thermochemistry, electrochemistry, the periodic law and spectrum analysis. There are questions to be worked out, and numerous summaries. We are not quite convinced that so many of these latter make for sound learning. Should not every student prepare a good many of his own abstracts after he has read a few chapters and compared them with some summaries provided as examples? This, however, is a small matter, as it is obvious that the existence of summaries in the text need not prevent any student from constructing his own abstracts during his reading. We feel sure that the new book will be welcomed by those who are familiar with its predecessor, and by many others, and we wish it and its companion volume all success. W. A. S.

OUR BOOK SHELF.

Elements of Natural Philosophy. By Alfred Earl, M.A. Pp. viii + 320. (London: Edward Arnold, 1899.)

MR. EARL is already well-known as the author of the admirable "Practical Lessons in Physical Measurement," and one naturally examines a new book of his with great expectations. The preface states that the present volume is "intended as a handbook for the laboratory," and "has been written for the use of beginners." The book does not, in our opinion, exactly fulfil these conditions; yet it may still prove of use, though rather to teachers than taught. A laboratory manual should give clear, precise instructions as to what the student has to do—guidance of a sufficiently explicit nature for the pupil to work from without unduly bothering the teacher, who, very often, has too large a number working at the same time for purely individual instruction. Yet, in dealing with the measurement of simple quantities, for example, Mr. Earl gives some nineteen pages of general description, with little or no practical work, contenting himself by adding thirty-eight exercises at the end of the chapter. These exercises leave little to be desired, but a beginner will not always be clear about the several steps by which he is to arrive at the required result. The divisions adopted by the author lead to some very miscellaneous chapters; thus Chapter vi., entitled "Changes Belong to Several Classes," runs to thirty-two pages, and includes a brief treatment of inertia, the electrophorus, voltaic cells, the thermopile, gravitation, expansion, the Gulf Stream, Trade winds and several other subjects. Chapters viii. and ix. take the pupil "along the well-beaten track of chemical rudiments," and were written by Mr. F. Collins. Too much is attempted in this section, and things are often taken for granted of which a beginner has no knowledge whatever. Thus, on p. 185, the modes of chemical action are partly explained by chemical equations, though the only guidance towards understanding them which has been given to the pupil is the table of elements, with their symbols and atomic weights, on p. 181. The value of the book would have been much increased by using simpler language, and adding more illustrations.

Elementary Practical Chemistry. By A. J. Cooper, B.A., B.Sc. Pp. viii + 86. (London: Whittaker and Co., 1899.)

SOME idea of the profound changes which have occurred in the teaching of elementary chemistry during the last decade can be obtained from the large number of books recently published, all of which claim to supply a long-felt want. Mr. Cooper's book covers familiar ground in a more or less familiar way. He starts with a brief account of the metric system (which, however, is too short to be of much use), describes the balance, how to determine relative densities, and to measure liquids and fit up apparatus. No wonder the student often asks why these subjects must be studied both in the chemical and physical laboratories. But like many another recent writer of an elementary course of chemistry, Mr. Cooper rightly avoids the thaumaturgic art of test-tubing, and it is in this connection we are able to perceive an advance has been made in the way of studying science. Though the "Heuristic" method, of which so much is heard nowadays, is not suitable throughout a complete course of chemistry, it is unfortunate that so many statements occur like "note the white powder of metastannic acid that is formed"; "the name of the gas which you have just prepared is nitrous oxide"—which have no significance to a beginner.

The Teaching of Geography in Switzerland and North Italy. By Joan Berenice Reynolds. Pp. xii + 112. (London: C. J. Clay and Sons, 1899.)

NO more hopeful indication of the growing desire on the part of British teachers to improve the methods of instruction in our schools could be desired than this little volume provides. It is particularly gratifying to find that the old insular prejudice is giving place to an intelligent study of foreign educational systems, and that it is at last becoming recognised there is much to be learnt from Continental pedagogic authorities. Miss Reynolds was, in 1897, awarded the Travelling Studentship for Teachers in connection with the University of Wales, and her report, which she presented in 1898 to the Court of this newest of our Universities, demonstrates conclusively that she made the best use of her opportunities. Equipped with the information provided by a wide course of reading in the geographical literature of the countries she intended to visit, Miss Reynolds was able to intelligently note all the features of Swiss and Italian teaching practice which would prove of assistance to our own teachers, and she has here set them down in a clear and interesting manner. Her book should be read by every teacher of geography.

Liverpool Marine Biology Committee's Memoirs. I. Ascidia. By Prof. W. A. Herdman, D.Sc., F.R.S. Pp. v + 52; with five plates. (Liverpool: T. Dobb and Co., 1899.)

THIS is the first of a series of memoirs which is being prepared by the Liverpool Marine Biology Committee under the editorship of Prof. Herdman, to supply a want which "has been constantly felt of a series of detailed descriptions of the structure of certain common typical animals and plants, chosen as representatives of their groups, and dealt with by specialists." The expense of preparing the plates in illustration of the first few memoirs is being met by a donation of Mr. F. H. Gossage, of Woolton. Prof. Herdman has omitted detailed references to original memoirs, the object of his manual being more to provide students of marine biology with a concise and accurate description of the appearance, structure, and life-history of the Ascidian than to publish a bibliography.

In an appendix a statement is given of the classification and characters of the Tunicata, in order to indicate the position of *Ascidia* as a type of the group and its relations to the other British Ascidians.

The Story of the Wanderings of Atoms, especially those of Carbon. By M. M. Pattison Muir, M.A. Pp. 192. (London: George Newnes, Ltd., 1899.)

AN attractive title does not by itself make an attractive book. Assuming that "The Library of Useful Stories" is intended for the general reader, we are afraid that this short account of the compounds of carbon is largely beyond his comprehension. There is an abundance of information, but the repeated references to Mr. Muir's "Story of the Chemical Elements" will tantalise the man who expects to get knowledge and recreation by the same process. A sound knowledge of organic chemistry is only obtained by experimental methods based upon a thorough grounding in the elements of chemistry, and this end is most satisfactorily obtained by studying simple inorganic substances first. The author has adopted a style more suited for the class-room than the platform of the popular lecturer, and the ordinary person who takes up this little volume will, after reading very few pages, find himself completely out of his depth.

General Index, by Robert Newstead, F.E.S., Curator of the Grosvenor Museum, Chester, to Annual Reports of Observations of Injurious Insects, 1877–1898. By Eleanor A. Ormerod, F.R. Met. Soc., &c. With Preface by the author. Pp. xii + 58. (Simpkin, 1899.)

THE twenty-two annual volumes of Miss Ormerod's Reports are known to all students of agricultural entomology, and their usefulness as indispensable works of reference will be largely increased by the present compendium, which includes, in addition to the general index, separate indices of plants, animals and unclassified "hosts." Miss Ormerod's preface contains remarks on the origin and method of the reports, notices of a few of the more important insects which have been dealt with, and miscellaneous observations. It is worthy of special note that she considers all birds which are even moderately insectivorous as beneficial to such an extent as to overbalance any mischief they may do in other ways, unless they are present in overwhelming numbers; but she especially excludes the house sparrow, which she denounces as a national evil. W. F. K.

A Hand-List of the Genera and Species of Birds. By R. Bowdler Sharpe, LL.D. Vol. I. Pp. xxi + 303. (London: Printed by order of the Trustees of the British Museum, 1899.)

THE system of classification adopted in this new "hand-list" is that proposed by Dr. Bowdler Sharpe in 1891. The book is founded upon the "Catalogue of the Birds in the British Museum," a large part of which was written by Dr. Sharpe, but the new species described since the publication of the twenty-seven volumes which comprise the "catalogue" are here included. Proofs of the work have been read and corrected by a number of leading ornithologists throughout the world, assistance sufficient, as Dr. Sharpe says, to give the work "the importance of an international publication."

Human Nature: its Principles and the Principles of Physiognomy. By Physicist. Part ii. Pp. viii + 175. (London: J. and A. Churchill, 1899.)

THE nature of the volume can be indicated by stating one of the propositions of the author's theory of colour: "That exhausted viable matter absorbs the luminous rays, and reflects the invisible (potential) rays, therefore it is dark or nearly colourless, sometimes violet or purple being perceptible; and that viable matter stored with energy reflects the luminous rays, therefore it is yellow or some colour containing excess of yellow, as brown, or cream colour, &c., and absorbs the invisible or potential rays."

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Cause of the Darjeeling Landslips.

PROF. JOHN MILNE'S prompt contradiction in the *Times* of October 3, and in NATURE (5th) of the telegraphic statement concerning the cause of the recent Darjeeling landslips is a distinct "score" for the seismograph. With the Committee appointed by the Bengal Government to investigate the causes of the recent disaster, and to formulate measures for anticipating its possible recurrence, I made special inquiries into the alleged occurrence of earthquakes at Darjeeling on the night of September 24–25, and we all agreed that there was no evidence to show that any seismic phenomena whatever occurred. No movements were felt in well-built houses, and those that were noticed, as well as the sounds which were heard during the violent cyclone, were only of a kind that might be expected in the ill-built, rickety structures which, for the shelter of those who temporarily reside in our hill stations, are known to their owners as "houses." Local earth-tremors may have resulted from the slips, but they were the effects, not the cause, of the latter.

The unprecedented rain which accompanied the September cyclone was a sufficient and satisfactory immediate cause for the numerous landslips near and in Darjeeling. Up to the morning of the 23rd, the monsoon rains measured some 17 inches in excess of the average for previous years, and the thick soil-cap was consequently already saturated. The cyclonic depression first reported by the Meteorological Department to be formed to the south-east of False Point in the Bay of Bengal moved northwards until its centre, on the 24th, had reached lat. 25°, causing heavy rain over most of the province. During the twenty-four hours ending at 8 a.m. on the 23rd, 5·31 inches of rain fell at Darjeeling, followed by 19·40 inches during the next twenty-four hours. Of the latter amount 14·32 inches fell between 4 p.m. on the 23rd and 4 a.m. on the 24th, being thus over an inch an hour for a stretch of twelve hours. It was during this last period, when the rainfall was at its heaviest, that the disastrous slips occurred.

The hill-sides in the neighbourhood of Darjeeling are by natural means already at or near their angle of repose for earth-slopes, and the reduction of frictional stability, due to the thorough saturation by the heavy rainfall of September 23–24, was sufficient to permit slipping of the less stable portions of the soil-cap. The biotite-gneiss massif below is undisturbed and perfectly stable: there is nothing here comparable to Naini Tal, where the slates, by differential movement along their bedding planes, have caused cracks in the masonry structures built upon them. In Darjeeling the slips were confined entirely to the soil-cap, which ran down the steep hill-sides as rivers of mud, and, with occasional included boulders, bombarded the back quarters of some of the houses. A more interesting example on the eastern side of the Jalapahar ridge shows movement on a comparatively large scale now in progress. The sides of the moving mass are defined by longitudinal shear cracks, whilst its upper region—the *Abrissgebiet* of Heim—shows gaping fissures with, in the uppermost ones, a vertical displacement of about 8 feet. A description of this interesting landslip, with map and photographs, will be issued at a later date by the Geological Survey Department.

T. H. HOLLAND.

Geological Survey of India, Calcutta, November 8.

Barisal Guns.

I MUST first state how I came to notice this phenomenon so well known in Bengal. Early in February, 1890, I was posted to Backergunge, as District Superintendent of Police, and remained there till December, 1891, a period of twenty-two months. In order to travel quickly over the district a steam launch was always at my service, and as I had to visit each of the numerous police stations scattered all over the district at least twice every year, there are few places in Backergunge I have not visited repeatedly.

Shortly after my arrival I received a letter from my friend, Mr. G. A. J. Rothney, of the firm of Messrs. John Dickinson and Co., 65, Old Bailey, who has a very wide experience of India, and takes a keen interest in natural phenomena, asking me to try and elucidate this phenomenon of the Barisal Guns; to make careful observations and record them on the spot. This I did, and I now forward a copy of the note I sent him.

The causes usually assigned for this phenomenon are three in number, viz.:—

(1) High banks of rivers falling in;
(2) Surf breaking on the shore, and
(3) Subterranean explosions.

The first of these theories cannot stand in face of the undisputed fact that any such sound would be purely local and could be heard only at very short distances, whereas it is admitted these guns are heard at places a hundred miles apart. The second is equally untenable when we remember the whole delta is composed of alluvial deposit, without a rock for hundreds of miles. And, thirdly, this alluvial deposit entirely does away with the possibility of subterranean explosions.

It is well known to all navigators of these waters there is a peculiarly deep depression to the south of this delta, which either has never been sounded, or, if sounded, has shown a most unaccountable depth, and it is assumed these reports emanate from this depression. But I am not inclined to accept this as a sufficient explanation, as the sounds are so very irregular in their frequency. We all know that Geysers in various quarters of the globe are celebrated for shooting out great masses of water from time to time; but these usually have some periodicity, and their times for discharge have been, more or less, tested and reduced to some well-known law or theory. Now the very irregularity of the Barisal Guns proves they can be subject to no such law, for, if they were, the phenomenon should be heard with some regularity, whereas, as I have shown in my note to my friend, their irregularity is one of their most noticeable features.

There are two special occasions to which I would draw attention: the first in February, 1891, when from the southernmost outpost, Chaltabuni, I followed the reports for some forty miles out to sea; the second, mentioned in my letter to the Surveyor-General of Bengal, when, in August, 1891, for more than six hours, I followed the reports without getting any appreciably nearer, and also never hearing them to the north of me.

HENRY S. SCHURR.

34, Bloomsbury Street, W.C., November 28.

(*Report.*)

BARISAL GUNS are heard over a wide range extending from the Twenty-four Pergunnahs through Khulna, Backergunge and Noakhali, and along the banks of the Megna to Naraingunge and Dacca. They are heard most clearly and frequently in the Backergunge district, from whose headquarters they take their name.

These Guns are heard most frequently from February to October, and seldom in November, December or January. One very noticeable feature is their absence during fine weather, and they are only heard just before, during, or immediately after heavy rain.

The direction from which they are heard is constant, and that is the south or south-east. I have heard them west of me when down in the extreme south of the district, but never north of me. On the other hand, I have been told by captains of river-going steamers that they have heard these reports to their north. These gentlemen, however, ply along waters outside the range of my observations, which lie on the mainland and its adjacent waters.

These Guns are always heard in triplets, *i.e.* three guns are always heard, one after the other, at regular intervals, and though several guns may be heard the number is always three or a multiple of three. Then the interval between the three is always constant, *i.e.* the interval between the first and the second is the same as the interval between the second and the third, and this interval is usually three seconds, though I have timed it up to ten seconds. The interval, however, between the triplets varies, and varies largely, from a few seconds up to hours and days. Sometimes only one series of triplets is heard in a day; at others, the triplets follow with great regularity, and I have counted as many as forty-five of them, one after the other, without a pause.

The report is exactly like the firing of big guns heard from a distance with this peculiar difference, that the report is always double, *i.e.* the report has (as it were) an echo. This echo is so immediate that I can best describe its interval by an illustration. Suppose a person standing near the Eden Gardens heard the 9 o'clock gun fired from Fort William, he would first hear the report of the gun and its immediate echo from the walls of the High Court. The Barisal Guns sound exactly like this, only as if heard from a distance of several miles, very much the same as the sound of the Fort gun heard at Barrackpore on a clear night in the cold weather.

The report varies little in intensity, and I cannot recollect that there was much difference in the sound, whether heard at Barisal itself or some 70 or 80 miles to the south at the extreme end of the district. The state of the atmosphere may affect it, but to no appreciable extent.

The Backergonian peasant is celebrated for the bombs he is in the habit of firing at his weddings and festivals, and many residents have asserted they can distinguish no difference between the reports of these festive bombs and the so-called "guns"; but to any one with a fairly acute sense of hearing, who listens attentively, the difference is very marked, and their assertions are completely refuted by the facts—

(1) that wedding bombs vary very noticeably in the intensity of their sound;

(2) are wanting in the very marked feature of the triplets, and

(3) are naturally confined to the wedding season, a very short season in each year, whilst the Barisal Guns are heard almost throughout the year, and very noticeably during the annual fast—the Roza—when, of course, there can be no festivals of any kind.

Letter from Geological Surveyor-General, Bengal.

I have to thank you for your most interesting report on the Barisal Guns. What you say about following the sounds in a launch is very interesting, and points to a Seismic origin, that is to say, that wherever the sounds came from they really originated locally, wherever you were at the time. In this case, following them would be like trying to reach the foot of a rainbow, whereas if they originated in surf on the sea-shore, or the falling-in of river-banks, they should be traceable to their source. R. D. Oldham.

Butterfly Shadows.

While photographing insects lately in the hills above Pegli (Italy), I was much struck by the curious way in which many of the butterflies turned and shifted their position after they had settled, their apparently eccentric behaviour making it difficult to obtain a good picture. It suddenly struck me that this turning and shifting was the result of an endeavour to settle in such a position as would cast no shadow, thereby ensuring to themselves less risk of detection. This seemed to be a motive particularly with such butterflies as Circe, Semele and Janira; and its success as a method of concealment was very striking in the case of Circe, which constantly settles on the bark of trees or on the rocky ground.

I submit this observation with the hope that it may attract the notice of others who are able to give more attention to the matter; it may, too, be of interest in connection with the recent letters which have appeared dealing with the capture of butterflies by birds.

Continental butterflies appear to be remarkably tame. I was constantly able to catch Podaliarius and other kinds with the hand. D. Wilson-Barker.

Greenhithe, November 27.

A Canadian Lake of Subterranean Inflow.

Imagine a cliff about 180 feet in height, rising almost perpendicularly from the steamboat landing at Glenora on the south side of the Bay of Quinte, a great arm of Lake Ontario, and perched immediately on the top of the cliff, within 300 feet from the edge, a lake of clear fresh water about one a half miles long, with a width of about three-quarters of a mile, its waters continually flowing out to give the power which operates the Glenora mills, but its inflow invisible, and yet steadily maintained from month to month and from year to year. This is the Lake-on-the-Mountain.

Various origins have been suggested in accounting for the inflow. That its source is not attributable to springs from any possibly higher grounds in the same county seems established by the fact that during the long drought in the months of August and September of this year the level of the lake was well maintained. The source is, I think, rather to be sought in the Trenton limestone area twenty-five or thirty miles to the north-eastward of the Bay of Quinte. The dip of the rocks is favourable, and for the whole distance and into the Laurentian area beyond there is a steady rise until at about fifty miles away a height of nearly 400 feet above Lake Ontario is reached. A fair amount of rain fell in this higher country during the drought elsewhere.

To ascertain their bearing on the origin of the inflow, I this past summer took a series of depths and temperatures in the lake. Whilst a considerable part of its area was shallow, not exceeding a few feet, the lake was found to have, close alongside its southern boundary, a great rent, as it were, in its bottom, of towards a mile long, one-third of a mile or more wide, and varying from 75 to 100 feet deep. That this rent is due to a widened fault in the Trenton limestone here is very probable, and the same forces which gave rise to this fault may also account for a subterranean connection with higher ground many miles away. The temperature readings were equally interesting. In Lake Ontario, at its outlet opposite Kingston, during August, the surface of the water ranged in temperature around 72° F., and at a depth of 78 feet (the bottom) it was 56½° F., which latter was very much colder than during last and some previous years. At the Lake-on-the-Mountain, whilst the temperature of the surface was 74¼° F., at 30 feet depth it was 69½° F., at 45 feet 47° F., at 60 feet 43° F., and at 99 feet 42° F. Thus, whilst during the first thirty feet there was not very much change in the temperature, between thirty feet and forty-five feet there was a rapid fall of twenty-two and a half degrees, and between the latter depth and the bottom at ninety-nine feet a further fall of only five degrees.

Andrew T. Drummond.

Cause of Recent Sunset Colours.

May I suggest to your readers that the striking colours of the recent sunsets are possibly due to the dust in the air from the Leonid meteors?

They certainly remind one of the sunsets after the Krakatoa eruption. Horace Darwin.

The Orchard, Huntingdon-road, Cambridge, December 4.

Substitute for Gas in Laboratories.

It is proposed to extend the modern side of a large secondary school by the erection of chemical and physical laboratories and lecture-rooms. The school, however, is some miles distant from any town which has a gas supply, so that it is necessary to consider what is the best substitute. I am interested in the arrangements, and shall be thankful if any of your readers will give me their experience on this point. It is proposed that the laboratories will accommodate forty boys working at one time. William Gannon.

County Technical School, Stafford, December 4.

THE METHODS OF INORGANIC EVOLUTION.

In the study of the facts of inorganic evolution presented to us by stellar spectra, there is one point of paramount importance to be inquired into. In the problems of inorganic evolution which we have now to face, it is sufficiently obvious that we have to deal with a continuously increasing complexity of chemical forms, precisely as in organic evolution the biologist has had to deal, and has dealt successfully with, a like increase of complexity of organic forms.

How has this inorganic complexity been brought about? In the case of known compound bodies an easy answer is given by analysis. Chloride of sodium, for instance, is formed by the combination of chlorine and sodium. But when we wish to deal with the formation of the so-called "elements" themselves, no such easy solution of the problem is open to us.

If in order to investigate this problem we take the analogy furnished by compound bodies as our guide, we should say that the molecules of the elements themselves were produced by the combination of unlike forms.

But as a matter of fact, this method of producing complexity is not the only one known to chemists. There are bodies of the same percentage composition which differ in molecular weight; the methane series of hydrocarbons is a case in point; the higher molecular weights or greater complexes are produced by additions of the unit $C.H_2$, so that these higher complexes are produced by the combination of similar lower complexes. This process is termed polymerisation.

We are then familiar with two methods of increasing complexity, which we may represent by $a + a$ (polymerisation) and $x + y$ (combination), producing a form A.

This, then, is the problem from the purely chemical side. On which of these methods have the elements themselves been formed, now that we are justified in considering them as compound bodies? I suppose that chemists when hypothetically considering the possible dissociation of the chemical elements would favour the view of depolymerisation; that is, the breaking up of a substance A into finer forms (a) weighed by A/2 (or A/3), rather than a simplification of A into x and y.

The method of attacking this problem from the chemical point of view in the first instance, must be a somewhat indirect one.

The Stars and the Periodic Law.

In a recent lecture I referred to the hypothesis put forward by Newlands, Mendeléef and others in relation to the so-called "periodic law," which law indicates that certain chemical characteristics of the elements are related to their atomic weights. I further showed that the order of the appearance of the various chemical substances in the stars of decreasing temperatures did not appear to be on all-fours with the requirements of the periodic law.

It will be well to study this question with a view of discussing it more fully in the light of all the facts known to us, among which the stellar evidence and that afforded by the study of series are, I think, of especial importance, since it may be said that we are now absolutely justified in holding the view that of the lines which make their appearance in the spectra of chemical substances when exposed to relatively high temperatures, a varying proportion is produced *by the constituents of the substance*, whether it be a compound like the chloride of magnesium, to take an instance, or of magnesium itself.

Now the periodic law based upon atomic weights deals with each "element" as it exists at a temperature at which the chemist can handle it; that is, if it be a question, say of magnesium, the chloride or some other compound of the metal must have been broken up, and the chlorine entirely got rid of before the pure magnesium is there to handle, and of this pure magnesium the atomic weight is found and, having also regard to its chemical characteristics, its position in the periodic system determined.

But if the magnesium be itself compound, the position thus assigned for the element is certain not to tally with the stellar evidence if the temperature of the star from which information relating to it is obtained is high enough to continue the work of dissociation; that is to break up magnesium itself into its constituents as certainly as the chloride of magnesium was broken up in the laboratory in the first instance.

It is now known that dealing with this very substance magnesium, high electric tension brings us in presence of a spectrum which consists of at least two sets of lines, numerous ones seen also at the temperature of the arc, and a very restricted number which make their appearance in the spark.

If this be the work of dissociation—and, as I have shown elsewhere, the proofs are overwhelming—the "atomic weight" of the particle, molecule or mass, call it what you will, which produces the restricted number of lines—the enhanced lines—must be less than that of the magnesium by the breaking up of which it is brought into a separate existence.

And now comes the chief point in relation to the periodic law. *Seeing that the smaller masses which produce the enhanced lines have not been yet isolated, their "atomic" weights and their chemical characteristics have not been determined, and so of course their places in the periodic table cannot be indicated as it at present exists.*

My contention, therefore, is that some, at all events, of the apparent discrepancies between the stellar evidence and the "periodic" hypothesis arise from this cause.

The magnesium, and I will now add calcium, which the chemist studies at relatively low temperatures have atomic weights of 24 and 40 respectively, and the stellar evidence would be in harmony with the periodic law if magnesium (24) made its appearance after sodium (23), and calcium (40) after chlorine (39), and generally each substance should make its appearance after all other substances of lower atomic weight than itself.

But, and again for the sake of simplicity I shall confine myself to magnesium and calcium for the moment, in the stars we find lines in the high temperature spectrum of magnesium and calcium appearing before known lines in the spectrum of oxygen which has an atomic weight of 16.

How are these results to be reconciled? I suggest that the explanation is that the substances revealed by the enhanced lines of magnesium and calcium and noted in the hottest stars have lower atomic weights (smaller masses) than the oxygen of the periodic table.

Let us next, then, see what these atomic weights may possibly be. Assuming A/2 the atomic weight of proto-magnesium would be $24/2 = 12$; of proto-calcium $40/2 = 20$, supposing only one depolymerisation has taken place. If we assume two, we get 6 and 10 as the "atomic" weights of the simpler forms of magnesium and calcium which make their appearance in the hottest stars.

In this way we can explain the appearance of those finer forms of magnesium and calcium before oxygen, with a small number of depolymerisations, and the stellar record of the order of atomic weights would be the same:

Hydrogen	1
Proto-calcium	10
Proto-magnesium	12
Oxygen	16

So much, then, for a possible reconciliation. The next point to be considered is, is depolymerisation on such a small scale sufficient?

To do this we have to see the basis of the atomic weight of oxygen 16, and consider the series question in relation to oxygen. This necessitates a digression.

The simplest case presented in series phenomena is that placed before us by sodium and other elements which run through all their known spectral changes at a low temperature. Dealing with the line spectrum stage we have three "series," one principal and two subordinate (first and second). The former contains the orange line D, constantly seen at all temperatures, the first subordinate the red line, the second subordinate the green line, representatives of two series of lines which are best seen both in the flame and arc.

The two subordinate series of sodium, like those of all other elements so far examined, have the peculiarity that they end at nearly the same wave-length, while the end of the principal series occurs at a different, sometimes widely different, wave-length. This is a touchstone of the highest importance, as we shall see; it points to a solidarity of the two subordinate series, and to a difference between them and the principal series.

Although the original idea was that all three series were produced by the vibrations of the same molecule, observations of the sodium phenomena alone are simply and sufficiently explained by supposing that we have three different masses vibrating, and that two of them, producing the subordinate series, can be broken up by heat, while that producing the principal series cannot. The series represented by the red and green lines seen best at the lower temperatures have been seen alone, and it is a matter of common experience that the orange line representing the principal series is generally seen alone: it is not abolished at high temperature as the others are. Because the mass the vibrations of which give us the orange line is produced by the breaking up of more complex forms at a low stage of heat, and it cannot be destroyed by the means at our command, it is the common representative of the element sodium. Because the masses the vibrations of which produce the two subordinate series represented by the red and green lines are easily destroyed by heat, they are more rarely seen, scarcely ever at high temperatures when the quantity is small, since, as I pointed out years ago, "the more there is to dissociate, the more time is required to run through the series, and the better the first stages are seen."

This view is greatly strengthened by considering another substance which, if we accept Pickering's and Rydberg's results, has, like sodium, three series, one principal and two subordinates in quite orthodox fashion. I refer to hydrogen.

Till a short time ago we only knew of one "series" of hydrogen, and on this ground Rydberg assumed it to represent the finest form of matter known, regarding the other substances which give three normal series as more complex. This idea is in harmony with the view expressed above.

Pickering in 1897 announced the discovery in the stars of another series, and seeing that this ends in the same part of the spectrum as the other, we can provisionally regard the terrestrial and stellar hydrogen as representing the first and second subordinate series.

Rydberg in the same year gave reasons for supposing that one line seen chiefly in the bright-line stars may represent still another series of hydrogen which we may take as the principal series. The other lines in this series he calculated to be out of range.

If we accept all these conclusions we must regard hydrogen as identical with sodium in its series conditions. But there is this tremendous difference. In sodium we easily at low temperatures—the bunsen is sufficient—see all three series, while in the case of hydrogen even the Spottiswoode coil can show us nothing more than one of the subordinate series. At the same time, the other subordinate and the principal series are visible in stars which we have many reasons for believing to be hotter than the spark produced by the Spottiswoode coil.

The argument for the existence of three different masses producing the three different series derived from the sodium observations is therefore greatly strengthened by what we now know of hydrogen.

I shall therefore assume it in what follows, and now return from the digression.

Oxygen, instead of having three series like metals of low melting point such as sodium, and the gas hydrogen, has *six*. These six have been divided by Runge and Paschen into two normal sets of three, each set possessing one principal and two subordinate series.

There is evidently a new problem before us; we require to add the series of hydrogen to the series of sodium to get a "series" result similar to that obtained from oxygen.

Before we go further it will be well to consider the possible order of simplifications. Let us take the simplest case represented by sodium and hydrogen in the first instance. The facts are shown in the following table:—

High temperature.

Sodium.			*Hydrogen.*		
Line stage	Principal	Celestial and terrestrial vapour.	Line stage	Principal	Celestial gas.
	Subordinate	Terrestrial vapour.		Subordinate	
	Subordinate			Subordinate	Terrestrial gas.
Flutings			Structure spectrum ...		
Continuous		Solid and liquid.	Continuous		

Low temperature.

We may now bring these results to bear upon oxygen. We learned first from Egeroff that this gas at ordinary temperature and pressure is so molecularly constituted that it produces a fluted absorption in the red part of the spectrum. On account of the constancy of the results obtained by chemists we cannot be dealing with a mixture of molecules, the fluting absorption therefore must be produced by molecules of one complexity having an "atomic weight" of 16.

If we subject it to an induced current at low pressure (at which the action of such a current is feeblest), it at once breaks up into two normal sets of three series, that is six series altogether; it is almost impossible to consider this state of things in the light of what happens in the case of sodium and hydrogen without assuming on the ordinary chemical view that the "molecule" with the fluted spectrum is broken up into two, until finally we get—

High Temperature.

	SET A.	SET B.
Line spectrum ...	Principal series	Principal series.
	Subordinate	Subordinate.
	Subordinate	Subordinate.

Fluted spectrum.

Low temperature.

But if we accept this, we give up depolymerisation, for the molecules of the subordinate series of sets A and B thus produced cannot be identical because their spectra are not identical.

If we hold to depolymerisation we must arrange matters thus—

Set B or A	Principal
	Subordinate
	Subordinate
Set A or B	Principal
	Subordinate
	Subordinate
	Fluted spectra

and we get six depolymerisations.

The number of lines measured by Runge and Paschen in the spectrum of oxygen at low temperature was 76; of these the six series referred to contain 56, leaving 20 residual lines. Now if we employ a strong induced current at atmospheric pressure, we practically extinguish these six series of lines and produce a new spectrum altogether, containing a still greater number of lines: 114, according to Neovius. Only one line is common to his table and that of Runge and Paschen. About the series conditioning of these new lines we are at present profoundly ignorant.

Let us take the simplest course in harmony with the principle of continuity, and suppose that the great number of new lines is due to the breaking up of the molecules of the upper principal series given in the previous table into representatives of a still finer form, as hydrogen, as we know it, is broken up into a finer form at the highest stellar temperatures.

Have we, on the line of reasoning we are pursuing, any means of estimating the number of finer forms which may be at work to produce the 113 new lines?

One possible way—a statistical way—seems open to us. Taking the number of lines already recorded in the spectra roughly between λ 7000 and λ 2600 of the following substances, which give us three series—lithium, sodium, potassium, helium, asterium, hydrogen—we find that the number of lines in each series and the total numbers are as follows:—

	Maximum number.		Minimum number.		Average number.
Principal series ...	10 Ast	...	1 H	...	7
First subordinate ...	17 He	...	6 Na	...	9
Second subordinate...	12 He	...	4 Li	...	8
Totals	39		11		24

This indicates that in oxygen we are slightly above the average with $\frac{56}{2} = 28$ lines per set. If we take the facts for oxygen itself, which give us 56 lines for two sets of three, the 113 lines will give almost exactly four additional sets of three series, and therefore the possibility of twelve more depolymerisations if this method of simplification is considered.

Of course we can halve the number of depolymerisations by assuming that the fluting molecule instead of being depolymerised is broken up into x and y, the bases of the two systems of series.

Now it is this last crop of new lines alone which are represented in the hottest stars, and no one, I think, will now urge that some kind of simplification which may include depolymerisation has not taken place before they were brought into evidence.

Our base of 16 then vanishes, and with it the previously considered possible atomic weights of the forms of magnesium and calcium which precede the appearance of oxygen in the hottest stars. We must therefore assume further depolymerisations in the case of these metals beyond those considered in the first instance.

I now come to another point. How do the above considerations bear upon hydrogen with its atomic weight of 1? Of this hydrogen we know nothing spectroscopically. There is evidence that it is broken up into something which gives the complicated structure spectrum with hundreds of lines not yet sorted into series, again into the one series seen in our laboratories and in the cooler stars, still again into two other forms we cannot get here.

Let us apply the statistical method we employed in the case of oxygen.

In the region included in these inquiries the number of hydrogen lines in the three series referred to is 17. Hasselberg has measured 454 lines in the structure spectrum between λλ 642 and 441. Now if this spectrum is built up of series similar to those observed at the highest temperatures, we must have more (seeing that Hasselberg's work was limited) than $\frac{454}{17} = \pm 27$ series or 9 sets of 3 each. We deal then altogether with 12 depolymerisations.

But to be on the safe side, let us assume 6 on the ground that the lines in the series may be more numerous, and that some of Hasselberg's lines may be due to flutings. It will be clear that the masses or "atomic weights" we arrive at must be very small. Here is the story:—

Spectrum.	Where existent.	Series, &c.		Mass.
Line spectrum ...	Celestial	Principal	...	·0019
		Subordinate	...	·0039
	Terrestrial	Subordinate	...	·0078
Fluted spectrum	Set B Terrestrial	Principal	...	·0156
		Subordinate	...	·0312
		Subordinate	...	·0625
	Set A Terrestrial	Principal	...	·125
		Subordinate	...	·25
		Subordinate	...	·5
Continuous spectrum...	...	Hydrogen weighed in the cold	...	1·

Such a conclusion as this, and therefore the reasoning which has led up to it, must stand or fall according as science knows anything of such masses.

I shall show subsequently that, thanks to the investigations of Prof. J. J. Thomson, science is beginning to know a great deal of such masses, and the result of this work may therefore favour the view that polymerisation is a *vera causa* for molecular complexity, at all events in the cases of elements of low atomic weight.

Let us then consider the case of those elements the atomic weight of which is greater. In the first stages of evolution, in which we deal with substances of relatively low atomic weight, the stellar evidence supplies us with definite landmarks, and these are definite because the spectra of the hottest stars are not overcrowded with lines. After we have passed the gaseous and proto-metallic stages, however, we find the spectra full of lines which we see at the temperature of the arc, and metals of relatively high atomic weight and melting point are involved; the exact sequences are naturally more difficult to follow, and therefore the *method* of evolution may escape us.

Kayser and Runge have shown that the melting point has a profound influence on the "series" conditions. Those with the highest melting-points, such as barium and gold, present us with no series. There is generally such a flood of lines that it has been so far impossible to disentangle them; we have the "structure spectrum" of hydrogen repeated in these metals at arc temperatures in the so-called "arc spectrum."

NORMAN LOCKYER.

(To be continued.)

TESTIMONIAL TO MAJOR-GENERAL SIR J. F. D. DONNELLY, K.C.B.

AT a meeting in the Lecture Theatre of the Victoria and Albert Museum on Wednesday, November 29, which was very numerously attended by members of the present and past staff of the Department, and by men of science and artists who have been connected with it, Sir John Gorst presented, on the behalf of some five hundred subscribers, the testimonial to Sir John Donnelly.

This consisted of a silver salver, a set of library furniture, a collection of books of reference, a Zeiss binocular, and a diamond brooch for Lady Donnelly, and the inscription on the salver stated that it was in recognition of their high regard and in remembrance of their cordial relations of more than forty years.

Sir John Gorst, in presenting the testimonial, said: Ladies and gentlemen—I have been invited this afternoon to perform one of the most pleasant duties that has fallen to my lot since I have had the honour of being Vice-President of the Committee of Council on Education. It is to present, in the name of the gentlemen who have been employed at South Kensington as colleagues of Sir John Donnelly, a memento of the long period of public service which he has performed in this place, and a testimonial of the affection and sympathy with which he is regarded by the gentlemen who have been his colleagues.

I have myself been a colleague of Sir John Donnelly for about four years, and speaking of my own personal experience, I can only say that I have received from him, upon all occasions, the most loyal co-operation, which has been enhanced by a very strong personal friendship.

I had an opportunity about three years ago of seeing an attack, made ostensibly on the department of which he was the head, but which really had a considerable amount of personal animus in it.

There was an inquiry by a Committee of the House of Commons, in which Sir John Donnelly was virtually put upon his trial, and I can only say that, in the opinion of his official chiefs—the Duke of Devonshire's opinion was the same as my own—from that inquiry Sir John Donnelly emerged with the conclusion, in the minds of those who have read the evidence, that he had been a most loyal servant of the Department, that there were no allegations made against him which could be substantiated, that his administration of the Department had deserved the approbation of the country, and that the insinuations made against him were absolutely baseless.

Sir John Donnelly had served the department for upwards of forty years, and the testimonial, of which you have been good enough to ask through me his acceptance, is before you on the table. There is one point about it which deserves special allusion on my part. Among the objects which Sir John Donnelly has been asked to accept is a binocular, and, I think, you will be interested to know that that binocular is entirely the gift of the junior staff of the Department. It has been subscribed for by 150 persons, comprising stokers, ex-policemen, labourers, boys, and those who form quite the bottom of this great Department. I think the value of this gift—which shows the estimation in which he was held by this very important but not very wealthy class of the public service—will be to him as much as any of the more costly gifts. I am also asked, at the same time, to present a diamond brooch to Lady Donnelly, and I am sure that it will be extremely gratifying to Sir John Donnelly to know that the estimation in which he has been held by this Department has been shared by Lady Donnelly. In the name of the employés of the Department of Science and Art I beg your acceptance, and Lady Donnelly's acceptance, of these testimonials.

Sir John Donnelly and Lady Donnelly made suitable replies.

It has been arranged to entertain Sir John Donnelly at dinner at the Victoria Room, Criterion, on Tuesday next, December 12. Many representatives of science and art, who are or have been connected with the Department and its affiliated Institutions, will be present as a recognition of the valuable services he has rendered.

THE NOVEMBER METEORS.

IN nearly all the accounts of the observations of the Leonids the same result is recorded, namely, the apparent dearth of these bodies. It is true that unfavourable weather conditions were experienced in many localities; but even taking this fact into account, it may be safely said that the expected shower did not arrive in anything like the density it was expected, at any rate during the nights in which watches were kept.

In a previous number of this journal (vol. lxi. p. 81) many communications were published describing, for the main part, observations made in the British Isles. Several accounts of other observations have recently come to hand, and the following brief summary shows that the result of these watches did not differ very much from that mentioned above.

Paris was evidently blessed with more favourable weather conditions than London. In the first balloon ascent, on the morning of November 14–15, the following number of Leonids was seen:—

	h. m.		h.			
From	1 45	to	2	...	2	Leonids.
,,	2	,,	3	...	13	,,
,,	3	,,	4	...	10	,,
,,	4	,,	5	...	26	,,
,,	5	,,	6	...	40	,,

Of these 19 were of the first magnitude, 43 of the second, 29 of the third, and 9 of the fourth. It is further stated that this number would probably have been considerably increased if the moon had been absent.

At the second ascent, on the night of November 15–16, in a watch from 1h. 20m. a.m. to 6 a.m., only 8 Leonids were observed. M. Bailland, at the Observatory of Toulouse, observed from 1–6 a.m., on the morning of the 16th, and only saw 43 Leonids in that long watch. M. Deslandres, at Paris, who had made great photographic preparations, was no more fortunate than the British observers.

From Strasbourg we learn that on the morning of the 15th many Leonids were seen; the maximum number occurred about six o'clock, when the rate reached sixty per hour. This seems to be the greatest number per hour this year recorded, and is in harmony with the observations made at the first balloon ascent referred to above.

The above accounts corroborate the statement that night observations made in different parts of the world have failed to record a *great* shower. If the earth did not actually pass through the dense part of the swarm in the daytime at some place, then we must conclude that the actions of some of the planets have so perturbed the orbit of the meteors that this year we have only skirted the outlying portion of the stream.

Two accounts of "daylight" observations of the Leonids have come to hand, and for one of these we must thank Prof. N. Story Maskelyne, who, when he heard of them, requested a written statement of the display from each of the spectators, asking them to describe in simple words what they were quite certain they saw.

The place of observation was Little Hinton, Wanborough, Swindon, Wilts, a village about 400 feet above sea-level, and a mile or so from the old Roman road from

Cricklade to Newbury; to the east of that road where it traverses Wanborough (a few miles east of Swindon).

The observers, whose descriptions are given below, were Miss May Jeans, aged eighteen; Mr. Purcell Jeans, aged sixteen; and Miss Emily Swayne.

Miss Jeans' description is as follows:—

"*November* 22.—Last Wednesday afternoon, November 15, as I was lying down in an easy chair, looking out of a window facing north, and was not thinking of seeing the meteors, but suddenly I noticed them. Immediately I called Miss Swayne to come and look and see if she could also see them. We then went out of doors to look at them; the air seemed full of them, both large and small meteors. There was a thick mist at the time, which cleared off after the shower was over. The element seemed alive with them; small ones were on the background, and larger ones suddenly appearing and shooting across the sky. The shower lasted about an hour. It was half-past one o'clock when first I noticed them. Just before half-past two, my brother, Purcell Jeans, came in from a walk, and I called him to see them. They were nearly over then. We also called Mrs. Prismall of this village, our washerwoman. They were like silver balls shooting about everywhere, shining brightly, more like a very starlight night; only the stars, instead of being a gold colour, were silver, and every star shooting in all directions. It is so difficult to describe, as I have never seen anything like it before."

Mr. Purcell Jeans writes:—

"When I came back from a walk, on Wednesday, about a quarter-past two o'clock, Miss Swayne told me to come and look at the Leonids, which I did. They were nearly over then, but the elements seemed full of them. I went indoors for a few minutes, and when I came out there was nothing more to be seen of them. There was a mist prevailing at the time, which we thought must have been the cause of our being able to see them. I was very much surprised at the sight, as I never thought it possible to see stars in the daylight. They looked like a lot of little silver balls floating about, and apparently falling to the earth."

Miss Emily Swayne's description of the shower is as follows:—

"I had just come indoors, on Wednesday last, November 15, at half-past one o'clock, and remarked to the washerwoman what a peculiar feeling there was in the air, as if we should have snow, and yet it did not feel cold enough. Almost as I finished speaking Miss Jeans called me. I found her sitting in an armchair quite close to the window. She exclaimed, 'Come and see. I believe I can see stars.'

"I thought it impossible, and would not believe it, but I looked, and certainly saw what appeared to be stars. We then went out, calling the washerwoman to come with us.

"I was facing the north. The air seemed filled all round me with little floating silver balls, which apparently fell from the sky, and on looking right up I saw what seemed to be large shooting stars, all starting from one point, some going east and others west; some leaving longer lines of light behind them than others. I thought it a very wonderful sight, and have never seen anything at all like it before."

The above descriptions give a fairly good account of a meteor shower seen during the daytime, and it will be interesting to hear if any other people in that neighbourhood noticed anything on that date.

The second communication hails from Aveley, in Essex, and the correspondent, Mr. E. Shaw, writes as follows:—

"We observed what appeared to be the meteor shower yesterday (Wednesday, November 15) afternoon between the hours of three and half-past four, resembling a shower of snow, only they were stars, working in and out and round about. We are not mistaken, for two persons in my house saw them."

Considering the accounts of these "daylight" observations in conjunction with those made at Paris and Strasbourg, there seems to be a certain amount of continuity between them.

At both the latter places the shower had every appearance, judging by the numbers of meteors observed, of increasing in intensity as the morning of the Wednesday wore on, and there seems no reason why the actual maximum should not have occurred about mid-day on the same day, and thus escaped more general notice. At the time of the observations made at Little Hinton, the constellation of Leo was already well below the horizon, so that the shower should also have been seen from some place during the night time. As no news of any such display having been seen has come to hand, these observations therefore receive no corroboration. Miss Swayne's statement that the shooting stars were "all starting from one point, some going east and others west," shows that they could not have been Leonids in any case. The observations are, however, worth recording, but that they refer to the Leonids is very much open to doubt.

The Andromedes.—This swarm of meteors, which follows the Leonids somewhat closely as regards the time of year, seems to have been seen by several observers.

From America we learn that Prof. Young, at Princeton, on the night of November 24, saw forty-two Andromedes and secured several photographs, but the period of observation is not stated. Mr. E. C. Willis, of Norwich, made many observations on the same night, and these are given below:—

November 24.

Time.	Meteors seen.		Remarks.
	Andromedes.	Others.	
10.0 –10.15	20	1	Fine.
10.15–10.30	9	2	Fine, but some cloud.
10.30–10 45	4	2	Fine.
10.45–11.0	6	2	Fine.
11.0 –11.15	9	2	Fine.
11.15–11.25	4	1	Partly clouded, moon just risen.

Before 10h. no systematic watch was made, but if the meteors had been exceptionally abundant, they would have been noticed.

11h. 30m.–16h. 45m. Sky entirely overcast.

16h. 45m.–17h. 15m. Slight breaks in the cloud, but no meteors seen.

W. J. S. Lockyer.

FERDINAND TIEMANN.

Chemists will learn with regret of the death of Prof. Ferdinand Tiemann, which occurred at Meran, of heart disease, on November 17.

Johann Carl Wilhelm Ferdinand Tiemann was born at Rübeland in 1848. He graduated as Ph.D. at Göttingen in 1870, and afterwards held the post of demonstrator under Hofmann in Berlin, in whose laboratory most of his researches were carried out, frequently in collaboration with students and pupils. In 1882 he was appointed professor of chemistry in the University of Berlin, and in the following year he succeeded Wichelhaus as editor of the Reports of the German Chemical Society, a post which he resigned in 1897.

Tiemann's best known researches deal with the constitution of odoriferous principles. In 1874 he showed that the glucoside coniferin, which occurs in the sap of coniferous trees, could be hydrolysed by emulsin into glucose and coniferylic alcohol, and that the latter compound, when oxidised, yielded vanillin, identical with the odoriferous principle of vanilla. A manufactory was established at Holzminden under the direction of his pupils, Haarmann and Reimer, both of whom had been associated with him in his researches on vanillin, and the commercial production of this substance from the cambium of the larch became an accomplished fact. But Tiemann was not content with this merely material success; in a masterly series of researches, the constitution of vanillin and various allied naturally-occurring compounds — the protocatechuic series—was established. Fresh syntheses of vanillin—from eugenol and from guaiacol—were also discovered.

In 1893 he published, along with Krüger, his well-known paper "On the Aroma of the Violet." It was, however, the aroma rather of the iris root or orris root (with which that of the violet may or may not be identical) that he investigated. The quantity of the odoriferous principle contained in iris root is so infinitesimal, and that of the root to be extracted, consequently, so large, that, as he states, the resources of a mere scientific laboratory proved unequal to the task, and this preliminary part of the investigation had to be carried out in the works at Holzminden. The substance thus isolated was thoroughly investigated and its constitution established. In order to indicate its origin and, at the same time, its ketonic constitution, he termed it *irone*. His attempt to synthesise it was not, from the point of view of the pure chemist, successful, although for the manufacturing chemist it was of the utmost value. Starting with citral, obtained from oil of lemons or from lemon-grass oil, he condensed this substance with acetone, converting it into a compound which he termed pseudo-ionone; this, when treated with dilute sulphuric acid, yielded ionone, isomeric—not identical—with irone, but so closely resembling it in smell that very few people can detect the difference. For the purposes of the perfumer, therefore, ionone is every whit as good as irone. It is now manufactured, and the value of the process to the patentees may be judged of from the attempts that have been made to evade or to invalidate the patent—attempts that have been foiled in courts of law both in this country and in Germany.

Amongst Tiemann's numerous other researches may be mentioned his work on the terpenes, on camphor, and on the synthesis of amido-acids.

He was a brother-in-law of the late A. W. von Hofmann.

NOTES.

AT a general monthly meeting of the members of the Royal Institution, held on Monday, the following letter from the Clerk of the Goldsmiths' Company, Sir Walter S. Prideaux, was read:—"I am directed to inform you that the attention of the Court of the Goldsmiths' Company having been drawn to the fact that the Royal Institution of Great Britain has lately celebrated its centenary, they have, in order to mark their sense of the importance of that event, been pleased to make to the Institution the further grant of 1000*l.*, for the continuation and development of original research, and especially for the prosecution of further investigations of the properties of matter at temperatures approaching that of the absolute zero of temperature. I enclose a cheque for this amount, and I shall feel obliged to you to acknowledge the receipt." The following resolution, proposed by the Lord Chancellor, and seconded by Sir A. Noble, was then passed:—"That the members of the Royal Institution of Great Britain, in general meeting assembled, having been informed that the Court of the Goldsmiths' Company have made a donation of 1000*l.* to the funds of the Royal Institution in commemoration of its centenary, and in aid of the investigations which are being carried on in its laboratories into the properties of matter at low temperatures, desire to express to the Court their profound and grateful appreciation of this second munificent manifestation of their practical interest in the work of the Institution—a manifestation which has been made on this occasion at once reminiscent of past services to science and prescient of services yet to come."

THE Dover Town Council has received a letter from the President of the French Association for the Advancement of Science, enclosing a handsome silver medal, presented to the municipality in commemoration of the Association's visit to the town in September last. The Mayor, Sir William Crundall, said the medal would be placed with the corporation plate. It was decided to make a grateful acknowledgment of the gift.

DR. T. E. THORPE, F.R.S., has been appointed to succeed the late Sir Edward Frankland in the work of analysing the water supplied by the London water companies.

THE death is announced of Dr. Birch-Hirschfeld, professor of pathology in the University of Leipzig, at the age of fifty-seven. Prof. Birch-Hirschfeld was one of the most distinguished pathologists in Germany.

THE *British Medical Journal* states that a State Institute of Serumtherapy, Vaccination, and Bacteriology, to bear the name of Alfonso XIII., has been created in Madrid. The new institute is organised on the lines of the Institut Pasteur.

AN International Congress of Mining and Metallurgy will be held in Paris on June 18–23 next year. The congress, like that of 1889, will be under the direct patronage of the French Government. In the provisional programme the following subjects are down for discussion:—Mining: use of explosives in mines; use of electricity in mines; mining at great depths; labour-saving methods as applied to mining. Metallurgy: progress in the metallurgy of iron and steel since 1889; application of electricity to metallurgy—(*a*) chemical, and (*b*) mechanical; progress in the metallurgy of gold; recent improvements in the dressing of minerals. The general secretary is M. Gruner, rue de Châteaudun, 55 Paris.

A COURSE of twelve demonstrations will be given in the psychological laboratory of University College during the Lent Term, commencing on January 19, 1900, by Mr. W. McDougall, Fellow of St. John's College, Cambridge. The Class will meet once a week on the day and at the hour that are found to be most convenient to the majority of the students. The methods of investigating experimentally all the chief types of elementary mental process will be demonstrated, and the students will be afforded opportunities to practise the methods. The subjects will include the several aspects of skin-sensibility and the "muscular sense"; the colour sense, visual distance and optical illusions; appreciation of tone-intervals and localisation of sound; sensibility to pain; simple measurements of memory; estimation of periods of time, &c. Students should send in their names to Mr. McDougall, St. John's College, Cambridge, before Tuesday, January 16, 1900, when the Term begins.

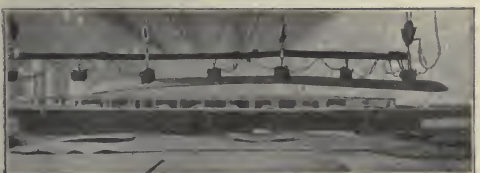
IN the early part of last week a "Bottlenose" whale was reported to have stranded on the river-bank at North Woolwich. The animal was a female, and on Wednesday, November 29, it was delivered, some time after death, of two young. On Friday a visit was made to Woolwich to see if either of the specimens were required for the Natural History Museum. That morning the carcase of the mother had, however, been towed out to sea by the sanitary authorities; but the body of a young one (which measured sixteen feet in length) was on view in front of the station, where it had attracted crowds the previous day. A glance showed that, instead of being a "Bottlenose," it was a "Finner" or Rorqual; and, since the mother was stated to have measured over sixty feet in length, there could be no doubt that it was the common species (*Balaenoptera musculus*), of which there is now a life-sized half-model in the Natural

History Museum. The young one differed from the adult in that the under-surface of the body was flesh-coloured instead of white.

WE learn from a German contemporary that a complete horn—that is to say, both the horn-core and its sheath—of the Avrochs or extinct European Wild Ox (*Bos taurus primigenius*) was disinterred some years since from a peat-bog at Treten, in Pomerania, and is now preserved in the zoological museum of the high school. The specimen has been examined by Dr. A. Nehring, of Berlin, who pronounces it to be about 300 years old; it is only in peat, or in an extremely dry cave, that the conservation of horn would be possible for such a lengthened period.

OWING to the frequent settlement of the land in the salt districts it has always been found a difficult matter to maintain in proper order bridges and other similar structures. To meet this difficulty the engineer of the Weaver Navigation, in constructing two new swing bridges over the river at Northwich, has so designed these that, instead of resting on the land, the weight of the bridges is carried on steel pontoons floating in the water, and the bridges are therefore independent of any settlement of the land so far as their foundations are concerned, and they are so built as to be easily adjusted to any settlement of the ground at the two ends. These bridges also are opened and closed by electric power, being the first to be so operated in this country. The two bridges have cost 25,000*l*.

AN interesting use of electro-magnets in steel works is referred to in the *Electrical Review*. It appears that in the works of the Illinois Steel Company, which makes very extensive use of electric power for all the purposes of steel manufacture, electro-magnetic cranes are used to carry plates from the rolls to the shears. A long plate being conveyed in this manner is shown in the accompanying illustration.



Electro-magnets carrying a steel plate.

MONSIEUR CHARLES JANET, President of the Zoological Society of France, has for some years been engaged in investigating the minute anatomical structure of ants, wasps, and bees. The results of his investigations are published at intervals under the title of "Études sur les Formis, les Guêpes, et les Abeilles"; and of these we have just received Nos. 17, 18, and 19, the last published in the *Mémoires* of the French Zoological Society for 1898. All these treat of the anatomy of different portions of the body of the Red Ant (*Myrmica rufa*). Another memoir, on the cephalic nerves of the latter insect, appears in the journal last mentioned for 1899, although not under the same general title. The work being of an extremely technical nature, its details cannot be described in a note; but we may observe that these are worth the best attention of all students of insect morphology. The illustrations alone serve to indicate the extreme care and labour that the author has devoted to his subject, the elaboration of detail being little short of marvellous.

WE learn from the *Scientific American* that the Naval Board appointed to inspect and report on the performance of the *Holland* submarine boat has reported that in the recent tests, held on November 6, in New York Harbour, she fulfilled all the requirements laid down by the Department. These requirements were that she should have three torpedoes in place in the boat, she should have all arrangements for charging torpedoes without delay, and that she should be prepared to fire a torpedo at full speed both when submerged and at the surface. Lastly, the *Holland* was to make a run for two miles under water, starting from one buoy, running submerged for a mile to a second buoy, rising to discharge a torpedo at a mark near the second buoy, and then, after diving again return submerged to the starting point. In his report Chief Engineer John Lowe, U.S.N., who was specially ordered to observe and report the preliminary trial, says: "I report my belief, after full examination, that the *Holland* is a successful and veritable submarine torpedo boat, capable of making a veritable attack upon the enemy unseen and undetectable, and that therefore she is an engine of warfare of terrible potency which the Government must necessarily adopt into its service."

THE November number of the *Journal* of the Franklin Institute contains several of the addresses delivered on the occasion of the recent celebration of the seventy-fifth anniversary of the Institute. Dr. J. W. Richards, president of the chemical section, which is the oldest of the sections, inaugurated the proceedings of the commemorative week with an address in which he showed that the Institute has always stood for the happy combination of theory and practice—the union of pure and applied science. Mr. H. W. Wiley gave an address on the relation of chemistry to the advancement of the arts. The following remark illustrates the dominant influence of chemical science in one direction: "The agricultural experiment stations of the United States which have been directed by chemists, have taken such a leading position in the development of agricultural science as to practically monopolise all those investigations which have been most useful to agriculture throughout the country." Dr. E. J. Houston gave an account of the position of electrical science at the time of the birth of the Institute, in 1824, and showed that the Institute has exerted a marked influence on the extension and application of electricity by its great international exhibition of 1824, and through other means. Mr. R. W. Pope gave an address on a similar theme, namely, the influence of technical societies in promoting the progress of the arts. All the addresses in the *Journal* are of interest in connection with the subject of the bearing of science upon industry.

THE current number of the *Lancet* contains an article of particular interest dealing with the effects upon the wounded of the Mark II., the Mauser, the Dum-dum, and the Mark IV. bullets. The article, which has been written by Dr. Arthur Keith and Mr. Hugh Rigby, gives a clear idea of the relative amount of destruction caused by each of these modern military bullets, and the experiments upon which the writers' views are founded, confirm fully the experiences which have already been reported from the seat of war in South Africa. A glance at the illustrations shows the terrible havoc wrought by the Mark IV. and Dum-dum bullets and shows also that the old Martini-Henry bullet made an enormous and jagged wound compared with the neat little track that is left behind the Mark II., which our forces are using in South Africa, or the Mauser which is being used by the Boers. Dr. Keith and Mr. Rigby have not, however, been able to obtain results in their experiments with Dum-dum bullets that endorse Prof. von Bruns's statement of the case against the English open-nosed bullet. All open-nosed bullets cause fearful injuries, but it is contended that Prof. von Bruns must have used Dum-dum bullets of an exceptional nature to get the results which he recorded.

DR. F. A. COOK, who recently returned with the *Belgica* expedition, contributes to the December number of *Scribner's Magazine* an interesting article, accompanied by a number of illustrations reproduced from photographs, on the possibilities of Antarctic exploration. He shows that important results of immediate practical use to both science and commerce are likely to be obtained by Antarctic exploration. Referring to the need for exploration merely from a geographical point of view, Dr. Cook remarks:—"The actual existence of a land corresponding to what is charted as Graham Land is a matter of considerable doubt. On the map it extends from the sixty-ninth parallel of latitude, northward four hundred miles. But Alexander I. Land, the southern termination, is an island, and we saw no land eastward. The character of the land which may or may not exist between this and the newly-discovered Belgica Strait is in doubt. It offers scientific and commercial prospects promised by no other new polar region. At the one hundredth degree of east longitude, close to the circle, there is another interruption in the unknown. This is the much disputed Wilkes Land. It is by far the largest land mass in the entire Antarctic area. Including Victoria Land, its better known eastern border, it covers more than one-sixth of the circumference of the globe. In a territory of this extent, even under the most hopeless spread of snow, would it not be strange if something of value and much of interest were not found? Enderby Land and Kemp Land furnish other problems. They are probably not fixed to the continent, for the American, Morrell, found open sea below them; but whether they are isolated islands or parts of an archipelago remains to be ascertained. Does Peter Island exist? The *Belgica* drifted close to the position assigned to it by Bellingshausen, but saw no land. These are but a few examples of the many geographical problems to be solved in the Far South."

IN the *Journal de Physique* for November, M. A.-B. Chauveau discusses the diurnal variations of atmospheric electricity, to explain which no less than about thirty different theories have been proposed, of which four appeared in a single year (1884). M. Chauveau's principal conclusions, based on a comparison of curves from the Bureau central, Batavia, Sodankylä (Finland) Trappes, the College de France, and Greenwich, are as follows:—(1) That the influence of the soil which is greatest in summer (and of which the principal factor probably is the evaporation of negatively electrified water from the surface of the earth) intervenes as a disturbing cause in the diurnal variation. (2) That the general law of variation is represented by a simple oscillation having a maximum in the day, and a minimum (moreover, remarkably constant) between 3.30 and 4.30 a.m.

FROM the *Bulletin* of the French Physical Society we learn that M. Sagnac has given a theory of the propagation of light through matter which supposes that the light waves are transmitted by the same ether as *in vacuo* without the properties of this medium being in any way altered by the presence of material particles; the only effect of these is to scatter the vibrations in the same manner as small conductors, each of which reflects and diffracts all vibrations of sufficiently great wave-length. The author shows that, without introducing any electromagnetical or dynamical considerations, it is possible to give a *purely kinematical* explanation of the laws of reflection and refraction, the existence of the optic layer, and the existence of refractive indices greater than unity. M. Sagnac shows how the optic phenomena of entrainment of ether by matter can be explained by his hypothesis without the assumption of either an ether denser than the ether of a vacuum or any mechanical reaction between the ether and matter. This kinematical theory of the entrainment of the ether presents no difficulties or complications in accounting for the existence of dispersion or double refraction; and M. Sagnac has extended the theory to the explanation of anomalous dispersion and to the investigation of certain new optic phenomena.

IN the year 1891 the Hydrographic Office of Vienna established an elaborate service of rainfall and river observations in all the principal river systems. The volumes for the year 1897 have just been published and contain results of rainfall observations for no less than 2615 stations, together with tables showing the general distribution of temperature in the Austrian Empire. The depth of snow is also regularly gauged at over 40 stations. The work is accompanied by numerous diagrams and by a general discussion of the results for each of the 14 districts into which the service is subdivided.

WE have received the *Boletin Mensual* of the Manila Observatory for the first quarter of the year 1898. It is satisfactory to note that observations have been regularly recorded at this important observatory, under the direction of the Jesuit Fathers, for the last thirty-three years. The present volume contains hourly and daily means of the principal meteorological and magnetical elements, together with maximum and minimum values for Manila, from self-recording instruments and eye observations made twice daily at a number of secondary stations in the Philippine Islands. It also contains a monthly discussion of the observations and of earthquake phenomena, with curves of the meterological and magnetical elements.

MESSRS. BAILLIÈRE, TINDALL AND CO. have published the fourth edition of "A Synopsis of the British Pharmacopœia," compiled by Mr. H. Wippell Gadd, with analytical notes and suggested standards by Mr. C. G. Moor.

MR. A. C. SEWARD reprints from the *Proceedings* of the Cambridge Philosophical Society a paper on the Binney collection of Coal-Measure plants, in which a new genus, *Megaloxylon*, is described, belonging to the Cyadofilices, and considered by the author as furnishing an additional link between the Palæozoic representatives of this family and recent ferns. The paper is copiously illustrated.

THE sixth edition of M. Eric Gerard's "Leçons sur l'Électricité" has been published in two volumes by MM. Gauthier-Villars, Paris. The first volume deals with the general principles of electricity and magnetism, and the theory and construction of dynamo-electric machinery. The second volume is concerned with the most important industrial applications of electricity. The work has increased in size, and many new illustrations have been added.

THE additions to the Zoological Society's Gardens during the past week include a Macaque Monkey (*Macacus cynomolgus*, ♀) from India, presented by Mr. J. A. Ewen, J.P.; a Brown Capuchin (*Cebus fatuellus*) from Guiana, presented by Mr. Douglas Mason; a Badger (*Meles taxus*), British, presented by Mr. G. A. Bronson; two Golden Agoutis (*Dasyprocta aguti*) from Central America, presented by Mr. C. Bevan; a White-bellied Sea Eagle (*Haliaëtus leucogaster*) from Tasmania, presented by Captain Francis Mayor; a Common Trout (*Salmo fario*), British fresh waters, presented by Mr. Arthur Irving; a Rufous Rat Kangaroo (*Æpyprymnus rufescens*, ♂) from New South Wales, two Ornamental Lorikeets (*Trichoglossus ornatus*) from Moluccas, a Banded Parrakeet (*Palaeornis fasciata*), four Starred Tortoises (*Testudo elegans*) from India, two Undulated Grass Parrakeets (*Melopsittacus undulatus*) from Australia, a Lapwing (*Vanellus vulgaris*, var.), four Bewick's Swans (*Cygnus bewicki*), European; two Wrinkled Terrapins (*Chrysemys scripta rugosa*) from the West Indies, two Emperor Boas (*Boa imperator*) from Central America, deposited.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN DECEMBER:—

December 9. 12h. 14m. Minimum of Algol (β Persei).
10–12. Epoch of Geminid meteoric shower (radiant 106° + 33°).
12. 9h. 3m. Minimum of Algol (β Persei).
15. 2h. 48m. to 3h. 34m. Occultation of the star κ^2 Tauri (mag. 5·5) by the moon.
15. 2h. 55m. to 3h. 27m. Occultation of the star κ^1 Tauri (mag. 4·6) by the moon.
15. 5h. 52m. Minimum of Algol (β Persei).
15. Venus. Illuminated portion of disc = 0·928.
15. Mars. Illuminated portion of disc = 0·998.
16. Partial eclipse of the moon.
11h. 45m. First contact with shadow.
13h. 26h. Middle of the eclipse.
15h. 7m. Last contact with shadow.
Magnitude of the eclipse = 0·995.
16. 15h. 36m. to 16h. 11m. Occultation of Neptune by the moon.
17. 5h. Neptune in opposition to the sun.
18. 18h. 31m. to 19h. 9m. Occultation of *f* Geminorum (mag. 5·2) by the moon.
20. Jupiter 9° W. of Mercury, on Dec. 24, 11°, and on Dec. 27, 14°.
21. Saturn. Outer minor axis outer ring = 15″·76.
21. 18h. 4m. Transit of Jupiter's Sat. III. Egress.
22. 17h. Mercury in conjunction with Uranus (Mercury 2° 17′ N.).
25. 1h. Mercury at greatest elongation (22° 5′ W.).
25. 14h. 39m. to 15h. 47m. Occultation of the star D.M. − 10°, 3570 (mag. 6) by the moon.
26. 16h. 22m. to 17h. 3m. Occultation of the star 83 Virginis (mag. 5·8) by the moon.
29. 7 a.m. Jupiter, 6° E. of the moon.
30. ,, ,, 8° W.N.W. of the moon.
31. ,, Mercury, 5° W.N.W. of the moon.

The red spot on Jupiter will be about central on Dec. 21, 7.44 a.m.; Dec. 26, 6.54 a.m., and Dec. 28, 8.33 a.m.

MERCURY AND JUPITER AS MORNING STARS.—In the dark mornings of December it is almost as convenient for amateurs to effect observations of celestial objects as it is in the evening hours. It may therefore be of interest to mention that at about Christmas time Mercury and Jupiter will be favourably visible above the S.E. horizon just before sunrise, and that the crescent of the moon will be placed near these planets on the last three mornings of 1899. The following are the times of rising of Jupiter, Mercury and the sun on thirteen days:—

	♃ rises. h. m.	☿ rises. h. m.	☉ rises. h. m.
Dec. 18	5 36 a.m.	6 7 a.m.	8 3 a.m.
19	5 33	6 6	8 4
20	5 30	6 5	8 4
21	5 27	6 5	8 5
22	5 24	6 6	8 5
23	5 21	6 8	8 6
24	5 19	6 9	8 6
25	5 16	6 11	8 7
26	5 13	6 12	8 7
27	5 10	6 14	8 7
28	5 8	6 17	8 8
29	5 5	6 20	8 8
30	5 2	6 24	8 8

HOLMES' COMET (1899 *d*).

Ephemeris for 12h. Greenwich Mean Time.

1899.	R.A. h. m. s.	Decl. ° ′ ″
Dec. 7	2 5 48·62	+45 44 16·0

SPECTRUM OF P. CYGNI.—Herr A. Belopolsky has recently obtained several photographs of the spectrum of the variable star P Cygni (mag. 5), and states the results of his measurements in the *Astronomische Nachrichten* (Bd. 150, No. 3603). The instrument used was the two-prism spectrograph (camera 25 cm. long) attached to the 30-inch refractor of the Pulkowa Observatory. Both bright and dark lines are given, and it is noted that while the *bright* lines generally occupy a normal position, the *dark* lines are displaced towards the violet or more refrangible end of the spectrum. It is also interesting to note that several of the lines found are ascribed to nitrogen. The following table gives the wave-lengths of the lines in the star's spectrum with their probable origins:—

Bright Lines.	Dark Lines.	Wave Length Rowland, Runge, Neovius.	Origin.
4861·6	4858·2	4861·5	Hβ

ANNIVERSARY MEETING OF THE ROYAL SOCIETY.

FOLLOWING the usual custom, the anniversary meeting of the Royal Society was held in the apartments of the Society at Burlington House on St. Andrew's Day, November 30. The auditors of the Treasurer's accounts read their report, and the Secretary read the list of Fellows elected and deceased since the last anniversary. The President, in his anniversary address, referred to M. Haffkine's experience and views regarding preventive inoculation, and then proceeded to the award of the medals.

COPLEY MEDAL.

The Copley Medal is conferred upon Lord Rayleigh for his splendid services to Physics.

Lord Rayleigh's investigations have increased our knowledge of almost every department of physical science, covering the experimental as well as the mathematical parts of the subject. Acoustics, optics, electricity, and magnetism, the molecular theory of the constitution of bodies, the theory of elasticity, the composition of the atmosphere, are but a selection from the subjects of his investigations. In acoustics he has added to our knowledge of resonance (the subject of his first paper in the *Philosophical Transactions*), the behaviour of singing flames, the vibrations of jets, the general theory of the vibrations of dynamical systems, while his masterly "Theory of Sound" has thrown light on and given unity to the whole of the subject. In optics, his researches include the theory of the scattering of light by small particles, with its application to the explanation of the blue of the sky, anomalous dispersion, the nature of white light, reflection from crystals, and the general theory of optical instruments. In electricity and magnetism, in addition to theoretical investigations of great importance on the distribution of alternating currents in conductors, he has made, in co-operation with Mrs. Sidgwick, those classical investigations of the value of the ohm in absolute measure, the electromotive force of the Clark cell, the electrochemical equivalent of silver, and the specific resistance of mercury. His researches on the theory of elasticity are valued by all students of mathematical physics. In his researches on the density of gases he met with small discrepancies between the density of nitrogen derived from the air and that derived from chemical compounds. Investigations into the cause of this discrepancy, followed up with wonderful skill and perseverance, led to the discovery of a new element (argon) existing in large quantities in the atmosphere, and possessing qualities of a very novel and remarkable kind. Lord Rayleigh's researches, from the range of subjects they cover, their abundance and their importance, have rarely been paralleled in the history of physical science.

ROYAL MEDALS.

One of the Royal Medals is conferred upon Prof. G. F. Fitzgerald, for his brilliant contributions to Physics.

A foremost position has been occupied by Prof. G. F. Fitzgerald during the last twenty years in the domain of Radiation and Electrical Theory. At the time when very few people had definite notions of the changed aspects which these subjects had assumed after Maxwell's theoretical advances, he was prominent as an expositor and developer of the new views. Thus his paper on "Electromagnetic Effects due to the Motion of the Earth" (*Trans. Roy. Dub. Soc.*, May 1882) was, perhaps, the earliest explicit effort to bring the facts regarding the astronomical aberration of light and general optical knowledge as to the relation of the æther to moving matter, into relation to electrical theory. Enough was there established, in both the optical and the purely electrodynamic domain, to show that no fundamental discrepancy was to be anticipated in the new point of view. Again, his paper "On the Quantity of Energy transferred to the Æther by a Variable Current" (*loc. cit.* November 1883), forms probably the earliest investigation of the field of an electric radiator. The case explored is that of a uniform current of periodically varying intensity; but the historical significance of the investigation is not impaired by the circumstance that subsequent research has transferred the source of actual radiation to the oscillations of the ions in the molecule. Already, in the preceding year, reflecting that crucial evidence with regard to the new standpoint of Maxwell was probably to be sought only in the domain of radiation, he had pointed to the oscillatory electric discharge in a condenser as a means of obtaining actual electric radiation, if only the period of the oscillations could be sufficiently reduced. Reference may also be made to the paper "On a Model illustrating the Properties of the Æther" (*Proc. Roy. Dub. Soc.*, January 1885), which has been widely useful, owing to the very simple manner in which the model—which is on the principle of Maxwell's own idle-wheel representation—visualises a large range of relations of the æther that had previously been amenable only to abstruse mathematical representation.

At an earlier period, Prof. Fitzgerald was occupied with magneto-optic phenomena, particularly with the theoretical bearing of Dr. Kerr's then recent discovery of the peculiarity in the reflection of light from a magnetised substance. That subject is considered at length, with restrictions, however, to transparent media in the analysis, in the latter half of the memoir, "On the Electromagnetic Theory of the Reflection and Refraction of Light" (*Phil. Trans.*, 1879). But the main interest of this memoir consists, perhaps, in the dynamical formulation of the electric theory of light on the basis of the Principle of Least Action, and in the comparison of that theory with the optical work of the author's countryman, MacCullagh. He has thereby contributed to a broader appreciation of that writer's position, and has shown that his theory of light, which was reached inductively along purely optical lines, runs parallel, and is, in fact, identical with the theory of Maxwell which presented itself in the course of a far wider induction originating in the domain of electrodynamics. The remark with which this memoir concludes, as to the advantage of "emancipating our minds from the thraldom of a material æther," has not, perhaps, yet lost all its force.

Not the least of Prof. Fitzgerald's services has been his success in guiding and energising an Irish School of Natural Philosophy. His efforts, and those of his pupils, have had a prominent share in the development and illustration in this country of the phenomena of electric radiation. Thus, in 1889, he was engaged, with Mr. F. T. Trouton, in verifying the laws of polarisation, by reflection, for Hertzian radiation; in 1890, he brought forward a new means of detecting such radiation by a galvanometer inserted across the spark-gap; in 1892 he returns to the problem of practical electric vibrators by a series of suggestions as to ways in which a continuous vibration of the requisite high frequency might possibly be established. He has experimented, with Dr. Trouton, in 1896, on the scattering of Röntgen radiation in passing through paraffin; and, along with Mr. W. E. Wilson, he has conducted a research on the effect of the pressure of the surrounding atmosphere on the temperature of the electric arc, which must have important bearings on the theory of radiation from solid bodies. He has also completed the work of Maxwell and Chrystal on Ohm's law of conduction by minutely testing its validity for the case of electrolytes.

More recently his efforts have contributed to the elucidation of the modifications impressed on the lines of a radiant spectrum, by change of pressure of the atmosphere surrounding the radiator, and by a field of magnetic force.

His critical activity pervades an unbounded field, enlivened and enriched throughout by the fruits of a luxuriant imagination.

The other Royal Medal is given to Prof. William Carmichael McIntosh for his very important labours as a zoologist.

Prof. McIntosh may be regarded as one of a distinguished succession of monographers of the British Fauna who, beginning with Edward Forbes, have during the last fifty years done work highly creditable to British Zoology.

McIntosh's great monograph of the British Annelids, published by the Ray Society, is still in progress. Two folio volumes appeared more than twenty years ago, a third is now in the press, and a final volume is contemplated. As a result of this work, and of numerous papers on the subject, McIntosh is justly regarded as the European authority on this group of animals. But his work has by no means been wholly that of a systematist. He is the author of one of the large and important *Challenger* Reports (that on the Polychæta), and of several minor reports of the same and other Government expeditions. His other papers extend over a wide range of subjects, and deal with many structural points. His name, moreover, is associated with the discovery or the description of several of the more remarkable or problematical of marine animals—such as *Pelonaia*, *Phoronis*, and *Cephalodiscus*.

Some of Prof. McIntosh's earlier papers were on fishes and their life history, and during the last ten or twelve years he has returned to that subject, and has added to the knowledge of our sea fisheries to a remarkable extent—both by observations anatomical and embryological (published in the *Trans. Roy. Soc. Edin.*), and in his book on British marine fishes, and by experiments on a large scale calculated to yield results of industrial importance.

Finally, Prof. McIntosh has been a notable teacher in Scotland, and many of those he has trained now occupy zoological posts and have conducted important researches. He is himself still a very active worker, both in his own investigations and in directing the researches of others. He was the first to found a marine biological station in this country, and the establishment of the present well-known Gatty Marine Laboratory at St. Andrews is entirely the outcome of his energy and influence.

DAVY MEDAL.

The Davy Medal is bestowed upon Edward Schunck for researches of very high importance in Organic Chemistry.

Edward Schunck is the author of a remarkable series of contributions to the chemistry of vegetable colouring matters, dating from 1841 up to the present time, and it is noteworthy that his first English paper appeared in the first volume of memoirs issued by the Chemical Society of London.

His earlier work includes two investigations which are everywhere regarded as classical, the one relating to the Madder plant, the other to the Indigo plant, from which the two most important dye-stuffs known to us are derived. In these, besides establishing the fact that the colouring matters are not present as such in the plant, but as glucosides, he brought to light much other information of importance in relation both to alizarin and indigo, and to allied substances with which they are associated.

In 1871, by his discovery of anthroplavic acid in artificial alizarin, he gave an important impetus to the further study of the dye products of the manufacture of this substance, and thus contributed to a development of the industry which soon became of the utmost consequence.

Of late years he has devoted himself to the study of the green colouring matter of plants, and has contributed a series of remarkable papers to the Royal Society on the "Chemistry of Chlorophyll." These deal with one of the most difficult and at the same time most interesting chapters in the whole range of organic chemistry; they are full of observations of fundamental importance, and will serve as a sure foundation for all future researches on the subject. For the first time Schunck has succeeded in obtaining well-defined crystal-like products bearing a close relationship to the natural substance. Nowhere is his remarkable skill as a manipulator, his extreme delicacy of touch, more apparent than in this his latest work.

The Society next proceeded to elect the officers and Council for the ensuing year. The list of Fellows recommended for election has already been given (p. 38), and the only change was the substitution of the name of the Right Hon. James Bryce, M.P., for that of Sir John Murray.

The following are some of the subjects dealt with in the Council's Report:—

ASSOCIATION OF ACADEMIES.

With reference to the proposal for an International Association of Scientific Academies, mentioned in the Council's last Report, letters have been received from the Académie des Sciences, the Lincei at Rome, and the Imperial Academy of Sciences at St. Petersburg, expressing their approval of the suggestion and their readiness to join such an organisation. A preliminary Conference was held at Wiesbaden on October 9, to which the two Secretaries, with Prof. Armstrong and Prof. Schuster, were appointed as delegates from the Royal Society (the Senior Secretary was, however, unable to attend). The Conference exhibited the most perfect accord in the desire to further the practical establishment of an Association for the purpose in view, and proposed a draft scheme for the organisation of the Association on the following lines:—

(1) The Association shall consist of a General Assembly and a Council.

(2) The General Assembly shall consist of delegates appointed by the constituent Academies, each Academy having the right to appoint as many delegates as it may think necessary. On matters of organisation, each Academy shall have but one vote. No Academy shall be bound to take part in enterprises approved by the Association.

(3) The Assembly shall meet once every three years, but under specified conditions the time of such meeting may be altered.

(4) The Assembly shall be divided into two sections, for Natural Science and for Literature and Philosophy respectively. These sections shall have the right of separate meeting. Decisions arrived at by them shall be reported to the General Assembly for information, and, in case the decisions affect both sections, for confirmation.

(5) In the interval between the meetings of the General Assembly, the affairs of the Association shall be managed by a Council, to which each Academy shall send one or two representatives according as it belongs to one or both sections. In either case each Academy will have but one vote. The Council will have a President and a Vice-President, who must belong to different sections.

INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.

The Second International Conference, held in the Society's rooms in October, 1898, appointed a Provisional International Committee, which was to consider reports on various questions discussed at the Conference, to be obtained by the Delegates to the Conference from local committees in their several countries.

The Committee met in the Society's rooms on August 1–5, those present being Prof. Armstrong, Sir M. Foster, Prof. Klein, M. Köppen and Profs. Poincaré, Rücker, Schwalbe and Weiss.

At the close of a series of very arduous sittings, during which questions of great difficulty and delicacy were discussed, a Report was agreed to; and in accordance with the decision of the second Conference, this has been issued by the Royal Society to the various Governments concerned, and will in due course be considered by the Council of the Society.

It should be mentioned that it was agreed to recommend: "That an International Conference, to arrive at a final decision on all matters concerning the catalogue, be held at Eastertide, 1900."

NATIONAL PHYSICAL LABORATORY.

The questions of detail concerning the establishment of this Institution, mentioned in the Council's last Report, having been settled with H.M. Treasury, a scheme of organisation prepared by a Committee of the Council has been approved by the Lords Commissioners of the Treasury. Under this scheme the Kew Observatory Committee, as at present constituted, will cease to exist, and will be incorporated with the National Physical Laboratory, but six members of the Committee have been appointed to serve for a definite period on the Executive.

The ultimate control of the Laboratory will be placed in the hands of the President and Council of the Royal Society, and the income and all other property will be vested in the Royal Society. The Governing Body will consist of a General Board and an Executive Committee, the former composed of the Officers of the Royal Society, the Permanent Secretary of the Board of Trade, twenty-four nominees of the Council, and twelve members nominated by the Councils of the six leading technical Societies, viz. The Institution of Civil Engineers; the Institution of Mechanical Engineers; the Institution of Electrical Engineers; the Iron and Steel Institute; the Institution of Naval Architects; and the Society of Chemical Industry.

The Council, on the recommendation of the Executive Committee, have appointed Mr. R. T. Glazebrook, F.R.S., to the Directorship of the Laboratory, and he will assume the duties of that post on January 1, next year. In the meantime, a number of sub-committees have been appointed to advise the Executive with regard to important questions as to the nature of the work to be undertaken in the Laboratory. Upon their Reports must depend largely the decision which will be taken by the Executive with regard to the buildings for the Laboratory and their site, subjects which are engaging the earnest attention of the Committee.

PROTECTION OF ROYAL OBSERVATORIES.

The protection of Royal Observatories from the effects of magnetic influence, referred to in the Council's last Report, having received the attention of the Government, delegates were appointed at the invitation of the Treasury to represent the Council at a conference of the officers of that Department. After some discussion, a model clause has received the sanction of the Chairmen of the Committees of the Houses of Lords and Commons respectively, and has been introduced into the Bills which were passed during the last Session of Parliament, for electric railways or tramways in the neighbourhood of London.

Under this clause, any Government Department which desires protection against the electrical or magnetic disturbances produced by electric railways or tramways will be at liberty to appeal to the Board of Trade, which will have power to decide whether the return conductor shall be insulated, or what other precautions shall be adopted.

SCIENTIFIC ADVICE TO THE GOVERNMENT OF INDIA.

Early in the year a letter was received from the India Office relating to scientific inquiry in India, and stating that, when the question had arisen of devising a scheme of investigation, the responsibility of suggestions had usually fallen on officials who were not competent to give advice. The Government of India suggested that they should have the advantage of the advice of leading men of science in England, who would exercise a general control over researches instituted by the Government. Lord George Hamilton having inquired whether the Royal Society would be willing to meet the wishes of the Indian Government by assisting in this capacity, the Council decided to appoint a Standing Committee to give such advice as it can on matters connected with scientific inquiry in India. Since the researches on which such a Committee would be consulted would probably in most instances refer to biological matters, the Committee has been chosen chiefly from among the biological Fellows.

The Committee thus constituted has a parallel in the Indian Observatories Committee established at the request of the Government some time since, and mentioned in various Reports of the Council.

CHELSEA PHYSIC GARDEN.

Towards the end of last year the Council received from the Charity Commissioners a request for their views upon a scheme which, at the request of the Society of Apothecaries, the Commissioners had drawn up for the future government of the Chelsea Physic Garden, in the ownership of which the Royal Society had by the deed of grant of Sir Hans Sloane, a reversionary interest. The Council appointed a Committee to consider the Charity Commissioners' scheme, and this Committee having reported to the Council in favour of the scheme, with certain amendments which the Charity Commissioners expressed their willingness to adopt, the Council have concurred in the scheme, which provides for the maintenance of the Garden, under the Charitable Trusts Acts, for the purposes of botanical study, and gives to the Royal Society, among other Institutions, a representation upon the Committee of Management.

"PRIVILEGED" CANDIDATES FOR FELLOWSHIP.

The attention of the Council having been drawn to the regulations governing the election of Fellows under privileged conditions, a Committee was appointed early in the year to consider whether any alteration in them would be desirable. The Committee have duly reported, and, in accordance with their report, the Council have under consideration a modification of the Statutes, enabling the Council to recommend to the Society for election persons who either are Members of Her Majesty's Privy Council, or have rendered signal service to the cause of science, provided that not more than three such persons shall be elected in any one year, the persons so recommended to be selected by the Council by ballot in accordance with a procedure to be established by Standing Orders of Council. The Standing Orders which the Council propose to make correspond in the main with the procedure for the adjudication of the medals, but are still more stringent in character.

In the evening the Fellows and their friends dined together at the Whitehall Rooms.

STEREOCHEMISTRY AND PHYSIOLOGY.

IN a recent number of the *Zeitschrift für physiologische Chemie*, Prof. Emil Fischer has reviewed the facts by which, in conjunction with Thierfelder, he has sought to explain the selective action exhibited by the enzymes either in effecting fermentation or in producing hydrolysis.

Pasteur was the first to show that a solution of racemic acid becomes lævo-rotatory in presence of penicillium, owing to the destruction of the dextro-tartaric acid by the fungus—an observation which has been frequently utilised in the attempt to isolate one of the optically active constituents of a racemic compound.

Configuration and Alcoholic Fermentation.—This selective action is exhibited in a very marked degree by the beer yeasts in producing fermentation of the carbohydrates. Of the eleven known aldohexoses (glucose type) only the three natural products are fermentable, viz. dextro-glucose, dextro-mannose and dextro-galactose, and of the ketohexoses only dextro-fructose is decomposed.

All the yeasts susceptible of inducing fermentation transform dextro-glucose, mannose and fructose with about equal velocity; but the action of yeast on dextro-galactose is slower, and certain species—*Saccharomyces apiculatus* and *productivus*—are totally without action upon it.

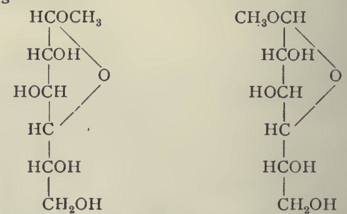
A comparison of the configuration of these four sugars will exhibit the differences in molecular grouping.

COH	COH	COH	CH_2OH
HCOH	HOCH	HCOH	CO
HOCH	HOCH	HOCH	HOCH
HCOH	HCOH	HOCH	HCOH
HCOH	HCOH	HCOH	HCOH
CH_2OH	CH_2OH	CHOH	CH_2OH
d-glucose.	*d*-mannose.	*d*-galactose.	*d*-fructose.

In glucose, mannose and fructose the grouping of the H and OH round the three lower asymmetric carbon atoms is the same, but differs from that of galactose, a fact which may account for the slower fermentive action of the latter. The other hexoses are not fermentable. The small difference in configuration which suffices to arrest the action is seen in the case of *d*-talose, which only differs from *d*-galactose by the position of one hydroxyl group.

COH
HOCH
HOCH
HOCH
HCOH
CH_2OH
d-talose.

Configuration and Zymolysis of the Glucosides.—By the combination of glucose with methyl alcohol, to form methyl glucoside, a new asymmetric carbon atom is created, and consequently two stereo-isomeric derivatives are possible. E. Fischer has obtained from *d*-glucose both modifications, which he terms α and β methyl *d*-glucosides, also the corresponding α and β methyl *l*-glucosides and similar products from the other aldoses. Fischer has allotted to the α and β methyl *d*-glucosides the following formulæ.



An aqueous solution of the emulsin of bitter almonds hydrolyses the β modification, but has not the least action on the α modification. Exactly the reverse happens with an aqueous extract of dry yeast. In this case the α compound is hydrolysed, whilst the β modification remains unchanged. The ethyl and phenyl glucosides, which are only known in one modification, behave like the α methyl compound, and probably belong to the same category. Neither emulsion nor yeast affect the two methyl *l*-glucosides.

D-galactose forms two methyl derivatives, one of which is attacked by emulsin and the other by the enzyme of yeast, but more slowly than the corresponding glucosides, the difference in rate corresponding with that observed in fermentation. Neither methyl *d*-mannoside nor methyl *l*-mannoside is attacked by emulsin or the enzyme of yeast. The second *d*-mannoside, which would probably be hydrolysed by one or the other ferment, is still unknown. The pentoses and heptoses are non-fermentable, and their methyl glucosides are likewise indifferent to both enzymes.

The following is a list of natural and artificial glucosides. The action of the enzyme is denoted by a + when it produces hydrolysis and by a − when it is without action.

		Artificial glucosides.	Emulsin.	Enzyme of yeast.
Aldosides.	Hexosides.	α methyl *d*-glucoside ...	−	+
		β methyl *d*-glucoside ...	+	−
		α methyl *l*-glucoside ..	−	−
		β methyl *l*-glucoside ...	−	−
		α ethyl *d*-glucoside ...	−	−
		phenyl *d*-glucoside ...	+	−
		α methyl *d*-galactoside ...	−	+
		β methyl *d*-galactoside ...	+	−
		methyl *d*-mannoside ...	−	−
		methyl *l*-mannoside ...	−	−
		methyl arabinoside ...	−	−
		α methyl xyloside	−	−
		β methyl xyloside	−	−
		methyl rhamnoside ...	−	−
		methyl gluco-heptoside ...	−	−
Ketosides.		methyl sorboside ...	−	−
		methyl fructoside (not crystallised)	−	+

	Natural glucosides.	Emulsin.	Enzyme of yeast.
Simple derivatives of glucose.	Salicin	+	−
	Helicin	+	−
	Æsculin	+	−
	Arbutin	+	−
	Coniferin	+	−
	Phylbyrin	−	−
	Aprin	−	−
	Syringin	+	−
	Saponin	−	−
	Phloridzin	−	−
	Glucoside of mandelic nitrile	+	−
	Amygdalin	+	−
	Quercitrin	−	+

It would appear that the natural glucosides, which are for the most part phenol derivatives, probably belong to the group of β-glucosides. The indifference of some of these glucose derivatives to both enzymes is at present unexplained.

Configuration and Zymolysis of the Polysaccharoses.—The recent researches of E. Fischer on the hydrolysis of the polysaccharoses point to the fact that none of these carbohydrates is directly fermentable by the enzyme of yeast, but that without exception they first undergo hydrolysis by a hydrolytic enzyme associated with the ferment. The di-saccharoses—cane sugar, maltose, milk sugar, melibiose, trehalose, &c.—are anhydrides formed by the union of two hexoses. The structural formulæ of maltose and lactose are probably identical, seeing that each splits up on hydrolysis into two molecules of aldohexose, but since maltose yields only glucose, whereas lactose forms an equal number of molecules of glucose and galactose, the two compounds must be regarded as stereoisomeric. They probably correspond, too, with the α-methyl- and β-methyl-dextroglucoside, for emulsin hydrolyses lactose, but not maltose; whereas the enzyme of yeast produces the reverse effect.

Without discussing in detail the ingenious methods by which Prof. Fischer has successfully attacked the problem of the hydrolysis of the polysaccharoses, the following results may be briefly recorded.

The action of invertase, an enzyme which accompanies beer yeast, in hydrolysing cane sugar into glucose and fructose previous to fermentation, was first observed by O'Sullivan, and although Bourquelot and Lintner recorded a similar decomposition in the case of maltose, the experiments were not decisive. Fischer, however, extracted with water from dry yeast an enzyme which, unlike invertase, hydrolyses maltose, and which he has therefore named maltase of yeast. Instead of the aqueous extract, the dry yeast itself may be employed; in which case a little toluene must be added to the maltose solution to arrest the alcoholic fermentation.

The conclusion may be drawn that yeasts incapable of inducing alcoholic fermentation of cane sugar and maltose are destitute of invertase and maltase. This conclusion has been fully corroborated by subsequent experience.

Kephir grains and the yeast which ferments milk sugar do not ferment maltose, and are also without hydrolytic action upon it.

Saccharomyces martianus, which according to Hansen does not ferment maltose, does not hydrolyse it, and is therefore free from maltase. Beyerinck's *Schizosaccharomyces octosporus*, which acts on maltose but is indifferent to cane sugar, contains maltase but no invertase. *Monilia candida* is a particularly interesting case, since it contains neither invertase nor maltase, but nevertheless produces fermentation of both cane sugar and maltose. No aqueous extract which hydrolyses these two sugars could be obtained from it, but if the dried yeast is added to a solution of cane sugar in presence of toluene a vigorous hydrolysis is produced. The hydrolytic enzyme is present, but in this case it is insoluble in water.

Milk sugar, which is not attacked by beer yeast, is fermented by kephir grains and milk sugar yeast, which Beyerinck suspected to contain the hydrolytic enzyme lactase. The existence of this enzyme has been placed beyond question by Fischer, who has prepared the enzyme from kephir grains and milk sugar yeast in the dry state. It is accompanied by invertase, but maltase is entirely absent, and indeed no substance is yet known in which maltase and lactase are associated.

The hydrolysis of trehalose by an enzyme contained in *Aspergillus niger* and in green malt was observed by Bourquelot, and has since been confirmed by Fischer, who found also that a Frohberg dry yeast affected a similar but much more feeble decomposition.

Melibiose, which is a disaccharose, is obtained from raffinose. It is fermented by a low fermentation brewer's yeast. Fischer and Lindner have now been able to prove the existence in this yeast of a hydrolytic enzyme which they call melibiase.

In regard to the action of different yeasts on α-methylglucoside and its congeners, Fischer has shown that all yeasts which ferment maltose attack the α-methyl glucoside. The question then arises, has each glucoside or polysaccharose its special enzyme and each fermentable sugar its special ferment or zymase? Fischer considers such a proposition untenable, but inclines to the view that one and the same enzyme of yeast, maltase, attacks α-methyl glucoside as well as melibiose and the complex carbohydrates known as dextrins.

Theoretical considerations.—All these facts indicate that the chemical action of enzymes, in which may be included the zymase of yeast, is of quite a special character and distinct from that of the more simple organic and inorganic compounds. The cause of this selective action probably resides in the asymmetrical structure of the enzyme molecule. Although these substances are not yet known in the pure state, their relation to the proteids is so close and their derivation from the latter so probable, that they may be regarded as optically active molecular aggregates, and consequently asymmetrical. Fischer and Thierfelder have based upon this the hypothesis that between the enzymes and those substances which they attack, there must exist a correspondence in molecular configuration, which they compare to a lock and key. The observations of G. Bertrand on the relation of the polyvalent alcohols to their oxidisability by the sorbose bacteria, shows clearly that stereochemical considerations may be applied to other fermentive processes. Fischer applies the same idea to the chemical changes occurring in the bodies of higher organisms, which lead to the conclusion that in the chemical changes in which the proteid substances take a part as active masses, undoubtedly the case with protoplasm, the configuration of the molecule (*i.e.* space arrangement of the atoms) plays a part fully as important as its structure (*i.e.* plane, or relative arrangement of the atoms). It is easy to conceive on this hypothesis that the three isomeric tartaric acids should be assimilated at an unequal rate in the organism of the dog, and that of two sugars so closely allied as glucose and xylose, it is only the former which is oxidised or converted into glycogen, whereas xylose passes unaltered through the system.

The results of stereochemistry may also throw some light on chemical transformations occurring in the organism. The four sugars, *d*-glucose, *d*-mannose, *d*-fructose and *d*-galactose are not only those that are exclusively attacked by yeast, but those which in the animal system are assimilated as glycogen. The conversion of glucose, mannose and fructose into one another was first achieved by Fischer by a process of alternate reduction and oxidation, since when Lobry de Bruyn and van Ekenstein have arrived at the same result by simply warming with alkalis.

As von Baeyer pointed out twenty-eight years ago, all these phenomena may be explained by the intramolecular migration of an oxygen atom from one carbon atom to the other. The intermediate phases of this process are unknown; but alcoholic fermentation is an example of the facility with which the operation is effected. In regard to the assimilation of carbon dioxide by plants, which gives rise to exclusively active sugars, a similar explanation may be found, seeing that the carbon dioxide in process of assimilation is associated with the optically active chlorophyll bodies.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. F. C. Kempson, of Caius College, has been reappointed a Demonstrator of Anatomy for one year; and Dr. Elliot-Smith, Fellow of St. John's College, a Demonstrator of Anatomy for five years.

The work of Mr. W. Rosenhain, advanced student of St. John's College, which includes the joint Bakerian Lectures, with Prof. Ewing, delivered this year, has been approved for the University certificate of research.

Dr. Hill, Dr. Allbutt, Dr. Sladen, and Prof. Woodhead have been appointed representatives of the University for the organisation of a Congress on Tuberculosis to be held in London in 1901.

AT the annual prize distribution of the Merchant Venturers' Technical College, Bristol, on December 20, an address will be given by Sir W. H. White, K.C.B., F.R.S., Director of Naval Construction to the Admiralty.

WE learn from the *British Journal of Photography* (December 1) that Dr. Hans Harting, formerly of Messrs. Zeiss, of Jena, has joined the Board of Management of Messrs. Voigtlander and Sohn. He succeeds Dr. Miethe, who was recently appointed Professor of Chemistry and Spectrum Analysis at the Technical High School, Berlin.

THE annual prize distribution and conversazione of the Northampton Institute, Clerkenwell, will be held to-morrow evening, December 8. Sir Henry Roscoe will distribute the prizes. A comprehensive programme of exhibits and short lectures referring to the various sides of the Institute's work has been prepared. Dr. Walmsley will describe alternating currents; Mr. John Ashford, flying machines in fiction and fact; and Mr. A. W. Martin, high speed telegraphy. There will also be special demonstrations of liquefaction of air, alternate currents, ice-making, mortising by machinery, colour photography, rapid stereotyping, and other subjects.

THE *Pioneer Mail* announces that the Government of India have given their cordial approval to the Tata scheme for an India University of Research, recently formulated by a conference at Simla, and already referred to in these columns. As soon as all the details have been worked out, the necessary legislation for the incorporation of the new University will be undertaken. Meanwhile the Government of India commend the scheme to the liberality of the public, and wish it every success, while they acknowledge in the most cordial manner the public spirit shown in Mr. Tata's munificent endowment. The Government of Bombay will be asked to appoint an officer to arrange with Mr. Tata for the transfer of the property which is to constitute the endowment.

THE Calendars of University College, London, and the University College of Sheffield, for the session 1899-1900, have been received. In the former, the Dean of the Faculty of Science, Prof. T. Hudson Beare, refers to the part taken by the College in connection with the reorganisation of the University of London, and expresses pleasure that in the new University engineering is to be put on an equal with the sister professions, law and medicine, and that (if the draft statutes are adopted) it is to have its own Faculty and its own representatives on the Academic Council. A noteworthy addition to the Dean's report is a complete list, covering nine pages, of the original memoirs and writings which have emanated from the different scientific departments of the College during the past two years. In the Calendar of the University College of Sheffield it is announced that a bacteriological laboratory has been established, with a special demonstrator to devote the whole of his time to bacteriological investigations.

SOME interesting particulars with reference to the relative attention given to science in our secondary schools, as judged by the number of candidates who present themselves in scientific subjects in the public examinations usually taken by the pupils, is given in the December number of *The School World*. It appears that in January of this year, of 1250 candidates examined for matriculation in London University, 842 selected a language as their optional subject, and 408 a branch of science. The total number of candidates who were examined in the five optional science subjects was little more than half the number that selected French as the optional subject. At the last Oxford Senior Local Examinations, the number of papers worked in English subjects was 6977, in languages 2418, in science subjects 796; in addition to which 969 candidates took mathematics. In the Senior Cambridge Local Examinations in 1898, the number of papers in English subjects was 10,327, in languages 3391, in mathematics 1590, and in science 1838. Similar proportions are shown to exist among candidates who present themselves for other general examinations. The numbers show clearly that in most of our secondary schools science still occupies but a minor place in the curricula.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Microscopical Society, November 15.—Mr. E. M. Nelson, the President, in the chair.—Mr. C. L. Curties exhibited a new form of portable microscope by Leitz. It had a folding foot and a movable stage, to enable the instrument to be packed in a small compass. The body was not made to incline, but was furnished with coarse and fine adjustment, and the stage was fitted with a modified form of Abbé condenser, with iris diaphragm. The President thought the instrument would be useful to those requiring a very portable one; its great compactness was effected in an ingenious manner, while the working parts were well made and finished.—The President read a short note descriptive of a set of three simple hand microscopes on the Coddington principle sent for exhibition by Mr. Edward Swan. They were apparently made for a medical man, and could not be very old. Dr. Hebb said Prof. Groves had made some modification in the form of a hand microtome, and had sent it for exhibition. The President called attention to six photomicrographs of the larvæ of gnats, taken from life by Mr. J. T. Holder. The President exhibited an old Gillett condenser, dated July 20, 1849, which had a collar adjustment.—Dr. H. C. Sorby's paper on the preparation of marine worms as microscopical objects was read by the President in the unavoidable absence of the author. The subject was illustrated by beautifully mounted slides under microscopes.—The attention of the meeting was then directed to a fine exhibition of *Foraminifera* by Mr. A. Earland, shown under a large number of microscopes, with written descriptions explaining the points of interest in each slide.

Linnean Society, November 16.—Mr. G. R. Murray, F.R.S., in the chair.—Mr. J. E. Harting communicated particulars of several cases in which parrots had been poisoned by eating parsley. After commenting on instances in which plants that were innocuous to man had proved fatal to some of the lower animals, he mentioned in support of the converse case that the berries of the yew and privet, which are generally considered to be poisonous to man, were greedily eaten by blackbirds, thrushes, bullfinches, and other birds; while, on the other hand, several cases were on record of pheasants having been poisoned by eating yew leaves. The immunity of goats from yew poisoning was remarkable in view of the fact that deer and cattle died after eating the leaves of that tree, although it had been stated that the ill effects were due to the leaves having been eaten in a desiccated state, and not while growing on the tree.—Mr. W. C. Worsdell read a paper on the comparative anatomy of certain species of *Encephalartos*. The chief features of the anatomy were shown to be the presence of several vascular cylinders in the stem, a character found also in *Cycas* and *Macrozamia*; and the *medullary* system of vascular bundles, forming, as in *Macrozamia Fraseri*, Miq., a complex network, intimately united with a corresponding network of mucilage-canals. The system of mucilage-canals in the pith is continuous with that of the cortex, but the medullary bundles form an independent *primary* system. The mucilage-canal-system is probably of use as a storehouse of moisture during the dry season, when the roots and foliage die away.—Mr. W. T. Calman read a paper on a collection of *Brachyura* from Torres Straits. These Crustacea had been collected by Prof. Haddon on his first expedition to Torres Straits in 1888. It comprised about seventy-five species, three of which were described as new, namely, *Cryptocnemus Haddoni*, *Pilumnus cristipes*, and *Lambrus confragosus*. Among the species already known, concerning which some fresh details were given, was the minute parasitic *Hapalocarcinus marsupialis*. Although described forty years ago by Stimpson, it had escaped re-examination until now, notwithstanding that the curious gall-like growths to which it gives rise on corals are well known. The occurrence in this collection of the three known Indo-Pacific species of *Palicus* (*Cymopolia*), two of which have been recorded hitherto only from widely distant localities, afforded the author of this paper an opportunity for a detailed examination of their distinctive characters.

Geological Society, November 22.—W. Whitaker, F.R.S., President, in the chair.—On some remarkable calcisponges from the Eocene Tertiary Strata of Victoria (Australia), by Dr. George Jennings Hinde, F.R.S. The greater number of the sponges described were discovered by Mr. T. S. Hall, of Melbourne

University, in incoherent detrital beds of Eocene age, in the southern part of Victoria; a few were picked out of some washings of fragmental polyzoa from the same district and horizon, by Mr. B. W. Priest. Some of the specimens are in an extremely perfect condition, and their structural details are as distinctly shown as in recent sponges. They are also of more than local interest in that they are the first fossil forms described of a group of calcisponges, the Lithonina, characterized by the peculiar aberrant forms of some of the spicules, and the mode in which they are closely fitted and organically fused together to form the skeletal mesh. This structure has, so far, only been recognised in one recent species, *Petrostroma Schulzei*, Döderlein, from the Japanese sea. The sponges are small, unattached, with a glassy, firm resistant skeleton, calling to mind that of siliceous Lithistida. They are built up of a great variety of spicular forms, some are simple rods, with three and four-rayed spicules, similar to those in recent calcisponges; but the majority are aberrant four-rayed forms, with three of the rays curved and with obtuse or expanded ends which are clasped, and fused as well, to the surfaces of adjacent spicules. The connected spicules form continuous anastomosing or radial fibres resembling those in the fossil Pharetrones, to which they are in some other respects similar, and it is probable that the spicules in the fibres of some members of this family were likewise organically cemented together. The common *Porosphæræ* from the Upper Chalk, generally regarded as Hydrocorallines allied to the recent *Millepora*, are also closely related to the above sponges, and the author hopes shortly to publish the evidence for their affinity to this group. The Victorian sponges are placed in four new species, belonging to three genera: two of these are new, the other, *Bactronella*, Hinde, was founded on some peculiar calcisponges of Jurassic Age, now known to be Lithonine in character.—In the discussion which followed, Prof. Sollas referred to the importance of these sponges from an evolutionary point of view.—The Silurian Sequence of Rhayader, by Herbert Lapworth. The stratigraphical relations of the Silurian formations which occur in the country surrounding the town of Rhayader (Radnorshire) were described in detail. Typical and confirmatory sections were given, demonstrating the complete local sequence of the rocks of the Rhayader district. These were illustrated by lists of characteristic graptolites. These fossils were compared with those of Southern Scotland, Sweden, and North Wales, showing that the graptolite succession is everywhere similar, and fixing the age of the Rhayader series as representing the Lower Llandovery, Upper Llandovery, and Tarannon of other areas. Finally, several new species of *Climacograptus* and *Diplograptus* were described. Tables of fossils enabled the author to establish a complete comparison of the whole of the local zones of the Rhayader district with those of Southern Scotland, Wales, and Sweden. In the Rhayader area there is found, for the first time in Britain, the entire Valentian succession developed in one general sequence of rocks, with a more or less common lithological character and with a fauna composed throughout of similar palæontological types.

MANCHESTER.

Literary and Philosophical Society, November 28.—Prof. Horace Lamb, F.R.S., President, in the chair.—Prof. F. E. Weiss exhibited some specimens of *Melanospora parasitica* found by Mr. H. Murray at Flixton. This species is now known to be parasitic on another fungus, *Isaria farinosa*, which infests the larvæ and pupæ of various insects. The latter fungus (*Isaria*) is now recognised as being another stage of growth of *Cordiceps militaris*, which has been particularly common this autumn.—Report on the Marine Mollusca obtained during the Jackson-Harmsworth Expedition to Franz Josef Land 1896–97, by J. Cosmo Melvill and Robert Standen. The collection was formed by Mr. W. S. Bruce, naturalist to the expedition, mainly at Franz Josef Land, and at Kolguev, the results from the first-named locality being by far the most voluminous both in quantity and quality, and forming an important contribution to science as being the most northerly dredgings of Mollusca yet obtained in the Polar regions. Only one species—a *Buccinum* (*B. Brucei*) of peculiar form—is considered new to science, but a *Thracia*, of which only very imperfect valves were obtained, is also probably so; whilst a *Sipho* (*S. togatus*) is particularly interesting on account of its peculiar epidermis. Considering how fully the Arctic mollusca have been studied, especially during the past thirty years, the results of this expedition are very gratifying. The total number catalogued are Kolguev, 36; Franz Josef Land, 66. Naturally, the nearer the poles are attained, life—pelagic as well as terrestrial—is adversely affected; for instance, the total number of northern mollusca round the Norwegian coasts is, according to Sars, 460 species.

DUBLIN.

Royal Irish Academy, November 30.—The Lord Bishop of Canea, Vice-President, in the chair.—Mr. Trouton showed an apparatus with which he had determined the heat required to evaporate steam from saturated salt solutions. The plan adopted consisted of an inner vessel completely surrounded by a larger one. The same solution is placed in both. The outer one is kept boiling by the application of external heat; the inner by an electric heater. The steam from the inner vessel is collected and weighed. In this way by knowing the heat supplied electrically the latent heat is found. Determinations made with various salts were described. The connection was also considered between the latent heat of evaporation from salt solutions and the cooling which accompanies the solution of the salt in water. In addition an apparatus was shown by means of which the cooling can be observed, through bringing the salt and water together at a temperature higher than the boiling point. This consisted of two spherical vessels placed over each other and connected by a tube which passed through the upper to near the bottom of the lower one. By means of a stopcock connection is closed till required. The water is placed in the lower, the salt in the proper proportions in the upper one. The whole is heated in a thermostate to such a temperature that on mixing, the resultant solution falls to the boiling point. In the case of sodium nitrate this cooling was 40° C.

PARIS.

Academy of Sciences, November 27.—M. van Tieghem in the chair.—The Perpetual Secretary gave an account of the present state of the fund for the Lavoisier monument.—The propagation of a pencil of parallel light, limited laterally, in a heterogeneous transparent medium; integration of the equations of motion, by M. J. Boussinesq.—Experiments on the destruction of Phylloxera, by M. Lanfrey. An aqueous 1 per cent. solution of picric acid is applied during June, July or August. The same treatment may be advantageously applied to other fruit trees.—Observations on the Leonids made in 1899 at the Observatory of Lyons, by M. J. Guillaume. Fog prevented observation on the nights of November 14 and 15, but on November 12, 13 and 16, only twenty-six Leonids were noted.—Observations of the Leonids made at the Observatory of Algiers, by M. Ch. Trépied. The numbers observed were, on November 13, three; on the 14th, thirty-six; the 15th, thirty. Forty per cent. of the shooting stars observed did not belong to the Leonid swarm. The classification of the Leonids in order of magnitude showed that 10 were of the 1st magnitude, 22 of the 2nd, 19 of the 3rd, 9 of the 4th, and 6 of the 5th.—Observations of the Leonids at Algiers, by M. Harold Tarry. During the three nights 92 shooting stars were counted.—On the definition of the area of a surface, by M. H. Lebesgue.—On the number of roots of an algebraical equation comprised in the interior of a given circumference, by M. Michel Petrovitch.—On the generalisation of Lagrange's development in continued fraction of the function $(1 \times x)^m$, by M. H. Pade.—On the stability of equilibrium of floating bodies and particularly of a ship carrying a liquid cargo, by M. P. Duhem. Referring to a recent note of M. P. Appell on this subject, in which a paper by the author is quoted, it is here pointed out that this work was completed in a second paper, with results agreeing with those recently published by M. Appell.—Remark on the preceding communication, by M. Appell.—On the transmission of sound by electricity, by M. Dussand. A description of a microphone by which the spoken sounds can be transmitted with very slight loss of intensity.—On the chemical action of the X-rays, by M. P. Villard. The X-rays, freed from kathode rays by an aluminium screen, cause a violet coloration of the glass, apparently due to an oxidising action.—The action of dry hydrochloric acid upon silver and the reverse reaction, by M. Jouniaux. The interaction of hydrogen and silver chloride in sealed tubes was studied at various temperatures—350°, 440°, and 600°. A limiting value for the percentage of hydrochloric acid formed was found in each case, but the velocity with which this limit was attained differed greatly with the temperature, requiring several months at 250°, five weeks at 350°, seventy hours at 440°, and only one hour at 600°. Starting with the system silver, hydrochloric acid, a limit was similarly obtained for each temperature; but the final state of equilibrium was not the same as in the first case for temperatures below 600°. It is an example of the false equilibrium of M. Duhem.—On camphenylone, by MM. E. E. Blaise and G. Blanc. Camphene is treated with nitrogen peroxide at 0°, and the nitrate converted into camphenylone by treatment with potash. This ketone is treated with hydroxylamine, and the oxime dehydrated with acetyl chloride. The nitrite thus obtained gives on reduction a base, which is not identical with dihydroaminocampholene or the aminocampholenes. Hence camphenylone and its derivatives do not contain the trimethylcyclopentanic ring which exists in bodies belonging to the camphor series.—The colouring matter of digitalis, by MM. Adrian and A. Trillat. The new substance forms yellow needles, and has the composition $C_{16}H_{12}O_4$. It is very stable towards chemical reagents.—On an experiment relating to submarine currents, by M. J. Thoulet.—The resistance of seeds to high temperatures, by M. Victor Jodin. If seeds are gradually dried they will resist a temperature of 100°. Thus some seeds heated directly to 98° for ten hours were all killed; but if heated for twenty-four hours at 60° and then ten hours at 98°, from 30 to 60 per cent. of the seeds germinated.—On the glacial period in the Central Carpathians, by M. E. de Martonne. A detailed topographical study confirmed the views of Lehmann, showing undoubted signs of glacial action in the Carpathians.—The negative variation is not an infallible sign of nervous activity, by M. A. Herzen.—Cellular embolism, by MM. Charrin and Levaditi.—On a case of endothelioma of bone, by M. Paul Berger.

DIARY OF SOCIETIES.

THURSDAY, DECEMBER 7.

ROYAL SOCIETY, at 4.30.—Vapour-density of Bromine at High Temperatures: Dr. E. P. Perman and G. A. S. Atkinson.—Polytremacis and the Ancestry of Helioporidæ: Dr. J. W. Gregory.—Gold Aluminium Alloys: C. T. Heycock, F.R.S., and F. H. Neville, F.R.S.—On the Association of Attributes in Statistics; with Examples from the Material of the Childhood Society, &c.: G. U. Yule.—Data for the Problem of Evolution in Man. III. On the Magnitude of certain Coefficients of Correlation in Man, &c.: Prof. Karl Pearson, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—The Cost of Steam Raising: John Holliday.—Influence of Cheap Fuels on the Cost of Electrical Energy: R. E. Crompton. (Adjourned Discussion.)

LINNEAN SOCIETY, at 8.—On some Vegetable Poisons used for the Capture of Fish by the Australian Aborigines: J. W. Fawcett.—On some New Zealand Schizopoda: G. M. Thomson.—On the Structure of Porites: H. M. Bernard.

CHEMICAL SOCIETY, at 8.—Ballot for the Election of Fellows.—The Oxidation of certain Organic Acids in presence of Iron: H. J. H. Fenton, F.R.S., and H. O. Jones.—The Determination of the Constitution of Fatty Acids, Part II.: Dr. A. W. Crossley and H. R. Le Sueur.—On Sulphates of the Form R'_2SO_4, $2M''SO_4$, especially those of Isometric Crystallisation: F. R. Mallet.

RÖNTGEN SOCIETY, at 8.—Observations on Practical X-Ray Work, with Exhibition of Apparatus and Stereoscopic Skiagrams: Mackenzie Davidson.—Bullet in the Brain: J. Moore.

FRIDAY, DECEMBER 8

PHYSICAL SOCIETY (City and Guilds' Technical College, Leonard Street, Finsbury), at 5.—Cylindrical Lenses: Prof. Silvanus Thompson, F.R.S.—Exact Formulæ for Lenses: T. H. Blakesley.—On an Organic Compound of Great Double-Refraction: Prof. Silvanus Thompson, F.R.S.

ROYAL ASTRONOMICAL SOCIETY, at 8.—Note on the Values of the Coefficients of the Terms of the Third Order in the Lunar Theory: E. W. Brown.—Observations of the Leonids at the University Observatory, Oxford: H. H. Turner.—On the Proper Motions of Berlin B. 5072 and 5073: F. A. Bellamy.—New Nebulæ discovered Photographically with the Crossley Reflector of the Lick Observatory: J. E. Keeler.—Observations of the Leonids: Durham Observatory.—On the Relation between Magnetic Disturbance and the Period of Solar Spot Frequency: W. Ellis.—The Extra-Equatorial Currents of Jupiter in 1899: Rev. T. E. R. Phillips.

MALACOLOGICAL SOCIETY, at 8.—On the Anatomy of *Hemiplecta Floweri*, Smith, from Perak, with Notes on some other Eastern Genera: Lieut.-Colonel H. H. Godwin-Austen.—(1) Note on *Ampullaria Brohardi*, Granger; (2) Description of a New Species of *Leptopoma* from Borneo: E. A Smith.—Note on the Anatomy of *Zonites Rollei*, Kobelt: W. E. Collinge.—On some Recent Conchological Discoveries in Victoria: Mrs. A. F. Kenyon.

INSTITUTION OF MECHANICAL ENGINEERS, at 8.—A Continuous Mean-Pressure Indicator for Steam-Engines: Prof. William Ripper.

MONDAY, DECEMBER 11.

SOCIETY OF ARTS, at 8.—Art Enamelling upon Metals: H. H. Cunynghame.

ROYAL GEOGRAPHICAL SOCIETY, at 8.30.—A Journey through Abyssinia to the Nile: H. Weld Blundell.

TUESDAY, DECEMBER 12.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Combined Refuse-destructors and Power-plants: C. Newton Russell.

ANTHROPOLOGICAL INSTITUTE, at 8.30.—Survival in Primitive Rites of the Disposal of the Dead, with special reference to India: Wm. Crooke.

ROYAL PHOTOGRAPHIC SOCIETY, at 8.—(1) Notes on the Use of the Dallmeyer Focometer; (2) The Origination of Printing Types by Photographic Methods: T. Bolas.

WEDNESDAY, DECEMBER 13.

SOCIETY OF ARTS, at 8.—Sea Angling and Legislation: F. G. Aflalo.

THURSDAY, DECEMBER 14.

ROYAL SOCIETY, at 4.30.

SOCIETY OF ARTS, at 4.30.—Round about the Andamans and Nicobars: Colonel R. C. Temple.

MATHEMATICAL SOCIETY, at 8.—Sums of Greatest Integers: G. B. Mathews, F.R.S.—Note on Circular Cubics: A. B. Basset, F.R.S.—Formulæ involving Central Differences; and their Application to the Calculation and Extension of Mathematical Tables: W. F. Sheppard.—On the Expression of Spherical Harmonics as Fractional Differential Coefficients: J. Rose-Innes.—The Genesis of the Double Gamma Functions: E. D. Barnes.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Discussion on Mr. Crompton's and Mr. John Holloway's Papers.—Electrical Time Service: F. Hope-Jones.

FRIDAY, DECEMBER 15.

EPIDEMIOLOGICAL SOCIETY, at 8.30.

INSTITUTION OF CIVIL ENGINEERS, at 8.—On Sludge: Blamey Stevens.

CONTENTS. PAGE

THURSDAY, DECEMBER 14, 1899.

THE HISTORY OF GEOLOGY.

Geschichte der Geologie und Paläontologie bis Ende des 19.Jahrhunderts. Von Karl Alfred v. Zittel. Pp. xi + 868. (München und Leipzig: Druck und Verlag von R. Oldenbourg, 1899.)

WHEN the illustrious author of the "Handbuch der Palæontologie" undertook to write this history of geology and palæontology, he entered upon no light task, for special difficulties must attend the labours of any author who, in bringing together material to illustrate completely the rise and development of these wide-embracing sciences, would produce a volume acceptable to professionals and laymen alike. For such a task as this Prof. Zittel, by his wide scholarship and long experience as a teacher, no less than by his acquaintance with an abundant special literature and his proficiency as a linguist, is eminently qualified; and the work before us amply shows those evidences of patience, thoroughness, and indefatigable zeal, which have characterised the previous literary undertakings of its author. Some idea of the labour involved in the preparation of this volume may be gained from the fact that upwards of 2000 authors receive mention in its pages: it may be doubted indeed whether a single writer whose work has had important bearing on the development of geology in its various branches has been overlooked, while many, the significance of whose labours is unquestionably small, are here accorded recognition. As stated in the author's prefatory remarks, the original scope of the work, which was primarily intended to comprise a history of geology in Germany, was subsequently extended, in accordance with the necessity of treating from a wider standpoint the development and progress of a study to the growth of which all civilised nations have contributed.

The difficulties of expediently arranging so vast an amount of material as that embodied in this work have been perhaps most aptly met by the general plan, chronological and categorical, here adopted. The book is divided into four main sections, each dealing with a given period in the history of the science; and while these periods are of very unequal length, their limits have been so chosen that the mass of detail dealt with under more special headings may be advantageously grouped, thus enabling the reader to obtain the more readily a connected idea of the successive advances made in the study of the subject in its various departments.

The first section, comprising only a few pages, is principally devoted to the works of the ancient Greeks and Romans, and it is clearly shown in what small degree the labours of these early writers have furnished sound foundation for the development of geology in later times. In a short introduction to the second section the author points plainly to those causes which for so many years effectually retarded the progress of scientific thought and discovery, and gave rise to that intellectual lethargy which only became dissipated at the close of the middle ages. The early opinions regarding the nature of fossils, the origin and history of the earth, and the phenomena of volcanoes and earthquakes, are then successively discussed; and it may be well to indicate here the method adopted by the author in dealing with the work of the numerous observers and writers in these various branches of the subject, for the manner of treatment here employed is more or less closely adhered to throughout the succeeding portions of the book. For the most part under special sub-headings, the work of successive contributors to the science, when the names of these are deserving of more than mere mention, is concisely and impartially summarised, and numerous useful biographical footnotes have been appended. In many cases criticism is totally withheld, and the treatment of the material is in great measure purely objective. In illustration of the thoroughness and impartiality with which the author has carried out his work, we note the space accorded in this second period not only to writers such as Steno, Lehmann, Füchsel and Guettard, whose work has marked important points of progress in these earlier days of geological science, but also to others—for example, Fallopio, Burnet and Justi—whose almost valueless efforts consisted so largely in the proposal of wildly fantastic theories.

The third section, under the happily chosen title "Das heroische Zeitalter der Geologie von 1790 bis 1820," deals with a period which was witness of such remarkable activity in the study of geology; a period during which, indeed, the foundations of the science as we know it to-day may be said to have been laid. Here are to be found some of the most fascinating pages in the book, and the sketches of Saussure, Werner, v. Buch and Humboldt may be cited as examples of apt and terse delineation. But in a work of such wide scope as the one before us, brevity must of necessity characterise the condensed accounts in which are set forth the achievements of these and of other men whose influence has left its indelible mark in the onward march of the science, and we must not look for that degree of fulness and literary embellishment to be found in works of narrower limits, as, for example, in the admirable sketches furnished by Sir Archibald Geikie in his "Founders of Geology." If, in Prof. Zittel's account of Werner and his work, we perceive a certain reluctance to estimate at its true value the detrimental effect produced for a time by the hotly promulgated and falsely based theories of that influential teacher, we speedily find compensation in the eulogistic narratives of Hutton and Playfair, whose philosophical ideas were so effectually opposed to the baneful dogmatism of the Freiberg school.

The development of stratigraphy during this period is dealt with at considerable length, and the progress made in each country receives separate treatment. Prominent amongst the many workers whose labours here find ample record are Freiesleben, v. Buch, Ebel, Brongniart, Cuvier and William Smith. The early development of petrography is then traced, and the views held respectively by the neptunists, vulcanists and plutonists are briefly discussed. In following the progress of palæontology during this time, the author first draws attention to works of a more general character, such as those of Schlotheim, Defrance and Parkinson, and then proceeds to indicate the advances made by the publication of more special work confined to the consideration of single classes of animals. With the exception of the important labours and influence of Cuvier, to which both merited tribute and critical consideration are here accorded, this portion of the subject is dismissed with a scantiness of treatment that is somewhat disappointing. In this work geology and palæontology are dealt with together, in correspondence with the fact of their close association and concurrent development, for it is only of comparatively recent years that the study of palæontology has come to be rightly regarded in its true relation to that of zoology.

Fully three-quarters of the volume are occupied by the fourth section, dealing with the newer development of geology and palæontology, and for convenience of treatment the large mass of material here to be incorporated is divided into seven chapters. In the first three of these the more recent advances in the study of cosmic, physiographical and dynamic geology receive careful and detailed attention. In the third chapter we are presented with an excellent summary of the work of Lyell; while from a good epitome and brief criticism of Suess's "Antlitz der Erde" we learn in what high estimation that work is held by Prof. Zittel. The chapter on the development of dynamic geology is throughout exhaustive; but in attempting to give credit to the work of so many contributors, the author must often impose a tax on the attention of his readers. This will be noticeable, indeed, in all these later chapters of the book, when the historian has approached a period in the development of the science marked by an ever-increasing prolificacy in the production of special publications, and as a result of this effort to give recognition to a legion of authors great and small, the pages show a tendency to become burdened with the mere lists of names of many who have contributed to our knowledge in the respective branches of the subject. A chapter devoted to topographical geology, in which the most prominent position is accorded to Germany, gives useful information regarding the growth of geological surveys.

The three concluding chapters deal with the more recent development of stratigraphy, petrography and palæontology. In tracing the growth of stratigraphy, the several geological systems are separately treated, and the Triassic System is dealt with at greatest length. The development of study in the Alpine Trias here finds a prominent place, and in this connection it is noteworthy that Prof. Zittel, even when recounting the progress of a recent warmly-conducted polemic discussion on a question of nomenclature, has succeeded in preserving neutrality. Chapter vi. furnishes a brief though comprehensive account of the later development of petrography, in which the principal work of recent years, for the most part without criticism, is recapitulated.

The volume concludes with an account of more recent labours in palæontology, but it must be with a feeling akin to disappointment that we complete the perusal of this portion of the work. In a chapter dealing with that subject in which Prof. Zittel has acquired his well-merited reputation as the leading authority, the method and fulness of treatment fall below our expectations. The endeavour to refer, though it be by mere mention, to so much that has been of recent years accomplished in this department, and this at the risk of reducing a certain proportion of the text to the character of a mere compendium of authors' names, is here too plainly apparent. By this objective presentation of details the author must in great measure forfeit that interest which a broader and more critical treatment would have commanded.

Great care has been bestowed in editing this work, and such errors as the misspelling of the name "MacCulloch" on p. 165, and the omission of two reference numbers on p. 793, are of rare occurrence. Carefully quoted literature references have been appended, on the whole, with sufficient liberality; but the author's apology for devoting so much space to this purpose appears superfluous, and it must be obvious, especially when looked at from the student's point of view, that frequency in referring to original sources of information can only enhance the value of a book of this kind.

Little need be added in recommendation of this comprehensive work; the terse and lucid style of its author will commend it to English readers. By the completion of his arduous task, Prof. Zittel has well supplied a long-felt want, and all who interest themselves in the study of geology, towards the development of which Great Britain has so conspicuously contributed, will warmly welcome the appearance of this volume from the pen of one who takes rank among the ablest living expounders of a noble science.

F. L. K.

THE FLORA OF NEW ZEALAND.

The Student's Flora of New Zealand and the Outlying Islands. By Thomas Kirk, F.L.S. A Fragment. Pp. vi + 408. Large 8vo. (Wellington, N.Z., 1899.)

List of the Genera and Species of New Zealand Plants. By A. Hamilton. (Wellington, N.Z., 1899.)

IT was well known in botanical circles that the late Prof. Thomas Kirk, of Wellington, New Zealand, who died about a year ago, had long been engaged in the preparation of a comprehensive, descriptive, and illustrated work on the flora of that country; and it was a great disappointment when it transpired that he had left his work in an unfinished state, because it was felt that it would be extremely difficult, perhaps impossible, to find another botanist so well qualified for the task. Prof. Kirk spent some thirty years of his life in the investigation of the flora of his adopted country, and his various writings thereon betoken the careful and accurate botanist. From time to time he published the new species discovered by himself and others; but his fully illustrated "Forest Flora of New Zealand" gave evidence of the extent of his knowledge of his subject. A more remarkable and, in a scientific sense, a more important contribution to the botanical literature of New Zealand is contained in an address delivered before the Philosophical Society of Wellington, N.Z., a few years ago (see *Transactions* of the New Zealand Institute, vol. xxviii.). In this address he dealt with the "Displacement and Replacement of the Native Vegetation of New Zealand" in such a manner as to be of permanent value to science. He has there put on record facts connected with the introduction and colonisation of exotic plants in New Zealand that positively throw a new light, and suggest new ideas, on the present distribution of plants in cultivated countries generally. Fortunately the botanical investigation of New Zealand was begun before its settlement by Europeans; and it has been continued by a small band of them with such ardour and exactitude, that future workers in the field have a substantial foundation to build upon. In the absence of authentic records, the present conditions in the vegetation of the country could not have been understood. Kirk estimated that about 500 exotic species of plants had become more or less completely established in New Zealand; and they are spread all over the country, from the sea-coast almost to the altitudinal limits of vegetation. But the most surprising part of it is the extent to which vigorous native plants have been displaced by comparatively delicate foreigners; and it would indeed be incredible in the absence of indisputable evidence. However, I must not pursue this subject here, and I have only alluded to it in connection with the plan and scope of the fragment of Kirk's "Flora" before me. The Government wisely decided to publish so much of this work as was printed off, or ready for the printer, at the time of the author's death. This contains the natural orders Ranunculaceæ to Compositæ, in the sequence of Bentham and Hooker's "Genera Plantarum"; and its value only makes one wish that the author had lived to complete it. Perhaps the only serious criticism one could fairly bring to bear upon the work before having had considerable practical experience in using it for the determination of species, is its size and weight, which would preclude its being used in the field. Rather less than half of the known flowering plants (671), and 260 introduced plants, are described on some 360 pages. Completed on this scale it would make, with glossary, index, &c., at least 850 pages. By using a smaller type with less spacing, and a lighter paper, it would be possible to reduce the book to pocket dimensions. This objection has been raised here, because we believe the New Zealand Government is making arrangements with another botanist to write a complete Flora.

It might be suggested that the introduced plants should be left out; but, considering that they constitute something like a third of the number of species occurring in a wild state, that some of them are dispersed from one end of the islands to the other, and that in some districts or localities introduced plants preponderate, it is as absolutely essential that they should be included as that the European element should figure in any account of the present inhabitants of New Zealand. To begin with, the young student cannot distinguish between the introduced and indigenous elements. To the beginner, one is as good as the other, and, as a matter of knowledge, to know the one is of as much importance as it is to know the other; and we think it would be a grave mistake to exclude the foreign element from a book treating of the flora of the country. Kirk gives less detailed descriptions of them, and prints them in a smaller type, so there is no difficulty in distinguishing between the two.

When we come to consider the question, "What have the discoveries made since the publication of Sir Joseph Hooker's 'Handbook of the New Zealand Flora,' in 1864, added to our knowledge of phytogeography?" the answer must be "next to nothing." Perhaps the most interesting thing in this connection is the discovery of a number of Tasmanian species, especially on Stewart Island, in the extreme south. The outlying islands, such as Macquarie, Antipodes, and the Kermadecs, have been more fully explored; but the results merely go to strengthen the previously conceived idea that the highest southern vegetation, like the highest northern, is very much the same all round the world.

With regard to botanical discoveries in New Zealand since 1864, it may be truly said that they are of comparatively little interest. Only one new generic type (*Tetrachondra*) of a really distinct character has been found, and this is a minute herb, having the habit of *Tillaea*. It is of anomalous structure, and has been provisionally placed in the Boraginaceæ, though it has opposite leaves. Two new genera have been proposed for species formerly referred, in part, at least, to the curious leguminous genus *Carmichaelia*. The differential characters are chiefly in the form of dehiscence of the pods. Perhaps the very rare and imperfectly known *Siphonidium*, allied to *Euphrasia*, deserves generic standing, but it is almost certainly a congener of Hooker's section *Anagosperma* of *Euphrasia*, which has recently been raised to generic rank.

Coming to species, it is true that the number has been nominally increased by upwards of one-third. In other words, more than 500 species of flowering plants have been proposed in addition to the 935 described by Hooker; but of these probably not less than a third will prove untenable. For instance, in *Olearia*, Kirk retains thirty-four species, and reduces a dozen of the so-called new ones. As compared with what was previously known, there are few striking plants among the recent discoveries. The majority of the new species belong to such familiar genera, of almost world-wide range, as *Ranunculus*, *Epilobium*, *Senecio*, *Veronica* and *Carex*, and to such characteristic Australasian genera as *Coprosma*, *Olearia*, *Celmisia*, *Carmichaelia* and *Astelia*. Among Australian genera, not previously found in New Zealand (as distinguished from Australasian), new or old species have been recorded of *Actinotus*, *Liparophyllum*, *Caleana* and *Calochilus*.

I have not entered into strict criticism of the late Prof. Kirk's work, because, had he been spared, he might have corrected errors and made good many omissions; but I may mention that the derivation of generic names is partially given; the same of the native countries of introduced plants; several published names have been overlooked; and a key to the species of *Oxalis* is wanting.

The illustrations referred to in the opening sentence of this notice are to be issued in a separate volume. They will include the unpublished Banksian copper-plates of New Zealand plants, kindly placed at the disposal of the New Zealand Government by the Trustees of the British Museum. I may note in this connection that the Trustees have now made provision for the reproduction of the whole of the valuable collection of plates, about 700 in number, engraved at the expense of Sir Joseph Banks, but never printed; and illustrating the botany of Cook's voyages.

In conclusion, I may add that Mr. Hamilton's list of the flowering plants will be found useful, as it contains references to the place of publication, mostly in the

Transactions of the New Zealand Institute. In consequence of the want of a good botanical library, some species described in European publications are not included. W. BOTTING HEMSLEY.

ENCYCLOPAEDIA BIBLICA.

Encyclopaedia Biblica. Edited by Rev. T. K. Cheyne, D.D., and J. S. Black, LL.D. Vol. i. A to D. Pp. xxviii + 572. (London: A. and C. Black.)

IN this work we have an illustration of the fact that similar ideas spring up contemporaneously in different minds. In the same year in which Dr. Hastings' "Dictionary of the Bible" reaches its second volume extending to the letter K, we have the first volume of the work here under review issued to the public. Both have their source and publishers in Edinburgh, testifying to the high interest which Scotland has ever shown in Biblical criticism and Biblical subjects. To us it appears that both works are very much on the same lines, though the writers of the articles are for the most part different, and include those of other nationalities besides British. It would be difficult to say why one of these works takes the title of an "Encyclopædia" and the other of a "Dictionary," as the articles in both are equally elaborate and comprehensive. Perhaps, in the case of the latter, the idea of a dictionary, as first contemplated, gradually expanded in the minds of the editors, and under force of circumstances, till it became merged in that of an encyclopædia; the more recent work has had the advantage of starting with the more ambitious title. Both works, however, have had their origin in the late Dr. Smith's invaluable "Bible Dictionary," which for many years past has been a companion to students of Holy Scripture. But so great has been the advance in the critical study of the sacred pages, as well as in our knowledge of Bible lands, for which we are largely indebted to the labours of the committee of the "Palestine Exploration Fund," that a new work embodying these investigations has become a necessity which the authors of both the Dictionary and Encyclopædia have endeavoured to meet.

In looking over the subjects bearing upon natural history and topography within the compass of this volume, extending to the letter D, we observe little that requires criticism. The word "adamant" is considered to be corundum rather than the diamond, which was unknown out of India till the time of Alexander's successors; at the same time it is not impossible that the stone translated diamond in Exodus xxviii. may have been simply quartz, or rock crystal, which is inferior in hardness to either corundum or the diamond, and, therefore, capable of being engraved with the name of one of the tribes. Needless to observe that the rendering into Greek, Latin or English of the precious stones of the Old Testament will ever be attended with much uncertainty.

The description of the Dead Sea by Prof. Gautier is lucid and correct as regards its present condition; and we are glad to observe that he gives no countenance to the view that the waters of the Jordan once ran into the Gulf of Akabah, which would have required that their surface n the position of the Dead Sea must have risen, not only to the level of the Red Sea and Mediterranean, which was the case, but higher by about 650 feet; of this supposed high level there is no evidence in the form of old terraces in the Arabah Valley, as is the case with regard to the Mediterranean level. The geological changes which have brought about the formation of the Dead Sea basin may be looked for in a future volume, under the head of Palestine.

Under Deluge the various myths and legends found in countries widely separated are related in much detail by Dr. Cheyne and Prof. Zimmern. That the Hebrew tradition, as contained in Genesis, had its origin in Babylonia there can be no doubt, as the late Mr. George Smith has shown in his remarkable work, "The Chaldean Account of Genesis" (1876). But the question still remains to be decided—whether the original story had its origin amongst a myth-generating people or in the tradition of an actual physical catastrophe, such as a great inroad of the sea due to subsidence of the land in prehistoric times. This latter is the view taken by Lenormant in "Les Origines de l'Histoire," supported by Sir J. William Dawson, and more recently by Sir Joseph Prestwich. The Biblical story of the Deluge is necessarily restricted to the Euphrates Valley; but the more widely extended tradition seems to imply a more extended region wherein there was a submergence of the lands during the human period. Of such submergence we have ample evidence in many countries, including the British Isles, Northern Europe and Scandinavia, the Nile Valley, and Western Palestine. Such movements have left their vestiges in the high-level gravels with existing shells, and are certainly of more recent date than the early Glacial stage, the close of which may be assigned as the age of man. According to Dawson, this subsidence of the land after a period of high elevation brought about the extinction of palæocosmic man, an inhabitant of caves, and a mighty hunter before the Lord, like Nimrod. We must beware of watering down what is really founded on a historic basis in the Bible into legend. When we find the patriarch Abraham treated "not so much an historical personage as an ideal type of character, on the ground of the 'dreamy, grand, and solemn' impression which this patriarch makes upon us," we may well pause and ask whether this process of idealism is to extend to succeeding characters, such as Isaac, Jacob, Moses, David and the rest; and whether the whole of the Old Testament is not to be regarded in the same light as the "Æneid," the "Odyssey," or "Paradise Lost"? We protest against this extravagance of criticism. Whatever may have been the mythical origin of the earlier chapters of Genesis, the historical narrative clearly commences with the call of Abraham, and the history of that "grand personage" claims to be treated with as much scrupulous deference as any personality of ancient history. As Prof. H. E. Ryle observes—

> "the endeavour to find in Abraham's story a philosophical description of abstract qualities seems to presuppose a stage of literary development to which the materials of the Hexateuch can make no claim, and to desiderate a literary unity which those materials emphatically contradict."

With such exceptions as the above the work must be accorded very high literary merit coupled with wide research. E. H.

OUR BOOK SHELF.

Statistical Methods; with special reference to Biological Variation. By C. B. Davenport, Ph.D. Pp. vii + 149. (New York: John Wiley and Sons. London: Chapman and Hall, Ltd., 1899.)

THIS little volume is a kind of "Molesworth" for the statistical biologist. Some two-thirds of the book are taken up with numerical tables (ordinates of normal curve, probability integral, gamma functions, squares and cubes, logarithms, &c.), a brief introduction, giving an outline of methods and formulæ, occupying only the first fifty pages.

The idea is a good one, and the tables, collection of formulæ, &c., are arranged in a handy form. The introduction should, however, be subjected to revision before the next issue. The sentence on p. 19, "Here x is the actual deviation from the mean expressed in the unit of the maximum," appears to be an abbreviation of "x/σ is the deviation from the mean expressed in the unit of the standard deviation, and y/y_0 the ordinate in the unit of the maximum," or some such sentence. The y_0 on p. 22 should be defined as the ordinate at the origin, not the mode; it is not the modal ordinate, *e.g.*, in Type IV. The methods of measuring correlation do not necessarily depend on the assumption that the frequency-distribution is normal (p. 30). The author does not appear to have fully grasped the physical meanings of correlations and regressions, as he speaks of them as interchangeable (p. 36), for the correlation coefficient always measures the approach towards a single linear law true for every case, and ranges only between ± 1, while the regression coefficient measures the average alteration in one variable corresponding to unit alteration in the other, and may take any value. The word "binomial," on p. 38, appears to be a misprint for bimodal. On p. 33 we notice a lengthy method, quoted from Duncker, given for reducing the product-sum; this should be replaced by the ordinary straightforward process of reduction to the mean. The definition of the probable error, on p. 14, needs revision; it is not a measure of "closeness of approximation to the truth," but of degree of unreliability.

In a subsequent issue the author might reconsider the question of retaining some sections. New and untried suggestions of measurements and indices are, in our opinion, somewhat out of place in a reference pocket-book. These remarks apply to some sections of chapter i. and chapter iii. ("Index of Isolation"), &c., and from the same point of view the brief chapter v. is hardly necessary.

The selection of tables seems very good; the only addition we would suggest is a brief table giving probable errors of the correlation coefficient.

Evolution of General Ideas. By Prof. Th. Ribot Translated by Frances A. Welby. Pp. xi + 231. (London: Kegan Paul and Co., Ltd., 1899.)

PROF. RIBOT is a leading exponent of the newer experientialism which, having mastered the lesson of evolutionist theories, declares for continuity through transformism. All that he writes is lucid and suggestive, and the course of lectures here translated is a characteristic contribution to psychology.

A dissociative act of attention brings some one element in a presentation into high relief, while reducing the rest by impoverishment to a residual form. This is abstraction, and, where we have a fusion of abstracted resemblants, we get generalisation. These processes have three stages: first, that to be found in brutes, infants, and deaf-mutes. With these we have the generic image, best known through the composite photograph. We have what is sometimes called inference from particulars to particulars, and we have analogy. But there is no use of the sign, no method involving substitution. Second, a phase of mean abstraction, where the image is associated with the word, increasing stress being laid as we proceed upon the latter, though it never becomes a pure symbol. Third, a stage of advanced abstraction, where the accompanying perceptual imagery is already symbolic, while at last there is no consciousness of any.

The second stage is introduced by a chapter on speech, which is of some interest. The third is discussed in relation to Prof. Ribot's personal inquiries into types of ideation. When asked for replies within a few seconds as to what they experienced when such terms as "cause" and "animal" were suggested, more than a hundred persons gave answers, of which the visualisation of the printed word, the sound of the spoken word, and alleged vacuity were the farthest from unsymbolic picturing. He seems not to have come across the "Je ne pense qu'en parlant" type. His connection of the *flatus vocis* of extreme nominalism with verbal imagery reminds us of his clever association elsewhere of Berkeley's idealism with visualisation. In his insistance that symbolic or substitutional thought implies the actual existence of that for which it is substituted, he shows the dependence for him of psychological appearance upon a wider psychophysiological reality, and effects the transition to a future treatment of the unconscious. In a further chapter Prof. Ribot traces the development of such concepts in the algebra of thought as space, time, cause. Here, as in his account of the universal as such, he is handicapped by the exclusion of epistemological and metaphysical considerations. A short paragraph would have shown the irrelevance of Kant's apriorism for a psychology such as the present. The notes on metageometry are too short if they are to find a place at all. Some of his terms trespass on other people's rights, *e.g.* "the *logic* of images," "schema." The translation is well done, though probably "experiential" would be better than "experimental" in more than one place.

H. W. B.

Handbook of Optics for Students of Ophthalmology. By Prof. William Norwood Suter, B.A., M.D. Pp. viii + 209. (London: Macmillan and Co., Ltd.)

Optics: A Manual for Students. By A. S. Percival, M.A., M.B. Pp. x + 399. (London: Macmillan and Co., Ltd.)

PROF. SUTER gives a simple and yet clear account of the science of optics, as applied to the most important problems connected with ophthalmology. The study of the eye as an optical system has many points of interest, both for the physicist and for the medical student. In many works on optics only scant consideration is given to this part of the subject, so that the book before us may be said to fill a recognised gap in scientific literature. Its value would have been greatly enhanced, however, if measurements in connection with the various optical constants of the eye had been considered in greater detail. Mr. Shelford Bidwell's researches on the formation of multiple images in certain circumstances, due to the cellular structure of the eye, might have been mentioned with advantage; but it is, perhaps, hardly fair to criticise a book of the dimensions of the one before us for errors of omission. A serviceable index has been provided.

In a few cases, the descriptions might have been improved. Thus, on p. 42, line 7, the expression "the planes perpendicular to the curved surfaces" should read "the planes tangential to the curved surfaces." On p. 37, line 10, the term "centre of the refracting surface" might be altered, with advantage, to the "centre of curvature of the refracting surface." Mathematical expressions such as the following (see p. 44) are likely to cause unnecessary trouble:—

$$AF_1 = \frac{r}{n-1} = F_1$$

where the symbol F_1 is used, in a single formula, to denote both the position of a point on the diagram, and the distance of that point from another point A. With a few such exceptions, however, Prof. Suter's book handsomely fulfils the purpose for which it was written.

The aim of Mr. Percival has been to supply the reader, within reasonable compass, with such a knowledge of optics as would be of use to an ophthalmic surgeon. The author further expresses a hope that mathematical students may find it useful as an introduction to more advanced works on geometrical optics. The subject is treated throughout, from a mathematical point of view, in a manner that leaves little to be desired. An ophthalmic surgeon might possibly prefer to have the subject presented less from the mathematical, and more from the physical point of view; whilst a student of physics would probably wish to see greater prominence given to experimental methods. Lord Rayleigh's investigation on the advantage of stopping out the middle of a lens, in preference to its peripheral region, is not mentioned. Further, the name of Helmholtz is not mentioned in connection with the ophthalmoscope. But the most serious blemish is the total absence of an index; this absence is particularly damaging to a book which, from its nature, should serve as a work of reference. The type and general structure of the book are otherwise admirable. A few sentences, such as the following, could be improved:—

"The *first principal focus* (F_1) is the point on the principal axis where the incident rays intersect, or would intersect if produced, which emerge from the system parallel to the axis" (p. 253, lines 6–9).

"The two nodal points are mutually the image of each other" (p. 253, lines 30–31). E. E.

A Practical Introduction to the Study of Botany; Flowering Plants. By Prof. J. Bretland Farmer, M.A. (London: Longmans, Green and Co., 1899.)

PROF. FARMER'S work is that of an expert dealing with a science with the details of which he is thoroughly familiar, both as a student and as a teacher. Its pages show the firm grasp that enables him to make clear even abstruse parts of the science, and that gives confidence to those who use the book with the care and close attention that it deserves. The plants employed as examples are excellently selected, and the necessity of verifying each point described upon the plant itself is constantly enforced. The discipline and information gained by any one that works honestly through the course of study here planned out will be found most valuable as a sure base on which to build up a thorough knowledge of botany. The woodcuts are good, but might have been more numerous with advantage to those that use the book without the aid of a teacher. In the absence of figures a beginner may, if unaided, find it difficult to obtain some of the plants named, though the selection has been very largely made from species that ought to be known to most people of ordinary education. The use of technical terms is restricted within due limits, and their meanings can be gathered from the examination of the specimens in connection with which each is first employed. The procedure to be followed in the examination of the specimens and in the experiments in physiology is simply and clearly explained, though here and there one meets with evidences of haste or pressure.

Primeval Scenes; being some Comic Aspects of Life in Prehistoric Times. By Rev. H. N. Hutchinson, B.A. Illustrated by J. Hassall and F. V. Burridge. (London: Lamley and Co., 1899.)

THE drawings in this volume are similar in character to the amusing "Prehistoric Peeps" contributed to *Punch* by Mr. E. T. Reed a few years ago. In preparing his drawings, Mr. Reed worked to produce striking effects; and as there is artistic as well as poetic licence, he was justified in introducing into his pictures any objects which would appeal to the sense of the ludicrous. But to the mind of the palæontologist, a picture containing prehistoric humans in company with such old forms of life as Pterodactylus and Stegosaurus, and creatures which had their origin in the artist's imagination, appears a trifle grotesque, though it may afford amusement to thousands of persons who do not understand the incongruity of the arrangement of characters depicted.

In the present volume an attempt is made to combine instruction and amusement by representing creatures in various comical aspects which were possibly all seen by some of our primeval ancestors. In other words, the drawings are in keeping with the discoveries of prehistoric archæology and the facts of geology. Twenty scenes are depicted, and adjacent to each is a brief description of the chief characteristics. The pictures are, in the opinion of the writer, not to be compared as regards their diverting character with Mr. Reed's inimitable sketches, and the descriptions which accompany them are of too general a character to call for criticism. But the scientific accuracy of the drawings in so far as they represent animals which are known to have been contemporaries of man is certainly a merit; and for this reason the book is a suitable present for a boy with scientific predilections and a lively imagination.

A Treatise on Surveying. Compiled by R. E. Middleton, M.Inst.C.E., and O. Chadwick, M.Inst.C.E. Part i. Pp. xiii + 283. (London: E. and F. N. Spon, Ltd., 1899.)

THIS work seems to have had its origin partly out of consideration for the needs of surveyors whose home-training is too restricted to qualify them for colonial appointments, where a knowledge of geodetic work is required, and has in addition no less an object than the raising of the standard of qualification for English diplomas in surveying. We are told that the Council of the Surveyors' Institute was approached by the authors and others interested in these matters, and agreed to adopt this text-book if satisfied with it, but we are left in doubt as to whether it has received the approval of that body.

A general idea of the scope of the present volume may be gathered from the titles of the chapters, namely, "chain surveying; optics, magnetism, &c.; description and adjustment of instruments; traverse surveying; minor triangulation; the plane-table and methods of using it; levelling and contouring." Geodetical and astronomical determinations, as well as marine, route, and other special surveys are left for the companion volume, so that the form of publication is well suited to the requirements of the two chief classes of students. We find the explanations of the various instruments, processes, and principles sufficiently full and clear, while sound practical methods of making and entering observations and presenting the final results are given throughout. No particular originality is claimed, but the special merit of the book lies in the great care with which the compilation has been made, and the thoroughly practical spirit which pervades it. It certainly makes a good bid for a place among standard text-books.

The X-Ray Case Book, for Noting Apparatus, Methods and Results. By David Walsh, M.D. (London: Baillière, Tindall and Cox, 1899.)

FORMS are provided for recording the electrical and photographic conditions under which Röntgen photographs of medical and surgical cases are obtained, and for the entering of notes on the points brought out by an examination of the photographs, or by visual observations with a fluorescent screen. Full diagrams of the human body are given for convenience in recording observations.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Proposals of the Stockholm Fisheries Conference.

As one closely connected with scientific fisheries work on the North Sea, I cannot help taking a keen interest in the proposals that emanated from the Stockholm Congress, and in the criticisms that have appeared in NATURE on those proposals. These criticisms have been decidedly adverse, and readers of this journal who take an interest in fishery questions and research, but who have not been in a position to obtain the knowledge necessary to judge fairly the points in dispute, will naturally feel somewhat perplexed over the difficulties that have arisen. As the matter is of the greatest importance to Great Britain, with its large fishing industry, this perplexity is to be regretted, because it is very necessary that something like unanimity should obtain amongst those who have charge of affairs. This unanimity will come with greater clearness on the points at issue, and in order to aid towards this clearness I would ask your permission to allow me to continue the discussion.

The criticisms on the proposals of the Stockholm Congress may be resolved into two portions—direct criticisms of an adverse kind on the proposals in part or as a whole, and counter-proposals which it is considered the British Government should accept in preference.

Under the first heading come the criticisms of Prof. Herdman, and with them we may begin. Prof. Herdman considers that too much stress is laid on the hydrographical and meteorological work than on the biological. Two reasons may be given for this criticism. Firstly, at the present time, the biological investigations of the fisheries in the North Sea are in certain respects in a more advanced state than the hydrographical and meteorological. On such questions as those of migration, for example, many facts have been accumulated and theories founded thereon, but we are at a loss to follow up the investigations and test the theories because trustworthy statistics of the meteorological conditions—direction of the surface and deep water currents, temperatures in different places at different depths, fluctuations in salinity, and so on—are utterly lacking. Hence, biologists should really welcome this work, and not object to its seemingly greater prominence. This work, however, was not intended to hinder the further prosecution of strictly biological research, and here we come to the second reason for Prof. Herdman's criticism.

He does not seem to have fully appreciated the scheme proposed by the Congress under the heading of "The Biological Work." He says: "Surely what we need most at the present time in the interest of more exact fisheries knowledge, is the nearest possible approximation to a census of our seas—beginning with the territorial waters. Most fisheries disputes and differences of opinion are due to the absence of such exact knowledge. . . . The Stockholm report unfortunately says nothing to the point in regard to all this."

Now, the Stockholm report states clearly and definitely what is wanted, and how we are to obtain it. Under "Biological Work," in addition to other practical recommendations for the taking of this "census," under Parts I. and II., III.(*a*) and III.(*b*), run:—

"It is desirable to collect uniform statistics of the number, weight, and value of the fish landed, of the means of capture, and of the persons engaged in the industry; for example, as in the General Reports of the Scottish Fishery Board."

"It is desirable to collect material for the preparation of maps, showing the fishing grounds and the kinds of fishing there practised."

Under "A.—The Hydrographical Work," further recommendations are given under VI.–X. as to the taking of the "census." As these recommendations are quite clear, and fully cover the ground of all research into the total numbers of fish, the varying numbers at different times and places, as well as the total quantities of the different forms of fish-food and their fluctuations at different places and seasons, it seems impossible to ask for anything more. What more does Prof. Herdman see under the word "census"?

That Prof. Herdman has not fully weighed the scheme proposed is again shown in his statement, "Part of the report is called a programme of work, but it contains no definite programme of biological work." It is needless to discuss this until we have Prof. Herdman's conception of a "definite programme" before us, and then we shall be able to compare the two. If Prof. Herdman can show a better, more definite and workable programme, it is only right that he should do so after passing such criticism on the other.

"In my opinion," says Prof. Herdman, "what we want is not conferences, or committees, or a central bureau, so much as boats and men, *and work at sea*." This catches the eye at once as being eminently practical, but surely Prof. Herdman does not mean that the Congress did not contemplate the use of "boats and men, *and work at sea*"? But he fears evidently that an "opportunity" is being lost because the Congress has advocated the formation of the central organising body before starting to actual work. But where so much has to be done, so many different studies to be organised, so many different arrangements and experiments to be made, we should rather approve of the methodical and calculating arrangements of the Congress, even though for the moment progress is *seemingly* slow, just as we approved of the slow but certain progress of General Kitchener to Khartoum.

As Dr. Murray has ranged himself with Prof. Herdman in his criticisms, and as his proposals can be discussed under those of Mr. Allen, I trust he will not think it from disrespect that I pass on now to the points raised by Mr. Allen. These have been thought out with great care, and one cannot but acknowledge his fair and generous method of treating the subject. The general plan of the investigations is approved of, and only on minor points can there be differences of opinion. The matter of the areas of investigations will assuredly come under reconsideration, as he suggests. The only question—and the chief one—that will repay discussion, is that of the "central bureau."

Mr. Allen recommends that the British Government, in order to give effect to the proposals of the Congress, should first of all co-ordinate the work of the different stations in the British Isles. (Would this not harm their "originality"?) When this is done, the "essential requirements" are a sufficient number of capable naturalists and sea-going steamships efficiently equipped. The experts of the different countries would meet once a year in order to co-ordinate the investigations and insure uniformity of method This scheme is contrasted with that of the Congress, and it is maintained that the establishment of a "central bureau" is too elaborate and expensive.

Now, if Mr. Allen had restricted himself to asking further particulars regarding the central "laboratory," one would have taken no exception to his remarks; but since he objects to what seems very necessary—namely, a central body to organise and keep the different researches and departments in actual touch with one another, to do the secretary work and look after the printing of reports, &c.—one must turn and ask what he intends to put in its place. Mr. Allen surely does not think that a meeting of experts once a year is equally adequate?

Until Mr. Allen unfolds this part of his scheme a little further, we may regard certain other aspects of it. No one will deny that the co-operation of the various marine stations in England for definite fisheries work would be of immense value; but why has this not been considered and done before? Again, if this scheme were effective and less expensive than that proposed by the Congress, would the representatives of the other countries not have taken it into consideration? These representatives have had much greater experience of fishery work than Mr. Allen has had, and a much better notion therefore of what is needed, and it is unlikely that they would ask their Governments to pursue a course which is more expensive than another equally effective. This is said without intending any disrespect for Mr. Allen; it is merely drawing a comparison between two experiences, and the comparison tells against Mr. Allen.

Again, is Mr. Allen's scheme workable and adequate to the work that is wanted? It should be remembered that Great Britain has not been asked to co-ordinate its various small marine stations, however desirable this may be. It has simply been asked to carry on a certain programme of work for a period of five years at least. The course of events, let us imagine, will be somewhat as follows:—The Scottish Fishery Board will be asked by Government to carry on a certain amount of routine hydrographical work, with the instruments suggested and the methods proposed, at certain periods of the year over the area prescribed, also biological plankton investigations similarly. What extra expense this will be to the Board it is not for me to say; but with its staff and knowledge of the methods to be employed, the experience and equipment it has at its command, this will not be anything very great. There is no necessity here for co-ordinating, first of all, the work that might be done at St. Andrews, Millport, and Granton. These places will carry on their own work in their own way, because biological research must always be acceptable. But, if the Fishery Board should desire any special work to be done at those stations, it has the staff, the knowledge of ways and means, and the funds at its disposal, and the work will be done.

England, unfortunately, is not prepared to the same extent. It has no central body whose knowledge and experience of fishery work in this and other countries could command the co-operation of the different stations. It is doubtful also whether the biologists in England have worked on the methods suggested by the Congress. If so, they have not yet published any results. They are so far removed, further, from the centre for work, viz., the North Sea, that their work is formed on a different plan; they have not the same aims, and they do not look at fishery problems as the biologists along the coasts of the North Sea do. And it is a curious comment on this condition of England, that on its East Coast—from which as much fishing is carried on, and where the value of the fisheries is as great, as in all those of the other countries round the North Sea combined—it is curious that there is no station there which can adequately take up the work proposed, and that a great part of this coast is ascribed to Holland as within its area of investigation. All this is said without intending any disrespect whatsoever to Mr. Allen, but it comes to one's mind in reading over his proposals.

The co-operation of the marine stations in England would not remedy this. "A central bureau" for England alone would require to be established, with experienced trained men at its head. This would take much time and money, and when Great Britain has been offered a "central bureau" of more power and value at a less cost, there can be little doubt for which the Government will decide.

Without intruding further upon your space by entering into the advantages of the organisation proposed by the Congress, and of co-operation with foreign countries, let me, in conclusion, express my earnest desire to do justice to both sides. If Prof. Herdman can prescribe a better programme of work, if Mr. Allen can show a better organisation, then let us have them by all means. The British Government will then have two definite schemes to consider, and if it finds it cannot decide between the two, then let us have two definite rival organisations, each doing its best with the means at its disposal to add to the knowledge and power of our country. Here we should be at one, and rivalry will not be tinged with envy or bitterness, but stimulate to greater exertions, and breed that respect and community of sentiment which springs from a common ideal and hard work well done. H. M. Kyle.

Naples, December 8.

Supposed Daylight Leonids.

The interesting details referred to by Dr. W. J. S. Lockyer (Nature, December 7) of a shower of Leonids having been witnessed by Miss Jeans and others at Swindon, and by Mr. E. Shaw at Aveley, in Essex, on the afternoon of November 15 last are corroborated by several other descriptions of a similar nature which recently appeared in the newspapers. One of these referring to a later date, was published in the *Liverpool Echo* of November 21, and runs as follows:—

"Sir,—Not having seen any account in the papers concerning the arrival of the meteoric showers, I beg to state that I saw them on Thursday afternoon, the 16th inst. I first noticed them at 12.15; they were shooting in all directions and kept on until about 4 o'clock. Then on Friday, the 17th, I again saw them at the same time. I called the attention of several people, with the result that they could also see them. Owing to the bright sky, one had to stare for a few seconds before perceiving the stars, as they were very dazzling to the eyes.

"Yours, &c.,

"Liverpool, November 20." "Mima Arden.

I need not quote any further descriptions, for there is not the slightest doubt that the objects were illusory and had nothing whatever to do with the November meteors. On November 15 the radiant of the Leonids sets at 2.30 p.m., so that the observations of Mr. E. Shaw (quoted by Dr. Lockyer), Miss Arden and some others are entirely put out of court, for we cannot have a shower of Leonids with the radiant below the horizon.

The objects seen must have been purely imaginary, and they may be easily produced by bending the neck and gazing intently for a few minutes at a bright sky. I have observed many of these spectral meteor showers on occasions when I have been looking for Venus or some other object in bright daylight.

It is astonishing that if one calls the attention of people to imaginary phenomena of this kind and asks them to look, they will, in ninety-nine cases out of one hundred, see the same thing and encourage similarly mistaken ideas! Yet if we observe an unequivocal object, it is often very difficult to make others perceive it and comprehend its character and the nature of the observation. Fictitious objects are in point of fact often seen more readily and apparently under more convincing aspects than real ones, but this applies usually to inexperienced observers.

In addition to the two reports of the recent shower of Andromedids mentioned in the last number of Nature, there is a third from Austria (*Daily Chronicle*, November 25). It appears that the astronomers of the Vienna observatory, watching the sky "from the beginning of evening up to moonrise, saw sixty-seven shooting stars, mostly from Andromeda. A magnificent fireball was also observed shining in the constellation. Twelve photographs were taken." W. F. Denning.

Bristol, December 8.

Birds Capturing Butterflies.

Referring to the letters on this subject in your papers of September 28 and November 16, I can certify to the fact of robins chasing and catching large white butterflies on the wing and swallowing them whole. In June we had ten robins coming freely to the hand for food, and thus had frequent opportunities of observing them daily. My gardener and his son have witnessed the same habit of the robins. Howard Fox.

Rosehill, Falmouth, December 7.

VALVE MOTIONS OF ENGINES.

Engineers want a diagram which for any position of the main crank of a steam engine (the angle θ which it makes with the inner dead point being given) shows at once, with sufficient accuracy for practical purposes, the position of the piston in its stroke, and the distance of the valve from its mid position. This is a mathematical problem. Men who are cunning in geometrical constructions ought to help the engineers; but hitherto they have not done so. In the hope of enlisting their services I venture to put before the readers of Nature the only easy construction with which I am acquainted. It has never before been published, except to his students, by the inventor, Mr. J. Harrison, of the Royal College of Science. Until I became acquainted with this method, I used a very laborious method of working, which necessitated the drawing of sine curves of different periods as described in my book on "Steam."

It will save trouble in expressing my meaning if I assume a uniform rotation of the crank. If we assume that the motions of piston and valve are simple-harmonic, a construction is very easy. When the valve is worked directly by an eccentric its motion is very nearly S.H., and in this case a construction, taking account of the shortness of the connecting rod, is easy.

But, as I have been trying to impress upon students for many years, when a valve is worked by any ordinary link motion or radial valve gear, the motion is not simple-harmonic; there is a small octave or kick of twice the fundamental frequency, and if this is taken into account, as well as the fundamental S.H. motion, it will be found that higher harmonics are of very little importance. Now in radial valve gears it is not at all difficult to write down the values of the terms a, α, b, β of the following expression from mere inspection of the gear. In link motions it is more difficult at present, but we are already seeing our way to easy rules. Here, then, is the problem which Mr. Harrison has solved :—

Given the ratio of length of connecting rod to that of the crank. Given that the distance of the valve to the right of its mid stroke (Fig. 1) is

$$y = c + a \sin(\theta + \alpha) + b \sin(2\theta + \beta),$$

b being small in comparison with a, show on a diagram the position of the piston and the value of y when θ has

For any value of θ: Make AOK $= \theta$, project K vertically to P; P shows the position of the piston, EP is its distance from the beginning of its stroke. OK cuts the valve circle in Q. The perpendicular distance QN of Q from DC_1D' is y, and the part of it QM is the opening of the left-hand port to steam. Similarly, in the *out* stroke, when the crank has passed through the angle AOK′ which is greater than 180°; project K′ to P′ to get the piston position in the out stroke. Let OK′ cut the valve circle in Q′; then the perpendicular distance Q′N′ is the distance of the valve to the left of its mid position (Fig. 2), and Q′M′ is the opening of the right-hand port to steam.

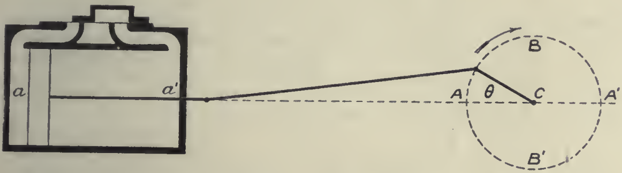


FIG. 1.—A is called the inner dead point. A′ " outer " "
The motion from a to a' is called the *in* stroke. " " a' to a " *out* "

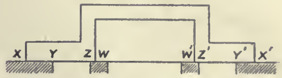

FIG. 2.—Valve shown in the middle of its stroke. X Y and X′ Y′ are the *laps* (sometimes called the *steam laps*). Z W and Z′ W′ are the inside laps (sometimes called the *exhaust laps*).

any value. Further, the laps XY and X′Y′ (Fig. 2) being given, show on the diagram the amounts of opening of the ports to steam, these being obtained by subtracting the laps from y or $-y$.

With centre C (Fig. 3) and radius CA or CA′ representing the crank, describe the crank circle ABA′B′. Draw BCB′ at right angles to ACA′. With centre on CA produced, and radius equal to length of connecting rod, describe the arc BOB′. Make angle $COC_1 = \beta - \alpha$ and $OC_1 = 2b$. We give the name "false centre" (relatively to both circles) to the point O.

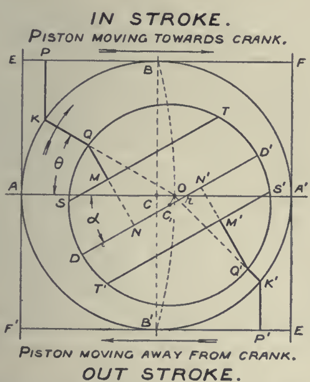

FIG. 3.—Mr. Harrison's diagram showing positions of piston and valve when crank makes an angle θ with inner dead point. The valve displacement to right of mid position (Fig. 2) being y, where $y = c + a \sin(\theta + \alpha) + b \sin(2\theta + \beta)$.

With centre C_1 and radius a, describe the circle DQD′Q′. Draw DC_1D' making an angle with AA′ equal to α. Draw ST parallel to DD′ at a perpendicular distance from it equal to the lap XY of Fig. 2. Draw S′T′ also parallel to D′D at a perpendicular distance from it equal to the lap X′Y′ of Fig. 2.

Draw tangents at A, B, A′, B′. In the *in* stroke of the piston, when the crank moves from A to B to A′, let us show on EF the positions of the piston, and in the *out* stroke, when the crank moves from A′ to B′ to A, let us show on E′F′ the positions of the piston.

It is easy to see how we get the openings of the ports to exhaust in exactly the same way. Lines joining O with S, T, S′, T′ show the angular positions of the crank when admission and cut off take place. In fact, we see that this diagram gives us the positions of the piston when admission, cut off, release and compression occur both in the *out* and *in* strokes. It gives us an easy way to study how changes in b and β enable us (even when the laps are equal) to balance, or even more than balance, the inequality of admission of steam on the two sides of the piston due to shortness of connecting rod.

It is easy to see how such a diagram may be modified for problems concerning cut off valves on the back of the main slide valve.

The same expedient of false centres may be used to show the velocity or acceleration of a slide.

In a modified diagram Mr. Harrison sometimes lets the two circles coincide, using two false centres.

The solution is a close approximation to the truth in all the usual cases, because b is always small in comparison with a.

JOHN PERRY.

INSECTS AS CARRIERS OF DISEASE.[1]

THE recent researches of bacteriologists into the *rôle* played by insects as carriers of infection, and the hunt after microbes to locate their natural habitat, is a necessary procedure before it becomes possible to enter on a scientific crusade against them. In those diseases which may be caused by infection carried by insects, it is a more hopeful task to deal with the insects which we can see, than to deal with the microbe which lurks unseen and unheeded. At the same time, it is an uncomfortable thought that insects which we have regarded as undesirable but harmless may be the cause of a serious illness.

The bacteriologist has now shown a fair-sized category of diseases to be caused by microbes, and having arrived so far the hygienist steps in and wants to know firstly, what is the habitat of these microbes outside the human or animal body if they have one, and secondly, by what means they are conveyed to the body from their resting-place outside or from one patient to another?

[1] "On the *Rôle* of Insects, Arachnids and Myriapods, as carriers in the spread of Bacterial and Parasitic Diseases of Man and Animals. A critical and historical study." By Dr. G. H. F. Nuttall (from the *Johns Hopkins Hospital Reports*, vol. viii.).

That certain diseases may arise from the "bites" of insects has been surmised long before the microbial origin of disease was known, many theories were naturally based on insufficient evidence because the key to the riddle had not then been found. In some of the earliest records of epidemics any concurrent phenomena was thought to be the cause, thus the plague at Nimeguen, in Holland, in the seventeenth century, was said to be announced by swarms of insects and meteors.

All observations are of use, although in the light of present knowledge they may not bear the same interpretation as was originally put upon them; as a suggestion for investigation by experimental methods they may serve a purpose.

Dr. George H. F. Nuttall in this monograph has been at great pains to collect observations on the point from all sources, and has supplemented these with some experimental researches of his own.

Insects—using the term in its popular sense—may play a passive *rôle* in the propagation of disease. It is obvious that flies, for instance, after soiling their bodies in contaminated matter, may afterwards infect articles of food, especially milk; and no doubt many cases of typhoid fever are caused in this way. In India, where typhoid fever attacks so many of our troops, the refuse matter is placed outside the camp, and it has been suggested that articles of food in the camp might become infected by dust carried by the wind when it blows from the direction of the refuse matter; but it is more than likely that flies carried by the wind play a more important part, for they would seek out the food. The same may be said of cholera; in fact, an instance is given where milk was left out in the open in a jail in India at the time of a cholera epidemic, and it became infected with the cholera microbe by means of flies, whereas milk left out in another yard where there were no cholera cases and which was separated from the other yard by a high wall did not become infected.

In playing an active *rôle* insects may conceivably cause infection by "biting" after having "bitten" an individual suffering from an infectious disease or after feeding on contaminated substances, for instance, the body of an animal dead of anthrax. Experiments in this direction do not seem to have been very successful in the cases of bugs and fleas, which were the insects experimented with; but it was shown that anthrax and plague microbes do not survive more than a few days at most in the bodies of the insects. Even if the "bite" of an infected insect is harmless, it might be otherwise if the insect were crushed on the spot bitten, and the place scratched; such a procedure might be fraught with danger supposing the insect had recently been feeding on infected matter.

With respect to the tsetse-fly disease in domesticated animals, there is conclusive experimental proof that the fly carries the micro-organism or hæmatosine in this case from diseased to healthy animals.

The filariae, according to Manson, go through changes in the stomach of the mosquito, and finally make their way out into water in which the insects have died, and man becomes infected by drinking the water. In this case and in malaria the insect seems to act as an intermediary host to man. The mosquito—of which one species, the anopheles, seems to be mostly concerned—takes up the organism in the blood of the malarious subject, and, according to Manson, infects soil or water by dying in it; Ross and others, however, say it infects healthy persons by biting them after biting a malarious patient.

It is interesting to note that most of our previous notions as to the localities and time of year that malaria occurs, and the precautions adopted to prevent being attacked still hold good, *mutatis mutandis*, for the mosquito theory. C. B. S.

ETHNOGRAPHICAL MUSEUMS.

IN NATURE of September 14, attention was called to the rapid progress of ethnographical museums in Germany, and to the unsatisfactory state of ethnography in our own country. Since that time two things have happened which confirm the view then taken of the position of our national collections.

In the first place, one of the distinguished keepers of the Museum für Völkerkunde in Berlin has recently visited London, and has stated that the enlargement of the museum or its supercession by a completely new building will be seriously considered in the near future. When it is remembered that the Museum für Völkerkunde is already so enormously superior to anything which we have in this country, that it stands absolutely in a class by itself, it can easily be guessed that the projected improvements threaten to leave us in a position of inferiority positively humiliating. For even as matters now stand, the German collections are nearly ten times as good as our own.

The second occurrence to which we have alluded, is the issue of a report upon European anthropological museums by Mr. George A. Dorsey, of the Field Columbian Museum, who made a tour of the principal European cities in the autumn of last year. Extracts from his report have been published in the form of a short paper in the *American Anthropologist* for July, 1899, and it is therefore accessible to every one who feels any interest in the subject.

Mr. Dorsey begins by complaining that the collections illustrating the various branches of anthropology in Europe are all scattered about in different buildings. In London, if you wish to study man as an animal, you must go to the British Museum of Natural History in Cromwell Road, or to the Royal College of Surgeons; if you wish to study primitive art and industry, you must go to Bloomsbury. In Paris you must wander from the Jardin des Plantes to the Trocadéro, and so on in other cities. The great fields of anthropology are nowhere adequately represented in a single building, and the advantages of concentration are lost.

After this preliminary condemnation, Mr. Dorsey proceeds to discuss several museums in detail. He has a well-merited word of praise for the Pitt-Rivers collection in the University Museum at Oxford, where the development of different branches of human industry may be studied in a manner impossible anywhere else. Coming to Berlin, he thinks that the Museum für Völkerkunde contains the largest amount of ethnographical material to be found in any one museum in the world; and he is inclined to believe that it possesses a greater number of specimens than any other two museums combined. The one drawback is that, large as the building is, it has long proved inadequate to the enormous expansion of the collections, and is in consequence terribly overcrowded. As we have already seen, this is an inconvenience which will in all probability soon be remedied.

Of the ethnographical collections in London, our American critic has naturally something to say. After noticing that, from the ethnographical point of view, London, like Paris, is disappointing, he continues: "The large hall [gallery] devoted to this subject in the British Museum is not well adapted to the purpose for which it is used; it is rather inaccessible, poorly lighted, and does not admit of a ready scientific classification of the objects therein deposited. Naturally, this hall contains many of the rarest and most valuable objects that have ever been obtained by any museum in the world; but owing to the causes already mentioned, and to the crowding of the cases, it is practically impossible for the visitor in a short time to form any idea of the value of the collection. There are many rare and unique specimens, but the collection as a whole cannot be regarded as well illustrating the various fields of ethnography. . . . It is to be regretted that the capital of a nation which embraces in its domain so many and such diverse peoples should not possess a museum which shows the ethnic characteristics of some of these peoples in an adequate manner."

Mr. Dorsey has returned to his own country convinced that in the matter of the housing and exhibition of anthropological collections the United States have nothing to fear from comparison with Europe. He thinks that there is no building in Europe so admirably planned for museum purposes as the American Museum of Natural History at New York. Here ample space for future expansion has been allowed on a scale unequalled in Europe, and large, well-lighted and commodious quarters have been provided for storage and workrooms. He truly says that numerous workrooms with abundant light should be an essential feature of every museum. It is clear that in the United States the study of ethnology is being pursued with the same enthusiasm as in Germany, and that it has succeeded in a similar manner in securing a large measure of popular support. Viewed in the light of these facts, the conditions of things in Great Britain appears doubly deplorable.

NOTES.

THE complimentary dinner given to Major-General Sir John Donnelly on Tuesday, by his friends and former colleagues of the Department of Science and Art, is a testimony of the esteem in which he is held by all who have been associated with him in the work of the Department. Sir John Gorst presided, and in proposing the health of the guest of the evening, he pointed out that in 1859, when Sir John Donnelly was entrusted with the control of the science branch of the Department, the total number of science students under instruction was 395, and the payments made on account of their instruction amounted to 2000*l*. In 1897, the number of students in Departmental classes was 197,796, and the grants amounted to 169,000*l*. These figures form the best of evidence as to the growth of the work of the Department under Sir John Donnelly's administration. In addition to Sir John Gorst and Sir John Donnelly, among other speakers at the dinner were:—Captain Abney, Major-General Festing, Sir Norman Lockyer, Prof. Rücker, Sir George Gabriel Stokes, and Rear-Admiral Sir William Wharton.

DRS. STEVENS AND CHRISTOPHERS, of the Royal Society Malaria Commission, left Liverpool on December 9 for Sierra Leone, where they will continue their investigations on malaria. At Blantyre, in East Africa, where they were before, they gave more attention to investigating the relation of malaria to blackwater fever, which is very prevalent at that spot. Many persons deny the connection between the two, but it is a point that still requires to be settled. On the West Coast they will probably investigate the disease from the point of view of the mosquito theory.

PROF. GEORGES LEMOINE has been elected a member of the section of chemistry of the Paris Academy of Sciences, in succession to the late Prof. Friedel.

THE following are among the lectures to be delivered at the Royal Institution before next Easter:—Mr. C. Vernon Boys, six Christmas lectures (specially adapted for young people) on fluids in motion and at rest, experimentally illustrated; Prof. E. Ray Lankester, twelve lectures on the structure and classification of fishes; Dr. W. H. Rivers, three lectures on the senses of primitive man; Prof. H. H. Turner, three lectures on modern astronomy; Dr. Charles Waldstein, three lectures on recent excavations at Argive Heræum (in Greece); Lord Rayleigh, six lectures on polarised light. The Friday evening meetings will begin on January 19, when a discourse will be given by Lord Rayleigh, on flight; succeeding discourses will probably be given by the Hon. C. A. Parsons, Prof. J. Reynolds Green, Mr. H. Warington Smyth, Prof. J. H. Poynting, Major Ronald Ross, Prof. Frank Clowes, Sir Benjamin Stone, M.P., Prof. J. Arthur Thomson, Sir A. Noble, Prof. Dewar, and other gentlemen.

AN agricultural conference for the West Indies will be held at Barbados on January 6 and 8, 1900. His Excellency, Sir James Hay, K.C.M.G., the Governor of Barbados, has promised to meet the representatives at Bridgetown on Saturday morning, January 6, and offer them a welcome to the island. Immediately after, the President (Dr. D. Morris, C.M.G.) will deliver the opening address, and the business of the conference will begin. A characteristic of the conference will be the presence of representatives of the leading agricultural societies in the West Indies. By this means it is anticipated that the conference will act as an educative agent of great value, and by enlisting the co-operation of those practically engaged in agriculture, its deliberations will have wider scope, and the influence of the conference will be more widely recognised. The list of subjects to be dealt with covers practically every branch of West Indian agriculture.

ORNITHOLOGY has suffered a severe loss by the death of Arthur Cowell Stark, M.B., who was killed by a Boer shell at Ladysmith on November 18. Dr. Stark was an ardent naturalist, and specially conversant with South African ornithology, having devoted many years to the study of the birds of the Cape Colony and adjoining countries. At the time of his death he had just completed for the Press the first volume of a work on South African birds, which is to form a portion of Mr. W. L. Sclater's "Fauna of South Africa." Dr. Stark was in England during the past summer engaged in the preparation of his book, but returned to the Cape in September last, and proceeded to Natal in order to continue his collections in that colony. When war broke out he offered his services as a volunteer on the Medical Staff, and was sent up to Ladysmith by the last train that passed the Boer army. Standing at the door of the Royal Hotel in Ladysmith, on November 18, he was struck by an exploded shell, and died shortly afterwards. Dr. Stark was a graduate of the University of Edinburgh, and a well-known member of the British Ornithologists' Union.

A CONGRÈS international des sciences ethnographiques will be held in connection with the Paris Exposition, on August 26–September 1, 1900. There will be seven sections, dealing respectively with general ethnology, sociology, and ethics; ethnographical psychology; religious sciences; linguistics and palæography; sciences, arts, and industries; descriptive ethnography. The treasurer of the organising committee is M. Leclère, rue Lecourbe, 54, Paris, and the general secretary, M. Greverath, rue d'Athènes 3 bis, to which address foreign correspondence should be sent.

THE essay on the scientific work of Lord Kelvin, contributed by Prof. G. F. Fitzgerald to an elegant volume just published by Messrs. James MacLehose and Sons, Glasgow, is a masterpiece of appreciative writing. The volume contains a complete account of the celebrations on the occasion of Lord Kelvin's jubilee as professor of natural philosophy in the University of Glasgow; it is thus of particular interest to the many friends who took part in the ceremonies, and to the scientific bodies who sent delegates and messages of congratulation. Preceding this report is Prof. Fitzgerald's essay, in which the nature and significance of Lord Kelvin's contributions to science are described with such remarkable lucidity that every one interested in the progress of natural knowledge would do well to read it. A striking photogravure of Lord Kelvin, from a portrait taken in 1898, forms the frontispiece, and a portrait is given engraved from a photograph taken in 1846. The volume will doubtless be treasured by Lord Kelvin's many admirers, as a slight tribute of regard for the versatility of his genius.

THE *British Medical Journal* announces that Dr. Yersin, whose name is well known for his researches on the plague, has been charged by the Government of Cochin China with a special mission to Java.

IT is reported in *Science* that the Russian Astronomical Society has finally given up its attempt to revise the Julian calendar. The reason assigned for its failure by the Society is "the impossibility of establishing an agreement between the dates of the religious festivals appearing in both calendars."

IN connection with the Institution of Electrical Engineers, a number of local centres are being established where papers will be read and discussed at the same time, or shortly after, their reading in London. In Cape Town these informal meetings have been held for some time past, and advance copies of the Institution's papers have been read at them. A meeting for the formation of a north-eastern centre was to be held yesterday at the Durham College of Science, and the Council have received a petition for the establishment of a similar organisation in Dublin.

WE regret to see the announcement of the death of Mr. N. E. Green, F.R.A.S. An artist by profession, Mr. Green was well known for his admirable astronomical drawings—especially those of Jupiter and Mars. On the occasion of the opposition of the latter planet in 1877 he went to Madeira, where he made a fine series of drawings, a selection from which was published in vol. xliv. of the *Memoirs* of the Royal Astronomical Society. A number of his drawings of Jupiter were reproduced in vol. xlix. of the same publication, and he left behind him a long series of unpublished lunar and planetary drawings. Mr. Green was President of the British Astronomical Association in 1897–98.

THE Institution of Electrical Engineers held their annual dinner on Wednesday, December 6, in the Hotel Cecil, Prof. Silvanus Thompson in the chair. Among the speakers was Lord Kelvin who proposed the toast of "Science." In the course of his remarks, he said:—When the electric telegraph came into practical existence in 1837, when ten years or so later the first submarine cables connected England and the Continent of Europe, and when another ten years or so saw the first Atlantic cable laid, electrical science in all the Universities of Europe was in a very backward state compared with the position in which it is now. A very great stimulus indeed was given to its study from its application to electric telegraphs, and especially to the great system of electric measurements which is so valuable now in pure science—a system which originated certainly not among practical engineers, but among University professors. Gauss and Weber gave from Germany the foundation of the system of electric measurements, the benefits of which are now enjoyed, and the first practical use of which was made in connection with submarine cables.

A PAPER on the manufacture of artificial silk or lustrocellulose was read by Mr. Joseph Cash at a meeting of the Society of Arts on December 6, and is printed in the *Journal* of the Society. A public company for the manufacture of this material by the Chardonnet process has been formed in England, and the factory will be capable when filled with machinery of producing 7000 lbs. of artificial silk per week. The first stage of manufacture is the nitration of cotton or wood pulp producing pyroxyline, discovered by Pelouze in 1838. The greatest care must be employed in conducting this operation, as it is the most important one in the whole process; mistakes sometimes even occur at the long-established factory at Besançon, in France. The process of nitration of cellulose is the displacement of a few molecules of hydrogen by nitric peroxide. There are several varieties of pyroxyline which are obtained by using different mixtures of acid. When the pyroxyline has been obtained, it is placed in a cylinder with a mixture of alcohol and ether; the cylinder is then slowly revolved for twelve hours, with the result that the pyroxyline is dissolved and collodion is produced. After filtration by forcing it through a sheet of cotton-wool between calico, under a pressure of fifteen atmospheres, the collodion is ready for use.

FOR the manufacture of artificial silk a pressure of forty to forty-five atmospheres is required to force the collodion from the reservoirs to the spinning machines, which are constructed with pipes running on each side. Into these pipes are screwed a number of taps with a glass capillary tube fixed on the end, called a silk-worm, through which the collodion is forced; immediately it comes into contact with the air it solidifies, enabling the operative to take hold of the thread or silk, as it can now be called, and convey it to the bobbin. From twelve to twenty-four of these threads are run together on to one bobbin, according to the size of silk required, as is the case with natural silk. After the silk has been dried it is very inflammable and quite unfit for use in textile goods; therefore, a process called denitration is next carried out, which reconverts the product into cellulose. One of the uses of the material is for mantles for the incandescent gas light, it being found that the salts of the rare metals can be mixed with the collodion with greater economy than with any other thread. Large works are in operation at Besançon, in France, producing 7000 lbs. weight per week; but the demand is so great that extensions of the works are being made in order to enable them next January to produce 2000 lbs. per day. The production at Sprietenbach is 600 lbs. daily. Other factories are about to be established in Belgium and Germany.

MENTION is made in *Science Abstracts* of a method of thawing water service pipes by means of electricity, successfully used in Canada. The frozen pipes are thawed by passing alternating currents through them. A pressure of twenty to fifty volts is used, obtained from a portable transformer connected with the street mains. A current of 200 to 300 amperes is passed through the frozen pipe until the water flows freely, which usually takes place in a few minutes.

IN 1894, Prof. van der Waals found a remarkable property of the molecular potential function occurring in his theory of capillarity, namely, that if a constant coefficient be left out of account the potential of a homogeneous sphere at an external point is the same function of the distance from the centre of the sphere as if the whole mass were concentrated at the centre. Dr. G. Bakker, writing in the *Proceedings* of the Royal Academy of Sciences of Amsterdam, now investigates the most general form of potential function possessing this property, and he obtains for the potential at distance r the form

$$\phi(r) = \frac{Ae^{-qr} + Be^{qr}}{r} + C.$$

For the potential function required in the theory of capillarity Dr. Bakker remarks that $B = 0$. The author further investigates whether it is possible to obtain a potential differing in form from the Newtonian potential and satisfying the further condition that the potential is constant throughout the interior of a spherical shell. It is found that a solution exists, but as the expression for the potential function involves the radius of the shell, the result is in no way contradictory to Laplace's conclusion that the Newtonian potential is the only potential which is constant throughout the interior of a spherical shell, *irrespective of the size of its radius.*

WE have recently received the annual report for 1898–99 of the Bacteriologist of the Government of India. The report deals chiefly with experiments on Rinderpest carried on in the laboratory at Muktesar, a preliminary note of which appears. The methods of protective inoculation that are used in South Africa are not convenient for a country like India; Koch's method of using bile from an animal just killed, requiring the slaughter of mai ‐ ‐nimals, is contrary to the religious susceptiilities of the people. The disease, which has been in India for centuries, seems to be of an endemic character, and not liable to spread with the same alarming rapidity as it does in South Africa, so it does not seem all-important to produce a very lasting immunity to check the disease in any particular locality. Since the disease will probably have been going on for some time in a place before measures can be adopted, a rapidly immunising agent is desirable. The serum method seemed to be the most fitted to the purpose, and it is this that is being tried. It is a great loss that the laboratory at Muktesar, the only Government laboratory anything like properly equipped, has recently been burnt down, but we trust no time will be lost in rebuilding it; India at the present time can ill-afford to do without laboratories.

WHETHER ants can hear is a question which has for some time been engaging the attention of Mr. Weld, of the Iowa University, who has published an account of some of his experiments, and the conclusions he draws from the same, in *Science* of November 24. He states that for many years it has been the accepted opinion amongst naturalists that these insects are not endowed with an acoustic sense, at least within the range of sounds perceptible to the human ear. This opinion is based upon the failure of experiments to show that even the loudest and shrillest noises produce the slightest effects on ants subjected to their influence. This, however, is not the result of Mr. Weld's experiments upon several American species of these insects. In one case an ant confined in a test-tube was brought near a milled disc rotating in the air. At each sound from this apparatus the ant showed unmistakable signs of agitation, quickly moving its head and antennæ. Again, when shrill sounds were produced close to a colony protected under glass, the ants instantly showed by their rapid movements signs of excitement and alarm. This leads the experimenter to conclude that at least some (and possibly only American) species of ants are capable of perceiving vibrations, conducted through the air or other media, which are audible as sound to the human ear. He is, however, careful to add that this does not necessarily demonstrate that they hear in the strict sense of the word, but merely that they are capable of perceiving ordinary sound vibrations.

IN the course of an article on the late Mr. P. H. Gosse, published in the March number of the *Journal of the Jamaica Institute*, Mr. Duerden has some interesting observations on recent changes in the fauna of that island. He first of all states that in spite of its being less abundant around country residences, the Indian mungoose appears to be as common as ever in the island, over 1400 head having been trapped on two estates in eight weeks. His next subject is ticks, which have become a terrible plague in certain districts. Although they always existed, originally there appears to have been but one species in the island, but many others have been introduced on foreign cattle and sheep. A few years ago a virulent disease broke out in the cattle, which was at first diagnosed as being allied to the well-known "Texas fever." Subsequently the characteristic symptons of that disease were found to be absent, as were the well-known parasitic organisms by which it is accompanied; but there still seems no doubt that the bovine epidemic is in some way connected with the presence of myriads of introduced ticks.

IN a second communication to the same journal, Mr. Duerden gives the results of the attempts to improve the sea-fisheries of Jamaica. Unfortunately these attempts have not met with the success that was hoped for. The two chief reasons for the failure—and they are amply sufficient—are, firstly, the amount of coral on the sea-bottom, which renders trawling impracticable; and, secondly, a general scarcity of fish, especially those of the valuable flat-fish group (*Pleuronectidae*) On one place where trawling is practicable, it was considered a remarkable feat that a dozen small soles were taken in a day. There are no shoals of fish corresponding to those of the herring, mackerel, and cod of other seas; so that the whole outlook is gloomy in the extreme.

THE *American Naturalist* for November contains the fifth instalment of Messrs. Cowstock and Needham's important contributions to the study of the structure of the wings of insects, for the details of which we must refer our readers to the memoir itself.

MESSRS. FRIEDLÄNDER AND SON, Berlin, have just issued a catalogue (No. 439) containing classified lists of books and papers on crystallography.

MESSRS. DAWBARN AND WARD have published the third edition of Dr. P. H. Emerson's "Naturalistic Photography." The first part is concerned with the æsthetic side of photography, but in the second part technique and practice are treated, and from it both amateur and professional photographers may derive sound philosophy and serviceable hints.

IN the part just received (1899, 1te Hälfte) of the *Sitzungsberichte* of the Niederrheinische Gesellschaft für Natur und Heilkunde zu Bonn, the most important papers are by Dr. Max Koernicke on the spiral thickening bands in the conducting tubes of plants; and by Prof. W. Voigt on artificial regeneration in Planaria.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus rhesus*, ♀) from India, presented by Mr. F. G. Stenning; a Lesser White-nosed Monkey (*Cercopithecus petaurista*) from West Africa, presented by Mr. R. Caton Woodville; two Hobbys (*Falco subbuteo*), captured in the Indian Ocean, presented by Mr. J. H. Ingram; a Fieldfare (*Turdus pilaris*), British, presented by Mr. Herbert Goodchild; a Delaland's Gecko (*Tarentola delalandii*) from Teneriffe, presented by Mr. J. Chappell; a Mozambique Monkey (*Cercopithecus pygerythrus*) from East Africa, a Bee-eater (*Merops apiaster*). a Partridge (*Perdix cinerea*), European; two Brown's Parrakeets (*Platycercus browni*) from North Australia, a —— Tortoise (*Testudo nigrita*) from the Galapagos Islands, three Blanding's Terrapins (*Emys blandingi*) from North America, deposited; a Yellow-footed Squirrel (*Sciurus ludovicianus*) from Texas, a Tufted Duck (*Fuligula cristata*), European; two Common Scoters (*Œdemia nigra*), British, purchased.

OUR ASTRONOMICAL COLUMN.

ORBIT OF FIFTH SATELLITE OF JUPITER.—Prof. E. E. Barnard has had the fifth satellite of Jupiter under close observation for some considerable time during the oppositions of 1898 and 1899. Although the increasing southerly declination and the bad season in which the oppositions now occur make the satellite a difficult object, good measures have been secured on several dates. Tisserand having drawn attention to the fact that the measures previously given provided evidence of the eccentricity of the satellite's orbit (*Comptes rendus*, vol. cxix., October 8, 1894), Prof. Barnard decided to observe it as continuously as possible, to settle this question. Tisserand's results indicated that the line of apsides of the satellite's orbit should also have a motion of + 882° a year, or + 2°·42 daily, giving a complete revolution in five months. From the Lick measures he computed the semi-major axis of the orbit to be 47″·906, the eccentricity 0·0073, and longitude of Perijove for 1892, November 1, = –4°. Prof. Barnard's more recent measures enable him to revise these values, and his results are contained in the *Astronomical Journal*, No. 472. On calculating the position of the satellite from Tisserand's value of the motion, a considerable error is found, and the daily motion of the apse line is probably more nearly +2°·465 or 900° yearly, giving a complete revolution of the orbit in 4·9 months.

An interesting question that may also be settled by continued observation of the satellite is the distribution of matter at the equator of Jupiter itself, as the motion of the perijove of the satellite does not agree with that deduced from the actual polar compression of the planet.

During the whole of the measures half the field of view was covered with a piece of smoked mica, through which the bright limb of the planet was observed, and the distances measured from the limb afterwards reduced to the centre by previous measures of the planet's diameter with the same instrument. The increased number of elongations measured gives a much more correct value of the period. The value now given is

11h. 57m. 22·647s.,

which Prof. Barnard considers correct to one-hundredth part of a second.

PARTIAL ECLIPSE OF THE MOON, DECEMBER 16.—There will be a partial eclipse of the moon, visible at Greenwich, during the early morning of Sunday next, in respect to which the following particulars apply:—

First contact with penumbra = 10h. 33·7m.; with shadow = 11h. 44·6m.

Second contact with penumbra = 16h. 18·1m.; with shadow = 15h. 17·2m.

Magnitude of eclipse (moon's diameter = 1) = 0·995.

First contact with shadow occurs at a point 66° from the north point towards the east, measured along the moon's limb.

Last contact with shadow at a point 59° from north point towards the west.

The eclipse is visible in Western Asia, throughout Europe and Africa, and in Eastern America.

OCCULTATION OF NEPTUNE, DECEMBER 16.—There will be another occultation of Neptune during the early morning of Sunday, while the moon is still in the penumbra of the earth's shadow after the partial eclipse. The following are the particulars for observers near London:—

	Sidereal time.	Mean time.	Angle from North Point.	Angle from Vertex.
	h. m.	h. m.	°	°
Disappearance...	9 18	15 36	158	118
Reappearance ...	9 53	16 11	222	180

Greenwich Mean Time of conjunction in R.A.... } 1899 December 16d. 14h. 53m. 15s.

Limits of latitude, 90° N. to 30° N.

Neptune passes the meridian of Greenwich at 13h. 40m., so that it will be well situated for observation of the occultation.

MERIDIAN OF UNIVERSAL TIME.—In the *Revue Scientifique*, Ser. 4, vol. 12, p. 526, M. C. Tondini di Quarenghi summarises most of the evidence in favour of and against the adoption of the meridian of Greenwich as the initial meridian for universal time. The chief objection is cited as a physical one, viz., the extreme uncertainty of the meteorological conditions, rendering celestial observations impossible on a large proportion of the days and nights throughout the year. The advantages of the site at Jerusalem suggested by the Italian Government are the superior observing conditions and the possibility of the district being declared neutral ground, thus ensuring the permanence of the station irrespective of political changes. A further advantage would be the possibility of establishing other subsidiary stations at intervals along the meridian.

THE DEVELOPMENT OF GANGLION-CELLS AND NERVES.[1]

THE results of this memoir largely are in keeping with certain revolutionary changes in embryological doctrine, with which the names of Klaatsch, Miss Julia Platt, Goronowitsch and others are identified. According to their views certain vertebrate structures, which have hitherto been genetically referred wholly or in part to the mesoderm, such as scales, certain cartilages, and even bones, are in fact directly or indirectly products of the outer layer of the embryo, the ectoderm or epiblast. This is only a brief and very general statement of the tendency of their lines of research, and it may be added that as to the details there exist important differences between the different observers. It will not be needful to review all their conclusions here. Our concern is solely with the aspect of the question presented to us by Dr. Goronowitsch in his memoir.

Researches on the development of nerves and ganglia date back to Remak, whose conclusions as to their mesoblastic origin from the protovertebræ or mesoblastic somites were commonly held as recently as twenty-five years ago. About then date the researches of Balfour and Marshall, who maintained that these structures arose as outgrowths of the central nervous system, and that therefore they were epiblastic in origin.

Later on their conclusions were somewhat modified by Beard, in the discovery that the posterior root-ganglia, both cranial and spinal, did not develop as actual outgrowths from the central organ, but that their foundations were to be traced to the deeper portions of the epiblast outside the limits of the future brain and spinal cord. It was also demonstrated that the cranial ganglia received additions from special regions of sensory epiblast, since termed by Kupffer "placodes," on the level of the notochord and above the gill-clefts. Thus, for the sensory portion of each cranial ganglion, two sources of origin could be identified, and the parts so derived were termed neural and lateral respectively. A few years ago Kupffer added a third source, and described an "epibranchial" ganglionic foundation as arising from it. Kupffer's results were obtained in the lamprey, unquestionably one of the most difficult forms among vertebrate animals for the study of organogeny. His results have never been confirmed by any other observer, either in the lamprey or in any other vertebrate.

Whilst it is certain that his epibranchial ganglia have no existence in Elasmobranch fishes, it is also in embryos of these easily demonstrated how Kupffer fell into the error of supposing their presence. In fine, had his researches been carried to sufficiently early "stages" or phases he would have seen that his lateral and epibranchial ganglia merge into one, the foundation of a lateral ganglion.

Since Kupffer's researches were fully published in 1894–5, embryological investigation of the development of cranial and spinal nerves and ganglia has been put somewhat in the shade by brilliant researches into their comparative anatomy at the hands of Allis, Dixon, Ewart, Fürbringer, Haller, Strong and F. J. Cole. Pages and pages might be filled in review of these, along with a critical digest of numerous other papers, embryological and morphological, issued since 1885. Controversies have been waged as to the morphological nature of certain nerves and ganglia, as to their mode or modes of development, and as to the way—apparently a simple problem, but by no means such—in which nerve-fibres arise.

The work under review is only in a minor degree a contribution to a knowledge of the morphological nature of nerves, *i.e.* in so far as it relates to the olfactory and auditory nerves. On the other hand, it emphatically claims to furnish decisive replies to the two latter questions, as to the mode or modes of development of ganglia and of nerve-fibres. If the conclusions drawn by Goronowitsch from his researches can be upheld, it would seem to follow that the investigations of the past twenty-five years—except those of Sedgwick—have been largely in vain.

According to Dr. Goronowitsch, what Balfour and Marshall regarded as outgrowths of the central nervous system, and termed "the neural ridges," have nothing to do with the development of the cranial ganglia. The existence of these "ridges" of cells he does not dispute, but he maintains that the component cells become resolved into the surrounding meso-

[1] Untersuchungen über die erste Anlage der Kranialnerven bei *Salmo fario*." By N. Goronowitsch. Nouveaux Mémoires de la Société impériale des Naturalistes de Moscou, T. xvi. L. 1, pp. 1-55, 3 plates.

blast. The cranial ganglia take their entire origin from Froriep's "Kiemenspaltenorganen." These structures were first discovered by Froriep, and independently by Beard, who identified them as the foundations of the lateral sense organs, and termed them, because of their genetic relations to the gill-clefts, the "branchial sense-organs." Moreover, as previously stated, these patches of sensory epithelium, the "placodes" of Kupffer, were shown to be the sources of ganglionic elements, forming the lateral ganglia. Goronowitsch has now, therefore, endeavoured to limit the cranial ganglia in their origin to these lateral sources alone.

Peculiar, though not confined to himself, are the views maintained by Dr. Goronowitsch as to the mode of attachment of the ganglion with the central organ, and as to the formation of nerve-fibre in general.

In the solutions offered of these problems—which, of course, are really one and the same, to wit, that of the development of nerve—he places himself entirely on the side of A. Sedgwick.

The latter zoologist has maintained, without thus far illustrating his thesis by figures, that nerve-fibres arise *in situ* in the mesodermic reticulum, connecting together the various portions of the developing embryo and filling all the spaces between skin and central nervous system.

The logical conclusion attaching to this view is that nerve is mesodermal in origin. This conclusion Goronowitsch does not hesitate to draw. In his own words in literal translation he says (*inter alia* on p. 40) "the nerve-forming tissue of the complex nerve-trunk is furnished by axial mesoderm."

Incidentally he, like Sedgwick, rejects the doctrines of His, Golgi and their followers, that nerve-fibres arise as processes of ganglion-cells. Naturally! The two views are mutually exclusive. If nerve-fibres arise in a reticulum of mesoderm or mesenchyme, they cannot also be processes of ganglion-cells.

Whatever is to be said for the full acceptance of the process-theory of His and Golgi, and whatever the ultimate fate of the germ-layer theory, no fact in vertebrate embryology stands on a firmer basis than the origin of all nervous structures from the outer layer, the ectoderm or skin, and to fall back upon the mesoderm or its reticulum as the source of nerve appears to us a retrograde step to the embryological standpoint of thirty years ago.

While readily and willingly acknowledging Goronowitsch's industry and zeal in working out this memoir, evidenced by the detailed and laborious description, the carefully drawn and beautifully lithographed plates, his main thesis must remain in abeyance until proof further and more convincing, that this is so for representative members of each of the great vertebrate classes, can be brought forward.

THE UTILITY OF KNOWLEDGE-MAKING AS A MEANS OF LIBERAL TRAINING.[1]

THE subject on which I wish to address a few remarks to you to-day, by way of opening the fortieth session of our College, is the utility of knowledge-making as a means of liberal training.

That the main work of the highest of educational institutions should consist of original research, and that ability to make additions to knowledge should form the chief test of qualification for the highest academic distinction, may be said to have received world-wide recognition; but the value of research work in institutions or departments of a lower grade has not been similarly recognised, and the tests for lower academic degrees and certificates do not, in general, at least formally, include a research test. I wish to bring to your notice some considerations which go to show that the work of all educational institutions, from the highest to the lowest, should be, to a considerable extent, at least, of the nature of original research—understanding by that term, however, the effort to make additions to our own knowledge, not necessarily to the knowledge of the race.

In this sense we have all been engaged more or less in original research from our earliest years; and we probably attained greater success in infancy than in youth or in later life. The young child is completely cut off from all external sources of information; and it could acquire no knowledge beyond a remembrance of confused sensations, if it did not possess the power of "putting that and that together" and finding things out for itself. By applying this power, however, the child succeeds in bringing a large measure of order out of the chaos of sensations which it experiences. The method which it uses is the scientific or knowledge-making method. It finds out the usage of a word, for example, by putting together various instances of its use, constructing a theory as to the meaning of the word, testing the theory by subsequent observation, and modifying the theory as experience widens—in fact, by subjecting its experience to imagination, induction and deduction, and thus, as the logicians would say, generalising such experience. How exactly the process is carried out, even the New Psychology has not yet told us. But it certainly gets carried out somehow; and the result is a series of brilliant, though possibly to some extent sub-conscious, discoveries. The evolutionist would tell us, perhaps, in his learned phraseology, that this phenomenon is a case of the ontogenetic recapitulation of phylogeny, by which he would mean that the young animal in learning its mother-tongue passes in a few months or years through an epitome of the course of development for which the race required as many æons. Even so, the phenomenon does not lose its suggestiveness from our present point of view.

Whether it be because, when the mother-tongue has been acquired, the period of octogenetic recapitulation is complete, and the child brought thereby up to date, or because it is then brought into communication with encyclopædic friends, I cannot say; but certainly once the child is able to question its mysterious neighbours and to understand their answers, its power of applying the scientific method rapidly diminishes, becoming weakened apparently because of the readiness with which information may now be obtained by simple appeal to authority. But though weakened the power is not wholly lost; for it exhibits itself, more or less, in the study both of language and of natural phenomena, during the period of tutelage between early childhood and incipient manhood, and it comes into greater or smaller activity when the young man goes forth to engage in the work of life. And what his degree of success is to be in such work as his hand may find to do will depend, in no small measure, upon his power of putting that and that together and making knowledge for himself from his own experience.

The value of experience in the direction of the work of life does not need to be established by argument. It has become proverbial. But the connection of its value as a directing agency with the making of knowledge may need a few words of exposition. That the mental process which enables us to learn by experience in later life is a knowledge-making process—the same as that used by the child in acquiring its mother-tongue, though perhaps more consciously performed—becomes obvious if we consider any particular kind of work in which men engage. The merchant, to take a single case, in order that he may be able to foresee what kinds and qualities of the many articles in which he deals it will be desirable for him to have in stock, must watch the purchases of his customers, and make mental note of their satisfaction or discontent. The transactions are too numerous to be carried in the memory or to admit of written memoranda. If he is to make progress in judging as to what his stock should include, he must put related experiences together, weld the lessons he learns from them into general rules, and make these rules more and more accurate as time goes on. And the same is true of many other questions which he must settle for himself. Unless, in fact, he can generalise his mercantile experience, as a child generalises its linguistic experience, he must continue to buy and sell with no greater intelligence than he did at the outset of his business career.

> "Till old experience do attain
> To something like prophetic strain,"

as Milton puts it, he can have no complete success.

A similar statement may be made with respect to the physician, the farmer, the investigator, the housewife, the artisan, the politician, the clerk,—with respect, in fact, to all classes of workers, whatever the form of work in which they may be engaged. It may be made also, not only in regard to their main work, but in so far as they may in addition be engaged in athletic, literary, artistic, political, social, religious, or any other effort, and whether that effort take the form of work or play. In short, it is applicable to a greater or smaller extent to at least the great bulk of the various forms of activity of which the lives of most of us are made up. The subject-matter of experience, the material with which we must deal, is different in different cases; but there is one condition

[1] Inaugural address delivered at the opening of the fortieth session of Dalhousie College, Halifax, Nova Scotia, on September 13, by Prof. J. G. Macgregor.

of success which is common to them all,—the possession of the power of foreseeing; and there is one method of acquiring foresight,—the making of knowledge for ourselves from our own experience.

If this be so, it is obvious that this power of knowledge-making should be raised to as high a pitch of efficiency as possible before we enter upon the active work of life. Its growth, like that of all intellectual faculties, is slow; and the facility of its initial cultivation diminishes with advancing years. It is hazardous, therefore, to postpone its cultivation until we are face to face with the problems of life, or even until we enter upon the special study of the main work of life in the technical or professional school. It should be cultivated, and cultivated with especial care, during the whole period of tutelage, whether it be spent at the school only or in part in a department of liberal training of the college. And in order that it may be cultivated, it must be kept in continual exercise.

I do not know that provision for the exercise of this faculty has ever been generally made, with full consciousness, in either school or college; but it can readily be shown that it was given far more exercise in the educational institutions of two or three generations ago, than it is in general in those of the present day.

The curriculum of the old schools, which is also that of the old-fashioned conservative school of our time, consisted largely of classics and mathematical science (including natural philosophy), its backbone being the study of classics; and while the study of mathematics, though an admirable discipline, is for the most part deductive in character, and thus gives only a limited exercise to the power under consideration, the study of language, and especially the study of Latin and Greek, gives it very abundant exercise. Even if the study of a language is carried out with the aid of a grammar and a lexicon, *i.e.* with frequent appeal to authority, it involves continual putting together of instances of the usage of words and phrases which have come to our notice, formation of hypotheses as to their usage, and repeated modification of such hypotheses, after they have been brought to the touchstone of experience. The lexicon, especially the lexicon of the old school, would give little more than a clue in many cases to the English equivalents of say, Latin words, the exact equivalents, whether words or phrases, being determinable only by a study of the context and a fruitful drawing upon experience. And when we think how large is the number of words and phrases and constructions, of the usage of which the student of a language is gradually forming more and more accurate conceptions, we see at once how abundant is the exercise which this study provides of the putting of that and that together. The material on which the knowledge-making power is thus exercised, is of course of one kind, and therefore in general of a kind quite different from the material on which it must be exercised in after life. The exercise afforded is thus one-sided and by no means complete. But it is nevertheless exercise of the same intellectual power which we must later on apply to the more varied and complex material which life will afford.

While the study of the classics gave the student under the old régime considerable experience in the making of knowledge, the curriculum as a whole gave him both the key to his own literature and the literatures of Greece and Rome, and an introduction to the principles of the systems of knowledge which existed at the time. His stock of information we should now consider small; but it bore a great ratio to the whole body of available information. And it should be noted that such knowledge as the student had acquired, had been acquired in a leisurely, thoughtful way, and largely by his own effort, and would thus have become a permanent possession.

The men of the schools, therefore, in those days, had acquired, besides facility of access to the great storehouses of human wisdom, two things of direct importance for success in the work of life—an outfit of knowledge and the power of adding to it from their own experience. They were consequently men of power, and were recognised as such. And as it was the knowledge they possessed that was the only readily recognisable part of their outfit, their knowledge came naturally to be regarded as the secret of their power.

It appears to be Bacon to whom the credit belongs, of having coined the aphorism: "Knowledge is power." If so, to Bacon also must attach the opprobrium of having perpetuated a false and vicious generalisation. However important knowledge may be, it is not *the* essential condition of power. It is only one of the conditions. A second, perhaps the first, is the ability to make knowledge, which *may* be developed in the acquisition of knowledge, but also may not. No knowledge, no power: would have been sound doctrine; Knowledge *is* power: was false doctrine.

And while the possession of knowledge is essential to power, it is not the possession of an outfit of knowledge at the beginning of active life that is essential, but the possession of such outfit when it is wanted. In the old days the world's whole stock of knowledge was so comparatively small, that it was possible in the period of tutelage to get an outfit of its principles at least. At the present day the world's stock is so large, that the school and college can no longer furnish a corresponding outfit. Yet the men of the present day are at little disadvantage on that account. For as the volume of knowledge has increased, its accessibility has increased also. And thus, provided the student of to-day has been trained to acquire knowledge, has been taught, in fact, the most important of the three R's, the art of reading, with all that the art of reading involves, he can readily provide himself at any time with such information as he may require. Thus, nowadays, it is not so much knowledge that is even one of the conditions of success, as a well developed power of acquiring knowledge.

It was largely on the basis of Bacon's false generalisation that the fight was waged in later years between classics and the rapidly growing sciences. The advocates of the introduction of science into the curriculum of the school and college, based their demand mainly on the importance for success in life and for general culture, of a knowledge of the laws of natural phenomena. And their opponents, though relying largely on the excellence of the results achieved under the old system, met the utilitarian arguments of men of science by urging various minor utilities involved in the study of Latin and Greek. Neither party seems to have realised, at least fully, the more profound utility which might be involved in both kinds of study.

The introduction of science into the curriculum under this mistaken conviction could not but have unfortunate results. Its primary effect on the study of classics was to diminish the time devoted to it. But there was a more serious secondary effect; for, since knowledge was power, and as much knowledge of Latin and Greek must therefore be acquired, if possible, as before, the student had to be subjected to a forcing process. Helps of all kinds consequently developed a vigorous, nay a rank, growth—elaborate grammars full of detailed information, lexicons giving all the shades of meaning that words might have, annotated texts removing all difficulties from the student's path, even translations, fitly described in college slang as *cribs* and *ponies*. Power of translating was acquired by the aid of such educationally illegitimate helps; but it was acquired to a smaller extent than formerly, by the student's generalising his own experience and to a greater extent by the use of information derived from authority. The study of the classics consequently, first because of the diminution of time, and secondly because the time was no longer so well employed, came to provide a doubly diminished exercise of the knowledge-making power. The command of the classical languages, too, which was thus acquired, became for these reasons a less permanent possession; and the study of them no longer served to open up to the student, to the extent to which it had previously, the great literatures of the past.

Nor did the science study itself atone for the deterioration which its introduction involved in the study of classics. I need hardly point out that the method which is used in the making of knowledge in any branch of science, is the same as the method we must apply in making knowledge from the experience of everyday life. Indeed, it gets the name of the scientific method, because, though it had been used by men in all ages in the learning of languages and in learning by experience of all kinds, it was first brought to the notice of logicians by the rapid development of science, which resulted from its systematic application to the study of natural phenomena. Any single science, therefore, may be studied as any language may, so as to afford practice in knowledge-making. Language study has the advantage of affording a larger number of simple problems on the material of which the student has the widest experience. A science has the advantage of presenting problems with a greater range of difficulty on a material which is in general more complex. A group of sciences has the further advantage over even a group of languages, of affording a greater variety of subject-matter for the exercise of the knowledge-making power, and consequently giving the student practice in learning from experience under such different conditions as to fit him more completely for using his experience under the conditions of actual life.

The combination of linguistic and scientific study, therefore, if both had been conducted by knowledge making methods, might have been expected to produce better results in the cultivation of the knowledge-making power, than the study of either singly. But under the domination of the conviction that knowledge is power, science could not be studied in this way. The main object for which it had been introduced into the curriculum was the provision of an outfit of useful information, and the study must be carried on, so as to provide as large an outfit as possible. The obvious means of furnishing this outfit was the synoptic text-book, an epitome of the latest results in any branch of science; and all that the student had to do, in order to possess himself of it, was to get up the book. Clearly with this as his method he could not learn to use his own experience, but must become

"Deep versed in books and shallow in himself."

It is true, that when, after a time, the new science study was found to have become a mere getting up of books, the cry of "Back to nature!" was raised. As Wordsworth put it:

"Come forth into the light of things,
Let Nature be your teacher."

As a result, experimental demonstrations were tried; but they were found insufficient. And now laboratory work has been introduced into school and college, and students are made, themselves, to carry out many scientific processes. They are taught to use the balance, to verify Boyle's law, to measure electric currents, to prepare gases, to analyse solutions, to dissect frogs to classify insects, to use the microscope, to hunt out the names of plants. But they are always shown how to do the things required of them. And thus, from our present point of view, this mode of coming into the light of things can be of little avail. For while it makes the student's conceptions more vivid and the knowledge acquired more accurate and less transitory, and while it affords subsidiary training, *e.g.* of the hand and the eye, it gives but little additional opportunity of acquiring power in the making of knowledge. Even such additional opportunity as was at first afforded, when the student had no book to follow and was thrown to a certain extent upon his own resources, has now been withdrawn. For it was soon perceived that a greater amount of ground could be covered if he spent no time in working things out for himself. And so the text-book of laboratory work was devised, telling him exactly what to do and exactly how to do it. "Back to nature!" has thus meant: Back to books! And it could not have been otherwise. For under the conviction that it is knowledge that is power, practice in the putting of that and that together must appear to involve a waste of precious time.

There is another influence which has tended to strip the study of science of the high educational value which it might possess, viz., the influence of the written examination. Men of knowledge under the old régime having been found to be men of power, it became desirable that they should be certified by competent bodies. The degree and the diploma thus came into prominence; and the tests applied to candidates for them, when the candidates became numerous, took generally the form of written examinations. Now it is quite possible to test in this way the possession of command over a language, of deductive power in such subjects as mathematics or philosophy, and of information on any subject. But it is impossible to test by examinations of this kind, directly, the possession of the knowledge-making power. The making of knowledge, even in its humbler forms, is a creative process. It occurs only when the flash of imagination lights up the storehouses of experience and reveals the relations of its accumulated observations. And as the wind bloweth where it listeth, so imagination does not become luminous at command. Put even such men as Faraday or Darwin into the examination hall and tell them to spend an hour in exhibiting on paper their ability to find things out for themselves, and they must almost inevitably fail. It would, in fact, be no more absurd to ask a poet to exhibit true poetic inspiration, at a given date, than to ask a knowledge-maker to make knowledge.

If, therefore, the possession of knowledge-making power is to be tested at all by written examinations, it must be tested indirectly. And in some cases it can. The exercise of this power in the study of a language, besides strengthening the power itself, produces a command of the language which is not otherwise attainable. And consequently it is possible to test the acquisition of this power in linguistic study, indirectly, by a skilful testing of the candidate's command of the language. Its exercise in science study, however, produces in addition to increase of the power itself, nothing but a stock of information, which is much more readily obtainable from books. The acquisition of the knowledge-making power in science study cannot therefore be even indirectly tested by the written examination.

Now written examinations, when used either as the only tests, or as the chief tests, for a degree or a certificate, must tend to encourage the acquisition of what they are capable of testing and to discourage the acquisition of what they cannot test. For candidates soon find out what kind of work will pay, and they naturally confine themselves to it. Hence if such examinations are used as tests for degrees, while they may encourage the cultivation of the knowledge making power in linguistic study, they must discourage and repress it in the study of science.

And if this is the effect of written examinations generally, the effect is of course intensified when they are conducted by a central examining body. For the central examiner, who sets a paper for, say, the schools of a district, can obviously find out even less about the knowledge-making power of candidates than the examiner who can adapt his paper to the work done in a particular school. Centralised examining has serious evil effects of its own. But apart from such effects, which it would be foreign to my subject to discuss now, it must exert a specially strong influence in repressing the cultivation of the knowledge-making power, and in transforming the student into Pope's

"bookful blockhead, ignorantly read,
With loads of learned lumber in his head."

A third difficulty with which the sound teaching of science has met, arises from the complex character of its subject-matter. To compare different usages of words, for example, one has but to turn over the leaves of a book; to compare instances of the occurrence of natural phenomena, the phenomena must be watched for or reproduced under varying conditions. Knowledge-making, therefore, especially in its early stages, finds more difficult problems in science than in language; and the young investigator meets with greater hindrances to progress. The early investigators felt this difficulty, and banded themselves together in societies in order to enjoy the suggestions and criticism of their fellows. The science student of course needs the helping hand still more; and the teacher must be able to give the requisite aid in a judicious way. He must be a knowledge-maker himself, must have sufficient experience in the subject he is teaching, and must be largely endowed with tact and common sense. Unfortunately the old curriculum furnished men with practically no experience of science, the new curriculum furnished men with little knowledge-making power, and no curriculum could furnish the tact and common sense. The available teachers have thus in general been incompetent. And in the making of scientific knowledge, a pupil under an incompetent teacher must stick fast.

Competent teachers in classics, on the other hand, have always been more readily obtainable. And—what is of more importance—in the making of linguistic knowledge, a pupil under an incompetent teacher does not stick fast. He has the experience of his childhood to help him, is capable of exercising the knowledge-making power, without the teacher's aid, on the familiar material which language affords, and in his effort to make progress, cannot help exercising it to a greater or smaller extent. Let me draw special attention to this point; for the fact that in the study of language, exercise of the knowledge-making power is not only possible, but in a large measure inevitable, even under an incompetent teacher, gives to language study a great advantage over science study, as a means of discipline in all educational institutions, but especially in those of lower grade, in which, owing to their large number, the difficulty of securing competent teachers is especially great.

The conclusions we have now reached may be summarised thus:—(1) Few of the subjects of the old curriculum could be studied without exercise of the knowledge-making power;—

many of the subjects of the new curriculum can. (2) The demand for useful information did not affect the old curriculum;—it seriously diminished the exercise of the knowledge-making power in the new. (3) Written examinations might stimulate such exercise in the old curriculum;—they could not but repress it in the new. (4) Competent teachers could readily be secured for the old curriculum;—they have not generally been available for the new. (5) Incompetent teachers could not largely exclude practice in knowledge-making under the old curriculum;—they could not fail to exclude it largely under the new. Obviously, therefore, the more intensely modern the curriculum has become, *i.e.* the more linguistic study has been excluded and science study introduced, the less efficient in general must the curriculum have become, so far as practice in knowledge-making is concerned.

If the above discussion is sound, any system such as our modern system, from which the method of investigation is largely excluded, must be distinctly inferior, as a means of preparing young people for the work of life, to a system such as the one which has become old-fashioned, in which it is given abundant exercise. It is difficult, however, to establish an inferiority in a case of this kind from experience. For in any trial that may be made of the two systems there must always be extraneous circumstances on which the burden of any observed inferiority may be laid. On the present occasion I cannot take time even to summarise such evidence as goes to show that the inferiority which is to be expected has been found to be actual. I must content myself with a mere reference to the result of what is perhaps the most decisive of all the trials which have been made, viz., that made in Prussia as to the relative educational efficiency of the Gymnasium, with its largely classical course, and the Realschule, with its largely scientific course. Both institutions had been conducted with characteristic German thoroughness with respect to the training of teachers and the provision of equipment, and the written examination system had been applied in a non-centralised form. Except in so far as tradition and the wider privileges of Gymnasium graduates may have led the more promising men to enter the Gymnasium, the two institutions seem to have worked under equally favourable conditions. Yet when in 1880, after a trial of more than ten years, the question of continuing to admit graduates of the Realschule to certain courses of the University of Berlin came up for discussion, even the scientific professors testified that for the work of their departments, mainly scientific research, the men nurtured in the Gymnasium had been found better qualified than those who had come up from the Realschule. The effect of tradition and privilege may have had much to do with this result; and the means of instruction in science twenty years ago were of course not so elaborate as they are now. But it is significant, that in the light of the present discussion, it was to be expected that for success even in scientific research, *i.e.* the making of new knowledge of natural phenomena, power of knowledge-making, though cultivated on linguistic study only, would be of greater importance than the stock of scientific knowledge which it is the aim of the modern curriculum to afford.

Our own experience in Nova Scotia is less definite. We have not had the two systems running side by side, and can only compare the present state of things with the past; and the comparison is complicated by the fact that the present state of things is in many respects in advance of the past. But there is no doubt that the country is full of a deep and growing discontent, which, though it finds vent at times in ill-grounded criticism, rests in the main on a solid basis. The farmer, to take a single example, finds that the boys he sends to the High School rarely return to the farm. He blames the school, with its Latin and its multiplicity of sciences, and demands the provision of something more practical, such as the teaching of agriculture. There are probably many reasons why the farmer's boy does not return to the farm; but there can be little doubt, if my position is sound, not merely that he is not fitted, but that he is actually unfitted, by his High School course, for the farmer's work. The farmer must, above all things, be able to learn quickly and accurately from his own experience. His boy, after passing through an intensely modern curriculum, under the pressure of a centralised examining system, and under the guidance of teachers in whom, for the most part, the colleges have failed to develop the investigating spirit and power, must almost inevitably be less able to make knowledge for himself out of his own experience, than he would have been, had he remained on the farm; while even that part of his large stock of acquired knowledge which bears upon agriculture must consist in general of inaccurate and ill-digested epitomes of sciences, in which he has little, if any, genuine interest. The farmer's discontent is therefore probably justified; but he is wrong in the details of his criticism. With the teachers who are at present available, Latin is the subject from which his boy will acquire, more than from any other, the essential power of putting that and that together. Although it is true that the usual synoptic study of the whole circle of the sciences will make his boy neither a farmer nor anything else, it is also true that a more informal study, a knowledge-making as distinguished from a mere information-supplying study, of bodies and the changes they undergo, and of plants and animals, rocks and soils, would cultivate in him the power of using his experience, give him, not much perhaps, but certainly some real knowledge bearing on agriculture, give him the scientific experience requisite for the reading of agricultural books, and give him a living interest in all the operations of the farm. Fruitful teaching in agriculture, however, is impossible. The teacher could teach it only if he were a somewhat experienced farmer himself; and even if he were, he could not teach it adequately to beings with such limited experience as boys.

Nor is the farmer the only exponent of discontent. The feeling of dissatisfaction is general. And if my position is sound it might be expected to be general. For if our school discipline fails to cultivate in our youth the power of learning by experience, it fails to give them what is at least one great essential of success, not in farming merely, but in whatever form of work they may be called upon to undertake.

There is one other educational experience, perhaps specially characteristic of our time, to which I should like to refer, viz., the frequency of the success of the self-made man. His success is usually attributed to innate ability, organising power, push, knowledge of men, and what not. To my mind it is largely due to a well developed power of learning by experience; and he owes that in great measure to the school of practical life in which he has had his training. This school provides an entirely different curriculum from the one we have been considering. It furnishes its pupils with no outfit of information whatever; but compels them to hunt out for themselves such information as they may require. And instead of devising cunning ways of stopping the putting of that and that together, it compels its pupils, by sending them early into active life, to cultivate that power for themselves. Many of them of course go down; for no helping hand is extended to them, and the method is rough. But many manage to obtain the knowledge they require, learn how to put the that and that of their experience together, and graduate, often, as we should say, with high honours, in one or other of the departments of active work. They may not have been brought into contact with much that makes for sweetness and light, and may thus be deficient in literary and general culture; but for all forms of activity that demand the generalising of experience, their rough school has given them a training which is, in some respects at least, admirable. Can we wonder then that the practical man, who rightly regards ability to tackle the main work of life as the most important component of a complete culture, and who sees daily the comparative helplessness of the products of the modern curriculum, decides to send his son as early as possible to the school of practical life?

If, notwithstanding the imperfect manner in which I have presented the value of the knowledge-making power, you are convinced of its great importance, you cannot fail to be interested in the question: How are we to secure its cultivation in the school and college?

We may dismiss at once the proposal suggested by what has been said as to the efficiency of the old-fashioned school, that we should return to the classical curriculum, or, at any rate, to language, as the chief means of educational discipline. Such harking back, even looked at from our present point of view only, would be bad policy, for two reasons, (1) because a combination of language and science study, if both are properly carried out, affords a far better training in knowledge-making than either singly, and (2) because, though an outfit of knowledge of science, adequate for use in the work of life, is no longer capable of being provided beforehand as part of a course of liberal training, the acquisition of power of acquiring knowledge demands considerable scientific experience. A curriculum of which science is an important component, therefore, should be retained, provided the science as well as the language be studied by knowledge-making methods.

Nor need we stop to consider the assertion, made by eminent educational authorities, that in the school at least, such methods cannot be employed in science, or that they have been tried and have failed. Both assertions are sufficiently met by the fact that under favourable conditions, they have been tried and have succeeded.[1] But it must be admitted that knowledge-making methods could not be introduced generally with success, under the prevalent conditions of the present day. For so long as a large body of varied information is an essential condition of academic distinction, so long as the written examination is used as the main test of proficiency, and so long as teachers themselves have not had the investigating spirit developed in them, the school cannot cultivate the knowledge-making power in any large measure.

Reform, to be radical, therefore, must begin with the universities, and with the leading universities. They only can make the conditions for degrees what they please, and they only can hold the examiner completely in check. The smaller universities and colleges must, in the interests of their students, follow more or less the lead of their bigger sisters; and though Councils of Public Instruction and other bodies which govern schools may be largely free to modify their curricula and to regulate their examinations, they cannot secure the services of teachers who are imbued with the investigating spirit, until that spirit has become embodied in the universities.

But while radical reform may not be possible at present, partial reform can be carried out even by a college such as ours, by its steering a middle course between encouraging the use of knowledge-making methods and supplying the information demanded by the larger universities, and by thus cultivating the power and the spirit of investigation to as great an extent as may be possible under present conditions. And the reform thus inaugurated may be extended to the schools of its district, through the teachers supplied by the college, if the governing body of the schools is willing to co-operate. . . . . . .

It is true that as the early investigators in science made progress without the complex and therefore costly appliances which the investigator of to-day in general requires, so students can get an astonishingly large amount of practice in knowledge-making with very simple materials, and that consequently a knowledge-making equipment involves much smaller expenditure than that which is required by the up-to-date course. Nevertheless, even for practice in the making of knowledge which was made by others long ago, not to speak of the making of knowledge of a later date, or of new knowlege, our equipment is entirely inadequate.

There is still another aspect in which we are deficient, viz., in the working facilities afforded to professors. That the professor of a scientific subject may cultivate the knowledge-making power in his students, he must be a knowledge-maker himself; and to do so in full measure he must be enabled to prosecute original research under favourable conditions. His work may be humble, and its value may be comparatively small; but provided its value is real, it will help him to kindle in his students the enthusiasm which springs from the conviction that the subject they are studying is a growing subject, and that it is possible for them to assist in its growth. It is not therefore in the interest of the professors, but in the interest of their students, that I hold it to be the duty of the college to give professors both the time and the necessary outfit for research. Giving them the requisite time means the provision of competent assistants. Giving them the requisite outfit means the provision, not necessarily by any means of completely equipped laboratories, but of books and other working appliances sufficient for at least a few lines of research.

At first sight the considerable expenditure which would be required for this purpose, will appear to most of you to be expenditure on luxury; and possibly the benefit which a college derives from the fact that its professors are known as original investigators, although undoubtedly great, may be of the nature of a luxury. But when we reflect on the importance of training all our young people to use their experience, and consequently of stimulating our college students, many of whom are to be the teachers of our youth, to acquire the knowledge-making power in the highest possible degree, it becomes apparent that research facilities for our professors are not a mere luxury, but are necessary for the performance of thoroughly successful educational work.

I have referred so far only to what liberal training requires. In addition, it is desirable, especially from the point of view of the provision of teachers of higher grade, that those of our students who have shown great promise of power in the making of knowledge, should, without leaving their own country, have ready access to the requisite facilities for research in any department in which they may wish to carry on special study. In other words, Canada ought to have at least one university thoroughly equipped for investigation in all the main departments of knowledge—and I say one, because, however desirable such equipment would be in all, with our local art schools and agricultural schools and other technical schools undeveloped, the country cannot probably afford more than one. And this is desirable, not in order that Canada may take her place worthily among other nations by contributing her share to the growth of knowledge, and not because of the material progress that might result from the advance of science, but mainly because the fruitful investigating work that would be conducted at a fully equipped university, would tend to foster the spirit of investigation in all the colleges, and through the teachers they supply, in all the schools, and would thus tend to make even those who never enter a college better knowledge-makers, and therefore more successful men, in whatever department of work they might be engaged.

It is for this reason that the young people of Canada are to be congratulated, even more than the institution immediately concerned, on the great strides which McGill University has recently been enabled to make towards complete equipment; and for the same reason, I may express the hope, in which I know you will all join, that she may soon acquire as thorough an outfit in all departments as she has already acquired in some. If but one of our universities is to receive complete equipment at present, it is fitting that the one having its seat in our commercial metropolis should be selected for the trust. And if McGill University, regarding herself as the trustee of a rich endowment, held for the benefit of the whole Dominion, is able to rise to the level of her opportunity, her influence will, at no distant date, be felt for good in the life work of every Canadian.

The friends of our smaller colleges must therefore rejoice in the rapid enrichment of their more fortunate sister. Nevertheless its first effect upon them has naturally been one of depression. It is obviously impossible for them to do for the colleges in which they are interested, what McGill's benefactors are doing for her. And, although in a country of such magnificent distances as Canada, it is obviously desirable that our young men should have colleges, or at least a college, provided for them in their own section of the Dominion, in order that as many of them as possible may enjoy the advantage of the higher forms of education, and also that their own section may retain their services for its own development, those who have hitherto supported the smaller colleges naturally ask: Is it worth while for us to make any further effort? Indeed, are we justified in encouraging our young people to attend the smaller colleges when a university so much more fully equipped is open to them?

Such questions receive their answer from the present discussion. Liberal training does not demand, as the provision of encyclopædic knowledge does, that students should be supplied with all the books and all the latest contrivances in all departments of knowledge, or even in any department. It demands only, so far as subjects requiring costly equipment are concerned, that they should have access to such equipment in the chief departments as will enable them to have sufficient and sufficiently varied exercise of the knowledge-making power. Complete equipment is requisite only in an institution which aims at furnishing opportunity for original research on all lines, in fact, at the making of specialists rather than the making of men. Only a small part of such an equipment is necessary for, or can be used in, even the most thorough liberal training.

It follows that the small college with incomplete equipment can furnish quite as sound and thorough liberal training as the completely equipped university, provided it is not too small to supply the important training which college life affords, and provided its equipment, though comparatively small, is adequate; and consequently, that if both these conditions are fulfilled, it is completely justified in inviting students to trust their training to its care.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—A statute will be promulgated early next term with the intention of instituting degrees of Doctor of Letters and Doctor of Science. The present statutes provide for the degree of Bachelor of Letters and Bachelor of Science, for which a course of special study or research, and a residence of two years, are required. Several of these research degrees have been granted during the last four years. It is now proposed that the Doctorate should be instituted, for which a candidate shall submit published papers or books containing an original contribution to the advancement of learning or science. A candidate for the degree of Doctor of Science must either be a Bachelor of Science of twenty-six terms standing, or a Master of Arts of thirty-nine terms standing.

The B.Sc. degree has been granted to Mr. H. N. Dickson, of New College; his dissertation consisted of a chemical and physical examination of the surface waters of the North Atlantic collected during 1896 and 1897, and contained 4000 estimations of the salinity.

The lecture list announced for next term contains those to be delivered under the newly instituted School of Geography.

Dr. John Scott Haldane has been reappointed lecturer in physiology for a period of three years.

The newly instituted John Locke scholarship in mental philosophy has not been awarded.

The following alternative subjects are recommended for the Johnson Memorial Prize in 1903: (1) periodic orbits; (2) meteors; (3) an investigation of the image of a star in a telescope as affected by the physical properties of light.

Dr. J. A H. Murray, editor of the "New English Dictionary," has been appointed Romanes lecturer for 1900.

The annual grant of 300*l.* to the chemistry department of the University Museum has been renewed for five years, and the sum of 170*l.* is to be spent on cases for the Pitt-Rivers Museum.

CAMBRIDGE.—Prof. Marshall Ward has been elected a member of the General Board of Studies.

Mr. Timothy Holmes and Prof. W. Burnside, F.R.S., have been elected Honorary Fellows of Pembroke College.

A Shuttleworth Scholarship in Botany and Comparative Anatomy will be awarded at Caius College in March next. The value is 55*l.* a year for three years, and candidates must be medical students of the university of not less than eight terms' standing. Application is to be made to the senior tutor before March 1.

MR. R. T. GLAZEBROOK'S successor as principal of University College, Liverpool, is Mr. A. W. W. Dale, Fellow and Tutor of Trinity Hall, Cambridge.

SIR WILLIAM C. MACDONALD, of Montreal, has founded a Chair of Geology for McGill University in that city, as a memorial of the late Sir William Dawson. According to the terms of the gift, the income of the endowment will be paid to Lady Dawson during her lifetime, and on her death will become available for the maintenance of the new Chair.

AT University College, London, a course of eight lectures dealing with the methods of spectroscopy especially in connection with the photography of the spectrum will be given on Friday evenings, at 5.30, by Mr. E. C. C. Baly, commencing on January 19, 1900. Among the subjects to be treated and illustrated by experiments are:—The history of the determination of the modern standards of wave lengths; the comparison of spectra and determination of wave lengths visually and photographically with prism apparatus; the determination of wave lengths with the grating; and methods of producing emission and absorption spectra.

A COPY of the special report on the new department of agricultural chemistry of the University College of Wales, Aberystwyth, recently submitted to the Court of Governors, has been received. The work of this promising department of the College is carried on in premises specially designed for the purpose. This accounts for the convenient arrangements for access and inter-communication shown upon the plan which accompanies the report. The rooms and the laboratory fittings give evidence that much care has been taken to design arrangements which will conserve the energies of the staff, and give facilities for good practical work by the students.

ON Thursday last, upon the occasion of the distribution of prizes and certificates to the successful students of the Goldsmiths' Company's Technical and Recreative Institute, New Cross, Mr Asquith made a few remarks on the work of polytechnic institutes in London. He pointed out that in the metropolitan area, north and south of the Thames, there are no less than eleven institutions of this kind, with four or five subsidiary branches, upon which a capital expenditure of no less than 500,000*l.*, at the least, has been made, with an annual expense to those who promoted them of something like 130,000*l.*, and with an attendance of no less than 50,000 students. The Goldsmiths' Institute is not only one of the most flourishing among London polytechnic institutions, but in some respects it is unique. Unlike every other institution of the kind in London, it does not receive grants of money either from the Technical Board of the London County Council or from the Central Parochial Foundation of the City of London. The whole cost, except the comparatively insignificant sum received from the students' fees, is defrayed out of the funds of the Goldsmiths' Company.

THE *Times* reports that the executive committee of the Agricultural Education Committee has recently passed a series of resolutions including the following:—(1) That, in view of the importance of concentrating the control of agricultural and rural education in the hands of one Government department, it is expedient that all the educational work of the Board of Agriculture should be transferred to the new Board of Education; (2) that the staff of the new Board should include an adequate number of inspectors, well acquainted with the needs of the agricultural classes and the conditions of country life; (3) that the Board's inspectors should be instructed to see that the curricula of rural schools are differentiated from those of urban schools. With regard to training, the committee think that provision should at once be made at certain of the teachers' training colleges for giving those students who desire it practical as well as theoretical instruction in subjects bearing on agriculture and horticulture; and that a special rural teachers' certificate should be awarded to those teachers who have gone through a full course of instruction, practical and scientific, in agricultural subjects. As to higher agricultural instruction, it is suggested that the Board of Education should encourage those county authorities, who have not yet done so, to provide, or to contribute to, school and experimental farms, and should inspect and report annually on such farms; that no more certificates for proficiency in the "principles of agriculture" should be granted to persons who have not completed an adequate course of practical instruction; and that the courses for Schools of Science situate in country districts should be differentiated from those of urban schools of science by substituting instruction in agricultural science and experimental agriculture for that in other subjects. Another resolution suggests that, with a view to interest agricultural societies in the work of agricultural education, they should be supplied with leaflets, reports, &c., to distribute among their members, who should be invited to visit agricultural schools and experimental plots in their neighbourhood, and to discuss them at their meetings.

SOCIETIES AND ACADEMIES.

LONDON.

Physical Society, December 8.—Prof. G. Carey Foster, F.R.S., Vice-President, in the chair.—Prof. S. P. Thompson read a paper on obliquely crossed cylindrical lenses. Any two cylindrical lenses crossed obliquely are optically equivalent to two other cylindrical lenses crossed rectangularly, and hence to a sphero-cylindrical lens. Owing to the difficulty of manufacturing cylindrical lenses with the axes of the opposite faces in different directions, it becomes of importance to the optician to be able to calculate the constants of the equivalent but more easily ground sphero-cylindrical lens. To a first approximation a surface of radius of curvature "r" will impress upon a plane wave a curvature of $\frac{\mu - 1}{r}$ where "μ" is the refractive index of the material. If we suppose an equiconvex cylindrical lens cut by two planes at right angles, the line of intersection of the planes passing normally through the centre of the lens, then the sections of the lens will in general be portions of ellipses. It is possible, therefore, to write down in terms of the angle which one of these planes makes with the axis, the convergivity which would be impressed by the lens upon plane waves travelling in these planes. The effect of a second lens crossing the first obliquely can also be written down with respect to the same two planes. The joint effect of the two lenses can then be resolved along any two lines at right angles. Differentiating the expressions for these effects and equating to zero, we get the directions of maximum and minimum cylindricity. These directions are at right angles, and represent two lenses crossed rectangularly, which are the optical equivalent of the original pair considered. The sphero-cylindrical lens is then easily obtained. From the mathematical expressions Prof. Thompson has deduced a graphical solution of the problem. The author exhibited a convenient combination of two cylindrical lenses for giving varying degrees of cylindricity. Let two lenses be ground, each being a mixed equi-cylinder consisting of a concave and convex ground at right angles to one another on the opposite faces of the glass. Two such mixed cylinders, if rotated with equal motion in opposite directions, will give a varying cylindricity of fixed direction in space. With the axes of positive cylindricity coincident they give the maximum; but when each is rotated 45°, their resultant is zero. When rotated beyond 45°, the resultant axis of cylindricity is negative in the fixed direction in which it was formerly positive.—Mr. T. H. Blakesley read a paper on exact formulæ for lenses. In this paper the author makes use of the definition of focal length with respect to magnifying power, which he has described in the *Proceedings* of the Physical Society for November 1897. By this method the focal length of a lens combination is simply a line and not the distance between two definite points. Following the methods of his previous paper, Mr. Blakesley showed how it was possible to determine accurately the constants of lens combinations, and pointed out practical applications to the racking of telescopes for camera work, the determination of refractive indices of liquids, &c.—Prof. W. E. Dalby exhibited a friction dynamometer. The torque to be measured produces a twist in a spiral spring, and the object is to determine the amount of this twist. Side by side upon the shaft are two pulleys, one keyed to the shaft and the other fastened to the end of the spring. The lead of one pulley upon the other, therefore, measures the twist. Two other pulleys are mounted upon a slide, and are joined up to the first ones by means of a continuous band similar to a Weston's differential pulley block. When the shaft is at rest, the two pulleys on the slide are touching; but any motion of the shaft produces a twist in the spring, and therefore a lead of one of the shaft pulleys on the other. This produces a separation of the slide pulleys, which is proportional to the lead, and therefore to the torque, and so from a knowledge of the constants of the dynamometer and its number of revolutions per second the power transmitted is at once determined.—Prof. S. P. Thompson read a note on an organic compound of great double refraction. This substance is crystallised naphthaline, and it is 60 per cent. more doubly refracting than Iceland spar. It is exceedingly brittle, and therefore difficult to work into prisms. Any worked surface must be at once covered with glass to prevent sublimation.—The Society then adjourned until January 26, 1900.

Zoological Society, November 28.—Dr. Henry Woodward, F.R.S., Vice-President, in the chair.—Mr. Lydekker exhibited (on behalf of Messrs. Rowland Ward, Ltd.) and remarked on a headless skin of a kob-like antelope from Lake Mweru, which he proposed to call *Cobus smithemani*, after its discoverer, Mr. F. Smitheman. He likewise exhibited the skull and horns of another kob, belonging to Sir E. G. Loder, for which the name *C. vardoni loderi* was suggested.—Mr. Oldfield Thomas exhibited the skull of a baboon recently obtained at Aden by Messrs. Percival and Dodson. It appeared to represent a new species allied to *Papio hamadryas*, but distinguished by its small size, the row of upper cheek-teeth being only 41·5 mm. in length. It was proposed to be named *Papio arabicus*.—Mr. W. Saville-Kent exhibited, with the aid of the lantern, a series of slides demonstrating the utility of trichromatic photography as applied to the correct colour-registration of biological subjects. Photographic transparencies representing various species of plants and animals were included in the series —Mr. J. S. Budgett gave a general account, illustrated with lantern-slides, of his recent expedition to the Gambia Colony and Protectorate, undertaken primarily for the study of the habits of *Polypterus*. Some living and spirit specimens of this fish were exhibited, and remarks were made upon it, as also upon *Protopterus*, of which examples were likewise obtained. Special reference was made to the antelopes met with during a trip up the Gambia River to the end of its navigable waters, and specimens of the heads of those obtained were laid on the table. A collection of Gambian birds was also exhibited.—A communication was read from Mr. L. A. Borradaile, in which it was shown that both genera (*Coenobita* and *Birgus*) of the Pagurine land-crabs (*Coenobitidae*) are hatched in the *Zoaea*-stage.—Dr. W. G. Ridewood read a paper on the relations of the efferent branchial blood-vessels to the *circulus cephalicus* in the Teleostean fishes, based upon an examination of specimens of sixty-one species. He demonstrated the great variation that is met with in the arrangement of the efferent vessels, and discussed the possibility of utilising the characters as a means of arriving at a natural classification of the group.—Mr. G. A. Boulenger, F.R.S., read a paper on the reptiles, batrachians and fishes collected by the late Mr. John Whitehead in the interior of Hainan. The collection contained specimens of fifteen species, embracing four species of reptiles, six of batrachians, and five of fishes. Of these, two species of reptiles, three of batrachians, and three of fishes were described as new.—A communication was read from Dr. A. G. Butler on a collection of butterflies made by Mr. Richard Crawshay in British East Africa. Sixty-eight species were enumerated and remarked upon, of which four were described as new.—A second communication from Dr. Butler contained a list of a small collection of butterflies made by Captain Hobart, of the Grenadier Guards, in the Nandi District of the Uganda Protectorate. Of the seventeen species represented in the collection, one (*Cymothoe hobarti*) was described as new.—A communication was read from Mr. J. Y. Johnson, containing a note on the habit and mode of growth of the corals belonging to the genus *Pleurocorallium*.—Mr. W. E. de Winton made some supplementary remarks to those published in the *Proceedings* for 1898 (p. 900), on the moulting of the King Penguin (*Aptenodytes pennanti*) now living in the Society's Gardens.

Entomological Society, November 15.—Mr. G. H. Verrall, President, in the chair.—The President announced the death of Dr. C. G. Thomson, one of the honorary fellows of the Society.—Mr. J. J. Walker exhibited four examples of a species of Curculionidæ—*Cleonus sulcirostris*, taken on red sandy soil at Barr's Hill, near Oxford. These examples, he pointed out, were of a reddish tint, harmonising with the colour of the soil on which they were found, and in marked contrast to that of normal grey specimens, some of which, taken at Deal and Reading, he showed for comparison.—The President exhibited specimens of *Chersodromia hirta*, which were found under sea-weed at Brora in August 1899.—Mr G. W. Kirkaldy exhibited two species of Hemiptera of economic interest, one a Pyrrochorid—*Dysdercus cingulatus* (Fabr.), sent by Mr. E. E. Green from Ceylon, where it was found appearing in abundance on the cotton plants, the other a Psyllid—*Aleyrodicus dugesii* Cockl., forwarded by M. A Dugès, who stated that it is attacking the white mulberries in Mexico.—Mr. J. H. Leech contributed part iii. of his paper on Lepidoptera Heterocera from Northern China, Japan, and Corea.

CAMBRIDGE.

Philosophical Society, November 13.—Mr. Larmor, President, in the chair.—Intumescences on *Hibiscus vitifolius*, by Miss E. Dale. *Hibiscus vitifolius* is a plant which is common in the hotter parts of Asia, Africa and Australia. It is usually very hairy, but the hairiness is subject to considerable variation, and the hairs are of several different kinds. On plants grown in greenhouses there are formed abnormal outgrowths of the epidermal and the subepidermal tissue of the stems and leaves. These emergences, especially on the leaves, usually bear stomata at their apices, and those on the stem are characterised by the formation of a cork-cambium at the base of each, which cuts off the older outgrowths. No traces of fungi or mites have been found, but experiments show that these outgrowths are not formed on plants in the open, where transpiration is more freely promoted. Seedlings and cuttings from such plants devoid of outgrowths, when placed in a greenhouse, develop outgrowths, while seedlings from plants provided with them, and which themselves have developed them, lose them if transferred to the open. It seems therefore probable that growth under glass may promote the production of some actively osmotic body in the young cells, and that the over-turgescence is expressed in the abnormal protrusions. Hence the application of the name "Intumescences."—Note on the name *Balanoglossus*, by Dr. Harmer. It was suggested that the species which belong to *Balanoglossus* as restricted by Spengel should be placed in a new genus *Balanocephalus*, whose type-species would be *B. kupfferi*. *Balanoglossus* should be dropped as a generic name, but may conveniently be retained as a semi-popular designation in cases where it is not desired to restrict a statement to any particular genus of the Enteropneusta.—The skeleton of *Astrosclera* compared with that of the Pharetronid sponges, by J. J. Lister. The structure of *Astrosclera willeyana*, the representative of a new family of sponges, obtained by Dr. Willey in the Loyalty Islands, was described, and attention was drawn to the resemblance between its skeleton and that of some members of the *Pharetrones*, a group of sponges which are found as fossils in formations ranging from the Carboniferous to the Cretaceous period. It was pointed out that the resemblance between the skeletal elements formed within the living protoplasm of *Astrosclera* and the bodies formed by purely physical processes in the St. Cassian fossils may have a bearing on the problem of the mode of origin of sponge spicules.—Note on hypotheses as to the origin of the paired limbs of Vertebrates, by J. Graham Kerr. In a paper on hypotheses as to the origin of the paired limbs of Vertebrates, which was taken as read, Mr. J. Graham Kerr referred first to the two hypotheses which were predominant at the present time as explaining the origin of the paired limbs—that which derives them from portions of a once continuous lateral finfold, and that which derives them from the septa between adjacent gill-clefts. The first portion of the paper consisted of a brief statement of these two views together with the fundamental facts upon which they rest, followed by a critical examination of them in the light of modern research. The author came to the conclusion that both views must be looked upon rather as suggestive hypotheses than as scientific theories of the facts as at present known to us. He therefore ventured to bring forward a third view, confessedly a mere hypothesis, which seemed to him to have received very inadequate attention—that the paired limbs are homodynamous with the somatic or true external gills.—Observations upon Polypterus and Protopterus, by J. S. Budgett. Two distinct species of Polypterus occur in the Gambia, *Polypterus lapradii* and *Polypterus senegalus*; the latter was observed in captivity and also in the wild state. The pectoral fins are distinctly organs of propulsion and not as in Teleosts almost exclusively balancers. Polypteros uses its bilobed air bladder as a lung, and can survive an exposure to a damp atmosphere of twenty-four hours. The spiracle is used to emit the excess of air in the pharynx but not for the passage of water. Both species migrate from the river to the flooded meadows in June and July and, spawning in August and September, return to the river in October and November.

EDINBURGH.

Royal Society, December 4.—Lord Kelvin in the chair. As usual at the first meeting of the session, the President gave a brief sketch of the work accomplished last session. Lord Kelvin then proceeded to discuss two physical problems, namely, the problem of the spinning top, and the question as to the manner in which ether is affected by the motion through it of attracting and repelling points. Many mathematicians of the highest order had attacked the problem of the rotation of a rigid body of which one point is fixed; but the peculiarity of the spinning top was that no point was fixed until it settled into the so-called "sleeping" condition. Mr. Archibald Smith, in a paper published in the first volume of the *Cambridge Math. Journ.* (1837), seems to have been the first to have correctly considered the question, Why does a spinning top rise to the sleeping state and then fall away again? And no later mathematician seems to have taken up this question at all. Lord Kelvin had recently worked out a simple case in which the centre of gravity was constrained to move in a vertical line. The minimum angular velocity, for which the upright "sleeping" motion was stable, depended in a simple way upon the curvature of the assumed hemispherical apex on which the top spun. The second problem was a fresh attempt to reconcile the apparently opposite properties of ether which render it so mobile to mass motions through it and yet so sensitive to rapid molecular vibrations. Briefly stated, the idea was to have an intermediate link between the molecule and ether in the form of a "doublet feeler." This doublet consisted of repelling and attracting points, which produced appropriate strains in the ether when themselves set in vibration by the vibrating molecule. The idea, however, gave no clue as to the nature of electricity and magnetism.—In a paper on the rectal gland of the Elasmobranchs, Dr. J. Crawford gave an account of an investigation into the structure and function of this appendage in the dog-fish and skate. The evidence was in favour of its being an excretory organ of the nature of a kidney.—An obituary notice of Dr. Charles Hayes Higgins, prepared by Dr. Sydney Marsden, was read.—Dr. Noel Paton gave an account of further investigations of the life history of the salmon in fresh water. This second instalment dealt chiefly with the fish taken in the months February, March and April, and the general conclusions agreed with those already drawn, the chief result being that the migration of the salmon is regulated wholly by the question of nutrition. The comparative scarcity of male fish caught prevented any certain conclusions being drawn in regard to them. From a comparative study of the pigments Miss Newbiggin had collected strong evidence in favour of Sir John Murray's view that the colour of the salmon was derived from the pigments in the Crustacea, which supplied directly or indirectly the chief food for these fish.—Dr. Thomas Muir communicated a paper on the eliminant of a set of general ternary quadrics, Part ii.

Mathematical Society, December 8.—Mr. R. F. Muirhead, President, in the chair. The following papers were read:—On the evaluation of a certain determinant, by Prof. Crawford.—A special case of the dissection of any two triangles into mutually similar pairs of triangles, by Mr. Alex. D. Russell.—Elementary proof of the potential theorems regarding uniform spherical shells, by Dr. Peddie.

PARIS.

Academy of Sciences, December 4.—M. van Tieghem in the chair. Justification of Fermat's principle on the economy of time in the transmission of a luminous movement through a heterogeneous transparent isotropic medium, by M. J. Boussinesq. Researches on the phenomena of phosphorescence produced by the radiation of radium, by M. Henri Becquerel. The rays given off by some milligrams of barium chloride containing radium were allowed to fall upon various substances, such as calcium and strontium sulphides, rubies, diamond, calc spar, fluorite, and hexagonal blende, in a Becquerel phosphoroscope. When placed first in the dark, and then brought up to within a few millimetres of the radiating substance, all those minerals which became luminous under the influence of the X-rays, also became luminous under the radium rays; but ruby and calc spar, which only become phosphorescent under luminous rays, remained dark. There are, however, differences between the X-rays and these new radiations. Thus a specimen of diamond which was brilliantly luminous under the action of radium did not become luminous when exposed to the radiation from a focus tube, and similar differences were noted for other substances. The whole of the facts observed show that there is really a continuous giving out of energy by radio-active bodies.—On the metallic compound radicals: mercury derivatives, by M. Berthélot. Measurements of the heat of combustion and formation of mercury-methyl, mercury-ethyl, and mercury-phenyl.—Lactic acid, by MM. Berthélot and Delépine. A thermochemical study of lactic acid, and lactones derived from it.—On the explosion of potassium chlorate, by M. Berthélot. If potassium chlorate is introduced suddenly into a vessel which has been previously heated to a temperature much above that at which decomposition commences, an explosion takes place, as with picric acid under similar conditions, although under a slow heating potassium chlorate shows no explosive properties. The explosion produced is clear and sharp, although a little prolonged, resembling a slow powder. These facts give a probable explanation of the recent explosion of chlorate at St. Helens.—On the normal existence of arsenic in animals, and its localisation in certain organs, by M. Armand Gautier. From a consideration of the use of arsenical compounds as a specific in certain diseases, especially in anæmia and Basedow's disease, the author came to the conclusion that the activity of arsenic in such diseases must be to its forming a constituent part of some organs, more particularly the thyroid gland. A search for arsenic showed that it is present as a normal constituent of the thyroid gland in weighable amounts in herbivora, carnivora, and in man. It is also present in smaller quantities in some other organs. In the normal state, there would appear to be about 1 milligram of arsenic in 127 grams of thyroid gland. Further research showed that if the gland is slowly digested at 38° in presence of acidulated pepsine solution, the peptone formed contained no arsenic, the whole being concentrated in the residue of cellular nuclei.—Research and estimation of minimal quantities of arsenic in the organs, by M. Armand Gautier. The tissues are warmed with pure nitric acid (containing about one per cent. of sulphuric acid) until the whole is liquefied, then strong sulphuric acid is added and heat again applied, the oxidation being completed by the addition of nitric acid in small quantities. The liquid is diluted largely with water, sulphurous acid added, and hydrogen sulphide passed for some hours. After purification, the arsenic sulphide is oxidised and poured into a Marsh's apparatus.—M. Georges Lemoine was elected a Member in the Section of Chemistry in the place of the late M. Friedel.—Particulars of a destructive earthquake in the Moluccas on September 30, by the French Consul at Batavia.—Remarks by M. Lœwy on the "Annales de l'Observatoire de Toulouse."—Observations of the Leonids and Biélids made at Athens, November 1899, by M. D. Éginitis.—On some properties of certain systems of circles and spheres, by M. C. Guichard.—On the theory of groups, by M. R. Baire.—On differential equations of the second order with fixed critical points, by M. Paul Painlevé.—Generalisation of a formula of Gauss, by M. E. Busche.—On the transformation of Abelian functions, by M. G. Humbert.—Influence of the X-rays upon the electrical resistance of selenium, by M. Perreau. The X-rays were found to reduce the resistance of selenium in a similar manner to light rays, the reduction caused by the Chabaud tube used being nearly the same as that caused by diffused daylight, or a gas flame at 1·5 metres.—On the proof of the fluorescence of aluminium and magnesium in water and in alcohol under the action of the currents from an induction coil, by M. Thomas Tommasina.—Dissociation of potassium and ammonium iodomercurates by water, by M. Maurice Francois. The decomposition of $(NH_4)I.HgI_2.H_2O$ and of $KI.HgI_2.5H_2O$ is a limited one, and is reversible. When the state of equilibrium is attained, the amount of alkaline iodide present in the liquid is constant for a given temperature.—On the heats of partial neutralisation of carbonyl-ferrocyanic acid compared with those of ferrocyanic acid, by M. J. A. Muller. Carbonyl-ferrocyanic and ferrocyanic acids are of the same order of strength.—On some new combinations of benzene with phosphoric anhydride, by M. H. Giran.—Preparation of tetrachloro- and tetrabromo-orthoquinones starting from the corresponding tetrahaloid derivatives of guiacol and veratrol, by M. H. Cousin. The tetrachloro-derivatives of guiacol and veratrol are first hydrolysed by nitric acid, and the resulting pyrocatechols oxidised to the corresponding quinones.—On a case of hysterical hemiplegia cured by hypnotic suggestion and studied by chronophotography, by M. G. Marinesco.—Biological observations on *Peripatus capensis*, by M. E. L. Bouvier.—On the hybrid fertilisation of the albumen, by M. Hugo de Vries.—The Cretaceous minerals of Aquitaine, by M. Ph. Glangeaud.—On the history of the Jiu valley, in the Central Carpathians, by M. E. de Martonne.—On the vestiges of an ancient vitrified stronghold in the upper valley of the Dore (Puy-de-Dôme), by M. J. Uselade.

NEW SOUTH WALES.

Royal Society, September 6.—The President, W. M. Hamlet, in the chair.—"Sailing birds are dependent on wave-power," by L. Hargrave. The author points out that sailing birds passed most of their time over the face or rising side of waves, and that by so doing they abstracted power from the moving water as the progress of the wave raised the air above it at a velocity proportional to its speed and slope. He used Prof. S. P. Langley's results to show that the uplift of a moderate swell was amply sufficient to support a plane and keep it moving at about thirty-five miles per hour in a calm.—"Some applications and developments of the prismoidal formula," by G. H. Knibbs. Starting with a demonstration that the prismoidal formula was rigorously applicable to solids with parallel plane ends, whose mantles were ruled surfaces, the paper showed how the volumes of series of longitudinally contiguous solids, with plane ends, and skew or warped—ruled quadric—surfaces on the other sides, could most conveniently be calculated. The determination of the volumes of solids whose longitudinal axes were plane-curves, or curves of double curvature, was also considered, and it was shown that the prismoidal formula was also rigorously applicable to circularly warped solids, the centre of gravity in such changing its position linearly with the distance along the curved longitudinal axis. When the change of the centre of gravity of a right section is a non-linear function of the distance along the curved axis, or when the radius of curvature is not constant, the prismoidal formula is not rigorously applicable. The paper closed with suggestions as to the application of the formulæ.—Among the exhibits were twenty-four mounted photographs, including a series of photographs of aboriginals representing two types, male and female, a few illustrative of camp life and corroborrees, and a special series illustrating some of the details of an aboriginal Bora ceremony. The photographs were taken and exhibited by Mr. Chas. H. Kerry, and afterwards presented to the Society.

Royal Society, October 4.—Prof. T. W. E. David, Vice-President, in the chair.—Current Papers, No. 4, by H. C. Russell, C.M.G., F.R.S. This paper began by calling attention to the fact that during the years 1896 and 1897 the prevalent winds over Australia and the Indian Ocean were north-west, and that as a result, comparatively few current papers were received, because the wind forced the bottles carrying current papers towards the south, and in this way prevented them from resting in the Australian Bight, the great dumping ground for bottles. It was also shown that during the past year north-west winds had been few and light, while southerly winds had been frequent, and, as a consequence, current papers had been frequently received. On many days they came in pairs, and on one day three current papers had been seen, which is the maximum for one day, and during the past year 105 had been received. Referring to the drift of the disabled steamer *Perthshire*, it was shown that the direction the steamer took was just that which the author had found to be the course of bottle-papers, and that although the *Perthshire* was driven by many winds, it would appear that the final result did not produce any deviation from the drift-line of that part of the Tasman Sea. Reference was made to the unusual number of breaks in propeller shafts, and to the greater speed of current papers and the great number of violent storms, which the author thought all pointed to unusual energy in the sea and atmosphere, which may have caused the unusual strains on propeller shafts.—Note on the occurrence of Glaciated Pebbles in the Permo-Carboniferous Coal-field near Lochinvar, New South Wales, by Prof. T. W. E. David. These glaciated pebbles occur on a geological horizon over 1000 feet below the level of the Greta Coal-seams, whereas the horizons, where Mr. W. G. Woolnough and Mr. R. D. Oldham discovered their glacial pebbles, are from 1500 to about 2000 feet above the level of the Greta Coal-seams. These glacial beds at Lochinvar are at the very base of the Permo-Carboniferous System, and in general appearance closely resemble the Bacchus Marsh Glacial beds of Victoria, a locality where there is evidence of ice action on a grand scale over a wide area. These last belong probably to about the same geological age as the beds near Lochinvar. The height of the glacial beds at Lochinvar is about 200 feet above the sea, and the thickness of the beds probably not less than 200 feet. The pebbles were probably transported by floating ice. Those at Lochinvar were carried to their present resting place before the Greta Coal-seams were formed, and those at Branxton some time subsequent to the formation of the Greta Coal, in either case at times when this part of the Hunter Coal-field was submerged under the sea, as marine shells of Permo-Carboniferous age occur immediately above the glacial beds.

AMSTERDAM.

Royal Academy of Sciences, October 28.—Prof. Stokvis in the chair.—Prof. Martin reported on behalf of Prof. Behrens and himself on a treatise by Mr. Fritz Noetling, entitled "The miocene of Burma." The conclusion of this report was adopted, viz. to insert this treatise in the *Transactions* of the Academy.—Mr. H. E. de Bruyn read a paper on the relation between the mean sea level and the height of half tide. The author proved that various causes, such as (1) the height of the flood tide, (2) the average sea level, (3) the time of year, (4) the presence of drift ice, influence the difference between the above two averages, and he determined the amount of this influence in the case of the sea level at Delfzyl.—Prof. Bakhuis Roozeboom presented Dr. H. J. Hissink's dissertation, entitled "On mixed crystals of sodium nitrate with potassium nitrate and of sodium nitrate with silver nitrate," and made a communication on the subject. He also read a paper on the nature of inactive carvoxime.—Prof. Behrens read a paper on Isomorphous compounds of gold and mercury. The following communications were presented for insertion in the *Proceedings*: by Prof. Kamerlingh Onnes, on behalf of Dr. E. van Everdingen, jun., a paper on the Hall effect and the increase of magnetic resistance in bismuth at very low temperatures; by Prof. Van der Waals, a paper of Dr. G. Bakker, entitled "Observations on Van der Waals' molecular potential function"; by Dr. J. P. Van der Stok, a paper on tidal constants in the Lampong and Sabargbay; by Prof. Jan de Vries, a paper by Prof. L. Gegenbauer of Vienna, entitled "Neue Sätze über die Wurzeln der Functionen $C_n^v(x)$.

Göttingen.

Royal Society of Sciences.—The *Nachrichten* (Mathematico-physical Section), Part 2, contains the following memoirs contributed to the Society:—

March 11.—Eduard Riecke: Free electricity on the surface of Crookes' tubes.

May 6.—H. T. Simon: The law of action of the Wehnelt interruptor; and on rapid spark-discharges.

May 13.—O. Wallach: Researches (vii.) from the University Chemical Laboratory. (1) On substituted cyanamides and thiocarbamides. (2) On phenyl- and tolyl-butyric acid. (3) Conversion of pentacyclic into azotised hexacyclic compounds. (4) On mixed diazoamido-compounds.—H. Liebmann: Proof of two theorems on the determination of "ovaloids" by the measure of curvature or the mean curvature for all normal directions.

June 24.—J. Orth: Researches from the Göttingen Pathological Institute.

July 22.—Eduard Riecke: On the pressure within certain radiometers.—A. Schönflies: On the distribution of stationary and non-stationary points in certain functions of a real variable.—E. Wiechert: Seismometric observations in the Göttingen Geophysical Institute.

August 13.—O. Wallach: Researches (viii.) from the University Chemical Laboratory. (1) On the oxidation of pinene. (2) On compounds of the fenchone-series. (3) Condensation products from hydro-rubeane, aldehydes and secondary bases.

August 28.—C. Hartlaub: Preliminary communication on the genera *Margelopsis* and *Nemopsis*.

DIARY OF SOCIETIES.

THURSDAY, December 14.

Royal Society, at 4.30.—The Piscian Stars: Sir Norman Lockyer, K.C.B., F.R.S. On the Origin of certain Unknown Lines in the Spectra of Stars of the β Crucis Type, and on the Spectrum of Silicon: Joseph Lunt.—A Note on the Electrical Resistivity of Electrolytic Nickel: Prof. J. A. Fleming, F.R.S.—Investigations on Platinum Thermometry at Kew Observatory: Dr. C. Chree, F.R.S.—Observations on the Morphology of the Blastomycetes found in Carcinomata: Dr. K. W. Monsarrat.

Society of Arts, at 4.30.—Round about the Andamans and Nicobars: Colonel R. C. Temple.

Mathematical Society, at 8.—Sums of Greatest Integers: G. B. Mathews, F.R.S.—Note on Circular Cubics: A. B. Basset, F.R.S.—Formulæ involving Central Differences; and their Application to the Calculation and Extension of Mathematical Tables: W. F. Sheppard.—On the Expression of Spherical Harmonics as Fractional Differential Coefficients: J. Rose-Innes.—The Genesis of the Double Gamma Functions: E. W. Barnes.—The Theorem of Residuation, being a General Treatment of the Intersections of Plane Curves at Multiple Points: Dr. F. S. Macaulay.

Institution of Electrical Engineers, at 8.—Discussion on Mr. Crompton's and Mr. John Holloway's Papers.—Electrical Time Service: F. Hope-Jones.

FRIDAY, December 15.

Epidemiological Society, at 8.30.—Precautions against Plague and Cholera at the Quarantine Station at El Tor: Dr. Armand Ruffer.—The Behaviour of Plague at Oporto: Dr. Arthur Shadwell.—The Control of Plague in India by the Medical Inspection of Railway Passengers: Dr. Spencer Low.

Institution of Civil Engineers, at 8.—On Sludge: Blamey Stevens.

MONDAY, December 18.

Royal Statistical Society, at 5.30—Some Notes on Makeham's Formula for the Force of Mortality: H. P. Calderon.

TUESDAY, December 19.

Zoological Society, at 8.30.—General Remarks on the Mammal-fauna of South Africa: W. L. Sclater.—Contributions to the Osteology of Birds. Part IV. Pygopodes: W. P. Pycraft.—On the Myology of the Edentata, Part II.: B. C. A. Windle and F. G. Parsons.

Institution of Civil Engineers, at 8.—*Paper to be further discussed*: Combined Refuse-destructors and Power-plants: C. Newton Russell.—*Papers to be read, time permitting*: The Purification of Water after its Use in Manufactories: Reginald A. Tatton.—Experiments on the Purification of Waste-Water from Factories: W. O. E. Meade-King.

Royal Statistical Society, at 5.—Some Statistics relating to Working-Class Progress since 1860: G. H. Wood.

Royal Photographic Society, at 8.—Negatives for Three-colour Work: Captain W. de W. Abney, C.B., F.R.S.

WEDNESDAY, December 20.

Society of Arts, at 8.—Bi-Manual Training by Blackboard Drawing: H. Bloomfield Bare.

THE COMING WHEAT SCARCITY.

The Wheat Problem. Based on remarks made in the Presidential Address to the British Association at Bristol in 1898. Revised, with an answer to various critics. By Sir William Crookes, F.R.S. (London: John Murray, 1899.)

THIS essay by Sir William Crookes, as will be remembered, called forth much criticism when it was delivered as the Presidential Address at the Bristol meeting of the British Association. Now that it is reprinted with additions, it may demand a more careful review than was possible at the time. The general idea, it may be said, is by no means novel, and it is one which approved itself to common sense. The population of the world and of different races in the world increases at rates which are more or less ascertainable. The means of supplying its wants, either in the shape of coal, or metals, or food, is also limited, either by the amount of the accumulated stocks, or the means of working them, or the extent of the earth's surface available for producing the food. What more natural then than to calculate, as has been done by Malthus, as to food generally, by other statisticians as to food in particular districts, such as India at the present time, by Jevons as to coal in England, by Prof. Cairnes as to metals generally, and by Prof. Suess, an Austrian geologist and statistician, as to gold specially, that at a given date in future the supply must run short, and then a crisis arrive? Sir William Crookes applies specially to the study of wheat production this leading idea. The consumers of wheat, he tells us, are a little over 500 millions at the present time, having increased to that figure from about 370 millions in 1870, while the quantity of the earth's surface available for wheat is itself limited both by the capacity of the soil and the necessity for cultivating other products. He calculates accordingly that by the year 1931, if population increases as it has done, the supply of wheat will be seriously short, and he suggests that chemistry should come to the rescue by devising means to fix the nitrogen of the atmosphere so as to permit the growth of more wheat on the same soil.

In all this argument, except as to the last suggestion, Sir William Crookes is plainly on the common ground of men of science and philosophers. He may be right or wrong as to details, such, for instance, as fixing 1931 for the time when the "shortage" of wheat will be felt; but given the initial hypotheses, there must be in time a deficiency of the supply to meet the demand for wheat—as well as for other food articles, it may be added—if present conditions of growth of population, and growth of wealth per head in that population, continue.

But at this point I fear the main commendation of Sir William Crookes' essay must stop. His attempt to give precision to the prospect as regards wheat (and the whole gist of his paper is to emphasise the precision of the forecast) appears to me rather to fail, while he does not handle statistical data in the skilled, scientific manner we should expect from a man of his eminence even in a field which he does not usually cultivate. Above all, instead of confining himself to the forecast that a certain position will be arrived at at a future date, if present conditions continue, the conclusion to which expert statisticians now confine themselves, he assumes the continuance of the conditions, and argues for practical measures to meet the apprehended difficulty. In other words, although the general idea of the essay is sound, the execution appears to be somewhat wanting, and the result is not altogether what we should expect from a man of science so distinguished as Sir William Crookes.

To take first the last point mentioned, the failure to recognise the necessary limitation of all such speculations in consequence of the assumption that must be made that present conditions continue unaltered. I hold this to be a capital error on the part of Sir William Crookes. There has been much experience of these discussions since the time of Malthus, and the whole effect of the experience is that, as yet, we are either too far away from the limits when shortness of supply of food and raw materials, which men of science and philosophers anticipate, will be felt, to engage in a precise discussion, or that we know too little as to the ultimate causes of existing conditions to be able to predict whether they will be soon changed or not. The forecasts of Malthus regarding England and the older countries of Europe that the supply of food would run short have not yet come true, because an outlet in the shape of emigration to new countries has been provided, with the double effect that the multitudes who were expected by Malthus to live in the old countries and press on the narrow supplies there are now largely settled in new countries, and are not only growing food for themselves, but for some of the multitudes remaining in the old countries as well, this last condition being rendered possible by the entirely new developments of means of communication which have taken place since Malthus wrote. Since Malthus wrote, also, there has been a general and vast improvement in the art of cultivating the soil. Similarly, as regards coal, the growth of the demand has by no means continued at the rate which Jevons found in existence when he wrote, while the influence of the price of coal as a factor in production has diminished in consequence of the greater effectiveness of the machinery which coal is used to drive. The scarcity of the supply of gold, which the Austrian geologist anticipated, seems also to be deferred indefinitely by the discoveries in the Transvaal, Western Australia, and the Klondyke; while as to the demand for gold, it is equally plain that nothing is more uncertain than the continuance of the present condition of an overwhelming desire by military governments to secure and lock up enormous sums of gold. Experience is thus altogether against making precise forecasts on the lines laid down by Malthus. Consequently, when a new authority takes up a similar subject, we should expect him to be wide-awake to such considerations, as have been found so important in like cases. The conclusions should always be stated with an "if"—a big "if"—and there should be no attempt at precision in the forecasts, against which there are so many chances that they will not, in fact, be realised. The man of science should be content with pointing out that if his previsions are not realised then existing conditions must change, and the future inquirer should be vigilant in observing the changes. Sir William Crookes has not done this, but has assumed that present conditions will continue, and that his prophecy must come true almost to the letter, which places the discussion altogether on a wrong basis.

The handling of the statistical data also, as I have said, is not what one should have expected from Sir William Crookes. To begin with, the relative place of wheat as an article of food supply to the Caucasian race appears to be very much exaggerated. Sir William Crookes, though he does not say so explicitly, really speaks of wheat as the principal food.

"My chief subject," he says, "is of interest to the whole world—to every race—to every human being. It is of urgent importance to-day, and it is a life and death question for generations to come. I mean the question of food supply. Many of my statements you may think are of the alarmist order. Certainly they are depressing; but they are founded on stubborn facts. They show that England and all civilised nations stand in deadly peril of not having enough to eat. As mouths multiply food resources dwindle. Land is a limited quantity, and the land that will grow wheat is absolutely dependent on difficult and capricious natural phenomena."

And more to the same effect. The identification of "wheat" in particular with "food" in general without any discussion of the relative importance of wheat among food articles, in the economy of the peoples concerned, is thus complete. The fact is, however, that wheat is only a fractional part of the food of some of the peoples who consume wheat, especially of the European peoples and the people of the United States, who are by far the largest consumers, and that it could be dispensed with and replaced by other articles wholly or in great part if necessity should arise. Take the case of the United Kingdom alone. Our imports of wheat and wheat-flour last year amounted to rather less than thirty-eight millions sterling, and if we allow for home production we may place our national expenditure on wheat at about fifty millions annually at the outside. Our total annual expenditure on food must be about eight times that sum. Our expenditure on imported food alone—meat, cereals, sugar, rice, &c.—was last year over 170 millions sterling, and if we add to that the home production of meat, dairy produce and cereals, we very soon get to a total figure of 400 millions or thereabouts. Sir William Crookes is thus anxious about an article of food on which we depend only to the extent of one-eighth. It may be rejoined that wheat is specially important on physiological grounds, but if so, these grounds should have been stated, and there is certainly no statement in the paper. The money test, the test of actual expenditure, is in any case not an unfair one. It would be the same, we believe, if Sir William Crookes were going farther afield. The people of the United States are very like ourselves as regards food consumption, and, to some extent, the peoples of France and Germany; while among others, whose diet is different from ours, wheat is still relatively unimportant, because, though they do not consume meat as the peoples of this country and the United States do, yet articles like rye and potatoes really constitute their main food, wheat being almost an article of luxury by comparison, and not a principal food. Nowhere, according to Sir William Crookes' own showing, is so much wheat consumed per head as in France, the United Kingdom, and the United States, the very countries in which its relative importance is lowest as an article of diet. It may be suggested, then, that in a scientific inquiry as to the possible shortage of food supplies in the near future the various chief articles of food of the peoples concerned, such as meat, dairy produce, fish, potatoes and sugar, should have been considered, and not merely wheat. There is another reason for this course. Suppose, as I believe to be the case, that a large part of the earth's surface is now used for the production of expensive articles of food like meat and dairy produce with the minimum of cultivation, the most that could happen as supplies became short might be a change of cultivation, involving some addition, but perhaps no great addition, to the cost of production, but resulting in a simultaneous increase of the quantities of meat, dairy produce and cereals produced. The play, then, between different articles of food must be considered. If one article like wheat is taken by itself, it is plainly only a question of price. At a point, the soil now used in growing meat and dairy produce by means of permanent pasturage could easily be taken to produce wheat or other cereals without any diminution, but rather along with an increase, of the production of meat and dairy produce at the same time, though at perhaps rather more cost. At what point will shortage of all supplies, taken together, be felt, and how? are the questions for the man of science and agriculturist, and they are not to be answered by the sort of rule of thumb which is here applied to wheat.

There is yet another serious oversight, in my judgment, when we look at the paper from a purely statistical point of view. Sir William Crookes goes into great detail as to the acreage under wheat in different countries at different periods, but regarding the other side of the comparison, the population of bread-eaters and their rate of growth, he gives no details at all. He confines himself to the following assertion:

"In 1871 the bread-eaters of the world numbered 371,000,000. In 1881 the numbers rose to 416,000,000; in 1891 to 472,600,000; and at the present time they number 516,500,000. The augmentation of the world's bread-eating population in a geometrical ratio is evidenced by the fact that the yearly aggregates grow progressively larger. In the early seventies they rose 4,300,000 per annum, while in the eighties they increased by more than 6,000,000 per annum, necessitating annual additions to the bread supply nearly one-half greater than sufficed twenty-five years ago."

Clearly a statement like this ought not to be made in a scientific paper, where a great deal turns upon the statement, without the details and references enabling any one to verify and appreciate it. Of course, it is quite possible for any one knowing population statistics, and content to classify large populations as bread-eating, without inquiring in detail what proportion in each population is really bread-eating, to make up a statement for himself; but there are cases of difficulty in any such grouping, and we are entitled to know what Sir William Crookes has done. In a scientific question like this he should have been more specific for another reason. As the consumption of wheat per head in different wheat-eating populations varies a good deal, much may turn upon the nature of the increase, whether it is largest among the communities consuming wheat largely, or among the communities who consume little. To comprehend, in fact, the real growth of wheat-consuming power, we must have an average which allows for the different rates of consumption among the wheat-eating peoples, with references to the authorities for the statements as to each people. To set out this was of the essence of the problem Sir William Crookes had before him, and he has omitted it altogether. The nature of the increased consumption in each country should also have been investigated. It is asserted among farmers, for instance, that a considerable quantity of wheat, more than used to be the case, has of late years been taken in England for other purposes than the food of man, the wheat being given to cattle. Every one knows, again, that flour itself in domestic economy is more and more being applied as an element in cooking articles of luxury, and that it is not really used to a large extent as a principal food at all. All this adds to the interest of the problem as to any approaching shortage of wheat, and the means of making it good, because so much may at need be diverted back from other purposes to the primary use as food; and it shows also that the question of wheat consumption is not one that can be studied, for any such purpose as that contemplated by Sir William Crookes, without an infinity of detail. In any case, it was a matter of scientific good faith that he should have given the details and the references for the important statement we have quoted, which he has not done.

I am not making a mere formal objection. It is, of course, difficult to criticise without having before us the details which Sir William Crookes has not given, but I have not the smallest doubt that the largest increase of bread-eaters, which his details would show, is among the peoples consuming little per head, and not mainly among the peoples consuming much. One of the countries where wheat consumption per head is largest is France, and France is stationary in population.

Having made these general observations on the method followed in the essay, I do not feel called upon to go into detail respecting the actual acreage, and possible acreage, of wheat, in different countries, on which Sir William Crookes has so much to say. There is no question really more difficult. The capacity of a given population for agriculture is here just as much in question as the capacity of the soil, and I quite agree in principle with Sir William Crookes, that although additional soil might be available indefinitely for wheat in proper hands, yet as a matter of fact the soil practically available may be strictly limited. But what he fails to take sufficient note of, I believe, is the question of price. Land that would not be available for wheat with the price at 20*s.* to 25*s.* per quarter, might become available in indefinite quantities with the price at 40*s.* to 50*s.*, and even 60*s.*, which are by no means famine prices. But Sir William Crookes has little to say on this factor of pr ce. Altogether, I may suggest, he relies too much on American statisticians, without having himself verified their methods. Mr. Davis for his purpose is not a quotable authority. He should have gone behind Mr. Davis and verified everything for himself.

The point on which the reference is made is rather a side one, but the danger of putting forth a sweeping statistical statement without adequate support is so well illustrated by it, that it may be useful to quote it. Sir William Crookes states, p. 35:

"Taking the cost of producing a given quantity of wheat in the United Kingdom at 100*s.*, the cost for the same amount in the United States is 67*s.*, in India 66*s.*, and in Russia 54*s.*"

Surely it is altogether erroneous statistically to put forward a statement like this without references. How does Sir William Crookes know that England and the United States and the other countries mentioned differ so much as he states? The cost of production he refers to is either a maximum or a minimum, or a mean of two extremes, or an average; but which is it? As he makes the statement it is really unintelligible. If he means an average, as I presume must have been intended, how does he get the average? The statement is not one to be made in a scientific study without references and authorities, and full explanations of what is really meant.

In conclusion, I may express the hope that in some future essay Sir William Crookes will revise his present work, and not only look into his statistics, but inquire into the question of the play among different articles of food in agricultural production and in human consumption, instead of dealing with one article only. As to his suggested remedy for too little wheat, the fixing of the nitrogen of the atmosphere, it is one which may well be disconnected from the paper itself. Whatever may happen to wheat, the problem is one which should be attractive to the chemist on its own merits. It is, perhaps, unfortunate that the suggestion should have been appended to an alarmist statistical paper, instead of being made from the chemical side only, as the statistics seem to give little support to the suggestion.

R. GIFFEN.

THE PHYSICAL ATLAS.

Atlas of Meteorology. A series of over four hundred Maps prepared by J. G. Bartholomew, F.R.S.E., and A. J. Herbertson, Ph.D.; and edited by Alexander Buchan, LL.D., F.R.S. (Westminster: Archibald Constable and Co., 1899.)

OF the making of meteorological observations there is no end, and some, who have only a partial acquaintance with the subject, might be tempted to add, no result. But such a criticism, however smart, is eminently unjust, and as a protest against such an uncharitable opinion it was a wise and happy thought to endeavour to combine the outcome of the labours of many observers into a monumental form, which could appeal to the eye of many untrained in scientific methods, and convince them that time and thought and money had not been lavished in vain on mere childish records, but that earnest endeavour had harvested an abundance of facts, which only needed orderly arrangement and skilful grouping to make them available for instruction and edification. To the scientific mind well versed in such matters this compilation can appeal more strongly and more worthily, for it demonstrates not only what has been successfully accomplished already, but exhibits the deficiencies that demand attention and offer prospects for hopeful exploration. These deficiencies will be mainly of two kinds. One, due to the dearth of information from sparsely inhabited districts in inhospitable climates, or from regions where no well-ordered government obtains. Such lacunæ are regrettable, but will gradually disappear in presence of individual enterprise, employing the same means as those which have been successful in more settled lands. The other is more serious, and may be traced to the want of greater originality in the construction and management of instruments devoted to particular ends. Imitation and repetition have probably been two of the main causes from which meteorology has suffered. We have been too content with the readings of barometers and thermometers in convenient positions, and have made but few attempts to investigate meteorological phenomena at elevated stations above the earth's surface, leading, it may be, to a knowledge of vertical gradients of pressure, temperature, humidity, &c., and suggesting new lines of useful inquiry. It may seem an ungracious remark with this collection of valuable facts before us, but it would appear that we have been too much engaged in recording the results of particular combinations of the atmosphere in particular districts, and too little concerned in the antecedent processes that have produced the effects we are so eager to register.

This existing wealth of meteorological observations makes us gratefully recognise the amount of labour that has been bestowed upon the production of this atlas. The task must have been a leviathan one, and it has been grappled with manfully. The meagre bibliography of four pages attached to the work, and which we cannot help regarding as somewhat unworthy of its place, can only very feebly indicate the sources of information that must have been consulted in the preparation of this record of the climate and the weather of the world. Scattered over many lands and described in various languages are valuable observations and memoirs, which it must have been the object of the compiler and his assistants to weld into this convenient form; and the eminent authorities who have associated themselves with the editor of this undertaking are a sufficient guarantee that all that is serviceable, all that is trustworthy, has been extracted from these hidden journals and memoirs. The general result is a collection of maps which are to a certain extent diagrams or the pictorial representation of much tabular work, and their study affords not only grounds for congratulation, but will tend to prevent unnecessary duplication and suggest the necessity for more strenuous and more scientific application of the methods open to us.

The atlas, consisting in all of thirty-four plates, is arranged to afford information on two distinct objects of meteorological inquiry, climate and weather—that is to say, variations of the atmospheric conditions for short and ong periods. Under the first heading, climate, we have eight subdivisions. These are (1) isotherms, showing the seasonal and annual distribution of temperature over the world generally, and in greater detail for those countries where a sufficient number of observations exists to permit the lines of equal temperature to be drawn with exactness; (2) isobars showing the distribution of atmospheric pressure, and arrows to indicate the prevailing direction of winds; (3) the relations existing between isotherms and isobars; (4, 5, 6) showing respectively the general distribution of sunshine, cloud and rain over the globe; (7) maps of hyetal regions and the seasonal distribution of rain; and (8) isobars and isohyets indicating monthly and annual distribution of barometric pressure and rainfall as related to each other for various countries.

It is impossible to enter here into details of the manner in which each and every of these subdivisions is treated, to discuss the principles which have guided the editor in constructing the maps and in overcoming the difficulties which naturally beset a diagrammatic representation. It goes without saying that the highest authorities have been consulted in the preparation, and, indeed, are to a certain extent responsible for the accuracy of the maps. These are executed in a very admirable manner, though sometimes the very neatness of execution makes it a little difficult to rapidly grasp the detail printed on them. As a rule, successive changes in the climatic element are shown by more intense washes of the same colour; and we could have wished that this rule had been more uniformly observed, since no abrupt change, such as that suggested by a change of colour, distinguishes the gradual variation of climate with latitude. For example, there is no sudden change of temperature to the north or south of an arbitrarily selected isotherm, yet one passes on these maps from red to yellow and from yellow to green with startling suddenness, as though some new feature had been introduced.

The second main division, under the generic title "weather," naturally deals with the atmospheric conditions which have to be taken into account in making a forecast whether for a shorter or longer period. Here possibly there is opportunity for the exercise of greater originality in the selection of the necessary material than in the earlier section, which deals simply with the direct results of observation. For the systematic study of anomalous weather is of comparatively recent growth, and the information, based as it usually is, on shorter series of observations made in districts where observatories are more sparsely scattered, is not so definite nor so precise as that which characterises the older observations made in climates which do not experience those typical storms whose careful study has been attended always with interesting, and generally with beneficial, results. In this section, if anywhere in the volume, some alteration may be necessary hereafter in the detail and arrangement, occasioned either by the deductions from more recent observations, or by greater generalisations due to theoretical application. But it is safe to say that a very admirable use has been made of the information that at present exists, and in the description prefixed to the maps will be found a careful summary, not only of the inquiries instituted by national bureaux, such as that of the United States with its widespread network of stations, but also of the individual researches of such physicists as Hann, Eliot, Van Bebber, Doberck and others whose names are household words.

The sections into which the editor divides the subject of typical and anomalous weather, or the groups under which our present knowledge of this subject can be presented, are five in number. Barometric pressure of necessity plays the principal part in the arrangement and subdivision of the section. The maps are constructed to exhibit the pressure conditions which obtain in abnormally hot and cold seasons and months in differen regions, those which produce recognised types of wind and weather, or accompany typical storms of all kinds. To these are added maps showing the tracks of storms and the distribution of storm frequency, with a final series showing typical distributions of deviations from the normal monthly pressure, upon the study of which the forecasting of the probable weather for a season will be based, as well as the distribution of the mean deviations from these normals. From this description of the contents of the two sections, it will be seen that the atlas is essentially a book of results. It summarises what has been already accomplished by patient effort and long-continued observation, and the result is encouraging. Mr. Buchan, who signs the introduction in his capacity of editor, contends—

"If the present state of the science [of meteorology] as regards the geographical distribution of results be compared with that of the other sciences, such as geology and the biological sciences, it stands second to none. None of these sciences can show such a world-wide distribution of precise results as are collected in this Atlas of Meteorology in illustration of the geographical distribution of temperature pressure, humidity, cloud, rainfall and movements of the atmosphere, with illustrations of their influence over, and inter-relations with each other."

How far this remark is justified must be left to the individual judgment of those who it is hoped will read and digest this first instalment of the Physical Atlas.

W. E. P.

THE NORTH AMERICAN SLIME MOULDS.

The North American Slime Moulds. By Prof. T. H. McBride. Pp. xvii + 231, and plates. (New York: the Macmillan Company. London: Macmillan and Co., Ltd., 1899.)

THE group of organisms known as Myxomycetes, or as Mycetozoa of De Bary and Rostafinski, has of late years received much careful study in the United States. In 1834 Schweinitz published his "Synopsis of North American Fungi," and his large collection of Myxomycetes has been recognised in that country as the standard authority for reference. In 1848 Curtis contributed articles to journals on the subject, and both he and Ravenel made extensive gatherings in the south-eastern States. Since that time American investigators, conspicuous among whom should be mentioned Prof. Peck and the late Dr. G. A. Rex, have done excellent work; new species have been discovered, and large collections have been made in different parts of the States. The professors of botany have brought the Myxomycetes into their course of instruction, and a literature has sprung up founded to a considerable extent on local research.

Prof. McBride, of the University of Iowa, has made an important addition to this literature in the work under notice. In an interesting preface he pays a well-deserved tribute to the labours of Rostafinski, and we are glad to see that he founds his classification on the lines laid down in Rostafinski's monograph of the Mycetozoa, but he prefers the older name Myxomycetes for the designation of the group. In this he follows Dr. Scott in his admirable book on structural botany; at the same time, Prof. McBride fairly discusses, from a botanist's point of view, the claims that have been advanced for including them in the animal kingdom, and sums up by saying—

"Why call them either animals or plants? The Myxomycetes are independent. All that we may attempt is to assert their nearer kindred with one or other of Life's great branches."

From this standpoint, however, we do not think that the adoption of the name "slime moulds" is a happy one. If, as the professor remarks, their position is "a matter of uncertainty, not to say perplexity," and in the face of the high authority of Rostafinski, under De Bary's supervision, for the name Mycetozoa, an English translation of either word seems to be hardly needed.

The question of nomenclature is perhaps a more burning one in the States than it is with us, where De Candolle's law is very much accepted in practice.

Prof. McBride speaks warmly on the subject on p. 10 of the preface. Instead of adopting the earliest published specific name of a species in the genus in which it now stands, and giving as the authority the name of the person who first placed it in that genus (leaving the history of the first describer to be traced in the unfortunately necessary list of synonyms), he aims at giving the earliest published specific name, under whatever genus it appeared, giving as the authority the name of the first describer in brackets, followed by the name of the placer in the present genus. If an important object in appending the authority were to commemorate the name of the first recorder, we should agree with the professor, and as a matter of sentiment there is much to be said in favour of his view; but if the object in quoting the authority be solely to establish the identity of a species, apart from personal considerations, De Candolle's rule has the advantage of simplicity. The ideal conception of a uniform system of classification universally accepted appears to be unattainable, at least in the present generation, considering the strongly-held and diverging views which now prevail; but Prof. McBride has devoted much labour to searching the oldest records, short and incomplete as many of them are and compiled with the aid of imperfect instruments, and we cannot but admire the thoroughness with which he has endeavoured to carry out his principle.

When we bear in mind the wide variation which we find in many species that offer abundant material for observation, as, for example, in *Physarum nutans* Pers., the adoption of a main centre as the type and the description of diverging forms as varieties appears to be in accordance with the actual facts, and is of assistance to students. Prof. McBride, however, avoids the introduction of varieties, and therefore multiplies the species recorded in his work to an extent which may not meet with universal approval; but it is fair to note that in many cases he leaves the specific value an open question.

On the other hand, in those species which have come under his personal observation—and these embrace a very large proportion of the whole—his descriptions are admirable. We read them with the confidence that they are accurate and drawn from nature; they give us new information and a graphic picture of many species which have seldom or never been recorded in Europe, and it is needless to say that the measurement of spores can be entirely relied upon.

To those who are within reach of the University of Iowa, the fact that the species described are represented by type specimens in the herbarium of that institution is of the utmost value; for, however excellent the description, it is to the type itself that we must fall back as the last resource when so much depends on minute microscopical examination.

The physiology of the Myxomycetes does not appear to have received the careful study in Iowa which we may hope for in the future, considering the wealth of material which the region affords. On more than one occasion Prof. McBride refers to formation of spores as preceding that of the capillitium. On p. 108 he says, in speaking of the capillitium:

"It is necessary to recall the fact that in the best case all such structures of the fructification are but forms of the residue after the formation of the spores."

A laboratory experiment of no great difficulty shows, by a series of stained preparations of maturing sporangia, that the capillitium material, together with the calcareous matter when present, is separated from the spore-plasma before the karyokinetic division of the nuclei takes place preparatory to the formation of the spores; thus the capillitium is formed before the spores.

With regard to the systematic part, Prof. McBride's work must take a pre-eminent position as a guide for students in America, and its value will not be confined to those on the other side of the Atlantic. We lay the book down with a refreshing sense that it is a trustworthy history written in a pleasing manner by one who has a wide grasp of his subject.

A NEW MATERIA MEDICA.

An Introduction to the Study of Materia Medica. Being a short account of the more important crude drugs of vegetable and animal origin. By Henry G. Greenish, F.I.C., F.L.S. With 213 illustrations. Pp. xxi + 511. (London: J. and A. Churchill, 1899.)

THE position of Mr. Greenish as Professor of Materia Medica and Pharmacy to the Pharmaceutical Society of Great Britain has enabled him to produce in the book before us a very useful aid to the students attending his lectures, as well as a valuable handbook to the subject for the use of those of riper years. In his preface the author is careful to explain the meaning of the term Materia Medica, and to qualify the meaning of the words "crude drugs" as distinct from those that have been subjected to preparation. In this connection he says:

"The term Materia Medica literally interpreted signifies all remedial agents of whatever kind, but it is more commonly used to designate that department of medicine devoted to the consideration of simple medicinal substances known as 'drugs.' In medicine the term is usually employed in this sense, but in pharmacy it is generally understood to include only those drugs that are derived from the animal and vegetable kingdoms, and have not undergone any process of elaboration whereby their characters have been materially altered; such drugs are termed crude drugs. Thus the poppy capsule is a crude drug, and opium, which consists of the dried latex of the unripe capsule, is also classed as a crude drug; but the alkaloid morphine, which is the chief constituent of opium, and can be extracted from it only by a comparatively elaborate process, is not regarded as such. Similarly the resins, oleo-resins, gum-resins, various dried juices, &c., are included amongst the crude drugs. The term is also extended to certain vegetable extracts imported from distant countries in which alone they are prepared, even if they have been partially purified, as, for instance, Cutch and Gambier, although similar extracts prepared in this country would no longer be considered as crude drugs."

This explanation will serve to show the nature and aim of Mr. Greenish's work, which is carried through with much distinctness, and each subject is treated in the clearest possible manner and on the same system throughout.

The arrangement of the subjects under the headings of leaves, flowers, fruits, seeds, woods, barks, resins, oils, and so on, is a novel one in works of this kind, so far as English publications are concerned, and for students' purposes it is perhaps the best that could be adopted, especially with the aid of the tabular classification according to the natural orders, which Mr. Greenish gives at the end of the book; but we are inclined to think that this classification would have been more useful, especially to those with a botanical knowledge, had it been arranged in scientific sequence rather than alphabetical, and, further, to have separated the plant products from those of animal origin. This classification, however, will be found of much use, inasmuch as one sees at a glance what medicinal plants are included in any given order, together with a statement as to what part of the plant is used and a reference to the page where the description is to be found.

That the arrangement of each individual subject under its special head is the best that could have been devised there can be no possible doubt. Each drug appears first under its English name, as, for instance, Red Rose Petals in large capitals, followed by its Latin equivalent *Petala Rosae Gallicae;* or, again, Foxglove leaves, *Folia digitalis.* Following these are paragraphs under the heads of source, &c., description, constituents, and uses, and, where necessary, substitutes and adulterations. The whole is written in such a clear style, and in such plain language, that there is no difficulty in understanding at once what is intended. Moreover, the summing up of the description and the points to be observed by the student are terse yet sufficient, and being printed in italics at once catch the student's eye. Thus under Chiretta (*Swertia Chirata*) the following occurs:

"The student should observe—
(*a*) The purplish-brown colour of the stem.
(*b*) The large continuous pith.
(*c*) The intensely bitter taste.
(*d*) The opposite leaves.
(*e*) The bicarpellary, unilocular fruits."

The first three characters will suffice to distinguish the genuine drug from other species of *Swertia* which sometimes are mixed with it or substituted for it, as well as from other substitutions that have been occasionally noticed. The last two are characteristic of the natural order Gentianeæ, and are also useful in identifying the drug.

That the book is not without errors and omissions we are not prepared to say. What book, especially in its first edition, can ever be so regarded? Thus, for instance, under the head of capsicum fruits, Mr. Greenish, though mentioning that the plant is cultivated in Eastern Africa, does not mention Zanzibar in particular as one of the commercial kinds known in the British markets, nor does he even allude to Japan as a source of these pungent fruits, though of late large quantities have been imported thence to this country. But with a book so carefully worked out and so thoroughly well got up, it is ungracious to find faults, many of which have no doubt already been observed by its author and noted for correction in a new edition, which will probably not be long before it is called for, as the book is one that must be in the hands of the continuously increasing number of pharmaceutical students.

We had almost forgotten to say that the numerous illustrations add much to the value of the book. They have been carefully selected, and the source from which they are taken is acknowledged beneath each figure.

OUR BOOK SHELF.

Descriptive General Chemistry. By S. E. Tilman. Second Edition. Pp. x+429. (London: Chapman and Hall, Ltd. New York: John Wiley and Sons, 1899.)

THE author of this volume is professor of chemistry, mineralogy and geology in the United States Military Academy, and the book embodies an attempt to present chemical science in a form and compass adapted to special circumstances. Whilst in the opinion of the author "the chemical knowledge most requisite to the average professional soldier differs but little from that essential to other educated men . . . the experience and judgment of the Academic Board and of their military superiors" has limited the course to about two months. From this statement, as well as from the concentration of three sciences in one professor, it would appear that the dogged resistance to the encroachment of science on the art of war which distinguishes the Anglo-Saxon in this country, is well maintained in America. It is evident, also, that the task of the author is no light one. He has discharged it by presenting a tolerably full and very lucid account of the chief principles of chemistry, followed by a considerable amount of descriptive matter, illustrated, and we may say illuminated, where possible, by reference to things of military interest. The outcome is a very readable volume, containing information which, if it could be conveyed under reasonable conditions, would be of great value to the future soldier. But it need hardly be said that a mass of scientific information, however skilfully selected and well written or well spoken, will give in no important measure a scientific habit of mind, or an animate knowledge of science. On the whole, however, Prof. Tilman has probably done the best possible under the circumstances.

Among matters of special interest in the book are the accounts of American metallurgical processes. The descriptions of important chemical industries are also clear and concise. The weakest point to be noticed in the book is the treatment of fuel calorimetry. There is no description of a calorimeter or a pyrometer, and the old misleading formulæ for the calculation of "calorific power" and "calorific intensity" are introduced. The exhaustive experiments of the late Scheurer-Kestner, which showed the uselessness of such formulæ, do not seem to have become as well known as they should be.

A. S.

Zoologia. By Prof. Achille Griffini. Pp. xvi + 384. (Milan: Ulrico Hoepli, 1900.)

THIS book is divided into an introductory part (26 pp.), dealing with the history and scope of zoology, and the broader principles of morphology and physiology of animal forms, followed by a main part (337 pp.), in which the great groups of animals are successively dealt with in a roughly descending order, the whole ending with an "epilogue" (16 pp.), embodying an ambitious classificatory table, and certain philosophic deductions which, in deference to the scruples of his countrymen, the author is willing to let pass unread! It is in places very thin and antiquated, and its illustrations are on the whole the most interesting feature, since they alone proclaim it a text-book mainly begotten of the text-books, with little fresh thought or aim at originality. There are five hundred and five figures in all, many representing animals in a state of nature, at times with theatrical sensationalism, others delineating the facts of anatomy and minute structure, still others schematic. Taken collectively, they are an *omnium gatherum* of an inferior order. Page after page bears the time-worn figures which we find in nearly every text-book under the sun, here reproduced without acknowledgment and in some cases in a disguised form; and when originality is attempted the result is in places ludicrous; as, for example, in the physiological scheme on p. 81, and the figure of the Molluscan nervous system on p. 329. A set of figures is repeatedly introduced in supposed representation of the eggs and larvæ of the frog (*Rana*)—the egg-mass is that of *Pelodytes*, the larvæ are a combination of the old, old figures of Rösel von Rosenhof (which, for that matter, still do duty in current works in our own tongue), of Ecker and others with which we have long been familiar. On p. 224 there is a figure of a presumed *Ascidia*, which, as Huxley would have said, "illustrates, but does not adorn" the text, since it is that of a *Ciona*, curiously enough copied (but with reversal) from Huxley's "Manual of the Invertebrata," in which it is erroneously named *Phallusia mentula*. The figure of a horse (p. 121) simply insults that graceful beast. The author in a lengthy preface deplores, with just cause, the existing methods of teaching natural science in the Italian schools, for which his book is especially designed in accordance with the requirements of the State; and in support of his plea for improvement he cites forcible passages from addresses on the subject by Profs. Emery, Camerano (his teacher) and others. Proceeding to the question of nomenclature, he excuses himself the adoption of its modern rules on the grounds of his having been on a former occasion reproached for writing *Molge* instead of *Triton*. For this, something may perhaps be said from his point of view, but there is no excuse for the elevation of the racial names of mankind to specific rank (*Ex. Homo arcticus*, *H. cafer*, *et sic de caeteris*). Both figures and Latin names of some of the humbler creatures—transcribed from books which are old and out of date—are antiquated, and we deem further comment unnecessary, except to remark that the treatment of many great groups is so meagre that it is well-nigh useless.

G. B. H.

The British Journal Photographic Almanac for 1900. Edited by Thomas Bedding. Pp. 1516. (London: Henry Greenwood and Co., 1899.)

REGULARLY every year we receive this most useful annual, and as regularly we have to record its growth.

This year the volume reaches the grand total of 1516 pages, and is the largest yet issued, exceeding that of last year by about 40 pages. The popularity of such a book can be best judged by its sale, for photographers soon find out which of the numerous books on this subject are suited to their needs. We gather from the *British Journal of Photography* that the 1899 edition of this almanac, an edition which was composed of 20,500 copies, was rapidly disposed of within three months of publication, a fact which speaks for itself. This, the thirty-ninth annual issue, is quite up to, even if it does not exceed in interest, the previous volumes. It will be found an absolute mine of information : we notice a great number of articles dealing with all branches of the art which gives the reader hints for future work, and results of the experience gained by others. Other parts are devoted to a summary of the progress made during the past year, practical notes and suggestions, miscellaneous information, and many other sections of interest. As usual, the advertisements form a great portion of the book.

The almanac is carrying on the crusade of advocating the use of the metric system in all photographic matters, and has great hopes of the practice becoming universal. To further this object the metric equivalents of the British system are given in all tables and formulæ. Much more might be written about the contents of this volume, but it is hoped that sufficient has been said to enable the reader to form the opinion that it ought to find a place in every photographic studio.

The frontispiece is an excellent bromide print by Messrs. Wellington and Ward from a negative by Mr. H. Walter Barnett, and numerous other illustrations will be found intermingled with the text.

The Elements of Blowpipe Analysis. By Frederick Hutton Getman. Pp. 77. (New York : The Macmillan Company. London : Macmillan and Co., Ltd., 1899.)

THE contents of this slight book include the orthodox blowpipe tests such as are found in most books on qualitative analysis, together with an account of the behaviour of some of the principal ores before the blowpipe. A meritorious feature is that the general chemical action of the common fluxes is explained. In other respects it is not easy to find points calling for special praise. An incorporation of some at least of the admirable tests described in Bunsen's "Flammenreactionen" would have made an improvement. The following minor errors are perhaps worth noting. On p. 10, decrepitation is described as "the crackling of a substance due to the sudden expansion of combined water on heating," and incandescence as "the white light emitted by a substance that is infusible when subjected to a high temperature." On pp. 11 and 13, silver oxide is printed AgO. On p. 17, the formulæ of borax and microcosmic salt are given without water of crystallisation—an important omission from the assayer's point of view. On p. 40, the only test for phosphates is that of flame colouration, the reduction with sodium or magnesium being omitted.

The Elements of Euclid. Books i.–vi. By R. Lachlan. New and revised edition. Pp. ix + 489. (London : Edward Arnold, 1899.)

THE editor of these Elements tells us in the preface that he has endeavoured to make the subject as easy as possible for beginners by the use of simple language, and by presenting the argument in the clearest form. Further, he has attempted to embody in the book, and with great success, the additions and improvements in statement and method which twelve years' experience as an examiner and teacher has shown to be desirable. Throughout the book Euclid's sequence of propositions has been maintained, but in many cases several well-known alternative proofs have been substituted for those of Euclid. In places where the student might experience difficulties fuller notes are added ; and attached occasionally to propositions are others which it is important for the beginner to know. The appendix to the last book contains many interesting problems of theorems for more advanced students, and this is followed by a considerable number of miscellaneous exercises. Students and teachers should find this form of the Elements of Euclid in many respects serviceable.

Essais du Commerce et de l'Industrie. By L. Cuniasse and R. Zwilling. Pp. viii + 302. (Paris : Carré and Naud, 1899.)

THE essential features of a book dealing with the subject of commercial analysis, whether intended for student or professional analyst, are careful elaboration and extreme minuteness of detail. As it is impossible for any analyst to have had an experience of more than a limited number of analytical processes, or at least such an experience as would justify him in publishing them, one naturally expects a book on commercial analysis to be devoted to special branches of the subject, unless, of course, a number of writers co-operate in its production. There are many special treatises of the kind relating to assaying, iron and steel analysis, to the analysis of soaps and fats, tanning materials, &c., which supply everything that is needful in this respect. To state that the present volume contains an account of nearly every branch of commercial analysis within the compass of 279 small octavo pages, that the subjects of leather, glue, vinegar, &c., are dismissed in one page, and that the analyses of other products are treated in the same cursory and superficial manner, is a doubtful recommendation.

Dairy Chemistry : a Practical Handbook for Dairy Chemists and others having control of Dairies. By H. Droop Richmond. Pp. xix + 384. (Charles Griffin and Co., 1899.)

THIS is a handbook for the chemist's laboratory, and deals especially with the matters on which his opinion will be asked, and with the methods of examination he may employ. Although of considerable size, it by no means includes the whole subject of dairy chemistry. The relations of the cow's diet to milk production, and its influence on the quality of the milk, and also the chemistry of dairy operations, are not discussed, though some parts of these subjects are referred to by the way. The author has had peculiarly favourable opportunities for becoming a master of his subject, and the book is full of information which will be valuable to the dairy chemist. Nevertheless, it is not unfrequently disappointing. The different parts of the subject are treated with very different degrees of fulness, and the expositions are not always clear. The book will be of most use to those who are already acquainted with the subject.

A Manual of Surgical Treatment. By Prof. W. Watson Cheyne, F.R.S., and F. F. Burghard, F.R.C.S. In six parts. Part ii. Pp. xix + 382. (London : Longmans, Green and Co., 1899.)

THE second part of this manual of surgical treatment fully justifies the good opinion which was recently expressed in these pages of the first part. It deals with deformities, the surgical affections of the skin, nails, lymphatics, bursæ, muscles, tendons, nerves and blood-vessels. The authors prefix to the volume a very proper statement that it is their endeavour to give only the salient points in the symptoms and pathology of surgical diseases, whilst they enter more fully into the question of treatment. The various topics are treated in a clear and concise manner, the information is accurate and modern, and there is an excellent index. If the future parts fulfil the promise of those already issued, the work will take rank as one of the best amongst the many surgical treatises which have recently issued from the English press.

D'A. P.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Stockholm International Conference on the Exploration of the Sea.

MR. KYLE's letter in the current number of NATURE is interesting as an expression of individual opinion as to the proposals of the Stockholm Conference, but it may be doubted whether he succeeds in his aim of conducing to "greater clearness on the points at issue."

I do not know to what extent Mr. Kyle is authorised to represent the British delegates who attended the Conference. They remain silent, while he replies—interpreting their report. In one place he tells us that "this [hydrographical] work was not intended to hinder the further prosecution of strictly biological research"—for which assurance I hope biologists will be duly grateful—and further on he says that "the areas of investigation will assuredly come under re-consideration." Will the delegates endorse that? Re-consideration of certain points was exactly what I asked for (see NATURE, p. 78).

But whether authorised to speak for the delegates or not, Mr. Kyle is certainly not entitled to say that I do not fully appreciate, and have not fully weighed, the Stockholm report. I have weighed it over and over again, and still adhere to my statement that it does not contain a definite programme of biological work. The sections Mr. Kyle quotes and refers me to (I., II., III*a.*, III*b.*, &c.) consist merely of statements of a quite general nature as to what is "desirable"—admirable sentiments which are neither new nor definite, but have been before the public for some years, and are in the main agreed to on all sides. We looked for something more from this Conference under the heading "programme" than pious wishes of the same unexceptionable nature as—that it is desirable to have full information about everything. If Mr. Kyle is satisfied with a "definite programme" of this nature, I am not; and, moreover, I think we have reason to believe that *the delegates themselves are not*. What are we to understand from their ominous silence; and what is the meaning of the following remarkable statement in the protocols of the Committee No. II. (see Report, p. lv.)? "It is thereupon expressly stated on different sides that a more precise and detailed elaboration of the biological programme is desired." And then further on: "such a detailed elaboration of the programme is rejected. This document is agreed to in the more general form in which it has been proposed, in order that *unanimous* acceptance of it may be arrived at." It is evident then that some of the delegates felt the same want of a more precise and detailed programme that I do. It would be interesting to know if the biological delegates played the part of the eleven obstinate jurymen who had to be convinced in order to secure unanimity. At any rate, this reference to the words of the report must effectually dispose of Mr. Kyle's contention that the programme is sufficient. It was evidently *not sufficient* in the eyes of some of the delegates themselves.

Finally, Mr. Kyle asks if I can show a more definite programme. There can be no great difficulty in that, but I would rather it came from those who were officially appointed to draw it up; and I hope that those delegates who evidently had something of the kind in their minds will publish it. It will be too absurd if any idea of official reticence is allowed to deprive independent biologists of such ideas and advice as the delegates can furnish, whether unanimously or no. If, however, our official representatives do not speak, I shall probably publish soon a detailed programme I have had in my mind for some time in connection with the work of the Lancashire Sea Fisheries Committee.

It is unnecessary for me to answer the latter part of Mr. Kyle's letter, which deals with Mr. Allen's criticisms, and contains a curious caricature of the work of the Marine Biological Association. But however much I may differ from the rest of Mr. Kyle's remarks, it gives me pleasure to agree most cordially with the sentiment expressed in his final paragraph.

Liverpool, December 16. W. A. HERDMAN.

Meteorology at the Berlin Geographical Congress.

IN the report of the Geographical Congress at Berlin (NATURE, vol. lx. p. 633), it is said that the last meeting of the Congress was to have been addressed by Prof. Hergesell, but as he had somewhat rashly made an ascent in a balloon the previous day, the Congress had been formally closed before he returned to Berlin.

In justice to my colleague, the President of the International Aeronautical Committee, and to maintain the customary accuracy of NATURE, I beg to correct this statement by saying that although Prof. Hergesell, in my stead, did make a high balloon ascension with Dr. Berson, and so co-operated in the eighth international ascent of balloons on the Continent, yet he also presented his paper to the Congress at the appointed time the next day.

It may be well to explain that with the idea of extending the sphere of geography, it was arranged to have recent results of the exploration of the atmosphere brought before the Congress by members of the Aeronautical Committee. Accordingly, Prof. Hergesell, of Strassburg, spoke of the instructional balloon ascents in Europe, in which, unfortunately, England has not participated; Prof. Assmann, of Berlin, described the scientific balloon ascents executed by the German Aeronautical Society; M. Teisserenc de Bort, of Paris, explained the work that he has been doing with *ballons-sondes* to get information about the high atmosphere; and I myself gave an account of the use of kites in America to study the meteorological conditions of the lower mile or two of air. A. LAWRENCE ROTCH.

Blue Hill Meteorological Observatory, Mass., U.S.A. December 1.

I AM happy to hear that Prof. Hergesell returned to Berlin in time to read his paper. My mistake is due to hearing it officially announced in the morning that it was feared he could not return in time, and to the report in a Berlin newspaper that he had not returned. It was of course impossible for me to attend all the meetings, and in summarising so vast a programme as that of the Seventh International Congress, some mistakes are sure to be made. It is almost unnecessary to add that no aspersion on Prof. Hergesell was intended, the completion of an unexpectedly prolonged experiment is worth more to science than the reading of many papers.

THE WRITER OF THE REPORT.

Shadows of Insects.

I HAVE only just seen the letter of your correspondent (Capt. D. Wilson-Barker) in your issue of the 7th inst. on the subject of "Butterfly Shadows."

The habit he observes in the butterfly of always adjusting its position after alighting, I have also frequently remarked in the ordinary garden fly and bluebottle. They are fond of congregating on shrubs or ivy in bright sunlight, whence they make short excursive flights in the air returning as nearly as possible to the same place; but no matter which way they are turned when they alight, they immediately readjust their position, and will always be found with their heads directed to the same point of the compass.

I have constantly observed this habit of theirs, but have never seen it mentioned in any natural history. It seems hardly likely that in the case of flies the practice can have anything to do with *shadows*. WM. PARKINSON.

Deerhurst, Coventry Park, Streatham, December 15.

Mosquitoes and Malaria.

IT may be of interest to record the fact that though during the months of June, July and August I collected and examined about 300 mosquitoes in this town, I only came across one specimen of the spotted-winged mosquito which is described as the malaria-conveying species by Major Ross. The majority, quite 75 per cent. of the specimens captured, were the harmless grey kind, the rest being chiefly the equally harmless tiger or brindled species. The single spotted-winged specimen I found in my house on a mosquito curtain. The rarity of its occurrence will, according to Major Ross's theory, account for the comparative absence of malaria in Singapore.

An account of this was given in the *Straits Times* of Sept. 4. A selection of the three species caught in the town of Singapore, together with about three other species from the neighbouring jungle, were sent in August to the British Museum, where they await further examination. R. HANITSCH.

Raffles Museum, Singapore, November 24.

THE GREAT PARIS TELESCOPE.

DURING two or three visits to Paris and Nice some years ago, I discussed with many French astronomers, whom I was privileged to count among my personal friends, the question of the large telescopes of the future. Among the conclusions come to, the first was that the glass industry was not in a position to grapple with astronomical requirements, and hence when reflectors of 8 or 10 feet diameter were talked of it was understood that they must be made of porcelain with a glass surface. Other conclusions were that the coudé mounting designed by M. Lœwy, and carried out so far as the optical parts were concerned by the brothers Henry, should be replaced with object-glasses of or about 25 inches by the use of a siderostat.

I subsequently (1884) gave two lectures at the Society of Arts on these and other questions,[1] in which I pointed out what I considered the best way of using an 8-foot reflector, and with regard to refractors I said: "With an object-glass of 30 inches diameter for physical observations I should certainly prefer the siderostat, thus reducing the cost of an instrument of this size to about one-third of the present price."

During the last few years we have heard a great deal of an enormous telescope to be constructed on the

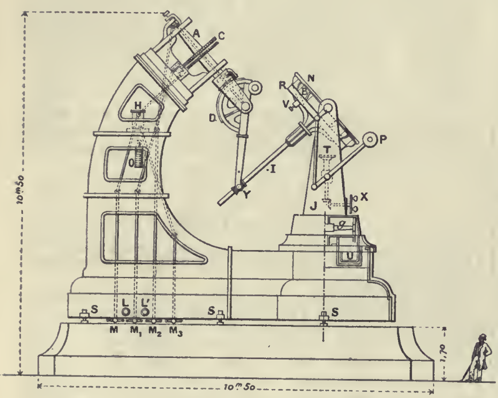

FIG. 1.—The siderostat.

occasion of the Paris Exhibition of 1900; a reflector of 10 feet aperture, such as was discussed in 1875, was indeed spoken of at one time, and renewed one of the old discussions, but it would seem that now as then the glass industry is not able to furnish a disc of this size, for after all it has been determined to construct a refractor, and mount it as I suggested nearly twenty years ago in front of a siderostat.

I have recently received from "Le Conseil d'Administration de la Société l'Optique" details of the scheme which it is proposed to carry out; while information regarding the telescope and siderostat has been given in the *Annuaire du Bureau des Longitudes*, and more recently in the *Scientific American*.

The Council in its memorandum is at some pains to excuse the exaggerations which have been so generally made regarding the power of the new telescope. They state that they hope for such a magnifying power that the surface of the moon will be seen as if our satellite were only 67 kilometres away from us. Under these conditions it was calculated that an object of one metre square might be seen. Hence the short phrase "La lune à un metre," and the consequent nonsense. One of the objects which finally determined the siderostat arrangement was the desirability of having a very long focus, and a focal length of 100 metres (328 feet) has been decided upon.

[1] Cantor Lectures: "Some New Optical Instruments."

M. Deloncle seems to be the chief of the band of astronomical amateurs who have enabled MM. Gautier and Mantois to employ their well-known skill. M. Despret, the Director of the Jeumont Glass Works, has produced the siderostat mirror which has a diameter of 2 metres, a thickness of 30 centimetres, and a weight of 3600 kilos. This certainly could not have been produced with the appliances in use twenty years ago.

The siderostat avoids all the expense of a dome—even if one of 340 feet diameter could be constructed—and saves considerable expenses for installation; it secures greater stability, and saves the astronomer unnecessary fatigue and serious loss of time.

The apparatus constituting the instrument termed a siderostat comprises a pedestal of cast iron, the north part of which supports the polar axis, and the south part the mirror with its frame. The cast iron pedestal, 8 metres long by 8 metres high, is furnished with six screws, which fit in sockets fixed to the stone base 1·70 metres high.

The north part of the pedestal supports the polar axis with its divided and driving circles. This axis is driven by a clock-work movement by means of a tangent screw.

At the lower end of the polar axis a fork is fixed, to which are adjusted the pivots of the declination circle. The toothed declination wheel is set in motion at the foot of the instrument by a handle placed beside that one which produces movement in right ascension; both of these are near the two telescopes which serve for the reading of the two circles.

The mirror, with its cell, has a total weight of 6700 kg. This cell of cast steel is furnished with two pivots; to the back is fixed the directing rod. The interior of the cell is covered entirely with felt, in such a way that the mirror has no point of contact with the metal. Being supported by as great a surface as possible, all deformations are avoided.

The mirror and its cell are kept in equilibrium by a system of levers and counterpoises; the pivots rest on rollers adjusted at the top of the frame, which permits a circular movement by a vertical shaft and a system of independent rollers between two rails.

The base of this frame floats in a cavity two metres in diameter on the south side of the pedestal, containing sufficient mercury to float $\frac{9}{10}$ of the total weight of the movable part, which weighs 15,000 kg.

The clock-work movement is set in action by a weight of 100 kilos. The total weight of the siderostat is 45,000 kg.

To cast the mirror a special furnace was made at the Jeumont Works, capable of holding over twenty tons of glass. This enormous plane mirror was, naturally, the most difficult part of the apparatus to make.

The mould, 2·05 metres in diameter and 0·30 metres in height, was placed on a wagon near the furnace, in order to receive the melted glass coming from the crucible. When the mould was full, the wagon was immediately taken to an annealing oven of the right temperature and then walled up; the cooling lasted a month. The operation of annealing the glass is very difficult to carry out; numerous experiments had to be made; out of twelve discs only two have been successful.

The transportation of such a huge disc of glass to Paris was a difficult matter, and a special train carried it there, and it was conveyed to the optical establishment at night, in order to have a clear roadway.

The disccs for the object-glasses, visual [and photographic, of 1·25 metres in diameter, were cast by M. Mantois; the flint weighs 360 kilos., and the crown 220, and the figuring, polishing and mounting of these enormous discs have been confided to M. Gautier.

The following interesting account of the casting of the glass for the lenses is given in the *Scientific American*:—

"Great attention was paid to the casting of the glass. Specimens of the glass were constantly taken out during the heating and examined with a lens under different conditions of illumination in order to judge of the degree of purity which they have reached. After several specimens have been found to be free from bubbles the temperature is reduced, the glass thickens, the crucible is opened, and a certain portion of the surface is skimmed off to get rid of impurities. The glass is then stirred, and the cooling is allowed to proceed rapidly for five or six hours until the surface of the glass emits a well-defined sound when it is struck with an iron bar. After this step it is necessary to proceed with annealing. The furnace is walled up and a cooling is allowed to proceed, which requires from four to six weeks. When the crucible is opened the glass is found to have been broken into pieces of varying sizes. In order to obtain a 792 pound flint glass lens it is necessary to find a block which weighs nearly 1300 pounds, and such a block having been found among those in the furnace it is removed and placed upon a car. Slabs of glass are sawed from two parallel sides in order to obtain polished surfaces that facilitate a perfect examination of it. The striæ in the surface are removed, and if after this the block exhibits any defects situated at such a depth that they cannot be removed, it is submitted to a moulding which changes its form and brings the chief defects near the surface. The block is placed in a mould of refractory clay and put into a furnace and heated to 800° to 900° Centigrade. By this means it becomes slowly heated and softened until it assumes the form of the mould, but it must not become fused, or the whole operation must be gone over again. If the outcome of the process is successful, the glass is slowly annealed, and is then taken from the mould and examined anew. If any defects deep in the glass are seen, a second operation is begun with a mould of another form. Finally, when the glass is very pure and perfect, another and final moulding produces the plano-convex lens. After this comes another heating and cooling which takes two or three weeks."

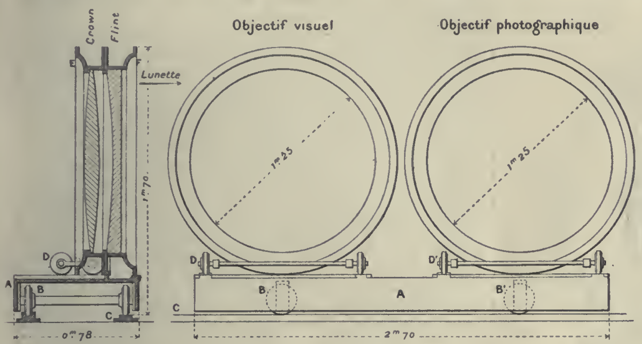

FIG. 2.—The object-glasses.

Telescope.—The telescope tube, which is of sheet steel 2 mm. thick, weighs 21,000 kg.; it is 1·50 metres in diameter, and is composed of twenty-four pieces united by bolts. It rests on eight supports of cast iron resting on stone pillars. In view of expansion, the supports move on rails fixed to the pillars.

I confess this *iron* telescope tube astonishes me.

The two object-glasses are both mounted on the same carriage, which moves on rails in such a manner as to place them easily, the one or the other, at the end of the tube; the weight of each of these object-glasses, without their cell, is about 600 kg., and with the cell 900 kg. Each lens is adjusted in a separate cell; that of the crown is carried on rollers, in order to be able to remove it from the flint and render the cleaning of each disc easy.

The tube carrying the eye-piece is supported by four wheels on rails. It is attached to the telescope tube by an adjusting screw 1·50 metres long, which is used for focussing. In the interior of this tube there is another 1·20 metres in diameter, which can be rotated by clock-work. This carries the adapter for the eye-piece end, which is made to slide in two rectangular directions by means of screws. The eye-piece end can carry either an eye-piece, a micrometer, a photographic plate, or a projecting lens.

By means of the arrangements realised in the eye-piece the observer is rendered independent of the apparent movement of the heavens, and is enabled to follow the object in right ascension and declination.

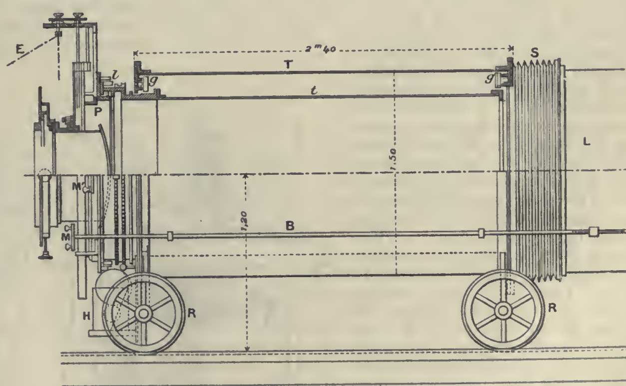

FIG. 3.—The eye-piece and travelling adapter. (Side view.)

It is stated that M. Gautier has been entirely successful, not only with the plane mirror, but with the two object-glasses.

The grinding apparatus consists essentially of a large cast iron plate, *C*, covered with an inch of flannel, upon which the glass disc, A, was carefully laid. The *Scientific American* thus describes it:—

"This plate revolves slowly around a vertical axis by gearing, G, the whole being stepped in a cone. Above

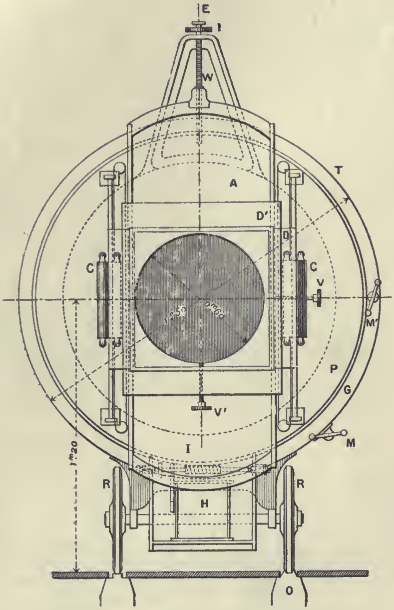

FIG. 4.—Details of the eye-piece. (Front view.)

there is a stationary circular bronze rubber, B, 47¼ inches in diameter, which is given a reciprocating motion by a slider, I, thus passing across the face of the mirror travelling in a circle beneath it. The perfect revolution of the plate and the accurate adjusting of the slides and their parallelism resulted in the production of a perfect mirror. It required three months to adjust the slides alone. The grinding of the mirror was done with a mixture of emery and water. During this operation a workman always stood at a respectful distance from the apparatus so as not to change the temperature of it. From time to time he injected a mixture of emery and water by means of a syringe into a channel running through the grinding plate and ending at the centre. This work was carried on generally from 2 till 5 o'clock in the afternoon, the time of day when the temperature does not change perceptibly. The entire morning was devoted to the cleaning of the machine, and to the verification of the parallelism of the grinding plate with the surface of the mirror, an operation which was performed with four scales which were accurate to $\frac{1}{1000}$ of a millimetre."

"As the grinding proceeded, finer and finer emery was used, and the closer the grinding plate was brought to the surface of the glass. With the finest emery the distance between the plate and the glass was 0·008 inch. The grinding lasted eight months and was followed by the operation of polishing, which required two months The lower surface of the polishing plate was covered with a sheet of albumenised paper like that used in photography, but unsensitised. The workmen spread upon this paper a small quantity of the finest Venetian tripoli and as much as possible was removed with a soft brush. The distance between the rubber and the surface of the glass was 0·0012 of an inch."

"This method of treatment, notwithstanding its delicacy, produces enough heat to render the mirror slightly convex and cause it to draw away more strongly in the centre, so that, upon cooling, it was hollowed at this point. In order to surmount this difficulty the slides were given a curve of which the pitch was 0·4 of an inch. The heat was diminished by operating the machine for a minute and then stopping for a quarter of an hour. When the hand is applied to the mirror, there occurs an extension of 0·0012 of an inch, which is sufficient to distort completely for four or five minutes the image of the flame of a lamp placed at one side of the plate and observed from the other with a small telescope arranged for the purpose. The next operation to be performed is the silvering, and, of course, it will have to be silvered anew from time to time. The mirror protrudes 5·4 inches from its tube or cell, which will be made to swing so as to bring the surface to be silvered underneath. The reservoir containing the bath will be lifted by means of a winch until the mirror enters it at a proper depth. When the operation is finished, the reservoir will be lowered and the silvered surface turned upward and the mirror readjusted in its cell."

I am indebted to M. Gautier for the use of the illustrations, which have already appeared in the *Annuaire Scientifique du Bureau des Longitudes.*

It is the intention of the Syndicate to erect in connection with this telescope a Palais de l'Optique near the Eiffel Tower, containing a hall capable of holding some 4000 persons, and in fine weather images of the various celestial bodies are to be thrown on a screen 20 metres in the side by means of secondary magnifiers. Thus an image of the moon 16 metres in diameter, and of Mars 3·70 metres in diameter, are promised to the abonnés.

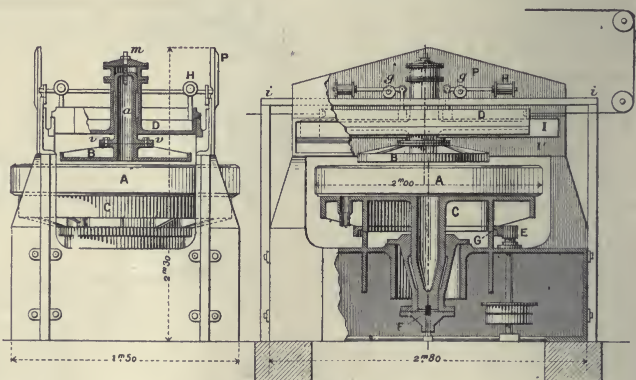

FIG. 5.—The polishing machines.

No doubt the great telescope will be largely capable of advancing science, and this will certainly be taken advantage of by the highly skilled French astronomers. Its erection, therefore, will be a great gain.

Whether the hoped-for 6000 visitors (paying, we presume, a franc each) per half-hour night and day will visit it and help to provide the sinews of war is another matter.

NORMAN LOCKYER.

GEOLOGICAL SURVEY OF THE UNITED KINGDOM.[1]

REPORTS of the progress of the Geological Surveys in India and Canada have already been noticed in NATURE. The report of our home survey has since been issued by the Director-General, Sir Archibald Geikie. It is more voluminous than those of the other countries, and appears rather to be a full record than a "Summary" of the observations made during 1898 by the staff of the Survey. Whatever may be said concerning the state of our knowlege of geology in England and Wales, in Scotland and in Ireland, it cannot be gainsaid that very much remains to be done both from a scientific and a purely economic point of view. The report before us is a striking testimony to this, and when we consider the limited staff and poor equipment of our Survey, it is surprising how much has been done to further the progress of knowledge.

So far as the main field-work of the Geological Survey is concerned, the mapping of entirely new areas has been confined to the mountainous regions of Scotland and to the islands of Arran, Jura and Skye; but it is not in these areas alone that fresh observations of striking importance have been made. Re-surveys are being made of the coal districts of South Wales, North Staffordshire, Leicestershire and South Derbyshire; of the mineral districts of Cornwall and Devon; and of the agricultural districts of the southern and midland counties. In all these cases the work done actually amounts to a new survey, on a larger scale than the original map, and carried out with that attention to minute accuracy which nowadays is absolutely essential. Revisions have also been made in the Silurian areas in Ireland.

A glance at the little index-maps which accompany this report show how much field-work yet remains to be done. Of the 131 sheets of the Scottish one-inch map, fifty-nine only have been published. In England and Wales ninety-nine only of the 360 one-inch new series maps have been published. It has long been recognised that for practical purposes a survey on a scale smaller than six inches to a mile is of little value. The work of the Survey has for many years been conducted on the larger maps, MS. copies of which are deposited for public reference in the Survey Offices in London, Edinburgh and Dublin. In illustration of certain mineral areas and other regions, a number of six-inch maps have been published, but the issue of further maps was some few years ago discontinued, mainly, we believe, on account of the expense of engraving. Cheaper processes, however, are available, and it is to be hoped that the publication of six-inch maps may ere long be resumed. It is not only in mineral areas that these maps are utilised—they are quite as necessary in inquiries relating to water-supply, sanitary engineering, and agriculture. In these important questions the highest attainable accuracy is as necessary as in mining questions. Those who compare the earlier published one-inch maps with the new series of geological maps in England and Wales will recognise the great advances which have been made in the method of mapping, and if these again are compared with the six-inch maps (*e.g.* of the South Wales coal-field) it will be seen how much work is lost or obscured in the small one-inch reproduction. This difference was strikingly shown in the one-inch and six-inch maps of the Durness area in Scotland, published a few years ago.

[1] "Summary of Progress of the Geological Survey of the United Kingdom for 1898." Pp. v + 216. (London: Printed for H.M. Stationery Office, 1899.)

The present "Summary," like the first of the series which was issued a year ago, is arranged stratigraphically, commencing with the Pre-Cambrian and continuing to the Recent deposits; it contains also records of new railway-cuttings and well-borings, and accounts of the microscopic and chemical work carried on in the Petrographical Department and of the varied work performed in the Palæontological Department. Brief notice is also taken of the numerous public and private inquiries made at the offices of the Survey, work which increases from year to year, as help and advice in reference to water-supply, soils, sites for houses, building-materials, various ores and minerals, are as far as possible freely given to those who seek them.

That the field-work of the Survey must be conducted on a strictly scientific basis is not to be questioned. Economic results must follow, and they may not always be apparent at the time of the survey. It is, however, satisfactory to find that discoveries of importance have been made.

The puzzling question of the age and origin of the Highland schists continues to attract a large amount of attention. The evidence gathered tends to show that the "Moine-Schists" of the north-west highlands are metamorphosed arkoses, sandstones, and argillaceous rocks, and that there is unconformity between them and the older (Archæan) gneisses. Associated with the schists are several types of foliated igneous rock, and these in some cases were intruded into the original sediments before their present foliated structures were developed. The Dalradian or so-called Younger Schists of the central highlands have also received much attention, and structures similar to those seen in the Moine Schists have been recognised in these rocks in the Braemar area. What is termed the "hornfels" type of alteration, producing a cordierite-hornfels, has been found where the old granites, such as that of Ben Vuroch, were intruded prior to the movements causing schistosity. This type of metamorphism is not observed in connection with later granitic intrusions, such as those of Cairngorm and Lochnagar. Interesting observations are made on the intrusions of these younger granites, and it is inferred that in the case of Cairngorm the mass, on its southern side, took the form of a cake or sill with vertical or highly inclined edges. The metamorphic changes produced in the bordering rocks by the masses of granite and by various igneous dykes are fully dealt with.

The Cambrian limestones in Skye have yielded a number of fossils which connect them with the Balnakiel and Croisphuil groups of Durness. Several of the species occur also in Newfoundland—and these indicate a horizon below the Arenig formation.

Analyses have been made of Cambrian dolomites from Skye and Durness.

Among the Silurian rocks in Ireland several horizons have been determined by means of Graptolites and other fossils. It is observed that the older rocks of the south-eastern portion of that country have undergone much crushing and deformation, and in the Ribband Series (of Arenig age) the grit-bands are curiously broken up, portions of grit having been pushed into the argillaceous strata so as to produce a brecciated appearance, deceptively like that of a conglomerate; indeed, some of these crush-breccias have actually been described as conglomerates. From the Upper Silurian rocks of Central Scotland a new genus of fishes (*Ateleaspis*) is recorded, and also a new species of *Eurypterus*.

Observations are made on the Old Red Sandstone of Caithness, Ross-shire, the Lorne, and South Wales. In the Lorne district a fish-bed has been discovered on the mainland shore of Kerrera Sound, about three miles south of Oban. The volcanic rocks in the Lower Old Red Sandstone form a conspicuous feature in this region.

Particular attention has been given to the granites of Ben Cruachan and Glen Etive, and it is noted that the porphyrite dykes and sills so numerous in the Cruachan granite are entirely absent from the Glen Etive mass. The evidence tends to show that the chronological order was (1) Ben Cruachan granite, (2) Porphyrite dykes and sills, and (3) Glen Etive granite and quartz-porphyry dykes and sills. It is observed that the huge granitic mass of Ben Cruachan affords special facilities for the study of the phenomena of contact-metamorphism, of which particulars are given. A careful study was made of the Cordierite-bearing rocks which occur among the altered sediments at the back of Loch Awe Hotel, and the discovery in them of Corundum is noted and discussed.

Among the Devonian and older slaty rocks of Devon and Cornwall and the associated eruptive rocks much interesting work is in progress.

In Carboniferous regions the chief work has been done in the coal-fields of South Wales, North Staffordshire and Leicestershire; and there are some new observations on the volcanic rocks in the Carboniferous Limestone of Somerset.

The changes which take place in the Carboniferous Limestone series of Glamorganshire are duly noted, and we have some account of the Millstone Grit and its beds of "silica stone," from which the celebrated Dinas fire-bricks are made. The faulted anticlinal disturbances of the Vale of Neath and Cribarth are described and illustrated. A study of these disturbances is of the highest practical importance, an instance being given where the Pennant escarpment exhibits a gentle and uniform dip, while the soft Lower Coal-measures below are thrown into sharp folds. Explorations are now showing that the lower measures are too much crushed and broken over considerable tracts near the head of the Rhondda valleys for their coals to be workable, though the Pennant rock overlying them is unbroken. Reference is made to the anthracitisation of the coals which proceeds from the eastern side of the South Wales coal-field in a direction somewhat west of north. It is remarked that the lower seams of the north crop in the Vale of Swansea are true anthracites, while one seam becomes a steam-coal at Resolven, and is intermediate between a steam-coal and an anthracite at Crynant. Of the Neath seams, one alone is a house-coal, all the others being steam-coals, although they correspond to the Llantwit group, the most noted house-coals of the coal-field. No connection has been traced between the anthracitisation and the faulting of the district, but the change seems rather to be a form of regional metamorphism dependent upon the temperature to which any part of the coal-field has been subjected during depression, as was suggested many years ago by De la Beche. The results of further investigations on this subject will be looked for with interest, for although much has been done by local observers, the question can only be solved by patient detailed and continuous mapping, and the tabulating of evidence over a large area.

In the North Staffordshire coal-field much has been done to determine and map in detail the main subdivisions of the Coal-measures. The uppermost division, known as the Keele series, comprises a considerable thickness of red sandstones, marls, and occasional bands of cornstone—beds formerly regarded as Permian, but now recognised to be strictly conformable to the Upper Coal-measures. Some of the red marls in this series contain plants of Coal-measure species, and it is remarked that the division cannot be classed with the Permian formation of Lancashire and the north-eastern counties. It remains to be proved how far it corresponds with the Supra-Carboniferous or Permo-Carboniferous division which is engaging much attention on the continent and in other regions abroad. It is remarked that the determination of the horizons in the Coal-measures may prove to have an important industrial and commercial bearing. The fact that the limestone-bands of Newcastle-under-Lyme lie at the base of a group of grey Coal-measures, intercalated between an upper group of red strata (Keele Series) and a lower group of red strata (Etruria Marls), has enabled the survey to detect true Upper Coal-measures in Keele Park, Shutlanehead, and to the west of Leycett; and there seems to be little doubt that the Coal-measures of the Pottery Coal-field lie not far from the surface under Little Madeley and Craddocks Moss. Evidence has been obtained that the strata on the north-west side of the North Staffordshire anticline do not uninterruptedly descend beneath red rocks (so-called Permian) to the west of Leycett, but rise locally westward under Hayes. The effect of this change of inclination is to bring to the surface strata which lie considerably below the unproductive red series, and to bring the principal coals and ironstones within reach further west than might have been expected. Iron-ore has been discovered in the Fenton Park Clay-pits. It is a sphero-siderite yielding 38·7 per cent. of metallic iron. This may prove to be of considerable importance.

A small patch of Carboniferous rocks has been determined at the Bridge of Awe, in the Lorne area, a fact interesting in connection with the discovery, made many years ago by Prof. Judd, of Carboniferous rocks on the east shore of the Sound of Mull, near Ardtornish. Further evidence of Lower Carboniferous rocks in Arran has also been obtained.

Brief observations on Permian rocks in Leicestershire and in Arran are recorded, and there are fuller notes on the Trias (including the Rhætic Beds) in South Wales, and on the Trias of the Midland Counties and Skye. Short notes again are given on the Lias of Glamorganshire, but the only reference to the Oolites is in a note of a deep boring (439 feet) at Oxford. We hope to hear more of this boring, as it is stated to pass from Inferior Oolite into Lower Lias with no evidence of Upper and Middle Lias, which outcrop at Fawler, near Woodstock.

The Cretaceous rocks have received attention in the southern and eastern counties. There are notes on Chalk inliers which form remarkably bold features in the neighbourhood of Cranborne Chase. There are detailed accounts of the Lower Greensand series of Norfolk, but these facts, which convey much new information, have now been printed in full in the Geological Survey memoir on "The Geology of the borders of the Wash." It is mentioned that the name Selbornian, from Selborne in Hampshire, is proposed as a term for the Gault and Upper Greensand, formations which have long been held to be portions of one stage, although it is useful and necessary on geological maps to separate the clayey Gault from the sandy Upper Greensand. The Selbornian stage will include the Red Chalk of Norfolk, Lincolnshire and Yorkshire, as well as the Gault, and the sands Malmstone and Chert-beds of the Upper Greensand. Where fully developed it is divisible into four palæontological zones, in descending order: (4) zone of *Pecten asper* (as usually known), which would more conveniently be called the zone of *Holaster fossarius;* (3) zone of *Ammonites rostratus*, with its local sub-zone of *A. varicosus;* (2) zone characterised by *Ammonites lautus*, *A. denarius*, and *A. interruptus;* (1) the zone of *Ammonites mammillatus*.

The observations on Tertiary strata refer to Bagshot Beds, and to records of new wells at Mundesley and North Walsham which passed through Pliocene strata as well as Glacial Drift. More important are the researches on the volcanic rocks of Skye, which tell of the numerous sills of basalt and diabase which have been intruded into the basaltic lavas. Though the lavas are older, these sills are younger than any of the great plutonic intrusions of gabbro and granophyre. Reference is made also to the presumably Tertiary granite of Arran, whose intrusive character was so clearly appreciated more than a hundred years ago by Hutton.

The Pleistocene notes include some general remarks on the method of investigation of the deposits of this and Recent ages. These notes are followed by an excellent account of the Drifts near Uttoxeter. It is remarked that the prevalent drift of the higher ground is a red sandy loam, or more rarely clay, containing numerous rounded quartzite and other pebbles mainly derived from the Bunter. Evidence was obtained that in spite of its general resemblance to rain-wash the material is the local equivalent of the true boulder clay, and has had a similar derivation from the moving mass of land-ice by which the whole country has been covered. It is remarked that the movement of the ice has not been determined by the shape of the ground in the vicinity, nor by the presence of the elevated Carboniferous Limestone tract of the Weaver Hills, but has been consequent upon the pressure of the great ice-sheet which was piled over the lower ground to the westward and north-westward. The occurrence in new localities of marine shells in the Drift of North Staffordshire is likewise noticed. Further particulars are also given of the Glacial Drift in South Wales. The height to which this extends seems limited only by that of the ground. Not only till with glaciated boulders, but numerous striated rock-surfaces have been observed at heights ranging up to 2000 feet on the Old Red Sandstone. In the Isle of Man the Glacial series has been found by a deep boring to be of unusual thickness, apparently descending to between 470 and 500 feet below sea-level.

From various parts of Scotland observations on the Drifts are recorded. In Aberdeenshire there is evidence of the occurrence of blocks of the Glen Derry diorite on the hillside above Allanmore, at a distance of more than six miles to the south-east of the parent-mass. These blocks could not have been brought to their present position by the later or local glaciation, but must have been transported by the ice-sheet over ridges nearly 3000 feet in height. In Inverness-shire the high-level terraces of fluvio-glacial gravel have been traced to an elevation of 1020 feet. Many observations have been made on the Drifts in Ross-shire and in the Black Isle. Again, in Skye it has been observed that at the epoch of maximum glaciation only the highest summits of the Cuillins stood above the ice. This is true also of Blaven, and probably of the Red Hills, though the crumbling granite of which these latter are composed is not so well fitted as the gabbro to retain evidences of glaciation.

In the southern counties of England, as well as in Scotland and Ireland, various notes have been made on Pleistocene and Recent deposits, on the "Head," clay-with-flints, raised beaches, sand-dunes, peat and other accumulations.

The new railway-cuttings which have been examined are those made by the Great Western Railway Company between Stert, near Devizes, and Westbury, in Wiltshire, and those between Wootton Bassett, in Wiltshire, and Patchway, in Gloucestershire. Cuttings on the Great Eastern Railway between North Walsham and Mundesley are briefly noted.

In this abbreviated account of some of the leading observations recorded in the "Summary of Progress of the Geological Survey for 1898," we have sufficiently indicated the work that is being done, and which we hope will be carried on until the whole country has been mapped as carefully as possible on the six-inch scale. Until that work is accomplished, it can never be considered that the more pressing work of the Survey has been carried out. Regarding this as necessary, and looking to the work already performed, it is not to be denied that a very great deal of the more important work of the Survey has yet to be done. This remark applies, not only to the maps, but to the explanatory memoirs so needful in illustration of each map. The list of publications which is appended to the report before us shows that a number of new memoirs have been issued, while others are in progress; and it is hardly necessary to add that the surveying alone will not supply the public needs if the maps are not accompanied as soon as possible with the memoirs which describe the facts and explain the structures depicted on the maps.

SIR RICHARD THORNE THORNE, K.C.B., F.R.S.

Sanitary science has suffered a severe loss by the death, on Monday, of Sir Richard Thorne Thorne, K.C.B., F.R.S., principal medical officer to the Local Government Board. As a guardian of the public health, he was largely responsible for the security of the United Kingdom against serious epidemics, and for the introduction of sanitary measures which have resulted in a diminution of mortality; and as an investigator he made numerous important contributions to the science of preventive medicine.

Sir Richard Thorne Thorne was born at Leamington on October 13, 1841, and was therefore fifty-eight years of age at the time of his death. From an obituary notice in the *Times* the following particulars concerning his career have been derived. He received his medical education at St. Bartholomew's Hospital, and obtained the membership of the Royal College of Surgeons in 1863. In 1866 he became M.B. of the London University, taking a double first class, and for a short time he held some hospital appointments in London; but about 1870 he accepted office in the Medical Department of the Privy Council, which was afterwards transferred to the Local Government Board. In this capacity he continued for many years to discharge the routine work of the office, in the way of inspections and reports, until 1885, when his mastery of the French language led to his selection as delegate of the British Government at a first International Sanitary Conference, which was held at Rome, and was followed by others at Venice, Dresden and Paris. In these conferences he took from the first a leading part, and was mainly instrumental in convincing the representatives of other Governments of the futility of quarantine and of the facility with which, notwithstanding the presence of infectious disease, commerce might be liberated from vexatious restrictions which had previously hampered it. In this way he became a conspicuous public benefactor, not of this country alone, but of many others; and he was appointed her Majesty's Plenipotentiary for signing the Sanitary Convention of Dresden in 1893 and that of Paris in 1894. He early received the distinction of C.B., and that of K.C.B. was conferred upon him in 1897, soon after he had succeeded the late Sir George Buchanan as the head of his department. He was a Crown member of the General Medical Council, vice-president of the Epidemiological Society, Fellow of the Royal Society and of the Royal College of Physicians, LL.D. of Edinburgh, Doctor of Science of the Royal University of Ireland, and held numerous foreign distinctions. Apart from his many official reports relating to the public health, he was the author of works on the progress of preventive medicine during the Victorian era (1887), the "Milroy" lectures on the natural history and prevention of diphtheria (1891), and of the "Harben" lectures on the administrative control of tuberculosis (1898).

By these and other publications Sir Richard Thorne Thorne assisted scientific progress, and improved the conditions of public health. The influence of his works on national sanitation will long be felt.

NOTES.

At a recent meeting of the Paris Academy of Sciences, M. Berthelot reported that the total amount subscribed for the erection of a statue to Lavoisier was 98,000 francs. M. Barrias has been commissioned to construct the statue and the bas-reliefs for the pedestal. The Municipal Council of Paris has granted a site for the statue in an open space behind the Madeleine Church. The monument will be unveiled when the Paris Exhibition is open, probably some time in July.

The Brussels Academy of Sciences has awarded the prize of six hundred francs, for an important contribution to geometry, to M. Léon Autonne, of the University of Lyon. The prize of six hundred francs for anatomical and systematic investigations of insects of the group Apterygota (Thysanura and Collembola) has been awarded to M. Victor Willem, of the University of Ghent. M. F. Keelhoff, of the same University, has been awarded the Prix Charles Lemaire (interest on twenty-five thousand francs) for a work entitled "Note sur le travail des forces élastiques." The decennial prize of five thousand francs for botanical science has been awarded to Prof. Alfred Cogniaux; and a prize of the same value for chemistry and physics has been given to Prof. Louis Henry. To fill vacancies caused by death, the Academy has elected as foreign associates in the section of mathematics and physics, Sir G. G. Stokes, Prof. Moissan and Prof. Jordan. In the section of natural sciences M. C. Vanlair has been elected a *membre titulaire*, Profs. Pelseneer and Gravis have been elected correspondents, and Sir John Murray and M. Maupas have been elected associates.

The Berlin Academy of Sciences will celebrate the second centenary of its foundation on March 19 and 20, 1900.

The annual meeting of the Australasian Association for the Advancement of Science will be opened at Melbourne on January 9, under the presidency of Mr. R. L. J. Ellery.

In the December number of *Natural Science*, the announcement is made that the magazine is to be discontinued, the reason being insufficient support. The journal has always been of interest and value to students of the biological sciences, and it is to be regretted that financial considerations necessitate its withdrawal.

The Council of the Manchester Literary and Philosophical Society have awarded the Wilde Medal for 1900 to Lord Rayleigh, for his contributions to mathematical and experimental physics and to chemistry; a Dalton Medal (struck in 1864) to Sir H. E. Roscoe, for his remarkable original researches in chemistry and for his distinguished services to scientific education; and the Wilde Premium for 1900 to Prof. A. W. Flux for his papers on economic questions read before the Society. The presentation of the medals and the premium will take place at a special meeting in February next, when Lord Rayleigh will deliver the Wilde Lecture for 1900.

A Reuter telegram from St. Petersburg states that the expedition of Baron Toll, organised for the exploration of the New Siberia Islands and Sannikoff Land, will set out in June next from a Norwegian port, whence it will proceed to the mouth of the Lena, on the banks of which river, at a point above the town of Yakutsk, it will pass the winter. During the summer of 1901 the expedition will begin its explorations towards the north, picking up *en route* a detachment which will be sent forward from the main body during March, with a sufficient supply of dogs.

The death of Dr. John Frederick Hodges, professor of agriculture and lecturer on medical jurisprudence in Queen's College, Belfast, is announced in the *Times*. Dr. Hodges was an honorary member of the Academy of Agriculture of Sweden, and of many other scientific societies. He was one of the oldest members of the Chemical Society of London, having been elected a Fellow in 1844—three years after the formation of the Society. Dr. Hodges was the author of the following works:—"First Book of Lessons in Chemistry for Farmers and Teachers" (a work which reached a twelfth edition in 1862), "First Steps in Chemistry," "The Structure and Physiology of the Animals of the Farm," and of several papers published in the proceedings of scientific societies. He was for some years editor of the *Journal* of the Chemico-Agricultural Society of Ulster.

At the international congress on tuberculosis recently held at Berlin (see vol. lx. pp. 108, 154) it was decided to hold a similar congress in England in 1901. A meeting was held in Gray's Inn Hall, on Monday, under the presidency of the Earl of Derby, to make preliminary arrangements for the forthcoming congress. The following resolutions were unanimously adopted:—(1) In view of the fact that tuberculosis, although a preventible disease, still devastates health and destroys lives in all parts of the world, this meeting, consisting of representatives of medical, veterinary, and sanitary science, and also principal officials of municipal and county authorities, is unanimously of opinion that it is desirable to hold a national congress on tuberculosis in the spring of 1901, to which representatives from India and all dependencies of the Empire should be invited, and, in addition, honoured guests from other countries. (2) That this meeting has learned with very great pleasure that H.R.H. the Prince of Wales has graciously consented to preside over the proposed congress, and to open it in person, and desires to convey to his Royal Highness the appreciation of all present of this expression of his sympathy and support. (3) That this meeting heartily approves of the steps already taken by the National Association for the Prevention of Consumption to initiate the undertaking, and earnestly invites the co-operation of representative bodies interested in the public health in carrying out the necessary organisation. (4) That this meeting is of opinion that steps should be at once taken to obtain subscriptions and to open a Congress Fund.

The death is announced of Mr. E. C. C. Stanford, Fellow of the Institute of Chemistry and Chemical Society, and managing director of the British Chemical Company. Mr. Stanford introduced several original methods of chemical manufacture, and prepared a number of new bodies. From the *Chemist and Druggist* we learn that while he was an assistant to the late Prof. Redwood, he began a research on kelp and iodine manufacture; and afterwards delivered lectures on the subject before the Society of Arts. These brought him into notice, and the improved processes of manufacture which he had invented were adopted on a practical scale by Mr. Patterson, of Glasgow, with whom Mr. Stanford became associated, and under his direction the production of iodine at Clydebank became a very profitable industry until the advent of Chilian nitrate crippled it. Mr. Stanford's original idea for the manufacture of iodine was to extract the salts from seaweed by diffusion and without burning it. This was found to be impracticable on a large scale, and therefore he turned his attention to less wasteful production of kelp. Through his efforts the kelp-makers of Ireland and the Hebrides gradually improved the quality of their product, while the Norwegian kelp-makers under Mr. Stanford's instructions have produced a kelp richer in iodides and more suitable for treatment than either Irish or Scotch kelp. The monograph upon the iodine industry in Thorpe's "Dictionary of Applied Chemistry" was written by Mr. Stanford. Arising from his researches on the isolation of iodides from seaweeds by diffusion, he about fifteen years ago introduced into chemistry a new body called algin, the substance which gives seaweed its peculiar texture. This algin is an exceedingly viscous compound, and there appeared to be a future before it as a sizing-agent, but it never succeeded. One of Mr. Stanford's latest researches with the body was the preparation of an iron salt of it which has been found of considerable therapeutic interest, the compound being apparently more readily assimilated by the blood than any other iron compound. His last research was on the active principle of the thyroid gland, and it resulted in the isolation of thyroglandin. The results of this investigation were communicated to the meeting of the British Pharmaceutical Conference at Belfast.

THE Bavarian Government has granted a sum of 6000 marks to Dr. K. Giesenhagen for a botanical investigation of Malacca.

WE learn from the *Botanical Gazette* that Prof. R. von Wettstein, the director of the botanical garden at Vienna, has established a biological experiment station near the Bremerhütte, in the Gschnitzthal, in the Central Tyrolese Alps, at an elevation of 2300 m. The first object of research will be the production of species by direct adaptation.

THE United States Navy Board has issued a report on the results of investigations of the Marconi system of wireless telegraphy. The report is published in full in the *Electrician*, and from it the following statements concerning the efficiency of the system have been taken :—It is well adapted for use in squadron signalling under conditions of rain, fog, darkness and motion of speed. Wind, rain, fog, and other conditions of weather do not affect the transmission through space, but dampness may reduce the range, rapidity, and accuracy by impairing the insulation of the aërial wire and the instruments. Darkness has no effect. When two transmitters are sending at the same time, all the receiving wires within range receive the impulses from transmitters, and the tapes, although unreadable, show unmistakably that such double sending is taking place. In every case, under a great number of varied conditions, the attempted interference was complete. Mr. Marconi, although he stated to the Board before these attempts were made that he could prevent interference, never explained how nor made any attempt to demonstrate that it could be done. Between large ships (heights of masts 130 feet and 140 feet) and a torpedo-boat (height of mast 45 feet), across open water, signals can be read up to seven miles on the torpedo-boat and eighty-five miles on the ship. Communication might be interrupted altogether when tall buildings of iron framing intervene. The rapidity is not greater than twelve words per minute for skilled operators. The sending apparatus and wire would injuriously affect the compass if placed near it. The exact distance is not known, and should be determined by experiment. The system is adapted for use on all vessels of the navy, including torpedo-boats and small vessels, as patrols, scouts, and despatch boats, but it is impracticable in a small boat. For landing parties the only feasible method of use would be to erect a pole on shore and then communicate with the ship. The system could be adapted to the telegraphic determination of differences of longitude in surveying. The Board respectfully recommends that the system be given a trial in the navy.

THE great explosion which occurred in the central crater of Etna, on July 19, is by far the most striking phenomenon exhibited by the volcano since the eruption of 1892. According to Mr. S. Arcidiacono, who describes it in the last *Bollettino* (vol. v., No. 4) of the Italian Seismological Society, it exceeded in violence those which preceded the eruptions of 1886 and 1892. A gigantic "eruptive pine" rose to a height of more than 5000 metres above the summit of the mountain, and was then blown to the south-east into an elongated dark cloud, which covered a large part of the sky and hid the sun. Strangely enough, the great seismometrograph (25·3 metres in length), with which the observatory of Catania is now provided, was absolutely unaffected by the explosion. Three shorter tromometers showed, however, that it was preceded and followed by very slight and rapid vibrations ; and a slight earthquake, accompanied by a prolonged rumbling sound, was felt by a few persons at Zafferana Etnea. Six days later there was a second, but much less violent explosion, which produced no disturbance whatever in the instruments at Catania. The observatory on Mount Etna was unfortunately damaged by falling stones during the first explosion.

A PAPER was read by Mr. C. Newton Russell before the Institution of Civil Engineers on December 12, upon the subject of refuse destruction, particularly in reference to its employment for raising steam. Details were given of ten combined plants, the data of which all tend to prove that a considerable amount of energy in the form of heat may be obtained from the burning of ordinary domestic refuse. At Shoreditch, where the largest of these plants is in operation, the total amount of refuse destroyed during a period of twelve months was about 26,000 tons. The plant consists of six Babcock-Willcox water-tube boilers and twelve refuse-furnaces of the Manlove-Alliot type, each boiler being placed between two refuse-furnaces, the hot gases from which are led into the boiler-tubes through short side-flues, each boiler being provided with a special grate, on which coal might be burned if required. Forced-air draught is supplied to the fires by electrically-driven fans, the pressure in the ashpits being one inch of water. No coal or other fuel is mixed with the refuse, which burns freely ; the maximum temperature observed is 2500° Fahr., and the average, 1500° F. The steam generated in the boilers, at an average pressure of 140 lbs. per square inch, is disposed of mainly by the engines attached to the electric generators, although a small portion of live steam is supplied for clothes-washing purposes to the public baths and washhouses adjoining the electricity works ; exhaust steam is also supplied to the Baths and Free Library, which are entirely heated from the steam produced by the refuse-destructor.

IT may be interesting to some of our readers to know that the U.S. Weather Bureau has just issued a *Bulletin* (No. 27), showing the probable state of the sky along the path of total eclipse of the sun on May 28, 1900, so far as relates to the United States. The track of totality begins on the Pacific Ocean just west of Mexico at sunrise, and leaves the United States near Norfolk (Virginia), and Cape Henry. It then crosses the Atlantic Ocean, and touches Europe at Coimbra, Portugal, takes in Algiers and Northern Africa, and terminates near the northern end of the Red Sea at sunset. This is the third report, and includes the results of observations made in the years 1897–9. The observations are divided into two parts ; (1) the general state of the sky, and (2) the state of the sky near the sun, and show that Central Georgia and Eastern Alabama, about south of Atlanta, is the most favourable part for avoiding the tendency to cloudiness. It is, however, needless to remark that any special cyclonic disturbance on the day in question would seriously modify these calculations as to the mean amount of cloudiness.

IN *Das Wetter* for October, Dr. van Bebber publishes the first part of the results obtained in an interesting discussion on the possibility of scientific weather prediction for several days in advance, with special reference to the requirements of agriculture. Instead of attacking the subject in the usual way of dealing with the more mobile areas of low barometric pressure, he keeps in view the behaviour of the simpler and more persistent areas of high pressure, among which he distinguishes five principal types, in which an anticyclone lies (1) in the neighbourhood of the British Isles (with depressions lying to the eastward); (2) over Germany (with depressions at a considerable distance off); (3) over North or North-East Europe (with depressions to the southward); (4) over East or North-East Europe (with low pressure in the west); (5) over South and South-West Europe (with low pressure to the northward). Tables are given showing the frequency in days of the weather types during twenty years, and of their mean duration. The cases in which the high pressure is situated in the western half of the horizon are much more frequent than those in which it lies to the eastward, especially in the summer season. The distribution of pressure corresponding to type (4) is a winter type, and shows a decided minimum during summer. The occurrence of type (3) in April is very marked, and it is comparatively rare in the summer season. The duration of the different types varies considerably in the twenty years' period, but the average time is about three days. The chief characteristics of the various types is explained; but although these refer more particularly to the weather of the Continent, the lines on which the investigation has been carried out may probably be followed with advantage in other similar discussions.

IN the number of the *Biologisches Centralblatt* for October 1, Dr. L. Reh, of Hamburg, contributes a discussion on symmetry and asymmetry in animals, in the course of which he disputes the correctness of several current views. It has, for instance, been asserted that asymmetry occurs only in land animals of a sluggish disposition and in aquatic creatures. But, observes the author, the majority of fishes are some of the most symmetrical of all animals; while in contrast to the unsymmetrical claws of land-crabs is the symmetry of those of their aquatic cousins. In regard to the occurrence of symmetry in rapidly moving creatures and of asymmetry in those of stationary habits, Dr. Reh admits that, so far as external characters are concerned, the former condition obtains in insects, most fishes and birds, while many tube-dwelling worms, univalve molluscs, and flat-fish are as markedly unsymmetrical. On the other hand, conspicuous asymmetry is met with in the intestines of birds and in the skulls of the toothed whales; while many barnacles, bivalve molluscs, and brachiopods are as distinctly symmetrical.

CAPTAIN GUIDO COUARDE contributes to the *Mittheilungen* of the Vienna Geographical Society an interesting paper on the island of Mayotto, the member of the Comoro group nearest to Madagascar. A short history of the island is given, and notes on its trade, population, climate, flora, and fauna.

PETERMANN'S *Mittheilungen* contains the first part of a detailed study of the geology of Celebes, by Prof. H. Bucking. The region described is that of Minahassa, in the extreme north-west of the island. Minahassa is remarkable for volcanic activity; there are large numbers of active volcanoes, solfataras, mud-volcanoes, and hot springs.

WE have received the first part of the fifty-sixth volume of the *Verhandlungen des naturhistorischen Vereins der Preussischen Rheinlande, Westfalens, und des Reg.-Bezirks Osnabrück*. The general meeting for 1899 was held at Aix-la-Chapelle, and the report contains papers on "Eyes and Industry," by Dr. Thier, oculist in Aix; on the rainfall of the Rhine Province, by Dr. P. Polis; on the geology of volcanic islands, by Paul Grosser; and on the spiders of the Rhine Province, by W. Bosenberg.

THE Hull Scientific and Field Naturalists' Club sends a copy of its *Transactions* for the year 1899. The club wisely confines its publications to local topics. Mr. J. W. Boult contributes a list of Macro-Lepidoptera collected within eight miles of Hull. Mr. Thomas Sheppard deals with the contents and origin of the gravels around Hull. Some of the gravels he regards as Pre-Glacial, although the evidence furnished by the mammalian remains is inconclusive. The mosses of the East Riding form the subject of an article by Mr. J. J. Marshall. Other papers relate to local water-supply, and to "A whale hunt at Goole over thirty years ago."

APPENDIX II. for 1899 of the Kew *Bulletin of Miscellaneous Information* consists of the names and origin of the new garden plants brought for the first time into cultivation during 1898, and the most noteworthy of those which have been re-introduced after being lost from cultivation. The list includes about 300 species.

HERR J. DÖRFLER (Barichgasse 36, Vienna iii.) is about to publish a second edition, revised and enlarged, of his *Botaniker Addressbuch* (Botanical Directory) and asks the co-operation of British botanists, who are requested to send him their full name and address, with their scientific distinctions or appointments, together with the special branch of botany in which they have worked. The price of the Directory will be, to subscribers 7*s*. 6*d*., to non-subscribers, 10*s*. post free.

Bulletin No. 17 of the U.S. Department of Agriculture (Division of Vegetable Physiology and Pathology) consists of a report by Mr. Erwin F. Smith on the "Wilt disease" of cotton, water-melon, and cow-pea (*Vigna sinensis*). It appears to be due to the attacks of a fungus, which is polymorphic, assuming somewhat different forms in the three host-plants. Besides ascospores, it produces three different kinds of conidial reproductive bodies. The fungus has hitherto been known as *Fusarum vasinfectum*, but Mr. Smith regards it as the type of a new genus, *Neocosmospora*, allied to *Cosmospora*.

WE have received a report on the spraying of Charlock and Runch (wild radish) issued conjointly by the Yorkshire College and the East and West Ridings Joint Agricultural Council. The writer, Mr. J. R. Campbell, advocates the destruction of these weeds by a spraying machine, the spray used being either iron sulphate or copper sulphate, preferably the former. It can, however, be used to advantage only in bright, sunny and calm weather. Solutions of the strength of 10 to 15 per cent. iron sulphate have no injurious effects on corn or young seeds, but they are injurious to other cruciferous crops, such as mustard or turnips, and to beans.

EARLY in the New Year Mr. John C. Nimmo will publish the first volume, by Prof. Sayce, of Oxford, of "The Semitic Series," an important new series of standard hand-books intended to present compactly and in popular scientific form a knowledge of the more important facts in the history, religion, government, language, customs, &c., of the Babylonians, Assyrians, and allied Semitic races of ancient history in a way that will be serviceable to the reading public generally, as well as to teachers and masters, students, the clergy, and others. The first volume is "Babylonians and Assyrians—Life and Customs (with special reference to the Contract Tablets and Letters)," by the Rev. A. H. Sayce, Professor of Assyriology at Oxford. Other volumes will follow at regular intervals; each will be complete in itself, and the series, taken as a whole, will neglect no phase of the general result of recent scientific research.

THE additions to the Zoological Society's Gardens during the past week include a Flying Squirrel (*Sciuropterus*, sp. inc.) from Chitral, presented by Captain S. A. Harris, I.M.S.; a Pheasant (*Phasianus colchicus*, ♂) from Russia, presented by the Hon. E. A. Stoner; two Crossed Snakes (*Psammophis crucifer*), two Rhomb-marked Snakes (*Trimerorhinus rhombe-*

atus), two Cape Bucephalus (*Dispholidus typus*), a Puff Adder (*Bitis arietans*) from South Africa, presented by Mr. J. E. Matcham; a Common Rattlesnake (*Crotalus durissus*), two Horrid Rattlesnakes (*Crotalus horridus*) from North America, deposited; four Common Sheldrakes (*Tadorna cornuta*), two White-fronted Geese (*Anser albifrons*), European, purchased; a Harnessed Antelope (*Tragelaphus scripta*, ♀), a Brush-tailed Kangaroo (*Petrogale penicillata*, ♂), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

NEW MINOR PLANET (1899 E.Z.).—Circular No. 25 from the Centralstelle at Kiel contains an ephemeris of the planet observed by Mr. E. F. Coddington in October and November last. Herr Kreutz thinks there seems no doubt that this is identical with the planet found by Dr. J. Palisa (1896 C.O.), and the ephemeris is given with the possibility that more observations may definitely settle the point.

Ephemeris for 12h. Berlin Mean Time.

1899.	R.A. h. m. s.	Decl. ° ′
Dec. 22	0 58 39	−4 59·0
24	1 0 45	4 36·4
26	2 56	4 13·3
28	5 12	3 49·7
30	7 33	3 25·8
Jan. 1 (1900)	1 10 0	−3 1·5

CHANGE IN PUBLICATION OF THE "ASTRONOMISCHE NACHRICHTEN."—We have received a card from Herr H. Kreutz, of the Central Bureau at Kiel, respecting an important alteration in the method of publishing the astronomical information hitherto given in the *Astronomische Nachrichten*, which is one of the most important foreign journals dealing with current astronomical observations. With the beginning of the New Year the original publication will be confined to the recording of general observations, while a separate paper will be issued to contain the ephemerides of comets, planets, &c. The subscription to the new part will be 10 marks yearly. Arrangements are being made for this addition at Kiel, Niemannsweg 103, and subscriptions should be sent there direct.

COMPANION TO THE OBSERVATORY.—We have received the *Companion to the Observatory* for the year 1900. In arrangement this closely resembles those of previous years, giving most of the more important data for the observation of celestial objects. Beginning with one page showing for every week the time of rising and setting of the sun, its declination at noon, mean and sidereal time, and the moon's phases, there follows a calendar, giving for every day in the year the setting, southing, declination of the moon and the longitude of its terminator. Mr. Denning again contributes his list of radiant points of the principal meteor showers during the year. Then follow useful particulars of the R.A., Decl., diameters, times of rising, southing and setting of the planets, with the times of elongation, opposition, conjunction, &c. Occultations, configurations of the satellites of Jupiter, Saturn, Uranus and Neptune occupy the next ten pages. Mr. Crommellin contributes an ephemeris of Eros for the period about the opposition in December. The rest of the book is occupied with an ephemeris for physical observations of the sun, and the mean places and times of maxima and minima, of the more noticeable variable stars.

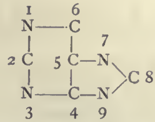
RECENT RESEARCHES ON URIC ACID.

THE uninterrupted stream of new researches which has issued from the laboratory of Prof. Emil Fischer at Berlin since 1895 threatens to bewilder even the careful student of chemistry or physiology. The following brief summary of the results may be found useful.

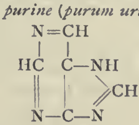
Uric acid is an excretory or waste product of animal life, and is closely related chemically to many substances such as paraxanthine and heteroxanthine, which are associated with it in urine; xanthine, adenine, and guanine, which probably form part of the nucleins of cells, and theobromine, theophylline and caffeine, the physiologically active constituents of tea, coffee and cocoa.

An accurate knowledge of the constitution of these substances is therefore of the first importance to physiologists, whilst a satisfactory process for utilising uric acid—which is a plentiful constituent of guano—in the synthesis of theobromine or caffeine would possess considerable therapeutic interest as well as commercial value. The many difficulties encountered by Prof. Fischer in the solution of these problems have been met with his accustomed skill and resource, which are the admiration and despair of the present-day chemist, and we are now not only in possession of a clear and complete knowledge of the relationship which exists between these complex products of animal and plant life, but we may anticipate before long their appearance as commercial products.

Fischer has shown that in all these compounds the same atomic framework is present and may be represented as follows, the relative position of the atoms being denoted by the numbers 1 to 9.

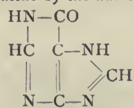


If the four additional hydrogen atoms necessary to satisfy the valencies of the carbon and nitrogen atoms be now added, the structure of the mother substance of the whole series is obtained, a compound which has been actually prepared by Fischer, and named *purine* (*purum uricum*).

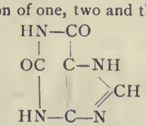


Purine.

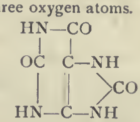
Hypoxanthine, xanthine and uric acid may be derived from purine by the addition of one, two and three oxygen atoms.



Hypoxanthine (6-oxypurine).

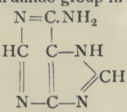


Xanthine (2:6-dioxypurine).

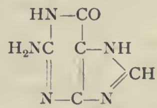


Uric acid (2:6:8-trioxypurine).

Adenine is purine in which the hydrogen atom in position 6 is replaced by an amido-group, whilst guanine is hypoxanthine with an amido-group in position 2.

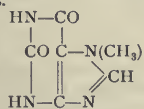


Adenine.

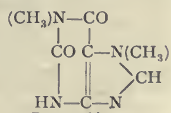


Guanine.

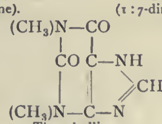
Heteroxanthine, theophylline, paraxanthine, theobromine and caffeine are respectively mono-, di- and tri-methyl xanthines.



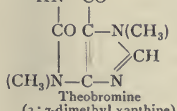
Heteroxanthine (7-methyl xanthine).



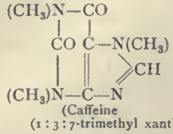
Paraxanthine (1:7-dimethyl xanthine).



Theophylline (1:3-dimethyl xanthine.)



Theobromine (3:7-dimethyl xanthine).



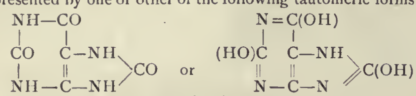
(Caffeine (1:3:7-trimethyl xanthine).

Although most of the natural products are represented in the foregoing formulæ, the list of purine derivatives is not exhausted; for, as in the case of the sugars, the natural products have been supplemented by an even longer list of artificial compounds. Thus 4 monomethyl, 5 dimethyl and 2 trimethyl xanthines are possible, and most of them are known, and all the fifteen theoretically possible methyl derivatives of uric acid have been prepared together with an additional one, whose existence has not yet been accounted for.

Even this does not complete the list of purine derivatives, for there remain methyl purines, methyl adenines and methyl hypoxanthines still to record, as well as an 8-oxypurine isomeric with hypoxanthine and a 6:8-dioxypurine isomeric with xanthine, and many others.

It now remains to indicate the manner in which the constitution of these substances has been determined and their synthesis effected.

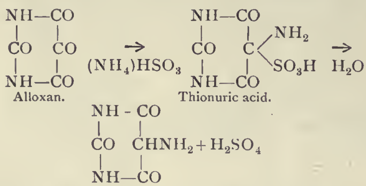
The structure of uric acid was pretty clearly established in the year 1884 by Fischer's discovery of a second methyl uric acid, in addition to the one obtained by Hill, both of which are formed simultaneously by treating the lead salt of uric acid with methyl iodide. Since one of these compounds gives on oxidation methyl alloxan and urea, and the other by similar treatment alloxan and methyl urea, the formula of uric acid must be represented by the fusion of an alloxan and a urea nucleus, so as to form an unsymmetrical grouping after the manner proposed by Medicus. The complete methylation of uric acid yields a tetramethyl derivative from which all the nitrogen is removable in the form of methylamine. It follows, therefore, that the four methyl groups in tetramethyluric acid, and probably therefore the four hydrogen atoms in uric acid itself, are linked to nitrogen. The structure of uric acid is represented by one or other of the following tautomeric forms:—



Uric acid.

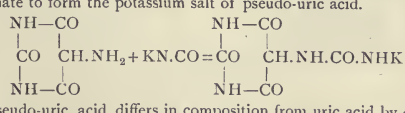
This structure is confirmed by its synthesis from uramil, a synthesis which, it may be interesting to remember, was first suggested by Liebig and Wöhler, then carried forward a step by v. Baeyer's discovery of pseudo-uric acid, and finally realised by Fischer in 1895.

Uramil was first obtained by Liebig and Wöhler from alloxan and ammonium sulphite, which form together thionuric acid, the latter decomposing on boiling with hydrochloric acid into uramil.

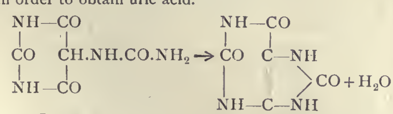


Alloxan. Thionuric acid. Uramil.

Uramil, as v. Baeyer showed, combines with potassium cyanate to form the potassium salt of pseudo-uric acid.



Pseudo-uric acid differs in composition from uric acid by one molecule of water. To effect its removal, which the usual dehydrating agents fail to do, Fischer found that it is only necessary to heat the compound with 20 per cent. hydrochloric acid in order to obtain uric acid.



Pseudo-uric acid. Uric acid.

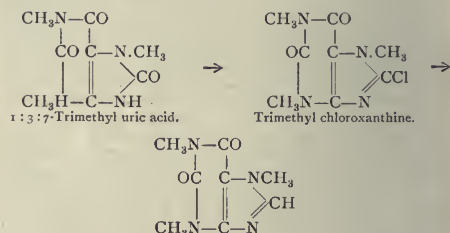
If in place of uramil its methyl derivatives are employed, various methyl uric acids are obtained; an important point, since the positions of the methyl groups in the acid are thereby determined.

Thus from 1 and 7-monomethyl uramil, 1 and 7 methyl uric acid have been obtained; 1:3- and 1:7-dimethyl uramil yield 1:3- and 1:7-dimethyl uric acid; 1:3:7-trimethyl uramil can be converted into trimethyl uric acid, whilst the imido-pseudo-uric acid of Traube is converted into an amido-uric acid.

Having then established the structure of uric acid and the methyl uric acids as hydroxy-derivatives of xanthine, guanine, theobromine, theophylline and caffeine, &c., the question arises, How can these various compounds be obtained from the single raw material, uric acid? Since xanthine can be methylated and converted into theobromine, as Strecker first showed by treating the silver salt with methyl iodide, and since theobromine and theophylline, by a repetition of the same process, can be converted into caffeine, there are several ways in which the above problem might be attacked.

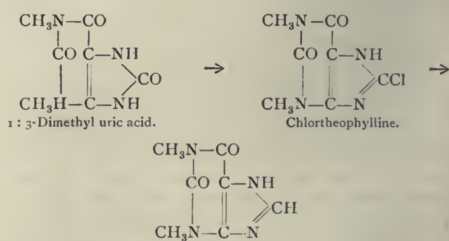
Uric acid might be reduced to xanthine and the xanthine methylated, or uric acid might be converted into monomethyl uric acid, then reduced to monomethyl xanthine and further methylated; or, finally, the di- and tri-methyl uric acids might be first prepared and then reduced to the corresponding di- and tri-methyl xanthines. All three methods have been utilised in turn by Fischer and carried to a successful issue; and since the process is similar in each case, one or two examples may suffice by way of illustration.

When 1:3:7-trimethyl uric acid is heated with a mixture of pentachloride and oxychloride of phosphorus, it yields trimethyl chloroxanthine. Tetramethyl uric acid yields the same product by the elimination of a methyl group in the form of methyl chloride. Trimethylchloroxanthine is then reduced with strong hydriodic acid to caffeine.



1:3:7-Trimethyl uric acid. Trimethyl chloroxanthine. Caffeine.

1:3-Dimethyl uric acid behaves similarly and forms theophylline.

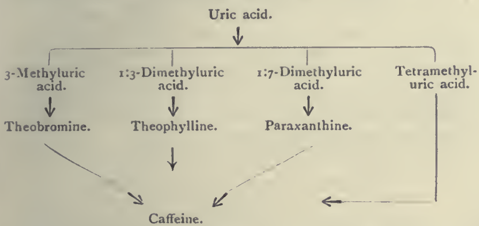


1:3-Dimethyl uric acid. Chlortheophylline. Theophylline.

This process cannot, however, be applied to uric acid in order to obtain xanthine, or to 3 or 7 monomethyl or 3:7-dimethyl uric acid, which might lead to the synthesis of theobromine; since in the first case the substance is destroyed, and in the other cases the chlorine atom replaces the wrong oxygen atom, *i.e.* instead of replacing it in position 8, which is essential to the success of the operation, it enters position 6.

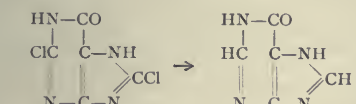
The happy idea of employing phosphorus oxychloride alone in place of the mixture of pentachloride and oxychloride has overcome this unforeseen difficulty, and given a fortunate turn to the investigation.

By this modification 3 : 7-dimethyl uric acid may be made to yield chlorotheobromine and theobromine, or better still, 3-methyl uric acid, which can be obtained by the direct methylation of uric acid, may be converted successively into 3-methyl-8-chloroxanthine, which may be either methylated with methyl iodide in presence of caustic potash to chlorotheobromine and chlorocaffeine, and then reduced, or first reduced to 3-methyl xanthine and then methylated. As a rule, however, the methylation of the chlorine compound is more easily effected than that of the reduced product. Paraxanthine (1 : 7-dimethylxanthine) may be obtained from 1 : 7-dimethy luric acid in a similar manner and also converted by methylation into caffeine. The following scheme will make clear the various directions in which the synthesis of caffeine has been accomplished:—

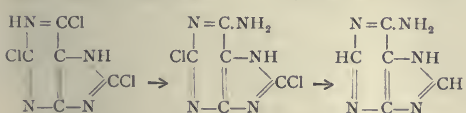


Heteroxanthine (7-methyl xanthine) has been obtained by the action of phosphorus oxychloride on theobromine, which by the elimination of one methyl group forms 7-methyl dichloropurine. By boiling this substance with hydrochloric acid, 7-methyl xanthine is formed. Xanthine cannot be prepared in so direct and simple a manner as the above from uric acid, even when phosphorus oxychloride alone is used, for the first product obtained in this way is 8-oxy-2 : 6-dichloropurine instead of 8-chloro-2 : 6-dioxypurine; but by the action of a large excess of phosphorus oxychloride uric acid may be made to part with its last atom of oxygen. Trichloropurine is then produced, and this compound has served for the synthesis of xanthine and its more nearly related derivatives hypoxanthine, adenine and guanine.

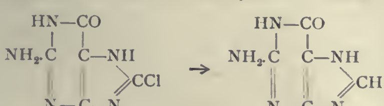
When trichloropurine is treated with aqueous potash it yields 6-oxy-2 : 8-dichloropurine. The latter compound may be directly reduced with hydriodic acid to hypoxanthine, or converted with alcoholic ammonia into chloroguanine, which on reduction forms guanine. Aqueous ammonia converts trichloropurine into 6-amino-2 : 8-dichloropurine, which yields adenine on reduction.



6-oxy-2:8-dichloropurine. Hypoxanthine.

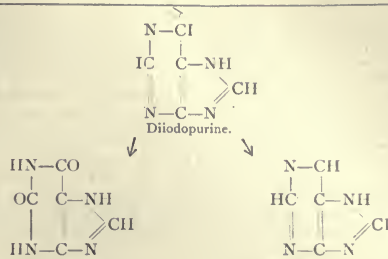


Trichloropurine. 6-amino-2:8-dichloropurine. Adenine.



Chloroguanine. Guanine.

With strong hydriodic acid, trichloropurine is converted into diiodopurine, which yields, on the one hand, with hydrochloric acid xanthine, and with zinc dust and water purine, the mother substance of the whole group of compounds. Though neutral to litmus, purine forms salts, the nitrate and picrate being the most characteristic of these compounds.



Diiodopurine.

Xanthine. Purine.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

MR. FRANK LENEY, of the Geological Department of the British Museum (Natural History), who has been trained under Mr. Smith Woodward, has been appointed Assistant Curator of the Norwich Museum.

MR. A. RENDLE SHORT, a student of University College, Bristol, was awarded the scholarship in physiology at the recent final B.Sc. examination of London University. The scholarship is of the value of 50*l.* per annum for two years.

DR. J. W. GREGORY has been appointed professor of geology and mineralogy in the University of Melbourne, in succession to Sir Frederick M'Coy, F.R.S. Dr. Gregory has been an assistant in the geological department of the British Museum (Natural History) for several years, and is a member of the council of the Geological Society. He has been engaged in very successful explorations—notably in British East Africa in 1892–93, and in Spitsbergen in 1896—and has, in addition, contributed more than fifty papers to scientific societies. The salary attached to the post to which he has been appointed is 1000*l.* a year.

THE London Technical Education Committee have arranged for a second conference of science teachers to be held during the forthcoming Christmas vacation. Meetings will be held on Wednesday, January 10, and Thursday, January 11, 1900, in the morning and afternoon of each day. On the first day the meetings will be held in the conference room of the English Education Exhibition at the Imperial Institute, when the Rt. Hon. Sir John Lubbock, F.R.S., will preside at the morning meetings, and Sir Henry Roscoe, F.R.S., at the afternoon gatherings. The second day's proceedings will take place at the Shoreditch Technical Institute, Pitfield-street, Hoxton. The following addresses will be delivered:—Wednesday at 11 a.m., "Teaching of Botany in Schools," by Prof. L. C. Miall, F.R.S., and "Object Lessons in Botany," by Miss Von Wyss; at 2 o'clock, on "Juvenile Research," by Prof. H. E. Armstrong, F.R.S., this address will be illustrated with lantern slides and experiments by juvenile assistants; on Thursday at 11 a.m., on "Teaching of Natural History in Schools," by Prof. Woods Hutchinson, and on "Object Lessons in Natural History," by Mr. J. W. Tutt; at 2 o'clock, "Metal Work as a Form of Manual Instruction in Schools," by Prof. W. Ripper. Free admission will be granted to as many teachers as the conference rooms will accommodate. Applications for tickets of admission should be made to Dr. Kimmins, Bermondsey Settlement Lodge, S.E., or to Mr. C. E. Buckmaster, 16, Heathfield-road, Mill Hill Park, W.

THE following gifts to science and education in the United States are announced in *Science*:—The money, amounting to 11,400,000 dollars, obtained by Mrs. Jane Stanford for her 285,000 shares of Southern Pacific stock, which she sold recently, will at once be made available for the use of the Stanford University.—Mr. James Jennings McComb, of New York, one of the founders of the South-western Presbyterian University at Clarksville, Tenn., has given 70,000 dollars to the endowment fund, making his contributions amount in all to 100,000 dollars.—Brown University has received an unconditional gift of 10,000 dollars from the heirs of the late Lucian Sharpe.—The Rev. John Pike has left the reversion of half his property to found two scholarships in Bowdoin College.—Mr. Thomas Armstrong, of Plattsburg, New York State, who died in 1897, left his property, amounting to 300,000 dollars, to Union College, Schenectady. Suit was brought on behalf of his wife and children, and half of the estate has been awarded to them, while the remaining 150,000 dollars goes to Union College.—Vassar College has received a gift of 5,000 dollars towards the proposed biological laboratory, for which 25,000 dollars has been promised on condition that an equal additional sum shall be raised.—The University of Pennsylvania has received a gift of 250,000 dollars for the construction and equipment of a laboratory of physics.—Wesleyan University has received a gift of 38,000 dollars from Miss Elizabeth A. Mead, subject to an annuity during her lifetime.—St. Lawrence University has received 34,000 dollars from various sources.

SCIENTIFIC SERIALS.

American Journal of Science, December.—The highest aim of the physicist, by H. A. Rowland. Physics is the science above all sciences which deals with the foundation of the universe, with the constitution of matter from which everything in the universe is made, and with the ether of space by which alone the various portions of matter forming the universe affect each other, even at the greatest distances. He who makes two blades of grass grow where one grew before is the benefactor of mankind; but he who obscurely works to find the laws of such growth is the intellectual superior as well as the greater benefactor of the two.—Notice of an aerolite that recently fell at Allegan, Michigan, by H. L. Ward. The mass in question, about 20 inches long and 10 or 12 inches thick, was seen to fall, and dug up a few minutes after it was buried. It was reported to be hot all through, and not cold at the centre as might have been suspected. The stone is very chondritic in structure. It is of a light ash-grey colour, and exceedingly friable, with a black crust averaging 1 mm. in thickness. Optical examination reveals the presence of enstatite, chrysolite, felspar, troilite and iron, the two last being distributed evenly and thickly as small irregularly shaped grains.—A new meteoric iron found near Iredell, Bosque County, Texas, by W. M. Foote. The meteoritic iron in question was not seen to fall. The three best instances of cleavage are exhibited in one specimen. These are three pairs of perfect adjacent planes forming angles of 120°. The fracture presents a glistening tin-white finely crystalline surface. Grains and plates as much as 2 mm. thick, of a brittle magnetic mineral of pyritiferous aspect are common. A qualitative examination showed the presence of iron, phosphorus and nickel, indicating it to be schreibersite.—Some of the results of the international cloud work for the United States, by F. H. Bigelow. The penetration of ordinary cyclones into the higher regions of the atmosphere is slight. They are only two or three miles deep. Hurricanes are five or six miles deep. The anticyclonic and cyclonic areas are hardly to be considered as centres of motion except in the very lowest strata, since currents of air blow directly across them from west to east, even in the cumulus region of the Rocky Mountain districts. The ordinary circulation theory does not hold good. In each stratum from the surface to the cirrus level about as much air moves north as south, for there are enormous counter currents passing by each other at the same level, and not over one another at different elevations. This puts a new aspect upon the entire problem of the general circulation.

Wiedemann's Annalen der Physik und Chemie, No. 11.—Moving bodies in the electric field, and the electric conductivity of air, by A. Heydweiller. If a sphere rotates uniformly in a medium of different conductivity and in an electric field, and the conductivity of the medium is negligible in comparison with that of the sphere, a couple acts upon the sphere tending to stop its motion. If the conductivities are reversed, the couple tends to accelerate the motion. The author shows that this may account for the stoppage of the moon's original rotation.—Ratio of the electric charge of kathode particles to their mass, by S. Simon. Using Kaufmann's method of magnetic deflection, the author determined the ratio e/m as accurately as possible. He found it to be $1 \cdot 865 \times 10^7$ C.G.S. units, or slightly higher than Kaufmann's value.—On the highest audible and inaudible notes, by R. König. The author investigates notes of pitches ranging from 4096 to 90,000 vibrations per second, produced by bowed tuning-forks. The method of beats is useful for estimating pitches up to the limits of audibility, but the method of Kundt's dust figures is available up to the highest pitches, and is easy to apply and to deduce results from.—Origin of frictional electricity, by C. Christiansen. A mercury jet was surrounded by twelve jets of zinc amalgam, and both were made to fall side by side through oxygen. As long as the oxygen was somewhat moist, the normal difference of potential of 0·88 volt was indicated between the amalgam and the mercury. But when the moisture was gradually reduced the difference of potential steadily decreased, and finally was reversed in sign at a point where the vapour pressure was about 0·5 mm.—Influence of Becquerel rays upon electric sparks and brushes, by J. Elster and H. Geitel. A spark gap 1 cm. wide, between a positive knob and a negative disc, was exposed to the influence of a radium preparation. The sparks or brushes were immediately converted into a glow dicharge, a violet glow surrounding the knob. When the disc was made of cardboard instead of metal, the gap became so sensitive that the radium affected the discharge at a distance of over a metre.—Behaviour of the brush discharge in a magnetic field, by Mr. Toepler. The stratification of the brush discharge is considerably modified by a strong magnetic field. The latter has the effect of crowding the stratifications together, and also of displacing them laterally with respect to each other. An unstable brush discharge is converted into a spark discharge.

SOCIETIES AND ACADEMIES.

LONDON.

Chemical Society, December 7.—Prof. Thorpe, President, in the chair.—The following papers were read.—The oxidation of certain organic acids in presence of ferrous salts, by H. J. H. Fenton and H. O. Jones. The authors have examined the oxidation products of a number of carboxylic acids and of picric acid by hydrogen peroxide in presence of ferrous salts.—Oxalacetic acid, by H. J. H. Fenton and H. O. Jones. Free oxalacetic acid, $C_4H_4O_5$, is obtained on oxidising malic acid in presence of ferrous salts.—Determination of the constitution of fatty acids (Part ii.), by A. W. Crossley and H. R. Le Sueur. Ethylisopropylmalonic acid yields ethylisopropylacetic acid,

$$C_2H_5.CH(C_3H_2).COOH$$

by elimination of carbon dioxide. Ethylic α-bromethylisopropylacetate yields, on treatment with diethylaniline, a mixture of ethylic dimethylethylacrylate and ethylic methylisopropylacrylate.—The reaction between sulphuric acid and potassium ferrocyanide, by R. H. Adie and K. C. Browning. The action of acid of the composition H_2SO_4 or H_2SO_4,H_2O upon potassium ferrocyanide consists in the formation of potassium sulphate and hydroferrocyanic acid and in a partial evolution of carbon monoxide; all the cyanogen in potassium ferrocyanide is converted into carbon monoxide by acid of the composition $H_2SO_4,2H_2O$. Acid of the composition $H_2SO_4,4H_2O$ to $H_2SO_4,10H_2O$ similarly converts the salt into hydrocyanic acid and Everitt's salt, $K_2Fe_2Cy_6$ —The sulphates of bismuth, by R. H. Adie. By the action of sulphuric acid of different concentrations, the author has obtained solid salts of the following compositions:

$$5Bi_2O_3,11SO_3,17H_2O\ ;\ Bi_2O_3,4SO_3,7H_2O\ ;\ Bi_2O_3,4SO_3,3H_2O\ ;\ Bi_2O_3,4SO_3,H_2O\ ;\ Bi_2O_3,4SO_3,10H_2O.$$

—On sulphates of the form $R_2SO_4,2MSO_4$, especially those of isometric crystallisation, by F. R. Mallet. By fusing the constituent salts together, the author has obtained cubic double salts of the following compositions:

$$K_2SO_4,2MgSO_4\ ;\ K_2SO_4,2ZnSO_4;\ K_2SO_4,2MnSO_4\ ;\ K_2SO_4,2NiSO_4\ ;\ K_2SO_4,2CoSO_4\ ;\ Rb_2SO_4,2MgSO_4.$$

—Reactions of the so-called dibenzylamarine, by F. R. Japp and J. Moir. The authors describe the chemical behaviour of dibenzylamarine, which they have previously shown to be benzoyl-*s*-dibenzyl-*i*-diphenylethylenediamine.—Note on isoamarine, by H. L. Snape. The author has resolved isoamarine into its optically active components, thus confirming Japp and Moir's view of its constitution.—On the preparation of benzeneazoorthonitrophenol, by J. T. Hewitt. Benzeneazophenol is converted into benzeneazoorthonitrophenol by dilute nitric acid.—Some new osazones and tetrazones, by H. A. Auden.—A series of substituted nitrogen chlorides. Part ii. The trichlorophenylacyl chlorides, by F. D. Chattaway and K. J. P. Orton.—The reaction between cupric sulphate solution and magnesium, zinc and iron, by R. M. Caven.

Geological Society, December 6.—W. Whitaker, F.R.S., President, in the chair.—Dr. Blanford described certain photographs sent by Mr. E. H. L. Schwarz, and representing the Dwyka boulder-bed and the rounded and grooved underlying surface, in the neighbourhood of the Orange River near Hopetown and Prieska. The importance of these photographs lay in the evidence which they afforded on a disputed point. Dr. Sutherland and Mr. Griesbach had called attention to the evidence of ice-action presented by the Dwyka Conglomerate in Natal, and additional evidence had been brought forward by several observers, especially by Mr. Dunn from the Orange Free State and Cape Colony, and recently by Dr. Molengraaff from the Transvaal. Other observers, however, and especially the late Prof. Green, had disputed the glacial origin of the Dwyka beds. The photographs now exhibited would, the speaker thought, convince most geologists that the phenomena presented were due to ice-action. The resemblance to similar photographs shown to the Society in 1896 by Prof. T. W. Edgworth David, and representing the beds corresponding to the Dwyka Conglomerate in South Australia, was noteworthy. Evidence of glacial action in Upper Palæozoic times had gradually accumulated from India, Australia, and South Africa, and there was a probability that similar indications existed in South America.—On the geology and fossil corals and echinids of Somaliland, by Dr. J. W. Gregory. British Somaliland consists of a high plateau, of which the northern scarp is separated from the Gulf of Aden by a belt of low hills and plains known as the Guban. The southern plateau consists of Archæan gneisses, quartzites, amphibolite-schists, chloritic schists, and pegmatites. It is capped by purple grits, red sandstones, and conglomerates, which are covered by limestones of Neocomian, Turonian (? Cenomanian), and Eocene ages. The Neocomian limestone, which may be correlated with that of Singeli described by Rochebrune, occurs at Dobar in the Guban; while a Jurassic limestone, probably of Bathonian date, occurs at Bihendula in the Guban. Fossils collected from these limestones and from raised reefs of Pleistocene age, have been examined by the author, who tabulates a list of corals and echinids. The evidence of the collections is sufficient to show that a Neocomian limestone occurs both on the summit of the Somali plateau and on the floor of the Guban, and that some marine limestones of Lower Tertiary age (probably Eocene) also occur on the plateau. It is therefore evident that the foundering of the Aden Gulf is post-Eocene in age.—Note on drift-gravels at West Wickham (Kent), by George Clinch. The author describes two beds of drift-gravel at West Wickham. The first, occupying the bottom of a dry valley, yields in a section exposed at Gates Green, material derived from the Chalk and the Lower Greensand; and distinct, although perhaps not direct, relation with the denudation of the Weald is claimed for it. The other bed of gravel is of later age, and has yielded many Palæolithic implements and flakes.—On the occurrence in British carboniferous rocks of the Devonian Genus *Palaeoineilo*, with a description of a new species, by Dr. Wheelton Hind. The family Nuculidæ is represented in carboniferous rocks by the genera *Nucula*, *Nuculana*, and *Ctenodonta*, and to these must now be added *Palaeoneilo*, which the author describes from two fine specimens in the Museum of Practical Geology, from carboniferous shale (Yoredale Shale) south of Hammerton Hall, Slaidburn, Yorkshire. It is remarkable that a genus so well developed in Devonian times should be found at the top of the carboniferous limestone series, but not in intermediate beds. Hall's diagnosis of the genus is given, with additional remarks, and a new species is described and contrasted with *Ctenodonta* (*Palaeoneilo*) *lirata*, Phil., from the Devonian of Baggy.

Entomological Society, December 6.—Mr. G. H. Verrall, President, in the chair.—Mr. J. J. Walker exhibited a specimen of *Colias marnoana*, Rogenh., taken at Massowah, on the Red Sea. He considered this form to be only a dwarfed race of *C. hyale*, Linn.; and for comparison with it, he showed specimens of the var. *nilgherriensis*, Feld., from Central India, and of the var. *simoda*, De L'Orza, from Japan.—Dr. Chapman exhibited a series of specimens, selected from various English collections, together with a few foreign examples, to illustrate the English forms found within the genus *Fumea*. He read some notes relating to the genus, and to characters, chiefly drawn from structure, by which the different species may be distinguished.—Mr. Malcolm Burr called attention to Dr. Sharp's paper on the modification and attitude of *Idolum diabolicum*, recently published in the *Proceedings* of the Cambridge Philosophical Society (vol. x. part iii.). He exhibited the plate, drawn after nature by Mr. Muir, which illustrates the paper, pointing out that no drawing of this kind showing a Mantid in its natural colours simulating the petals of a flower, had hitherto been published. He also exhibited species of Mantodea of various genera, to show the different modifications by means of which insects of this group are made to resemble leaves and flowers.—Mr. Kenneth J. Morton communicated a paper entitled "Descriptions of new species of Oriental *Rhyacophilae*."

DUBLIN.

Royal Dublin Society, November 22.—Prof. E. J. McWeeney in the chair.—Prof. T. Johnson read a paper on the yellow blight of the potato-plant, an examination of which he had undertaken at the request of the Congested Districts Board of Ireland. The disease is especially prevalent in the west, but is found throughout Ireland. The two fungi held mainly responsible for the disease, of which an illustrated account was given, are considered to be *Sclerotinia sclerotiorum* (Lib.), Massee, and *Rhizoctonia Solani*, Kühn, the "small-pox" fungus of the potato-tuber. At the Winter Show of the Royal Dublin Society, of several hundred dishes of potatoes there was scarcely a dish with tubers free from the sclerotia and mycelium of *Rhizoctonia*, hitherto not recorded in Ireland.—Mr. G. H. Carpenter read a paper on some Collembola from Franz-Josef Land, collected by Mr. W. S. Bruce, of the Jackson-Harmsworth Expedition in 1896 and 1897. Seven species are represented in the collection, one of which—an Isotoma—is new to science. Mr. Carpenter also presented a paper on Pantopoda from the Arctic Seas, dredged by Mr. Bruce in 1897 and 1898.—Dr. F. T. Trouton, F.R.S., exhibited Caldwell's modification of the electrolytic interrupter, and drew attention to his explanation of the curious transference flow which occurs from one side to the other through the narrow opening or hole in the dividing partition. The direction of the flow being independent of the direction of the current points to a heating effect. When the explosion in the hole occurs through the sudden evolution of vapour liquid is ejected to both sides; but should the position of the explosion in the hole move, through any cause, to one side, more liquid will be thrown to the other. The bubbles of vapour must tend to form on the side of lowest pressure, thus accounting for the phenomenon. In the apparatus shown, the number of breaks per second was about 750, the volume of the hole about ·0011 c.c.; thus the limit to the rate of flow is about ·4 c.c. The maximum observed was about ·3.

Royal Irish Academy, December 11.—Dr. Benjamin Williamson, F.R.S., in the chair.—Dr. Henry H. Dixon read a paper on the first mitosis of the spore-mother cells of lilium. In this paper observations and arguments are adduced in favour of regarding the double twisted condition of the nuclear thread in this mitosis as arising from the folding and twisting together of parts of the dolichonematous thread. The double thread parting transversely forms the chromosomes, which are thus composed of two twisted portions, each a primary chromosome. In the equatorial plate each *primary chromosome* divides longitudinally. A pair of the longitudinal halves forms the V-shaped daughter chromosome. It is also shown that the unravelling of the halves of the twisted primary chromosomes naturally explains the constant V-form of the daughter chromosomes. From this it will be seen that the mitosis is not a "reducing" division in Weismann's sense. The manner of the formation of the chromosomes brings into proximity in the dispirem stage parts of the nuclear thread which were, in the spirem stage, distant from one another.—Prof. C. J. Joly read a paper on some applications of Hamilton's operator ∇ in the calculus of variations. In the case of positional variations, the conditions for a stationary value of the integral $\int f d\rho, f d\rho$ being a linear and distributive function of the vector element $d\rho$ of a curve, may be expressed by the relation $f\delta\rho = 0$ at the limits, and $f\nu\nabla\nu d\rho\delta\rho = 0$ at each point of the curve. In the second equation, ∇ operates on f alone. For surface integrals, $\iint F d\omega$ where $d\omega$ is a directed element of area, the conditions are $F\nabla = 0$ over the surface, and $F\lambda = 0$ over the boundary, λ being normal to a fixed surface on which the boundary lies. Examples were given for the use of these formulæ.

PARIS.

Academy of Sciences, December 11.—M. van Tieghem in the chair.—The perpetual secretary announced the receipt of the last American contribution to the Lavoisier Fund, the total amount received from the United States amounting to 3054 francs.—On the parallax of the sun, by M. Bouquet de la Grye. The Academy of Sciences in 1882 sent out ten parties of astronomers to observe the transit of Venus across the sun, and in the present paper the final results of these observations are given. The mean of the results obtained by Halley's method with the large telescopes is 8″·7996, with all the telescopes 8″·8068; the adopted result is: 8″·80 ± ·01. The calculations of the results from the photographical methods are not yet completed.—Note on the work done on Mt. Blanc in 1899, by M. J. Janssen. The note contains details of work done in two directions, (1) on the losses that an electric cable undergoes when it is placed bare upon the glacier, and (2) on oxygen in the sun. The first work was unfortunately attended by a fatal accident to one of the observers, M. Cauro, who fell on to the glacier on which the experiments were being carried out. The work was finished by M. Lespieau. It was found that naked wires of galvanised iron were quite serviceable for telegraphing between the observatory and points varying from 300 to 1700 metres distant, a 3 mm. iron wire lying on a length of 1700 metres of glacier ice not constituting a telegraphic "earth." As regards the solar oxygen, the photographs of solar spectra obtained during the year will be discussed subsequently.—Influence of the magnetic field upon the radiation of radio-active bodies, by M. Henri Becquerel. In a non-uniform magnetic field, constituted by a powerful electromagnet, the radium rays are bent and concentrated on the poles. The results were most clearly shown by the aid of photography, a horizontal sensitive plate, covered with black paper, being placed between the two poles 45 mm. apart parallel to the field. Before exciting the magnet the radio-active barium chloride was placed upon the plate half-way between the poles. The maximum deviation corresponds to the direction normal to the field. These results have been obtained independently by MM. Meyer and Schweidler by the use of a fluorescent screen.—On a general method for the estimation of some elements contained in organic compounds, by M. Berthelot. By combustions in oxygen in the calorimetric bomb, at a pressure of 25 atmospheres, accurate estimations of carbon, sulphur and phosphorus are readily carried out if suitable precautions are taken, the most important for the two latter elements being the addition of a certain quantity of naphthaline or camphor. The determination of potassium, the alkaline earths, copper, iron, silver, or mercury presents no difficulties.—On the molecular refractions, molecular dispersions and specific rotatory power of some alkylcamphors, by MM. A. Haller and P.-Th. Muller. Measurements are given for benzylidene-, piperonylidene-, cuminyl-, ethylsaligenyl-, metamethoxybenzyl-, and anisyl- camphors, and the results compared with the figures given by the calculations of Bruhl and Conrady; the experimental results are in general higher than the calculated values. The authors suggest the double linkage connecting the camphor and aldehydic residues as the cause of the deviations.—Remarks by M. Duclaux on his treatise on microbiology.—Note on the Bielids observed at Algiers on November 28–29, by M. H. Tarry.—On the theory of discontinuous functions, by M. R. Baire.—Method for determining the mean density of the earth and the constant of gravitation, by M. Al. Gerschun. If a heavy sphere is brought near the free surface of a liquid at rest, this surface takes the form of a surface of equal Newtonian potential, arising from the simultaneous action of the earth and the heavy sphere. The expression $\frac{R}{\rho} = 1 + \frac{d}{\delta}\alpha^3$ is deduced, where R is the earth's radius, d the density of the sphere, δ the mean density of the earth, and α the ratio of radius of the sphere to the distance of its centre from the free liquid surface, and ρ the radius of the osculating surface to the liquid at its highest point. To determine ρ an optical method is employed of great delicacy, given by Foucault for verifying the truth of plane optical surfaces. Some preliminary experiments on the method show that its precision is not less than those previously in use, neither are the experimental difficulties greater.—On the principle of equality of action and reaction, by M. André Broca.—Action of aluminium chloride upon camphoric anhydride, by M. G. Blanc. The chief product of this reaction is isolauronolic acid. The secondary products are a mixture of acids, having formulæ, $C_9H_{14}O_2$ or $C_9H_{10}O_2$ and a lactone $C_9H_{14}O_2$.—Alkalimetry of the amines, by M. A. Astruc. The fatty amines examined ranging from methylamine to diamylamine are monoacid bases with either helianthine or phenolphthalein as indicator. The primary aromatic bases, on the contrary, are neutral to phenolphthalein, but behave as monoacid bases to methylorange.—On the co-existence of a reducing and an oxidising diastase in animal organs, by MM. J. Abelous and E. Gerard. It is shown that in aqueous extracts of the kidney of the horse, two ferments are present, one of which can reduce a nitrate to nitrite, and the other produce the inverse reaction.—On the presence of mannocellulose in the ligneous tissue of gymnosperms, by M. Gabriel Bertrand.—A contribution to the history of intraocular pressure, and to our knowledge of the mechanism of blood pressure in the capillaries, by M. W. Nicati. Measurements of the hardness of the eye show that the blood pressure of the capillaries is proportional to the ratio between the volume of the body and its surface.—New observations of American *Peripatoïdes*, by M. E. L. Bouvier.—On a new pathogenic *Mucor*, by MM. Lucet and Constantin. This fungus was found to be the cause of a disease of the respiratory organs, at first mistaken for tuberculosis. The disease was cured by treatment with arsenic and potassium iodide. The fungus was found to be a new species, differing from the four pathological species previously known. The name proposed by the authors is *Rhizomucor parasiticus*.—On a new mode of formation of the egg in *Piptocephalis*, by M. Matruchot.—On the mountain chain of Chartreuse, by M. H. Révil.—The *facies* and conditions of deposit of the Turonian in Aquitaine, by M. Ph. Glangeaud.—On new subterranean researches in Dévoluy (Hautes-Alpes), and on the deepest natural well known, by M. E. A. Martel. The shaft found has a depth of at least 310 metres, and is probably greater.—Approximate determination of the denudation of Cretaceous rocks on the coasts of Normandy, by M. J. Thoulet.

CONTENTS.

THURSDAY, DECEMBER 28, 1899.

THE PEOPLING OF AUSTRALIA.

Eaglehawk and Crow: a Study of the Australian Aborigines, including an Inquiry into their Origin and a Survey of Australian Languages. By John Mathew, M.A., B.D. Pp. xvi + 288. Five Plates and a Linguistic Map. (London: David Nutt. Melbourne: Melville, Mullen and Slade, 1899.)

A GREAT deal has been written, and has yet to be written, about the origin of the Australian natives. Considering the immense area that they occupy, there is a considerable amount of uniformity both from a physical and a cultural point of view; but it is now recognised that this apparent uniformity does not necessarily imply purity of origin; indeed, a dual or multiple element in the population may be said to be generally accepted.

The latest investigator of this problem is the Rev. John Mathew, who in his "Eaglehawk and Crow" has boldly restated his previous solution that Australia was first occupied by a branch of the Papuan family; these first-comers occupied all the continent, and having spread across to the southern shores, they crossed what is now Bass Strait, and their migration terminated in Tasmania. Then followed a hostile Dravidian invasion. Mr. Mathew thinks that this ingredient of the population first touched on the north-east coast of Queensland, not in one boat-load, but in an unintermittent stream for many years, probably being forced southwards by the attacks of a more powerful race. Finally, a Malay invasion came later, and in a desultory way by detachments at irregular intervals.

The term Papuan is employed by Mr. Mathew as the equivalent of Melanesian, and is meant to include the Tasmanian Aborigines; hence the Tasmanian Papuans are invariably referred to in this volume as the substratum for the present Australian race; that in them there may be a strain of Negrito blood is not questioned, on the contrary, he inclines to that opinion. Dravidian is not to be understood as indicating the direct descent of Australians from Dravidians, but rather that one strong strain of the Australian people is of common origin with the Dravidians of India and their congeners. Malay refers generally to the people of that race to the north of Australia without distinguishing nationality. It is evident that Mr. Mathew uses these three race terms in a very broad sense, and his view on the two first migrations do not materially differ from those of Flower, Howitt and other students. There is reason to believe, with De Quatrefages and Hamy, Garson and Ling Roth, that the Tasmanians are closely allied to the Negritos, and it may be granted that this stock was formerly widely spread in Australia. Keane in his recent work, "Man: Past and Present," places the Australians, with the Tasmanians, as one of his three divisions of the "Oceanic Negroes," the "Negritoes" and "Papuasians" (Papuans and Melanesians) being the other two. He regards the Australians as a highly specialised type of a single ethnical division.

The Melanesian stock is itself either complex, as several anthropologists hold, or very variable, as Dr. A. B. Meyer advocates. So far as British New Guinea is concerned, there appears, speaking in general terms, to be a western group, traces of which also occur in the south-east, of a dark-skinned, frizzly-haired, usually dolichocephalic people, whose language, as Mr. S. H. Ray has pointed out, has a grammatical construction somewhat analogous to that of the Australian languages. To the south-east is a lighter-coloured people, more or less brachycephalic, and with typically frizzly, but also with curly and wavy hair, whose language is essentially similar to that of the Melanesian Archipelago, and allied to Polynesian; indeed, Dr. Codrington regards the latter language as degraded from the former. The ethnology of British New Guinea is more complex than this brief statement implies; but these two main elements in the population must not be overlooked. Unfortunately, Mr. Mathew states that his term "Papuan is applied, not in its narrowest application (dark New Guinean), but as the equivalent of Melanesian" (p. 5), which, as we have just seen, he leaves quite vague. Later on he tries to show that the Victorian speech has more "Papuan" (or Tasmanian) elements than the languages further north, and hence is by inference more Melanesian than other Australian languages. The radical difference between Melanesian and Australian grammar is not thought to be worthy of even an attempted explanation. The languages of the "dark New Guineans" (Kiwai, Bugilai, &c.), which are expressly excluded from Mr. Mathew's "Papuans," have some analogies in grammatical structure with those of Australia.

Mr. Mathew says a good deal about the colour of the skin and character of the hair of the Australians, and points out that numerous observers have recorded considerable differences in these two features. Unfortunately, these statements are general, and we have no direct comparison with recognised standards, and all the observers were by no means equally competent. We must assume that marked variations in colour do occur, and that the hair may be variedly curly, but without corroborative specimens we can scarcely admit that the hair is sometimes straight or woolly. The evidence collected by Mr. Mathew indicates that on the south-eastern and western coasts the hair is more curly than towards the interior. He speaks of "a decided Papuan fringe . . . with a departure from it landwards and in the north."

We must now consider the Dravidian element in Australia. The argument in favour of this view was first stated by Huxley, and it has been generally adopted (Huxley, it must be remembered, considered that the Australians belonged entirely to that ethnic group). The Sarasins in their elaborate monograph on the ethnology of Ceylon admit that the Australians belong to a "Primitive Dravidian" stem. Mr. Mathew makes the following remarks with regard to this migration:

> "Coming as a later offshoot from the first home of humanity, this invading band was of higher intelligence and better equipped for conflict than the indigenes of Australia. Physically, they were more lithe and wiry, and of taller stature. They were lighter in colour, though a dark race; less hirsute; and the hair of their head was perfectly straight" (p. 6).

Several of these statements are open to question. Some of the "Dravidian" peoples are amongst the hairiest of mankind, and perhaps none have perfectly straight hair. Although the present writer agrees with the hypothesis that the Australians arose in part from the same stock as the pre-Dravidians—that is, the indigenous population of Southern India—there are numerous difficulties which have not yet been thoroughly faced. Most writers assume that they arrived by sea, but there is no evidence that the pre-Dravidians were ever seamen; their descendants are not so to-day either in India or Australia. If they came by land, as Howitt suggests, it is strange that no trace of their migration has been noted in the East Indian Archipelago, and there are many other points that require explanation. There is also some ambiguity in the use of the term "Dravidian," as, from the researches of Thurston, it would appear that there is a dark, broad-nose, curly-haired primitive race in Southern India which may for the present be termed the pre-Dravidian race. The typical Dravidians (Telugus, Kanarese, &c.) are regarded by some as a later immigrant people. In his "Man: Past and Present," Keane states that "all attempts to affiliate this group [the Australian languages] to the Dravidian of Southern India, or to any other, have signally failed."

The Malay invasion is supposed to have taken place "also from the north, first with some degree of continuity and then intermittently" (p. 61). "In the extreme north-west, where Malay words might be most naturally expected, very few are distinguishable. . . . It is rather in unexpected places that Malay words turn up" (p. 57). ". . . A track across the centre of Australia from the Gulf of Carpentaria southward is marked by a few Malay words . . . another region where unquestionable Malay lingual traces exist is a tract on the east coast of Queensland, from about 17° to 21° S. lat., and inland to a distance of some two hundred miles" (p. 59). "There is proof positive that the best cave paintings have been executed by people of Malay blood from the island of Sumatra, a strong presumption also that the rite of circumcision was derived from the same people and place, and I am disposed to think that the Australian message-stick is a childish imitation of Malay writing upon bamboo and rattan as practised in Sumatra" (p. 60).

As the author lays great stress on the linguistic side of his investigations, the present writer consulted his friend Mr. L. H. Ray on this very matter in order to obtain the opinion of an expert. Mr. Ray informs me that 'the author's elaborate comparisons of Australian words with Malay and New Hebridean are absurd and misleading, and show that, in spite of his disclaimer on p. 44, Mr. Mathew belongs to that school of Australian pseudo-philologists who believe that a likeness of words in sound and meaning is a proof of common origin. In Chapter iv. we are asked to believe that Malay immigrants, presumably from various parts of the Archipelago, entered Australia from the north, and wandering about the interior scattered "astonishing relics" of the speech (of one of their sections) all over the island continent. They left the words for "father" and "where" in New South Wales and East Queensland, and "hand" in the extreme east. The word for "head" (not the Malay, but Indian) was left on the Hunter River, the terms for "elder brother," "little," and "louse" were scattered from the Gulf of Carpentaria, southward through Central Australia. "Father," "moon," and "rain" were stranded on the east coast of Queensland; there are other "remarkable analogies" which Mr. Mathew uses to support his theories. Philologists will scarcely be inclined to admit the "especially valuable analysis" which derives the Australian word "wenyo" or "wendyo" ('where') from a New Hebridean interrogative "wa" or "we," and the verb "to" ('to stand') (p. 157). Although Mr. Mathew has evidently taken great pains to make his book of real service to students, individual words in the languages quoted are not always accurately given or properly understood by the author, although he uses them as pegs upon which to hang a theory. For example, he regards the "bapa" type of terms for "father" as a mark of Malay descent, and the "mama" type as evidence of Papuan influence. Yet connectives of "mama" are more common in the Malay region than "bapa," and words like "bapa" are found in all kinds of unconnected languages, *e.g.* Dravidian and Tibeto-Burman in Asia, Bantu in South Africa, and in North America. Other examples are seen in the comparison of numerals (pp. 165, 169), where the New Guinea words are explainable compounds. "Ori Kaiza" (p. 67) is mongrel, "ori" ('bird') is Toaripi, Papuan Gulf, and "kaiza" ('big thing') is Saibai, West Torres Straits. Mr. Mathew might have made a stronger case if he had drawn his examples, not from the colloquial Malay of commerce, but from that common root-stock of the languages of the Indian Archipelago, which is undoubtedly akin to that of the Melanesian tongues. It would have been of great advantage to students if uniformity in spelling had been attempted in the numerous languages quoted.'

Mr. Mathew dwells at some length on some remarkable rock paintings discovered in North-West Australia by Grey and by Bradshaw. One of Grey's figures he identifies with Siva of Hindu mythology, the other he identifies as Daibaitch, a deity of the Battas of Sumatra. This identification is based on some marks on the figure which Mr. Mathew compares with specimens of Sumatran writing in Van der Tuuk's "Les Manuscripts Lampongs." Of course this interpretation assumes that Grey copied the painting with perfect accuracy, and that it was in perfect preservation. These two figures copied by Grey certainly have a non-Australian appearance. Bradshaw's figures are more complicated. The author considers

"it is obvious that there has been an attempt to present pictorial fragments of Hindu mythology in the confused form which has been developed by naturalisation in Sumatra."

These rock paintings are certainly very puzzling, and deserve renewed investigation on the spot. Mr. Mathew's interpretation of them strikes the present writer as somewhat far-fetched.

It is to be regretted that Mr. Mathew does not distinguish between the Malays and the taller, light-coloured Indonesian or non-Malayan inhabitants of the Eastern Archipelago. Keane in his "Ethnology" says:

"Dr. Hamy points out that the Battas and other pre-Malay peoples of Malaysia so closely resemble the

Eastern Polynesians that the two groups should be regarded as two branches of an original non-Malay [Indonesian] stock" (p. 326).

According to Mr. Mathew's theory, Indonesian and Malay elements are implicated in his third invasion of Australia.

Mr. Mathew devotes several chapters to a concise account of the handicrafts, institutions, social customs, sorcery and religion of the Australian natives, and one may gain from the book a very good idea of the Australians as a whole; this account is not a mere compilation from published sources, as Mr. Mathew has had practical experience with "black fellows," and numerous original and hitherto unpublished observations are scattered throughout the book. The careful grammatical study and vocabularies of Australian languages, which occupy nearly half the book, will be of great assistance to students of linguistics—the Kabi grammar is an original contribution. The appropriate title of the book is derived from the widely-spread names of the two main clan divisions of the Australians; the author asks (p. 19):—"Is there any better explanation of the facts possible than that the eaglehawk and the crow represent two distinct races of men which once contested for the possession of Australia, the taller, more powerful and more fierce 'eaglehawk' race ["Dravidian"] overcoming and in places exterminating the weaker, more scantily-equipped sable 'crows'?"

The present writer has endeavoured to give a fair summary of the views held by Mr. Mathew, but it appears to him that the author has not fully appreciated the complexity of the problem which he has set himself to solve. It is also evident that Mr. Mathew has not had access to a number of works that bear upon his subject; some excuse in this respect must, however, be granted to students who reside in the Colonies. The author must be credited with a broad grasp of Australian ethnography, and even if his theories do not receive the support of other students, he will have the satisfaction of knowing that he has done some good service, since generalisation is the salt of science. ALFRED C. HADDON.

CYPRIAN ARCHÆOLOGY.

A Catalogue of the Cyprus Museum, with a Chronicle of Excavations undertaken since the British Occupation, and Introductory Notes on Cypriote Archæology. By John L. Myres, M.A., and Max Ohnefalsch-Richter, Ph.D. Pp. xii + 224. With eight plates. 8vo. (Oxford: at the Clarendon Press, 1899.)

THIS work aspires to be at once a scientific catalogue of, and a handy guide to, the contents of the Cyprus Museum. For the latter purpose it is provided with a flexible cloth binding, for the former it is written in a logical and "scientific" manner, although, by the way, prehistoric archæology is not a science, and never will be one: it is simply a body of disconnected observations, from which one or two more or less probable conclusions can be drawn. The authors deal with an enormous mass of material, and the necessity of compressing this into a portable form has made their book resemble more a collection of transcribed shorthand notes than anything else. These notes, which are only rendered intelligible by reference to headings which themselves have sometimes to be elucidated by further headings, will no doubt be of use to the student of Cyprian archæology, but will hardly be understanded of the casual student tourist who essays to visit the Museum with this book in his hand. What, for instance, will he make of the following (p. 169): "6061–6063. Legs and feet. 6061. Colossal. 6062–6069. Sandalled. 6067. Corkscrew curls and diadem with quatrefoils in relief. 6068–6069. Faces." He will not at once realise the fact that for the necessary elucidation of these mysterious fragments he must refer back a page or so to the headings: "XI. TAMASSOS," "B. Statues of deity or votary in native style; colossal, life-size, or smaller: all male," "*a. Terra-cotta; moulded; hollow*," and that similar researches will have to be made whenever he wishes to obtain an intelligible description and explanation of any object which he may be looking at. Only persons with some knowledge of archæology will be able to find their way about this catalogue, and they will often have to complain of the marvellous epigrammatic manner in which many of the objects are described. No. 5569 is described as follows (p. 156): "H. o. 10.' That is all. Nor does the heading "Miscellaneous" lighten our darkness very much. We eventually discover that Nos. 5501–5569 are terra-cottas from Kition, but what kind of miscellaneous terra-cotta No. 5569 is we have not found out yet. And surely such a description as "SILVER VESSELS, &c. 4871–4873. Spoons. Cf. *Bibl. Nat.* 1635–7." (p. 139), is insufficient. Other similar instances might be quoted, but at the same time Mr. Myres' descriptions are often full and careful enough; *e.g.* Nos. 5017, 5048, 5571, or the group 5801–5826.

No doubt the form of the book is extremely logical, but this very characteristic, pushed to its extreme as it is here, makes it quite useless to the casual tourist, unless he has a very considerable knowledge, not only of Greek archæology generally, but also of the current theories on the subject. The two aims of this catalogue are, in fact, mutually exclusive.

Treating the book entirely from the point of view of the archæologist, we still find something to criticise as well as to praise. The commencement of the introduction (up to the middle of p. 16) is clear and good: nothing is more probable in early Greek archæology than the general position of the præ-Mycenæan and Mycenæan culture with relation to the general development of European civilisation; they were the local phases of the general European culture of the Ages of Copper and Bronze. But later on the introduction becomes somewhat wild and therewith also somewhat too dogmatic in tone; all its statements as to the predominant influence of *Cyprian* culture, as distinct from that of the "præ-Mycenæan" lands generally, on that of early Europe, or the derivation of the pottery-types of the Mondsee-area from that of Cyprus and of the Central European knowledge of copper from the same island are stated with very little intimation of the fact that they are one and all purely hypothetical, and are founded on a series of arguments from analogy which are often of doubtful validity. In fact, the whole gospel of the "Typology" of pots and pans, which is nowadays so fashionable, and is relied upon to explain the whole course of the development of early civilisation, probably rests on no firmer bases than do the similar gospels which profess to elucidate man's early history by means of a comparison of his languages or the varying shapes of his skull.

The statements in the latter part of Mr. Myres' introduction are, then, purely hypothetical. Many are probable enough, but they are not proven historical facts. Take, for instance, his reference to the date of the Mycenæan (he prefers the hideous and hybrid form *Mykenaean*) period of Greek culture. Now it seems very probable that the art of the Mycenæan period, marking the culminating point of the Bronze Age culture of Greece, came to an end in Greece proper in consequence of the overthrow of the Achaian hegemony by the Dorians, who very possibly introduced the use of iron and the rude "Geometrical" style of art into Greece about 1000–800 B.C. But this is only a theory. And neither this theory nor the fact that Mycenæan pottery has been found in the remains of King Khuenaten's city at Tell el-Amarna in Egypt (date about 1430 B.C.) justify Mr. Myres in saying (p. 20) that "the Mykenæan Age is placed between 1700 and 900 B.C. by the find-groups in Egypt, Rhodes and Mykenæ," although it is quite true that "this date agrees with the best Greek tradition." All we can say is that the Mycenæan Age *apparently* goes back to at least 1430 B.C., and probably earlier. That it ended in Greece proper about 800 (not 900) B.C. seems very probable, but that it continued in the always backward and conservative island of Cyprus till the beginning of the seventh century at latest seems to be shown by the new discoveries at Kurion and Enkomi, where, in conjunction with Mycenæan remains of a debased type, Babylonian cylinders of the eighth century have been found. Mr. Myres falls foul of this hypothesis (p. 20), as was to have been expected.

In some respects the catalogue is not quite up-to-date. It is a year or two since Prof. Petrie's theory of a "New Race" of "Libyans" was given up, and the true position of the "New Race" remains as those of the prehistoric Egyptians was pointed out by M. de Morgan. Yet in a book published in 1899 we read (p. 16) of

"the Libyan race, discovered in 1895 by Prof. Flinders Petrie in the settlements and tombs at Ballas and Nagáda . . . this civilisation, which fills the gap between the sixth and the eleventh dynasty . . .," &c.

The gap between these dynasties covers the period 3500–3000 B.C.: the remains from Ballas and Nagáda are those of the late Neolithic or "Æneolithic" periods in Egypt, and most certainly date long before 4500 B.C. It is a pity that Mr. Myres did not even at the eleventh hour insert a paragraph in his list of corrigenda noting this fact.

Prof. Petrie connected this "Libyan" culture with the early civilisation of Palestine, which he ascribed to the Amorites, of whom we know nothing more than their name. So Mr. Myres talks of a "Libyo-Amorite culture" (p. 17). Prof. Petrie also closely connected the præ-Mycenæan stage of southern European civilisation with the "Libyo-Amorite culture." But this connection Mr. Myres hesitates to accept, although he admits resemblances of pottery-technique, &c., between the two.

An acceptance of this theory means now an acceptance of the idea that the præ-Mycenæan stage of Greek culture goes back to at least 5000 years B.C., and that it was at that time closely connected with the primitive civilisation of Egypt. It is difficult to imagine how this connection can be maintained to have ever existed. The famous copper sword which was found in the prehistoric tomb 836 at Nagáda is of late præ-Mycenæan type ("quasi-Mykenæan," *teste* Mr. Myres, who also claims it as especially Cyprian in style), and so probably dates *after* 2000 B.C., while the things with which it was found belonged to the half-savage ancestors of the Egyptians of the first dynasty. This is an example of the uncertainties of the archæological method generally. The sword proves no connection. We are by no means inclined to grant the contention that the præ-Mycenæan culture may go back to an indefinite period B.C., and that such swords may have been in use as well 5000 as 2000 B.C. And the other evidence does not allow us to date even the earliest remains of the præ-Mycenæan age, the lowest towns of Hissarlik and Athens, a day earlier than 2500 B.C., so that the prehistoric Egyptian and prehistoric Greek cultures cannot be regarded as contemporaneous. Both were primitive, half-savage; hence the analogies between their artistic methods. To argue a contemporary connection from such analogies is impossible.

And no such connection can be shown to have existed by way of Libya: we cannot say that there is anything particularly Libyan about the prehistoric Egyptian pottery, &c., because we have not the slightest idea of what early Libyan pottery was like. In fact, the "New Race" objects were dubbed "Libyan" on account of their curiously isolated and strange appearance when placed chronologically between two well-defined periods of the regular Egyptian civilisation: it was foreign and barbarous, why not Libyan? (In much the same way every inexplicable object found in Egypt used to be called "Ethiopian," the remains of Mycenæan culture were dubbed Phœnician or Karian, and those of the Assyrizing civilisation of Asia Minor received the now somewhat discredited appellation "Hittite." It is quite true that unless some theory is made to account for inexplicable phenomena, little progress is possible. But such theories ought never to be, as they so often are, regarded as dogmas to be persistently maintained in spite of controverting evidence.) These inexplicable objects being then "Libyan," people began to think about Lake Tritônis and its legends, about the alliance of the Greek "Akaiuasha" (who may quite possibly have been Achaians) with the Libyans (*n.b.* as late as 1250 B.C.), and so the "præ-Mycenæan" culture of the north-eastern coasts of the Mediterranean was connected with the "New Race" culture through the medium of Libya. Even now that we know that the "New Race" culture is at least two thousand years older than Prof. Petrie's first dating, this Libyan-Greek connection seems to be maintained, although there is no need to suppose that the remains from Ballas and Nagáda are Libyan, or anything else than primitive Egyptian. Even those yellow-haired Kabyles from Ballas and Nagáda have been shown by the unenthusiastic Virchow to owe their Indo-Germanic locks to the action of the salt in the soil!

In a list of Egyptian (Naukratite) porcelain charms and ornaments on p. 137, Mr. Myres mentions "4726–4732. Hawk-headed deity with disc on head. . . . 4736–4737. Hippopotamus-headed deity. . . . 4746. Ram-headed deity." We are not informed whether 4746 is Amen or Khnemu, and the names of 4726–4732 (apparently Rā) and 4736–4737 (Taurt) might well have been given. And what is the inscription on the Babylonian cylinder, No. 4501, which, by the way, is not necessarily of early date, about? The "hieroglyphic inscriptions" on the scarabs (Nos. 4541, 4547–4549; p. 135) are ignored.

Turning to a comparatively unimportant detail, we note a frequent occurrence of the hideous Germanism, "snow-man technique." Cannot some better term than this be devised for the style of what are merely rude hand-made figures?

The labour of correcting misprints in such a work must have been colossal; but the result is extremely good. We only notice Ra-men-kepher for Ra-men-kheper on p. 135. To Mr. H. B. Walters, who read the proofs through, much praise is due. He is also responsible for the annexed reports on excavations at Kurion, Salamis and Maroni, from which a good idea of the marvellous mixture which the average Cyprian tomb contains may be obtained. We are still far from being able to dogmatise with regard to Cyprian archæology!

The indices also deserve praise, but the mistaken aim of making the book serve as a traveller's guide has, by restricting its size, sadly curtailed the number and size of the plates.

Generally speaking, the book will be to the "wayfaring man" (p. viii.) of little use, but to the archæologist it will no doubt prove valuable. Although, we expect, that if he already knows the collection, he will often find it difficult to recognise the objects from Mr. Myres' and "O-R"'s somewhat meagre descriptions of them, yet the care with which the known *provenance* of all objects is noted, and vague statements on the subject are sifted and verified by the authors, will be of great assistance to him. He will know how far Mr. Myres' archæological theories will be of service to him. If archæology is to be constructive, if it seeks to explain its discoveries, it must formulate hypotheses. These hypotheses are often suggestive, often really explain things in a manner which, as far as we can know, is perfectly satisfactory; but as often they are mere *ballons d'essai*, improbable and unsatisfactory. Hypotheses of both kinds occur in the introduction to the *Cyprus Museum Catalogue*: the archæologist will be able to distinguish between them, but the "wayfaring man" has no means of separating the wheat from the chaff. On him, therefore, it cannot be too strongly impressed that the whole story of the development of human civilisation in Cyprus and the Ægean basin before the 8th century B.C. is still merely a collection of hypotheses, sometimes agreeing, more often disagreeing, with one another, and therefore that any description of "Early Man" in Greece or in Cyprus is not a statement of historical facts, but a simple expression of the individual opinion of its author on the subject.

TEXT-BOOK ON THE STRENGTH OF MATERIALS.

The Strength of Materials. By Prof. J. A. Ewing, F.R.S. Pp. xii + 246. (Cambridge University Press, 1899.)

ALL teachers and students of applied mechanics will heartily welcome this book. It is based on the author's article, "Strength of Materials," which appears in the ninth edition of the *Encyclopædia Britannica*. As in his book on the "Steam Engine," the present book is characterised by Prof. Ewing's excellent style and clearness of exposition. The subject matter includes those portions of the subject which are usually taught at the higher colleges.

The author wastes no time in plunging into his subject. The first two chapters are devoted to a general analysis between stress and strain, and the relation between the three elastic coefficients in an isotropic body. Probably many teachers would prefer to postpone the consideration of part of these two chapters—particularly the contents of the second—to a later stage of the book, and this can readily be done without interfering with the usefulness of the book as a text-book. Chapter iii. deals with non-elastic strain, a part of the subject on which Prof. Ewing is particularly qualified to speak. A concise account is given of some of the recent experiments of Mr. Muir on the effect of heating in facilitating recovery of elasticity after overstraining, and it is to be hoped that in any future editions the author will give a full account of the very recent experiments by Mr. Rosenhain and himself on the crystalline structure of metals—a subject which, in the present edition, is merely referred to. The fourth chapter will be found exceedingly valuable to the teacher, dealing, as it does, with the testing of materials, and containing photographs of several pieces of self-contained apparatus designed (by the author) to determine the various elastic constants, and which have been proved to be serviceable in the author's laboratory at Cambridge. Chapters v. and vi. deal with uniformly-varying distributions of stress, and the bending and shearing stresses induced in beams. On page 98 will be found some interesting remarks on the variation of stress over different sections of a tie-rod. In dealing with this subject it is interesting to notice that in a uniformly strained piece of any shape whatever having parallel sides, the distribution of stress over any section might be graphically determined by Prof. Hele-Shaw's method of the flow of a viscous fluid between two parallel plates placed very near together, the boundaries having the same shape as the piece considered. The stress at any point will then be inversely as the distance between adjacent stream-lines, the stream-lines being supposed spaced at equal distances apart at a section where the stress is uniformly distributed. The deflection of beams and the question of continuous girders are discussed in Chapter vii., whilst in Chapter ix. will be found a luminous treatment of struts and columns. Chapter x. is devoted to a consideration of the torsion of shafts and of springs, whilst in Chapter xi. the stresses induced in thin and thick cylinders due to internal or external pressure, and in a thin rotating disc are treated in an exceedingly lucid manner. A valuable addition to the contents of these chapters would be an analysis of the stresses induced in the different parts of high speed connecting rods and crank shafts. Finally, Chapters viii. and xii. are devoted to a very concise discussion of frames, hanging chains and arched ribs.

In the preface, the author states that the book is only intended to be a lecture-room treatment of the subject, which to be effective must be supplemented by laboratory and drawing office work. We venture to think that the work usually done in the drawing office is, in many cases, of such a special and routine character that it only serves to illustrate a very few branches of the subject. It is, of course, true that a properly equipped laboratory, such as the one at Cambridge, enables the student to provide himself with examples which illustrate a very considerable portion of the subject, but some teachers of applied mechanics—fortunately few in number—do not possess a laboratory, and even many of those who do find it desirable to still further supplement the work done in it by means of tutorial classes. The complete absence of any numerical examples will be consequently much felt, and the author would considerably increase the value of his books as *class-room* text-books if he would add, at the end of them, a set of judiciously selected numerical examples which would forcibly illustrate the different points raised in the text.

A word of praise should be given to the Cambridge University Press for the excellent manner in which the book is printed and arranged. It is to be hoped that the present book, together with the same author's "Steam Engine," are intended to form the nucleus of a library of text-books dealing with engineering subjects.

S. D.

A NEW WORK ON LEAD.

Metallurgy of Lead and Silver. Part I. By Henry F. Collins. Pp. xvi + 368. (London: C. Griffin and Co., Ltd., 1899.)

THIS work is one of a series of metallurgical treatises edited by Sir W. C. Roberts-Austen, F.R.S., and written by one of his former pupils, who, besides having gone through a course of training at the Royal College of Science with distinguished success, has had a large amount of practical experience in mines and metallurgical works, which renders him well qualified to successfully undertake the compilation of a work on lead smelting. In these days of great metallurgical enterprises it is of the utmost importance that we should be kept acquainted with the up-to-date methods of our competitors all over the world; and although there are several good books in existence dealing with the metallurgy of lead, the present one is a welcome addition.

The author starts with methods of assaying lead and silver ores, which is a necessary part of the process, and gives valuable information on the method of correct sampling; he also points out those methods of assaying which yield the best results by the wet and dry ways. A very admirable feature of the book is the abundant reference to authority, in which he follows the notable example of his distinguished editor. With the object of economising space, as well as facilitating reference and comparison, details of the practice in particular localities have been thrown into the form of tabular statements and these should prove useful for reference.

It is much to be regretted that so many errors have been allowed to remain in the text and referred to in the table of errata, when by a little more care they might have been avoided. The section on alloys of lead is very meagre, and chiefly compiled from the writings of other metallurgists. Such loose statements as "No definite alloys of lead and antimony are known" (p. 24) are entirely misleading, as several varieties of lead-antimony alloys are used for type metal. The properties of lead as used in trade with the various defects experienced in practical work, such as plumbing, would have formed a valuable adjunct, as many persons are interested in lead-working who care little about the smelting of ores.

The chapter on lead ores, although somewhat condensed, contains the chief information required for practical purposes. The greater part of the book is devoted to lead smelting. It is treated in a sufficiently full manner, the information is reliable, and the language explicit. We are sorry to learn that the various forms of mechanical roasters are not more generally applicable, and that the hand-rabbled reverberatories, with the enormous cost of manual labour, are still in extensive use on account of the scarcity of skilled labour in many localities, mechanical furnaces only being adopted in the larger works where the required skill is available. Various kinds of roasting furnaces are carefully described and their merits discussed. The chemical side of the question is admirably dealt with, and greatly adds to the value of the book for scientific readers.

The principles of blast furnace practice here given forms the most prominent and important part of the work, and should be extremely useful to those engaged in the lead-smelting industry. A correct knowledge of the scientific basis of the processes has not been attained in the past by those responsible for *some* of our works, and possibly this method of treatment may enable some of our closed mines to be reopened and profitably worked. At any rate, we commend the suggestion to those concerned. The author has brought a wide range of knowledge to bear on the subject, and gives useful data for correct blast furnace practice. The nature of fluxes and composition of slags, with their proper chemical formulæ, are here given in considerable detail, and indicate a complete grasp of the subject.

Chapter ix. commences with some recognised methods of analysing ores and slags, so as to enable the operator to properly apportion the constituents of the charge. This is followed by instructions as to the method of calculating the charge, which is somewhat complicated in large works, dealing with a variety of complex ores. Chapter x. deals with blast furnace products, and as these may consist of lead speiss, regulus, slag and secondary products, which have to be separately dealt with, it will be seen how important their consideration to the lead smelter must be. It also contains a considerable number of analyses of mattes, speisses and slags very valuable for purposes of reference.

The subject of flue-dust, its composition, collection and treatment, is discussed in a clear and instructive manner. The difficulties met with in smelting mixed ores of lead and zinc, and the various processes, dry and wet, proposed from time to time by different authorities, are here discussed, and indicate how much more scientific most metallurgical processes are becoming.

The last part of the book deals with the highly important subject of desilverisation, and is written in no way inferior to the preceding pages. Altogether the author has succeeded in producing a trustworthy and fairly comprehensive treatise on the metallurgy of lead, and we trust his enterprise may be rewarded by a deservedly large sale.

OUR BOOK SHELF.

Zur Stereochemie des fünfwertigen Stickstoffes mit besonderer Berücksichtigung des asymmetrichen Stickstoffes in der aromatischen Reihe. By Edgar Wedekind. Pp. 126. (Leipzig: Veit, 1899.)

ALTHOUGH nearly fifty years have passed since Hofmann succeeded in preparing methylethylamylphenylammonium chloride—a compound in which the nitrogen atom is directly united with five different groups or atoms—very little progress has been made with the study of the stereochemistry of pentavalent nitrogen. It is true, no doubt, that the first and the most important step in advance was made nearly nine years ago by Le Bel, who succeeded in preparing an optically active liquid from a solution of methylethylpropylisobutylammonium chloride, but until quite recently, when Pope accomplished the resolution into its optically active isomerides of Wedekind's benzylphenylallylmethylammonium iodide, Le Bel's work afforded the only evidence which we had of optical activity due to pentavalent nitrogen. The number of known compounds which contain such an asymmetric nitrogen atom, and which might possibly be resolved into optically active components, was also comparatively limited.

In these circumstances it might seem a little premature to write a book on the stereochemistry of pentavalent nitrogen, since the facts to be dealt with are few in number, and the theories which have been advanced to explain them—although nearly as numerous as the facts themselves—still require a groundwork of experimental confirmation.

This difficulty of the lack of material no doubt forced itself upon the author, whose book is not merely an historical review of our present knowledge of the stereochemistry of pentavalent nitrogen; this portion of his subject is, in fact, disposed of within the limits of the first seventeen pages, and by far the largest part (ninety-five pages) of the book consists of an account of the work which the author himself has published during the current year in the *Berichte;* the remaining thirteen pages are devoted to a discussion of the theoretical conclusions to be drawn from the results of his experiments.

As the discussion or criticism of the author's investigations—interesting and important though they are—is a task which does not lie within the scope of this review, little remains to be said except that the whole book is written in much the same way as if it were a paper intended for publication in Liebig's *Annalen;* consequently it contains a great many experimental details, including even the results of many analyses, and this rather detracts from its value as a literary effort. Those, however, who take a particular interest in the stereochemistry of pentavalent nitrogen will certainly welcome the book, and principally on account of its historical survey and theoretical conclusions, for here they will find the scattered literature of the subject conveniently collected and discussed in the light of the author's own important observations. F. S. K.

Handbook of Metallurgy. By Dr. Carl Schnabel. Translated by Henry Louis. Two vols. Vol. i. Pp. xvi + 871; Vol. ii. Pp. xiv + 732; 927 Figures in the text. (London: Macmillan and Co., Ltd. 1898.)

BERGRATH DR. CARL SCHNABEL is professor of metallurgy and chemical technology at the Royal Academy of Mines at Clausthal, and his work has long enjoyed a well-deserved reputation. Prof. Henry Louis, who translates it, points out that it is a curious fact that there does not exist in the English language a single complete treatise on metallurgy. Dr. Percy's treatises remain only splendid fragments. Dr. C. Schnabel's object has been to give a complete account of the metallurgical treatment of all the metals ordinarily employed, together with all the recent improvements in the art. The two volumes before us are, however, incomplete, as neither they nor the original work deal with the vast section of metallurgy which includes iron and steel.

Prof. Louis modestly says that his chief object has been to present a faithful interpretation of the original. In this he has admirably succeeded. With the full consent of Dr. Schnabel, the translator has introduced brief rules of any new processes, or improvements on old ones, that have been brought out since the German original was produced. It is a pity, therefore, that the additions made by Prof. Louis are not distinguishable from the rest of the text. In a compressed work of this kind space is, of course, valuable; but it appears to have been in more than one case unequally allotted. The Augustin process, for instance, is now but little used, and is, in fact, nearly obsolete, but it has ten pages devoted to it, while the cyanide process for the extraction of gold from "tailings," which is now the most important wet process in the whole range of metallurgy, has only thirteen pages. The wet process for extracting copper, which does admit of brief statement, has no less than forty-nine pages. Many of the illustrations, from their freshness and originality, will be a great boon to students. In a second edition it would be well to devote more care to the illustrations; at present, though they give a good general idea of the processes or machines they illustrate, they are seldom drawn to scale. The writer of this notice has found general diagrammatic schemes of processes to be of great value to students, and some might well have been introduced into the present work. The sections devoted to the metallurgy of zinc and of aluminium may be mentioned as, considering the size of the volume, being singularly complete and conscientious. Viewed as a whole, the book is very accurate and trustworthy, and in welcoming this addition to metallurgical literature Prof. Louis is to be congratulated on the translation.

W. C. ROBERTS-AUSTEN.

La Philosophie Naturelle. By Dr. W. Nicati. Pp. xi + 308. (Paris: Giard and Brière, 1900.)

DR. NICATI has, it seems, published books on medicine, on physiology proper, and on psychology. A sense of incompleteness has led him at last to make a raid upon philosophy.

An uncompromisingly positive mind, which does its own thinking *en amateur*, is rarely uninteresting. And Dr. Nicati has ideas upon Rabelais and Zola, upon art and politics in general, on immortality and evolution, on the ultimate formulæ for matter and life. His art-criticisms and his political discourses with a socialist leaning are often readable and sometimes suggestive. A reduction of the idea of responsibility to causation does not lack ingenuity. Unfortunately, any further worth in the book it is impossible to discover, save as it reveals the writer's very abnormal psychosis. "Architectonic" faculty united with incoherence, naivety mostly seen in etymologies, but also in bizarre analogies as of existence to a tricycle, are salient faults of the book. But Dr. Nicati's obsession by what may be called the fallacy of the graphic formula is its dominant characteristic. In the logical calculus "it is atrociously done," has its adverb expressed by the radical sign; the anti-Dreyfusard admits fluxional considerations. In *l'energétique*, life is formulated by Cae decorated with arrows, because it arises in the decomposition of matter which has cohesion and other qualities. Pictures on p. 250 are quite exciting.

This sort of inanity throughout makes the writer's charge upon Kant, that he lacks logic in speaking of "empty space," and his attack upon evolution, with a view to substitute "a theory simply evolutionarist," quite devoid of weight. The index is quite excellent.

H. W. B.

Kleiner Leitfaden der Practischen Physik. Dr. F. Kohlrausch. Pp. xix + 260. (Leipzig: Teubner, 1900.)

EVERY physicist is familiar with Dr. Kohlrausch's "Text-book of Physical Measurements," either in the original or in its English translation. It is not too much to say that it was the foundation of the numerous text-books of practical physics which have since appeared. Owing to the successive additions that have been made, Dr. Kohlrausch feels that it has lost its original character, and now fails to be suitable, as formerly, to the needs of a beginner. This feeling has induced him to prepare the present "Kleiner Leitfaden" by selecting from and otherwise modifying the larger volume.

In what sense can this new volume be regarded as a book for beginners? One of the most difficult questions for a teacher to solve is: How far ought a student be left to work out his own salvation? No answer can be given which would be applicable to all students. A youth of keen intelligence only requires outline directions: the details he learns best by finding them out for himself. But such men are exceptions in any laboratory. The more ordinary student will miss a point unless it is explicitly brought before his notice. We think it is to the former class that this book will be most useful. Dr. Kohlrausch has certainly not erred on the side of superabundance of instruction. We think, for example, that it might be found better fitted as a general laboratory manual if a larger number of fully worked out numerical examples were supplied. But as for ourselves, we have only admiration for the dignified restraint which is everywhere displayed. This is no cram-book intended to meet the temporary requirements of an examining board; but it is what the author has aimed to make it—an aid to general culture.

Further, the volume is well and accurately printed. We have read it through, and only detect one small error. The G Fraunhofer line is, in the diagram on p. 133, apparently identified with the third line in the hydrogen spectrum; the difference between them would only be about a millimetre in the diagram; but it is a difference which ought to be exaggerated rather than diminished, in order to prevent a student running away with a wrong idea.

A. W. P.

Elementary Algebra. By C. H. French and G. Osborn. Pp. vii + 349. (London: J. and A. Churchill, 1899.)

THIS book has been purposely written to help elementary students who have to do much of their study privately, and with this aim in view the authors have avoided as far as possible all technical terms in the explanation of the various theorems. It is possible that there may be a tendency to leave too little for the student to think out for himself by this procedure, but that is matter for individual opinion. Apart from this, the treatise is excellent in its numerous selections of examples and for the clear arrangement of the various sections.

Magnetism and Electricity for Beginners. By H. E. Hadley. Pp. viii + 327. (London: Macmillan and Co., Ltd., 1899.)

THIS little manual is written specially to meet the requirements of students preparing for the annual examination of the Science and Art Department, and consequently it follows to a considerable extent the lines of the syllabus provided. In many details, however, it very ably satisfies the desirability of providing fuller treatment, while a conspicuous and commendable feature is the insertion of many original diagrams and photographs of actual experimental apparatus.

The general arrangement is to give certain facts or definitions, followed by one or more experiments to be performed for their complete verification, so that in this respect the book may serve very well as an introduction to the electrical side of practical physics.

The apparatus described is almost entirely simple enough for the average reader to make readily, and the very generous number of illustrations (197) will be very helpful to the clear understanding of the statements made.

Part i., on magnetism, occupies 103 pages, and all the chief phenomena are illustrated by facsimile reproductions of the fields of force as shown by iron filings or small magnetometers. The explanation of electrical screening is very simply and clearly stated; in fact, the text is brought up to date as far as is possible in an elementary manual.

Part ii., statical electricity (106 pages), is specially noticeable for the way in which the usual difficulty of dealing with potential is met by geometrical interpretations; potential-diagrams being given for fields of force, electroscopes, condensers, electrical machines and contact electricity.

Part iii., voltaic electricity (93 pages), is somewhat terse in style, probably necessarily owing to the number of matters in this part of the subject which need description, but the fundamental points in all the sections are well brought forward. The book is certainly an excellent one for elementary students, and is also likely to form a sound basis on which a teacher may frame his course of lessons.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Racial Aspect of Voluntary Enlistment.

THERE is one aspect of our voluntary enlistment system which has never been touched upon so far as I know. It is that by our method the most brave and warlike men of each generation are exposed to far more than the ordinary risks of life, and generally at an age when they have left no descendants. A process of selection has, therefore, been going on in the nation for centuries by which, in the long run, the non-fighters, such as commercial classes, luxurious people, and any cowards, have more descendants proportionally than the brave and warlike. So that the average opinion is growing more and more unwarlike, less brave, and more inclined for peace at any price. The above selection is brought home to us if we consider that of those soldiers killed during the last few weeks how few have left two descendants. I foresee two remedies for this state of things, but will not ask for any more of your valuable space.

The Wind during Eclipses of the Sun.

I WOULD like to draw attention to the importance of observations of the wind in and near the path of a total eclipse of the sun.

At the Indian eclipse of 1898 I employed at Sahdol, in

Central India, a simple arrangement for observing the strength and direction of the wind. On the morning of the eclipse, as on previous days, the wind was blowing strongly from the north-north-east with frequent gusts of greater force. As totality approached it diminished in strength and became a steady draught of air almost imperceptible to the senses. At the same time it shifted a little to the east. Before the moon had quite left the sun's disk it was again blowing in the same manner as at the beginning of the eclipse. Subsequently, as the sun approached the horizon, the wind diminished and blew with exactly the same force, direction, and uniform character as during totality.

Apparently the normal wind in the daytime at Sahdol contained two elements, one due to the distribution of pressure over Central and Southern Asia and the Indian Ocean, the other the result of comparatively local causes. The latter was suppressed by the eclipse, and the former was represented by the steady movement of the air that remained.

The total eclipse of 1900 does not present such simple conditions, but I believe that much might be learnt from similar observations. JOHN W. EVANS.

Royal College of Science for Ireland, Dublin,
December 16.

THE APPROACHING TOTAL ECLIPSE OF THE SUN.

THE astronomers of both Europe and America are now busy in making arrangements to observe the total eclipse of the sun which will occur on the 28th of next May. As usual, our American cousins are better off than we are, for they can observe the eclipse without going out of their own country. British astronomers will have to travel to Spain or Portugal. The eclipse path stretches from the west of New Orleans to Algiers and N. Africa on the east. The local times and conditions at certain points along this path are thus given in the "Local Particulars" published by the *Nautical Almanac* Office :—

Position W. of New Orleans.
Long. 90° 6′ W., Lat. 30° 4′ N.

	Local Mean Times. d. h. m. s.	Central Standard Mean Times d. h. m. s.	Sun's Altitude.
Eclipse begins	May 27 18 26 13	May 27 18 26 37	18°
Totality begins	,, 27 19 29 42	,, 27 19 30 6	30
Totality ends	,, 27 19 31 0	,, 27 19 31 24	
Eclipse ends	,, 27 20 43 10	,, 27 20 43 34	46

Duration of Totality, 1m. 17·8s.

Angle, from N. point, of	first contact, 104° towards the W.	for *direct* image.
	last contact, 76° towards the E.	
Angle, from Vertex, of	first contact, 40° towards the W.	
	last contact, 145° towards the E.	

Position near Union Point, Georgia.
Long. 83° 5′ W., Lat. 33° 29′ N.

	Local Mean Times. d. h. m. s.	Central Standard Mean Times. d. h. m. s.	Sun's Altitude.

	last contact, 38° towards the E.	

The accompanying map of the line of totality will show the parts of Spain and Portugal from which this eclipse can be observed. It will be seen that the track, after leaving Spain near Alicante, crosses the Mediterranean and enters Africa close to Algiers.

We may be perfectly certain that the astronomers of the United States and France will man the beginning and the end of the line quite efficiently. It is clear, therefore, that the attention of British astronomers with serious work to do will be directed to the observing stations in Spain and Portugal.

The weather chances were stated by Prof. Arcimis in a former number of NATURE,[1] and may be considered excellent.

There are many branches of work, such as securing photographs of the corona, in which amateurs may do good service. For them the well-found steamers leaving Marseilles may make the coast near Algiers more convenient.

[1] Vol. lix. p. 439.

HERO OF ALEXANDRIA.[1]

THE reputation of Hero of Alexandria has always been somewhat doubtful, and some difficulty has been felt in apportioning to him his proper place among the scientific worthies of the past. Mr. Schmidt, however, in the communication mentioned below, has attempted to do justice to his reputation, and to resuscitate the memory of him whom most of us remember only through the well-known experiment of Hero's fountain. In another place Mr. Schmidt has endeavoured to fix the approximate date of his career, and by his intimate acquaintance with the various MSS. and authorities, to do something to clear away the doubts that linger around a Hero the younger and some other anonymous writers. Mr. Schmidt may be said to have taken Hero under his particular care, and though, of course, it is unfortunate that many of the original writings are not extant, and that others have not been printed yet, Mr. Schmidt, by a careful study of the remnants, has probably placed himself in a better position to reconstruct the history of this ancient philosopher than any other commentator.

But though Mr. Schmidt attempts to place the object of his study in the most favourable light, to make us see in him one as influential as Euclid, we cannot say that

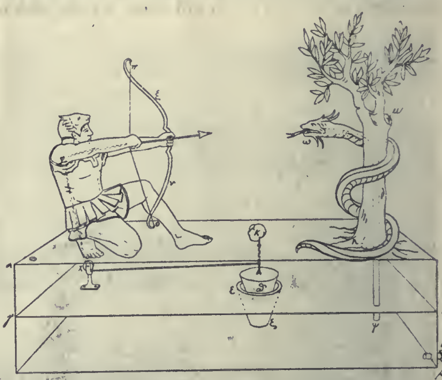

FIG. 1.—Hercules shooting at the apple.

we think the steps he has taken are the most judicious or the most successful. Instead of a philosopher we perceive rather an able artificer and an expert mechanician. The points selected for elaborate illustration are not those which exhibit Hero in the most capable light. There can be no doubt but that Hero successfully solved the problem of determining the area of a triangle from the three sides, and it would have been very interesting to see the method he employed set out in detail, but the author passes over this feat with a bare mention, although the treatment of such a problem appeals more potently to modern students, and bespeaks a higher position in the intellectual scale, than the skilful manipulation of automatic figures over the details of which Mr. Schmidt lovingly lingers. Again, we have indistinct ideas of his experiments on the elasticity of air and steam, and we should like to know whether he made any approach to a knowledge of Boyle's law, and in any way anticipated its enunciation by that philosopher. Of course it may be urged that these are among the best-known results of Hero's life and writings, and that as such they do not need the aid of a commentator, but

[1] "Heron von Alexandria." By W. Schmidt. Sonder abdruck aus den neuen Jahrbüchern für das Klassische Altertum Geschichte und Deutsche Litteratur. (Leipzig: B. G. Teubner, 1899.)

that on the other hand his numerous mechanical devices need to be insisted upon in order to obtain an adequate idea of his varied capacity. But the result is, nevertheless, to present Hero simply as the maker of philosophic toys.

Mr. Schmidt sketches for us, but without sufficient explanation, the devices by which fountains were made to flow, and doors to open by unseen mechanical agency, but one's enthusiasm is scarcely roused though Hercules may shoot at an apple and a serpent be made to hiss his discontent with the arrangement (Fig. 1). But the author does ample justice to the description of the automatic marionettes, whose behaviour and contortions afforded

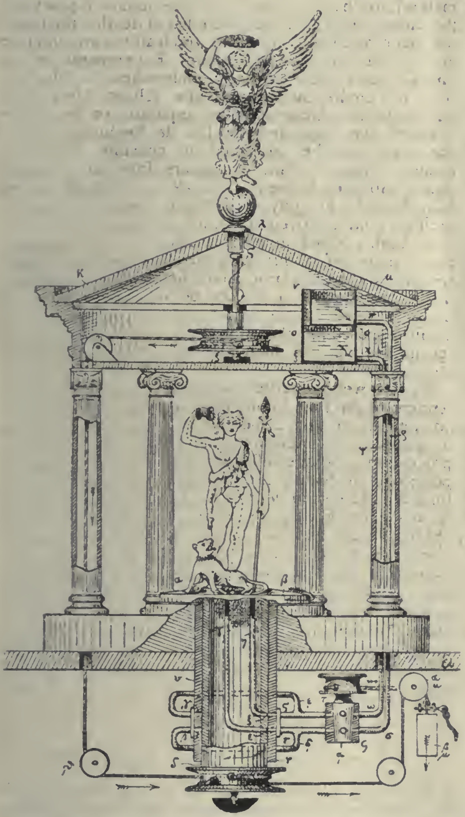

FIG. 2.—Showing the machinery for moving the Bacchante, &c.

sincere delight to the spectator. Two of these automatic theatres, in which some attempt at dramatic action was made, are described in detail, and we learn how the fire was suddenly kindled on the altar of Dionysius, while from the Thyrsus cup spouted respectively milk and wine, the Bacchantes urging their wild career at the same time (Fig. 2). The legend, too, of Nauplius seems to have been illustrated with great care and nicety in a succession of scenes, in which were represented the departure of the Greek ships, the rising of a storm, and the luring of the ill-fated Greeks by lighted torches to the dangerous promontory of Caphareus where they suffered shipwreck. All this tale is told, with the proper accompaniment of lightning and thunder, by means of moving and hidden machinery. Even Ajax is made to swim towards the land, and subsequently to perish in one of various ways according to the fancy of the stage manager. That Hero should devote himself to the construction of the necessary tricks, required to reproduce these scenes, when he seemed clearly capable of higher intellectual flight, does not increase our respect for his memory; but Mr. Schmidt, whose philological tastes seem to be in advance of his scientific, seems to think it would be worth while to reconstruct the machinery, and play the little drama over again to a select audience. He admits the difficulties, both in following the original MSS. and in filling up some necessary lacunæ, but considers the labour would be well spent, since it would illustrate in a most realistic manner the amusements of the ancient inhabitants of Alexandria.

THE SITUATION OF OPHIR.

A REUTER'S correspondent has had an interview with Dr. Carl Peters on the subject of the re-discovery and identification of the ancient gold-bearing site now so well known by the name of Ophir. According to the eminent German traveller, this much discussed locality is situated on or near the Zambesi river, and he is confident that the theories which would place Ophir either in India or in Arabia are both wrong. Dr. Peters is not the first who has convinced himself that Ophir lay somewhere on the east coast of Africa, for the late Mr. Bent and other recent writers believed that they had identified the famous emporium whence Solomon, the king of Israel, obtained gold for the temple at Jerusalem. It must, of course, be admitted that remains of extensive gold workings undoubtedly exist in the locality, and that these possess considerable antiquity cannot be denied. It is, however, open to discussion whether the ruins and workings are "of undoubtedly Semitic type," and also whether the emblems which Dr. Peters identifies as phallic are really connected with "the ancient Semitic sun worship." Until Dr. Peters distinctly states his case in print, and gives his reasons for the faith which is in him, we can do little more than point out that up to the present the theory which would place Ophir, or Aphar, or Sôphir (1 Kings ix. 28; x. 11; 2 Chron. viii. 18; ix. 10) the great metropolis of the Sabeans, which is described in the "Periplus" attributed to Arrian, on the Gulf of Akabah, has not been disproved. The theory which would place Ophir in India, on the banks of the Indus, has much in its favour, and when it is remembered that the precious stones and *almug* trees, which are mentioned with the gold of Ophir, are the peculiar products of India, it is a little difficult not to accept it without more ado. On the other hand, the apes and peacocks (or parrots as some would translate the word *tukkiyyîm*), which were brought to Solomon from the neighbourhood of Ophir, indicate that its site was nearer Palestine than India; for it is well known that peacocks would not survive a long voyage which must have lasted several months, and must also have been made in an open boat. The fact is that many places can produce, and must always have produced, gold in great abundance, and we are driven irresistibly to the conclusion that more than one place bore the name of Ophir.

It is not necessary for the Ophir, whence Solomon obtained gold, to have been situated as near as the northern end of the Red Sea, for it is most likely that the seamen, who traded through Hiram, with him obtained the goods which they had to sell from the larger boats which sailed through Bâb el-Mandeb either to India, or to ports on the north-east and east coasts of Africa. Meanwhile Dr. Peter's claim to the discovery of the Ophir mentioned in the Bible will evoke consider able interest, and we must hope that he will lose no time in bringing before the world the important facts which he must have collected, and the evidence which would connect the phallic rites and worship of the Northern Semites (which have been so carefully described by old John Selden in his "De Diis Syris") with the nature worshippers on the east coast of Africa.

FORMALIN AS A PRESERVATIVE.

ALTHOUGH as a preservative medium for perishable zoological specimens, formalin has scarcely realised all the expectations entertained on its introduction, yet there can be little doubt that it has a great future before it, and that for certain purposes it is likely to prove invaluable. It has, however, many undoubted disadvantages; and in the minds of some museum officials these disadvantages appear to outweigh its manifest valuable properties, so that an unfavourable opinion is entertained of it in general. On the other hand, those who weigh more carefully the *pros* and *cons*, realise that, under proper conditions and restrictions, its value is really very great.

As regards its disadvantages, it must be admitted that it is unsuitable for the permanent preservation of specimens that are likely to be manipulated, as not only are its effects on the hands of the worker most unpleasant, but in many cases it renders the tissues of the specimens themselves so hard that they are practically unworkable. Then, again, it is quite unsuited for all specimens containing calcareous matter, such as molluscs, echinoderms, and crustaceans; while unsatisfactory results appear to have been obtained in the case of certain insects and myriapods. Moreover, it does not seem to be well suited for the preservation of reptiles; and it is said to deteriorate the colours of bird-skins.

Turning to its advantages as a permanent preserving fluid, it is acknowledged to be unrivalled for specimens of watery and "flabby" animals, such as jelly-fish, rendering them more coherent and less likely to disintegrate than any other known medium. Apart from this group, it does not, however, appear to be at present used to any great extent in the exhibition series in the British Museum; although we have reason to believe that its possibilities are occupying the serious attention of the officials. In the series of worms, all the more valuable specimens that were received in formalin have been transferred to spirit, and only the commoner forms left in the original medium. Of the six specimens of eggs, embryos, and larvæ of *Lepidosiren paradoxa* recently added to the exhibition series from Mr. Graham Kerr's Paraguay collection, three are in alcohol and three in formalin; the latter having been sent home in that fluid, and it being thought not advisable that the medium should be changed. If these six specimens are carefully watched, they will afford a test-case of the comparative value of the media. At present, we believe, none of the exhibits in the "Index Museum" are in formalin.

For sterilising freshly killed specimens of mammals and birds, as well as eggs, that have to be sent some distance to a museum in the flesh, there can be no doubt that formalin is invaluable. And it is no less valuable to the field-collector of mammals, not only on account of the small bulk a sufficiency of the fluid occupies, but also from the marvellous preservative power of the fluid itself. According to Mr. O. Thomas (who reports very favourably of it for this purpose), commercial formalin, which is itself 40 per cent. under proof, must be diluted with no less than twenty-five times its own bulk of water before use. Moreover, whereas when mammals are preserved in spirit it is necessary to allow a very large amount of fluid to each specimen, when formalin is employed the vessel may be crammed as full as possible with specimens, which are preserved without exhibiting the slightest traces of putrefaction. When received at the British Museum all such specimens are, however, immediately transferred to alcohol, on account of their unsuitability for handling when in the original medium.

The foregoing instances suffice to show that for certain specific purposes formalin has advantages as a preservative medium not shared by alcohol. But, as many of our readers are aware, another application of formalin has been recently proposed by Dr. G. de Rechter, of the Brussels University, who, in the twelfth volume of the *Annales de l'Institut Pasteur* (1898), has advocated the use of currents of formalin vapour for the preservation of animal specimens. The advantages claimed for this method are that it preserves the specimens in practically the same condition as they were left at death; the tissues not being hardened, while hair and feathers are uninjured alike in texture and in colour. Experiments in this method have been recently undertaken in Mauritius by Mr. Camille Sumeire, of the Albion Dock Company, who has constructed an apparatus on the general lines of one suggested by Dr. de Rechter, in which specimens can be subjected to constant currents of formalin vapour. And it appears from an illustrated report published in the *Bulletin de la Société Médicale de l'Ile Maurice* for July 18, that the results of these experiments have proved eminently satisfactory.

A freshly killed guinea-pig placed in the apparatus for a period of twenty days was found to be in a perfect state of preservation, and when exposed in the open in the museum for a further period of eight days, was likewise found to be intact. Moreover, a culture of bacilli exposed in the apparatus at the same time as the guinea-pig was found to have become completely sterilised.

As was well remarked by Dr. de Grandpré, superintendent of the Port Louis Medical Museum, the potential advantages of such a method of preservation are likely to prove very important. And it is urged that the process may be specially valuable in cases of suspected poisoning, as bodies can be preserved for any length of time in a state suitable for examination. From a natural history point of view the invention has likewise almost unlimited possibilities; and Mr. Sumeire hopes to be able shortly to supply the museums of Europe with examples of the animals of Mauritius as fresh as when alive, instead of in the condition of ordinary spirit-specimens. Indeed, negotiations are already opened with the director of the Paris Museum for the transmission of such formalined specimens to the institution under his charge. We wish all success to the new venture. R. L.

A GREAT SALT LAKE PROBLEM.

AN alluring possibility has for a long time attached itself to the economic resources of Great Salt Lake, in the Western United States, in the way of establishing in its waters, as permanent residents, forms of marine life of commercial importance. The United States Fish Commission recently made an examination of the lake with a view to determining the feasibility of such a plan. The work was undertaken by Mr. H. F. Moore, of the Commission, who finds in the peculiarly interesting conditions which prevail in this unique body of water a decisive answer.

Crustacea, insect larvæ, and the lower plant-life abound in its fresher parts, but for the ordinary inhabitants of the sea the salinity is much too great in the main body of the lake. Great Salt Lake is a remnant of the prehistoric Lake Bonneville, which was fresh, or nearly so, until its drainage basin became isolated by climatic and other changes, its salinity then increasing by evaporation. Brackish springs are common in the vicinity, and these, with the salts of the feeding streams, still contribute to the accumulation of saline matter. On the authority of the United States Geological Survey, the present rate of accumulation will charge the lake with common salt within a period of 25,000 years. The present density is about 1·168, while that of the ocean is but 1·025. It appears that it is not the nature of the saline materials, but their excessive quantity alone, that makes the water unfit for ocean life; for the relative proportions of the solids in solution do not differ materially in the lake-water and sea-water. Three-fourths of these solids are common salt in both cases. The lake, while strongly salt, is not alkaline, and would presumably support the higher organisms of the ocean if properly diluted. Diatoms have been grown experimentally in the diluted Salt Lake water, and, indeed, have been found native in the lake, together with other low plant and animal life, in its brackish parts.

On account of the removal for commercial purposes of large quantities of salt, many have looked forward to a day when the consequent freshening process shall have reduced the density of the water sufficiently to make it an inhabitable medium. About 42,000 tons of common salt are removed annually, while 16,000 tons, according to the calculation of the 25,000 year period required to saturate the lake, enter it each year. From the present density, 1·168, the lake must now hold about 400,000,000 tons of salt, and with these figures as a basis, it appears that in 14,000 years—the processes continuing at the present rate—the lake-water will reach the density of sea-water. As this is a far cry into the future, some would believe that the solution of the problem was to be found in acclimatisation of marine forms to the present briny waters. There is no evidence that this is feasible or remotely possible; the oyster has the best possible opportunity to adapt itself to salt or fresh water, but clings to an intermediate brackish zone of a density between 1·010 and 1·020. The plan which seemed to offer the only possibility of success concerned the oyster, and the location, near the mouths of the fresh streams that feed the lake, of water-zones of a degree of brackishness favourable to oyster growth. The conditions which were found to exist were such as to show conclusively that there is no hope for the utilisation of the lake in this way. The favourable zones, which are narrow at best—in no case over three hundred yards—are subject to great fluctuations in position due to the wind and to seasonal changes. The variation in the volume of water carried by the inflowing streams is remarkable. In one of them the ratio of the greatest flow to the least was as 28 to 1. When they are flushed with the melting of snow in spring the oyster zone is carried lakeward, and during the period of minimum flow in autumn it travels up the mouth of the stream in which it is located. The wind alone sometimes makes a change of level of several feet, and a consequent change of density from 1·009 to 1·014 within five minutes has been observed. Moreover, the deltas of the streams, which must of necessity be the location of the oyster beds, are subject to deposits of silt in amounts fatal to oysters. All these conditions in conjunction make the difficulties of successful oyster culture insuperable.

The brackish springs characteristic of the Bonneville bed have a low density, none exceeding 1·005, and suggest a plan by which they might be utilised. By making them the sources of artificial ponds the evaporation, which is greater than the rainfall, would raise the density to the desired point at which it could be maintained by a proper regulation of the brackish inflow and outflow. On a commercial scale, however, the experiment would be expensive, and might or might not justify itself.

PAUL KNUTH.

BORN on November 20, 1854, Paul Erich Otto Wilhelm Knuth, Professor at the Oberrealschule of Kiel, was only in his forty-sixth year at his death on October 30. After graduating at Griefswald in 1876, he was engaged in teaching at Iserlohn in Westphalia, and from 1881 at Kiel. His first scientific investigations were in the realm of organic chemistry, his chief works a Handbook of Flower-Biology, a Flora of Schleswig-Holstein, and a series of short papers upon the botany of the islands off the German coast—Rügen, Heligoland, Sylt, &c.

The "Handbuch der Blütenbiologie" is based on the English edition of Hermann Müller's "Befruchtung der Blumen," and is destined to replace it. Increasing knowledge has swelled the literature-list from 825 entries to 2871, and Knuth's plan allowed for three volumes in the place of the single one issued in English in 1883; of these the last, designed to contain all we know of the fertilisation of flowers in lands outside Europe, remains unpublished. There is hope that the work may yet be completed. Knuth's own observations in Java, Japan, and California, made in 1898 and 1899, were made to add to the rather meagre knowledge available for this unpublished volume.

His observations on the flora of the North Friesian Islands, of Heligoland and of Rügen, demonstrate how the winds that blow over sea-girt islets, inimical to insect life, impose a limit to the distribution of plants whose highly specialised flowers need insect aid for their fecundation. The lesser the island the greater the influence. Rügen is large, and it is not evident; the Halligen are small, and it is very apparent. These Halligen are "low-lying, marshy islets, hardly rising more than a metre above high tide, wind-swept, where one wanders hour after hour without taking a single anthophilous insect, save on the rare hot and windless days which coax a few to fly from flower to flower." On them the high-types of floral development are rare.

His Flora of Schleswig-Holstein, named above, was largely a compilation, intended to supply a real need, and was followed by a History of Botany in the double province. These, however, as the first steps towards his botanical work, have their own interest. I. H. B.

NOTES.

SOME particulars concerning the vessel which is being built at the Howaldt Shipbuilding Yard at Kiel, for the German Antarctic expedition, are given by the Berlin correspondent of the *Times*. The ship will be built of wood, the only material strong and elastic enough to resist the pressure of the ice. In form she will be somewhat rounder than the *Fram*, and will not fall away towards the keel in the same manner. The length of the ship will be about 46 metres, the breadth between 10 and 11 metres, and the draught about 5 metres. She will be constructed to carry coal and other stores sufficient for three years, and will contain accommodation for five scientific observers, five officers, and a crew of about twenty men. Each of the observers, and each of the officers, will have his own cabin. The centre of the ship will be occupied by the rooms for scientific work, and the forecastle will contain space for fifty Arctic dogs. The ship will be rigged as a three masted schooner. Two steam winches will serve the anchor and will also be used for scientific purposes. The ship will be illuminated throughout with electric light. The Howaldt Shipbuilding Yard, which is under a contract to have the ship built by May 1, 1901, and fitted out not later than the end of August, 1901, has already begun the construction. A model of the vessel will be shown at the Paris Exhibition.

THE *British Medical Journal* states that the Italian Parliament has voted a sum of 1,300,000 lire for the erection of new buildings in the University of Bologna. The work will be begun next spring.

WE learn from the *Times* that M. Raphael Bischoffsheim has presented to the Paris University his observatory at Nice worth 2,700,000f., and 2,500,000f. the interest of which is to cover its expenses.

M. T. Ribot, professor of psychology at the College de France, has been elected a member of the Paris Academy of Moral Sciences in succession to the late M. Nourrisson.

GENERAL GALLIENI, Governor of Madagascar, has been elected a correspondant of the Paris Academy of Sciences. The Academy has also elected M. Méray as correspondant of the section of geometry, and M. Rosenbusch as a member of the section of mineralogy.

A SPECIAL correspondent of the *Times* reports: "six Marconi wireless telegraphy instruments intended for the Boers have been captured at Cape Town. The experiments at Orange River have been highly successful. The communication with De Aar, seventy miles distant, is perfect."

MR. C. VERNON BOYS, F.R.S., will deliver the first of a course of six Christmas lectures specially adapted for young people, at the Royal Institution this afternoon. The subject will be "Fluids in Motion and at Rest" (experimentally illustrated). The remaining lectures will be on December 30 and January 2, 4, 6, 9, 1900.

THE two astronomers whose names have been submitted to the French Minister of Public Instruction, who will select one to fill the vacancy in the Bureau des Longitudes caused by the death of M. Tisserand, are M. Radau and M. Bigourdan.

AN exhibition of food, clothing, medicines, and other articles suitable for travellers in uncivilised and unhealthy regions of the globe, will be held at St. Martin's Town Hall, Charing Cross, on January 1–5, under the title of the "Livingstone Exhibition." A loan collection of Livingstone relics and of objects of interest connected with the work of other travellers will be on view.

AN interesting account of experiments on the growth and regeneration of the tails of tadpoles, conducted by means of Born's method of grafting, is given by Mr. R. G. Harrison in the October number of the *Bulletin* of the Johns Hopkins Hospital. In the neighbourhood of Baltimore there occur two species of frogs whose embryos differ so markedly in colouration from one another, that in any case where parts derived from each are united by grafting into a single organism it is easy to follow in the living specimen, as development proceeds, the change in position of any group of cells in respect to the original line of section. During the development of the tail after grafting it was noticed that a remarkable shifting of the epidermis over the underlying organs took place; so that after a time the epidermis properly belonging to the tail was restricted to the terminal third of that appendage. Now it is well known that the cutaneous nerves of the trunk and tail of the full-grown larvæ and frogs, in passing from the vertebral column to their termination in the skin, pursue an oblique course; and this is obviously due to the above-mentioned backward shifting of the epidermis. Certain other interesting features were also brought to light in the course of the experiments.

WITH the view to ascertain what displacement, vertically or horizontally, took place in the Khási and Gáro Hills during the Indian earthquake of June 1897, a revision of the principal triangulations in the district was made by officers of the Survey of India Department during 1898, and the results are referred to in the report just issued. Horizontal and vertical observations were taken at thirteen stations, fixing the positions of twenty-two and the heights of twenty-five old stations, embracing an area of 1020 square miles. The results show that the whole of this area lay within the region affected by the earthquake, so it is impossible to state how much any one station has been displaced in comparison with the unaffected area outside, but apparently all have suffered more or less. The average horizontal displacement appears to be about 7 feet, whilst the changes in height vary from a subsidence of 4·3 feet to an upheaval of 24 feet; these, however, for the reasons already mentioned, cannot be considered as absolute, but only relative changes. The general apparent effect is that the area has been both widened and raised. If possible, the revision work should be continued and extended, with instruments of equal calibre to those employed in the original triangulation; for accurate measurements of the movement of the earth's crust due to a large earthquake are of deep scientific interest.

THE Antiquity of Man in America is an important problem, and it is well that Mr. W. H. Holmes should revise, as he has done in the *American Anthropologist* (N.S., I., 1899, p. 614), the evidence relating to Auriferous Gravel Man in California. He discusses this special aspect of the question in a full, lucid and judicial spirit. His conclusion is that the testimony furnished is greatly weakened by the facts (1) that the finds on which it was based were made almost wholly by inexpert observers, and (2) that all were recorded at second hand. Affidavits cannot redeem it. Nothing short of expert testimony, amply verified and vigorously stated, will convince the critical mind that a Tertiary race of men, using symmetrically-shaped and beautiful implements, wearing necklaces of wampum and polished beads of marble or travertine bored accurately with revolving drills, fishing with nets weighted with neatly-grooved stone sinkers, and having a religious system so highly developed that at least two forms of ceremonial stones had been specialised, occupied the American continent long enough to develop this marked degree of culture without leaving numerous and distinctive traces of its existence. All these objects resemble modern implements in every essential respect. They are such as may have fallen in the mines from Indian camp sites or been carried in by the Indians themselves.

AN article upon electrolytic processes in industrial operations, contributed to the *Engineering Magazine* by Dr. W. Borchers, shows some of the remarkable developments of electro-technology during late years. Descriptions are given of the various processes by which industrial products are obtained electrolytically. The Castner process for manufacturing sodium is well known, and several similar devices have recently been introduced. Magnesium is obtained from melted magnesium salts by a process founded upon Bunsen's investigations. For the production of aluminium, the Pittsburg Reduction Company use a mixture of chlorides and fluorides of the metals of the alkalis and alkaline earths as electrolytes and solvent for the aluminum oxide. Copper, nickel, silver, and gold, in so far as electrolysis may be said to be applicable to them, are chiefly obtained in pure form by electrical means from the crude metal produced by the smelter. Gold is also electrolytically deposited from weak solutions obtained by chemical lixiviation processes. Caustic soda, caustic potash, chlorate of potash, and chlorine are obtained by electrolysis from aqueous alkali-chloride solutions. By suitable appliances and working conditions, the chlorine and caustic alkali solution may be carried off separately to produce chloride of lime and solid caustic soda, or they may be made to form a solution of chlorate of potash in the place of caustic potash and chlorine. The methods by which these and other electrolytic products are obtained are briefly described by Dr. Borchers in his interesting paper.

WE have received from Dr. L. Carnera, Voluntary Assistant at the Royal Observatory of Turin, a discussion of the amount of bright sunshine recorded at that Observatory, showing *inter alia* the mean duration of sunshine during the different hours and months of the years 1896–8, together with a comparison with the means obtained in a discussion by Dr. Rizzo of the values of the previous six years. While the variations between the two series show that the period is much too short for the deduction of trustworthy means, the results are valuable owing to the comparative rarity of this important climatic factor; for although observations of barometric pressure, temperature, &c., have been made at that institution for more than a century, a sunshine recorder has only been in use there for the last ten years. In fact, the instrument has only come into general use during the last twenty years, principally owing to improvements made by Sir G. G. Stokes in a recorder devised some years previously by the late Mr. J. F. Campbell.

THE Government Astronomer of Western Australia has sent us a copy of the meteorological observations made at the Perth Observatory and other places in that colony during the year 1898. This is the second of a series of annual publications issued by the Perth Observatory; annual meteorological reports have been published since 1876, but the new series shows a marked improvement. In past years the observers were dependent solely upon written instructions without inspection, and had to find out how to do their duties as best they could. In addition to the usual observations, a set of four Platinum Resistance thermometers have been sunk to various depths at Perth, and daily weather forecasts are now issued, which, on the whole, have been remarkably successful. In the year 1898 there were 31 stations provided with barometers and other instruments, and 213 rain-gauge stations, but the monthly charts show that large tracts are still unrepresented.

THE U.S. Government is pushing on its researches of the economical resources of Porto Rico. *Bulletin* No. 25 of the U.S. Department of Agriculture (Division of Forestry) consists of a report by Mr. Robert F. Hill, of the U.S. Geological Survey, on the forest conditions of the island. He states that the climate and soil are well adapted to the growth of a large number of trees and shrubs of great economical value, and he advocates a reversal of the deforesting policy pursued by the Spaniards. Besides those valuable for timber and constructing purposes, he names, as specially adapted to the climatal conditions, the tamarind, the papaw, the castor-oil plant or "palma Christi," the all-spice, the lime, a large number of edible fruits, as the orange, citron, lemon, guava, anona, mango, banana, and many others whose names are less known in this country. The coffee cultivated is of a superior quality. There are comparatively few harmful animals or poisonous plants.

PROF. W. B. SCOTT (*Trans.* Wagner Free Inst. of Science Philadelphia, vol. vi.) describes and figures a series of Ungulate Mammals from the Uinta and White River formations (Oligocene) of Utah and Colorado in North America. The mammals belong to the sub-order of "Selenodont Artiodactyls," and they include two groups; the first comprises forms generically identical with, or clearly related to, Old World anthracotheres and true ruminants, which reached the American continent by migration; the second group includes forms indigenous to America, the successive stages of whose descent may be traced through several of the Tertiary formations.

THE ninth volume of the Iowa Geological Survey (1899) contains the Annual Report for 1898, with accompanying papers. Statistics of mineral productions, including coal, clay, stone, lead and zinc, are contributed by Mr. S. W. Beyer. There are also reports on the Counties of Caroll, Humbolt, Story, Muscatine, and Scott, accompanied by colour-printed maps, and followed by an account of the Artesian Wells of the Belle Plaine Area. The county reports contain concise accounts of the various formations including Silurian, Devonian, Carboniferous, Cretaceous, Pliocene, Glacial and more recent deposits, together with notes on their economic products. In Muscatine county the Devonian rocks afford many points of special interest, and they have yielded a number of fossils.

THE *Mittheilungen* of the Vienna Geographical Society contains an excellent abstract of a paper by Dr. Eduard Richter, published by the Swiss Geological Society at the end of last year, on the advance and retreat of the glaciers in the Alps during the Ice Age. Dr. Richter arrives at the important result that the variation of climate was probably much smaller than has been supposed, because the resistance to the outflow of the ice increases with its quantity in a rapid ratio, and the level of the snowfields would therefore rise quickly to levels where the temperature was lower. The variations of level due to this cause would themselves give rise to sudden and irregular changes in the glaciers according as the ice-surface rose above, or fell below, the snow-line. They also account for the enormous amount of moraine detritus carried by these glaciers; each was made up of a large number of small ice-streams, and the debris was not carried as a ground moraine, but in the body of the ice.

THE *Biologisches Centralbatt* for November 1 contains an article by Dr. L. Kathariner on the influence of light on the colours of the pupæ of butterflies, in which many interesting points are recorded.

THE following lectures will be delivered at the Royal Victoria Hall, Waterloo Road, S.E., on Tuesday evenings during January:—January 2: "Chronicles of a Clay Cliff," by W. H. Shrubsole; January 9: "A Peep Behind the Scenes," by Metcalfe Wood; January 16: "Birds at Home and Abroad," by Mrs. Lemon; January 23: "Plants of Long Ago," by A. C. Seward, Esq., F.R.S.; January 30: "The Fathers of Geology," by F. W. Rudler.

THE *Journal* of the Franklin Institute for December contains several additional addresses delivered on the occasion of the recent celebration of the seventy-fifth anniversary of the Institute. Dr. C. F. Himes describes the history of photographic discovery from the time of Daguerre and Niépce; Mr. C. Kirchhoff surveys the achievements in mining and metallurgy during the past three-quarters of a century; and Mr. J. Fritz gives some reminiscences of the development of iron manufacture in the United States in the same period.

OUR ASTRONOMICAL COLUMN.

ASTRONOMICAL OCCURRENCES IN JANUARY, 1900.

January 2–3.	Epoch of January meteors (radiant $230° + 53°$).
3.	4h. Venus in conjunction with the moon (Venus 6° S.).
6.	7h. 12m. to 8h. 10m. Occultation of 19 Piscium (mag. 5·2) by the moon.
8.	17h. 32m. Jupiter's Sat. IV. in conjunction N. of planet.
10.	7h. 1m. to 7h. 59m. Occultation of τ^2 Arietis (mag. 5·2) by the moon.
10.	7h. 55m. to 9h. 1m. Occultation of 65 Arietis (mag. 5·6) by the moon.
11.	10h. 27m. to 11h. 34m. Occultation of κ^1 Tauri (mag. 4·6) by the moon.
11.	10h. 40m. to 11h. 23m. Occultation of κ^2 Tauri (mag. 5·5) by the moon.

January 13. 10h. 1m. Minimum of Algol (β Persei).
15. Venus. Illuminated portion of disc = 0·873.
16. 6h. 50m. Minimum of Algol (β Persei).
16. 17h. 17m. to 17h. 50m. Occultation of α Cancri (mag. 4·3) by the moon.
20 12h. 46m. to 13h. 46m. Occultation of B.A.C. 4006 (mag. 5·7) by the moon.
21. 11h. 22m. to 12h. 26m. Occultation of q Virginis (mag. 5·7) by the moon.
23. 15h 35m. to 16h. 45m. Occultation of B.A.C. 4722 (mag. 5·5).
26. 1h. Conjunction of Jupiter and the moon (Jupiter 2° 3′ N.).
26. 15h. 40m. Transit of Jupiter's Sat. III. (Egress).

ASTRONOMICAL AND ASTROPHYSICAL SOCIETY OF AMERICA.—Prof. E. B. Frost, of the Yerkes Observatory, contributes to *Science* a full account of the proceedings at the first meeting of this new society, which is the permanent outcome of the two congresses of astronomers and astrophysicists held in the past two years. The following notes are from the report:—

Prof. S. J. Brown discussed his measures of the changes in the orbit of the satellite of Neptune, in order to determine the position of the polar axis and flattening of the planet. This flattening is found to be $e = \frac{1}{102\cdot2}$, an amount corresponding to only 0″·03 between the polar and equatorial diameters.

The period of the revolution of the pole of the satellite's orbit is 531·75 years.

Prof. A. S. Flint described the new Repsold transit micrometer of the Washburn Observatory.

Mr. Kurt Laves read a paper on the "Determination of the constant of nutation from heliometer measures of Eros." The opposition of this planet at the end of 1900 will offer special facilities for this purpose.

An account was given of a proposed new "Harvard Photometry." In the original work all stars were included of sixth or brighter magnitude, as obtained from the principal catalogues then extant; but it has been found in the course of the work that in this way many have been included which are fainter than mag. 6·2. The stars of the Photometry were again observed in 1892–94, and, including special series of measures, there are now prepared *seven* photometric catalogues, giving measures by different observers with different instruments, but all made on the same plan. It is therefore proposed to issue a catalogue of all the stars from the north to the south pole, showing the brightness given by the meridian photometer in all seven catalogues, and to call the work the "Revised Harvard Photometry." As much reference information to other catalogues will be given as is possible, and it is thought a quantitative measure of the colour will be furnished by giving the type of spectrum and photographic magnitude.

Prof. G. C. Comstock described his experiments of placing a very coarse grating before the object glass of a telescope, and measuring the distance between the mean centres of the pairs of star spectra formed on each side of the central image. He finds incidentally that the mean refrangibility of the light of Mars is marked by *less* than that of any red stars yet examined. He has also examined the satellites of Jupiter in this way, and finds different values from those adopted by Michelson and Hamy.

Mr. F. L. Chase has taken heliometer observations of red stars, &c., in order to determine the possibility of there being a slight difference of refraction between these and white stars, thus introducing a disturbing element into measures of parallax. In all his experience, however, he was unable to detect any difference whatever.

Prof. S. I. Bailey said that out of the 900 stars counted in the cluster M.5., eighty-five were variable. Detailed examination of the light curves and periods of many of them showed a remarkable similarity both in the magnitude and range of variation. The periods vary from 10h. 48m. to 14h. 59m. The uniformity of period, magnitude, and light curve among so many variables, points to a common origin and cause of variability.

DAY NUMBERS OF "NAUTICAL ALMANAC."—We have received a pamphlet giving the separate day numbers for use with the tables for finding star constants for the years 1900, 1901, 1902. From the past three years' experience, Prof. Turner says that his restriction of the tables to three figures has been followed by no loss of accuracy, and therefore their publication is continued. In accordance with the decisions of the Conference of Superintendents of Ephemerides held at Paris in 1896, the constants of aberration, precession, and nutation have been altered from the commencement of 1901; but, for the convenience of observers still desiring to use the Struve-Peter's constants, both have been included in the present tables.

"POPULAR ASTRONOMY" FOR DECEMBER.—The issue of *Popular Astronomy* for this month contains, among much generally interesting matter, two useful articles by Profs. H. C. Wilson and W. H. Pickering. The former describes a photograph of the nebula of Andromeda obtained by him at Goodsell Observatory, using the 8-inch Clarke refractor, with an exposure of twelve hours given on three nights. Reproductions of the picture accompany the paper, and the minute structure of the many spirals first photographed by Roberts are magnificently shown.

Prof. Pickering writes to keep up hopes of the meteor shower still being observable. He has examined the times of appearance of the maximum from 902 more minutely, and finds they occurred at regular 100 years' intervals until 1698, when there was a perturbation of four years. Since then thirty-four years would appear to more closely satisfy the period, so that 1901–2 may still be the maximum year.

THE SOUTH-WESTERN POLYTECHNIC.

ONE of the best equipped and most intelligently governed of the London polytechnics is that built at a cost of 55,000*l.*, and located at Manresa Road, Chelsea. Situated as it is in the midst of a densely-populated district, its work, which a large staff of lecturers and demonstrators, under the able guidance of Prof. H. Tomlinson, F.R.S., the Principal, are year by year steadily accomplishing, cannot be overestimated. The work of the polytechnic is carried on in a fine suite of buildings placed within a stone's throw of the Chelsea Town Hall, and the institution is provided with laboratories and lecture-rooms for each of the many departments of science and technology which its work comprises. It is designed more especially to meet the educational needs of the inhabitants of Chelsea, Fulham, Kensington, St. George's (Hanover Square), and Westminster, though students from other parishes are admitted if accommodation is available and other circumstances permit.

Financial Position.—The financial outlook of the South-Western Polytechnic may certainly be regarded as hopeful. Both the fees received from the students and members and the grants earned last session from the Science and Art Department showed a very large increase. The total annual income received from the Technical Education Board of the London County Council amounts to over 4000*l.*, and the annual subsidy from the Charity Commissioners is 1500*l.* The inadequate accommodation which the already extensive buildings offer the increasing number of students to be provided for, has necessitated a further extension, and the governing body are now spending some 7000*l.* on new buildings.

Departments.—The operations of the institution are divided into two distinct portions—day classes and evening classes. In the day classes are included (1) a Day College for men; (2) a Day College for women; (3) a School of Art; (4) a School of Science for boys and girls; and (5) a School of Domestic Economy for girls. The evening classes embrace the following sections: (1) Mathematics; (2) Physics and Electrical Engineering; (3) Mechanical Engineering and Building Trades; (4) Chemistry; (5) Natural Sciences; (6) Languages; (7) Commerce; (8) Domestic Economy; (9) Art; (10) Music; (11) Miscellaneous; (12) Recreation.

Numbers of Students.—The most notable fact, and one of the most encouraging features of the work of the South-Western Polytechnic, is the regular and substantial increase from year to year in the numbers of students attending the different departments. The number of students in the day classes during the session 1897–8 was nearly half as many again as that during 1896–7. Taking all the day classes for both sexes together, the number of individuals attending during the present session is about 30 per cent. greater than for the last school year, the number undergoing instruction at the present time being about 900.

The number of individual students in all evening classes together is about 2000 for the current session, during 1897–8 it was 1844, and the preceding year, 1896-7, 1520. The relative popularity of the different departments among evening class students can be seen at a glance from the number of class entries during the session 1897-8, which was as follows :—

Mathematics	85
Physics and Electrical Engineering... ...	578
Mechanical Engineering and Building Trades	942
Chemistry	185
Natural Sciences	137
Languages	246
Commerce	342
Domestic Economy	233
Art	287
Music	455
Gymnastics	306
Miscellaneous	233

The trades and industries of the evening class students show great variety, and indicate graphically the widespread influence which a polytechnic is able to exert. Of the 1844 students attending evening classes during 1897-8, 304 were clerks, 192 teachers of one kind or another, 183 were salesmen and shop-assistants, 175 apprentices, 65 servants, 59 carpenters and joiners, 42 artists, 37 electricians, 37 painters, 34 builders' clerks, 32 civil servants, and 31 telegraphists. In addition to these, rather smaller numbers of bricklayers, plumbers, fitters, engineers, draughtsmen, dressmakers, milliners were in attendance, while doctors, architects, and merchants were represented ; one or two postmen, porters, and others were also reaping the benefits of education.

Day College for Men.

This college is intended for males above the age of fifteen, and is at the present time attended by over a hundred students, whose ages range from fifteen to forty. It comprises two departments—one technical, the other general. The courses of instruction in the former are arranged to occupy at least two years. On entering, the student is expected to state whether he wishes to be trained as a mechanical or electrical engineer, whether he wishes to be educated with a view to some branch of chemical industry or of the building trade, or whether he desires to study applied art. Except in the last contingency, complete courses of study have been arranged, involving laboratory instruction, tutorial work, attendance at lectures, mathematical exercises, drawing, and workshop instruction.

The general department of the day college, on the other hand, aims at giving either a good all-round education or special training in each of its various sections.

Students admitted to a regular and fully prescribed course of study in the technical department are first required to pass an elementary examination in mathematics and to give evidence of possessing a fair knowledge of English. In the general department the students are not required to pass any entrance examination. Students in the technical department who successfully work through the second year's course may compete for a college diploma.

A few words about the different courses of instruction in the technical department will best indicate the nature of the work in this part of the day college for men. The full scheme of work is :—

FIG. 1.—The Chemical Laboratory, South-Western Polytechnic.

(*a*) *The Mechanical Engineering and Architecture Section* is spread over two years, and aims at providing progressive instruction of a theoretical and practical nature, suitable for students just leaving school and who intend in the near future entering the works of an engineer or the office of an architect. At the same time it is designed to be of service to those who have already spent three or more years in a workshop, and who require a course of technical instruction to fit them for positions of greater responsibility.

(*b*) *The Civil Engineering and Surveying Section* also takes up two years, and trains young men who will hereafter be engaged in surveying, civil engineering, constructional work of any kind, or who propose to proceed to the colonies.

(*c*) *The Electrical Engineering and Applied Physics Section* is intended to familiarise students with methods of accurate measurement and observation, as well as to give a sound knowledge of physical laws and their application to industrial and engineering operations. The laboratories are capable of accommodating fifty students at one time, and are equipped throughout with the most recent apparatus for the study of physics.

(*d*) *The Chemistry Section* is arranged to assist students who intend carrying on work involving the applications of chemistry as industrial, consulting, or analytical chemists. The course includes other subjects required by technical chemists, and students who wish to do more advanced work can only complete the course in three years.

DAY COLLEGE FOR WOMEN.

This college is the counterpart of the day college for men, and the Principal is aided in its direction by a lady superintendent. It is at the present time attended by 200 students. The aim of the college is to provide women with a thorough and liberal education, not only in art, science, literature, and commerce, but also in domestic economy and physical training. While it is a little difficult to make selections where the whole work is so satisfactory, the training offered for lady secretaries and the training college for gymnastic teachers call for special mention. The growing demand for ladies to act as secretaries or confidential clerks renders the question of the competent training of candidates for such posts one of great practical importance, and there is no doubt that the arrangements which have been made at Chelsea to provide a complete course of study for those wishing to obtain employment as secretaries or clerks will have a very beneficial effect.

The training college for gymnastic teachers is under the direction of Fräulein Wilke. The complete course of training extends over two years, and the fee for the whole time is seventy-two guineas. A noteworthy feature of the method of instruction adopted is that the candidates are taught each of the systems of gymnastics, German, Swedish, and English, and are consequently not handicapped like students in many similar colleges where one system only is taught. The instruction is both practical and theoretical, and the most careful precautions are taken to ensure the physical well-being of the embryo instructors.

EVENING CLASSES.

The time table of the evening classes at this polytechnic gives the impression that it would be difficult to name a subject which is not included. There are classes in all branches of pure and applied science, languages and literature, domestic science, commercial subjects, art, music, and many other subjects. The fees are low, and the classes well attended, while the examination results show that the students make substantial progress.

HIGHER SCIENTIFIC INSTRUCTION AND WORK IN RESEARCH.

A special characteristic of the work of the South-Western Polytechnic is the higher instruction in science and the interesting development of education in the methods of research, to which reference has already been made in these columns (No. 1523, p. 236). Both in the day and evening classes great attention is given to electrical engineering. The following table shows the number of individual students attending the more important classes in this section :—

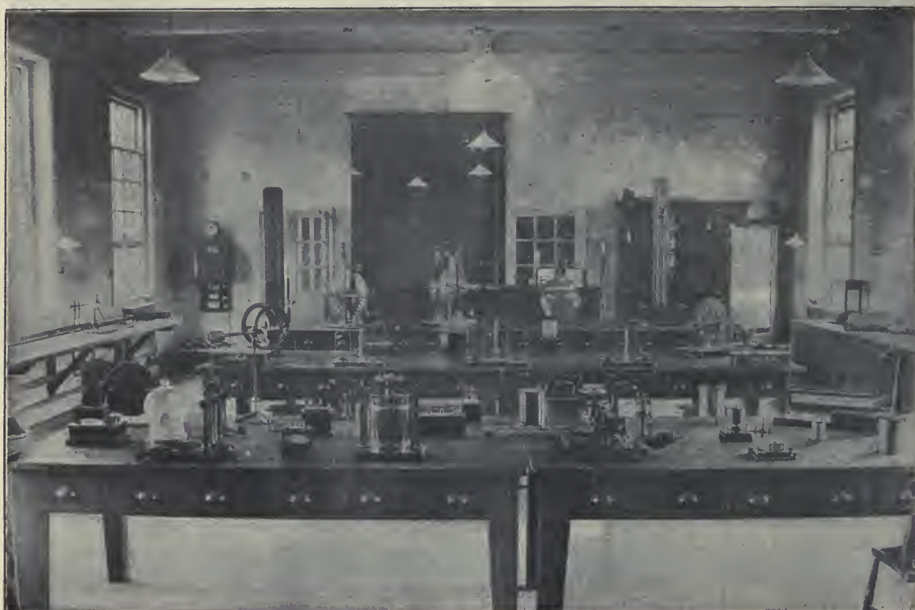

FIG. 2.—The Physical Laboratory, South-Western Polytechnic.

Advanced Electrical Engineering	58
Elementary Electrical Engineering	55
Alternating and Polyphase Currents	24
Calculus for Electrical Engineers	21
Electric Wiring and Fitting	69
B.Sc. Physics for London University	20
Telegraphy	14

The equipment of the laboratories for this work contains some interesting apparatus and machines. The polyphase generator, which consists of three small alternators of identical construction mounted on one bed plate and coupled together with graduated couplings, which admit of any given phase difference being produced between any of the alternators, deserves particular mention. There are also examples of the most recent continental three-phase and induction motors, on which careful tests are now being made. There is an ingenious combination of motor generators, which can be driven either mechanically or electrically. The switchboard and starting appliances for this combination of motor generators were designed and made in the institute.

A small workshop, with electrically driven tools, affords a good scope for the construction of original apparatus. Only typical instruments and standards have been purchased for the physical and electrical laboratories; the great bulk of the instruments and fittings have been both designed and made up in the polytechnic itself. Among the more recent pieces of original apparatus of home manufacture may be mentioned (1) a modified form of Michelson's interferometer, and another adaptation of the same for measuring to a millionth of an inch, and (2) an electro-magnetic speed indicator for use with dynamos and motors. Examples of original apparatus made at the South-Western Polytechnic have been exhibited at the Royal Society, the Royal Institution, and the Institution of Civil Engineers.

Good research work has been accomplished, including a series of tests on insulating materials, investigations on selenium cells, the effects of repeated heating and cooling on the magnetic properties of wrought iron, the relation between the thickness of metallic surfaces and the phase change of the reflected beam, tests with the Nernst lamp, and the negative resistance offered by certain metallic oxides. The results in the last piece of work have been published in the *Electrician*.

OTHER POINTS OF INTEREST.

Several general considerations must be taken into account before the educational position of the South-Western Polytechnic can be rightly estimated. The recreative side of the polytechnic is not considered of prime importance, and the tendency seems to be to minimise its influence. In this respect it departs somewhat from the general type of polytechnic in the metropolis. There is also a laudable desire to initiate new departments as the need for them becomes evident, so that the institution may keep in touch with all the needs of the inhabitants in its neighbourhood. In this connection may be cited the work now being done on the women's side of the institute in the direction of offering ladies of the middle classes such instruction in domestic science as will make them independent of servants. Finally, it should be borne in mind that in more than one department the work being done is of quite as advanced a character as that in some university colleges.

A. T. SIMMONS.

PRIZE LIST OF THE PARIS ACADEMY OF SCIENCES.

AT the Annual Meeting of the Academy, held on December 18, M. von Tieghem gave his Presidential Address, and announced the prizes awarded for 1899. In his address, the President reviewed the scientific progress for the year, and then gave a short account of the life-work of the Members, Foreign Associates, and Correspondents who have died during the past year, MM. Naudin, Friedel, Frankland, Bunsen, Richards, Wiedemann, Marsh, Flower, and Riggenbach.

The prizes were awarded as follows: in Geometry—the Bordin Prize is not awarded, but M. Jules Drach receives an honourable mention, the Francœur Prize to M. Le Cordier, with an honourable mention to M. Le Roy, the Poncelet Prize to M. Cosserat, for the whole of his contributions to geometry and mechanics.

In Mechanics: the Extraordinary Prize of 6,000 francs to M. Bailles for his treatise on the Geometry of indicator diagrams, MM. Charbonnier and Galy-Aché, and Perrin, receiving supplementary prizes, the Montyon Prize to M. Partiot, the Plumey Prize to M. Bonjour for his inventions in connection with steam engines, and the Fourneyron Prize to M. A. Rateau for his theoretical and experimental researches on the theory of pumps.

In Astronomy: the Lalande Prize is awarded to Mr. W. R. Brooks for his important discoveries in connection with comets, and the Valz Prize to M. Nyrén, of Pulkova, for his work in sidereal astronomy.

In Physics: M. Blondlot receives the La Caze Prize for the whole of his researches in experimental physics.

In Statistics: the Montyon Prize is divided equally between the Office central des Œuvres de Bienfaisance, for the memoirs entitled "La France Charitable" and "Paris Charitable," and MM. Dumesnil and Mangenot, for a complete economic study of the trades, income, and mode of living of the inhabitants of Pointe d'Ivry.

In Chemistry: the Jecker Prize is given to M. Maurice Hanriot for the whole of his contributions to organic chemistry, the Wilde Prize to Dr. P. Zeeman for his important discoveries of the relations between the magnetic field and the nature and polarisation of light rays, and the La Caze Prize to M. Engel.

In Mineralogy and Geology: the Delesse Prize is awarded to M. Kilian for his studies in the French Alps, and the Fontanne Prize to M. Émile Haug for his palæontological studies.

In Botany: M. l'Abbé Hue receives the Desmazières Prize for his work on the anatomy and classification of the Lichens, M. Leuduger-Fortmorel an honorable mention for his memoir on the diatoms of the East Coast of Africa, MM. Jules Cardot and Hériband Joseph Montagne Prizes, the Thore Prize being divided between MM. Parmentier and Bouilhac.

In Anatomy and Zoology: the Grand Prize of the Physical Sciences is not awarded; the Bordin Prize is accorded to M. Viré for his memoir on the subterranean fauna of France, and the Savigny Prize to M. Guillaume Grandidier for his researches in Madagascar.

In Medicine and Surgery: Montyon Prizes are given to MM. Nocard and Leclainche for their book on microbial diseases, to Prof. Mayet for his "Treatise on Medical Diagnosis," and to M. A. B. Marfan for his work on the treatment and feeding of young infants. MM. Lejars, Fournier and Garnier receive mentions, and MM. Guillemonat and Labbé citations. The Barbier Prize is divided between MM. Houdas and Joanin, Lapicque, and Schlagdenhauffen. Since no work has been received meriting the Bréant Prize for cure or treatment of Asiatic cholera, the Commission has decided to divide the sum accumulated (6000 francs) between M. Vaillard, and MM. Courmont and Doyon for important work on the pathogeny and pathology of tetanus, MM. H. de Brun, Ch. Besnoit, and J. Guillé receiving mentions. The Godard Prize is awarded to M. Pasteau, the Serres Prize to M. Roule, with honourable mention to Prof. J. Beard, M. Maurice Caullery, and M. Félix Mesnil, the Chaussier Prize to M. Charrin, the Mège Prize to MM. Félix Terrier and Marcel Baudoin for their memoir on intestinal suture, the Baron Larrey Prize to MM. Arnaud and Lafeuille for their memoir on Tuberculosis in the Army, the Bellion Prize being divided between M. Cestan and MM. Crespin and Sergent.

In Physiology: the Montyon Prize for Experimental Physiology is given to Prof. Le Hello for his studies on the locomotion of the horse, M. Quinton receiving honourable mention, the La Caze Prize (Physiology) to Prof. Morat for his contributions to Experimental Physiology, and the Pourat Prize to MM. Weiss and Carvalho for their paper on the specific characters of muscular contraction in the animal series, the Philipeaux Prize not being awarded this year. In Physical Geography, M. Albert Vayssière receives the Gay Prize.

Of the General Prizes, the Arago Medal was awarded to Sir G. G. Stokes on the occasion of his jubilee at Cambridge. The Montyon Prize (unhealthy trades) is given to M. E. Collin for his memoir on the microscopy of foods of vegetable origin, M. P. Razous receiving a mention. M. Louis Ducos de Hauron is awarded the Trémont Prize for his invention of photography in colours by the method of superposed coloured images, M. Vaschy, the Gegner Prize, M. Moutard, the Petit D'Ormoy Prize (Mathematics), M. Alfred Giard, the Petit D'Ormoy Prize (Natural Sciences), M. Verbeck, the Tchihatchef Prize, M. Maurice Leblanc, the Gaston Planté Prize, M. René Metzner, the Cahours Prize, M. Lecaillon, the Saintour Prize, the Pasteur Institute, the Jean-Jacques Berger Prize, M. J. P. Siegler, the Prize founded by Mme. la Marquise De Laplace, the Prize founded by M. Félix Rivot being divided between MM. Siegler, Heurteau, Aron, and Becquerel.

RESULTS OF RECENT SOUNDINGS IN THE PACIFIC.[1]

CAPT. MOSER and I decided not to make any soundings nor do any deep-sea work until we had passed beyond the lines of soundings already run by the *Albatross* and *Thetis* between California and the Hawaiian Islands.

[1] Abridged from a letter received by the U.S. Fish Commission from Prof. Alexander Agassiz, and published n *Science* of December 8.

In latitude 31° 10′ N., and longitude 125° W., we made our first sounding in 1955 fathoms, about 320 miles from Point Conception, the nearest land. We occupied 26 stations until we reached the northern edge of the plateau from which rise the Marquesas Islands, having run from station No. 1, a distance of 3800 miles, in a straight line.

At station No. 2 the depth had increased to 2368 fathoms, the nearest land, Guadeloupe Island, being about 450 miles, and Point Conception nearly 500 miles distant. The depth gradually increased to 2628, 2740, 2810, 2881, 3003, and 3088 fathoms, the last in lat. 16° 38′ N., long. 130° 14′ W., the deepest sounding we obtained thus far in the unexplored part of the Pacific through which we are passing. From that point the depths varied from 2883 to 2690 and 2776, diminishing to 2583, and gradually passing to 2440, 2463, and 2475 fathoms, until off the Marquesas, in lat. 7° 58′ S., long. 139° 08′ W., the depth became 2287 fathoms. It then passed to 1929, 1802, and 1040 fathoms, in lat. 8° 41′ S., long. 139° 46′ W., Nukuhiva Island being about 30 miles distant. Between Nukuhiva and Houa-Houna (Ua-Huka) islands we obtained 830 fathoms, and 5 miles south of Nukuhiva 687 fathoms. When leaving Nukuhiva for the Paumotus we sounded in 1284 fathoms about 9 miles south of that island. These soundings seem to show that this part of the Marquesas rises from a plateau having a depth of 2000 fathoms, and about 50 miles in width, as at station No. 29 we obtained 1932 fathoms.

The deep basin developed by our soundings between lat. 24° 30′ N., and lat. 6° 25′ S., varying in depth from nearly 3100 fathoms to a little less than 2500 fathoms, is probably the western extension of a deep basin indicated by two soundings on the charts, to the eastward of our line, in longitudes 125° and 120° W., and latitudes 9° and 11° N., one of over 3100 fathoms, the other of more than 2550 fathoms, showing this part of the Pacific to be of considerable depth, and to form a uniformly deep basin of great extent, continuing westward probably, judging from the soundings, for a long distance.

I would propose, in accordance with the practice adopted for naming such well-defined basins of the ocean, that this large depression of the Central Pacific, extending for nearly 30° of latitude, be named Moser Basin.

The character of the bottom of this basin is most interesting. The haul of the trawl made at station No. 2, lat. 28° 23′ N., long. 126° 57′ W., brought up the bag full of red clay and manganese nodules with sharks' teeth and cetacean ear-bones; and at nearly all our stations we had indications of manganese nodules. At station No. 13, in 2690 fathoms, lat. 9° 57′ N., long. 137° 47′ W., we again obtained a fine trawl haul of manganese nodules and red clay; there must have been at least enough to fill a 40-gallon barrel.

The nodules of our first haul were either slabs from 6 to 18 inches in length and 4 to 6 inches in thickness, or small nodules ranging in size from that of a walnut to a lentil or less; while those brought up at station No. 13 consisted mainly of nodules looking like mammilated cannon balls varying from 4½ to 6 inches in diameter, the largest being 6½ inches. We again brought up manganese nodules at the Equator in about longitude 138° W., and subsequently—until within sight of Tahiti—we occasionally got manganese nodules.

As had been noticed by Sir John Murray in the *Challenger*, these manganese nodules occur in a part of the Pacific most distant from continental areas. Our experience has been similar to that of the *Challenger*, only I am inclined to think that these nodules range over a far greater area of the Central Pacific than had been supposed, and that this peculiar manganese-nodule bottom characterises a great portion of the deep parts of the Central Pacific where it cannot be affected by the deposit of globigerina, pteropods, or telluric ooze; in the region characterised also by red-clay deposits. For in the track of the great equatorial currents there occur deposits of globigerina ooze in over 2400 fathoms for a distance of over 300 miles in latitude.

Manganese nodules we found south of the Marquesas also, where in 2700 fathoms we obtained, perhaps, the finest specimens of red clay from any of our surroundings. As we approached close to the western Paumotus, and rose upon the plateau from which they rise, globigerina ooze passed gradually to pteropod ooze, then to fine and coarse coral sand. In the channel south of the Paumotus to Tahiti the coral sand passed to volcanic sand mixed with globigerinæ in the deepest parts of the line, and towards Tahiti passed to volcanic mud mixed with globigerinæ, next to fine volcanic sand, and finally, at the last sounding, off Point Venus, to coarse volcanic sand.

We made a few hauls of the trawl on our way, but owing to the great distance we had to steam between San Francisco and the Marquesas (3800 miles) we could not, of course, spend a great deal of time either in trawling or in making tows at intermediate depths. Still the hauls we made with the trawl were most interesting, and confirmed what other deep-sea expeditions have realised: that at great depths, at considerable distances from land and away from any great oceanic current, there is comparatively little animal life to be found. Where manganese nodules were found the hauls were specially poor, a few deep-sea holothurians and ophiurans, and some small actiniæ which had attached themselves to the nodules with a few other invertebrates, seemed to be all that lived at these great depths, 2500 to 2900 fathoms, far away—say from 700 to 1000 miles—from the nearest land.

The bottom temperatures of the deep (Moser) basin varied between 34·6° at 2628 and 2740 fathoms, to 35·2° at 2440 fathoms, and 35° at 2475 fathoms; about 120 miles from the Marquesas. At station No. 23, off the Marquesas, in 1802 fathoms, the temperature was 35·5°.

On our way to Tahiti from the Marquesas we stopped a few days to examine the westernmost atolls of the Paumotus.

It is premature from the examination of the western extremity of the Paumotus to base any general conclusions regarding the mode of formation of these atolls; certainly as far as I have gone there is absolutely nothing to show that the atolls of the Paumotus have not been formed in an area of elevation similar to that of Fiji. The evidence in Rairoa and in the atolls of the western Paumotus is very definite. Makatea is an elevated mass of coralliferous limestone similar in all respects to masses like Vatu Vara, Thithia, and others in Fiji. Like them Makatea is surrounded by a comparatively narrow shore platform cut out from the base of the limestone cliffs and on the seaward extension of which corals grow abundantly to depths of seven to eight fathoms, when they appear to become very much less numerous. So that it is not unnatural, as I am inclined to do, to look upon the area of the Paumotus as one of elevation, the raised and elevated land of which has been affected much in the same way by denudation and erosion as have the masses of elevated coralliferous limestone of Fiji. Only there seems to have been, from the evidence thus far presented, a far greater uniformity in the height of the elevation of the Paumotus. This would render the explanation I have given less evident had I not the experience of the Fiji group to guide me. I am informed that there are other islands and atolls in the Paumotu group, showing traces of this elevation, so that I am at any rate justified in denying that the Paumotus as such are situated in an area of subsidence and that subsidence has been the great factor, as is maintained by Darwin and Dana, in the formation of the characteristic atolls of the group.

It may be well to point out also that the Paumotus, like the Marquesas on one side and the Society Islands on the other, are situated upon a plateau similar to that upon which the last-mentioned groups are placed—this plateau having a depth of from 1200 to 1500 fathoms, and rising from the general oceanic basin which surrounds them, and which has a depth of from 2300 to 2500 fathoms. Furthermore, evidence of this elevation is found at the two extremities of the Paumotu plateau at Makatea, an elevated island consisting of tertiary coralliferous limestone, and at the Gambier Islands, which are volcanic islands of considerable height.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

DR. T. E. STANTON, of University College, Liverpool, has been appointed professor of engineering in University College, Bristol, in succession to Prof. Ryan.

DR. EDWARD TAYLOR JONES has been appointed professor of physics in the University College of North Wales, in succession to Prof. A. Gray, F.R.S. The Drapers' Company has made the College a grant of £200 a year for a period of three years towards the maintenance of the department of electrical engineering, pending the establishment of the department on a permanent footing.

SCIENTIFIC SERIAL.

Bulletin of the American Mathematical Society, November.—Dr. G. A. Miller gives a short account of the meeting of the American Association for the Advancement of Science (held August 21–26) as it bore upon the Society, with a short abstract of some of the mathematical papers. A hope is expressed that the Society and the Society for the Promotion of Engineering Education may meet next year with sections A and D respectively of the Association.—Prof. Oskar Bolza reviews Harkness and Morley's introduction to the theory of analytical functions, and Prof. A. S. Hathaway discharges a like office for MacAulay's Octonions. Prof. Bolza considers the former work to be not only of high scientific and pedagogical value, but at the same time of a singular beauty and elegance. A certain freshness and originality pervade the whole, even in places where the authors follow along beaten tracks, and give at every turn evidence of the complete mastery of the subject with which the book is written.—Dr. Lovett gives a *résumé* of five recent theses in mathematics presented for the doctor's degree at the University of Paris. They are: Sur quelques points de la théorie des fonctions, by M. L. Desaint; Sur une classe particulière de groupes hyperabéliens, by M. H. Bourget; Sur l'intégration des équations de la chaleur, by M. E. LeRoy; Les équations différentielles linéaires de la théorie des groupes, by M. F. Marotte; and Essai sur une théorie générale de l'intégration et sur la classification des transcendantes, by M. J. Drach. In the copious mathematical "Notes," an account is given of the mathematical courses of lectures in the winter semester of several Continental and other universities.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, November 16.—"The Medusæ of Millepora." By Sydney J. Hickson, F.R.S.

The male medusæ were discovered in specimens of Millepora from Torres Straits in 1891. Since then no medusæ were seen in any specimens examined except in some from Funafuti collected by Mr. Gardiner, but these were also males and resembled in all essential respects the medusæ previously described. Last year Mr. Duerden sent to the author two consignments of preserved Millepora, one bearing immature and the other mature female medusæ. The immature female medusæ were about 0·4 mm. in diameter; the umbrella is a thin membrane slightly swollen at the margin containing no canals nor cavities of any kind. There is no velum and no tentacles. The umbrella cavity is almost entirely filled with a swollen manubrium bearing a centrally placed mouth and a broad band of ova. The mature female medusæ are 0·6 mm in diameter; three or four ova attain to a size of 0·2 mm. in diameter, the others undergo degeneration or become absorbed into the substance of the large ova. The endoderm of the manubrium is still very thick and vacuolated, but the mouth is usually closed. After the discharge of the medusæ from the corallum the ova become more vacuolated and increase in size to 0·25 mm. in diameter, the general appearance of the eggs being similar to that of the floating eggs of other Cœlenterates.

The medusæ were observed in the living state by Mr. Duerden, who describes them as being sluggish in their movements, feebly pulsating only now and again. Soon after they are set free the eggs are discharged one by one. The whole process, liberation of the medusæ and extrusion of the ova was completed in five or six hours.

Royal Society, December 14.—"The Piscian Stars." By Sir Norman Lockyer, K.C.B., F.R.S.

The classification of the Piscian stars (those in the spectra of which there are dark flutings of carbon) was arrived at nearly ten years ago from the observations of Dunér. The investigation indicated that these stars could be grouped into several distinct species, in the same way as those of Group II. (Antarian stars) which the author had already classified (*Roy. Soc. Proc.*, vol. xliv. p. 65, 1888).

Owing to the want of definite information regarding the line spectrum, the publication of the classification was postponed. Facts bearing on the line spectrum have now been furnished by the recent photographic work of McClean and Hale, and as these do not disturb the classification at which the author had previously arrived, it is unnecessary to further delay the publication of the memoir, which in the main stands as it was written. The original paper is supplemented by reference to the more recent work. The general conclusions arrived at are as follows:—

(1) The undoubted presence of carbon flutings in the sun, including that near *b*, and of solar lines in the Piscian stars, indicates that the Piscian stars are next in order of development to the Arcturian stars.

(2) The stars observed by Dunér may be divided into seven species, beginning with the hottest and ending with the coolest stars.

(3) The reported presence of bright lines in the Piscian stars must be received with caution, as similar evidence of bright lines might be adduced in the case of other classes of stars in which the spectrum is fully explained by dark lines alone.

(4) The redness of the stars increases as we pass from the earlier to the later species of the group.

(5) The variability in this group is less marked than in the Antarian stars, and may perhaps be accounted for by the revolution of secondary bodies of the nature of comets round the stars themselves.

(6) The place on the temperature curve assigned to these stars on the meteoritic hypothesis is fully confirmed by the more detailed inquiry, and the hypothesis is thereby strengthened.

Linnean Society, December 7.—Dr. A. Günther, F.R.S., President, in the chair.—Dr. Otto Stapf, exhibited specimens of Malayan and African species of *Kickxia*, Blume, to show the differences which exist between the two forms. These differences were noticeable in the shape and size of the corolla, the insertion and general relation of the stamens to the tube of the corolla, the placentation, the structure of the fruit, and the general habit of the plants. As the name *Kickxia* would have to be retained for the Malayan species, he proposed the name *Funtumia* for the African species, from *Funtum*, a vernacular name for *F. elastica*. He further pointed out, by means of flowering and fruiting specimens of *F. africana*, Stapf (*Kickxia africana*, Benth.), and of *F. elastica* (*Kickxia elastica*, Preuss), that the latter, and not the former (as was originally assumed), was the source of the so-called Lagos rubber, thus confirming the conclusion to which Dr. Preuss had come with regard to the origin of this rubber.—Dr. Stapf also showed, on behalf of the Director of Kew Gardens, a large infrutescence of *Musa Ensete*, Gmel., lately received from the Azores.—Mr. Gilbert Christy exhibited a preparation of india-rubber by a new process from *Castilloa elastica*, and also specimens of rubber obtained from *Kickxia elastica*.—Mr. A. D. Ferguson exhibited a series of photographic views taken in Demerara.—Mr. J. W. Fawcett read a paper on some vegetable poisons used for the capture of fish by the Aborigines of Australia.—Mr. B. Daydon Jackson pointed out how widespread was the practice of obtaining fish in this way, and gave a brief review of the literature bearing on the subject.—A paper was read by Mr. G. M. Thomson on some Schizopod Crustacea from New Zealand, in which a new genus (*Tenagomysis*) and some new species were described.—Mr. O. A. Walker, in criticising the paper, made some remarks on general distribution, and, in view of the paucity of material which existed, deprecated any attempt being made at present to draw general conclusions.—Mr. H. M. Bernard read a paper on the structure of *Porites*, the smallest of the stony corals.—In a former paper (*Linn. Soc. Journ.*, *Zool.* vol. xxvii. p. 127) he had endeavoured to show that the genus could be deduced from Madreporids as fixed young forms, so young that the skeleton was immature. The small size of the animals, and the fine reticular texture of the skeletal mass, may both be adaptions to their surroundings, for they are most frequently found at the outer edges of the reef and have to bear the full force of the breakers. Since reading his previous paper the author had been fortunate enough to discover the directive plane and the bilateral symmetry of the calicles in *Porites*—very difficult to see, but when once seen recognisable in nearly every specimen. By means of diagrams the variations of the septal system within the genus were described, and the pali were shown to appear in a regular system dependent upon the the fusions of the septa, which fusions always occurred in a definite order.

Mathematical Society, December 14.—Prof. Elliott, F.R.S., Vice-President, in the chair, and subsequently Dr. Macaulay and Dr. Larmor, F.R.S.—The following papers were communicated, in part, by their authors, viz.: (1) A method for extending the accuracy of mathematical formulæ; (2) Central difference formulæ, by Mr. W. F. Sheppard; Circular cubics, by Mr. Basset, F.R.S.; the theorem of residuation, being a general treatment of the intersections of plane curves at multiple points, by Dr. Macaulay.—The remaining papers were communicated by their titles, viz.: The genesis of the double Gamma functions, Mr. E. W. Barnes; on the expression of spherical harmonics as fractional differential co-efficients, Mr. J. Rose-Innes; and sums of greatest integers, by Mr. G. B. Mathews, F.R.S.

Royal Meteorological Society, December 20.—Mr. F. C. Bayard, President, in the chair.—Mr. Baldwin Latham read a paper on the climatic conditions necessary for the propagation and spread of plague. The bubonic plague is primarily due to a specific organism or microbe of infinitesimal size—so small that probably 250 millions of them would be required to cover a square inch of surface. Plague is infectious and contagious, and is greatly influenced by pestilential emanations from polluted and waterlogged soils. The author gives accounts of various outbreaks of plague in this and other countries, including the great plague of London in 1665, when 7165 deaths were recorded in one week in September. Plague is undoubtedly a disease of the poor, and attacks most readily those living on a low diet. The conditions which are conducive to the spread of plague are identical with those which give rise to the escape of malaria from the ground. That the ground itself exercises an enormous influence upon plague is shown by the fact that in all the epidemics persons living on the ground floors suffer to a much greater extent than those who live in the higher storeys of the houses. Mr. Latham says that there cannot be a doubt that the conditions which ordinarily produce evaporation from water or land surfaces are identical with those which produce exhalations from the ground; and these exhalations consist largely of vapour of water carrying matters injurious to health with them. Mr. Latham has discussed the meteorological observations (including the temperature of the soil at the depth of 9, 20, 60 and 132 inches), made at the Colaba Observatory, Bombay, and has compared them with the number of deaths from plague during the recent epidemics in Bombay. He says that if the temperature of the air increases beyond the temperature of the ground, so that its dew-point is above the temperature of the ground, condensation takes place instead of evaporation. To this increased high temperature may be due the sudden stoppage of plague after a certain high temperature has been reached, which, by raising the temperature of the dew-point, stops all exhalation from the ground and may cause condensation to take place instead of evaporation. So also a sudden fall of temperature causes plague to arise; for a fall of temperature means that the temperature of the dew-point must fall, and the tensional difference between a low dew-point and a high ground temperature would at once lead to exhalations escaping in large quantities from the ground, and so lead to the liberation of the plague bacillus from the ground, accompanied with the exhalations necessary for its development.—Dr. R. H. Scott, F.R.S., communicated a note on a remarkable dust haze which was experienced at Teneriffe, Canary Islands, on February 16 to 19, 1898. The haze during this period was exceptionally dense, so much so that a steamer was two days and three nights on a voyage from Teneriffe to Las Palmas, a distance she usually covered in five hours; while the *Tintagel Castle*, of the Donald Currie line, was delayed for thirty hours, and the *Roslin Castle*, homeward bound, had the dust so thick that for 900 miles the sun and stars were obscured, and the ship was delayed two days.

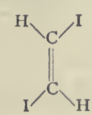
Zoological Society, December 19.—Dr. Henry Woodward, F.R.S., Vice-President, in the chair.—The Secretary read a report on the additions that had been made to the Society's Menagerie during the month of November 1899, and called special attention to two snake-fishes (*Polypterus senegalus*) from the River Gambia, obtained by Mr. J. S. Budgett, F.Z.S., during his recent expedition to the Gambia, and presented by him on November 22. These were believed to be the first examples of this fish ever brought alive to Europe.—On behalf of Mr. G. S. Mackenzie, a photograph was exhibited of two remarkably large tusks of the African Elephant. They each measured, on the outside curve, 10 feet 4 inches in length, and weighed respectively 235 lbs. and 225 lbs.—Mr. Sclater exhibited, on behalf of Mr. Alfred Sharpe, C.B., a portion of the skin of a giraffe which had been shot on the east bank of the Great Loangwa River, British Central Africa, in latitude 13° south, and which, according to Mr. de Winton, who had examined it, was undoubtedly referable to the southern form of this mammal.—Mr. Sclater also exhibited photographs of two young male musk-oxen (*Ovibos moschatus*), now living in the Duke of Bedford's park at Woburn. The animals were stated to have been obtained in Eastern Greenland. They were believed to be the first examples of this species that had reached Europe alive.—Mr. W. E. de Winton exhibited and made remarks upon a specimen of a new mouse of the genus *Dendromys*, obtained by Lord Lovat at Managasha in Southern Abyssinia, for which he proposed the name *Dendromys lovati*.—Mr. R. E. Holding exhibited a series of the horns of the Siberian roebuck (*Capreolus pygargus*) from the Obb River, and made remarks upon the characteristic variation in the horns of this species. Mr. Holding also exhibited a pair of the horns of a stag, from the same district, probably *Cervus eustephanus*, in which the third tine was absent in both horns.—Dr. Forsyth Major exhibited the fœtal skulls of various Malagasy lemurs, showing the development of the osseous tympanic bulla, in which the tympanic ring did not participate. The tertiary *Adapis* in this and other features closely approached the Malagasy lemurs.—He also exhibited an almost complete skull of a new species of *Nesopithecus* (*Globilemur*).—Mr. W. L. Sclater made some remarks on a forthcoming series of volumes which he proposed to issue under the title of "The Fauna of South Africa." The first volume, which was now nearly ready, and would deal with the first half of the Passerine birds, had been undertaken by the late Dr. A. C. Stark. The volume on the mammals, by Mr. Sclater himself, was now in the printer's hands, and would also shortly be issued.—Mr. W. P. Pycraft read the fourth part of his "Contributions to the osteology of birds," which dealt with the grebes and divers (*Pygopodes*). The author considered that the grebes and divers were closely related *inter se*, that they could not be associated with the auks, as had been done by some ornithologists, but were more nearly allied to the tubinares, impennes, and steganopodes. The author also stated that he was of opinion that *Hesperornis* undoubtedly belonged to the suborder pygopodes.—Mr. F. G. Parsons read a second portion of a paper "On the myology of the edentata," prepared by Prof. B. C. A. Windle, F.R.S., and himself. It dealt with the muscles of the hind limb, and also contained a summary of the conclusions that the authors had arrived at respecting the musculature of the order.

CAMBRIDGE.

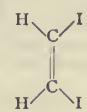
Philosophical Society, November 27.—Mr. Larmor, President, in the chair.—On the influence of temperature, and of various solvents, on the absorption spectra of Didymium and Erbium salts, by Prof. Liveing. Prof. Liveing exhibited a number of photographs prepared to illustrate his paper on the absorption spectra of solutions of salts of Didymium and Erbium in various conditions of dilution and temperature, and in various solvents, which was communicated to the Society at the Stokes Jubilee meeting. These photographs showed that dilution produced no increase of the intensity of the absorptions when the thickness of the absorbent was proportioned to the dilution. In strong solutions of the chlorides a diffuse continuous absorption creeps down the spectrum from the most refrangible end and extends further as the solution is more concentrated. This is not seen with most chlorides, not even with that of aluminium, but is shown by strong solutions of hydrochloric acid in water and in alcohol. The nitrates show a somewhat similar general absorption, and also a widening of some of the bands as the solutions become more concentrated. The effect of acidifying the solutions is to make the absorptions generally more diffuse, but not sensibly to weaken them, and to extend the general absorptions at the most refrangible end. A rise of temperature from about 20° C. to 97° or 98°, also makes the bands more diffuse, but does not increase their intensity. It seems to the author improbable that the metallic atoms should maintain such independence in combination as to have the same absorptions in such different compounds as chloride, nitrate and sulphate, and it is more probable that the common absorptions are due to common products of decomposition. These might be the metallic ions, but the facts that neither dilution nor rise of temperature increase the intensity, and that acidifying does not weaken the intensity of the common absorptions are against that supposition. Ionization implies an electrification of the ions, which again implies a communication of energy to the field, which may probably depend on the circumstances of the encounter when the molecule of salt is broken up, and so some molecules may be broken up without being charged; while there is no reason to suppose that the absorption by a molecule would be altered by its being charged with electricity. The absorptions which are intensified by concentration and also by heat must be ascribed to the condition of the molecules during encounters, which will be more frequent in more concentrated as well as in hotter solutions. The expansion of certain bands with increased concentration by the nitrate, must be ascribed to encounters of molecules derived from the metal with those derived from the acid, which are much more massive than the molecules of water and also than those derived from the chloride. During such encounters the absorbent molecules will be as it were loaded by the influence of the other molecules. This view seems confirmed by the influence which other solvents and other acids have on the absorptions. Didymium chloride in alcohol gives the same bands as the aqueous solution, but generally more diffuse and more or less shifted a little towards the red. The same solution acidified with hydrochloric acid exaggerates greatly these modifications, almost washing out the more refrangible bands and breaking up the very strong band in the yellow into several separate bands. Glycerol as solvent gives modifications similar to, but more strongly marked than, those of alcohol. The acetate in acetic acid and the maleate in water gives similar but much less marked modifications. The tartrate and the citrate in ammoniacal solution also give similar modifications. The borate in solid glass of borax also gives bands which are unmistakably modifications of those produced by the aqueous solution. All these modifications seem to be of the same *character*, though of greater intensity, than the differences between the bands given by nitrate and chloride, and may be attributed to the influence of the comparatively complicated influences of the various molecules during the times of encounter. In such cases as the acid alcoholic solutions there will certainly be at least four chemical compounds mixed in the solvent, which may well produce a complicated modification of the bands without destroying their identity.—"Researches in the Sugar Group," by H. Jackson. A summary is given of the joint researches of Mr. H. J. H. Fenton and the author, which may be conveniently divided into two parts. (α) Oxidation of the more common polyhydric alcohols. The remarkable part which iron plays as a carrier of oxygen was first pointed out by Mr. Fenton in the case of tartaric acid, and has since been extended by him to other hydroxy-compounds. An aqueous solution of the following polyhydric alcohols, glycol, glycerine, erythrite, dulcite, mannite and sorbite, was taken in turn, and after adding a small quantity of ferrous salt to each, hydrogen peroxide was added: in all cases a large evolution of heat took place. The oxidation products in the case of glycol, glycerine and erythrite quickly reduce Fehling's solution in the cold and restore the colour to an alcoholic solution of magenta, which has been decolourised by sulphur dioxide: on treatment with phenyl hydrazine acetate, osazones were obtained which, on analysis, were found to correspond respectively to glycolic aldehyde or diose, glycericaldehyde or triose, and erythrose or tetrose. The oxidation compounds of dulcite, mannite and sorbite do not reduce Fehling's solution in cold, but quickly on warming: they do not give the "magenta" test; facts which serve to distinguish the hexoses from the simpler members of the sugar group. On treatment with phenyl hydrazine acetate there was obtained from dulcite the osazone of inactive galactose, from mannite the hydrazone of mannose, and from sorbite an osazone identical with glucosazone. If an aqueous solution of glycol, glycerine or erythrite, to which a very small quantity of ferrous salt has been added, be exposed for a little time to the action of sunlight in the presence of atmospheric oxygen, it can be shown on examination that a certain amount of the sugar has been formed. These experiments may perhaps give a little support to the theory that iron, which occurs in hæmoglobin and is associated so intimately with chlorophyll, may act as a carrier of atmospheric oxygen. (β) Isolation of diose in a crystalline state and its condensation to a hexose. When dioxymaleic acid, suspended in water, is distilled on the water bath under very diminished pressure and the distillate evaporated to small bulk in a vacuum desiccator, a syrup is left which on standing crystallises out in flat plates of the oblique system. On analysis and examination it is shown to be crystalline diose. A determination of its molecular weight by the depression of the freezing point of water shows the crystal to be bimolecular, but on standing and taking frequent determinations the molecular weight gradually becomes normal and corresponds to the single formula $C_2H_4O_2$, and then remains quite constant. If a dilute aqueous solution of diose be treated with a 1 per cent. solution of soda at the ordinary temperature it quickly turns yellow and finally brown. After standing a few hours it no longer reduces Fehling's solution in the cold, but readily on warming: it no longer gives the "magenta" test: in fact, it has lost all the properties of diose and assumed those of a true hexose. This is confirmed on examining the osazone, which corresponds to a normal hexosazone. The melting point and action towards solvents of the osazone prove its identity with β acrosazone, which Fischer and Tafel isolated from the condensation product of glycerose.—On a new mineral by A. Hutchinson. A colourless transparent crystal of the new mineral was found on a specimen of Axinite from Cornwall in the Carne collection recently acquired by the University. The crystallographic and optical constants of the crystal prove it to belong to the Prismatic system. The results of a quantitative chemical analysis agree well with the formula $CaSn(SiO_3)_3.2H_2O$. The mineral has been named Stokesite in honour of Sir George Gabriel Stokes.—On the condition that five lines in space of four dimensions should lie on a quadric, by H. W. Richmond. In order that five straight lines situated in a space of four dimensions should lie on a surface of the second order a condition must be satisfied. It is here pointed out that the known properties of quadrics in space of five dimensions suggest a simple mode of expressing the necessary condition.

ST. LOUIS.

Academy of Science, December 4.—Dr. Edward H. Keiser described some derivatives of acetylene, exhibiting specimens of the new liquid acetylene iodide discovered by him in January, 1899. He described the methods of making the compounds, and gave an account of its chief physical and chemical properties. The liquid acetylene di-iodide solidifies at $-21°$ C. and boils at 185°. It has the percentage composition and molecular weight represented by the formula $C_2H_2I_2$, and is isomeric with the well-known solid acetylene di-iodide. The speaker announced the discovery of a new method of making the liquid acetylene di-iodide, namely, by heating the solid compound to 260° in a sealed tube. The solid compound is thereby partially converted into the liquid compound. Similarly, if the pure liquid di-iodide be heated to 260° in a sealed tube, on cooling down the liquid will be found to have been partially converted into the solid compound. All the facts known indicate that these two iodides of acetylene are stereoisomers, and that their configuration must be represented by the stereometric formulas



and



Since Dr. Keiser has found that the solid acetylene di-iodide can be converted into fumaric acid, it would follow that the first of the two formulas would represent the solid acetylene di-iodide and the second one the liquid di-iodide. Further experiments upon these compounds are under way, and the attempt will be made to convert the liquid di-iodide into maleic acid.—Dr. K. Bremer demonstrated some tests for glucose by means of aniline dyes, showing that nearly all of the "alkaline" aniline dyes, when rendered basic by the addition of sodium hydrate, become decolourised, or have their colour greatly modified, on heating, in case glucose is present. The reactions shown were especially pretty in the case of methylene blue and safranine.—Prof. Nipher announced that he had nearly completed preparations for the measurement of wind pressures on the sides of the main building of Washington University. The pressures are to be measured at various points along the west end of the building, having a width of about 50 feet, and along the north front, which is something over 200 feet in length. Simultaneous measurements of wind pressure, and wind velocity and direction will be made. The method used is that tested by him on the trains of the Illinois Central Railroad during the summer of

1897. The method was described in No. 1, vol. viii. of the *Transactions* of the Academy of Science of St. Louis. An invitation was extended to members to visit the University and inspect the apparatus.—Prof. H. Aug. Hunicke spoke briefly on some observations which he had recently made on the boiling temperature of hydrocarbons, from which it appeared that when T is the boiling temperature (absolute scale), ρ is radius of gyration of the molecule, and α is a constant, then $T^2 = \alpha\rho$. This holds for the entire series of saturated hydrocarbons, including all isomers.

AMSTERDAM.

Royal Academy of Sciences, November 25.—Prof. Van de Sande Bakhuyzen in the chair.—Prof. Kamerlingh Onnes read, on behalf of Prof. Lorentz and himself, a report on the treatise by Prof. R. Sissingh, entitled "The general properties of the optical image by central rays in a series of centred spherical surfaces." The conclusion, arrived at in the report, viz., to insert the treatise in the *Transactions* of the Academy, was approved. Dr. Hamburger made a communication concerning the absorption of fat and soap in the large and the small intestine. (1) It may now be considered as settled that the large intestine of the dog possesses the power of absorbing fat. (2) Contrary to what has hitherto been assumed, this power is considerable and not even inferior to that of the small intestine. (3) To bring about such a considerable absorption, it is necessary to take an emulsion which will keep a long time in the intestine. The usual Na_2CO_3 is not suitable for preparing such an emulsion, much less NaCl, because both are absorbed quickly and the emulsion consequently soon ceases to exist. A solution of sapo medicatus, however, appears to answer the requirements. (4) As regards the soap solution itself, it appears that it is absorbed, though much more slowly than Na_2CO_3, and that during the absorption it is, partly at least, converted into fat already in the mucosa. This conversion goes on in the severed intestine, nay, it is even effected when the mucosa has been chopped up. Heating to 80°, however, destroys the above mentioned property. (5) As regards the course, taken by fat during absorption in the large intestine, it is very likely that part of it is carried off by the blood capillaries. At any rate in the case of the small intestine, this has been proved beyond a doubt by the above described experiments.—Prof. Cardinaal made a communication concerning an application of the involutions of a higher degree.—Prof. W. Kapteyn made a communication on certain particular cases of Monge's differential equation. All these communications will be inserted in the *Proceedings*. The following were further presented for insertion in the *Proceedings*. (*a*) By Prof. Bakhuis Roozeboom, two papers, by Dr. Ernst Cohen, entitled respectively: (1) The enantiotropy of tin (III.), and (2) The alleged identity of red and yellow mercuric oxide. (*b*) By Prof. Lobry de Bruyn: (1) On behalf of Mr. W. Alberda van Ekenstein and himself, a paper on *d*-sorbinose and *l*-sorbinose (ϕ-tagatose) and their configuration. The inquiry into *d*-sorbose has shown that this ketose possesses the following configuration formula: $CH_2OH—CO—\underset{OH}{\overset{H}{C}}—\underset{H}{\overset{OH}{C}}—\underset{OH}{\overset{H}{C}}—CH_2OH$. On reduction it yields, besides *d*-sorbite, *d*-idite as well; its osazon is identical with idosazon and gulosazon. ϕ-tagatose, a new ketone, which, besides tagatose, is obtained from galactose, under the transforming influence of alkalis, has been found to be the optical antipode of *d*-sorbose, consequently *l*-sorbose with the configuration $CH_2OH—CO—\underset{H}{\overset{OH}{C}}—\underset{OH}{\overset{H}{C}}—\underset{H}{\overset{OH}{C}}—CH_2OH$. A detailed article on this subject will appear in the *Recueil*. (2) On behalf of Mr. J. J. Blanksma, a paper on the action of sodium mono- and disulphides on aromatic nitro compounds. The inquiry has proved that a nitro group of *o*-dinitrobenzol is easily replaceable, and that dithio combinations are formed (also obtained from chlorine nitrobenzol and bromine nitrobenzol), which on oxidation yield sulphonic acids. (*c*) By Prof. J. C. Kapteyn, on behalf of Mr. S. L. Veenstra, a paper on the results of his inquiries into systematical corrections of the stars' own motions in Auwer's Catalogue of Bradley and the coordinates of the apex of the sun's motion. The computations are founded on data, derived from a still unpublished catalogue, compiled by Prof. Kapteyn, which contains, besides the motions of the Bradley stars, a number of auxiliary magnitudes. The result of the computation of the apex does not point to a relative motion of stars of different spectral types. (*d*) By Dr. J. P. van der Stok, a paper on two earthquakes, observed respectively at Batavia and in Europe. (*e*) By Prof. Van der Waals, on behalf of Dr. G. Bakker, a paper on the potential functions $\phi(r) = \frac{Ae^{-qr} + Be^{qr}}{r}$ and $\phi(r) = \frac{A \sin(qr + \alpha)}{r}$, and Van der Waals' potential formula.

PHYSIOLOGY VERSUS *NATURAL SELECTION: AN UNNATURAL ANTITHESIS.*

Colour in Nature: a Study in Biology. By Marion I. Newbigin, D.Sc. (Lond.). Pp. xii + 344. (London: John Murray, 1898.)

THE authoress states in the preface that her object is "to set forth in systematic order the main facts at present known in regard to the Pigments and Colours of Plants and Animals," and especially to treat the physiological side of the subject, and bring together the scattered literature which deals with it.

The first three chapters are introductory, dealing with general questions of importance for the remainder of the work—such as the differences between pigmental and structural colours, and the classification of both these categories. Colours and pigments are then considered throughout the plant and animal worlds, the subjects treated in consecutive chapters being plants; Protozoa sponges and Cœlentera; worms; Crustacea and Echinodermata; Lepidoptera; insects in general and spiders; Mollusca and invertebrates generally; fish; amphibians and reptiles; birds (occupying two chapters); mammals and the origin of pigments. The concluding chapter "on the relation of facts to theories" contains a general summary and a brief exposition and criticism of various theories as to the origin of colour. The list of references, admitted to be incomplete, will nevertheless be useful, although it is to be hoped that in a future edition mention will be made of Colonel Swinhoe's complete paper "On the Mimetic Forms," &c., in the *Linnean Journal*, instead of to the brief abstract in the *Proc. Roy. Soc.*

The writer again and again protests against the interpretation of colour phenomena by natural selection, and implies that those who incline to accept this interpretation are satisfied with casual suggestions which they make no attempt to test. The present writer believes that the exact opposite is the truth, and that in the whole history of biological thought no theoretical suggestions have been so fruitful of extended and precise observations as those based upon this very hypothesis.

Whenever a writer ventures to suggest such an interpretation, it is assumed by opponents that he is satisfied to leave the matter at this point without the thought of any further investigation by way of confirmation. This is an assumption, and a most unfair assumption. Those who have found natural selection a sure guide to research, who cannot pursue all the varied lines which it indicates, are glad to offer the same inspiration to other workers. "A few magic words upon natural selection" (p. 24) are not intended to "dismiss" any problem in natural history, but rather to suggest lines of research by which it may be attacked.

It is interesting to note that this extremely critical attitude as regards natural selection is not accompanied by any special reticence in the use of other hypotheses. Thus, as regards birds and butterflies, "the fact of the exquisite structural coloration and a wonderful development of structures arising from the cuticle, suggests that the structural colours are merely a result of extreme differentiation of the cuticle, and therefore produced by the same cause which gave rise to this differentiation" (p. 11).

Again, on p. 155, the persistence of green pigments derived from the larval food into the ova (and, in fact, into the young which hatch from them) is quoted from the present writer; and the authoress then proceeds to suggest that the green colour found by Mr. F. Gowland Hopkins in the *Pierinae* is of the same kind. This unsupported suggestion is very probably sound, and had been independently arrived at by the present writer, who is also inclined to extend it to the green pigments doubtless derived from the blood (hæmolymph), which are stored, as in the *Pierinae*, between the two wing membranes, and give rise to the bright green or sometimes blue-green bands or spots in certain *Nymphalinae* (*Colaenis dido*, *Victorina steneles*) and *Papilioninae* (*P. sarpedon*, &c.). Such a suggestion is reasonable, and may well lead to specially directed research; but a similar spur to inquiry, if based on the theory of natural selection, would have been held up to contempt by the authoress.

The freedom with which even flimsy and worthless speculation is indulged in, if only an explanation founded on natural selection can be thereby avoided, is well seen on pages 161 and 162, where the warning colours of *Heliconidae* and the mimetic or convergent *Pierinae* are briefly discussed. The writer suggests that the slow flight and warning colour of *Heliconidae* and their mimics are due to "the relatively low organisation which renders pigmentation by waste products possible, which makes brilliant optical colours impossible."

First, as to "low organisation," the Insecta are admittedly among the most specialised of animals; excepting the Diptera there are no more specialised insects than the Lepidoptera; among Lepidoptera the *Ithomiinae* (Bates' *Danaoid Heliconidae*, Trimen's *Heliconoid Danaidae*) are the most specialised, and the *Heliconinae* proper (Bates' *Acraeoid Heliconidae*) only less so.

Secondly, as to "pigmentation by waste products," Mr. Gowland Hopkins' observations prove that the pigments of the *Heliconidae* are *not* the same as those of the Pierines which resemble them. The latter alone have been shown to possess wing pigments of uric acid or substances allied to it.

Thirdly, as to brilliant optical colours being rendered impossible. There are numerous examples of iridescence in *Ithomiinae*, and some structural blues in the far less numerous *Heliconinae* proper, while in the *Danainae* which are closely related to the former the structural blues of many much-mimicked *Euploeina* are magnificently developed.

The writer is apparently desirous of rejecting an interpretation which explains an immense body of facts, and has led to the discovery of an immense number more, in order to substitute a crude suggestion which, for its mere statement, requires the distortion of many well ascertained facts.

It is only fair to add, however, that the writer recognises and clearly points out the obvious difficulty that the resemblances in pattern are not to be explained by her hypothesis.

Similar bias is shown in the prominence given to unimportant and often partisan statements; while the original evidence on which an opposite conclusion has been based is neglected or barely alluded to.

Thus, referring to the variable coloration of caterpillars, we read on p. 147: "According to recent research, it is not so much the colour of the environment which directly affects the larvæ as the intensity of the light" (see Garbowski). To the conclusive experiments upon which an opposite contention is based no allusion is made, the bias of the writer permitting nothing more than a vague reference to "popular books besides those already mentioned." But, on the strength of the statement quoted above, we are treated with reflections upon the errors of a simple explanation in biology.

Again, on p. 325, in reference to the artifically produced variations in the colours of butterflies, we are told that "competent entomologists (*e.g.* Garbowski) are of opinion that the new colours have little or no phylogenetic importance," without the slightest indication that highly competent authorities have given very good reasons for an opposite conclusion. In fact, if the writer agrees with an authority, it is sufficient to quote his opinion without his reasons, and, above all, without any of the reasons which point in another direction.

The references to Piepers' easily answered and often superficial objections to the theory of mimicry (pp. 316–321) are given at considerable length, and the reader unacquainted with the subject might well suppose, from the writer's concluding remarks, that serious difficulties had been raised.

In a similar spirit the writer speaks of "the (by hypothesis) well-protected *Heliconidae*" (p. 149), thus assuming an assumption on the part of those who seek an interpretation based upon natural selection, and neglecting the considerable body of evidence, direct as well as indirect, which has been brought together.

The use of the contemptuous "so-called" occasionally recalls the jest about the "so-called nineteenth century."

The statement of the procedure of the Darwinian school (p. 306), in attempting to solve the problems of colour, is the merest travesty, quite unworthy of serious comment.

Apart from the obvious bias of the writer in dealing with natural selection, of which numerous other examples might have been adduced, the work is likely to be useful. The most interesting and valuable parts are those dealing with subjects which the authoress has herself investigated, such as the structural colours of birds' feathers. The book is, in fact, not a well-balanced and judicial account of the subject, "Colour in Nature," but an interesting exposition of those parts of her subject with which the authoress is in sympathy, other parts being either distorted or omitted. In the former category would doubtless be placed the interpretation of external colour, as the expression of internal structure, of which a single example is given on p. 226, and it is therefore remarkable that no reference is made to the numerous examples which the late Alfred Tylor was accustomed to explain in this manner.

The book is clearly printed, with few printer's errors, and the small number of simple illustrations sufficiently explain the writer's meaning. E. B. P.

THE GROWTH OF ANIMAL AND VEGETABLE ORGANISMS.

Experimental Morphology. By Charles Benedict Davenport, Ph.D., Instructor in Zoology in Harvard University. Part 2. Pp. xviii + 281 to 508. (New York: Macmillan Company; London: Macmillan and Co., Ltd., 1899.)

THE second part of Dr. Davenport's work—the first part appeared two years ago and was noticed in NATURE, October 14, 1897—deals exclusively with the effect of chemical and physical agents upon the growth of animal and plant organisms. In the preface the author draws attention to the importance of the study of the conditions which affect growth. "The possibility of increasing the human race beyond limits that are not far off depends upon a better knowledge of the conditions of growth. The reader has only to consider that the world's supply of 2500 million bushels of wheat, 2000 million bushels of maize, 90 million tons of potatoes, and its untold millions of tons of beef, pork, and fish are reproduced each year by growth." This importance has recently been emphasised by the remarkable result of Sir William Crookes' researches into the statistics of the world's wheat supply as set forth in his presidential address at the Bristol meeting of the British Association, and the controversy to which that address has given rise. Dr. Davenport selects as his definition of growth "increase in volume," a definition which is by no means safe from criticism. Although we all think we understand what is meant when growth is spoken of, biologists have been by no means in agreement as to how exactly it should be defined. Thus, as the author points out, while Huxley spoke of growth as "increase in size," Sachs regards the volume increase as necessarily intimately associated with change of form, while Pfeffer takes the qualifying part of Sachs' definition, and defines growth as change in form only, and this is accepted by Vines, who adds: "accompanied usually by increase in bulk." To us this definition appears far more satisfactory, even if it is associated with the idea of development, than the more limited definition adopted by Davenport. In the animal organism especially is it difficult to exclude the idea of change of form in association with growth, nor does it seem reasonable to place a mere swelling due to imbibition of water or to distension with gas upon the same footing as a new formation of bioplasm.

The book before us is, however, almost entirely concerned with vegetable organisms, in which, no doubt, the imbibition of water plays a much more important part in the process of growth than it is apt to do in animals. And as a matter of fact the percentage of water in many animal embryos undergoes a steady decrease as development and growth proceed.

With regard to the effect of chemical agents upon growth, one of the most interesting parts of the work is that dealing with the supply of nitrogen to growing plants, whether it be offered to them in the form of a salt (nitrate) added to the soil, or, as occurs in Leguminosæ, in the form of atmospheric nitrogen, fixed for their assimilation by the symbiotic bacteria at their roots.

Chemotropism, or the effect of chemical agents upon the direction of growth, and heliotropism (phototropism), or the effect of light upon the direction of growth, both receive their due share of attention. The effect of water upon growth is treated separately from that of other chemical agents, this amount of attention being accorded it on account of its immense importance—especially in plants—in the process. The effects of contact with solids and that of molar agents in general are duly considered, and the chapter devoted to them includes subjects so diverse as the results upon the growth of bacteria by violently shaking the vessel containing them, the tendency of twining stems and tendrils to grasp the solid objects with which they come in contact, the effect of wounds upon the growth of plants, and even the effect of flowing water in influencing the direction of growth. The effect of gravity upon the growth of sessile organisms (geotropism) and the results obtained by neutralising this effect by the employment of the klinostat is also considered, and illustrated by numerous diagrams. The effect of atmospheric electricity in increasing the rate of growth was supposed to be demonstrated by the experiments of Grandeau, who reared two similar plants—one in the open, and the other with an enclosure of wide-meshed wire netting—with a marked balance in favour of the one which was exposed freely to the influence of any electricity which might be present in the atmosphere; but others have obtained negative or discordant results.

The effect of heat in influencing the growth of organisms is familiar to every biologist, and Dr. Davenport illustrates it by numerous tables and charts taken from observations upon both plants and animals. It is indeed impossible here so much as to enumerate all the different aspects from which the subject of growth has been studied, and to which reference may be found; and although the book does not profess to be anything more than a compilation, and, in fact, contains no matter which is entirely original, it is that sort of compilation which will be of most use to the student of biology, as indicating to him where he may at once come across the work which has been done in each department of the subject of which it treats. That the information yielded should include everything upon so vast a subject is too much to expect in a book of less than five hundred by no means closely printed pages, and, in fact, one occasionally misses a reference to work of no little interest and importance, such as that of Ringer upon the influence of mineral salts upon the growth of tadpoles, and of Romanes upon the comparative effects of flash light and steady light in producing phototropism in seedling plants. Neither is the subject of the influence of drugs considered at anything like the length which its importance seems to deserve. Nevertheless, for the reasons indicated, and because the book is a painstaking and, on the whole, a successful attempt to furnish a connected account of an important branch of experimental morphology, it will be welcomed by the many workers who are devoting themselves to the pursuit of this interesting class of investigation.

A BOOK ON MOUNTAINS.

Die hochgebirge der Erde. Von Robert von Lendenfeld. Mit titelbild in Farbendruck 148 Abbildungen und 15 Karten. Pp. xiv + 532. (Freiburg im Breisgau: Herdersche Verlagshandlung, 1899.)

THIS is a most conscientious piece of bookmaking. The author appears to have read and made a summary of all the more important descriptions of the mountain masses of the globe. Beginning with a sketch of the physiography of mountains, their development and sculpturing, he passes on to describe them chain by chain. As he has himself travelled much, he can often speak from personal experience, while the numerous and generally excellent illustrations enable the reader to realise the different types of scenery. Reproductions of photographs are used in most cases, but occasionally, of course, copies of engravings, variable in quality, were alone available. Some, both of the one and the other, have done duty before, and a few perhaps may be more attractive to the general than to the scientific public. Pictures, for instance, of climbers in a mist seem more appropriate to a book of travels, and some of those representing mountain plants or animals are hardly such as to enhance the value of the book. Attractive also as are all Mr. E. T. Compton's sketches, we cannot but feel that in a treatise of this kind reproductions of photographs would have been better, for accurate delineation is sometimes sacrificed to artistic sensibility. This is especially true of the drawing of the Grivola on p. 128, in which we have not found it easy to make out the topography. These, however, are matters of opinion. The book contains a vast mass of information, brought down to the latest possible date, and collected with a thoroughness and accuracy truly German.

The book also exhibits one or two defects, which perhaps, like its merits, are related to its birth-place. In the treatment of the subject we are conscious of some want of lucid arrangement and of a comprehensive grasp. In regard to the former, a brief outline of the contents may perhaps best indicate our meaning. It begins with a short sketch of mountain building and sculpturing, followed by a glance at the characteristic flora and fauna: a subject so wide that any details can only be fragmentary, and we should have preferred to pass it by in a few paragraphs which stated the general principles by which the life distribution has been determined. The author then commences, at the seventieth page, his special descriptions with the mountains west of the Mediterranean, from the Atlas to the Pyrenees. Thence he passes on to the Alps, which are treated, perhaps not unjustifiably, at rather disproportionate length, and then in another section we jump from Sardinia and Corsica to the Apennines, run along the Carpathians to the Balkans, make a leap to the Caucasus, and finally land with the ark on Ararat. Next comes the radiating group of giant chains in Central Asia, of which some of the less known are very well described. In the next section, after a very brief glance at the northern mountains of Eurasia in general, we are transported to Spitsbergen and Iceland, and then restored to the mainland in Scandinavia and the Urals. After that we wander to Central and Southern Africa, taking flight at last for Arabia and the peninsula of Hindustan. Then, in a long section, we make the circuit of the Pacific together with a digression to Hawaii, and after jumping from Greenland to the Appalachians, and thence to Guiana, finally come to rest on the highlands of Brazil. We find traces, no doubt, of a geographical order in the above, but think that to have kept to continents, while carefully pointing out the relation to ocean basins, would on the whole have produced clearer ideas.

We also feel the want of a concluding chapter, giving a summary of the results which follow from a study of the details contained in the foregoing sections; the principles, if we may so call them, of mountain building and sculpture, and the connection between their forms and materials. The latter was sketched briefly, but accurately so far as it went, by Ruskin years ago in the fourth volume of "Modern Painters," and might now have been elaborated in more detail by Dr. von Lendenfeld from the mass of materials which he has collected. We may illustrate the want of inductive treatment by the case of Monte Rosa. The map, especially if slightly extended eastward, would have given the author an opportunity to discuss an interesting problem leading up to general principles. What causes the extraordinary gap between Monte Rosa and the Strahlhorn? The range of the Mischabelhörner seems to be cut off at the southern face of the latter, while another range, running from the west, terminates even more abruptly in the eastern and northern faces of Monte Rosa. In the intervening gap, some four miles wide, nothing on the edge of the great snow-field rises higher than the hump of the Cima de Jazzi itself, obviously terminating a ridge which extends eastward from the Riffelhorn. What is the explanation of this ridge—also cut off abruptly like the others, and of the gap itself? The map suggests to us a solution of the mystery. Beneath a precipitous descent, seldom less than 6000 feet vertical, lies the head of the Macugnaga valley. Here, as in many other cases in the Alps—it is probably equally true of the Théodule gap west of the Breithorn—the denuding forces have acted with greater potency on the Italian side of the watershed, and they have actually quarried away the mountain centre from which these great ridges once radiated and replaced it by the great amphitheatre into which the Macugnaga glacier now descends.

But while venturing on these criticisms we are thankful for what the book gives us, especially for a glossary to help the unlearned and for an excellent index. We lay it down with something like envy. It is one of a series illustrative of the Earth; it is well and almost profusely illustrated, excellently printed, and its price is 14 marks. We presume then that works of this nature find in Germany a sale sufficiently large to make them remunerative to publishers. But would any English firm be adventurous enough to undertake such a series, or even to publish the volume before us? We fear not. Our German cousins value education more than we do, and apparently desire mental food more solid than halfpenny newspapers, penny dreadfuls, shilling shockers, or even novels with a purpose.

T. G. BONNEY.

OUR BOOK SHELF.

Beginselen der Scheikunde. By Dr. M. C. Schuyten. Pp. 109. (Antwerp: Van Ishoven, 1899.)

THIS is an elementary text-book on qualitative analysis, which aims also at imparting some of the fundamental principles of chemistry. A short introduction explaining the difference between physical and chemical change is followed by a list of the more important elements (iron is omitted) with their symbols. From this we pass on to a brief account of some fourteen elements, which are to furnish material for experimental investigation. The author then selects the unfortunate case of copper and sulphur to illustrate the difference between a mixture and a compound. It is needless to say that a more illogical and false illustration could scarcely be conceived. 6·3 grams of copper powder and 3·2 grams of sulphur are mixed together. The student must puzzle out for himself why these precise quantities are taken. Having satisfied himself by the help of a pocket lens that both substances are still present when they are shaken up, the mixture is heated. The blue-black mass which results is now, we are told, a chemical compound consisting of 63·12 parts of copper and 31·83 parts of sulphur, when the author must be fully aware that it is a non-homogeneous mixture of cuprous and cupric sulphide and free sulphur. One is tempted to suggest another example of the same order. Take 1 lb. of sugar and $\frac{1}{4}$ lb. of butter, and mix them together. The butter and sugar may still be observed with a lens. Proceed to heat them until the required consistency is obtained. The substance is no longer sugar and butter. Consequently, the resulting toffy is not a mixture, but a compound made up of the original ingredients in the proportions taken.

Passing over this unsatisfactory start, the system laid down by the author has much to recommend it. Before the student begins systematic analysis, he is set to perform experiments on the preparation of simple compounds, as well as to study such general reactions as oxidation reduction, the action of acids on metals, &c. The text is interspersed with notes of interrogation, and, in addition, a few questions are appended to each lesson.

Where the book fails is in its attempt to condense a large amount of information into a small compass, and in the lack of sufficient experimental details and adequate illustrations of apparatus.

A beginner, who had no further help than this book affords, would meet with difficulties at every step. No doubt the author's object is to place something in the student's hands which will supplement his own laboratory teaching, and from this point of view its publication may be justified.

Student's Edition of a Standard Dictionary of the English Language. Edited by James C. Fernald. Pp. viii + 915. (New York: Funk and Wagnalls Company, 1898.)

The Standard Intermediate School Dictionary of the English Language. Edited by James C. Fernald. Pp. viii + 533. (New York: Funk and Wagnalls Company, 1899.)

BOTH these dictionaries are based upon Funk and Wagnalls' Standard Dictionary. The student's edition gives the orthography, pronunciation, meaning and etymology of upwards of 60,000 words and phrases. It is furnished with appendices of proper names, foreign phrases, faulty diction, disputed pronunciations and abbreviations, as well as with a number of useful tables, including those of the chemical elements, metric weights and measures and many others. The student's dictionary also contains some 1225 pictorial illustrations. The school edition provides brief and accurate etymologies, and is furnished with as many as 800 pictures. Both volumes are beautifully printed and serviceably bound.

Though the books have only recently been placed upon the British market, they have attained a wide popularity in America, and we shall be much surprised if their attractiveness does not lead to their becoming favourites in this country.

It is always interesting to compare dictionaries, and some of the results of a comparison of those before us with one largely used in English schools will not be out of place. The first word, the meanings of which were placed side by side, was *steelyard*. In the school volume under notice was found "a simple device for weighing, consisting of a scale beam, counterpoise, and hooks," while the book with which it was compared gave "a balance for weighing bodies, consisting of a single weight shifted backwards and forwards on a graduated beam." But it is only fair to add that a small cut, of a not very intelligible kind, illustrates the American definition. The second word looked up in both volumes, this time using the student's edition of the Standard Dictionary, was *nebula*. In the dictionary under review is to be found :—(1) "Any luminous cloud-like object in the sky, as a distant star cluster ; (2) A supposed gaseous body of unorganised stellar substance" ; that in the familiar dictionary on our table :—(1) "An appearance as of light gauzy cloud amongst the stars, usually only seen through a telescope, often resolvable by a powerful instrument into clusters of stars ; (2) A white spot or opacity in the cornea." Neither of the definitions is altogether satisfactory, for a nebula is not a star cluster any more than an amœba is a star-fish.

The new volumes have, however, several commendable characteristics, and will doubtless find a place in schools.

Outlines of Bacteriology. By Dr. L. H. Thoinot and E. J. Masselin. Translated by W. St. Clair Symmers, M.B. Pp. 318. (London: C. Griffin and Co., Ltd., 1899.)

THIS little volume, bound in leather, is evidently calculated to stand hard wear, and is put together in the hopes of becoming a bacteriologist's *vade mecum*. It differs from many such compressed manuals by the introduction of numerous quotations from the original memoirs ; these extracts would have gained in value had the source been acknowledged in all cases instead of in certain instances only, one of the principal advantages of such references being to encourage the intelligent student to consult such memoirs for himself, and so extend his knowledge of the subject beyond the necessarily confined limits of a small text-book.

The authors are medical men, and it is for the medical student that the book has been written, and for this purpose it appears to be admirably suited ; industrial bacteriology is not touched upon, and we think, therefore, the title is somewhat misleading, inasmuch as the authors deal with but one branch of bacteriology. It is clearly printed and copiously illustrated.

Lehrbuch der Experimental Physik. By Adolph Wüllner. Fifth edition, vol. iv., part 2. Pp. xii + 530. (Leipzig: Teubner, 1899.)

A TREATISE on physics which, by the issue of the above part, has now completed its fifth edition must evidently have been found useful ; and it may safely be said that this edition will be found still more useful than its predecessors. The book has been fully revised and considerably enlarged ; the additional matter representing the more recent advances in physics. The section which now lies before us treats of the propagation and perception of light, interference, diffraction, and polarisation phenomena and theories.

The thirty additional photographs in this edition are mainly owing to the advances in the electromagnetic theory of light, and to the increase of our knowledge with regard to the relations between light and magnetism (Zeeman effect, &c.) These and indeed all the parts of the book are treated with great lucidity, thoroughness, and accuracy. We may call particular attention to the chapters dealing with polarisation ; they specially please us. Those diagrams which represent three-dimensional phenomena in the plane of the paper do so in such a manner that the intention of each is evident at a glance ; and the mode of dealing with the optical properties of the crystals selected for illustration of the general theory is such as to give a very complete view of the cited cases, and strikes us when contrasted with the treatment in certain other text-books which might be mentioned. Altogether, although the volume shares the fault of so many German books—viz., that it is not always free from dryness—we recommend it heartily as a thoroughly sound and modern text-book suitable for the use of the senior students in our university colleges. A. W. P.

Proceedings of the Eleventh Annual Meeting of the Association of Economic Entomologists. (*Bulletin* No. 20, New Series, U.S. Department of Agriculture ; Division of Entomology.) Pp. 111. (Washington, 1899.)

THIS publication includes a series of useful and interesting articles on injurious insects, by Profs. Howard, Marlatt, Felt and other well-known entomologists. Fortunately, injurious insects seem to have their day of destructiveness, and then cease to do much mischief ; at least, for a time, owing to natural or artificial checks. Thus, respecting the much-dreaded San José Scale, Prof. Marlatt writes : "It is not especially feared to-day in California, and, in fact, it is looked upon by some of the largest fruit-growers (as I am informed by Prof. Washburn) as having been of positive advantage, the yearly treatment of trees having necessitated a system of regular short pruning, which has greatly improved the quality of the fruit, and much lessened the expense of gathering." He, therefore, argues against undue alarm and excessive preventive measures respecting sudden and perhaps temporary insect attacks. Prof. Howard prints a translation from the Russian, by Dr. Fireman, of a paper by Porchinski, respecting the destruction of Tabanidæ by pouring kerosene into the pools to which they resort to drink. Other articles deal with caprification in California ; the destruction of hairy caterpillars by birds ; the progress of the never-ending campaign against the Gipsy Moth in Massachusetts, &c. W. F. K.

Elementary Dynamics. By W. M. Baker. Ch. xix. Pp. 251. (London: George Bell and Sons, 1899.)

ALTHOUGH necessarily similar in subject matter to the many existing treatises on this subject, the above little work will recommend itself by many convenient minor originalities. The descriptions are exceedingly minute and clear, and are in most cases followed by more worked-out typical examples than usual.

In addition to a set of examples at the end of each chapter, there is a useful compilation of more difficult problems at the end, selected from past examination papers. The scope of subject included has been chosen chiefly for the benefit of students preparing for Woolwich and Sandhurst, or reading for scholarships at the Universities.

Handbook of Physics and Chemistry. By H. E. Corbin and A. M. Stewart. Pp. vi + 424. (London: J. and A. Churchill, 1899.)

WITHOUT attempting any originality of style or subject matter the authors of this work have culled from the many authoritative sources the requisite information necessary for students preparing for the First Examination in physics and chemistry of the Conjoint Board of the Royal Colleges of Physicians and Surgeons. The book will also be useful to those working for the Pharmaceutical Society and the Royal Veterinary College, the syllabuses prescribed by these institutes being fully covered.

LETTERS TO THE EDITOR.

Contemporary Meteor-Showers of the Leonid and Bielid Meteor-Periods.

PART I.—*Co-Leonid Showers.*

As a large proportion of the November shooting-stars observed and mapped in 1899 on and near the two chief shower-nights, of November 14th and 15th, were *non-Leonid* meteors emanating from various contemporaneous centres of much less conspicuous star-showers of that month, than the eagerly expected but unfortunately not witnessed great spectacle of the *Leonids* themselves, it may furnish a useful clue to some of the foreign-looking or unconformable meteors' sources of which several bright examples were no doubt mapped by observers in the many able watches kept for the recently expected shower, to mention some radiant-points which were noticed here to be particularly active in about twelve hours of tolerably productive meteor-watching, lasting one or two, to three hours, on each night of November 6th, 8th, 10th, 12th and 13th, in clear dark sky, before the moon had acquired sufficient strength to hide the smaller meteors. Mr. Denning also watched for about four hours on the nights of the 10th, 11th and 13th, seeing four *Leonids* and twenty-four other meteors; and among nine unconformable ones of which he sent me path-positions, three accorded in direction with radiant-points of my present list, and one of these, on November 10th, as well as a second meteor on that night, was simultaneously mapped here, enabling real paths of these two meteors to be concluded from the observations, as represented in this Table.

TABLE I.—*Real Paths of an* e-Taurid, *and of an* ι-Aurigid *Shooting-star, doubly observed at Bristol and Slough, on November* 10*th* 1899.

Hour G.M.T.	Apparent Magnitude.	Height in B.S. Miles, at: Beginning.	Height in B.S. Miles, at: End.	Radiant-point. α δ	Length of Path (Miles); and Duration (Seconds).	Observed, and (Theoretical Parabolic) Speed, Miles p. sec.	Appearance.
h. m. 13 16	2–4	58; over 5 miles S.E. from Cheltenham.	46; over 5 miles S. by E. from Evesham, Worcestershire.	$55°+4°$ *e Tauri* S., 15° W. alt. 42°.	$17\frac{1}{2}$; 0·8	22 ($21\frac{1}{2}$)	Uniformly bright, orange-yellow; no sparks or streak.
13 37	4	77; over 1 mile E. from Godalming, Surrey.	47; over 3 Miles W. from Chertsey, Middlesex.	72+30 *ι Aurigae* Due S., alt. 68°.	$33\frac{1}{2}$; 1·4	24 ($29\frac{1}{2}$)	Near radiant, at Slough, slow, tapered; yellow, with streak-like, red, tapered, spark-tail.

The first true *Leonid* seen here appeared at the close of a short very clouded watch of 30m., at 5h. 59m. a.m., on November 13th; at least as bright as *Sirius*, since it shone through clouds which hid all stars except those of Leo's Sickle, from which its course was directed.[1] In the earlier part, however, of that night, and during all the preceding night of November 11th, the sky here had been completely overcast; but Mr. Denning saw two small *Leonids* and three other meteors in 35m., at Bristol, after 14h. 50m. on the latter night. Two third magnitude *Leonids* were seen here on the following morning of November 14th, among four meteors mapped in a nearly clear hour after 4h. a.m., and Mr. Denning noted a small *Leonid* with two other meteors in about 20m., on that morning, after 5h. a.m.; but the few tracks seen till then showed no great activity yet of the looked for meteoric exhibition. A single bright *Leonid*, at 13h. 33m.,[1] seen here in the half-hour till 2h. a.m. on the morning of November 15th, when the sky for a short while was clear before thick fog and clouds intercepted all view of the sky for the rest of that night and through all the night of the 15th, with only a very partial break's exception for an hour preceding daybreak on the morning of the 16th, when nothing meteoric was seen, was the only view that I could here obtain of any well marked phase of brightness or abundance which the shower was expected to display, and which it did actually display with some small intensity elsewhere, on its two chief predicted nights.

While no rapid rate of appearance of the *Leonids* was yet noted here in the clear half-hour till 2h. a.m. on November 15th, I have learned from my brother, Sir W. J. Herschel, that at Littlemore, near Oxford, he observed, with a small party of watchers, quite an abundance of *Leonids* on that morning, in clear sky, between 1h. 15m. and 6h. 15m. a.m. The total list recorded there in those five hours was 62 *Leonids* and 40 *non-Leonids* or ordinary meteors. To the number of the *Leonids*, besides, should be added six or eight not charted, from their coming too rapidly in one or two minutes at 5h. 25m., and in five minutes after the appearance, at 5h. 40m. a.m., of the brightest meteor of this watch, which will be referred to more particularly below. Including those additions, the numbers of *Leonids* noted in the successive hours before, and half-hours after moon-set at 16h. 50m., were

Hours ending at	14h. 50m.	15h. 50m.	16h. 50m.
Numbers of *Leonids*	6	8	10
And Hourly rates..	6	8	10

Half-hours ending at	17h. 20m.	17h. 50m.	18h. 15m. (25m.)
Number of *Leonids*	14	25	7 (in. 25m.)
And Hourly rates..	28	50	17

The sky was generally clear, and extremely clear in the one dark hour after moon-set. The hourly rates then show a sudden increase; but a very sudden rise occurred also in the second half of that dark hour (from 28 to 50 *Leonids* per hour, very soon arrested then by gradually increasing daylight), much too abrupt and sudden an increase, it seems obvious, to be at all possibly ascribed to fading lunar twilight. These observed rates in the moonless sky seem thus pretty certainly to show that a maximum of the meteor-stream was either fast approaching and very near and imminent, or may perhaps even have been just attained, when a close was put by daylight to my brother's good view of the shower and to his carefully recorded notes of this *Leonid* display's appearance. The proportion of the number of *Leonids* to that of ordinary shooting-stars seen in the watch at Littlemore, 6 or 7 : 4, nearly resembles, although it did not quite attain the proportions noted at Romsey, Hants, and at the University of Pennsylvania, U.S., on the

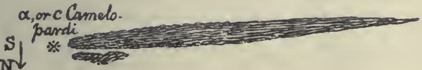
[1] This path was approximately from 99°, + 19° to 83°, + 15°; about 15° in ⅔ second.

[1] This 1st magnitude *Leonid's* path was from 113°, + 37° to 93°, + $39\frac{1}{2}$°; 15° in ⅔ second, leaving a greenish-white streak all the way for about 2 seconds.

following morning of November 16th, which, as reported in the *Times* of November 17th, were both about 2 : 1.[1]

One of the forty unconformable or *non-Leonid* meteors seen at Littlemore, which appeared at 5h. 40m. a.m. on November 15th, was so extremely bright that it could only be termed conventionally an "ordinary" shooting-star, since it was not only brighter than Sirius and than all the other fixed stars, but it left behind it a light streak along its path, the terminal part of which remained visible for five minutes. The general hue of the meteor was yellow, inclining to orange, and it described a path of 35° from *α Ursae Majoris* exactly to *α* (9, or *c*, Bode) *Camelopardi*, or about from 163°, +63° to 72°, +66°, in two, or two and a half seconds. A streak remained on all its long path, which thickened greatly in about the last third part, or last 12° of the flight, and remained shining there with surprising persistency, while on the earlier part of the track it quickly faded out. The light-wisp shortened gradually from behind, its front end remaining constantly near *α* (or *c*) *Camelopardi*; and when it had shrunk to about 8° in length, it grew slightly sinuous, as if windwafted, and its last visible light-trace at the end-point of the flight had drifted about half a degree northwards, altogether, or sideways from the streak's direction, when it disappeared. The first and final appearances which the streak presented near the star *α*, or Bode's *c Camelopardi*, are shown as they were represented by a sketch, in the adjoining Figure (Fig. 1).

Like multitudes of streak-leaving meteors which in the morning hours, on all nights of the year, stream from the neighbourhood of the earth's apex near the east horizon, this bright



Streak of the Meteor of 5h 40m am., November 15th, 1899, as seen at Littlemore, near Oxford.

FIG. 1.

meteor's path diverged from no conspicuously well known ordinary radiant-point of the *Leonid* epoch, but shot from far east of *Leo*, and must have passed about over the northern part of Oxfordshire from some radiant-point not far above the E. by S., or E.S.E. horizon among the stars of *Comae Berenices*, or near *ζ Virginis* and *Spica* which had then just risen in the E.S.E. Should it have been recorded elsewhere, therefore, descriptions of its apparent path at other places to compare with this one would be of special interest and value, as with only one exception, of a centre of five swift meteors leaving streaks, observed by Mr. Denning on the morning of November 16th–17th, 1885, at 190°, +21°, near *q*, or 35 *Comae*, in the southern portion of the constellation [1] (pretty close to which point, through 194°, + 23°, the present meteor's path-line passes backwards), no radiant point of marked activity near the yearly shower-date of the *Leonids*, appears, in Mr. Denning's splendidly comprehensive "General Catalogue of Radiant-points,"[2] to have been hitherto recorded in that quarter of the sky.[3] The altitude of 39° of the latter radiant-point, and its moderate distance, only 45°, from the beginning of the meteor-path, are not entirely inimical to this radiant point's adoption, as although the apparent path was very long for a rather steep-sloped descending real one, it should be noticed that the meteor passed nearly overhead and therefore in such near view at Littlemore that a great apparent length of path may on that ground alone be very readily accounted for, and the thickening and persistence of the streak in only the latter portion of the flight, favours the presumption of a pretty steep descent into the atmosphere, rather than a supposition that the real path was nearly horizontal. The observed speed of flight, 15° or 16° per second, is also too insecure a measurement to serve as an exact or very reliable criterion between a higher and a lower radiant-point position; but as it was not more than half the apparent speed with which one of the *Leonids* would seem to dart along,—about 30° per second,—in a similar position relative to its radiant-point and to the horizon, the slower real meteor-speeds of both the *α–ζ Virginids* and the *q-Comids*,—30-35 miles per second,—owing to their radiant-points' greater elongations from the earth's apex, as compared with that of the *Leonids*, about 43 miles per second, are evidently represented pretty nearly, although as usual in estimates of durations of flights and of apparent path-speeds, only with moderate exactness, by the observed, not very rapid angular velocity of the meteor's motion.

[1] Until 3h. a.m. on the 16th, the weather in the United States of America had been in general very unfavourable for meteor-watching; but from about that hour onwards until daybreak, good numbers of meteors, 102, 64, 59 and 30, were seen at Philadelphia, Harvard College Observatory, Bayport on Long Island, and Chicago; and at Denver, as reported in the *Times* of November 18th, the *Leonids*, after beginning to appear at 1h. a.m., were not very numerous until about 4h. a.m.; 63 were then counted in a quarter of an hour. The number of meteors seen at Romsey, in Hampshire, was 60; and at the Observatories of Madrid and Treptow (Stettin, North Germany), also, good numbers of meteors on the morning of the 16th were recorded. A period of considerable activity of the *Leonid* meteor-stream seems thus to have very distinctly presented itself on each of the two probably predicted mornings, for the shower's return, of November 15th and 16th. A lively shower of 80 or 100 *Leonids* seen on the morning of the 15th by Messrs. Tikhoff and Lespieau in the first of the two balloon ascents made by the astronomers of Meudon and the French Aeronautical Society, on the two foretold shower nights, and a very interesting description by Mr. W. H. Daw, in the *English Mechanic* of November 24th, of a rapid shower of 40 or 50 *Leonids* seen in exceedingly clear sky on Hampstead Heath, in about 40m. between moon-set and daybreak on the earlier one of those two mornings, both perfectly confirm the description given above of a considerably bright *Leonid* display just before daybreak on the morning of November 15th. It must, however, have then very speedily collapsed; for at Princeton, New Jersey, U.S., only about 20 *Leonids* were seen, in clear sky, from soon after midnight (about 5h.-6h. a.m., G.M.T.), until 5h. a.m. (10h. a.m., G.M.T.), by Professor C. A. Young, on the morning of November 15th; ("Popular Astronomy," December 1899, vol. vii. p. 543:—assuming that, in that account of a transitory good view of the *Leonids*, the date of rain and clouded sky given as the "night of Monday–Tuesday, November 14th–15th," may be corrected to November 13th–14th; and that by "Tuesday night," when the sky cleared up soon after midnight and about 20 *Leonids* were seen at Princeton, must no doubt be meant, as the description is regarded here as having been evidently intended to imply, the night of November 14th–15th).

[1] The shower is included in Mr. Denning's excellent list of 50 ordinary meteor showers contemporary with the period of the *Leonids* (which will soon again be more particularly referred to), as No. 43, at 190°, + 21°.

[2] "Memoirs of the Royal Astronomical Society," vol. liii. pp. 203–292.—The 278 showers' numbers in this List, and in its introductory "Index List" of all the showers' average positions and stellar designations, are quoted in the Tables and general matter of this letter, by the symbol D('99), with the showers' successive numbers.

[3] In a letter from Mr. Denning of November 25th, I am informed that he has been able to compute this meteor's real path from some additional observations sent to him by meteor-recording correspondents from Yeovil in Somersetshire, and from Woburn in Bedfordshire, which accorded very well with the data furnished by the above account at Littlemore. These observations he found to be consistent with the supposed direction of flight from the radiant point near *q* or 35 *Comae*, and to give a real path which also exactly corresponds with the above conjectured geographical position of the track; while the vertical height and the length of path agree with the usual results for very bright and slantingly descending meteors. The following are the particulars, in detail, obtained by Mr. Denning, of the meteor's real path.

Height, in miles, at		Length of Path and Velocity.	Radiant Point.		Parabolic Meteor-speed.
Beginning	End.		α	δ	
71 miles over 4 miles south of Buckingham.	42 miles over 3 miles south of Shipston-on-Stour, Warwickshire.	46 miles in 2¼ seconds; 20½ miles per second.	193°	+ 27°; 7° S. of East, altitude 42°; near *q Comae*.	36 miles per second.

The observed duration, of about 2¼ seconds, at Littlemore, gives, as here shown, a real speed, 20½ miles per second, so much slower than the presumptive one of either 36 or 30 miles per second, which should belong to parabolic-moving meteors proceeding from this radiant-point or from one near *Spica*, that the measure of duration and of apparent swiftness or slowness of the meteor's flight was really, as surmised above, in this meteor's case as in so many others, not an exact enough *datum* to be helpful towards a desired, but delicate discrimination of the meteor's radiant-point by astronomical considerations.

A good view of the meteor obtained by Mr. F. H. Wright, in Northamptonshire, is described in the *English Mechanic*, vol. lxx. p. 406, December 15th, 1899; Mr. Wright confirms the great visible duration of the meteor's light-streak, by stating that it appeared to change its position slowly from its original line of flight towards N.W., appearing first to be 5° or perhaps more in length, and that after being watched for four minutes, when it was still visible, it appeared to be directed more nearly towards N.E. The point where it "burst, midway between *Castor* and *Capella*," satisfactorily confirms Mr. Denning's determination of the real height and place of the meteor's end-point; and as regards the earlier portion of the real track which it pursued, although nothing precise enough to establish the radiant-point exactly, was supplied by the general description that the direction of flight was towards N.W. (more nearly in reality towards due W.),—yet this point's real position near *q Comae*, had already been certainly determined, and excellently well-defined at that position, by the exact apparent direction of the meteor's course, in Bedfordshire, supplied to Mr. Denning by Mr. W. C. Tetley.

The important calculations of the perturbations of the *Leonid* meteor-stream by the major planets since the year 1890, recently published by Dr. A. Berberich, of Berlin,[1] in which the effect of those perturbations to alter the form of the stream's orbit and hence the distances from the sun, at their nodes, of those parts of the stream which the earth would encounter, respectively in November of the years 1898 and 1899, led that distinguished German astronomer to the conclusion that inward deflections towards the sun of 0·0163 and 0·0048 earth's orbit-radius, or of about one and a half, and half a million miles respectively, would be produced in the two meteor clusters at their nodes, by the special perturbations exerted upon them respectively by the major planets; and as the orbit of Tempel's comet of 1866, which they may be supposed to have been nearly following, passed already at its node, in January of that year, at 0·0065 earth's orbit-radius, or 604,000 miles inside the earth's orbit, the offing distances of these two clusters' centres on the inside of the earth's track when the earth passed near them in November, 1898 and 1899, would be respectively about two million and one million miles, if they pursued the same orbit as the comet had in 1866, before undergoing the exceptionally strong perturbations; while in their previous revolution they would have been but little more than half a million miles inside the orbit of the earth; and if the meteor clusters passed through in 1866 and 1867 were also moving along the comet's orbit then, and sufficed to produce imposing meteor-showers when the earth approached to within about half a million miles from their stream-centres, it need certainly excite no wonder if no meteor-showers of extraordinary brightness should have happened to occur on the November dates of 1898 and 1899, when the earth approached no nearer than to two million and one million miles from the meteor-current's centre

But Dr. Berberich's investigation really showed what marked differences of effect are produced by the planetary perturbations on different portions of the long meteor-stream, so that instead of any parts of it now following exactly the same orbit as the comet, it must all have become waved and sinuous along a mean orbit path; and no prediction of the showers probable intensity at a new return can be at all based certainly on an apparent centrality and on great brightness of its just previous periodical appearance. The succession of fine showers of 1799, 1832–3, and 1866–7 appears to have been interrupted for the present by some such deformations impressed by past perturbations, during nearly twenty centuries, on the meteor-current. But these may be replaced next year, with equal probability, by new and contrary ones in the portion of the stream which the earth, it may be hoped, will pass through more centrally than seems to have occurred this year, in November, 1900. It may also still be somewhat premature to regard the strength of the November shower as having fallen this year beyond all traces of resemblance below its anticipated brightness, until detailed reports may still for a long time be expected from many anxious meteor-watching stations in the Antipodes, like the great observatories of Australia and the younger, but yet very well equipped meteorological and astronomical observatory at Hong Kong.

The following were the times of observation, (Table II.), and the radiant-point results, (Table III.), of my recent morning views, in clear sky, of 69 *non-Leonid* and five *Leonid* shooting-stars seen in the 12hrs. watch on November 6th–16th. The 74 meteors were for the most part small, only about twenty having surpassed third magnitude stars, and none having exceeded the brightest fixed stars in brightness. Only six or seven unconformable meteors, besides one *Leonid*, left momentary light-streaks; two from the radiant at κ, and two from radiants near π or ρ *Leonis*, and two more from the radiant near the equator at p, 29 *Monocerotis*. A greenish-streaked, 1st magnitude meteor from this latter point, on November 8th, had, in fact, so perfectly the appearance of a true long-pathed, swift *Leonid*, as quite to deceive me, at first, into a supposition that it must surely be a fine and very early harbinger of the coming meteor-shower, until its path was mapped and traced back to its real *Monocerotid* centre.

With the exception of a κ *Leonid* on the morning of November 14th, the thirty-eight meteors grouped under the five *co-Leonid* radiant centres in Table III. were all seen among sixty-four ordinary shooting-stars on November 6th–10th; the four remaining ordinary meteors added to the list in broken watches in the following very clouded star-shower nights, having all belonged to very feeble showers from other ordinary centres. But the five *Leonids* seen then in a few restricted glimpses of the sky, gave a pretty exactly defined radiant-point, which, though obtained from several different nights of observation, might yet, it was thought, be esteemed accurate enough, and of sufficient general interest to be included in the Table.

The paths were all projected on a chart of stars laid down for the epoch A.D. 1900, on the extraordinarily accurate gnomonic polar net drawn to single degrees of right-ascension and declination about a centre of projection in declination 45°, by Prof. Lorenzoni, and published at the astonishingly low price of 0·4 *lira* (about 4*d.*) per large "double-crown"-sized sheet of exquisitely printed zincographic engraving, at the Meteorological Observatory of Fontaniva, Venice, for the use of Italian and other shooting-star observers. The radiant-point positions were thus very accurately extracted, and the unusual precision of the gnomonically ruled map seems to have been very strikingly illustrated by the smallness of the areas from which the tracks referred back to each of the radiant-points diverged. The radii of these circular areas drawn round each radiant, as a centre, of just sufficient width to include the most distant of the path lines regarded as belonging to that radiant, are shown in the third column of the Table. But they sometimes overreached the proper smallness of a focal region, when only one or two very outlying path lines occurred, as happened in the plotted set of ξ *Taurid* paths, among an otherwise well centred group of path-directions. The concluded centre-places were compared with two radiant-lists published by Mr. Denning; one of fifty ordinary meteor-showers visible at about the same time with the *Leonids* (or, about a week later, also with the *Bielid* meteors),[1] and the other his extensive "General Catalogue" above referred to. The first and fourth columns of the Table give the Numbers in those two Lists, of separately accounted "*Co-Leonid*" streams, and of more or less long-enduring ordinary meteor-systems, or "shower-series," with which the present set of showers appeared to be identical; and the average positions of the latter "shower-series," as given with their running numbers in the catalogue, in the "Index-List" of Mr. Denning's "General Catalogue," are added in the fifth column of the Table to the preceding column's Numbers in that General Catalogue, or its Index-List. The agreements found, very closely confirmed the two lists' positions, excepting in the case of the main stream of *Taurids*, which, as I hope to recur to hereafter in a communication of some notes on large *co-Leonid* and *co-Bielid* meteors to supplement this letter, appears on this occasion to have proceeded from a rather outlying centre, rather nearer to α than to ϵ *Tauri*.

A shower centre at ξ, o *Tauri*, very prominent in October and November, apparently reaches its maximum on November 2nd, when Mr. Denning noted its place very exactly, in 1886, by a considerable shower of seventeen meteors, at 55°, +9°. One member of this stream, it has been already mentioned, with a radiant-point at 55°, +4°, was doubly observed at Bristol and Slough this year, on November 10th; and another as early as September 17th, in 1898, by Mr. A. King, at Leicester, and here, brighter than stars of the first magnitude, with a radiant-point at 57°, +7°. The shower was well defined this year by many tracks, very near its mean position in Mr. Denning's "General Radiant Catalogue," although no place seems to have been accorded to it in the select List of Fifty Showers visible at the same time with the *Leonids*. The p, q, or "30 *Monocerotids*" (No. 3), which form a rather weaker shower-series of similar duration to the ξ, or "e *Taurids*," and which furnished a few bright streak-leaving meteors this year from close to their mean centre in the "General Radiant Catalogue," are also missing from, and are no doubt properly passed over in the special *co-Leonid* List, as they not only formed a less plentiful shower than the ξ *Taurids*, in these watches, but they were also not all quite so certainly assignable as were the great majority of the ξ, o *Taurid* tracks, to their adopted centre.

Among many recorded radiant-points near *Leo's* Sickle, only that near κ *Leonis* was found to be distinctly active, presenting itself very sharply before any true-directed "γ *Leonid*" meteor-paths were charted; and though only a slender shower of slightly streaked and rather sparingly bright meteors, it must doubtless produce on ordinary *Leonid* shower nights some of the swift shooting-stars resembling *Leonids* which in yearly watches for the great shower's return, are sometimes seen diverging from a little north of *Leo*. On the morning of November 14th, 1877, a marked abundance of apparently just

Notes to the above six Showers; regarding the general appearances of their Meteors.

No. 1. ξ, ο *Taurids*:—Rather long-pathed, evenly bright, yellow, or orange, star-like meteors; with slight spark-tails, but leaving no streaks. One, on November 10th, as bright as Sirius, near the south horizon, burst in mid-course with a yellow spark-cloud, projecting a fragment to the right, and itself pursuing a deflected path onwards to sudden disappearance; like the annexed sketch (Fig. 2). This meteor may have been either a ξ, ο, or an ε *Taurid* (from 63°, + 22°), as the path-line prolonged backwards passed nearly through both those radiant-points. About half a minute after its appearance, an equally bright, white, *Sirius*-like *p Monocerotid* shot rapidly, 8° in 0·6 seconds, to very near the north-west horizon across *Lacerta*, leaving a fugitive white streak. These two were the only *non-Leonid* meteors seen in my watch, as bright as *Sirius*; and as they belonged to two entirely distinct meteor-streams, it was a curious coincidence that they should both present themselves, with great resemblance in appearance, within half a minute of each other.

No. 2. α *Taurids*:—Yellow star-like meteors, with sometimes intermittent and rekindling light; no streaks or sparks.

No. 3. *p Monocerotids*:—Swift, yellowish-white, *Leonid*-like meteors, leaving tapered, greenish-white streaks.

No. 4. σ *Ursae Majorids*:—Rather swift yellowish, stellar meteors, without sparks or streaks. An early member, apparently, of this meteor-stream was seen this year on October 5th; when among some meteor-paths mapped in two simultaneous watches, a 2nd magnitude shooting-star was noted here, and at Farnborough (Hants, 15 miles S.S.W. from Slough) by Mr. J. H. Bridger, at 10h. 55m., the two path-descriptions of which were in perfect geometrical accordance, and indicated the meteor's real path and radiant-point with much exactness. By the two mapped path-lines' backward intersection, a little way in rear of both the tracks, the latter point was at 138°, + 64°, close to this present shower's centre at 134°, + 67°, and to σ, τ *Ursae Majoris.* The meteor traversed 14 miles in 0·7 second, from 51 miles over a point near Leighton Buzzard, Bedfordshire, to 44 miles over Little Hampton, near Princes Risborough, Bucks, from a direction N.N.E., altitude 30°; and the speed of 20 miles per second fell much short of the shower's proper parabolic meteor-speed then, of 37 miles per second. But from the shortness of the base-line, affording but little parallactic displacement of the apparent paths, the concluded real height and length of path can scarcely be regarded as very dependable, and the duration of flight, 0·7 second, recorded here, may also very possibly have been somewhat overrated.

No. 5. κ *Leonids*:—Very swift, yellowish-white tapered meteors, leaving slight, white streaks.

No. 6. γ, ζ *Leonids*:—Swift, white or yellow, tapered meteors. (Mostly seen through mist; but one of 1st magnitude, seen in clear sky on November 14th, left a tapered, greenish-white streak for 2 seconds).

these κ *Leonid* meteors was thus observed by Mr. T. W. Backhouse at Sunderland,[1] who found a pretty exact radiant-point near μ *Leonis*, at $146°, +26°$, of seven "Leonids," one as bright as Jupiter, leaving a streak for three seconds, and the rest small; seen with eight other meteors in 1h. 20m. of clear sky during some hours' watch before daybreak on that morning. By an apparently just similar deception, in the bright shower of *Leonids* mapped and assigned here to various *foci* on the morning of November 15th, 1896, a pretty compact region of divergence was noticed north of *Leo*, in *Leo Minor*, of four or five meteor-paths, at about $155°, +35°$,[2] as apparently composed of "Leonid stragglers." But at $154°, +40°$, D('99) 118, there is a strong enduring shower-series of μ *Ursids*, first well recorded in November by Mr. Denning at $155°, +36°$, from about twenty swift white meteors on November 26th–29th, 1876,[3] and observed in late years very frequently on the *Leonid* dates of November 10th–17th, within a few degrees of that position. As it is found to present itself also as an active stationary shower during the preceding and following months of October and December, no very cogent reasons, it would seem, can be admitted to exist for describing this shower's meteors, or those of the contemporary shower near κ *Leonis*, for want of better designations, as stragglers or erratic members of the main meteor-stream of the *Leonids*.

One or two tracks seen here, and some mapped by Mr. Denning, on November 6th–11th, appear to have proceeded from known radiant centres south of the Sickle-stars, near o and π *Leonis*; but with these scarce exceptions no signs of swift-flighted meteors crossing *Leo* from south-eastern centres in *Hydra* and *Virgo* could be noticed with the brightness and abundance which those contemporary showers sometimes present on the yearly shower-nights of the *Leonids*. The main body of the ordinary meteors seen in these earlier nights' watches were pursuing leisurely, mostly short, but sometimes lengthy random

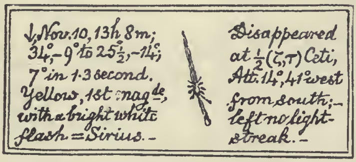

Fig. 2.

courses from many scattered radiant sources of more or less well-known positions among the constellations overhead, and in the north, west and south quarters of the sky. Of all these slow-paced systems, amounting in Mr. Denning's special list to thirty or forty centres of very undiversified looking meteor-flights, only one overhead radiant-point at σ *Ursae Majoris*, and the two south-westerly showers of the α–ϵ and ξ–o *Taurids* were marked abundantly enough by meteor-paths to be perfectly identifiable. A number of other centre-points absorbed the rest of the recorded tracks in single, or at most in two or three connected flights, too few to fix their radiants' real places certainly during the far too restrictedly short starlight time of my three or four fine nights' watch to show more of those scantily-escorted flights or lonesomely projected flashes, and to disclose their focal points and stellar features of appearance properly.

From their persistencies, however, enabling them to be reckoned as belonging to the *Bielid* meteor-period, a projection which I made last year of about 220 observations obtained by different observers in former years, since 1861, of meteors of that yearly period, November 20th–30th,[4] exhibited more fully than the less numerous observations made on earlier November nights this year could do, the relative strengths at that epoch (and therefore probably also in a nearly similar manner at the ten days earlier period of the *Leonid* displays), of several of these zenithal and western streams contained in Mr. Denning's Select List of Fifty ordinary *co-Leonid* Showers. To extend accordingly the illustrations which longer observations would have yielded, of the large array of ordinary showers included in Mr. Denning's Mid-November Radiant List a little further than the limited acquaintance, only with a few of them which this year's observations furnished, it may be useful to supplement this present partial review by a further position-list and some particular descriptions of several ordinary meteor-showers of the Bielid meteor-period, which were found to have been either transiently active or steadily productive during a long series of years, in those rather more comprehensive meteor-path projections.

[4] Prepared about this time last year for Dr. A. Hnatek, of Vienna, who has presented to the Vienna Academy of Sciences (*Sitzungs-berichte der kaiserlichen Akademie, Mathem.-Naturw. Classe*, Bd. cvii., Abth. ii.; December, 1898), an elaborate investigation both of the Bielids' radiant-point and of those of ordinary meteor-showers visible at the same time with the Bielids, from a widely amassed collection of meteor-observations for the period November 20th–30th, including among those made in Austria and supplied to him with numerous paths recorded at the Observatory of Vienna by Dr. Weiss, and in addition to similar contributions from Profs. Schiaparelli and Nyiland, and to many paths recorded in the works of Dr. Schmidt, some published by Von Littrow, which were made at the Observatory of Vienna as long ago as the year 1837.

The Royal Society Catalogue and Psychology.

In the original classification of the sciences for the purposes of the projected Royal Society Catalogue of Scientific Literature, Psychology was given an independent place. Recognising this, the International Psychological Congress at Munich, in 1896, appointed an English committee to do what they could to further the scheme in the name of the Congress. Following this, Dr. G. F. Stout, editor of *Mind*, then at Aberdeen, now at Oxford, was asked by Prof. Michael Foster to prepare a schedule for psychology. Dr. Stout sought the collaboration of the present writer, who represented the *Psychological Review* and its annual catalogue the *Psychological Index*. In the meantime, at the suggestion of Prof. Foster to the present writer, the question had come up in America as to the advisability of suspending our Index (which is now common to the *Zeitsch. f. Psychologie*, Berlin, and the *Année Psychologique*, Paris), with the preliminary understanding that if the Royal Society Catalogue issued an adequate list in psychology, it would be advisable to suspend the publication of the Index and support the Catalogue. Dr. Stout submitted the schedule he had prepared.

After a long period, in which no communication of any kind reaches Dr. Stout—nor has it yet!—the printed report of the conference of last June informs us that psychology has been classed under physiology, and the present writer learns from Sir M. Foster that the psychological schedule is to be cut up—if this action be finally confirmed by the Royal Society—and fractions of it inserted where place can be found for them under physiological headings.

Understanding that there is still a chance to reconsider this action, I venture as one of the joint proprietors and editors of the *Psychological Index*, whose existence is in question, and also in behalf of the reputation of psychology, to say:—

(1) If this action relegating Psychology to Physiology is carried out, the *Psychological Index* will continue to be issued and its subscribers retained.

(2) In that case some action is highly probable on the part of the International Congress of Psychologists meeting in Paris in the summer, seeing that they endorsed the former course of the Royal Society in giving the subject an independent schedule. At that congress the representatives of the French and German bibliographies mentioned are also to be in conference, with a result that may readily be foreseen.

(3) The present writer thinks he represents the competent opinion among psychologists in saying that the day is past for this sort of ignoring of the claims of one department of scientific knowledge at the instance of another. This was amply shown by the attitude of psychologists toward Prof. Richet's *Bibliog. Physiol.*, in which a similar treatment of psychology is carried out by one who attends psychological congresses and allows himself to be made prominent in them. It is interesting to know that Prof. Richet has been an active member of the Royal Society Conference.

Psychology is knowledge of the mind, not of the body—whatever method it may adopt to solve its peculiar problems—and to class it under physiology is about as reasonable as to class it under *cheese*—on the ground that cheese is sometimes green, green is a colour, and colour is a mental state!

It may be added that no criticism of the Royal Society

Committee is intended; but it is to be hoped it will adhere to its original classification. J. MARK BALDWIN.

Oxford, December 18.

The Stockholm Fisheries Conference and British Fishery Investigations.

FROM Mr. H. M. Kyle's letter in your issue of December 14, it is clear that he is ignorant of the present position of the British Government with regard to fishery investigations. The great obstacle in the way of such investigations, as every one who has taken any part whatever in their organisation is aware, has always been the want of adequate funds to carry on the researches. The investigations, if properly conducted, are very expensive, involving not only the employment of highly-trained naturalists, but also the equipment of laboratories on shore and of sea-going ships capable of visiting the fishing grounds. The latter item is so costly, that no vessel capable of keeping the sea has yet been systematically employed for scientific fishery work in British waters.

On account of the expense, there is little likelihood of investigations upon an adequate scale being attempted without the use of public money. This is recognised by the Government, and money has been spent by H.M. Treasury for biological and fishery researches in three different directions. In England the Marine Biological Association of the United Kingdom, which was started by private effort in order to promote (to use Prof. Huxley's words) "researches leading to the improvement of zoological and botanical science, and to an increase of our knowledge as regards the food, life-conditions and habits of British food-fishes and molluscs," received in 1885 a Government grant of 5000*l.* towards the cost of the erection of the first laboratory at Plymouth, and has since received an annual grant, which from 1892 has been 1000*l.* Altogether some 13,000*l.* of Government money has been spent, in addition to an equal amount derived from private sources.

In Scotland the Fishery Board receives from the public funds a yearly sum for scientific investigations which amounts, I believe, to about 3000*l.*; whilst in Ireland a single sum of 2,500*l.* has recently been granted to assist the fishery investigations of the Royal Dublin Society.

We may now examine in more detail the position of each of the three bodies entrusted by the Government with the expenditure of money for fishery work in England, Scotland, and Ireland respectively.

At the time of the foundation of the Marine Biological Association, the Government, in making the first grant of money, placed upon the Association the responsibility of doing for England work of the kind done in Scotland by the scientific department of the Fishery Board. Encouraged by the support received from public and private sources, the Association proceeded to lay down the necessary machinery for carrying out both scientific and economic work, and a sum of 12,000*l.* was spent in building and equipping the Laboratory at Plymouth as a first step in that direction.

The foundations of the Association were laid upon a liberal scale, involving the expenditure of a considerable capital, but the superstructure remained to be built. The subsequent yearly financial support was not on a scale commensurate with that given to the Association on its foundation, and it has never been possible to make full use of the machinery provided. By far the greater portion of the income of the Association is necessarily devoted to expenses of establishment and organisation, and only a small sum remains for the employment of naturalists to conduct investigations. The funds have never reached a figure which would render the maintenance of a sea-going vessel with which to reach the fishing grounds a question which could be practically considered. Having regard to the money at its disposal, the Association may fairly claim to have produced a body of work which in quality will compare with that done by any similar organisation elsewhere. It must not be supposed, however, that one man can produce the work of six, and it has never been possible to employ at Plymouth more than one naturalist devoting his attention to fishery work.

When, five years ago, the Council did me the honour of appointing me to the executive office of the Association, I undertook the duties of the post knowing that the justification for the yearly expenditure in maintaining the Laboratory in a state of efficiency lay, not in the amount of work which could be immediately produced, but in the fact that a solid foundation had been laid, which was capable, with an increased income, of producing a very large amount of valuable work. Further experience has confirmed this view, and I have also been forced to admit, perhaps reluctantly, that the only practical method by which the necessary increase of income can be obtained is by the development, on the part of the Government, of the fishery branch of the work. That the work of the Association was never intended to be confined to what can be done at Plymouth is shown not only by its name and the avowed objects of its promoters, but also by the fact that for a number of years the Association maintained a naturalist and kept open a laboratory at Grimsby for the study of North Sea fisheries. The investigations made by Mr. Holt and Mr. Cunningham in this connection will, in usefulness, rank with the best fishery work which has been done in the North Sea, and it was due only to lack of funds that these investigations could not be continued.

Turning now to the Scottish Fishery Board, it will be admitted that, so far as its scientific investigations are concerned, a similar condition of things exists, in a less pronounced degree. For years an urgent appeal for a steamer capable of keeping the sea has been a constantly recurring feature in the Reports of the Board, and the scientific superintendent will be the first to agree with me in saying that the scientific staff is by no means numerically strong enough to carry out the investigations upon the scale which their importance and difficulty demand.

In Ireland, where the Royal Dublin Society is working in close connection with the fishery inspectors, and is supported by Government money, it has also been impossible to provide a proper vessel, and Mr. Holt is working single-handed, except for occasional volunteer help, although he has accommodation for a number of naturalists.

All past experience has shown that the British Government is very reluctant to spend money upon scientific investigations of any kind, and at the present time it is practically certain that any increased expenditure in this direction will be limited in amount. It is of the utmost importance that what money is spent should be put to the best possible use. Under the circumstances described, and considering the amount of public money which has already been expended on organisations and establishments, all of which are awaiting development to produce their full return of work, I cannot see any justification for asking the Government, as a next step, to provide a considerable sum for a new organisation with a new laboratory, which to judge by all that has happened in the past would soon find itself as unable as its predecessors to adequately carry out its schemes, from the want of proper financial support.

The first demand should be for such a slight reorganisation of existing bodies as will bring them into working contact, a rearrangement which could be brought about with little if any increase of expenditure, and a proper provision of ships and naturalists for carrying out the investigations. When this has been obtained the co-ordination of British investigations with those of neighbouring countries will be a matter of no great difficulty, and one which, in my opinion, can be carried out with no such expenditure for organisation as that suggested by the Stockholm Conference.

As Mr. Kyle has seen fit to introduce matters of a somewhat personal nature into his letter, I may, perhaps, be permitted to say that I make no pretence whatever of being a specialist in fishery investigation, my scientific work having for the most part lain in other directions, nor is it my intention to attempt to alter this condition of things. Should the Government see fit to largely develop the work of the Marine Biological Association on the lines I have indicated, I fully realise that they will wish to have in the executive post a specialist in fishery matters, and this is an eventuality which I am prepared to meet. I should also add that the opinions expressed in this letter are entirely of a personal nature, and I am quite unaware whether or not they would be shared by a majority of the members of the Council of the Association. E. J. ALLEN.

The Laboratory, Plymouth, December 16, 1899.

Dr. W. Kobelt and the Mediterranean Fauna.

THE second part of Dr. W. Kobelt's "Studien zur Zoogeographie" has been in my hands since its issue, viz., about a year ago, and I have had ample time to become fully acquainted with its merits and its defects. The subject is one which has a singular interest to me, for I have been working out the fauna of Italy and its dependent seas, especially in relation to Vertebrata, for the last five and twenty years, and have formed a collection in which about 38,000 specimens (25,000 being fish) represent the vertebrate fauna of Italy and the seas which surround it. I soon found that although strong in Mollusca, Dr. Kobelt was weak in the knowledge of other classes of animals, and that along with solid fact" his book also contains a number of grave inaccuracies. Now I am very busy, and find that life is far too short to allow the waste of time caused by polemics; I usually, therefore, avoid them, and should certainly have passed over Dr. Kobelt's errors and omissions had not your reviewer's remarks in No. 1570 of NATURE (page 99) rendered it imperative that I also should ask you to allow me to make a few remarks. NATURE has now fully undertaken the noble task of keeping scientific investigators up to the mark as regards the general progress of knowledge, and it is not fair that it should unwittingly propagate error. Now of the several chapters of Dr. W. Kobelt's book, the poorest and the worst is by far the one (*viertes Kapitel*) which he has devoted to "Das Mittelmeer," the classic ground of the renowned labours of Edward Forbes and of so many before and after him. How ever could a German living in the land of bookworms and patient labourers in bibliography write such a chapter, and come amongst other incorrect and incongruous conclusions, to that pyramidal error that the abyssal parts of the Mediterranean are azoic? Good and learned Dr. Carpenter said something similar about twenty years ago, after the fruitless dredgings of the *Porcupine* and *Shearwater*, but he lived to know that he had been mistaken, and we discussed the very subject together at a dinner at his own house in June 1883.

It was on August 5, 1881, that I sent an express across Asinara to Porto Torres, North Sardinia, bearing a letter to the editor of NATURE in which I gave the first account of the discovery of typical representatives of the North Atlantic deep-sea fauna in the abyssal area off North-west Sardinia; on that occasion specimens of *Polycheles* (Willemœsia), *Brisinga* and *Hyalonema* had been secured with the trawl (NATURE, August 18, 1881, p. 358). A few days later, from depths between 3000 and 1500 metres, I got two new forms of Macrurid fishes, so characteristic of the abyssal fauna, viz., *Chalinura mediterranea* and *Hymenocephalus italicus*; of the former the two specimens then caught are as yet the only ones known. This was the first deep-sea campaign of the *Washington*; we were all new to such work, and yet a few weeks later, at the meeting of the Third International Geographical Congress at Venice, I was able to lay before the savants there assembled a preliminary report, in which the existence of a deep-sea fauna in the Mediterranean, similar to that of the North Atlantic, but evidently with some special features, was fully proven. Our greatest depth was then 3624 metres, between Sardinia and Sicily; thence we dredged up fourteen living animals: an Anomourous Decapod, an Annelid, and several singular small Holothuroids, as yet unstudied. The two following summers, about a month each year, were dedicated to thalassographic researches in the Mediterranean by the Italian man-of-war *Washington*, but the trawl was hardly ever used at the greater depths. The authorities of the navy, and I am sorry to add also those of the Lincei, appeared to have lost all interest in that fertile field of research. Years after, a little deep-sea trawling was done by the Austrians round about Crete; they got some good abyssals, amongst which *Bathypterois*, the singular tentacled fish; they also found the greatest depth yet recorded in the Mediterranean, over 4000 metres. The enlightened Prince of Monaco has also given a trial to some of his wonderful deep-sea traps, always with good results, but his systematic abyssal researches have all been outside our "Mittelmeer" hitherto.

I have never lost any opportunity since 1881 of doing my level best to promote the continuance of those thalassographic and especially abyssal researches, which had been so well begun by the *Washington*; my last appeal was made to the Third Italian Geographical Congress, which met at Florence last year, my proposals were adopted unanimously in the proper section, and I am beginning to hope that they may soon have a practical result.

I have not the slightest doubt that the abyssal fauna of the Mediterranean is a rich one, in which not a few novelties will turn up. I have already in my Italian collection about seventy species of typical abyssal fish—Elasmobranchs and Teleostei—and have, besides those already mentioned, described some very singular forms hitherto unknown, and apparently peculiar, such as *Bathophilus* and *Eretmophorus*.

After all this you will admit that it is rather sad to read in NATURE of November 30, 1899, that "the Mediterranean, as is well known, sinks in places to profoundly abyssal depths; the actually greatest depth appears to be 4400 metres; but here no living organisms have been found. It is purely azoic; the reason for the want of life is, according to the author, the want of oxygen and the abundance of carbonic acid." I should like to see the above assertion proved.

I may add that Dr. Kobelt, who is a specialist in Malacology, appears to be unacquainted with the abyssal molluscs which I dredged up from great depths in the Mediterranean, and which were described (several as new) shortly after by my lamented friend, J. Gwyn Jeffreys. And at p. 105 of his book he says that *Nephrops norvegicus* is not found in the Mediterranean. Now in 1881 I dredged up specimens from depths of 765–823 metres, in that sea, off the west end of Sicily.

Dr. Kobelt has a grim way of disposing of the Cetacea of the Mediterranean. These are much better known than he appears to be aware; I know positively that thirteen species occur, four being *Mystacoceti*; none are peculiar, and could hardly be expected to present that case, but it is of singular interest that the common porpoise (*Phocaena communis*) is certainly absent from the Mediterranean, and said to be common in the Black Sea. Our seal (*Pelagius monachus*) is nearly peculiar to the Mediterranean and Adriatic, where *Phoca vitulina* never occurs. This hardly looks like "an impoverished gulf of the Atlantic," as Dr. Kobelt is pleased to style our "Mittelmeer" as regards mammals. And, turning to terrestrial mammalia, what of the Mediterranean barrier *re* Muflons (*Ovis musimon*) in Corsica and Sardinia; *Cervus corsicanus*, with the same peculiar distribution—these mammals are found in a wild condition nowhere else—and *Cervus dama*, wild only in Sardinia? I will allow the *Inuus ecandatus* as an importation, but hardly as a native product of the "Rock" of Gibraltar!

Certainly I can hardly commend Dr. Kobelt's book to the serious student of zoo-geography; and I cannot help a bitter reflection when I come to compare mentally the favourable review it has had in these pages, where a few weeks earlier a volume, of which one of the co-authors may be styled the father of zoo-geography, and is emphatically one of the most meritorious of England's zoologists, was treated in a very different style (*vide* NATURE, No. 1549, vol. lx., p. 217).

HENRY H. GIGLIOLI.

Royal Zoological Museum, Florence,
December 8, 1899.

PROF. GIGLIOLI appears to blame me for a too favourable review of Dr. Kobelt's recent book. In that review I pointed out some errors, as I thought, of inference as well as of omission; I still think however that Dr. Kobelt has produced an usefully elaborate and painstaking work, and therefore beg for a short space wherein to reply to such of Dr. Giglioli's criticisms as affect my own review.

Dr. Giglioli justly comments upon the fact that many deep-sea animals have been dredged in the Mediterranean. But, as I understand him, Dr. Kobelt does not deny this; he merely observes that the abyssal fauna of the Mediterranean is not special to that sea. Dr. Giglioli himself remarks upon the occurrence of "typical representatives of the North Atlantic deep-sea fauna," which is in accord with what Dr. Kobelt says. That there are some forms peculiar to the Mediterranean does not necessarily invalidate the justice of Dr. Kobelt's generalisation. I do not read Dr. Kobelt as saying that "the abyssal parts of the Mediterranean are azoic." How could I, considering that he gives (p. 115) two lists of deep-sea Mollusca? I understood him to mean that one particular locality of 4400 metres in depth happened to be so. In this matter I simply referred to Dr. Kobelt's statement. I neither dissented nor assented. Dr. Giglioli is no doubt right in asserting that the whales of the Mediterranean are not only not peculiar but could not be expected to be. But if the number with which he is acquainted (13) represent the entire Cetacean fauna of that sea, then Dr. Kobelt is most emphatically right in speaking of it as an impoverished gulf of the Atlantic. THE REVIEWER.

THE ECLIPSE EXPEDITION AT VIZIADURG.

I.

SO much of the material acquired to science by the observations of the last total eclipse of the sun in India has now been published by the Royal and other Societies, that I now propose to give in the columns of NATURE a connected account of the work done and arrangements adopted at Viziadurg.

Four of us left London in the R.M.S. *Lusitania* on December 10, 1897, and that vessel reached Colombo on January 4, 1898. As we steamed into the harbour, about 1 a.m. on the 4th, the first ship we passed was Her Majesty's ship *Melpomene*, many lighted, white painted, her hull appearing phosphorescent in the dark night. Long before the *Lusitania* was moored, Lieut. Colbeck, R.N., of the *Melpomene*, and an officer of the Customs Department were on board, and such complete arrangements had been made that a few minutes after the mails had been put into one lighter, the instruments, which had been brought on deck the day before, were being delicately handled into another. There was therefore no sleep for any of us that night, and early in the morning Captain Chisholm-Batten, R.N., of the *Melpomene*, came on board. Shortly afterwards the eclipse party, with all their gear, were transferred from the mail steamer, after taking leave of Captain Veale and his officers, to the cruiser.

It did not require a keen observer to find out, after a very short time on board, that the Melpomenes had made up their minds to emulate the doings of their comrades on the *Volage*, in connection with the Varanger Fjord eclipse of August 1896, and also that this was in part due to the keen interest taken by Captain Chisholm Batten in all things scientific. He very soon put exactly the same question to me that Captain King-Hall had done two years before on the *Volage*, and I gave him the same reply. He said, "If you will explain to the ship's company what is wanted I will call for volunteers, and then we will see what can be done." I did as I was told.

We left Colombo at 5 p.m. on the same day. On the morning of the 5th (Wednesday) we sighted Cape Comorin, and in the early evening I explained, by means of lantern slides thrown on a screen under the bridge by an eighty-candle glow-lamp, the kind of work done during an eclipse, and how the ship's company of the *Volage* had organised themselves in 1896. When my talk was over, Captain Batten called for volunteers. To my delight and astonishment, and I must say rather alarm, about 120 officers and men at once stepped forward. Now that, of course, meant incessant school till the moment of the eclipse. However, we were all quite prepared for it, although it was evident that the Eclipse party of three had their work cut out for them.

The next delightful thing I found was that three or four of the officers of the ship were just as competent to give instructions on the various lines of work to be attempted as my assistants and myself were, so that the teaching was put into a very big commission.

FIG. 1.—The Fort.

This was an intensely interesting day to me, for while arrangements for the eclipse of 1898 were thus advancing, the *Melpomene* was following the sea-track of the flagship *Glasgow*, which carried the expedition of 1871. Cannamore was first passed, and later on Baikul, where my station was seven-and-twenty years ago. Heigh ho! Why is one not always young and full of energy, and why should the power of doing dwindle as one knows better what to do? But that is another story.

We began our drills the same night. An important part of the work was to get an idea of the outlines of the corona, and for that purpose I had taken out several discs which would hide the more luminous lower parts of it in order to shield the observers' eyes, so that they would be in the best possible position to note the delicate tracery outside. In addition to that, a large party had volunteered for drawing the corona, so we started drawing competitions; we had marks for form and for colour of the corona. For this purpose the ship rigged up a magic-lantern by means of one of the incandescent lights. We found a capital screen on deck in the shape of one of the casings; drawings and photographs (coloured) of the corona were thrown on the screen and copied under eclipse conditions. What do I mean by eclipse conditions? I mean this: experience shows that when the eclipse begins you must tell everybody how many seconds are left, otherwise they will lose time by trying to find out for themselves; if the eclipse is going to last 170 seconds, at the instant of totality we tell them so. After 10 seconds we say, "You have 160 seconds more"; after 20 seconds we tell them they have 150 seconds more, and so on, in as encouraging a way as we can. We adopted this plan in our practising.

The next thing which delighted me was, that not only was every rating in the ship represented two or three times over in the volunteers, but that almost all the men who volunteered to make these drawings had colour-boxes. Where they get them from I do not know, but colour-boxes they had. In the examination we gave 10 marks for colour and 10 for form; several of them got 18 out of a possible 20 marks. I mention that because it gives an idea of the thoroughness with which every part of the work was done.

It was a little over a day's run from Baikul to Viziadurg, where, on the 7th, Captain Batten, after a fine sweep into the bay, chose his station at 3 p.m. navy fashion, that is, pilotless, over the anchor shown on the chart. Soon after this the native pilot, in a boat which had hugged the southern shore, and had, perhaps, for this reason been unnoticed in spite of a tattered blue ensign with a lion in one of the corners, came on board, and after him a boat full of gorgeously-apparelled native officials accompanying Mr. Bomanji, Collector of the district of Ratnagiri, in which Viziadurg is situated, among them an overseer of the Public Works Department, who was on the spot in charge of some most excellent masons and carpenters, picked men from Ratnagiri as we later ascertained, and plenty of material for the construction of the necessary concrete bases and huts.

Mr. Bomanji came on board to report the arrangements which had been made for the expedition by the Government of India. As these were not quite completed, it was necessary for the first few days to return to the ship every evening, but afterwards Mr. Fowler, Dr. Lockyer, and myself took up our quarters at the Dak bungalow inside the fort, close to the instruments. Meals were provided at the Collector's camp, which was also inside the fort.

A party was landed at the fort on the afternoon of our arrival, Saturday, January 8, to inspect the site suggested by Mr. Bomanji, and it was at once evident that it would satisfy all requirements, provided the fluctuations of temperature of the great masses of masonry composing the fort had no disturbing influence on the steadiness of the air. In order to investigate this point a $3\frac{3}{4}$-inch telescope was set up, and observations of the surrounding landscape, and, at dusk, of various stars, were made, from which it appeared that the atmosphere was sufficiently steady for the observations.

We found a considerable number of coolies was also present to do such work as carrying packing-cases, sawing wood, clearing the camp, &c.

In the fort was also a police guard sent from Ratnagiri. The camp was watched both by day and night so effectively by them that no damage to any instrument was reported.

Description of Viziadurg.

Viziadurg, we found, is practically concentrated in its fort. A former collector of the district, Mr. Sinclair, had been good enough to send me a photograph of it. On landing, after the collector's visit, we found that the real thing is certainly far more extensive than the photograph suggested, and more than this, the building and its history are both of very high interest. The fort dates from the fourteenth century, but it was much strengthened in the sixteenth, when the towers and triple walls, the well-preserved ruins of which now encircle it, were added. These towers number twenty-seven; they rise to 100 feet, and, like the massive walls, are built of large blocks of stone, now coloured dark red, and almost black in places. The walls enclose about twenty acres, and within this space are habitable buildings, two wells, and a water reservoir, formerly lined with lead at the bottom and to about 10 feet up the sides, larger than the largest of the celebrated tanks at Aden. From the beginning of the sixteenth century the fort was the headquarters of piracy in the Indian seas. Kanhoji Angria, the admiral of the Maratha fleet, became a renowned corsair, and at his death was ably succeeded by his son, Julaji Angria. These gentlemen seemed to have had it all their own way. They respected no flag, captured many ships, sacked the coast towns, and, worst of all, repelled several expeditions sent against them by the English, Portuguese and Dutch. Julaji only finally surrendered in 1755 to a force of twelve men-of-war with some forty small native armed vessels, commanded by Admiral Watson, supported on land by an army of eight hundred European and six hundred native troops, under Lieut.-Colonel (afterwards Lord) Clive. Angria's fleet was destroyed, fifteen hundred prisoners were taken, and eight Europeans rescued. Two hundred and fifty cannon and eight brass mortars were found, and besides, stores and valuables worth 125,000*l.* After this the fort came under the Peshwa's government, and his admiral, Anandrav Dhulop, establishing himself therein, commenced a successful career, enriched himself, and added much to piratical science, until finally the British took possession of the district in 1818.

If the final cause of the pirates of Viziadurg was, as it seems to have been, the formation of an Eclipse camp, even to providing unexpended bombs for clock weights, the fact that they built the fort exactly where it is, commanding a harbour finer than that familiar to their-to-be *confrères* of Penzance, was evidently also connected with the present visit of the *Melpomene*. Equally sheltered from the fiercest blasts of both the south-west and north-east monsoons, the anchorage is as safe as it is convenient; but it must not at once be taken for granted that under these conditions the water surface is always smooth. The goddesses of meteorology have their smaller as well as their greater festivals, so that what the monsoons are to the year the land and sea breezes are to the day. The sea breeze sets in about noon with marvellous regularity, and is at its height about sun-down; as the night advances everything becomes calm, and at ten o'clock even the rattle of the jalousies in the windows of the fort has entirely ceased.

Precautions and Preparations.

While considering the desirability of establishing a station at Viziadurg, a friend of great Indian experience was loud in his praises of the Konkan as a health resort. He expressed his astonishment that yachtsmen, who generally know what is good for them, so constantly neglect to spend some winter months on a coast so delightful in many ways. Our experiences entirely justified my friend's views. Of course, great precautions have to be taken when so much work has to be done in the sun; but my Baikul experience told me the conditions are much better at Viziadurg than they are in South Canara. The sun's rays were almost always tempered by a breeze; the temperature at 8 a.m. was often about 70 degrees, and on shore 85 degrees was reached later on in the day.

Next morning, Sunday, January 9, the instruments were landed absolutely without the slightest difficulty. With reference to this a few words may be said concerning the preparations for an Eclipse Expedition, since few people have any idea of the labour involved or of the precautions to be taken. In the first place, all the instruments to be taken out must be adjusted for the place chosen for observation; that is, the so-called "Polar axis," on which each instrument turns, must be directed to the position which will be occupied by the pole star at the Eclipse station. Thus, while in London the axis points in a direction of 51½ degrees from the horizontal, in India this direction was about 16½ degrees. The instruments must then be made to work under these new conditions, and each position of all the optical portions which produces the best results must be marked most carefully, either by screwing down or by lines of white paint, so that each can be exactly replaced at the station. Then comes the taking down and packing. On this point I got a lesson in 1882 at Siout, in Egypt, which I shall never forget. It was a question of getting a stand, weighing about 3 cwt., of an equatorial telescope into the Khedive's yacht. There was no tackle, and the thing was got on board by the Egyptian authorities flogging a giant Soudanese up a plank with the stand on his back. Since then, in all the expeditions I have had to do with, all stands have been built upon the spot by filling a wooden and paper model with concrete; and, further, no packing case has weighed more than 60lb.; this enormously simplifies boat service. All mirrors and plates must be hermetically sealed up, parts of different instruments must not be mixed together in the packing cases, and all cases containing pieces of the same instrument must have the same index letter. As a result of this system we took to Viziadurg eighty cases, on which the skilled packers employed at the South Kensington Museum expended infinite care; they were all small and numbered and lettered, so that they could be easily landed the moment the sites for the several instruments were settled. The local labourers, under the efficient superintendence of the Public Works Department, had no difficulty in sorting the cases.

It was important to erect the huts as soon as possible, not only to shelter the instruments but the observers from the sun. Among the precautions taken in the camp I may mention that 10-feet square screens of excellent matting made locally and stiffened with bamboo were temporarily erected to the sunward of every working party, both at morning and evening. When it was necessary to go on with the work at mid-day, the same screens were supported over the workers by bamboos. As each instrument was erected it was permanently protected in the same manner.

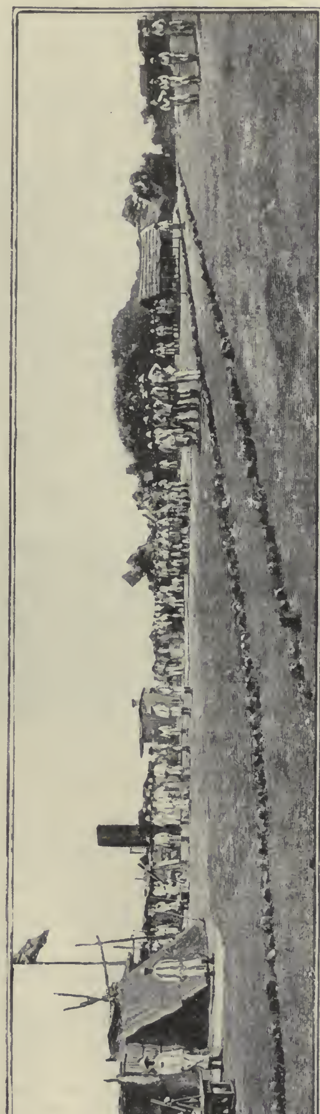

FIG. 2.—General view of camp.

With these precautions, and with such a climate, no one was sick.

The concrete pillars for the instruments were begun the day we landed. The men were brought on shore in the early morning in order to do the drills and erect the various instruments and all sorts of other work which turned up; but we had to knock off in the middle of the day in consequence of the extreme heat. It was very convenient for us that the *Melpomene* could lie at such a short distance from the camp that it did not take more than a quarter of an hour for the various parties to get to work. A signal station was at once established, so that, as at Kiö in Lapland, we could at once communicate with the ship in case anything were wanted.

In camp the work was incessant from sunrise to midnight, excluding the break in the middle of the day.

The instruments were set up as soon as their bases were ready. Mr. Fowler and Dr. Lockyer were enabled to report all the fixed instruments and huts, eight in number, erected and all but the final adjustments made after six days' work. Constant clear skies enabled all the adjustments to be made without difficulty, and by January 17 all the instruments were ready.

Life on Shore.

It became necessary on Tuesday, January 11, to transfer our quarters from the ship to the shore, as the erection of the instruments was by that time advanced to such a stage that it was possible to test the various adjustments by observations of stars. This change of front was accompanied by some difficulty, for many telegrams had been received telling us, now that this, now that that, was the shore arrangement which had been approved by the authorities, in one case of the Supreme Government, in the other of the Government of Bombay. The officials of the Bombay Government, in spite of letter from home of old date stating the exact opposite, were firmly convinced that independently of the supply of material for huts, the organisation of the camp and all the astronomical night-work on shore was a question of a tiffin basket; that it was rather exhilarating than otherwise in the climate of India to remain on shore with the aforesaid basket till one o'clock in the morning, and reach it again at sunrise.

They were also of opinion that a man-of-war of some three thousand tons could lie practically alongside the fort; that there was sleeping and other accommodation in a third-class cruiser for any number of shore hands; and finally, that it was open to anybody to walk on board and claim it.

The phantasmagoria of telegrams ceased on Saturday, and Captain Batten, who had insisted on sending his steward on shore to look after us, was now no longer dependent on the wardroom mess for his meals. As we had no servants and could not get any, he sent two Seedie boys to look after us and see to the lamps at night, which they did most satisfactorily. I was once more in the land of pantomime, and again came to the conclusion that after all spoken language may be a needless survival. The Collector, camping out some little distance away from the observatory, was now our host, and we had to thank him for unceasing forethought and kindness. We lunched and dined with him, and he supplied me with an interpreter, which facilitated matters greatly.

It took us some time to get through all Customs formalities, and the difference between Ceylon and Bombay methods we found curious. At Colombo, before the *Lusitania* had come to her moorings, Mr. Halliday, an officer of the Customs Department, came on board with a letter from Mr. Lionel F. Lee, the principal Collector of Customs, offering all possible assistance in landing and trans-shipping baggage and instruments. The Bombay officials were evidently of the opinion that the *Melpomene*, instead of coming from her station at Calcutta, had arrived straight from home full of contraband. The local official followed me round the camp with a bundle of forms, until at last, in despair, I informed him that, to my regret, I did not know the precise value of each article of wearing apparel brought out, but that all trunks could be opened for inspection on landing, and I would make any payment he might demand.

Our quarters in the fort were not without interest. They were in a building much more modern than the fort itself, and consisted of two rooms and a verandah on the first floor, approached by external stone steps. The ground floor, a little below the general level, we devoted to a dark room and a general store-room for the more delicate parts of the instrumental equipment. In each of the upper rooms, which were white-washed, with sanded floors, there was a bedstead, a chair and a tub; and after all, what more does one really want? I should add that there was also a looking-glass of much more gorgeous make, which did good service by blocking a door of which the fastening had given way. Further, in one of the bed-rooms there was a small table, now used for gastronomic and now for astronomic purposes. But the real furniture, both of rooms and verandah, were the pictures on, or rather in its walls. I mean the views from the windows when the jalousies were opened, especially some little time before sunrise and after sunset. I have never seen such effects of gorgeous, indescribable colours. Why was Lippmann not there to catch these colours, unknown in Europe—the fierce contrasts between the water and the land; between the beautiful river valley and the open sea; between the hard outlines of the gloomy ramparts below and the delicate landscapes which seem to float above them in the gloaming; and, finally, between the pure white of the *Melpomene* and the blue water on which she floated—a blue which at certain times of the day put the blue of the Mediterranean into the shade!

Of mosquitoes there were none; indeed, the absence of insect life was remarkable; of snakes we saw few, though the region has a very bad reputation, so bad that in 1876 the sum of 441*l.* was expended in killing 141,000. Of course, precautions were taken. Dr. Lauder Brunton and Prof. Fraser were good enough to provide me with the latest things in remedies, including *serum antiveneux*, which I handed over to Dr. Nolan, who posted up full instructions as to their use; but as this is a matter where prevention is better than cure, leggings by day and lamps by night were used by everybody.

And now a few words about the growth of the camp. The first shelter erected was for the use of the signalmen, for one of the guiding principles has been that no one need work in the sun unless he likes, and at the very first it was necessary that there should be signalmen to connect the camp with the ship. In relation to this first shelter, an idiosyncrasy of the blue-jacket, which I had a previous opportunity of studying at Kiö, came out. On landing in the morning I found this shelter already christened "Flaggies Villa"; the sailors on the staff of the other instruments were not going to be outdone, and as their shelters went up one got the idea of a village fair, for each carried a sign as I have previously mentioned: the 6-inch equatorial, of which Prof. Pedler arrived to take charge on the 13th, was the "Town Hall"; the 9-inch prismatic camera lived in "Mainsail Hall"; the 6-inch prismatic camera under Mr. Fowler's charge was accommodated in the "Central Hotel." The very much occupied hut which covered the cœlostat and the instruments which it feeds with light, that is, the integrating spectroscope and the two coronagraphs, was named the "Empire Palace." The whole fort was named "Batten's Camp," and the wall on which the discs were placed was called the "Common Hard"—the ship hailed from Portsmouth—and so on. In three or four days there was not a place which had not a name, and a very good name too.

The Lectures and Drills.

The lectures went on steadily from January 5 to 17. They were given by many of the ship's officers as well as by members of the Expedition.

The first drills of the work to be done at the chief instruments during the eclipse took place on the 13th. This statement, perhaps, requires some explanation. When a large instrument is brought out so great a distance to observe a fleeting phenomenon it is natural to try and get out of it the greatest possible amount of work. To secure this the greatest possible division of labour is the first and indeed the chief requirement. This means that many heads and hands must be employed in each of the operations necessary, and this spells drill, unceasing drill.

Now, if this crowd does not work together without the slightest hitch, failure is certain. I do not think I need say more as to the necessity for constant drill, but with regard to the complete operations something more than drill is necessary. With about 120 observers and helpers, on the principle of cutting the coat according to the cloth, a pretty large programme is permissible. When once this is settled, and the volunteers have selected a branch of the work in which they think they can render most efficient help, instruction as to the special points must be imparted. This was done without stint and almost entirely by the officers, and with such a will and skill that my own superfluity on the stage became increasingly obvious day by day. While this set one thinking in one direction along lines not untinged with regrets, in another there was great cause for rejoicing, for it will be a grand day for solar physics when the observations of eclipses will be among the recognised duties of a ship, such as the present one, on the station with a sufficient crew to tackle it.

While the instruments were being set up, one of the chief things accomplished was to organise the whole effort, so that when things were ready everybody could work together. As the number of volunteers was so large, I pointed out to Captain Batten, who had volunteered to aid in a special branch of the work, the importance of his taking charge of the whole camp and giving all the necessary orders for conducting the operations during the general rehearsals and the eclipse itself. He eventually agreed to this, and the procedure and time signals were arranged between us. To me, an old eclipser, it was a beautiful thing shortly afterwards to see the splendid drill commenced in eclipse form, along all lines, going on to the sound of the bugle.

It was found that with such a large number of volunteers we could practically undertake almost every kind of work which had ever been attempted during an eclipse. The

FIG. 3.—Preparing for a rehearsal. Captain Chisholm-Batten and time-party at the eclipse clock.

observers were divided into twenty-two groups, each in charge of a responsible person.

The groups of observers were as follows :—

(1) Time.
(2) 6-inch prismatic camera.
(3) 9-inch ,, ,,
(4) Integrating spectroscope.
(5) 6-inch equatorial.
(6) Coronagraph.
(7) Discs.
(8) Sketches of corona without discs.
(9) 3¾-inch equatorial.
(10) Observations on stars.
(11) Shadow-bands.
(12) Meteorological observations.
(13) Hand spectroscopes.
(14) Prisms for rings.
(15) Polariscope.
(16) Landscape colours.
(17) ,, cameras.
(18) Shadow phenomena.
(19) Kinematograph for eclipse.
(20) Kinematograph for shadow.
(21) Contact observations.
(22) Observations on natives, animals, &c.

NORMAN LOCKYER.

(To be continued.)

NOTES.

THE list of "New Year's Honours" includes the following names of men distinguished by their scientific attainments :—The dignity of a peerage has been conferred upon Sir John Lubbock, Bart. Dr. Lauder Brunton has received the honour of knighthood. Captain Abney has been promoted to a Knight Commandership (K.C.B.) of the Order of the Bath, and Major-General Festing has been created a Companion of the same Order (C.B.). Dr. Patric Manson, medical adviser to the Colonial Office, has been appointed a Companion of the Order of St. Michael and St. George (C.M.G.).

A WELL-ATTENDED meeting of the members of the Palæontographical and Ray Societies was held at the Geological Society's Apartments, Burlington House, on Tuesday, December 19; the Rt. Hon. Sir John Lubbock, Bart., M.P., President of the Ray Society, in the chair. The object of the joint meeting was to present to the Rev. Prof. Wiltshire, the hon. sec. of both the above-named societies, his portrait in oils, an illuminated address, and a cheque for 138*l.*—the balance of the sum subscribed after defraying expenses—in recognition of the services rendered by him to these societies and to palæontology and zoology during a period of more than thirty years. The portrait was executed by Miss Atkinson; the illuminated address by Miss G. M. Woodward. Among those present were Dr. Henry Woodward, F.R.S., President of the Palæontographical Society, the Rt. Rev. Bishop Mitchinson, Master of Pembroke, Oxford, Prof. T. McKenny Hughes, F.R.S., and Prof. W. J. Lewis, the Rev. R. A. Bullen, the Rev. G. F. Whidborne, V.P. Pal. Soc., the Rev. H. H. Winwood, Dr. W. T. Blanford, F.R.S., Mr. John Hopkinson, Prof. T. Rupert Jones, F.R.S., Sir Owen Roberts, Dr. D. H. Scott, F.R.S., Mr. F. W. Rudler, F.G.S., and Mr. A. Strahan; many ladies were also present. The presentation address was made by Sir John Lubbock, and the Rev. Prof. Wiltshire responded. Speeches were also made by Dr. Woodward, Prof. T. McKenny Hughes, Rev. G. F. Whidborne, and the Rev. H. H. Winwood; 132 subscribers took part in the testimonial.

A CONGRÈS d'Histoire des Sciences will be held in connection with the Paris Exhibition. As the development of all branches of scientific knowledge will be considered, the Congress will be of wide interest. Prof. Paul Tannery is the president of the organising committee, and Dr. Sicard de Plauzoles is the secretary. The official address is 10 boulevard Raspail, Paris.

PROF. MILNE-EDWARDS has been elected vice-president of the Paris Academy of Sciences for this year.

THE eighth Pasteur Institute existing in France was opened at Lyons on Monday, the seven others, in order of seniority, being Paris, Algiers, Tunis, Montpellier, Marseilles, Bordeaux and Lille. In connection with this, the *Times* points out that there are six Institutes in Russia, at St. Petersburg, Moscow, Samara, Kharkof, Warsaw and Odessa; five in Italy, at Bologna, Milan, Naples, Palermo and Turin; and two in Austria-Hungary, at Vienna and Budapest; while there are also Institutes at Saragossa, Malta, Bukharest, Constantinople, Aleppo and Tiflis. There are three in North America, at New York, Chicago and Havana, and two in South America, at Rio de Janeiro and Buenos Ayres.

THE important paper which Prof. J. J. Thomson communicated to the British Association meeting at Dover, on the masses of the ions in gases at low pressures, has been published in the December number of the *Philosophical Magazine*.

THE ion is now playing such an important part in physical investigations that many are anxious to become familiar with the work which has brought electrolysis to its present standpoint. An interesting article on electrolysis and the theory of ions has been communicated to *La Revue des deux Mondes* by M. A. Dastre, in which our readers will find the history of the subject fully stated.

WE regret to see the announcement that Sir James Paget, Bart., F.R.S., died on Saturday last, at the age of eighty-five.

THE *Times* states that the Paris Observatory will henceforth in all its publications reckon the day from midnight to midnight, the hours being numbered from 0 to 24. This system of time reckoning has been adopted in our *Nautical Almanac* since 1891.

WE learn from *Science* that Dr. G. A. Dorsey, curator of anthropology, Field Columbian Museum, accompanied by an assistant and the Rev. H. R. Voth, have gone to the Pueblo of Oraibi, Arizona. The object of the expedition is to secure additional ethnological material for the Museum, to witness the winter solstice ceremony just past in order to get suggestions for new groups, and also to start a systematic and somewhat extended excavation in order to strengthen the archæological exhibit from this interesting region. The expenses are covered by Mr. Stanley R. McCormick, of Chicago, who has placed 5000 dollars at the disposal of the Museum in addition to the 10,000 dollars already expended on the Hopis.

THE *Daily Chronicle* recalls that a London paper of the first week of 1800 alluded to the then recent hot disputes in France and England respecting the beginning of the nineteenth century. According to the paragraph, the famous Joseph Jérôme Lefrançais de Lalande, who then occupied the Chair of Astronomy in the University of Paris, had taken an active part in the controversy, and he had pronounced in favour of January 1, 1801. His decision had been generally accepted as correct on both sides of the Channel. The newspaper referred to remarks: "The same ridiculous question was agitated in 1700." So does history repeat itself.

AT the last meeting of the British Astronomical Association, Mr. Maunder made a statement with reference to the arrangements that are being made by the Association for the proposed expedition to Spain and Algeria to view the solar eclipse of May 28. Subject to a sufficient number of passages being actually taken before January 31, the Royal Mail steamer *Tagus*, or a sister vessel, will be engaged, and will start from Southampton on Friday, May 18, at 6 p.m., calling at Cadiz and Alicante, and arriving at Algiers at 6 a.m. on Thursday, the 24th. The vessel will stay there until after the eclipse, leaving at 6 a.m. on Tuesday the 29th, and calling at Alicante, Gibraltar, and Lisbon on the way to Southampton, which will be reached at 7 a.m. on Monday, June 4. It is hoped the members of the Association would divide themselves into three groups—those observing the eclipse (1) in the interior of Spain; (2) at Alicante or neighbourhood, and (3) in Algeria, where the ship will act as hotel for those who may wish to use it in that capacity.

UNDER the auspices of the Albany Institute and the Albany Historical Art Society, the anniversary of the birth of Prof. Joseph Henry was celebrated in that city on December 17th. In opening the meeting President Colvin paid a glowing tribute to Prof. Henry. The *Electrical Review* of New York reports him to have remarked:—"In 1831 Prof. Henry developed his system of magnetic telegraphy, and within these halls (Albany Academy) placed a telegraph wire a mile in length, over which signals were sounded by the self-same magnet and bell which you will hear to-night. The telegraph was now a reality—he would not patent it. Thus here began a greater phase of his character, his unselfishness and his devotion to the public welfare. We are now brought face to face with that noble nature, which as college professor, as director and developer of Smithson's magnificent bequest to the American people, as counsellor of the United States Government in its most important scientific and technical works, as a discoverer in many branches of science, made him great among our greatest—faithful, noble and true." An illustrated account of Henry's work appears in the *Scientific American* of December 23.

PROF. S. W. STRATTON, of the University of Chicago, has recently been appointed Inspector of Standards, Bureau of Weights and Measures. In accepting this position (remarks *Science*) Prof. Stratton takes immediate charge of the United States Office of Weights and Measures at a most opportune time. This Office has long had in its custody the national standards of length and mass, and has done much valuable work for science and the arts, which has been the logical outcome of this custody. Within the last two years the Office has taken up vigorously the matter of standards for electrical measurements, has acquired apparatus and made special studies, and is now ready to do valuable work along that line. It is especially well equipped for measurements of resistance of the highest degree of accuracy.

THE thirty-first volume of the *Zeitschrift für physikalische Chemie* just issued forms a pleasing novelty in scientific publication. This Jubelband, which is published as a whole and not in parts as usual, is dedicated by his pupils to Prof. J. H. van 't Hoff, to celebrate the twenty-fifth anniversary of his taking the degree of Doctor of Philosophy at the University of Utrecht. The introduction to the volume, by Prof. Ostwald, consists of a short biography of the distinguished Dutch Professor, and an appreciative *résumé* of his far-reaching discoveries, together with a complete list, compiled by Dr. E. Cohen, of his published researches. The authors of all the papers are old students of Prof. van 't Hoff, and each paper is written in the author's own language, with the exception of the Polish and Swedish contributors, so that German, English, French and Dutch are represented. As there are twenty-six papers in all, it is hardly possible to give a summary of them here, but the diversity of the subjects treated serves to show the many-sided originality of the author of the modern theory of solution. An excellent portrait of Prof. van 't Hoff in heliogravure is included in the volume.

DR. ROBERT WALLACE has republished as a separate leaflet his letter to the *Times* of November 29, on the African horse-sickness. The disease is a malarial fever produced by a minute fungus which grows during the summer on the *veldt*, but whether in water, on the soil, or as a parasite, is not yet ascertained. Although not contagious, it is contracted by animals exposed to the night air, especially in damp situations. The disease appears annually, but only in certain seasons attains alarming proportions. Its serious character may be gleaned from the statement that some 95 per cent. of the animals afflicted succumb. And unfortunately no effectual system of inoculation has yet been discovered to check its ravages. Certain precautions are, however, mentioned, which render horses less likely to be attacked; and we believe that horses fed on dry fodder, like those of the British cavalry, stand a better chance of escape than grass-fed animals.

AT a recent meeting of the Society of Arts, Mr. F. G. Aflalo read a paper on the necessity for legislative regulation of sea-angling. It was urged that angling from piers on the British coast resulted in a very appreciable diminution of the numbers of certain species of fishes, such spots being favourite feeding-grounds for fish of several descriptions. It was not that each boy that fished did much harm by himself, but the total catch by the entire army of boy-fishers must be very large indeed. And there is one very strong reason why legislation in regard to restoring under-sized fish to the sea should be enforced against the angler rather than against the steam-trawler. This is that while most of such fish are irretrievably injured by the trawler, the majority of those captured by the hook, if carefully removed, are little or none the worse for their temporary sojourn in the air. It is admitted that a large destruction of small fish takes place through trawling; but the only remedy for this would be to stop the industry altogether. On the other hand, the return of small fish captured by the hook to the water is a comparatively easy matter to enforce. The general sense of the meeting supported the author's views.

THE greater portion of the December issue of the *Zoologist* is taken up by the continuation of Mr. Distant's paper on mimicry; the illustration of "active mimicry" forming the subject of this section. Among many instructive examples, we may call attention to one very curious case. During the last decade gardens in Hamburg have been extensively planted with the white-leaved variety of the maple, and the common white butterfly has now accustomed itself to select that shrub on which to settle. Had Hamburg been a *terra incognita*, observes the author, there is little doubt that this practice would have been recorded as a striking instance of passive mimicry. Although not coming under the head of mimicry, we may mention that an analogous change of habit is taking place among many of the Argentine birds, which formerly built on the ground, but, as planting increases, are beginning to nest in trees.

WE learn from the U.S. *Monthly Weather Review* for September last, that the important international cloud work of the Weather Bureau, on which Prof. F. H. Bigelow has been engaged for several years, is now completed, and will be published in the annual report of that department for 1898–99. It will be remembered that about the middle of the year 1896 several meteorological services co-operated in taking a series of simultaneous observations on the height and motion of the ten standard types of clouds which have been defined by the International Cloud Committee, and that the observations were continued for at least a year. Those undertaken by the Weather Bureau were divided into two classes: (1) Those made by means of two theodolites placed at the end of a long base-line. These give the absolute height, velocity, and direction of motion of individual clouds at Washington. (2) Those made with nephoscopes at fourteen stations over the districts east of the Rocky Mountains, giving the relative velocity and direction of motion. The discussion of the data will show the distribution and average height of each type of cloud for every month, and the depth of the zone or horizontal belt in which each type may occur. A very important subject of investigation has been the determination of the direction and velocities of the horizontal motions of the air in each of the eight principal levels, on all sides of the areas of high and low barometric pressures as they move over the United States. This gives definite information regarding storm components, and will enable us to look more closely into the various theories of cyclones and anti-cyclones; it is stated that an attempt to interpret the analytical equations of motion has led to a different idea of the circulation in storms from that commonly taught by meteorologists.

SEVERAL drawings and reproductions of photographs of "the old moon in the young one's arms" are given in the *Bulletin* of the French Astronomical Society for December, 1899, with an article upon the subject of earth-shine, or *la lumière cendrée* as it is termed in France. Curious views have been held as to the reason why the whole dusky ball of

our satellite can be seen near the time of new moon. Posidonius thought that the moon was a diaphanous body, and that the rays of the sun passing through it caused the dull appearance observed. Tycho Brahe suggested that the appearance was produced by the illumination of the moon by Venus, and it was left to Leonard de Vinci to discover the real cause, namely, the reflection by the moon of sunlight reflected from the earth. The accompanying illustration of the phenomenon is from a photograph obtained by M. F. Quénisset.

APPENDIX III. to the Kew *Bulletin of Useful Information* for 1899 consists of a directory of the staffs of the Botanical Departments in these islands, in the colonies, and in India.

THE discovery of several lines in the infra-red spectrum of argon or of some associated gas is announced by Messrs. R. Nasini, F. Anderlini, and R. Salvadori in the *Atti dei Lincei*, viii. (2) 10. The spectrum, of which a photograph is given, was obtained from the residual gas of one of the fumaroli of

Vesuvius, but as it is stated to be perfectly identical in this region with that of argon obtained from air, and this again with the spectra of gases from other fumaroli of Vesuvius, from the rocks in the proximity of the crater, from the Grotta del Cane, from the Acque Albule of Tivoli, from the Bulicame del Viterbo, and from the carbon dioxide emanations of Pergine in Tuscany, the authors think that these lines belong to argon or to some gas accompanying argon in the air. The wave-lengths of the new lines are estimated by exterpolation to be 798, 803, 814, 832, 845, and 857·5, and Signor Anderlini has been able to see the first three lines in the Grotta del Cane gas. It is claimed that the lines in question have not been observed by Crookes, Kayser, Eder, Valenta and others.

IN the *Agricultural Gazette of New South Wales* for September, 1899, are several papers of more than local interest; especially one on the timber trade of New South Wales, by R. Dalrymple-Hay; protective inoculation against anthrax, by Dr. F. Tidswell, and entomological notes for 1898, by W. Froggatt. The last is illustrated by several excellent plates of insects destructive to timber.

WE have received *Bulletin* 175 (July, 1899) of the Michigan State Agricultural College Experiment Station (Entomological Department), edited by Messrs. Barrows and Pettit, and containing notes on about twenty species of insects observed during 1898, including a new moth destructive to peach, *Depressaria persicaeella*, Murtfeldt. The species now dealt with are different from those described in previous reports, and it is intended that future reports shall give a further selection, until all the more interesting or destructive insects of the State have been discussed. The greater part of the figures in this report are original.

WE are glad to notice that the first number of the second series of *The Library* contains a short section dealing with the progress of science, and some helpful notes for librarians on scientific works recently published. The selection of books is by no means complete, nor is it as representative as could be wished, but there seems no reason why this very useful part of an exceptionally interesting magazine should not be developed in future numbers. An excellent photogravure of Dr. Richard Garnett forms a suitable frontispiece to this first number.

DR. J. SANDERSON CHRISTISON'S little book "Crime and Criminals" has reached a second edition. It has been enlarged by the addition of an appendix containing analyses of the "Luetgert" case, which caused so great an excitement in America, and other noted crimes. The book is almost entirely made up of a series of articles on "Jail Types" which originally appeared in the *Chicago Tribune*. The photographs of actual criminals illustrating the volume will be of interest to students of criminology.

THE current number of the *Berichte* contains an important contribution by Dr. R. Scholl to the theory of the constitution of the fulminates. Of the numerous formulæ put forward since the first attempt of Kekulé, the simplest is that proposed by Scholl, and afterwards taken up by Nef, in connection with the views of the latter on divalent carbon, namely, that fulminic acid is carbyloxim, C : N.OH. The fact discovered by Nef, that the mercury salt of nitromethane on standing is partially converted, with loss of water, into mercury fulminate, is in good agreement with the above simple constitution. Further experimental support to this view is now given by Dr. Scholl in the present preliminary note, in which he aims at transferring the oximido group to a stable hydrocarbon radical. Silver fulminate and benzene react together in presence of aluminium chloride, forming benzaldoxim. The conditions necessary for securing good yields require very careful attention, and differ considerably from those generally favourable to the Friedel and Crafts reaction. Thus, with dry materials and freshly prepared aluminium chloride the yield was very bad; but the use of a commercial chloride gave good results. It was then found that the presence of a certain amount of moisture was necessary to obtain good yields, the highest being obtained when a mixture of pure, freshly prepared $AlCl_3$ and crystallised $AlCl_3.6H_2O$ was employed. These results are thus of interest from two points of view, the Friedel and Crafts reaction and the constitution of the fulminates.

THE additions to the Zoological Society's Gardens during the past week include a Black-backed Jackal (*Canis mesomelas*) from South Africa, presented by Mr. J. E. Matcham; a Mozambique Monkey (*Cercopithecus pygerythrus*) from East Africa, a Suricate (*Suricata tetradactyla*) from South Africa, two —— Chelodines (*Chelodina*, sp. inc.) from Australia, three Speckled Terrapins (*Clemmys guttata*) from North America, two Black-headed Terrapins (*Damonia reevesi unicolor*) from China, deposited.

OUR ASTRONOMICAL COLUMN.

HOLMES' COMET (1899 II.).—M. H. J. Zwiers gives a new ephemeris for this comet in the *Astronomische Nachrichten*, No. 3610. The object is getting so faint, however, that an abridgement for every fourth day only is given here.

Ephemeris for 12h. Greenwich Mean Time.

ORBIT OF EROS.—Signor E. Millosevich, of Rome, has communicated to the *Astronomische Nachrichten*, No. 3609, an ephemeris for facilitating observations of the minor planet Eros during the coming opposition at the end of the present year. The ephemeris extends over the period 1900 September 1–1901 January 31, the positions being computed from the following elements:—

Elements for Epoch 1900 *October* 31·5 *Berlin Mean Time.*

$$
\begin{aligned}
M &= 304° \ 23' \ 59''·7 \\
\pi &= 121 \ \ 9 \ \ 22·0 \\
\omega &= 177 \ 38 \ 41·6 \\
\Omega &= 303 \ 30 \ 40·4 \\
\iota &= 10 \ 49 \ 38·9 \\
\phi &= 12 \ 52 \ 48·2 \\
\mu &= 2015''·12740 \text{ (period } 643·14\text{d.)} \\
\log a &= 0·1638027
\end{aligned}
$$

THE SOLAR PARALLAX.—In *Comptes rendus* (vol. 129, pp. 986–993), M. Bouquet de la Grye furnishes the result of his discussion of the facts obtained by the various French expeditions sent out to observe the Transit of Venus in 1882. The reports hitherto published of the expedition have only dealt with the form of the planet's disc and the question of photography. The calculations of the solar parallax from the times of contact of the planet with the sun's limb have occupied several years. The author states that the external contacts are influenced by the size of the objectives of the observing telescopes, but the internal contacts do not show any such connection. Using Halley's method, and combining the observations from the several stations in all possible groups, he finds that:—

From observations with large telescopes $p = 8''·7996$.
,, ,, ,, small ,, $p = 8''·8068$.

and gives *mean parallax* $= 8''·80$ from the visual observations of French parties. A full discussion of the measures of the photographic records obtained will be presented shortly.

PRIZES PROPOSED BY THE PARIS ACADEMY OF SCIENCES FOR 1900.

THE Grand Prix des Sciences Mathematiques will be awarded in 1900 for an improvement, in any important point, of our knowledge of the number of classes of quadratic forms of two unknowns with entire coefficients; the Bordin Prize (3000 francs), for the development and improvement of the theory of surfaces applicable to the paraboloid of revolution; the Francœur Prize (1000 francs), for discoveries useful to the progress of pure or applied mathematics; the Poncelet Prize (2000 francs), for any similar work published during the last ten years.

In Mechanics: the Extraordinary Prize of 6000 francs will be given for any work increasing the efficiency of the French navy; the Montyon Prize (700 francs), for the invention or improvement of instruments useful to the progress of agriculture, the mechanical arts or sciences; the Plumey Prize (2500 francs), for improvements in steam engines or any invention contributing most to the progress of steam navigation.

In Astronomy: the Lalande Prize (540 francs) is offered for the most interesting observations, or work most useful to the progress of astronomy; the Damoiseau Prize (1500 francs), for a memoir on the theory of one of the periodic comets of which several returns have been observed; the Valz Prize, for the author of the most interesting astronomical observation made during the year; the Janssen Prize (a gold medal), for the most important discovery in physical astronomy; and an anonymous prize of 1500 francs, as an encouragement to the calculators of the minor planets, especially those discovered in the Nice Observatory.

In Statistics: a Montyon Prize of 500 francs, for a memoir on questions bearing on French statistics.

In Chemistry: the Jecker Prize (10,000 francs), for organic chemistry, and the Wilde Prize (4000 francs).

In Mineralogy and Geology: the Vaillant Prize (4000 francs) will be awarded in 1900 for a rigorous determination of one or more atomic weights, or for the study of alloys.

In Botany: the Barbier Prize (2000 francs) is intended to recompense whoever makes a valuable discovery in the medical, surgical, or pharmaceutical sciences, or in botany, in relation to the art of healing; the Desmazières Prize (1600 francs), for a memoir on the cryptogams: the Montagne Prizes (1000 francs and 500 francs), for work on the anatomy, physiology, development, or description of the lower cryptogams; and the Thore Prize (200 francs) to the author of the best memoir on the cellular cryptogams of Europe (algæ, mosses, lichens, or fungi), or on the anatomy of any species of European insect.

In Anatomy and Zoology: the Savigny Prize (975 francs), in aid of young travelling zoologists not receiving Government aid, more especially those occupying themselves with the invertebrates of Egypt and Syria; the Da Gama Machado Prize (1200 francs), for the best memoir on the coloured parts of the tegumentary system of animals.

In Medicine and Surgery: a Montyon Prize, for any discovery useful in the art of healing; the Bréant Prize (100,000 francs), for a specific antidote against Asiatic cholera, or for such a discovery of the causes of Asiatic cholera that those causes may be suppressed and the disease stamped out. The interest on the capital sum will be awarded for a rigorous demonstration of the existence in the atmosphere of materials capable of propagating epidemic diseases; the Godard Prize (1000 francs), for the best memoir on the anatomy, physiology, and pathology of the genito-urinary organs; the Parkin Prize (3400 francs), as a recompense for researches upon either the curative effects of carbon and carbon dioxide, or for the effects of volcanic action upon the spreading of epidemic diseases; the Bellion Prize (1400 francs), for works or discoveries especially profitable to the health of man; the Mège Prize, for a study of the causes which have favoured or retarded the progress of medicine; the Dusgate Prize, for the best work on the diagnosis of death, and on the means of preventing premature burial; the Lallemand Prize (1800 francs), for work on the nervous system; and the Baron Larrey Prize (1000 francs), for the best work treating of military medicine, surgery, or hygiene.

In Physiology: a Montyon Prize of 750 francs is offered annually; the Pomat Prize (1400 francs), for a determination of the principal anthropometric data; the Martin-Damourette Prize (1400 francs) and the Philipeaux Prize (890 francs), for work in experimental physiology. In Physical Geography, the Gay Prize (2500 francs), for the application to a portion of France, or a portion of the Alpine Chain, of the analysis of the geological circumstances which have determined the actual conditions of relief and hydrography.

Of the General Prizes, the following may be awarded in 1900: the Arago Medal, the Montyon Prize (unhealthy trades), the Cuvier Prize (1500 francs), the Tremont Prize (1100 francs), the Gegner Prize (4000 francs), the Delalande-Guérineau Prize (1000 francs), the Jérome Ponti Prize (3500 francs), the Tchihatchef Prize (3000 francs), the Boileau Prize (1300 francs), the Houllevigne Prize (5000 francs), the Cahours Prize (3000 francs), and the Saintour Prize (3000 francs).

GEOLOGY OF JAMAICA.[1]

THIRTY years have elapsed since the publication of the "Reports on the Geology of Jamaica," by James G. Sawkins and others, with an appendix by Robert Etheridge; a work published as one of the "Memoirs of the Geological Survey." In the work before us Mr. Robert T. Hill deals anew with the subject, his observations being based upon surveys made for Alexander Agassiz; and he has evidently spared no pains to investigate the geology and physical geography of the island in a thorough manner in accordance with modern knowledge. It is interesting to find him referring to the early paper written by De la Beche for the Geological Society in 1828 as "more in harmony with the conclusions to be presented by us than the subsequent and more extensive reports of the official surveys which supplanted them."

Mr. Hill considers that Jamaica presents a more favourable opportunity for detailed geologic investigation than any other tropical area. Highways, bridle-paths, and railways intersect the land in various directions, to say nothing of the coast-cliffs. Hence there is no lack of geological sections, and the author has had great advantages over those who preceded him. He remarks that the earlier researches "failed to solve the essential problems of the succession and age of the strata," and that the literature of no other region, especially that relating to palæontology, "presents so many erroneous conclusions." Curiously enough the author attributes this stratigraphic confusion, not to incompetence, but "to an act of Providence." It is well known that the original Director of the Jamaican Geological Survey, Lucas Barrett, was drowned in a diving-dress, and it is pointed out that the endeavours to interpret his opinions were the chief sources of subsequent erroneous conclusions. The stratigraphical errors were largely those of correlation, for it is admitted that otherwise the official reports were full of valuable data.

The author now starts afresh in naming and classifying the formations, using geographical terms, rather than those of a lithological or palæontological nature. The island is made up of Cretaceous, Eocene, Oligocene, Pliocene, and younger deposits, together with intrusive rocks. In adopting geographical names it would have been well, if possible, to have avoided the use of those names which are not original to the island, but are familiar elsewhere; to speak of the Jerusalem, Richmond, and Falmouth beds of Jamaica is at least unfortunate. So far as they go the Yallahs, Catadupa, and Manchioneal beds sound more appropriate, and the same may be said of the Bogue Island formation.

Evidence is given to show that locally the Cretaceous, Eocene and Oligocene formations were stratigraphically continuous, and we have a succession upwards from detrital to oceanic deposits. The higher Eocene beds contain *Cerithium*, *Lucina*, and Rudistes.

The white limestones of the Jamaican series are shown to represent several distinct ages, from Cretaceous to Recent, but the main mass belongs to the Oligocene. This mass forms the large plateau region which is really a dissected plain, rising in places to 3000 feet. It is known as "the cock-pit country," on account of the numerous swallow-holes, which vary from shallow circular basins to sink-holes 500 feet in depth. They are characterised by a bright red clayey soil, a residue from the dissolution of the limestone. Dykes of diorite and granitic rock penetrate Cretaceous, Eocene and Oligocene strata. The coastal deposits include various gravels, marls, and reef-beds of later Tertiary and Recent ages.

[1] "The Geology and Physical Geography of Jamaica: Study of a Type of Antillean Development." By Robert T Hill, *Bull. Museum Comp. Zool. Harvard Coll.*, vol. xxxiv., 1899, pp. 256; with 41 plates. (Cambridge Mass.)

The author discusses at some length the changes of physiography in tropical America, in their bearing on the history of the West Indian Islands. In Jurassic times there is evidence of a great expansion of land from the Rocky Mountains eastwards in North America, and over the north-eastern part of South America. "It is probable that the continental mass as a whole, practically equivalent in area to the present one, occupied a position slightly east of its present locus." The American fossiliferous marine Jurassic belonged to the Pacific area, and may have extended as far to the east as Havana. No evidence is recognised for establishing land connection between the islands and North and South American lands in Post-Jurassic time. The first evidence of Antillean lands is found in eruptive rocks of late Cretaceous time, when it is probable there were marine volcanoes. The land débris constituting the Eocene strata proves the pre-existence of extensive Cretaceous land-areas. In late Eocene and early Oligocene times there was a profound regional subsidence, and 3000 feet of purely oceanic deposits were accumulated. A great uplift occurred in late Oligocene or Miocene times, and subsequently many minor movements of elevation and depression have taken place.

In an appendix some Cretaceous and Eocene corals from Jamaica are described by Mr. T. Wayland Vaughan.

H. B. W.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

UNDER the will of Mr. James Brown Thomson, of Kinning Park, Glasgow, the University of Glasgow will receive 10,000*l*., and the Glasgow Technical College, 2000*l*.

MR. W. H. DERRIMAN, assistant lecturer in physics at the Technical College, Huddersfield, has been appointed to a similar post in University College, Liverpool.

Science states that Dr. Jokichi Takamine, of the University of Tokio, Japan, known for his researches on digestive ferments, is at present on a tour of inspection of the larger educational institutions of the United States. He has been sent by the Japanese Government to examine the scientific work and methods of American universities.

AN English Educational Exhibition will be held at the Imperial Institute on January 5-27. The exhibits will comprise students' work, and will refer to primary, secondary, technical, and higher education of both sexes. A series of lectures and conferences on educational subjects and demonstration lessons will be held at the Imperial Institute during the Exhibition. Particulars of the chief science conferences have already been given (p. 189).

THE *University Correspondent* has published its annual crop of amusing mistakes made by schoolboys in answers to examination questions. The following answers, selected from many similar ones, show how easy it is for pupils to receive inaccurate and confused impressions when given didactic instruction, and also how essential it is that examination questions should be explicit:—When would you expect an eclipse of the sun to take place? In the night.—The sun never sets on English possessions, because the sun sets in the west, and our colonies are in the north, south, and east.—The exports of Ceylon are peculiar to any other part of the world. The chief are piano steamers (sc. P. and O. steamers).—A cubic foot of water weighs 64 lbs. : ∴ a squate foot of water weights 16 lb., and a foot of water weights 4 lb.—The three principle parts of the eye are the pupil, the moat, and the beam.—A mariner's compass is a little poast stuck up in the sea, and when people want to know the way, the ships go and look at it.—Many other instances might be given, but those quoted are sufficient to show that there is much room for improvement in the teaching of scientific subjects while such hazy ideas exist in the minds of schoolboys.

SCIENTIFIC SERIAL.

Symons's Monthly Meteorological Magazine, December, 1899.—The aims of meteorology. This is a brief synopsis of a "Report on the Meteorology of Maryland," prepared by direction of the U.S. Weather Bureau. The article on special observations and investigations enumerates twenty-nine heads under which observations are made. While all are useful in different ways, any single service dealing with one-third of them would have little energy left for the improvement of the important work of weather prediction. Mr. Symons considers that the perusal of the work, consisting of about a hundred pages, is not merely instructive as a guide to the future, but also very useful as a record of past progress.—Kites and meteorology, by W. A. Eddy. This is a statement, in chronological order, of the various occasions on which kites have been used in meteorological investigations, from those in 1749, by Wilson and Melvill, near Glasgow, and in 1836 by Admiral Bach in Hudson Strait, in sending up thermometers, to those very successful experiments made in recent years at the Blue Hill Observatory, by means of the Eddy and Hargrave kites.—The same number also contains some interesting notes on damage by lightning, injurious effects of fog on plants, and unusual snow crystals.

SOCIETIES AND ACADEMIES.

EDINBURGH.

Royal Society, December 19, 1899.—Prof. Duns in the chair.—Dr. J. Souttar McKendrick, of Glasgow, read a paper on the zymolysis of tissues, physiological and pathological. After a short bibliographical sketch of the nature and action of enzymes as they exist in the digestive juices, with their methods of extraction, and mention of the observations of Nasse, Brucke, and others who had attempted to demonstrate the presence of ptyalin and pepsin in muscle, the author described in detail his method of procedure. He made glycerine extracts of between sixty and seventy tissues of the rabbit, child, adult, and those obtained post-mortem, and with each tissue extractive he endeavoured to demonstrate the presence or absence of enzymes similar in their action to ptyalin or amylopsin, pepsin, trypsin, inversin and rennin. A series of extractives were also made from certain pathological tissues, namely, carcinomata, sarcomata, tissues from an eclamptic, &c. The results pointed to the presence of pepsin, or a substance analogous to it, in all the tissues, physiological and pathological; to the presence of a diastatic ferment in most of the tissues; to the absence of tripsin except in the pancreas; to the absence of a milk curdling ferment except in those tissues in which it is known to exist; to the absence of an inversive ferment. Malignant tissues were found to have proteolytic and diastatic properties. Though rabbit's blood contained no diastatic enzyme, eclamptic blood contained such an enzyme in large amount; and all eclamptic tissues yielded extracts with markedly diastatic properties. The author in conclusion advocated the similar examination of the blood in all obscure diseases and of carcinomatous and sarcomatous growth.—Prof. Mitchell communicated a paper on the cooling of a body in a steady blast of air, Part II. In the later experiments the air currents had been varied from 10 to nearly 1000 metres per minute, and the temperature had been carried up to 120° C. Newton's law of cooling under these conditions was found to hold with great accuracy, and Newton's original statement, imperfectly quoted by most writers, completely verified. The rate of cooling was shown to be proportional to the difference of temperature for a given strength of blast, and to be proportional (for a given temperature) to the strength of blast up to a value of about 450 metres per minute, but to fall off from the law of proportionality for higher values. This was explained as a result of unsteadiness in the air current at these higher values—Dr. Mahalanobis described a new form of myograph, which consisted essentially of a T-shaped lever, pivoted so as to admit of horizontal movements free from the influence of gravity. The instrument was suitable for obtaining myograms of isometric and isotonic contractions of muscles, and most of the ordinary experiments on fatigue, tetanus, &c. The momentum of the lever during contraction of the muscle was approximately counterbalanced by the slight increase of tension in an elastic band, thus securing a fairly isotonic condition of the muscle.—Dr. C. G. Knott drew attention to the fact that Prof. Swan, of St. Andrews, had in 1859 constructed and used the form of photometer commonly associated with the names of Lummer and Brodhun, who described it in 1889. Swan's own description and figure will be found in the *Trans.* R.S.E., vol. xxii., 1861.—Prof. Tait, in a note on the claim recently made for Gauss to the invention of quaternions, showed that what Prof. Klein, both in the *Mathematische Annalen* and in his (and Sommerfeld's) treatise *Ueber die Theorie des Kreisels* ascribed to Gauss was not the Hamiltonian quaternion at all, but a particular and very limited kind of strain, which consisted of a simple rotation combined with an isotropic expansion, and thus involving four constants only. Klein and Sommerfeld's attempted identification of Gauss' operator with Hamilton's quaternion indicated a curious misapprehension on their part of the real essence of a quaternion.—Dr. C. G. Knott, in a paper on the same subject, gave a detailed criticism of the section in Klein and Sommerfeld's treatise devoted to the discussion of the theory of quaternions.

PARIS.

Academy of Sciences, December 26, 1899.—M. van Tieghem in the chair.—M. H. Milne-Edwards was elected Vice-President of the Academy for the year 1900.—Note on the work contained in the volume of the "Annales de l'Observatoire de Paris de 1897," by M. Lœwy. This volume inaugurates a new series of *Annales*, differing from preceding volumes both in the nature of the work carried out and the form chosen for publication.—On the radiation of radio-active bodies, by M. Henri Becquerel. There would appear to be a fundamental difference between the radiations of radium and polonium salts, in spite of their similar photographic action, as the polonium radiations placed in a magnetic field show no influence of the same order as observed for radium.—Experimental cultures on the adaptation of plants to the Mediterranean climate, by M. Gaston Bonnier. The object of these researches was to find out if plants taken from temperate climates to the Mediterranean could so modify their form and structure as to adapt themselves to their new surroundings. Experiments were carried out with a large number of different species, and nearly all showed, even after one season, notable differences in form, the stems becoming more ligneous, even stems of one year's growth, the leaves larger and thicker with the veins more strongly marked.—Researches on the tautomerism of benzoyl-benzoic acid, by MM. A. Haller and A. Guyot. From its mode of formation from benzene and phthalyl chloride, benzoyl-benzoic acid would appear to have the constitution of an oxylactone, and this view is confirmed by the formation of diphenyl-phthalide from its chloride. But, on the other hand, in many reactions both the chloride and acid exhibit undoubted ketonic properties. It thus appeared to be interesting to see if the tautomeric modifications of this acid could be obtained as methyl ethers. Methyl-*o*-benzyl benzoate was accordingly prepared by five different methods, direct etherification by hydrochloric acid, interaction of methyl iodide and the silver salt, interaction of benzoyl-benzoic anhydride and sodium methylate, action of sodium methylate upon acetyl-benzoyl-benzoic anhydride, and upon benzoyl-benzoic chloride. In all cases the same ether was produced, which would appear to be the true ketonic ether, $C_6H_5.CO.C_6H_4.CO.(OCH_3)$.—Remarks by M. Albert Gaudry, upon a work of M. Erland Nordenskjold.—General Gallieni was elected a correspondent for the Section of Geography and Navigation.—Observation of the eclipse of the moon of December 16, 1899, with the photographic equatorial at Toulouse, by M. Montangerand. Experiments with plates of different degrees of sensitiveness showed that panchromatic plates give better results with a total than a partial eclipse.—Observations of the new planet EY (Charlois), made at the Observatory of Besançon, by M. P. Chofardet.—Organisation of the daily registration of the entire chromosphere of the sun at the Observatory at Meudon. First results, by M. H. Deslandres.—Remarks on the preceding communication, by M. J. Janssen.—On the employment of triphase currents in Radiography, by M. Delézinier.—On the discontinuities produced by the brusque expansion of compressed gases, by M. Paul Vieille. Diaphragms of collodion were constructed capable of standing a pressure up to twenty-seven atmospheres. By the sudden rupture of this diaphragm, an explosive wave was set up, the front of which was more symmetrical than when explosives are used. The mean velocities of propagation of the wave were measured at different distances from the diaphragm. Velocities could thus be obtained of over 600 metres per second, greater than the velocity of sound.—On some phenomena presented by iron, by M. Galy-Aché. The results of the experiments upon a very pure sample of iron are in accord with the views of Osmond and Werth, that there are two allotropic varieties of iron, α-iron, stable at the ordinary temperature, and β-iron, stable at high temperatures.—On the changes in volume accompanying the hardening of hydraulic cements, by M. H. Le Chatelier. The contraction was measured by sealing up the cements in the bulb of a thermometer containing water. The absolute contraction after six months was between 4 c.c. and 5 c.c. per 100 grams of cement. There was at the same time an apparent expansion, sufficient in some cases to burst the bulbs of the thermometers.—On the temperature of transformation of the two varieties, quadratic and orthorhombic, of mercuric iodide, by M. D. Gernez. The transformation-temperature is 126°. The temperature of 75°, found by M. Wyrouboff, is due to an error caused by his working *in vacuo*.—New experiments upon the activity of manganese with respect to the phosphorescence of strontium sulphide, by M. José Rodriguez Mourelo.—On molybdenum silicide, by M. E. Vigouroux. Silicon combines directly with molybdenum in the electric furnace, forming Mo_2Si_3, which is obtained pure with difficulty. It burns in chlorine at 300°, giving silicon tetrachloride and molybdenum perchloride.—On molybdenum disulphide, by M. Marcel Guichard. Of the various methods suggested for the preparation of molybdenum disulphide, two only are satisfactory, the fusion of potassium carbonate and sulphur with molybdenum dioxide, and heating sulphur to a high temperature with ammonium molybdate. The first method gives a crystalline product, the second an amorphous one. By the action of heat a new sesquisulphide is formed, further particulars of which will be given in a subsequent note.—The action of nitrous acid upon the leucobase $C_{18}H_{24}N_2$, by M. A. Trillat.—Heat of neutralisation and acidimetry of cacodylic acid, by M. Henri Hibbert. Cacodylic acid is a feeble monobasic acid, being neutral to helianthine and monobasic to phenol-phthalein.—The hydrate of sodium dioxide and the prepration of hydrogen peroxide, by M. de Forcrand.—On the anhydrous sesquichlorides of rhodium and iridium, by M. E. Leidié. The double chloride $Rh_2Cl_6 6NaCl$. (with $3H_2O$ or $18H_2O$), heated in a current of dry hydrogen chloride up to 440° C gives a mixture of Rh_2Cl_6 and NaCl from which the latter can be removed by washing with water. The hydrogen chloride may advantageously be replaced by chlorine if the double salt is previously dried at 105°–110° C. The corresponding iridium chloride is best obtained by heating $Ir_2Cl_6 6NH_4Cl$ in chlorine at 440° C.—The biochemical oxidation of propylglycol, by M. André Kling. Following up his previous work on this subject, the author has now proved that the reducing body formed by the oxidation of $CH_2(OH)CH(OH)CH_3$ is acetal, $CH_3.CO.CH_2OH$.—On the preparation of the carbazides. Action of the hydrazines upon the phenolic carbonates, by MM. P. Cazeneuve and Moreau. By the interaction of phenyl carbonate and phenyl-hydrazine a good yield of carbohydrazide is obtained. Similarly hydrazine hydrate gives carbazide, $CO(NH.NH_2)_2$. The method appears to be capable of general application.—Combinations of lithium chloride with ethylamine, by M. J. Bonnefoi. From the dissociation pressures of the compounds $LiCl.C_2H_5(NH_2)$, $LiCl.2C_2H_5(NH_2)$, $LiCl.3C_2H_5(NH_2)$, the heats of dissociation are calculated by Clapeyron's formula to be 13·72 cal., 11·09 cal., and 10·50 cal. These numbers were also measured directly in the calorimeter, and found to be 13·83 cal., 10·98 cal., and 10·57 cal. respectively.—On narceine, by M. Émile Leroy. Measurements of the heats of hydration, combustion, and formation of narceine and its salts.—On the evolution of mineral matter during germination, by M. G. André.—On the estimation of the halogens in organic compounds, by M. Amand Valeur. The determination of the halogens in organic compounds can be carried out very rapidly and accurately in the calorimetric bomb, provided that a suitable quantity of naphthalene is burned at the same time. For chlorine and bromine, strong ammonia is placed in the bomb, and this liquid analysed volumetrically either by Mohr's or Volhard's method. The whole analysis can be finished in half an hour. For iodine the ammonia is replaced by potash solution. Tetra-iodo-ethylene, containing 95·5 per cent. of iodine, gave very good results by this method.—On some effects of electric discharges upon the heart of mammals, by MM. J. L. Prevost and F. Battelli. Under the influence of a current of suitable strength, the tremulous vibrations are replaced by true rhythmic contractions of the heart, with restoration of the blood pressure, if the current is applied within fifteen seconds of the appearance of the trembling.—General considerations on the male reproductive organs of the Coleoptera, by M. L. Bordas.—The evolution without heterogony of an Angiostome of the ringed adder, by M. Railliet.—On the pigment of the Arenicolæ, by M. Pierre Fauvel.—Chlorophyllian assimilation in solar light which has traversed leaves, by M. Ed. Griffon. The passage of light through a single leaf causes a notable weakening in the activity of those rays which are required for the chlorophyllian assimilation. The results vary much with the conditions of temperature and lighting.—On a bacterial zooglea of definite form, by M. Radais.—On the elements of limited symmetry, by M. Walleront.—Observations on the structure of the diluvium of the Seine, by M. Stanislas Meunier.—On a new hypothesis on the nature of the physical conditions of smell, by MM. Vaschide and Van Melle. The authors combat the view that the sense of smell is due to the emission of particles from the substance, and suggest that the effect is produced by rays of short wave-length, analogous, but not similar to, light rays, Röntgen rays, &c. They adduce ten arguments in favour of their hypothesis.—On a cranial campylogram, by MM. Blin and Simon. A description of an instrument for measuring the curves of the cranium in the living.—Barometric movements caused on the meridian of the sun by its movement in declination, by M. A. Poincaré.

CAPE TOWN.

South African Philosophical Society, November 29, 1899.—Mr. L. Péringney, President, in the chair.—The President recorded the deciphering, by Mr. Donald Ferguson, of an old stone which has been in the South African Museum since 1855. The stone was known to the late Dr. Atherstone and Mr. C. A. Fairbridge as the Mossel Bay stone. It is a rudely cubical block of sandstone with a cut inscription on one surface, which, however, has been broken across. On the fractured surface, at right angles to the inscribed face, there is a peculiarly shaped cross. Mr. Sclater sent an impression of the inscription to Mr. Ferguson, who translated it as follows:—"Here was lost the ship *Sao Gonzalo* in the year 1630. They made [built] two boats . . . ?" An account of the fleet of which the *Sao Gonzalo* formed a part is given in an old MS. in the British Museum, a transcript and translation of this being sent by Mr. Ferguson. The wreck occurred at Bahia Fermoza, now Plettenberg Bay, and the stone had originally marked the spot. Some of the present inhabitants of Plettenberg Bay remember a stone having been sent to Cape Town, and it is most probably this so-called Mossel Bay stone.—Dr. Gilchrist read a paper on, and showed a specimen of, a new Aplysia. The new species (*Paraplysia Lowii*), found at East London, is the third known one of the group of the Tectibranchiata, characterised chiefly by the peculiar position of the rhinophora. It differs from the other two species, *P. piperata* (Smith) and *P. monhoti* (Gilchrist) in several features which have been supposed to be characteristic of the genus Paraplysia proposed by Pilsbury.—Messrs. Rogers and Schwarz gave an account of the "Orange River Ground Moraine" in the neighbourhood of Prieska. Sections near Prieska show an ancient morainic conglomerate passing underneath the so-called Kimberley shales, and lying unconformably on the older Jasper rocks, quartzites and granite. The conglomerate contains numerous striated boulders, and the underlying rock often presents a rounded, scratched surface, which frequently forms distinct *roches moutonnées*. The ice passed from north to south. The authors could not say certainly what the exact relation of this conglomerate to the Dwyka conglomerate is, but are of opinion that it partially at least represents the land-formed ground moraine of the ancient glacier whose water-borne detritus has elsewhere formed the Dwyka conglomerate. The paper was illustrated by photographs and specimens of the striated boulders and floor.—An account of the earthquake of September 15, 1899, presented by the secretary, was taken as read.

DIARY OF SOCIETIES.

THURSDAY, JANUARY 4.

ROYAL INSTITUTION, at 3.—Fluids in Motion and at Rest: C. V. Boys, F.R.S.
RÖNTGEN SOCIETY, at 8.—The Interpretation of Skiagrams: Chisholm Williams.

FRIDAY, JANUARY 5.

GEOLOGISTS' ASSOCIATION, at 8.—Our Older Raised Beaches: Address by Sir Archibald Geikie, F.R.S.—A New Rhætic Section at Bristol: W. H. Wickes.

SATURDAY, JANUARY 6.

ROYAL INSTITUTION, at 3.—Fluids in Motion and at Rest: C. V Boys, F.R S.

MONDAY, JANUARY 8.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Colour Photography: J. W. Hinchley.—Cinchona: J. M. Vargas Vergara.—Microscopic Character of Vicunna, Camel-hair, and Alpaca: R. M. Prideaux.

TUESDAY, JANUARY 9.

ROYAL INSTITUTION, at 3.—Fluids in Motion and at Rest: C. V. Boys, F.R.S.
INSTITUTION OF CIVIL ENGINEERS, at 8.—The Purification of Water after its Use in Manufactories: Reginald A. Tatton.—Experiments on the Purification of Waste Water from Factories: W. O. E. Meade-King.
ANTHROPOLOGICAL INSTITUTE, at 8.30.—The Oak and the Thunder God: H. M. Chadwick.—Notes on some Caves in the Zitzikamma, or Outeniqua District, near Knysna, South Africa, and the Objects found therein: Dr. H. D. R. Kingston.—Notes on Skeletons found in the Zitzikamma and Knysna Caves: F. C. Shrubsall.

WEDNESDAY, JANUARY 10.

GEOLOGICAL SOCIETY, at 8.—On a Particular Form of Surface, the Results of Glacial and Subaerial Erosion, seen on Loch Lochy and elsewhere: Dr. W. T. Blanford, F.R.S.—On the Geology of Northern Anglesey, Part II.: C. A. Matley.—The Formation of Dendrites: A. O. Watkins.

THURSDAY, JANUARY 11.

MATHEMATICAL SOCIETY, at 8.—A Problem in Resonance, illustrative of the Mechanical Theory of Selective Absorption: Prof. Lamb, F.R.S.
INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Report of the Institution's Visit to Switzerland. The Report will be taken as read, and the discussion will be opened by Mr. Crompton by a Comparison between British and Continental Practice in Electrical Engineering.

FRIDAY, JANUARY 12.

ROYAL ASTRONOMICAL SOCIETY, at 8.
INSTITUTION OF CIVIL ENGINEERS, at 8.—The Theory of Structures and Strength of Materials: Prof. T. Claxton Fidler.

ASTRONOMICAL AND OPTICAL INSTRUMENTS.

Handbuch der Astronomischen Instrumentenkunde. Von Dr. L. Ambronn. Zwei Bände. Mit 1185 in den Text gedruckten Figuren. Pp. vi + 1276. (Berlin: Julius Springer, 1899.)

Die Optischen Instrumente der Firma R. Fuess deren Beschreibung, Justierung, und Anwendung. Von C. Leiss. Mit 233 Holzschnitten im Text und 3 Lichtdrucktafeln. Pp. xiv + 397. (Leipzig: Wilhelm Engelmann, 1899.)

WHOEVER undertakes to write a manual on astronomical instruments, or indeed on the instruments that the study of any branch of physics demands, engages in a task of no common difficulty. It is impossible to turn over the two handsome and ponderous volumes that Dr. Ambronn has compiled, without being struck with the wealth and variety of material that is submitted to our notice. The successive effects of ingenuity as detailed in these volumes are so bewildering in their extent, that it is quite impossible within the limits of a few paragraphs to do justice to the labour and research to which these volumes are an eloquent witness. We can only hope to sketch the scheme, to suggest the lines on which, in the opinion of the author, a text-book on astronomical instruments should proceed. The lucidity of explanation and the wealth of illustration only make the task the more difficult, by demonstrating the number of points that are worthy of comment and attention.

The history of construction, the gradual evolution of the telescope or equatorial, interesting and inviting as such a subject must be, is not allowed to any extent to interfere with the author's project of presenting before astronomers, and before mechanicians, the devices which have been sanctioned by experience and approved after repeated tests. Historical remarks there must be, the comparison of the work and methods of one maker with another, the growth of convenience and power of instruments necessitates descriptions which illustrate historical progress; but such remarks are incidental, and do not concern the main purpose of the work. The present standpoint of mechanical art and the achievements of workshops of known reputation, of themselves cover an enormous ground, which will be studied with profit alike by those who seek to modify existing instruments in a direction which will make them available for special investigations, and by those to whom are necessarily entrusted the duties of manufacture and the details of arrangement.

The work really consists of seven separate treatises, each fairly complete in itself, and the whole forming an encyclopædia, an invaluable work of reference on astronomical instruments. These seven sections are entitled: (1) Accessory apparatus; (2) clocks; (3) separate parts of instruments; (4) micrometers; (5) instruments devoted to special purposes; (6) complete instruments; (7) observatory buildings. The division is somewhat artificial, and cannot be rigorously maintained. For instance, a heliometer might be described as a complete instrument rather than as a special form of micrometer, and there seems no reason why chronographs should not be treated under clocks. Of course, no confusion can possibly arise from such a method of division, because each instrument serves a definite purpose, and its mode of use is perfectly defined. Simplicity of construction is perhaps the best guide to arrangement, and it may be that which the author has followed. Certainly he is well advised in selecting the screw as the first subject for detailed description, and the effective treatment applied to this simple piece of apparatus, whether as a tool in the hands of a mechanic or in the more delicate application to measurement as a micrometer, assures us that we are in presence of a master. We have many useful and ingenious hints both in construction and use, and it is of special importance to notice, as lifting the book out of the category of merely descriptive works, that the author has added an example of the method of determining the errors of a screw as the problem comes before the practical astronomer. But this, and other perfectly legitimate applications of theory to be met elsewhere in the book, suggest a difficulty which, we feel sure, the author has experienced, and introduce a feature which may be considered not altogether satisfactory. How far should a manual of this character concern itself with the theory of instruments? It was evidently the intention of the author not to supply a descriptive work simply, not a manufacturer's catalogue illustrated by many engravings, but to add also a theoretical treatise which might be useful to the astronomical student. But to enter into the theory with that rigorous detail which characterises many text-books, would evidently carry the author too far, and might add another volume to a work whose length is already sufficiently forbidding. There is, therefore, a constant struggle between the theoretical and descriptive parts, in which the former is usually worsted, and the maintenance of the same high standard of excellence common to both is rendered impossible. For instance, the theory of the sextant is in its way more complete than that of the heliometer, simply because the same actual space is approximately allotted to each. One cannot help feeling that the author has not done himself justice in the matter of theoretical discussion, and we hope that he may be tempted to return to the subject and complete his work by giving a theory as precise and thorough as the descriptive portion is clear and satisfactory.

From the screw it would have seemed natural to have gone at once to the reading microscope and the micrometer; but the author has preferred to interpolate the description of levels, collimators, and other mechanical devices, which are not so much astronomical instruments as aids to adjustment and means for inquiry into the stability of the instrument properly so-called. In the second section, Dr. Ambronn breaks away from his account of space measurement in order to describe clocks and time-recording instruments. The treatment here is mainly conducted from a German point of view, and more attention might have been bestowed on improvements that have been suggested by English authorities. But, of course, one admits readily enough that

M

he has to do with a German book, written in German for German students and workpeople, and some allowance must be made for patriotism. What would seem a fault in one longitude may be regarded as a merit in another. In fact, a comparison between rival methods of construction and the effort to apprehend the manner in which merits, fully recognised here, are appreciated abroad, constitute one of the main features of interest in this book. For instance, we should gather that the gravity escapement is not so highly considered in Germany as among ourselves.

The separate parts of the instrument which come under detailed description in the next section are axes, the telescope properly so-called with its optical arrangement, and circles. Each of these sections will be found to contain excellent matter, and though one might point out small omissions, to which accident has possibly directed special attention, it would be ungracious to do so without admitting that the author has also collected numerous facts that one has either forgotten or imperfectly apprehended. Under the heading of circles will be found some very interesting remarks on the subject of dividing engines. Whether the introduction here is legitimate we will not stop to inquire, for it might be urged that a dividing engine is no more an astronomical instrument than a lathe or a screwdriver; but the information is so pertinent, and, as we imagine, rather inaccessible, that we cannot but welcome this slight excursion from the observatory to the workshop.

The second volume opens with an account of the micrometer in all its various forms, with wires and without. Under this second head the author places the heliometer, and does not appear prepared to regard this peculiar device as a complete instrument. But his practical acquaintance with its use not only entitles him to speak authoritatively, but supplies him with instances and examples of the method of determining the corrections. We doubt, however, if the popularity of this form of measurement will increase in this country. The fifth section is the only one to which we are inclined to take any exception. In it we have to do with the modern developments of photography, as applied to astronomy, whether in the determination of stellar positions or the interpretation of spectroscopic results. Photometers, spectroscopes, heliostats, and a variety of other apparatus are dovetailed together into this section, with the result that we miss the minute and varied detail that lends a charm to so much of the work. Neither can we altogether accept the author's excuse that a thorough description would lead him too far from his purpose, or that able authorities like Müller and Scheiner have recently discussed in detail the matter treated in this section. To have compiled an account of the instruments used for the determination of position would have been a perfectly intelligible undertaking, and it is in fact what Dr. Ambronn has accomplished with great skill and elaboration. We think he would have been well advised, considering the completeness on which he had planned his work, to have limited his task to such instruments, and refused to consider those that are more particularly adjuncts to the physical laboratory. But it must be clearly understood, that it is only in comparison with the remainder of the book that we notice any falling off from the high level which is elsewhere uniformly maintained. Some 150 quarto pages with 134 illustrations is in itself a treatise of considerable size and merit, and one which we may accept with gratitude.

Under the heading of "complete instruments" we have descriptions of every kind of Transit Circle and Equatorial that ingenuity has suggested and engineering skill has constructed. Indeed, in some instances, such as the particular form of Transit Circle suggested by Dr. Common, the fertility of resource on the part of the inventor has outrun the makers' capacity to realise. Sextants and Altazimuths; the Almucantar and the Chronodeik are not only illustrated by a profusion of diagrams, but examples of results are added. It is impossible to do justice either to the wealth of information or the judicious arrangement which characterise this section on meridional and extra-meridional telescopes. For the numerous forms of equatorial receive the same share of careful attention and historical illustration as do the transit instruments. From Sissons early experiment down to the latest addition to the Cambridge observatory, one might say that no typical construction has been omitted. The more one studies the pages of this excellent encyclopædia of astronomical instruments, the more convinced will he be that it should find a place on the shelves of every observatory, and in the library of every instrument maker.

The second work placed at the head of this article must of necessity partake of something of the nature of a manufacturer's catalogue, but it is so much in advance of the usual compilations of that character, that a very feeble notion of its aim and contents is gained by such a comparison. The production betokens not only a very considerable amount of enterprise on the part of those who are responsible for its preparation, but it intimates the extent of the demand for high-class instruments in Germany, and shows the manner in which that demand is met and encouraged. In reading the book, or portions of it, we experience the same feeling as in being conducted through a scientific exhibition by the ablest of guides. A constant succession of pleasurable surprises meets one at every turn, in noting how difficulties are smoothed away by ingenious appliances. Dr. Leiss, who is well known from his contributions to the *Zeitschrift für Instrumentenkunde*, plays the part of the guide with a skill which suggests that many of the instruments, with whose adjustments he is so familiar, owe their final form to his ingenious skill. There is no necessity to enumerate the various classes of instruments that here find adequate illustration. All that is needed for the physical laboratory on the side of its optical equipment, whether for education or research, finds its place here. Spectrometers and spectroscopes, goniometers and polarising apparatus in wonderful variety, microscopes with endless accessories, are pictured and described. And not only is the student considered, but the lecturer also, for an excellent chapter on projection apparatus is added. The one fact that stands out clearly from this wonderful display is the progress that has been made in recent years, both in the variety of apparatus and the excellence of workmanship.

WIRELESS TELEGRAPHY.

A History of Wireless Telegraphy, 1838–1899. By J. J. Fahie, M.I.E.E., &c. Pp. xvii + 325. (Edinburgh and London: William Blackwood and Sons, 1899.)

La Télégraphie sans Fils. Par André Broca. Pp. vii + 202. (Paris: Gauthier-Villars et Fils, 1899.)

WIRELESS telegraphy is a subject of absorbing popular interest at the present time. Its sensational possibilities are being gradually demonstrated; and just now a special popular interest arises from its obvious applicability to the amelioration of the state of isolation of our beleaguered garrisons in South Africa. Telegraphy without tangible means of communication has, however, proved an attractive field of inquiry almost since Volta's discovery of the electric current a century ago. And when in later years the submarine cable became a success, the high earning power, and the high cost also, served both to attract and to stimulate many inventors and scientific enthusiasts in their search for a system of telegraphy which would dispense with the costly cable.

The first of the two books here noticed contains matter of great interest, and is written by an authority on the history of telegraphy. Mr. Fahie has unearthed with much diligence a great mass of almost, or quite, forgotten experimental work (largely relating to efforts based on the conducting power of water). This, together with descriptions of the more recent work of Preece, Lodge, Marconi and others, he presents to the reader chiefly in the form of copious extracts from original papers.

One is able to gain an idea from this book of the immense amount of experimental work continually being carried out; to be noticed possibly in the current literature of the day, and then to be forgotten save when some striking practical success, such as that of Marconi, calls forth a historian who will rescue such work from oblivion.

For a frontispiece, the book has a collection of small but excellent portraits of "the arch builders of wireless telegraphy," from Oersted to Marconi; and at the end are gathered a number of extracts embodying the views of Lodge, Henry and Rowland, followed by Prof. Branly's classical paper on the behaviour of imperfect contacts to electrical radiation, and by a most interesting letter to Mr. Fahie by Prof. Hughes, describing his hitherto unpublished work on what are now called "coherers," which he was led to carry out after his invention of the microphone in 1877. The book concludes with a reprint of Marconi's patent of 1896, which shows how extensive his experiments had been before he came to England.

All these appendices are worthy of the most careful reading in the light of recent events. In fact, the book teems with interesting matter from cover to cover.

While the work is certainly opportune, yet a careful perusal brings us to the rather opposite conclusion that it is also premature. It is opportune, for a work on wireless telegraphy from an authority like Mr. Fahie is very welcome now. It is premature, in that the subject is changing so rapidly that a consistent account is impossible. For Marconi's present arrangement, though arrived at after the most careful investigation, yet seems to be still very empirical, as for example in the almost arbitrary choice of the kind of electric waves or of coherers, out of the infinite variety of both which are possible. It is still to be hoped that some other set of waves and some different type of coherer may be found equally available, and furnishing and receiving signals more amenable to projection in any required direction. Success in localising the electric waves is vital to the extended adoption of wireless telegraphy, yet Mr. Fahie is of course unable to include an account of this part of the subject in his book.

The author has adopted a chronological arrangement. No other seems in fact possible. Yet we think that many would prefer the accounts of mere *conduction* experiments to be kept separate from *etheric* telegraphy. Among other anomalies of arrangement we may mention that Lodge's work on wireless telegraphy is described under the general title of "G. Marconi's Method" (pp. 227–235).

Apart from obsolete expressions and unfortunate quotations from public utterances (as, "the Röntgen form of telegraph," p. viii.), the author's own language is not always precise. Thus "a rapidly revolving rheotome which broke up the current into a musical note" (p. 152), though perhaps expressive, is not accurate. Again, the reference to Hertz's "experimental proof of the hitherto theoretical fact" (p. 183), of the identity of the velocity of propagation of light and of electric waves, is hardly felicitous. Some of the author's elucidations of theory, also, are not perhaps as clear as they might be. An edition prepared at greater leisure, however, would no doubt be free from such passages.

The most obvious criticism of the book relates to the disjointed reading which arises from the author's very frequent insertion of extracts. But this criticism Mr. Fahie meets half way, for in his preface he "seems to hear the facetious critic exclaim, 'Why, this is all scissors and paste,'" and he rejoins, "So it is, much of it"; and he further adds that "so is all true history when you delete the fictions with which many historians embellish their facts." If this rather pessimistic view be adopted, then it would seem that a readable history is an impossibility. At all events, we certainly think that the constant change in literary style, both in character and quality, combined with the obsolete scientific expressions in which many of the extracts are couched, does not contribute to make the book readable. Indeed, we would describe the book as an excellent and well arranged store of material for writing a book on wireless telegraphy. It may be, however, that the attempt to render a *history* readable is to be deprecated.

The author has dedicated his work to Sir William Preece. Its later chapters bear witness to the striking way in which a Government department has so consistently and actively encouraged advance and scientific investigation wherever results of importance to its own work were to be hoped for.

There remains to state in conclusion that Mr. Fahie's book is certainly the best, if not the only work of reference which has appeared on the history of wireless telegraphy.

For a lucid and thoughtful exposition of the theory of the propagation of electric waves we can cordially recommend a little book by M. André Broca, "La Télégraphie sans Fils," which has lately been published. Within the compass of two hundred small pages of large print will here be found, first, a description of simple telegraphic apparatus; then a number of chapters which, with the help of hydraulic analogy, serve in an effective and remarkable manner to introduce the electromagnetic theory of light; and, lastly, a good account of the action of the vertical-wire transmitter and of the most recent work on coherers.

M. Broca succeeds in giving in simple scientific language, and without the help of mathematical analysis, an explanation of many abstruse points, such as the flow of electric currents in submarine cables and of electric waves along wires.

The vertical wire, according to him, emits an electric disturbance having an axis of symmetry, the wire itself; and a wave having this quality distributes its energy mostly in a plane perpendicular to the axis, a horizontal plane in this case, the energy diminishing with the square of the cosine of the angle from the vertical axis. It is to this concentration of energy in a horizontal plane that the vertical wire owes its success as a transmitter, but real concentration of messages transmitted by this means is not to be expected. (The employment of two or more wires inclined at different angles in the same vertical plane, but not necessarily close together, might possibly, we think, furnish by the intersection of two or more planes of greatest action, a *line* of reinforced action—a kind of imperfectly *directed* message which might be received by an arrangement similar to the transmitter.)

An appendix gives in a few pages the mathematical theory of the propagation of waves along a conductor.

M. Broca's little book is a valuable addition to the fast accumulating literature of wireless telegraphy, and we shall be glad to see an English translation.

D. K. M.

WORK AND THOUGHT AT WOOD'S HOLL, U.S.A.

Biological Lectures from the Marine Biological Laboratory, Wood's Holl, Massachusetts, 1898. Pp. 343. (Boston: Ginn and Co, 1899.)

THIS volume, like its predecessors, is the joint production of several of the leading biologists of the United States, indicative to a certain extent of the trend of thought and investigation in their midst, and, like its predecessors, it teams with interest and suggestiveness. Of the sixteen lectures reported, the majority are by well-known authors, and the book is remarkable for the extent to which it deals with questions of a cytological and psychological nature, in contradistinction to those of a more strictly morphological, such as we are accustomed to associate with a marine laboratory. Not that the latter have been neglected! for a remarkable essay by A. D. Mead, on the "Cell Origin of the Prototroch," which would seem to justify once more the belief in the ancestral nature of the Trochophore larva, is a thorough-going piece of sea-side work. The subject of "Cell-Lineage and Ancestral Reminiscence," in the hands of Prof. E. B. Wilson, yields fresh support for the theory that homologies only gradually arise during development, and that "the ultimate court of appeal lies in the fate of the cells"; and in a preliminary account of some investigations into the "Structure of Protoplasm" the same author is led to conclude, with von Kölliker, basing his observations of the Echinoderm egg, that "no universal or even general formula for protoplasmic structure can be given, and that the foam-structure of Bütschli is in certain cases at least of secondary origin."

In the course of his work he has done a great service in pointing out that so-called "granules" are often really liquid in nature, and in emphasising the extent to which error has hitherto asisen from the general tendency to regard these as solid bodies.

Among the more recondite problems dealt with are "Adaptation in Cleavage" of the Egg, "Protoplasmic Movement as a Factor of Differentiation," "Equal and Unequal Cleavage in Annelids," and "The Relation of the Axis of the Embryo to the First Cleavage Plane." In the hands of Messrs. F. R. Lillie, E. G. Conklin, A. L. Treadwell and Miss C. M. Clapp, both the practical and philosophic aspects of these and cognate subjects receive adequate consideration. The whole series of essays are well worth reading, and except that the Filose Phenomenon has not come under observation, the present moot points in embryology have been for the most part boldly attacked. Interest amounting to curiosity attaches to the description by Mr. Lillie in *Unio* of what, following Conklin, he terms provisionally a "sphere-substance," said to be "derived entirely from the inner sphere of the second maturation-spindle," and to his allegation, which seems to us none too clear, that it "moves and elongates so as to mark out a definite horizontal plane in the egg, and that the first cleavage-spindle places itself in conformity with this predetermined arrangement."

More sensational, and to our thinking less sound, is a lecture by T. H. Montgomery, jun., on some "Observations on Various Nucleolar Structures in the Cell." Like that on "The Heredity of the Marking in Fish Embryos" (J. Loeb), and on "Injury" to the Lower Animals as concerning "Pain Sensations" (W. W. Norman), this appears to us premature, and the authors would have done well had they given both their observations and reflections fuller consideration. An essay on "Some Problems of Regeneration," by T. H. Morgan, is noteworthy, for the fact that its author emphasises the degree to which it is now becoming evident in the progress of biology, that, as we attempt "to reduce living phenomena to simpler terms," we sooner or later "meet with a factor that defies further physical analysis," with the refrain that "we gain nothing by calling it a vital force, unless we can define what we mean by vitality."

In a lecture on the "Elimination of the Unfit," Dr. H. C. Bumpus deals in an analytical form with the effects of a severe storm on the Introduced Sparrow, and his observations at least serve to remind us that we are perhaps not sufficiently on the alert for evidence of processes in organic evolution obtainable from the study of passing events. Dr. W. M. Wheeler, in an interesting essay on "The Theoria Generationis" of Wolff, justly controverts some adverse criticism by Sachs, and establishes Wolff's position as a pioneer among præformationists—

as the Siegfried who overcame "the monstrous theory of *emboîtement*, not only false in itself, but one jealously guarding the problem of development and preventing all access to it." The author points to an analogy between the rise and progress of præformationist and Darwinian schools, which, agreed in maintaining a transformation of the simpler into the more complex have neither succeeded in demonstrating how that process is achieved.

The three lectures which remain are somewhat more special than the rest. That by Dr. Watasé on phosphorescence gives welcome support to the theory of Quatrefages that this is intimately associated with contractility, and that a common cause would appear to underlie the two processes. Dr. Watasé has been for years engaged upon this fascinating subject. His treatment of it has been no less original than that of other topics upon which he has left his mark, and we sincerely hope, now that he has returned to Japan, he will promptly give us the definitive treatise of which we are expectant. Prof. W. B. Scott, whose patient, consistent work upon the palæontology of the American Artiodactyles has for years been eagerly followed by all interested in mammalian descent, has in the lecture which he contributes to the present volume built up a masterly defence of the principle of convergence—the first comprehensive defence from the palæontological side—by lack of appreciation of which it has long been patent to anatomists that not a few of our accepted classificatory schemes and conceptions of affinity are erroneous. He deals chiefly with recent discoveries in the now famous Uinta formations, and his thesis, like the work upon which it is based, is thoroughly English in method. By contrast to the bulk of the volume before us, it comes as a set off to the too frequent indications of that "Germanising" to which our American brethren appear somewhat prone. His chief deduction that "all the strictly indigenous North American selenodonts are branches of the great tylopodan stem" is replete with interest.

Finally, there is a lengthy lecture by Prof. C. O. Whitman on "Animal Behaviour," setting forth in detail, and with comment which is exemplary in its moderation and cautiousness, a series of experiments on the phenomena of response exhibited by certain American creatures under his hand (especially a *Clepsine*, *Necturus*, and certain pigeons). He frames a thoughtful argument, which leads to the conclusion that "instinct precedes intelligence," and that its primary roots lie in "the constitutional activities of protoplasm," which, as he justly remarks, relieves us of the inconsistencies "involved in the theory of instinct as lapsed intelligence." His aphorism that "organisation shapes behaviour" would seem destined to bear the fate of his truism, "organisation precedes cell formation," now prophetic; and to him, the guiding spirit in the work which necessitated the publication of the present volume, as to all his collaborateurs, we offer our hearty congratulations. A little more work and a little less theory would be acceptable in some cases, but so long as the connection between the two is maintained to the extent exemplified in the present volume, we shall remain content.

The book closes with a series of short obituary notices, which include those of the former Assistant Director at Wood's Holl and of the author of one of the lectures, together with a passing reference to the death of W. R. Harrington, an enthusiastic young American, well known and greatly respected on the European side of the Atlantic, who recently met his death in a second attempt to secure the young of the Bichir (*Polypterus*). G. B. H.

OUR BOOK SHELF.

Darstellung der 32 möglichen Krystallklassen. By Prof. H. Baumhauer. Pp. 36. (Leipzig: Wilhelm Engelmann, 1899.)

PROF. BAUMHAUER discusses the symmetry of crystals in accordance with recent views, and employs the axes of symmetry to distinguish the classes. Weiss and Mohs first recognised that crystals fell into seven groups depending on the relative lengths and inclinations of the crystallographic axes. The older school of crystallographers, following the lead of Naumann, commenced with the class of highest symmetry in each system, and derived the remainder by removing elements of symmetry. The logical method, as was pointed out by Gadolin, is to start with the class of lowest symmetry and add elements of symmetry until the most complicated class is reached. Each class is, in reality, quite independent of any other, even if in the same system. Groth adopted this view in the last edition of his "Physikalische Krystallographie," and rejecting all ideas of hemihedrism, introduced a nomenclature which has been here employed by Prof. Baumhauer. He, however, differs from the Munich professor, but joins Schönflies in dividing the thirty-two classes into groups depending on the axes of symmetry present. This method splits up the monoclinic system, two classes of which join the rhombic system to form the digonal group (*i.e.* the group with at least one axis of two-fold symmetry), whilst the third, which possesses a plane of symmetry only, remains by itself in the monogonal group. The triclinic class, according to the author, forms the anaxial group; Schönflies, on the other hand, splits it up and gives the holohedral class to the digonal group, and the other to the monogonal group. The latter arrangement is certainly more logical, though there is something to be said for Prof. Baumhauer's objection that a "2-zählige Spiegelachse" being in any direction, and therefore not necessarily parallel to a crystallographically possible edge, cannot be said to exist. The author follows Schönflies in placing the classes represented by phenacite and calcite respectively in the hexagonal group, whereas Groth includes them in the trigonal group. These two groups, however, might well be regarded as one.

A word must be said for the excellent diagrams, which show very clearly the symmetry of each class. At the end is given a description of illustrative models, to be obtained from Dr. F. Krantz, of Bonn.

The Essex Naturalist: the Journal of the Essex Field Club. Edited by William Cole. Vols. ix., 1895–6, and x., 1897–8. (Essex Field Club, 1899.)

THE *Essex Naturalist* has long been known as the ably conducted journal of one of the best field clubs in existence. Full accounts of the meetings and excursions of the Essex Field Club are given, and, in addition to these, any observations of interest to naturalists made within the limits of the county are recorded, and when necessary illustrated. The term naturalist is quite properly used in the very widest sense, so that the journal includes meteorological, geological, geographical and anthropological observations, as well as others dealing with ancient marks, boundaries and buildings, customs and trades.

The journal is an excellent example of all that the organ of a field club and county natural history society should be. It fulfils a double function, recording interesting observations which would otherwise have been forgotten, and stimulating its members to make fresh efforts in their own districts. Throughout every county opportunities for observation are continually occurring, opportunities which are often wasted for want of an alert local naturalist. A fresh cutting made on a railway, a new gravel pit opened, an old house pulled down, afford the chance of interesting and often valuable observations when the keen and trained observer is on the spot. The encouragement of such work is of no less importance for the progress of science than the comprehensive papers by acknowledged leaders of their subject which appear in the *Essex Naturalist*. These would be published under any circumstances, whereas the former are rescued from the multitude of observations which might have been.

The journal is exceedingly well printed, and is a model of careful and successful editorship. E. B. P.

Anleitung zur Darstellung chemischer Präparate. Ein Leitfaden für den praktischen Unterricht in der Anorganischen Chemie. Von Prof. Dr. H. Erdmann. Second edition. 92 pp. (Frankfort: H. Bechhold, 1899.)

THE great educational value of a well-chosen set of chemical preparations, as an adjunct to the usual analytical courses, is now generally admitted; it has been, however, usual to select the examples almost wholly from the field of organic chemistry. To Prof. Erdmann is due the credit of showing that a course of inorganic preparations was not only feasible, but on account of the greater variety of difficulties met with in many cases, even preferable for educational purposes to a selection wholly organic. In this second edition several additions have been made to the original text, including the preparation of ammonium perborate, dry aluminium chloride, arsenious oxide, violet chromium sulphate and potassium iodate.

The instructions throughout are very practical, the cost of the material having been borne in mind throughout, many laboratory bye-products or residues being utilised as the raw material for preparations.

In the few instances where the methods given are not the best available, the residues are worked up in other preparations. The book as a whole fills a gap in chemical literature.

The Boyhood of a Naturalist. By Fred Smith. Pp. vi + 227. (London: Blackie and Son, Ltd., 1900.)

THIS genial account of his boyhood by a naturalist, writing under the pseudonym Fred Smith, will afford unlimited interest to any youngster with a love for live things. That Fred Smith did not shine in school, and was only with difficulty made to play cricket fairly regularly, rather adds to his winsomeness. Indirectly, the book should prove useful in demonstrating the educational value of the study of nature at first-hand. Fred's education was unmistakably of the kind which it is at present fashionable to call "heuristic," and his progress in his numerous researches is further evidence of the possibility of a boy, though considered a dunce at school, arriving at manhood educated in the better sense of the term, since his faculties are properly trained and his perceptions keenly alert. As a gift book for a child with a natural proclivity for biological work the volume can be thoroughly recommended; it is both instructive and amusing.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The New Zealand Zoological Region.

IN a paper on "The Geography of Mammals" (*Geographical Journal*, vol. iii. p. 95, and vol. iv. p. 35, 1894), Mr. W. L. Sclater divides the land surface of the earth into three great divisions, Notogœa, Neogœa, and Arctogœa, and these are subdivided into six regions, the Australian region corresponding with the division Notogœa. It seems to me, however, that had Mr. Sclater considered what is natural rather than what is convenient, he would have divided his Notogœa into two regions, separating the New Zealand area from that of Australia, for these two areas are essentially distinct from one another in all their great fundamental zoological characteristics. According to Mr. Sclater, Prof. Huxley and Prof. Newton make the New Zealand area a primary zoological region (I have not seen the "Dictionary of Birds" or Huxley's paper). Mr. Sclater then says: "there is, no doubt, as has just been shown, a good deal to be said for this proposal; but, on the other hand, there are even more valid reasons for retaining New Zealand as a sub-region of the Australian region." Mr. Sclater then states his "more valid regions," which are three in number. The first is that as he is dealing with mammals only it would be absurd to give a small group of islands, which is almost entirely without terrestrial mammals, the rank of a primary region. Had Mr. Sclater therefore left the New Zealand area out of his considerations altogether, as was wisely done by Mr. P. L. Sclater in his lecture "The Geographical Distribution of Mammals" (Manchester Science Lectures, No. 5, Sixth Series, 1874), I should have been entirely in accordance with him, and there would have been no occasion for this paper.

The second reason given is that of "practical convenience." It seems to me, however, that convenience should only be a secondary consideration, and that what is natural is far more important. Mr. Sclater goes on to say that "other small insular areas might with some justice put forward nearly similar claims."

New Zealand, however, stands alone in its very remarkable physical and biological conditions, and presents with those of Australia the strongest contrasts rather than similarities.

It is, however, to Mr. Sclater's third reason that I have more especially to take exception. He says: "Although New Zealand possesses no indigenous terrestrial mammals, yet the fauna, such as it is, shows an unmistakable affinity of various degrees to that of Australia, and more especially to the tropical parts of that continent. It is, indeed, probable that the whole of the fauna of New Zealand has been originally derived from that source."

There are no doubt affinities between the faunas of Australia and New Zealand; but when we consider that in Tertiary times (probably Pliocene) the New Zealand land area extended far to the north and west of its present limits, probably as far as Lord Howe Island, and the facilities for the diffusion of species from the one area to the other were immensely greater than they are at present, the wonder is that these affinities are so slight and insignificant. It has been usual to look for similarities in the faunas, and to attach much importance to the occurrence of the same or representative species in both areas, and the great and essential differences of the faunas as a whole have been largely lost sight of or little understood.

I would first remark that the presence in Australia of a rich mammal fauna (marsupials and monotremes), and its total absence from New Zealand, is certainly significant. But let that pass, and, as Mr. Sclater has himself suggested, to determine the geographical affinities of New Zealand we must take "the fauna such as it is," consisting of birds, reptiles and other lower groups; and when we do this we find that the result is exactly opposite to what Mr. Sclater would lead us to expect.

Prof. Newton has no doubt ably dealt with the affinities of the New Zealand birds in his work, "Dictionary of Birds"; I need not therefore discuss them here, except to remark that one of the most interesting and remarkable features of our bird fauna is the fact that during recent times—at most a few hundred years back—there existed in these lands numerous species of two families of raft-breasted birds, *Dinornithidae* and *Apterygidae*, which are so essentially distinct in structure that they are probably not even distantly related to one another, but have arisen quite independently, and no representatives of these families have been found in any other country. (The supposed finding of *Dinornis* and *Apteryx* remains by Mr. De Vis in Queensland, having been discussed by Captain Hutton and Mr. Lydekker, is now considered to have been a mistake.)

As regards the reptiles, we have the well-known and peculiar Tuatara (*Hatteria punctata*) and a number of lizards, which Messrs. A. H. S. Lucas and C. Frost have recently revised, and they tell us that the New Zealand forms are not related to those of Australia (*Trans.* New Zealand Institute, vol. xxix. p. 264).

The land and fresh-water molluscs have been critically revised by Mr. H. Suter; and Mr. H. Crosse, in his introductory note to Mr. Suter's paper, summarises his conclusions thus:—"Les faunes malacologiques Australienne et Néo-Zélandaise sont, d'ailleurs, à première vue, fort différentes l'une de l'autre, et elles présentent souvent des caractères opposés. . . . En réalité, les Mollusques terrestres et fluviatiles de la Nouvelle-Zélande, et nous comprenons sous cette dénomination, non seulement les deux grandes îles du Nord et du Sud, mais encore les îles Stewart, Auckland, Campbell, et Kermadec, forment un ensemble d'espèces très particulières, toutes, ou à peu près toutes, indigènes, et constituant une faune locale, insulaire et parfaitement caracatérisée.

"Pourtant, à notre avis, il existe un archipel, dans la faune duquel, si originale qu'elle soit, on trouve des affinités marquées et des rapports incontestables avec celle de la Nouvelle-Zélande: c'est la Nouvelle-Calédonie" (*Journal de Conchyliologie*, 1894, vol. xli. pp. 215, 216).

Mr. C. Hedley has also pointed out that the land molluscan fauna of New Zealand is quite distinct from that of Australia, and has affinities rather with the faunas of Lord Howe Island, New Caledonia, Fiji, the New Hebrides, and Solomon Islands (*Records* Australian Museum, vol. i. No. 7, 1891; *Proc.* Linn. Soc. N.S.W., 1892 (2), vol. vii. p. 335; *Ann. and Mag. Nat. Hist.*, 1893 (6), vol. xi. p. 435). This is indeed significant, especially when the form of the "New Zealand Plateau" and the ocean-floor beyond is taken into consideration.

As regards the earthworms, Dr. Benham tells us that they "are very different from those of Australia, on the one hand, and Europe on the other" (*Canterbury Weekly Press*, May 3, 1899). I cannot, however, agree with Dr. Benham when he reasons that because species of one genus—*Acanthodrilus*—which is widely spread in other southern lands, are found in New Zealand and Queensland there must have been at one time a land connection between New Zealand and north-eastern Australia. There is another explanation which appears to accord better with the distribution of other groups, if a land connection is necessary. Far back in Cretaceous or early Tertiary times (Cretaceo-Tertiary of N.Z. geologists) before the north-eastern part of Australia had received its mammal fauna, the New Zealand area may have been connected with New Guinea *via* Lord Howe Island, New Caledonia, the New Hebrides, and the Solomon Islands; or more probably these islands were then connected with New Guinea and the main land, and afterwards when the land connection was broken up, some of them became connected with New Zealand, so that a few of the plants and animals which spread into Australia or northwards into New Guinea were also able to reach New Zealand. This is not a new suggestion; it has been proposed by Captain Hutton and others. Mr. H. Deane, in his presidential address, delivered before the Linnean Society of New South Wales, March 31, 1897, said:—"The difficulties are too great in the way of such a supposition (a Pacific continent), but only connections similar to that which we are certain existed between New Zealand, New Caledonia, the Fijis and the main land which was perhaps at its period of greatest development in a state of oscillation need be conceded." Regarding the alpine flora of the Owen Stanley Range in New Guinea, the late Baron Sir F. von Mueller, after enumerating a number of extra-tropical genera found there, said: "Many of these approach in their affinity to forms familiar to us in Europe, a few even being identical with British species, and appear thus to reach in New Guinea their most southern geographic limits. But, on the other hand, many of these Papuan highland plants are of far southern type, such as Drimys, Drapetes, Donatia, Styphelia, Phyllocladus, Libertia, Carpha, Oreobolus, Gahnia, Dawsonia; indeed, some of the species are absolutely the same as congeners of the Australian and New Zealand Alps" (*Proc.* Roy. Geographical Soc., Australia, Queensland Branch, vol. v. p. 20, 1889). But without the necessity of a land connection, when in Tertiary times the New Zealand land area extended as far as Lord Howe Island, and perhaps New Caledonia, a few earthworms and other animals may have been carried across the intervening comparatively narrow sea by birds and on floating timber.

New Zealand insects have been much neglected, and some groups have hardly been touched. The Coccids, however, have been admirably worked up by the late Mr. W. M. Maskell, so that a comparison is possible. When we add to Maskell's "Synoptical List of Coccidæ" the forms described in his three subsequent papers (*Trans.* N.Z. Inst., vols. xxviii., xxix., xxx.), and summarise the results, we find that of the 105 species and varieties which have been found in New Zealand, 78 (74 per cent.) appear to be endemic. Of the remaining 27 forms, 13 occur also in Australia. These 13 are widely ranging forms which have been found in other countries—North America, Europe, &c., and occur in New Zealand in greenhouses, and on introduced plants.

Most of them have no doubt been recently introduced to both Australia and New Zealand. Two or three, such as *Icerya purchasi*, may have originally come from Australia. Coccids often multiply and spread very rapidly when introduced to a country where the conditions are favourable to them. The number of forms peculiar to Australia is 202. As regards the distribution of the genera, twenty-three have been found in New Zealand, of which only two are peculiar to that country; two of them have been found in other countries but not in Australia; and two occur in New Zealand and Australia, but not elsewhere. These latter are *Ctenochiton* with eleven species in New Zealand and two in Australia, and *Coelostoma* with five species in New Zealand and three in Australia. This would seem to indicate that New Zealand was the original home of both. The remaining seventeen genera occur in Australia and other countries, most of them being cosmopolitan or almost so. Of the ten genera which have been found, so far, only in Australia, four belong to the sub-family *Brachyscelinae*, which is essentially Australian, four of its five genera, and forty-five species, being found only in Australia, and not one representative of this sub-family occurs in New Zealand. It has often been pointed out that the animals and plants characteristic of Australia are absent from New Zealand, and those of New Zealand from Australia.

A large number of beetles have been described by Capt. Brown ("Manual of New Zealand Coleoptera"); Mr. A. T. Urquhart and others have described many spiders in the *Transactions* of the New Zealand Institute; and Mr. R. W. Fereday has enumerated 617 species of lepidotera in the same publication (vol. xxx. p. 326). When these and the other groups come to be revised, and disentangled, and their affinities worked out, it may be reasonably supposed that the results will accord with what has already been done.

In view of the above facts it is clear that not only is it *not* "probable that the whole of the fauna of New Zealand has been originally derived from that source" (Australia), but that only a small and insignificant portion came thence; that the New Zealand terrestrial fauna, as a whole, is essentially distinct from all others; and that its alliance with the fauna of Australia is extremely slight. As far back as 1880 Captain Hutton pointed out that, "The better the fauna of New Zealand becomes known, the more prominently does it stand out distinct from that of any other country" ("Manual of N.Z. Mollusca," p. 2).

In discussing the affinities of the New Zealand fauna it is fair only to consider those groups which have been revised, for many animals have been recently introduced from Australia, and rapid changes have been going on since settlement began in New Zealand and the Australian Colonies. Also in former times collections often got mixed; naturalists and collectors were not very particular about localities, for they did not then know the immense importance and interest attaching to the distribution of species.

The paucity of New Zealand insects is not by any means so great as has been represented. The reason that so few species have been described in many groups is largely due to the fact that they have been neglected by New Zealand naturalists, rather than that there are few to be found. A diligent worker here will be amply rewarded by the discovery of many new forms, whatever group he may choose to take in hand. Mr. P. Marshall recently described sixty-six species in a first instalment of New Zealand diptera, fifty-four of which were new (*Trans.* N.Z. Inst., vol. xxviii.).

As the general laws regarding the distribution of species can only be discovered from the knowledge of a very great number of facts, I fully agree with the Rev. T. Blackburn that "the special task to be accomplished by this generation, and in the present state of knowledge, is that of collecting and recording *facts and data*" (Presidential Address, *Trans.* Roy. Soc. South Australia, 1891, vol. xiv. p. 371); and that when we attempt to generalise we find how very little is known in comparison to what is yet to be discovered, and feel "the need of that exhaustive collection of the data and records of the facts that we are at present engaged in procuring." Nevertheless, I cannot concur in the suggestion that we should altogether relegate "the investigation of the *reasons* of the facts of nature" to the naturalists of the next generation. Not only is it even now exceedingly interesting and important to summarise what we do know and to understand the direction in which our observations are tending, but it also makes all future work immensely more interesting, and enables the work to be carried out more intelligently and thoroughly. It is, however, very necessary when recording facts to have the mind free from all theories and preconceived ideas which might in any way influence one's observations and conclusions. H. FARQUHAR.

Wellington, N.Z.

The Resistance of the Air.

REFERRING to Mr. Bryan's summary, on page 107 of the current volume of NATURE, of the observations on the resistance of the air, made by Le Dantec and by Canovetti, it is but fair to say that the conclusion "No. 3," viz. that the resistance to a plane surface depends upon its contour, *i.e.* whether circular, square or triangular, is by no means new. Precisely this result was deduced by Prof. Hagen, of Berlin, in his most delicate experiments published by the Berlin Academy in 1874. His memoir is the first in Abbe's collection of translations, entitled "The Mechanics of the Earth's Atmosphere," and a detailed discussion of his results is given at pp. 234–238 of his "Treatise on Meteorological Apparatus and Methods." Hagen's results, when expressed in grams, decimetres and seconds, give the resistance per square decimetre as $(0{\cdot}00707 + 0{\cdot}0001125\,p)\,v^2$ where p is the contour of the plate and v the velocity. As his experiments were made with plates of only from 1 to 12 decimetres on a side, and as he showed that the size affects the coefficient quite as much as the shape, it would scarcely be proper to exterpolate from his small plates up to the large ones used by the French investigators. We should not expect any close agreement for a surface of one metre square between Hagen's figures and these newer ones, but the general law that the pressure per square unit depends upon both the size and the shape of the plate is due to Hagen. The explanation of this result is also largely due to him; it is not merely a question of gaseous viscosity or internal friction, but especially of that dissipation of energy that occurs in the ideal perfect fluid, and which has been called convective friction in the above-mentioned treatise and elsewhere. Le Dantec and Canovetti, by experimenting on a large scale, have necessarily encountered such irregularities and difficulties as must have limited the accuracy of their results quite as much as in the case of many other experiments since those of Sir Isaac Newton. In general, inasmuch as resistance per square unit varies with the size and shape of plane plates or other bodies, it can hardly be called an important physical constant of great scientific interest. It certainly has a practical interest to the aeronaut, the navigator, and the millwright, but the scientific interest of such experiments consist essentially in determining the lines of flow and the transformations of energy involved in the discontinuous motions. C. A.

Washington, December 13, 1899.

THE object of my notice was to give a general account of Le Dantec's and Canovetti's experiments, and certainly not to deliver judgment on those delicate questions of priority which are mainly of personal interest. The "law of perimeters" being so noticeably put forward as a new result, I could do no less than cite the views of Le Dantec and his referee, between whom and Hagen or his advocate "C. A." the matter must rest. There is surely a contradiction of terms in your correspondent's expression, "that dissipation of energy that occurs in the ideal perfect fluid, and which has been called convective friction in the above-mentioned treatise and elsewhere." A fluid which dissipates energy, especially by means of anything called friction, is not an "ideal perfect fluid" according to universally accepted definitions. As to the "scientific interest" of determinations, not only of the aërial resistance of a square metre, but also of the weight of a cubic centimetre of water, the so-called mechanical equivalent of heat, the electrical resistance of a copper wire, the E.M.F. of a Clark cell, or any other physical quantity whose value is affected by various conditions, this surely is a matter of opinion; but the great amount of attention which is now devoted to accumulating statistical data of this class is sufficient indication of a general consensus of opinion in favour of such researches being regarded as valuable from a scientific standpoint. G. H. BRYAN.

Grey's Rock Paintings.

IN Prof. Haddon's review of Mr. Mathews' "Eaglehawk and Crow" there are several references to Grey's rock paintings, amongst which your reviewer remarks, "These rock paintings are certainly very puzzling, and deserve renewed investigation on the spot." They were investigated by Mr. A. C. Gregory, the Australian explorer, who, about seventeen years ago, gave me the following particulars relating to them:—

"The importance of the native coloured drawings, published by Grey in his "Travels," is much exaggerated. The colours are by no means so bright as printed, and the drawings are generally of a very primitive kind, more or less crude outlines of hands or weapons placed on the face of rocks, and lines marked round the edge of the object" (see *Jour. Anth. Inst.*, xvi., p. 133). I have also a clear remembrance of Mr. Gregory blaming the printers for attempting to make comparatively finished drawings of the faces out of crude outlines much in the same way as was so commonly done in the elaborate plates that accompany the volumes of Cook's "Voyages." Mr. Mathews' "identification" may therefore be dismissed. H. LING ROTH.

Halifax, Yorks., January 1.

Evidence of Upheaval in Vanua Levu, Fiji.

DURING an examination of the geology of this large island evidence of very extensive upheaval frequently came under my observation. Speaking generally, the main elevated mass of the island is the product of submarine fissure-eruptions. Its surface is in great part traversed by mountainous ridges, which form an intricate system, and consist in each case of an axis of basic and often coarsely crystalline volcanic rocks concealed beneath calcareous tuffs and volcanic muds, which in their turn are covered over by agglomerates. During the movement of upheaval, and in the ages that have since elapsed, the denuding agencies have been so actively at work that it is not easy to restore the original form of the surface; but it may be observed that in the eighteen months of my stay no evidence of a crateral cavity came under my notice in the main mass of the island. By studying the contours it can be shown that Vanua Levu has been formed by the union during the process of upheaval of a number of smaller islands with a central larger island.

Foraminiferous and pteropod-bearing muds together with calcareous volcanic tuffs are not infrequent up to elevations of 1100 or 1200 feet. They are of scanty occurrence at greater heights; but they are to be found in different parts of the island at elevations of from 1500 to 2000 feet; and in one locality I found sea-shells in a coarse tuff at 2200 feet. Elevated coral-reefs have taken a very little part in the building-up of the island. They exist in a few localities at the coast, and do not attain a higher level than some 200 feet. In this connection it should be noted that flints and silicified corals occur on the surface of the lower regions all over the island. Corals in various stages of silicification are found in quantities in some places, especially where a low-lying district now marks the situation of what was once an inland sea. H. B. GUPPY.

R. C. Mission, Rewa, Fiji, November 21, 1899.

THE ECLIPSE EXPEDITION AT VIZIADURG.[1]

II.

WITH regard to securing the best possible observations along all lines, the perfect organisation of time signals was of the first importance; indeed, a fundamental condition for success. The headquarter staff, under Captain Batten, was stationed at the eclipse clock, about which a word must be said. In an eclipse, especially when there are as many observers as we had on this occasion, it is well that every one shall know that he will get a good square look at it some time or other. In early eclipse work this was not recognised, and I never felt more annoyed in my life than, when I was in India, in 1871, I found that in consequence of my ignorance of eclipse organisation, Captain Bailey, of the Royal Engineers, who travelled 400 miles to our camp to help us, did not see the eclipse at all. He volunteered to give us the time, and took to rehearsing the work daily. I said to him, "What you have to do is to put your chronometer on the table and then sit down facing the sun, so that at any time you like during the eclipse you can look off the face of the chronometer and see the eclipse; because now you have come so far it won't do for you to go away without seeing anything." He said, "Well, I have been practising for the last two days, and I find it very difficult." I said, "What are you going to do about it?" He replied, "Well, I shall go on practising it till I do it." But to my horror, just before the eclipse began, I saw him take his chair to the other side of the table, deliberately place his back to the sun and look at the chronometer, and he never saw the eclipse at all. I was determined that that should never happen again in any eclipse that I had anything to do with, and since then I have always doubled the timekeepers, and given one-half of the eclipse to one timekeeper, and the other half to another. The "eclipse clock" is of rather peculiar construction. It only possesses a seconds-hand controlled by a seconds-pendulum. The face of the clock shows seconds, and a spiral on which the times are marked, so that there can be absolutely no mistake made as to the time. Not only can the even seconds be given in that way, but if a signal at any particular time is requisite for any particular operation in any of the observatories, the time signalman can give that time as well, so that all the operations are kept perfectly steady. The pendulum (and therefore the clock) is started by cutting a thread at the word "go," which means the beginning of the eclipse. Then one of the timekeepers turns his back to the sun, stands in front of the clock, and reads out the time-signals "120 seconds left," and so on, which are marked along the spiral, as the hand reaches them, while the other is looking at the eclipse. The half-time signal ("60 seconds" on this occasion) is sung out by both, and then they right-about face, one man going off duty and the other taking it up. In that way both see the eclipse. In order to give an idea of the importance of keeping the time during an eclipse, I will give our eclipse time table.

At 11 o'clock the "Thermometer" party commenced work.
11.12 a.m.—The "first contact" took place.
12.16 p.m.—"Naturalists and Landscape" party commenced operations and were followed at
12.30 p.m. by the "Slit Spectroscope and Prism" parties.
Ten minutes before "totality" Lieut. de Wet, with an Admiralty chronometer "gave the word," on which the "alert" was sounded on the bugle.
At this signal—
The "stops" were taken off telescopes.
Caps off siderostat and cœlostat.
Clocks wound.
Timekeepers reported eclipse clock correct.
Observers at discs blindfolded.
Remainder of observers turned backs to sun.
Seven minutes before "totality". 3 "G's" were sounded on bugle as a signal to Prof. Pedlar with 6-inch.
25 seconds before "totality"—90° from Lieut. de Wet. 2 "G's" on bugle.
5 seconds before "totality"—45° from Lieut. de Wet. 1 "G" on bugle.
On the order "go" the first timekeeper, with his back to the sun, called out "127 seconds," and every 10 seconds till 17 seconds, followed by 10 seconds and 7 seconds, and then every consecutive second till "over" was given.

Why it was necessary to use the bugle will be seen at once. That was the order given to the various parties, several of whom, especially the disc observers, were a long distance from us. At the "alert" the stops were taken off the telescopes; a very wise precaution, for in some eclipses even caps have not been taken off at all—there were other things to think of! All the clocks were wound, and the observers at the discs were blindfolded. Then all the observers turned their backs to the sun in order that they might not weary their eyes by trying to see a series of phenomena of no interest to anybody. At 25 seconds before totality we had two "G's" sounded on the bugle. It had been determined that at that moment the uncovered arc of the sun measured exactly 90°. It was most important for the spectroscopic work that we should get a signal 5 seconds before totality—that is to say, 5 real seconds before totality quite independent of any errors in the *Nautical Almanac*. For the work of the prismatic cameras it was important to get a signal as nearly as possible five seconds before the beginning of totality, and, in order to eliminate the possible error of the chronometer, it was arranged to determine this by direct observations. Captain Batten did a thing which has certainly never been done in any eclipse expedition before. We expected, of course, a very definite shadow, and he was good enough to find a native dhow and charter it, and anchor it in the roadstead at such a distance that the shadow would strike it exactly 5 seconds before it struck the camp. For another signal we calculated that 5 seconds before totality the portion of the sun still visible would subtend an angle of 45°. The moment of totality was to be determined by means of the $3\frac{3}{4}$-inch.

THE WORK ATTEMPTED.

The Prismatic Cameras.

In the two prismatic cameras about sixty photographs were required, the exposures varying from one to fifty seconds. These included two series of ten snap-shots at the beginning of totality, and another ten at the end of totality, and shots of different periods, up to thirty-six seconds in one case, taken during the totality itself. That was done, of course, in the hope that one exposure would be better than any of the others, so that we should be sure of getting something at its best. Another reason was that we hoped to get records of fainter phenomena in the middle of totality than we were likely to do at the beginning and end of it. It was necessary to throw the sunlight into the camera by means of a mirror of a siderostat.

To carry out this programme of work, to secure the results required, a minute subdivision of labour was imperative. In the case of each of these two instruments six volunteers were employed, and they were distributed in the following manner:—

One observer with the finder, his duty being to keep the image in the centre of the field of view which corre-

[1] Continued from p. 233.

sponded (by previous adjustment) to the centre of the plate in the prismatic camera. He had a timekeeper to record the times of contact.

A third acted as timekeeper to record the exact moments at which the exposures were begun and ended.

A fourth volunteer, by means of a piece of cardboard, covered and uncovered the front of the prism, from directions given by Mr. Fowler and Dr. Lockyer respectively.

In one case two, and in another three, men were required to hand and receive the large dark slides before and after exposure, taking them out of, or placing them back in, bags made for this purpose.

Six-inch Prismatic Camera.

This instrument, the dispersion of which had been increased by the addition of a second prism, was worked by Mr. Fowler, with the assistance of Lieut. de Wet and five men. Mr. Fowler's programme was to begin taking a series of ten snap-shot pictures five seconds before the commencement of totality, to obtain a record every second or thereabouts of the spectrum of the chromosphere. After this he exposed eight other plates to secure photographs of the coronal rings, the exposures being of various lengths. It was also arranged that at five seconds before the end of totality he should commence another series of ten snap-shots, exposing the last of these some few seconds after totality.

FIG. 4.—Six-inch prismatic camera.

Nine-inch Prismatic Camera.

This instrument was in charge of Dr. W. J. S. Lockyer, who was assisted by Lieut. Percival Jones, R.N.R., and six men. This instrument was also fed by a siderostat, but the tube was not placed horizontally. It was intended with one of the prismatic cameras to so mount the tube that the arcs formed on the photographic plate should be symmetrical about the direction of dispersion, and it was decided that the 9-inch camera should adopt this plan of mounting.

The exact position of the tube to obtain this result was carefully determined by calculation. To facilitate the erection of the instrument at the station two wooden frames to carry the tube were previously made and taken out.

It is satisfactory to state that the photographs showed that the experiment was very successful, the arcs coming out exactly as forecasted.

FIG. 5.—Nine-inch prismatic camera.

Although this instrument was capable of only giving about half the dispersion of the 6-inch, the optical parts were better adapted for recording the ultra-violet region of the spectrum.

The programme adopted was similar to that of the 6-inch, there being two large plates ($16 \times 6\frac{1}{2}$) for recording a series of ten snap-shots at and near the times of second and third contacts, and nine smaller plates for exposure during totality.

Integrating Spectroscope.

This instrument consisted of a large collimator, two prisms of 60°, and a receiving camera. It was entrusted to the care of Lieut. G. C. Quayle, R.N., with two assistants. The light which fed this instrument was obtained from a cœlostat, and there was still sufficient room for another instrument to be utilised, so the coronagraph was set up in the same hut.

employed, of $4\frac{3}{8}$-inch aperture, was entrusted to Staff-Engineer A. Kerr, R.N., who was assisted by three volunteers from the engine-room staff.

There being still a small amount of available surface of the cœlostat for other purposes, this was utilised for the 10×8 landscape camera, which was operated by Mr. Turner.

Discs.

The discs, six in number, were put into position by Lieut. G. C. Quayle, R.N., and Lieut. C. E. B. Colbeck, R.N., being ranged along the southern wall of the fort, close to the Eclipse Camp. The great altitude (53°) of the sun rendered the operation of setting them up somewhat difficult. Their sizes varied from six to two inches, and they were so placed that they cut off 3, 5, and 7 minutes of arc round the dark moon.

FIG. 6.—The coronagraphs and the integrating spectroscope.

Six-inch Equatorial with Grating Spectroscope.

This instrument consisted of a 6-inch lens mounted equatorially. The small grating employed contained 17,296 lines to the inch, and in the focus of the eyepiece was placed a small photographic spectrum of iron for comparison.

Prof. R Pedler, who came to take charge of this instrument, was assisted by Mr. Steele, R.N., gunner, and three other volunteers.

The Coronagraph.

We made no attempt to obtain any very fine photographs of the eclipse, because we knew that the Indian observers would do that. But it was necessary to get some photographs which would give us the relationship between the different parts of the corona which we saw and those photographed by means of other instruments. The chromosphere and coronal rings we especially hoped to get in the prismatic cameras. The instrument

Each disc occupied the time of three men, so that in all eighteen volunteers were employed. Of each party of three, one volunteer kept the eye end in adjustment up to the time of totality, another who was blindfolded ten minutes before totality acted as observer, and the third wrote down the remarks of the observer.

The $3\frac{3}{4}$-inch Equatorial Telescope.

This telescope was used by me to observe the exact time of second and third contacts to give the signals "go" and "over" to the timekeepers. For the first fifty seconds of totality I employed this instrument myself to minutely observe the structure of the rifts and streamers. In my absence it was used by Assistant Engineer H. H. Willmore, R.N., for the examination of the structure of the corona.

Star Observations.

I will pass from the larger instruments and come to the star observations. These observations were entirely in charge of Lieut. Blackett, R.N., and what he did every night before the eclipse was to get his staff of seven or eight to observe certain groups of stars from the deck of the ship or from the shore, and determine their magnitudes as well as they could, and make maps of them. It was perfectly wonderful how, after three or four nights, they could make a map of the constellation of Orion, not going very far wrong. That stood us in very good stead during the eclipse.

Each observer was supplied with a photograph of a small star chart of the region near the sun, prepared by Dr. Lockyer. This was afterwards supplemented by another on a larger scale photographed at the office of the Trigonometrical Branch of the Survey of India at Dehra.

Observations of Shadow Bands.

Staff-Surgeon Nolan, R.N., observed these phenomena with the help of two assistants. Previous to the eclipse a large white table-cloth was spread on a flat piece of ground in front of two walls intersecting at an angle of 115°, which were whitewashed.

FIG. 7.—The kinematograph hut.

Small Prism and Grating Observations.

The spectroscopic work was in charge of Lieut. Colbeck, R.N., and Senior Engineer Mountifield, R.N. I took out several spare prisms and spectroscopes with me in the hope they would be of service, and they were used to the very great advantage of science.

Meteorological Observations.

Mr. Eliot, the Meteorological Reporter to the Government of India, brought with him several important instruments with a view of making observations similar to those he had arranged along the whole line of totality. He was assisted by twelve volunteers.

Landscape Cameras and Kinematographs.

All the available landscape and hand cameras were put in charge of Mr. Turner, of the Survey Department, Calcutta, who was assisted by five volunteers.

As a well-defined shadow had been anticipated, the kinematograph was used for the first time in an attempt to photograph its passage through the air.

The Marquis of Graham brought out with him two kinematographs, one for the recording of the whole phenomenon of the eclipse, and the other for photographing the moon's shadow as it swept across the earth's surface. The latter was put in charge of Mr. H. P. Barnett, R.N., Paymaster, with one assistant. The kinematograph for the eclipse was worked by the Marquis of Graham himself, and five volunteers. The instrument was fed by a small cœlostat.

The above statements will give an idea of the completeness of the organisation rendered possible by such a wealth of observers, and it is to be hoped that the example set in 1898 may be followed in the eclipses of this and the following years. NORMAN LOCKYER.

THE YANGTZE VALLEY.[1]

MRS. BISHOP'S volume gives an account of a journey undertaken, the author tells us, solely for recreation and interest after some months of severe travelling in Korea. The book is a valuable contribution to the literature of travel, both from the remarkable personality of the writer and from the public interest recently directed to our projected "sphere of influence" in the Yangtze Valley. The greater part of the route followed has become a "beaten track" for travellers who from time to time have recorded their experiences and supplied valuable statistical accounts of the potentialities of this part of China. The author, however, in her daring attempt to reach the heart of the Mantze country, entered upon new and untrodden ground, and has given a graphic account of her adventures in one of the most picturesque mountain lands of China, the home of this obscure aboriginal tribe.

The story is all the more fascinating because it is written by a woman who has been careful to note the details of her environment day by day in a manner quite her own, and always interesting. Some light has been thrown upon this race of mountaineers, who, physically and in their manners and customs, are a people apart from the Chinese, who have maintained their characteristics, their language, and their independence through the centuries, and at last have been driven by their foes to the mountain solitudes of Szechuan and other parts of the empire.

It is to be regretted that Mrs. Bishop was unable to add to her excellent series of photographs some types of the race, or to afford some clue to the language, which appears to be an unknown tongue written in Tibetan characters. They are, one would suppose, allied to the Sifan and Lolo visited by Baber.

The first chapter deals with the Yangtze Valley—our sphere of influence. Approximate figures are here set

[1] "The Yangtze Valley and Beyond." By Mrs. J. F. Bishop. Pp. xv + 557. (London: John Murray, 1899.)

down relating to geographical area and population, and the constant soil-creating and fertilising functions of the great river. The Yangtze and its many tributaries are described, supplemented by an account of the inestimable value of these affluents as highways of commerce. The annual rise of the Yangtze is dealt with, and its influence over the districts flooded during part of the year.

The burning questions of "spheres of influence" and the open door are noted as modes of expression designed to conceal (especially spheres of influence) "much greed for ourselves not always dexterously cloaked, and much jealousy and suspicion of our neighbours, and much interest in the undisguised scramble for concessions, in which we have been taking our share at Peking." All this while we ignore the men who have been for two thousand years making China worth scrambling for. The author dreads "breaking up the most ancient of earth's civilisations without giving any equivalent." After having read the book throughout, the impression left on one's mind is that China's most antiquated type of civilisation is not without its grave defects, and that it might be replaced with advantage by a fresh importation from any European state.

Theoretically, there is much virtue and goodness in the paternal government of China, while its practical results, as one sees them in the condition of the people, are far from satisfactory. The rulers have fallen away from the ancient paths of righteousness, and lapsed into iniquity. The *malfaisance* of Mandarins may not prove so oppressive in the interior of Szechuan as in other parts of China, where nature is less bountiful, and the consequent struggle for existence harder. The author says: "The human product of Chinese civilisation and government is to us the greatest of all enigmas," and so he remains to those who know him best. His best points are then catalogued correctly, and the qualities which are the making of him when an immigrant under a liberal and enlightened government in a colony such as the Straits Settlements, and which, at the same time, render him a most objectionable addition to a community where his thrift, sobriety and industry enable him to compete successfully in the lower fields of white labour. One peculiar phase of Chinese character may be noted, that is, the dignified gravity of the race, which one is disposed to think is the product of mingled vacuity and conceit, rather than the expression of deeply sensitive Confucian minds.

"The Yangtze basin is a magnificent sphere of influence for all the industrial nations for fair, if not friendly rivalry, and to preserve the open door there."

This squares with the consensus of opinions of travellers in that favoured region. It offers no field for emigration; it is now over-populated, hardly producing food enough for the requirements of its people, who during failure, or partial failure of crops, perish in thousands of famine and pestilence. It is alone to the commercial possibilities that will follow opening up the country, and exploiting its vast coal-fields and stores of mineral wealth, that foreign enterprise must look for its reward.

Shanghai is described and illustrated. The value of the exports and imports of this great trading centre is set down at 37,000,000*l.* sterling per annum. Here British, American and French settlements adjoin, and one notes that nothing is said in praise either of the French settlement or French colonial aspirations. Civilisation of an antique and obsolete sort may have its charms; but the contrast drawn between the model European settlement of Shanghai and the Chinese city of like name leaves no shade of doubt as to the respective merits of the two civilisations—the old and the new. Here one is confronted with another enigma. For the past half century the Chinese city, in insanitary and withal dignified apathy, has been looking on this splendid European settlement, a fitting outpost of all that is best in modern advancement.

FIG. 1.—God of Thunder, Lin-Yang.

Mrs. Bishop says: "On returning to the broad, clean, well-paved and sanitary streets of foreign Shanghai, I was less impressed than before that many of its residents are unacquainted with the dark, crowded, dirty, narrow, foul and reeking streets of the neighbouring city. So native Shanghai, with its 5,600,000 souls, goes its sweltering way as of yore, breathing the mingled precepts of Confucius, and malodours of the waste products of centuries."

We breathe again freely as the author conveys us to Hangchow, giving a popular description of its picturesque surroundings, the present condition of the grand canal, pointing out the cause of its falling into utter disrepair.

The city has a chequered history like that other favoured city Soochow. It is a centre of sereculture and resort of opulent and leisure-loving literates and merchants. The illustrations of this part of the work, in common with others scattered through the book, are remarkable for their artistic excellence and fine technical quality, reflecting great credit on the author, who is a lady successful in many pursuits.

There is an interesting account of Medical Missions in China, throwing light on the valuable work done by this important branch of Christian Missions. "I believe in Medical Missions, because they are the nearest approach now possible of the method pursued by the founder of the Christian faith." The Medical Mission has proved one of the most successful branches of mission work in China.

The division of missionaries into sects is unfortunate, and militates against success. Chinese are apt to inquire why such differences exist in the one faith, and within one's own experience to say that "when you have all made up your minds what to believe, come and teach us." But there remains the potent influence at work,

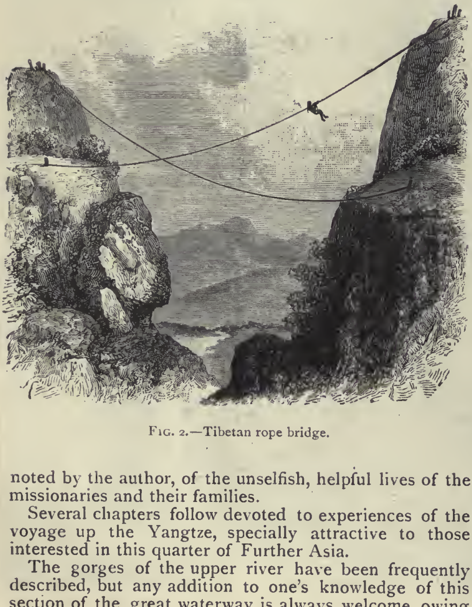

FIG. 2.—Tibetan rope bridge.

noted by the author, of the unselfish, helpful lives of the missionaries and their families.

Several chapters follow devoted to experiences of the voyage up the Yangtze, specially attractive to those interested in this quarter of Further Asia.

The gorges of the upper river have been frequently described, but any addition to one's knowledge of this section of the great waterway is always welcome, owing to the difficulty of navigation and danger caused by old and new rapids to native craft in the carrying trade. Mr. Little succeeded in taking a small steamer up the rapids to Chungkeng, but navigation of the gorges by steam must yet be more fully tested before it can be proved that the loss entailed by wreckage will not outweigh the advantages derived from the enterprise.

There are several mistakes in place names. One rather confusing error occurs in describing the Mi-tsang Gorge. It is set down in the index as Mitan Gorge, and the photograph showing the entrance to this gorge is labelled Ping-shan Gorge. It is at the entrance to this gorge that the great Ch'-ing-tan rapid bars the way to steam traffic on these upper turbulent waters. Blackuton, Thomson, Baber, Gill and others have passed this way, but Mrs. Bishop has been the first woman to give us the benefit of her keen observation, sense of humour, and literary talent in throwing some new light on native characteristics, and on weighty matters concerning this part of China.

The book must be read, and the reader will not be without his reward when he has finished the volume.

The most important part of the journey was the daring attempt to penetrate the mountain lands of the aboriginal Mantze, which nearly cost the author her life, and in which she succeeded so far as to be able to give a most interesting and graphic account of this obscure race. One would like to know something of their language, which is wholly different from Chinese, and written in Tibetan. It is also to be regretted that the camera of the intrepid explorer so scared the natives as to render portraiture impossible. The reader is purposely left to his own resources, and must read for himself the author's account of her adventures among the Mantze.

The work concludes with one or two brief essays:—"On the Poppy and its Use," "Christian Churches in China," "Secret Societies," "Questions of the Future," &c., subjects which have occupied the attention of other writers, disclosing a singular lack of unanimity of opinions on the part of the writers.

THE RELATION BETWEEN SCIENCE AND MEDICINE.

AN address upon the relation of science to experience in medicine, delivered to the Middlesex Hospital Medical Society by Sir J. Burdon-Sanderson, Bart., at the first meeting of the present session, is printed in full in the *Middlesex Hospital Journal* for December. The concluding part of the address is here reprinted, and the principles stated in it deserve careful consideration both from the point of view of science and of education. What Sir J. Burdon-Sanderson insisted upon throughout his address was that though the physician regards disease as a thing to be cured or prevented, while the investigator aims at discovering the causal relations between certain morbid changes and the conditions which give rise to them, both depend for their success upon the extent to which their faculties of observation have been developed. He held that medicine has hitherto advanced chiefly by the perfecting of its clinical method, using the expression in its modern and most comprehensive sense, but that future progress will be obtained by the scientific study of disease as a natural process. Some suggestions as to the best means to promote this advance are contained in the following extract from the address:—

We may, I think, rightly regard the Metropolitan schools collectively as constituting in themselves a great medical university. We do so in the hope that at no distant period they may be united for university purposes. Now, the two great functions of a university are education and the extension of knowledge by research. As regards the first I shall have nothing to say this evening. We may confidently anticipate that the clinical instruction given and the opportunity for clinical study afforded to students will improve year after year, and that practitioners will twenty years hence be even better informed, and their practice more sound than it is at present. But it is the other function of a university to which I would call your attention. Admitting, as I think must be admitted, that the Metropolitan schools have been hitherto, and will continue to be, admirable institutions for the training of men competent to exercise the healing art to the public advantage, it may still be asked whether our hospitals are, as they ought to be, observatories in which the scientific method is employed, not with a view to immediate utility, but for the eventual benefit of mankind by the advancement of knowledge. If we are right—as I am sure no one present doubts—in regarding a hospital school as an academical institution of which it is as much the function to make additions to knowledge as to educate, the organisation of every hospital school should comprise a special department for research in medicine—that is, that just as we have recognised for long the importance of pathological anatomy by the establishment in each school of a museum for the collection and display of morbid specimens, so we should provide what is of much more importance to the progress of medicine—a working place for the investigation of morbid processes. And, inasmuch as in most instances such investigation could be carried out much more effectually by the co-operation of several hospitals, I should further desire to see established a Hospital Association or an Association of Hospitals for the advancement of medicine by research. The organisation of such an Association would be simple. Each hospital would, as I have said, provide a research laboratory, under the direction of a working pathologist, the equipment of which would be the best that the resources obtainable for the purpose would admit of. The function of the Association would be the selection of subjects suitable for combined investigation.

Of the nature of these problems I need, I think, speak only very shortly. They would probably be of two kinds, namely, etiological and therapeutical, for it seems evident that for the investigation of the action of remedies—including under this term all the agencies which can be employed for the purpose of modifying pathological states—the same combination of clinical with physiological research is required as for the investigation of the processes of disease. But the greater part of the work of the Association would come under the other head. It would be advisable to restrict the scope of the investigation undertaken by well-defined limitations, and particularly to guard against the attractiveness of topics deriving their interest from their novelty, or from the rarity of the diseases to which they relate, rather than from their intrinsic importance. Preference would rather be given to the standing questions of clinical pathology, as, for example, to the investigation of the nature and causes of functional disorders or organic changes which, however frequently they may occur, are very imperfectly understood; and among these it might be well to select those in respect of which current medical opinion appears to be less in agreement than could be wished with the data of science. Let us take, for example, the case of gout. Here the difficulty which we find in harmonizing what is ordinarily believed as to the etiological relation of gout with uric acid, with the relatively complete knowledge we now possess of the physiological significance of that substance, at once suggests that it is desirable that the two kinds of knowledge now apparently at variance should be, so to speak, confronted. Another field in which it is difficult to reconcile the clinical and physiological aspects of the same phenomena is that of the relation between chronic renal disease and the functional disorders of the vascular and lymphatic system to which it gives rise. Here, again, the light which has been thrown on these subjects by such experimental investigations as those of Dr. Starling (which, I may mention in passing, have since their publication been confirmed by subsequent work in Germany) make us feel a certain degree of disappointment in finding ourselves still compelled to speak with the utmost reserve about such questions as the etiology of renal dropsy. Here, as in many other instances of a like nature, unsolved problems present themselves in connection with even the best-known diseases from the moment that we turn our attention to the underlying processes, of which the familiar clinical characteristics are but the outward and visible signs.

I trust that the suggestion I have made to you may not seem wholly unworthy of your attention, however imperfectly I may have been able to set it forth. I do not, myself, feel it to be premature. I should not, however, have the boldness to propose it even now, were it not that, as I have already told you, the reason which would have forbidden its being entertained no longer exists. We have now what we had not before—a sufficient number of men who, with youthful enthusiasm and with the best of their lives before them, have at the same time the scientific training necessary for pathological research.

If, as I trust may be the case, the new Metropolitan university is successfully constituted, it may be hoped that the economy of resources consequent on a better organisation of scientific teaching may set free the hospital medical schools from obligations which at present seriously impair their efficiency as academical institutions. At present, as we all know, elementary chemistry, elementary natural philosophy, and natural history are taught in schools of medicine; and large sums have, no doubt unavoidably, been spent in providing accommodation for subjects which lie outside the legitimate scope of medical study. It is surely not too much to hope that when these preparatory disciplines are duly provided for elsewhere, the resources hitherto required for their maintenance may be devoted to purposes in which we, as the representatives of medical science, can take a deeper interest, and particularly to the establishment in all hospital schools of well-equipped working places for clinico-pathological researches.[1]

In all that I have said this evening my aim has been to advocate the claims of scientific research in medicine; I have made no reference to the teaching of science. It is, however, easy to see that if the organisation of pathological research were to become more distinctly recognised as a function of a hospital medical school, the tendency of the change would be to infuse into the teaching of the science of medicine a reality and life which it has not as yet possessed.

Under present conditions there is much too wide a gap between the scientific and the practical part of the course of study for medicine. Let me take, for example, the case with which I am most familiar—that of the Oxford or Cambridge student, who, after receiving his preliminary instruction in the exact sciences in biology, and then acquiring a more thorough knowledge of anatomy and physiology, repairs to a Metropolitan medical school for the most essential part of his medical education. A considerable portion of these comparatively well-trained students are able to grasp the connection between science and practice, so as to appreciate the bearing of the science they have learned with the practical work in which for the rest of their lives they are to be engaged. But as regards the rest, we know what happens as soon as they have got rid of their last examination in science. It would be of little consequence that the details of the knowledge which has been so painfully acquired should fade from the memory, if one could believe that some notion of the scientific way of looking at questions was retained.

Whatever plan of study is followed, it is inevitable that the competent should succeed and the incompetent fail; but in our medical course there are causes of failure which it seems possible to obviate. One of these is no doubt the over-loading of our preparatory scientific curriculum with subjects which have no bearing on future work, an evil against which the General Medical Council has failed to protect us. The other is the unfortunate interruption of continuity which exists between the practical and the scientific stage in medical study.

It may, I think, be stated generally that every student when he enters on his hospital career feels that he is turning over a new leaf. It is quite natural that he should do so, and quite right, provided that he does not lose his interest in what he has previously learned. How is this to be prevented?

I have submitted to you this evening the proposition that research ought to be a recognised function of every medical school that lays claim to an academical position, on the ground that research is necessary for the advancement of medical science. The more this principle is acted upon the more effectually will the science of medicine be taught, for there is no qualification so essential to a teacher of science, and especially of pathology, as that he should himself be engaged in trying to master its difficulties.

Every advance in the direction I have indicated will have a direct effect upon teaching. The breach will cease to exist. The physiologically-minded student will no longer feel that in approaching the bedside he must leave his scientific preconceptions behind. In turning over the new leaf he will not forget what was inscribed on the old, but will rather find that the old has acquired a new value from its intimate connection with the work of his life.

But, gentlemen, all depends on whether you accept the proposition I have submitted to you—namely, that the science of medicine, even more than the art, holds the promise of the future.

[1] At the Middlesex Hospital a systematic investigation of the pathology of cancer is now in contemplation. I learn that it is intended to appoint a highly-qualified young pathologist to conduct the proposed research, and that in the necessary clinical work he will have the co-operation of the Registrar of the Cancer Department of the Hospital. The whole will be under the direction of a Committee of the Hospital staff. I refer to this as an example of the kind of work that can be done, and of the way of doing it.

SIR JAMES PAGET, BART, F.R.S.

THE death of Sir James Paget removes from our midst one of the ornaments of the medical profession. The loss is not an acute one since, though living up till some ten days ago, Sir James has for the last decade taken little active part in professional matters, but still, although the sphere of his activities has been during this period restricted by infirmity, one had evidence from time to time that he was there, using to the best of his strength that cultured mind, which never lost its vigour, for the benefit of those branches of knowledge which he loved so well.

This week's medical papers are so full of the professional attainments of the subject of this notice, and so rich in minute biographical detail, that there remains on these subjects little to be said. Sir James Paget was chiefly known to the world as a great surgeon, who, in addition to his actual professional abilities, exercised a profound charm over his patients. He was for the years he worked actively at St. Bartholomew's the student's model; not only what he did in the wards, but how he did it, served as a type to be imitated. His lectures and demonstrations were eagerly attended, and no note of discordance was there. The medical student, now of academic habits, was apt, in the early teaching days of Paget, to be rowdy, but there was never any disorder at his lectures, his fascinating diction rendering even the details of the most unæsthetic subjects sufficiently attractive to ensure the attention of his class.

Although Sir James Paget's practice as a surgeon, when he was at the height of his vigour, has perhaps never been surpassed, it was to the science of surgery rather than to its art, to its theory rather than to its practice, that he mainly contributed. He was no operating surgeon in the sense of Billroth. His surgery always contained in it an element of philosophy, a projection, so to speak, of his own philosophical spirit. He was a teacher, and enunciator of principles rather than mere facts.

In these days of what may be termed mathematical biography, one is apt to sum up a man's works, his contributions to knowledge, and regard the sum of them as an accurate measure, if not an actual expression, of his intellectual influence. This is not a fair test of the actual work of Paget. His original work on the catalogue of the Hunterian Collection at the College of Surgeons, and on that of the museum at St. Bartholomew's, his discovery of the trichina spiralis, his description of Paget's disease of the nipple and osteitis deformans, are perhaps the chief examples of his labours sufficiently sharp to wedge themselves through the crude and erratic surface of popular professional recognition. This, however, is no real measure of the man; he learnt from everything and taught from everything. He had the power of impressing the most varied subject-matter with his own philosophical individuality; the subject-matter in 1846 being the flora of Yarmouth; in 1896, or thereabouts, the medical student; his routine duties as warden at St. Bartholomew's affording to him material for a most valuable essay as to the ultimate fate and chances of success of the medical student.

In Paget's intellectual prime principles of exact science were beginning to be applied to medicine and surgery, such men *inter alia* as Pasteur, Liebig, Helmoltz, Brücke, &c., were busy examining with instruments of precision the fundamental phenomena and manifestations of life; not the least merit of Paget was that he kept well abreast of these stirring times, and gleaned from the purely scientific work of the great masters, facts and principles which he applied to surgery and surgical pathology. In these days of triennial medical congresses one can form but a very poor idea of what it meant in Paget's early days to be well up in contemporary science. His frequent advice to students to learn German seems now difficult to understand; it would be interesting to inquire how many men there are now who wish they had taken it.

Paget must be regarded, then, as an original teacher more than an original worker or writer; his ideas, perhaps somewhat metamorphosed in accordance with more exact technique, by his pupils, are springing up today on all sides, and will continue to do so. Like all truly great, he was truly benevolent, and many suggestions and ideas emanating from his mind have seen daylight under the names of his pupils.

F. W. TUNNICLIFFE.

NOTES.

THE Chemical Society's Victor Meyer Memorial Lecture will be delivered by Prof. T. E. Thorpe, President of the Society, on the evening of Thursday, February 8, at 8.30.

WE learn from *Science* that Prof. William Harkness, astronomical director of the U.S. Naval Observatory, retired as Rear-Admiral on December 17, on reaching the age of sixty years. Prof. S. J. Brown has been appointed to succeed him at the Observatory.

A SEVERE earthquake occurred on New Year's day in the province of Tiflis. The greatest amount of damage was done in the district of Achalkalak, in which six villages were completely destroyed and seven others had many houses ruined. Up to the present time, eight hundred dead bodies have been recovered.

WE regret to have to record the death, on January 1, after a very short illness, at his residence in Norwood, of Mr. W. T. Suffolk, the Treasurer of the Royal Microscopical Society, in his sixty-ninth year. Though but little known to the general public, and carried out in a very unobtrusive way, his services to microscopical science were great.

THE general manager of the South-Eastern and Chatham Railway, Mr. Alfred Willis, has made arrangements with the Wireless Telegraph and Signal Company for the Marconi system to be used in the course of a few weeks on the company's Royal Mail steamers between Dover and Calais, and also on their Royal Mail steamers between Folkestone and Boulogne. By this arrangement the vessels when in mid-Channel, or half-an-hour from either the French or English shores, will have telegraphic communication with either side.

THE Paris correspondent of the *Chemist and Druggist* remarks:—Prof. Riche, who was recently succeeded at the Paris School of Pharmacy by Prof. Moissan, was born at Gray (Hautes Saône) in 1829, and studied at the Faculty of Sciences and the Polytechnic School. He was appointed assistant professor at the School of Pharmacy in 1859, and professor of inorganic chemistry in 1873. His principal researches are on tungsten and its compounds. He has done some valuable work at the French Mint in compounding alloys, and is an active and usefu member of the Paris Council of Hygiene. His successor, M. Moissan, declares that it was in listening to his chemical lecture that he felt his first enthusiasm for the subject and resolved to become a chemist.

SINCE last week's issue we have received the *Connaissance des Temps* for 1901, the opening year of the new century. We then quoted a statement in the *Times* that the Paris Observatory "will henceforth in all its publications reckon the day from midnight to midnight." In spite of a suggestion to the contrary made some time ago, both the *Nautical Almanac* and the *Connaissance des Temps* have made no change, and the day is reckoned from noon to noon.

THE *Board of Trade Journal* states that nettle fibre has of late come greatly into favour in the manufacture of fine yarns and tissues. In Germany there are factories which use these fibres both in spinning and also for ulterior purposes. Nettle fibre produces one of the finest tissues obtainable from any known kind of vegetable fibre. In view of the importance which this seems likely to attain in connection with the weaving industries, it is intended to introduce the cultivation of nettles, if possible, into the Cameroons. The idea is to prepare the products of this experimental culture at the place where they are obtained, and test them in German factories. Should favourable results follow from these experiments, it is intended to organise nettle-growing enterprises on an extensive scale.

A NEW commercial intelligence branch of the Board of Trade has been established with a view to meet the constantly increasing demand for prompt and accurate information on commercial matters, so far as it can be met by Government action. In deciding to establish this new branch, the Board of Trade have been largely influenced by the recommendations contained in the report of a departmental committee appointed to consider and advise as to the best means of collecting and of disseminating among those interested prompt and accurate information upon commercial subjects, and as to the collection of samples, especially of goods of foreign manufacture competing with British productions, and the exhibition of such samples to manufacturers and traders in this country. The principal officer is Mr. T. Worthington, who recently acted as Special Commissioner to the Board in an inquiry into the condition and prospects of British trade in certain South American countries. The *Board of Trade Journal* will be the chief medium through which intelligence collected by the Branch and intended for general information will be conveyed to the public. The journal, which has up to the present been published monthly, is now issued weekly.

THE science of aerostatics has just lost one of its pioneers by the death of Mr. H. T. Coxwell, at the age of eighty-one. Mr. Coxwell's balloon ascents with Mr. James Glaisher, F.R.S., for the investigation of the meteorological conditions of the atmosphere at high altitudes, have long been prominent in scientific history. The circumstances which led him to take part in the work are described in an obituary notice in the *Times*. It appears that in 1862, hearing that a committee of the British Asociation at Wolverhampton had been making some unsatisfactory experiments with a Cremorne balloon, in order to take meteorological observations in the upper regions, he set about the construction of a special balloon for this purpose, finally producing one that stood 80 feet from the ground, had a diameter of 55 feet, and was capable of containing, when fully inflated, 93,000 cubic feet of gas. Mr. James Glaisher, F.R.S., who had not previously made an ascent, was to go up with Mr. Coxwell and take charge of the observations, while Mr. Coxwell himself was to attend to the balloon. The first of the long series of ascents thus carried out by them under the auspices of the British Association took place at Wolverhampton on July 17, 1862, and on that occasion they travelled sixty miles in two hours, and attained a height of four miles. It was on September 5, in the same year, that the pair made the record journey of rising to a height of no less than seven miles above the surface of the earth; and the story of this exciting exploit shows that the intrepid investigators had a very narrow escape indeed of their lives. The result of the many ascents by Mr. Coxwell and Mr. Glaisher was some important contributions to the science of meteorology. Moreover, they proved more clearly than had ever been done before, that ballooning was not merely a pleasant pastime, but might be rendered of great practical utility. From the same point of view Mr. Coxwell was most persistent in urging the advantages of employing balloons in times of war.

THE advantages of cremation as a means of disposing of the dead are too well known to need to be stated here. Neglecting sentimental considerations, the problem is, as Sir Henry Thompson puts it:—"Given a dead body: to resolve it into carbonic acid, water, and ammonia and the mineral elements rapidly, safely, and not unpleasantly." The present mode of burial is neither a satisfactory nor sanitary means of accomplishing this; and some of its dangers were pointed out by Dr. R. Farquharson in an address recently delivered at Aberdeen, and reported at length in the *Court Circular* of December 23, 1899. The lecture will be of service in enlightening people upon the subject of cremation, and directing their attention to the terrible condition of many old burial grounds.

IN the course of an interesting paper on lightning and its effect on trees, Mr. F. J. Brodie remarks in the *Journal* of the Royal Agricultural Society that in America much damage to live stock by lightning is believed to have arisen from the increasing adoption of wire fences. The director of the Iowa Weather and Crop Service, in his report on the thunderstorms of 1898, says: "Unquestionably wire fences, as now constructed, serve as death-traps to live stock, causing a vast amount of loss every year. And it is also quite evident that a considerable percentage of danger may be avoided by the use of ground wires at frequent intervals in the construction of wire fences." The point appears to be a practical one, deserving the notice not only of American but of English farmers, the means of protection from a real source of danger being after all very simple.

THE Meteorological Reporter to the Government of India has published a statement of the meteorology and rainfall of India during the past six months, and a forecast of the cold weather rains in Northern and Central India for the three months ending February 1900. The forecast issued in June last, from the conditions antecedent to the south-west monsoon, anticipated a rainfall slightly above the normal. This prediction was unfortunately not verified, as an area comprising nearly two-thirds of India is suffering from the most severe drought of the century. It is to be regretted that the meteorological conditions of October and November of last year strongly indicate the probability that the general character of the winter rains in the Persian area and North-Western India will be similar to that of the past four cold winters, and that the amount of the precipitation will probably be in general defect. The chief chance of the occurrence of more favourable rain than is anticipated lies in the early termination of the unknown causes which have produced abnormal conditions in the Persian and Upper India areas.

THE twenty-first yearly report of the Deutsche Seewarte, for 1898, has just been issued. The department of maritime meteorology continues to show great activity; the number of complete logs received from the mercantile marine alone amounted to 470, exclusive of 258 abstract-registers containing less complete observations. The great majority of the voyages were in the North Atlantic, but other oceans were fairly represented. In order to obtain as many observers as possible, agencies are established in many ports outside Germany, including the Consulates at Glasgow, London, Liverpool and Cardiff. The results of the observations are published in various ways useful to sailors, and have been frequently referred to in our columns. The system of weather telegraphy, and the possible acceleration and improvement of telegraphic weather reports receive considerable attention; storm warnings were issued to the various ports on 74 days, but the amount of success is not stated. In March last a conference was held under the presidency of Dr. Neumayer, on the subject of the rating and improvement of chronometers; those of German manufacture were recommended for use, as far as practicable.

THE Rev. John M. Bacon, on the occasion of a night balloon ascent, underwent an enforced detention in the upper regions of the atmosphere exceeding in duration that of any other English balloon voyage on record, and he made use of the opportunity to study the varying currents blowing at different altitudes. In the January number of *The National Review* he gives the results of these observations in an article, entitled "The War of Winds," which, together with the facts he has collected, forms an interesting commentary on weather forecasts.

DR. FREDERICK A. COOK'S description of the Belgian Antarctic expedition, of which he was a member, contributed to the January number of the *Century Magazine*, is accompanied by several exceptionally fine half-tone colour plates representing some of the Antarctic views seen during the journey of the *Belgica*. How promising the Antarctic is as a field of exploration may be judged from the following summary of the geographical results of the expedition:—"The work of the first two weeks when assembled proved the discovery of a highway perfectly free for navigation during the summer months from Bransfield Strait, two hundred miles south-westerly, through an unknown land to the Pacific. This highway has received the name of our ship, Belgica Strait. To the east of Belgica Strait we discovered a high, continuous country, which connects with the land charted as Graham Land. This has been christened Danco Land, in honour of our companion, Lieutenant Danco, who died on the ship during the long drift in the pack-ice which followed. The land to the west of the strait is cut up into islands by several channels, and was named Palmer Archipelago, in honour of Captain Nathaniel Palmer, the American sealer, who first of all men saw the outer fringe of this land. Scattered about in the waters of Belgica Strait are about one hundred islands and some groups of islands. About fifty of these are of considerable size. The islands, the capes, the bays, the headlands, and the mountains will mostly receive the names of Belgian friends of the expedition; but prominent outside workers have not been forgotten, as is evidenced by Nansen and Andrée Islands, and Neumeyer Channel."

MR. JOSEPH JACOBS, in an article, entitled "The Paths of Glory," in the current number of the *Fortnightly Review*, subjects the latest issue of "Who's Who" to a rough analysis, with the view of giving some idea of the kind of career which confers distinction on Englishmen. It seems that one Englishman out of every fifteen hundred throughout the British Empire attains popularity enough to secure a place in the biographical dictionary referred to. Among the results at which Mr. Jacobs has arrived, it may be noticed that "the comparative importance of politics as a means of figuring prominently in the world's thought" has changed but little during the thirty years since the publication of Mr. Galton's "Hereditary Genius." A comparison of the conclusions in this book with the contents of "Who's Who" leads to the remark that "scientific men must have increased more than fourfold in the interval (the last thirty years), yet their proportional parallax has declined from 73 to 42. Specialisation, doubtless, advances science and secures a man's position, but it rarely brings him prominently before the public." The argument as to the decline of the "proportional parallax" of men of science is, of course, unsound; for if "Who's Who" had been edited by some one familiar with the work of scientific men instead of a literary man, many minor writers would have been omitted from it and the names of more investigators well-known in the scientific world would have been included. The data from which Mr. Jacobs determines his "proportional parallax" are thus not comparable.

FOR several years Prof. W. O. Atwater has been engaged in investigations to determine whether the energy given off from the body of a man in the form of heat, or of heat and external muscular work, is equal to the potential energy or heat of combustion of the material actually burned in the body; in other words, whether the law of the conservation of energy holds good for the living organism. The lastest number of the *Physical Review* (vol. ix., No. 4) contains a concluding account, by Prof. Atwater and Mr. E. B. Rosa, of experiments made with the view of testing this point. A slight difference was found between the estimated income and measured outgo of energy in the experiments, and the authors conclude: "In view of defects and sources of error in methods and apparatus, we would, perhaps, be unwarranted in assuming that the experiments thus far made completely demonstrate the applicability of the law of the conservation of energy in the human organism. They do, however, seem to us to be reasonably near to such demonstration." The mechanical efficiency of a man was determined by a comparison of the energy used when at rest and when performing muscular work. The work done, divided by the total energy yielded by the body, gave 7 per cent. as the mechanical efficiency. As, however, a large amount of the energy received was used up in the body, only the excess of energy absorbed in the work experiment over that required when the subject was at rest should be charged against the work done. When this was taken into account the mechanical efficiency of man came out at 21 per cent., which equals or exceeds that of the best compound condensing engines with the highest efficiency boilers.

TWO more parts of the zoology of the Norwegian North Atlantic Expedition have recently been issued; one (No. xxv.), by Hans Kiær, dealing with the Thalamophora (Foraminifera), and the other (No. xxvi.), from the pen of Kristine Bonnevie, treating of the Hydroid Zoophytes. As usual, an English translation is printed in parallel columns with the Norwegian text; and although this, in the main, is well done, it would have been all the better for revision by an English proof-reader. The Foraminifera indicate that the portion of the Atlantic basin surveyed by the expedition is capable of division into three areas. Firstly, the southern grey clay, including the fjords and banks along the Norwegian coast, about as far as long. 19° E., as well as the similar clay area near Iceland and Jan Mayen. Secondly, the northern grey clay, comprising the fjords and banks along the aforesaid coast to the eastward of long. 19° E., and likewise the vicinity of Bear Island and Spitzbergen. Thirdly, the brown clay, subdivided into the *Biloculina* and the transition clay. So greatly does the brown clay differ in its fauna from the grey, that of the species of Foraminifera found on the former, only about two-thirds are common to the latter. It is also noticed that, with the exception of the eastern portion, the grey clay on the Norwegian coast is remarkably rich in these organisms, half of those met with during the expedition being taken there. From the great depths towards the coast the *Globigerinae* gradually diminish in number, until they almost disappear near the coast and in the fjords.

Modern Medicine states that Dr. A. Campbell White has been experimenting with liquid air on the tissues of the body. The results obtained encourage the belief that it will come into use as a local anæsthetic, and possibly for other medical and surgical purposes. The difference in temperature between liquid air and the human body is so great that it affords a unique means of producing a sudden and extreme shock to a localised part of the body, without localised destruction of tissue, or without affecting the general system.

MR. G. A. HEMSALECH, who, in conjunction with Prof. Schuster, recently published an account of their joint researches on the constitution of the electric spark (*Proc.* Roy. Soc., vol. lxiv. p. 331), has continued the research in the laboratory of M. Lippmann, in Paris. In the *Journal de Physique* (Series 3, vol. viii. pp. 652-660) he gives a detailed account of the action of the jar spark, with and without self-induction in the secondary circuit, on the metals bismuth, copper, cadmium, zinc, lead, iron, cobalt, silver, mercury and also on the gases hydrogen and oxygen. In every case the effect of self-induction in the secondary is to lower the temperature of the spark, the resulting spectrum being intermediate between that of the arc and the ordinary condensed spark, the air lines entirely disappearing and the long lines of the metals only persisting. With a very long exposure (fifteen times normal), the band spectrum of nitrogen was faintly perceptible in the spectrum of the self-induction spark. In the case of metals containing impurities, the spectrum of the impurity is well shown in the modified spark spectrum. Photographs of the metallic spectra mentioned accompany the paper, showing clearly the contrast between the two types of spark. The apparatus consisted of a 10-inch spark coil, three Leyden jars, each of 1200 sq. cm. surface, with self-induction varying from 0·00012 to 0·0038 henry in secondary circuit. The photographed spectra extended from λ 5900 to λ 3400.

THE Annual Progress Report of the Geological Survey of Western Australia for 1898, reached us at the close of 1899. Field-work has been carried on mainly by Mr. A. Gibb Maitland and Mr. Torrington Blatchford in areas which were considered to be of economic importance. Among these the crystalline rocks of the southern and western portions of the colony received attention. The schists and gneisses have a general strike to N.E. and S.W., but it was not found possible to draw any lines separating granite from gneiss or other schistose rocks. A belt of iron-bearing schist, about six miles in width, has been traced to the north of Northam. The country consists chiefly of granite, in which are belts of vertical mica- and hornblende-schists, and banded iron-bearing quartzites. In places these quartzites have proved to be auriferous.

THE anthropological aspect of primitive mathematics has recently been approached in two such very different ways by Herr L. Frobenius ("Die Mathematik der Oceanier"; *Naturwissenschaftliche Wochenschrift*, Bd. xiv. 1899, p. 573), and W. J. McGee ("The Beginning of Mathematics"; *American Anthropologist*, N.S. vol. i. 1899, p. 646) as in itself to constitute an interesting psychological study. The German investigator gives lists of numerals from numerous localities, and classifies them into structural groups, which fall naturally into geographical districts; for example, the group which has practically only two numerals lies to the south of Indonesia (*i.e.* part of New Guinea and Australia); that with five is found in the middle district (portions of New Guinea), while that with ten numerals is characteristic of the northern district, whence it has spread into Micronesia, Melanesia, and Polynesia. The various exceptions and variations are noted, as well as the way in which the numerals illustrate primitive addition, multiplication and subtraction. The American student starts with the axioms that (1) Primitive men are mystics; (2) Primitive men are egoists. The Australian binary concept of things is expressed not only by their numeration, but even more clearly by their social and fiducial systems. The most widespread of the mystical numbers is four, the devotee of the Cult of the Quarters is unable to think or speak without habitual reference to the cardinal points. To most of the devotees of the quatern concept—forming probably the majority of the middle, primitive tribes of the earth—the mystical number four is sacred, perfect, all-potent, of a perfection and potency far exceeding that of six to the Pythagoreans and the hexagram to Paracelsus. A somewhat higher stage is marked by the use of six as a mystical or sacred number; in this stage the cardinal points are augmented by the addition of zenith and nadir. In the case of the last two cults the exoterically perfect numbers of four and six are esoterically perfected through the unity of subjective personality; hence the mystical numbers of five and seven. The author denies that the quinary system was primeval. The method of treatment by Prof. McGee is sufficiently illustrated by these quotations.

AN account, with illustrations, of the most interesting of the medals awarded to students in London Hospitals, is contributed to the current number of the *British Medical Journal* by Mr. T. E. James.

THE twenty-seventh annual dinner of the old students of the Royal School of Mines will be held on Friday, January 26, at the Hotel Cecil. The chair will be taken by Mr. H. G. Graves, who, for the past eight years, has acted as hon. sec. of the dinner committee.

THE current number of the *Electrician* contains, as a supplement, a large sheet-table giving details concerning the Electricity Supply Works in the United Kingdom. An immense amount of information concerning the plant in stations in operation or in progress is given in the table.

THE fish hatching experiments recently started by the Crystal Palace School of Fish Culture have now been resumed, and the operations may be witnessed daily at the Palace. The first lot of ova salmonidæ was laid on Friday last.

MESSRS. WHITTAKER AND CO. have published the fourth edition of Mr. T. H. Blakesley's "Papers on Alternating Currents of Electricity for the use of Students and Engineers.' A prominent characteristic of the book is that various electrical problems are dealt with by geometrical methods.

A COPY of the seventh volume of *Natur und Haus*—an illustrated magazine for naturalists, using the word in its widest sense—has been received. Numerous excellent illustrations are distributed through the pages, and the articles will interest all students of natural history having even an elementary knowledge of the German language. The publisher is Gustav Schmidt, Berlin.

THE second of the Selborne winter lectures will be delivered at the Linnean Society's Room at Burlington House, W., on Tuesday, January 16, at 8.30 p.m. The subject will be "Man's First Contact with Nature," by Prof. G. S. Boulger. The February lecture will, it is hoped, be the one promised some months ago by the Hon. J. Scott Montagu, M.P., on "South African Fauna and Flora"; and the March lecture by Dr. Lubbock.

THE thirteenth edition of "Discoveries and Inventions of the Nineteenth Century," by Mr. Robert Routledge, has been published by Messrs. G. Routledge and Sons. In matters which have been brought prominently before the public, such, for instance, as Röntgen photography and wireless telegraphy, the book is up-to-date, but in some of the less familiar sections it is many years behind the times. The section on the spectroscope particularly needs to be revised. Used with discrimination, the book contains much instructive information concerning achievements of modern science and industry.

HORTICULTURAL science and practice are fortunate in having such a trustworthy exponent as *The Garden*, of which the first number of a new series has just been published. The journal was founded in 1871 by Mr. William Robinson, and during its existence has done much to promote improved methods in horticulture and extend the knowledge of beautiful flowers, shrubs and trees, and of the best ways of dealing with them. Botanists, horticulturists, and all lovers of plants should see the number which commences the new series. Among the articles we notice one on the Royal Gardens, Kew, illustrated, as are the other contributions, with several instructive half-tone pictures.

ASTRONOMY figures prominently in the January number of *Knowledge*. Mr. A. Fowler contributes an article on the constituents of the sun, in which he summarises the researches and conclusions of modern solar physics. Mr. E. W. Maunder commences a series of articles on astronomy without a telescope, and the Rev. J. M. Bacon describes the balloon ascent made by him with the object of observing the Leonid meteors. Among other subjects of articles are plants and their food, by Mr. H. H. W. Pearson, and the natives of Australia and their origin, by Mr. R. Lydekker, F.R.S.

OUR contemporary, *Science Gossip*, is doing good work in publishing a series of papers, by competent naturalists, dealing with different groups of the British invertebrate fauna, in the form of popular monographs. Portions of three memoirs of this series appear in the January number—namely, one, by Mr. Sopp, on dor-beetles; a second, by Mr. Soar, on freshwater mites; and a third, on spiders, by Mr. F. P. Smith. By the quotation from *Antony and Cleopatra*, the author first named seems to have proved beyond cavil that the Shakespearian term *shards* refers to the elytræ of the dor-beetle. While thus keeping in the main to the British fauna, the editor has admitted one descriptive paper dealing with a wider area—to wit, a contribution, by Dr. H. C. Lang, describing the Palæarctic butterflies, of which the present section is devoted to the numerous species of the beautiful genus *Parnassius*.

THE *Jubelband* of the *Zeitschrift für physikalische Chemie* contains an interesting memoir by Dr. T. Estreicher upon the solubility of argon and helium in water. The value given by Prof. Ramsay in his preliminary note in 1895 for the solubility coefficient of helium (·0073 at 18°·2) would make helium the least soluble of gases, a conclusion borne out by its exceedingly low critical point: but from the experiments of Dr. Estreicher it would now appear that the true value of the coefficient is about double this preliminary value. The apparatus used was identical in principle with that of Ostwald, but was improved in two important points: the use of a glass spiral connecting the measuring and absorption vessels, enabling the apparatus to be made wholly of glass, and the immersion of the whole apparatus in water. This water jacket rendered accurate determinations of the solubility coefficients possible at temperatures between 0° and 50° C. The results are plotted in the form of curves, nitrogen being also shown on the same scale for the sake of comparison. The solubility curve of argon is of the usual type, decreasing with rise of temperature from ·0578 at 0° to ·02567 at 50°. The solubility of helium varies very slightly with temperature, the curve exhibiting a minimum at about 25° C., the values being ·015 at 0°, ·01371 at 25°, ·01404 at 50°. The nitrogen and helium curves intersect at 30°, where their solubilities are the same; above this temperature nitrogen has a smaller solubility than helium. The author points out that although the occurrence of a minimum of solubility is peculiar, it is not unique, since Bohr and Bock found a minimum of solubility for hydrogen at about 60°.

THE additions to the Zoological Society's Gardens during the past week include a Diana Monkey (*Cercopithecus diana*) from West Africa, presented by Mr. S. W. Thompston; a Common Tern (*Sterna fluviatilis*), European, presented by Mr. J. Newton; a Tawny Owl (*Syrnium aluco*), British, presented by Madam de Bunsen; Moor Macaque (*Macacus maurus*) from the East Indies, a Crested Porcupine (*Hystrix cristata*) from West Africa, two Crossbills (*Loxia curvirostra*), European; three Serrated Terrapins (*Chrysemys scripta*), a Prickly Trionyx (*Trionyx spinifer*), a Bull Frog (*Rana catesbiana*) from North America, deposited; two White-eyebrowed Wood-Swallows (*Artamus superciliosus*), two Masked Wood-Swallows (*Artamus personata*) from Australia, purchased.

OUR ASTRONOMICAL COLUMN.

CENTRAL STAR OF RING NEBULA IN LYRA.—M. W. Stratonoff, of the Tashkent Observatory, has been engaged in measuring the brightness of the central star of the annular nebula in Lyra, and has communicated his results to the *Astronomische Nachrichten*, Bd. 151, No. 3607. A considerable number of photographs of the nebula have been obtained with the large telescope of 0·83m. aperture, extending over the period September 8, 1895, to September 15, 1899, the exposures varying from 30 to 90 minutes. From his measures of the brightness of the central star as compared with the magnitudes of 30 neighbouring comparison stars, M. Stratonoff shows that the magnitude varies from 13·1 to 9·5. A special series of photographs taken with extra long exposures, however, renders the question of variability, as measured from photographic impressions, somewhat doubtful. On a plate exposed for anything between 22m. and 1h. 23m. the mean magnitude of the star was 11·6. On a plate exposed for 10 hours, the magnitude was 10·1; while on exposing for 20 hours, the measured magnitude was 3·6. The author suggests, as explanation of this, that the star may really be simply a condensation of part of the whole nebulous matter, and the effect of long exposure will be to lessen the contrast between the condensed centre and the outlying fainter matter.

THE INDIAN UNIVERSITY OF RESEARCH.

A Conference was held at Simla at the end of October last to consider the Tata scheme for a Research University for India. A full report of the Conference is in the Madras *Educational Review*, from which the following particulars have been derived:—

The gentlemen invited by the Government of India to meet in conference with Mr. J. N. Tata regarding the proposed University were as follows:—The Hon. Mr. T. Raleigh, presiding, Mr. Jamsetji N. Tata (with his Secretary, Mr. Padshah), the Hon. Mr. Justice Ranade, Surgeon-General Harvey, the Hon. Dr. Duncan, Director of Public Instruction, Madras, Prof. Pedler, F.R.S., Director of Public Instruction. Bengal, Mr. Sime, Director of Public Instruction, Punjab, Principal MacMillan, Bombay, Mr. A. H. L. Fraser, Officiating Home Secretary.

The Conference first discussed fully the manner in which the scheme should be launched, so as to keep in view the ultimate ideal and at the same time make progress as funds permit. The Conference were of opinion that it is an essential feature of the scheme to have a central institution for research, as well as a central authority to control the operations conducted under the scheme. And they were of opinion that there is ample room, and indeed a clear necessity, for such a central institution.

At the same time they realised the necessity for taking advantage of existing facilities for research, whether in the shape of special local facilities (as of trade, products, &c.), or in the shape of good laboratories or museums, and men qualified for scientific research. They acknowledged that even in the unfavourable circumstances hitherto existing, students had shown in certain instances distinguished aptitude and capacity for research; and they believed that much good would be done by the grant of studentships, and also, where necessary, by assistance to the teaching and supervising staff. While, therefore, recognising that a central institution is necessary, and that there are certain departments of research (such as Technical Chemistry), which must even from the very first be provided for at that central institution, they recommended that at the outset every effort should be made to utilise existing facilities and so economise funds and resources. It is undoubtedly clear that certain branches of research must be conducted away from the central institution. But the Conference are of opinion that that institution should be gradually strengthened as circumstances permit.

The Conference also concurred fully in the view accepted by the Provisional Committee that certain parts of the scheme should be first carried out, and that the rest should follow as funds permit. They concurred in giving preference to Parts I. (Scientific and Technical) and II. (Medical) and leaving Part III. (Philosophical and Educational) to follow, though they were of opinion that the promoters of the scheme and its governing body ought to keep in view the scheme in its entirety. They were also of opinion that the scheme of studies and of subjects should be stated in the most general terms, and that provisions should be made for its revision from time to time so as to leave the authorities in charge of the work as free a hand as possible in taking up subjects that seemed specially at any time to demand attention, and in conforming to the progress of science. In regard to bacteriology, they were quite prepared to postpone action, both because there are many subjects to which the funds may at the first be at least as usefully applied, and also because they understood that the Government of India are taking such action as seems at present necessary in regard to this subject. They think that probably the best application of their funds to this subject, for the present at least, will be the provision of studentships in the Government institutions.

The Conference considered the question of the site of the central institution. It seemed to them that of all the sites named the choice lay between Bombay and Bangalore. In regard to the former the main considerations were (1) the fact that it is the home of the founder (who, however, rather favours Bangalore); (2) that it is a great centre of commercial and industrial activity; (3) that it is easy of access from all parts of India and from England; and (4) that a strong governing body could be easily obtained there. On the other hand, the climate, though not altogether unfavourable, is not bracing, and is injurious to machinery and apparatus. It would not be so favourably regarded by Europeans as Bangalore, and in Bombay land is not available in sufficient quantity. If (as is believed) special concessions in respect to site, and aid in regard to the scheme generally, be made in Bangalore on condition of the institution being there, the Conference would recommend that site.

The Conference considered the name or title of the institution. There was a strong opinion in favour of the title "Institute" as more suitable than "University" to the objects in view. But in deference to the views of Mr. Tata, and in consideration of the sentiment of the educated community of India, the Conference decided that it was expedient to adopt the well-known title of "University." They, therefore, decided to recommend that the institution be styled "The Indian University of Research." They were, however, of opinion that it should maintain its post-graduate character, and that it should, therefore, grant not degrees but fellowships.

The Conference are unanimously of opinion that there is great need for such an institution as has been indicated; that there is no reasonable ground for doubt that its work would be successful; that it would exercise a most beneficial influence on higher education and on the development of the resources of the country; and they strongly recommend it to the sympathy and support of the Government of India. They trust the Government of India will express their favourable opinion on the scheme, and give the promise of necessary legislation to be carried out as soon as it is matured, so that an appeal may be made to the public for funds, and that the details of the scheme may be definitely settled.

The Conference then proceeded to revise the Draft Bill and determined to recommend the Draft Bill as revised to the Government of India for publication. And at the request of Mr. Tata they resolved to ask the Government of India to nominate some officer to consult with him about the transfer of the property with which he proposed to endow the University.

The *Gazette of India* gives the following outline of the Tata University scheme:—It is proposed to found an institution which shall be or correspond to a teaching University for India, its primary aim being to teach, not to examine. Diplomas, therefore, will be conferred on those who have completed a certain course of higher education. This work of higher instruction will be conducted on principles followed now in Europe—*e.g.* in German Seminaria, French Conferences, and English and American Research Classes. These courses will be the beginning of a purely specialist training. In order not to interfere with the existing agencies, the new institution will take up teaching where Colleges and existing Universities leave off. The new courses will be post-graduate. The new specialist courses, which are post-graduate, will naturally be professional and technical, rather than simply literal school sanitary and science practice. For qualified medical men a school of pedagogics for those intending to be higher secondary teachers (inspectors, head-masters, &c.), and a school for higher studies, are some of the obvious directions of the development. It is not proposed to take all these up at once. The order in which they may be proceeded with will be best arranged by the committee. It is not intended to cut off the post-graduate students from education in Europe. It is contemplated to select the best for further training in Europe or America, with a view to their future return to this country. It will be necessary to make ample provision for scholarships and fellowships, both for the students in the institution and for those who proceed from it to Europe or America. The development of a scheme so complete must entail a vast capital annual expenditure, the construction of libraries, laboratories and museums, and the invitation to specialists to teach and prosecute research. All this must require large sums of money. A committee has been formed to secure the necessary financial support by making a general appeal for funds to take the preliminary steps in connection with the scheme, and to obtain a short legislative enactment enabling the institute to hold property.

His Excellency the Governor, the Chancellor of the University of Bombay, has kindly consented to let it be known that the proposed scheme has his personal approval and sympathy.

The Government of India accept the recommendations of the Conference, and they desire to place on record their appreciation of the generosity and public spirit displayed by Mr. J. N. Tata in making his munificent offer of an endowment for the proposed University of Research. They are confident that the proposed University will meet a great need, and will contribute to the advancement of higher education and the development of the resources of the country. They will be ready to proceed to legislation as soon as the scheme has been matured in all its details. They wish the undertaking every success. In accordance with the request made by the Conference, the Government of India have requested the Government of Bombay to nominate an officer to arrange with Mr. J. N. Tata for the transfer of the property with which he proposes to endow the University.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

DR. F. KOHLRAUSCH, president of the physikalisch-technischen Reichsanstalt, has been appointed honorary professor of physics at Berlin.

MR. G. F. HARDCASTLE, senior assistant in the chemical department of the Technical College, Huddersfield, has been appointed instructor in dyeing, and assistant in chemistry, at the Municipal Technical School, Leicester.

THE Annual General Meeting of the Association of Technical Institutions will be held on Wednesday, January 24, at the Mercers' Hall, London. The president (Earl Spencer, K.G.) will preside, and an address will be given by the president-elect, Sir Swire Smith.

A COURSE of fifteen lectures on organic chemistry will be given at the Goldsmiths' Institute, New Cross, S.E., on Friday evenings, at 8.30, by Mr. W. J. Pope, commencing on January 19. Particular attention will be paid to the discussion of recent work and current views relating to organic chemistry.

THE University of Pennsylvania's free museum of science and art at Philadelphia, one of the late Dr William Pepper's cherished hopes, was, says *Science*, formally opened in the presence of several thousand people on December 20. Immediately following the presentation to the board of trustees of the museum, a bronze statue of the late Dr. Pepper, the gift of friends, was unveiled. Mrs. Pepper, the widow of Dr. Pepper, has presented to the university trustees, as her memorial to the memory of her husband, a gift of 50,0.0 dollars, as a fund to carry on the work started by Dr. Pepper.

THE dissertation for which Mr. H. N. Dickson has received the B.Sc. research degree of Oxford University was "On the circulation of the surface waters of the Atlantic north of 40° N. lat." The work consisted primarily of a chemical and physical examination of the surface waters of the North Atlantic during the twenty-four successive months of the years 1896 and 1897. For the purpose of the investigations special arrangements were made for the continuous supply of samples by officers of ships trading in the North Atlantic. The results were exhibited in monthly charts showing the distribution of temperature and salinity, and the changes during the period are fully discussed. The existence of definite seasonal changes in the circulation has been established by the investigation.

WITH a view to encourage the adoption of scientific methods in the teaching of physical geography, the authorities of the Cambridge Local Examinations have issued a syllabus of a course of work which has several commendable characteristics. In the first place, it is distinctly stated at the head of the syllabus that "The object of the examination will be to ascertain as far as possible to what extent the candidates' powers of observation and reasoning have been cultivated." Even more noteworthy than this remark is the schedule which accompanies the syllabus and contains an outline of a course of practical instruction designed "(1) to develop the power and habit of observation; (2) to give the pupils clear and accurate conceptions of natural phenomena and their relations; and (3) to enable them to seek for the causes and rational explanations of the phenomena which they observe." Among the subjects in which practical instruction is to be given are: the drawing of sections from contour maps, the study of local land-forms, the use of meteorological instruments, the study of ocean current maps, simple astronomical observations, the determination of time and latitude, and the use of the terrestrial globe. It is to be hoped that the efforts of the Cambridge authorities to encourage the scientific study of the earth will meet with success. No subject stands in greater need of rational methods of instruction than geography.

THE English Education Exhibition, which was opened by H.R.H. the Prince of Wales at the Imperial Institute on Friday last, contains the materials from which the English educational exhibits for the Paris Exhibition will be chosen. The whole field of educational activity in this country is more or less satisfactorily represented by these exhibits, though a walk through the galleries shows the initiated observer how impossible it is to materialise certain factors of educational effort, which though intangible are none the less real and powerful. Every step in a career from the kindergarten to the university can be followed by the inspection of the objects collected in the different sections. It is satisfactory to be able to record that the equipment necessary for proper instruction in science takes a prominent place in the collections sent by nearly all the elementary schools, most of the secondary schools, the technical institutes, and the colleges of university rank. Hand and eye training is evidently now almost universal, for one exhibit after the other contains admirable examples of wood-work, metal-work, clay-modelling, and miscellaneous occupations of a varied kind having the same end in view. We noticed with some satisfaction an etching of Charles Darwin in the Shrewsbury School exhibit: even if he received little encouragement in science at the school, it is quite clear the authorities are proud of him.

SCIENTIFIC SERIALS.

Wiedemann's Annalen der Physik und Chemie, No. 12.—Magnetic deflection of kathode rays, by E. Wiechert. The velocity of kathode rays is determined by deflecting them at two different points of their path by currents of a Lecher wire system slightly retarded with respect to each other. The velocity comes out as about one-seventh of that of light, and the mass transported with each electron is about 1/1300 part of an oxygen atom.—Relation between electric conductivity and pressure, by G. Tammann. Gaseous ionisation is reduced by increase of pressure, while the ionisation of a solution is increased. In incompletely dissociated solutions, an increase of conductivity with pressure is observed. Thus, a deci-normal solution of acetic acid is reduced in resistance to one-half its original value by a pressure of 2500 atmospheres.—An experimental and theoretical fallacy in electrical doctrine, by E. Lecher. The author maintains that a magnetic line of force can in no sense be defined as a line along which a positive pole would move, and that as a matter of fact a pole never moves along a line of force.—Distribution of free electricity at the surface of a Crookes' tube, by E. Riecke. The author uses a mixture of red lead and sulphur to discover the free charges on the outer surface. The fluorescent patch is marked by a wide ring of sulphur, the interior of which is marked by irregular patches of red lead, showing negative charges distributed irregularly, probably owing to want of symmetry in the kathode. The remainder of the tube is coated with sulphur, except the portion behind the kathode, which is negative again.—Strains in Rupert's drops, by K. Mack. Rupert's drops show black on the screen in polarised light, but they can be made to show their colours by immersing them in a trough containing a liquid of the same refractive index, such as cedar oil or a mixture of carbon bisulphide and ethyl ether. The colours resemble those of peacock's feathers.—Magnetic deflection of Becquerel rays, by F. Giesel. The deflection may be demonstrated by means of a polonium preparation attached to a sensitive plate laid face downwards across the poles of an electro-magnet. The deflected rays on the negative show a curious hairy structure.—The photography of current curves, by J. Zenneck. Instead of using a sliding plate or a revolving mirror with the Braun kathode tube, the author produces the current curve direct upon the screen in the kathode tube.—He uses two deflecting magnets, one for producing the oscillation due to the current under investigation, and the other for imparting to the kathode beam a lateral movement proportional to the time.

Memoirs of the Novorossian (Odessa) Society of Naturalists, vol. xxii. Part 2.—The whole of this volume is given to the results of the exploration of the *liman* (salt lake) of Kuyalnik, situated near Odessa, which exploration was undertaken several years ago by the Odessa University. Most of the volume is occupied by a most exhaustive report, by A. Wassilieff, about the astronomical, topographical and bathymetric work made in connection with this liman. A large scale map (1 : 16, 800) of the lake and several vertical profiles accompany the report, which will be a precious document for all subsequent exploration.—The rest of the volume is taken up by a paper, by L. Silberberger and M. Weinberg, on the bacteria found in the mud of the liman. They originate partly from the surrounding air and partly from the waters entering the lake, their composition varying with the seasons. The mud is not favourable for the life of the bacteria, which add to the mud by their decay.

IN the *Journal of Botany* for December 1899, the most important article is by Dr. A. B. Rendle, Notes on *Xyris*, in which several new species are described.—Messrs. J. A. Wheldon and Albert Wilson conclude their paper on the mosses of West Lancashire. In the number for January 1900 we find papers on *Sphagnum medium* in Britain, by Mr. H. W. Monington (with a plate).—Some Welsh hawkweeds, by the Rev. Augustin Ley, in which one more is added to the long list of British "species" of *Hieracium*.—On some species of *Cracca*, by Messrs. Jas. Britten and E. G. Baker.

THE *Journal of the Royal Microscopical Society* for December 1899 contains a continuation of Mr. F. W. Millett's paper on recent Foraminifera of the Malay Archipelago, and the usual summary of current researches in zoology, botany and microscopy. In the latter section several valuable recent novelties in microscopic construction are described. This number also contains the list for 1899 of new terms introduced during the year in zoological and botanical literature.

SOCIETIES AND ACADEMIES.

LONDON.

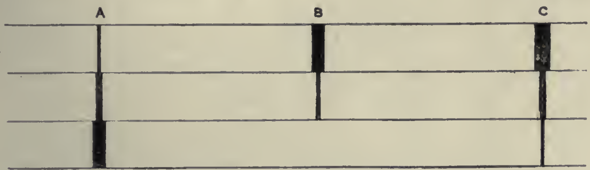
Royal Society, November 23, 1899.—"Note on the Spectrum of Silicium." By Sir Norman Lockyer, K.C.B., F.R.S.

The recent observations show that the lines of silicium may be divided into three sets, no two of which behave alike under varying electrical conditions. The wave-lengths of the lines composing the different sets are:—

$$\left.\begin{array}{l}3856\cdot1\\3862\cdot7\\4128\cdot1\\4131\cdot1\end{array}\right\}\text{A.}\qquad\left.\begin{array}{l}4089\cdot1\\4116\cdot4\end{array}\right\}\text{B.}\qquad\left.\begin{array}{l}4552\cdot8\\4568\cdot0\\4575\cdot3\end{array}\right\}\text{C.}$$

There is a line at λ 3905·8 which is associated in the spark spectrum of silicium with the lines in set A, but while these are entirely absent from the arc spectrum of silicium, 3905·8 is a strong line in the arc spectrum. This line differs from the others, therefore, in not being enhanced in intensity in passing from the conditions of the arc to those of the spark. So far as is known, the lines in sets B and C have not been recorded by any other observers of the silicium spectrum.

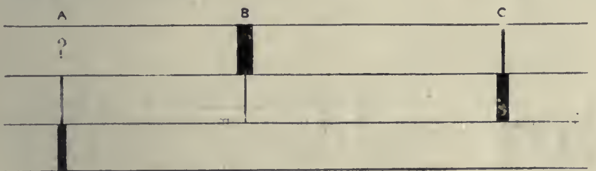
The behaviour of the three sets of lines in terrestrial spectra is shown in the following figure:—



1. SiF_4 vacuum tube (capillary). 2. SiO_2 spark with Spottiswoode coil. 3. Vacuum tube (bulb) SiO_2 spark with small coil.

It is found, on investigating the occurrence of these silicium lines in stellar spectra, that the three sets of lines respectively attain a maximum intensity at the three different levels of stellar temperature represented by β, γ, and ζ Orionis.

The accompanying figure shows the behaviour of the different sets A, B, and C in the spectra β, γ, ζ Orionis.



1. ζ Orionis. 2. γ Orionis. 3. β Orionis.

We find that set A is most prominent in the spectrum of β Orionis, that set C predominates in the spectrum of γ Orionis, and that set B is by far the strongest in that of ζ Orionis.

That the stars named represent three different grades of temperature, ζ Orionis being the hottest, and β Orionis the coolest, has been previously deduced by the discussion of other lines in their spectra. This result was embodied in a paper "On the Order of Appearance of Chemical Substances at different Stellar Temperatures," read to the Society in February, 1899. In that paper α Crucis was given as a typical star representing a stage of temperature between those of β Orionis and ζ Orionis. That star can be very well replaced for the purpose of the present discussion by γ Orionis, the two spectra being nearly identical.

It was recently shown that silicium made its appearance first at the temperature represented by α Ursæ Minoris, and strengthened at the higher temperature of α Cygni and β Orionis, afterwards weakening as we pass through the still higher temperatures of ζ Tauri and γ Orionis, until at the ζ Orionis stage it is bordering on extinction.

In the same paper the behaviour of a line at λ 4089·2 was plotted, and at the same time it was quoted as an "unknown" line.

It is interesting to note that this line is now traced to silicium, and is the strongest line in set B. It is apparently a short-lived line in stellar spectra, as it only occurs between the stages of temperature represented by γ Orionis and ζ Orionis, being one of the weakest lines in the spectrum of the former star, and one of the strongest in that of the latter.

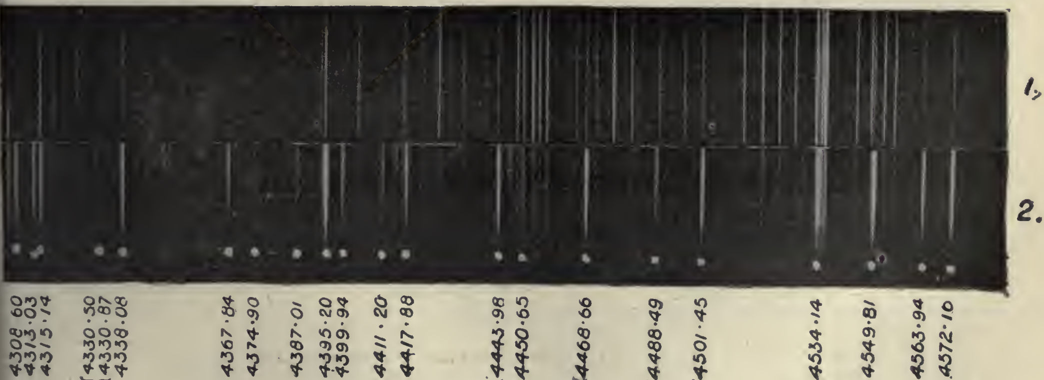
November 23, 1899.—"Preliminary Table of Wave-lengths of Enhanced Lines." By Sir Norman Lockyer, K.C.B., F.R.S.

The important part which the enhanced lines of the element play in the study of stellar spectra cannot be over-estimated, but a great advance can only be made in this direction by a systematic examination of the spectra of all the elements. Such an undertaking as this involves considerable time and labour. The author has been fortunate enough to have the use of the large 42-inch Spottiswoode coil, made by Apps, for a short space of time, and employed it in this work, for which it is specially adapted, as the brilliancy of its spark shortens the time of exposure.

The elements which have been dealt with in this investigation are the following:—"Aluminium, bismuth, chromium, copper, iron, magnesium, manganese, titanium, and vanadium."

For each of these elements the spark and arc spectra were photographed and compared, and the wave-lengths of the enhanced lines, that is, those lines which are intensified in passing from the temperature of the electric arc to that of the spark, were determined, and tables are given of their wave-lengths.

An illustration shows the enhanced and arc lines in the spectrum of titanium.



Titanium.—Enhanced Lines.
1. Arc. 2. Spark.

Chemical Society, December 21, 1899.—Prof. Thorpe, President, in the chair.—The following papers were read:—On the refractive and magnetic rotatory powers of some aromatic hydrocarbons, and on the refractive powers of mixtures, by W. H. Perkin, senr. The replacement of hydrogen in an aromatic nucleus by methyl is accompanied by a greater increase in molecular refraction, and a smaller increase in magnetic rotation, than is the replacement of hydrogen in a side chain by a methyl group.—Formation of α- and β- acrose from glycollic aldehyde, by H. Jackson. Tetrosazone and α- and β- acrosazone are obtained from the condensation product formed by the action of soda on a dilute glycollic aldehyde solution at 0°; on prolonged condensation at 0°, the quantity of tetrosazone obtainable decreases.—The interaction of mercurous nitrite and ethyl iodide, by P. C. Rây. Mercurous nitrite and ethylic iodide react to form nitroethane and ethylic nitrite.—On mercurous nitrite, by P. C. Rây.—The action of alkyl iodides on the mercuric iodide sulphides of the fatty series, by S. Smiles. The alkylic sulphides combine with mercuric iodide to form compounds of the type R_2SHgI_2 containing tetrad sulphur; these substances when treated with methylic iodide yield compounds of the type R_3SIHgI_2 which possibly contain hexad sulphur.—On brasilin and hæmatoxylin, Part III., by A. W. Gilbody and W. H. Perkin, junr. The acid $C_{15}H_{16}O_6$ previously obtained from brasalin yields metahemipinic acid on oxidation; the latter acid is also formed during the oxidation of tetramethylhæmatoxylin. It is shown that brasilin is a derivative of resorcinol and catechol, whilst hæmatoxylin is a derivative of pyrogallol and catechol.—The action of alcoholic potash on monobromoglutaric ester, by N. E. Bowtell and W. H. Perkin, junr. Monobromoglutaric ester is converted by alcoholic potash into transtrimethylenedicarboxylic acid.—Luteolin, III., by A. G. Perkin.—The action of chloroform and potassium hydroxide on orthoamidobenzoic acid, by W. J. Elliott. Orthoamidobenzoic acid yields an aldehydoorthoamidobenzoic acid on treatment with chloroform and potash.—Azo- and hydrazone compounds differentiated by bromine, by H. E. Armstrong.

Linnean Society, Dec. 21, 1899.—Dr. A. Günther, F.R.S., President, in the chair.—Mr. W. G. Freeman exhibited a tree of *Hevea brasiliensis* (Parà Rubber), showing the method of tapping adopted in Ceylon.—Dr. R. Braithwaite exhibited specimens of *Hypnum Hochstetteri*, Schimp., collected by him on the Isle of Barra, Outer Hebrides, the only known locality for it in Europe, though found in the Azores and Canary Islands.—The Zoological Secretary communicated a paper, by Prof. T. W. Bridge, on the air-bladder and its connections with the auditory organs in the *Notopteridae*. The anatomy of the air-bladder, auditory organ, and associated parts was described in detail in *Notopterus borneensis*, it being shown that their condition was essentially the same for that species and *N. Pallasii*, and that Cuvier and Valenciennes had erred in regard to the latter by confusing the auditory cæca-containing and cranial cavities. Comparison was instituted with other Teleosteans in which the air-bladder enters into relationship with the occipital region of the skull, and the physiological significance of the facts was discussed.—Mr. F. Chapman read a paper on some new and interesting Foraminifera from the Funafuti Atoll, Ellice Islands. The specimens described, and illustrated by means of lantern-slides, comprised the larger forms found at Funafuti and on coral-reefs generally, together with a new genus (*Haplocatenia*) and eight new species.

THE PRINCIPLES OF MECHANICS.

Newton's Laws of Motion. By Prof. P. G. Tait. Pp. viii+52. (London: A. and C. Black, 1899.)

HOW is the science of mechanics to be taught to medical students who have to "get up" natural philosophy in three months? If a teacher, confronted with such a problem, took refuge in sheer "cram," his action could cause no astonishment; an attempt, such as Prof. Tait has made, to provide a solution in which cram has no place commands admiration, even if it cannot be pronounced successful. The author's method is to furnish the student with a set of perfectly recorded lecture notes, and thus leave him free to follow the lectures instead of taking notes of them. Perhaps no better method can be devised, if the substance of the lectures is as good as the record in the notes is perfect, and if the student is made to apply the ideas explained in the lectures to simple examples. The latter of these conditions is doubtless fulfilled in Prof. Tait's classes; we are concerned here with what can be made out in regard to the former. After all the books that have been written on the subject, there was still room for a pointed statement of the principles of mechanics, with sufficient detail and sufficient illustration, but short; and such a summary, if only it were precise and lucid, could not fail to be useful to a class much wider than that immediately in view; but its value would be diminished in proportion as it was marked by vague statement, inexact definition and loose argument.

The work before us begins with three pages of introductory remarks, and these are followed by a chapter on kinematics and a chapter on dynamics. In the introductory pages we find a statement of the laws of the conservation of matter and of energy, and a reference to the laws of the inertia of matter and of the transformation of energy. As a specimen of the dogmatic tone adopted we may quote the following:—

"The objective realities of the physical world are of two kinds only—matter and energy. Our conviction of their objectivity is based on the experimental fact that we cannot alter the quantity of either."

No exception could be taken to this statement if the evidence for it were going to be adduced; and indeed the kind of summary that is likely to be most useful is just one that would trace the operation of the laws of conservation and transformation of energy, and of the law of the inertia of matter, in the processes of every-day experience and in easily observed phenomena. In picking out *mass* and *energy* as the two fundamental conceptions the author is certainly right, but much depends on the way in which they are discussed.

The same wisdom in the selection of the topics to be treated is apparent in the chapter on kinematics, and the arrangement also of these topics is excellent; it is to some of the details that exception must be taken. There is a general discussion of *vectors*, but the definition which is given of a vector is incomplete, and the necessary distinction between a vector associated with a particular line and one for which all parallel lines are equivalent is not explained. In the definition which is given of the *moment of a vector*, the fact that the rule of signs is a part of the definition is lost sight of, and the reason why the moment itself should be regarded as a vector is obscure. The proof, on p. 20, that angular velocity is a vector involves a *petitio principii*. In this, as in the proof of the parallelogram of velocities, what is most required is an explanation of the sense in which a point can be said to have two simultaneous velocities, or a body two simultaneous angular velocities. The definition of *velocity* is always one of the stumbling-blocks in the way of students; the author avoids giving a definition; he says, "Speed need scarcely be defined, as every one knows what it means." It may be that the writers of current text-books know what it means; they seem quite unable to explain it; nearly all of them proceed in a vicious circle, saying that the velocity of a point when variable is measured at any instant by the space that would be passed over in a unit of time if the velocity continued the same as it is at the instant—as well might one define the curvature of a curve at a point as the angle that would be contained between the tangents at the ends of an arc of unit length if the curvature continued the same all along the arc as it is at the point. If the student is not meek he will ask, "But what is it at the point?" It is only because he thinks he "knows what it means" that he does not ask the like question about speed. Prof. Tait gives countenance to the widely-spread vicious definition without reproducing it. Surely he might have spared some space to explain the mathematical notion of a limit, and to define velocity as a limit. Why do writers of elementary books treat the student as a baby when any limit is in view, and talk to him, for example, about "the next point" to a point on a curve? (p. 9). He knows as well as his teacher that there is no next point. The commonly received absurdities about what are really limiting processes secure acquiescence by frequent repetition, but they foster in the mind of the student a belief in the unreality of the whole business.

The chapter on dynamics suffers from defects which are not merely faults of detail, but arise from the position taken up, viz., that Newton's laws of motion still form the simplest foundation of the subject. Some remarks in Prof. Tait's address to Section A of the British Association in 1871, dealing with the use of Euclid's "Elements" by British mathematicians in the teaching of elementary geometry, apply, with at least equal force, to the use of Newton's laws of motion in the teaching of elementary dynamics. He said of the teachers:

"They seem voluntarily to weight alike themselves and their pupils for the race; and a cynic might, perhaps without much injustice, say they do so that they may have mere self-imposed and avoidable difficulties to face instead of the new, real, and dreaded ones."

The defect of the laws of motion as a statement of the principles of dynamics is not that the principles are not implicitly contained in the laws, but that the principles have to be extracted from the laws, and that the laws themselves are stated in terms of insufficiently defined abstractions. How much of the contents of the laws of motion is of the nature of definition, and how much is a statement of facts ascertained experimentally, is not disclosed. To assert that these laws still form the simplest foundation for the subject is to ignore the progress that has been made since the publication of Thomson and Tait's "Natural Philosophy." The difficulties into which writers who follow Newton uncritically must needs fall can be illustrated by sentences on pp. 27 and 28. On p. 27 we read, "Force is defined as any cause which alters the momentum of a body"; and on p. 28 we are told that force is "merely another name" for "the vector-acceleration of momentum." This makes the same word do duty for the cause of the change and the rate of the change. Others of the definitions given are wanting in precision. The definition of the *mass* of a body as the quantity of matter in it is a definition of one previously undefined thing in terms of another. The description of the first law of motion as a "statement of the inertia of matter" is not helpful; inertia is a property of matter under ordinary conditions, and the first law is a statement about matter under conditions in which it has never been observed. It ought to be realised that the three laws form a connected system, and that all of them are as much needed as any one of them for the precise definition of *force*, or the exact statement of the inertia of matter. The definition given of *work done* is obscure; the work of a force is defined as a product, and no indication is given of the sense in which this product can be said to be "done." What is wanted here is much the same as in the case of force: we all have an anthropomorphic idea that some cause must operate to start or stop the motion of a body; we have a similar idea that a man has done something when he has lifted a weight or thrown a cricket ball, and these ideas should be taken hold of and made precise by the introduction of measurable quantities which are adequate to represent them.

The difficult ground of definition and statement of principles once covered, the rest of the book is for the most part excellent, the geometrical methods employed being especially elegant. Room is found for an elementary discussion of strain, of compounded simple harmonic motions, of attractions, including the distribution of electricity on a sphere under influence, and of the velocity of waves along a stretched cord, in addition to interesting and unhackneyed accounts of the matters which are the stock-in-trade of books on the elements of mechanics. The book on the whole is thoughtful, in many parts it is much better than the current text-books, and the parts that call for criticism are no worse than the corresponding parts of most other books on the subject; but they are the most important parts, and they might have been so much better. There was a great opportunity, and it has been missed. A. E. H. L.

THE SCIENCE OF LAND FORM.

Physical Geography. By Prof. W. M. Davis, assisted by W. H. Snyder. Pp. xvii + 428 + 9 plates. (Boston and London: Ginn and Co., 1899.)

AN examination of this volume gives rise to feelings of both congratulation and regret—congratulation that so admirable a manual for the elementary student of physical geography has been produced, and regret that so little attention is given to the subject in our schools and colleges. Rational methods of instruction are now advocated for all the concrete sciences, and are being extensively applied to physics and chemistry; but geography has only been very slightly benefited by the pedagogic reforms of the last decade, and in the majority of our secondary schools it is still represented by definitions, outline maps, uninteresting statistics, and lists of names which make no real impression upon the minds of the pupils. Physical geography, the elements of which should be presented at the very beginning of the study of the earth, is usually neglected altogether, or taught in a fashion that fails entirely to place pupils in the receptive intellectual attitude reached after sound instruction in any science.

The present position results chiefly from the want of teachers with a broad conception of the field of geographical science. Every teacher is supposed to be qualified to give instruction in geography; and if the word merely signified the description of the political divisions of the earth, any one could put pupils in the way of acquiring that information. But, rightly defined, geography should be the consideration of the earth as the abode of man, and it should comprise the elements of astronomy, physics, meteorology, botany, zoology, and ethnology, as well as knowledge of commerce and government. To present the subject in these broad aspects, the teacher must be inspired by the scientific spirit and have given personal attention to the facts and phenomena of nature; and where such teachers are not available instruction in geography cannot proceed on scientific lines.

The volume under notice provides an admirable means of improving geographical teaching. Prof. Davis is not only an expert in most of the branches of physical geography; he is also a practical teacher who has devoted much attention to the educational side of the subject. The result is that, with the assistance of Mr. Snyder, he has produced what is certainly one of the best manuals of physical geography ever published. The book is well planned, trustworthy, clearly written, and liberally illustrated; it presents the facts of physical geography in such a way that the reader sees them as part of an organic whole—as organised knowledge which constitutes science. The facts are traced backward to their causes and forward to their consequences; indeed the phrase "causes and consequences" has served as a touchstone by which the treatment of each subject has been tested.

The order of treatment is the earth as a globe, the atmosphere, the oceans, and the lands. These facts are not, however, treated in equal detail; indeed, the last part occupies more than four times the number of pages devoted to the three preceding parts taken together. From this it will be seen that the book is not concerned with physiography as it is usually understood in this country, but with the science of land form In physiography the student receives practical instruction in physics, chemistry, astronomy and cognate sciences before he considers atmospheric phenomena the circulation of water on the land, the earth's solid crust, and the changes which take place in it: in physical geography, however, the facts of physical science are made subservient to the descriptions of land forms and other matters directly connected with the study of the earth. In the present volume, for instance, "the non-geographical elements of astronomy, the principles of physics, and the divisions of geological time, are carefully excluded." The authors are, of course, entirely justified in limiting the sections dealing with these subjects to any dimensions they please; and many teachers of physical geography will agree that the method of treatment adopted distinctly defines the scope of physical geography. At the same time, the opinion of the writer is that it is impossible for a student to clearly perceive many of the facts of physical geography unless he has a practical acquaintance with physical science. A student with a knowledge of Boyle's law can fully understand why half the earth's atmosphere is left behind in ascending to a height of three and a half miles above sea-level; but a student of physical geography may be told that this is the case, and have no real conception of the cause. Almost every fact concerning the constitution and movements of the atmosphere can be far more easily comprehended by students who have received experimental instruction in the principles of physics than by those who read them for the first time in connection with natural phenomena. Similar introductory knowledge is also required to intelligently follow the action of internal forces such as give rise to volcanic eruptions, the system of oceanic movements, the solvent and disintegrating actions of water, causes which affect climate, and many other natural operations and conditions. A practical knowledge of the principles of the science of matter and energy is indeed essential to the scientific study of the earth; and without such knowledge students of physical geography can have only a limited comprehension of the causes of natural processes.

As bearing upon this point, mention may appropriately be made of a new syllabus of physical geography which has just been prepared for the Cambridge Local Examinations. The syllabus includes a course of practical instruction drawn up with the distinct object of cultivating the pupils' faculties of observation and reasoning; it therefore represents a praiseworthy attempt to make lessons in physical geography of real educational value. So far as the descriptive part is concerned, the volume under notice is exactly the kind of book to use in classes which follow the Cambridge course, and the appendices will be found of service in showing the observations which may be usefully made out of doors. But the sections on the atmosphere and on astronomical geography are too brief to be clearly comprehended by students unfamiliar with the rudiments of physics and astronomy. In the Cambridge syllabus experimental work in each of these divisions of physical geography is rightly given prominence; and we consider that a larger amount of space might have been devoted to them with advantage in the present volume. As these sections now stand they will convey information, but will not do much to encourage individual observation. Moreover, most teachers will find it necessary to postpone the descriptions of atmospheric circulation to a later stage than is suggested by the place in which it is here dealt with; for though the volume contains a most admirable account of wind systems, every teacher knows that charts of winds and isotherms are not easily visualised by the student who has not learned to read such diagrams.

Apart from the question of the relative importance which should be attached to the different divisions of physical geography, it would be difficult to suggest how the volume could be improved. No better description of the lithosphere, and the changes which take place in it, could be desired by the student of physical geography than is given by the authors. The examples of characteristic land forms are naturally more often American than European or British; but as emphasis is always laid upon the association of land forms with settlements and industries, a useful lesson is conveyed even if the selected district is strange to the reader. Several words, such as *monadnock*, *cuesta*, *drumlin*, *peneplain*, *esker*, and *mesa*, not usually found in books of physical geography used in this country, are employed to describe particular formations, though no explanation appears to be given of more common terms in physical geography, such as *hydrosphere*, *lithosphere*, *erratic*, *volcanic dyke*, *geoid*, *Roches moutonnées*, *scoriae*, *tundra*, *selvas*, *pampas*, and *regelation*—or if they are mentioned they are not indexed. Little importance need be attached to this, for physical geography should be more than a collection of definitions; but as the student will in all probability meet with the words later, he should know their significance. This is, however, but a minor point, for a good dictionary will furnish the meanings of these words, but it is only occasionally that a volume of such an inspiring character as the one here noticed is produced, and where so many good qualities are exhibited, a judicious critic hesitates to suggest any alterations. R. A. G.

THE REMINISCENCES OF A. D. BARTLETT.

Bartlett's Life among Wild Beasts in the "Zoo." By the late A. D. Bartlett. Edited by E. Bartlett. Pp. xviii + 375. (London: Chapman and Hall, Ltd., 1900.)

THE issue of the present volume may be taken as an indication that its predecessor, "Wild Animals in Captivity," was a success and has met with the appreciation of the public. Obviously, therefore, it is not the part of a critic to decry what has practically been already approved, the work before us being a continuation of the first series of Reminiscences. Undoubtedly there is a very large amount of extremely entertaining matter in this second venture. Especially is this the case with regard to the author's experiences of Gorillas and Chimpanzees, his important practical experiments and observations with regard to hybrids, his account of the verification of the hunters' stories as to the annual shedding of its horns by the American Prongbuck, and his description of the habits of the Indian Panda, or Cat-bear. The latter observations afford, indeed, an excellent example of the acuteness of Bartlett's judgment as to the affinity of an animal by the study of its habits alone. The systematic position of the Panda was at the time in question much disputed. Mr. Bartlett insisted on its near relationship to the Racoons, especially the Kinkajou: and his opinions were more than borne out by the contemporary investigations of Sir W. H. Flower into its internal anatomy. The public, too, will be much interested to learn that Bartlett was a firm believer in the existence of a "sea-serpent," although whether they will be inclined to share his opinion that there are reptiles that can live for months at a time at the bottom of the ocean without coming up to breathe may be questioned.

But much as these and many other portions of the book may interest and attract the general reader (not to mention the scientific naturalist), there are other parts for which such commendation can scarcely be claimed. We have, for instance, several descriptions of species, such as that of the white-whiskered Lemur (*L. leucomystax*) on p. 22, and Monteiro's Galago (*G. monteiri*) on p. 24, which can be of no possible interest to any one but a specialist, especially in the absence of figures. But this is not all, as the aforesaid Lemur is now regarded by qualified naturalists merely as the female of (*L. macaco*), and its retention as a species is consequently a mere misleading of the public.

If this were the sole instance of a want of efficient editorship it might, indeed, well have been passed over in silence, but unfortunately it is only one among many. For instance, on the very first page of the volume we have a repetition of the old story that the Apes seen by Hanno, the Carthaginian, were Gorillas (in the modern sense of that term), whereas it has been shown over and over again that such could not have been the case; Mr. Winwood Reade believing the creatures to have been Baboons, while Sir Harry Johnstone thinks they were more probably Chimpanzees. Neither is it a true statement that the skull of the Gorilla obtained by Dr. Savage at the Gaboon was ever sent to Owen, who only received sketches of the same; the specimen itself having apparently gone to America. It is quite true that these statements were made by the author of the papers which constitute this volume, but it was for the editor to have made the necessary amendments.

Then, again, we have to deplore a lack of efficient editorship in the manner in which the different sections of the book are introduced, or rather not introduced. For example, who would guess that the dissertation on hybrid bovine animals, commencing on p. 71, is reproduced, with the exception of the opening sentence, word for word from the *Proceedings* of the Zoological Society for 1884? And if the quotation is not acknowledged as such by the usual marks in this place, why are such marks introduced in another equally long quotation from the same serial on p. 6? Neither is there any indication to show that the portrait of the Chimpanzee "Sally" on p. 7, as well as the picture of hybrid Cattle on p. 70, are copied from plates in the Zoological Society's *Proceedings*. And very indifferent copies at that, the reader will probably add! Indeed, the illustrations generally are far from being a strong point of the book, while, like the regiments in the British army, there are too few of them.

Neither can we avoid saying that the nomenclature is hopelessly out of date; this being sufficiently apparent when we mention that *Troglodytes* is given as the generic name of the Chimpanzee and Gorilla, *Ceriornis* for the Tragopan, and *Felis* for the Hunting Leopard or Chita! If popular writers will not keep somewhat in touch with the systematic work of the day, it is their fault if they are treated with contempt by professional naturalists.

In spite of the errors and imperfections to which we have called attention, we, as already said, fully recognise the large amount of interesting matter in the volume before us; and if our readers desire a really amusing story, we may refer them to the adventure of Mr. and Mrs. Jamrach with the Lions. At the same time, we think that the editor would have been much better advised had he reduced the present volume and its companion to the limits now occupied by one of them.

ELECTRICAL OSCILLATIONS.

Recherches Expérimentales sur les Oscillations Électriques. Par A. Turpain. Pp. 154. (Paris: Librairie Scientifique, A. Hermann, 1899.)

THE classical researches of Hertz on electromagnetic waves have opened up a new field of experimental research, which has already yielded a rich harvest of results. As regards the literature of the subject, we have, besides Hertz's original papers, two or three other works dealing with the theory and phenomena of electromagnetic waves. Dr. Lodge's little book contains a general and easily intelligible sketch of the whole subject. In Prof. J. J. Thomson's "Recent Researches" we have an elaborate exposition of theory, along with an account of the experimental development of the subject down to the date of publication. Poincaré's "Oscillations Électriques" is probably the best-known Continental work on electromagnetic waves.

The work before us is one which does not trench on the ground already covered by the above-named treatises. It is a record of original researches, some of which have already appeared in various scientific periodicals. The scope of these researches is limited to the propagation of waves along conductors.

After a brief introduction, the author gives us in Chapter i. a full and clearly illustrated description of the experimental arrangements used by him, including the various forms of oscillators, resonators and their micrometers, and methods of concentrating the electromagnetic field between wires or plates.

Chapter ii. deals with the methods of measurement. Besides the classical method of determining the sparking distance by means of a micrometer observed either with the naked eye or by the aid of a lens, the author used a resonator with an additional air-gap which was bridged by a battery and telephone receiver. Every time sparks passed across the micrometer-gap, the circuit of the battery and telephone was completed. This method of investigation—which, however, requires very careful adjustment—the author found less fatiguing than that in which the eye is unduly strained in trying to detect the presence of minute sparks.

Chapter iii. describes the methods adopted for adjusting the length of the wires so as to get a sharp division into nodal and ventral segments. This is followed by an account of the various positions in which the resonator was placed; of the results obtained with an ordinary Hertzian field between two wires, and round a single wire. The author next considers the *interference* field, which is obtained between two wires whose ends are connected to plates placed on opposite sides of the *same* plate of an oscillator. The effects on an ordinary 2-wire field of bending one of the wires so as to lengthen it by $\frac{1}{4}$, $\frac{1}{2}$ and a whole wave-length are next investigated. The author shows that all the effects obtained may be deduced from the results obtained with a single-wire field. An account of some experiments with 3, 4 and 6 wires concludes this chapter.

Chapter iv. deals with the action of the resonator. The effects of varying the position and direction of the micrometer-gap, the disturbance due to the presence of the resonator in the field, and the effect of varying the length of the resonator are studied in detail. The form of resonator with a gap bridged over by a cell and telephone receives careful attention, the effect of altering the position of the gap relatively to the micrometer spark-gap being fully investigated.

Chapter v. is concerned with the important problem of the propagation of waves in dielectrics other than air. Oil and water were the two dielectrics studied by the author, and the effects obtained clear up some rather obscure and apparently contradictory results obtained by other experimenters in this field.

Chapter vi. contains a useful *résumé* of the more important results obtained by the author.

In Chapter vii. the author describes a system of multiplex Hertzian wave telegraphy (*not* wireless), regarding whose practical value we may well be pardoned for feeling somewhat sceptical.

The book forms a valuable storehouse of facts, and the author is to be congratulated on the extremely lucid and well-arranged account of his important researches. They were all carried out on a large scale (in the experiments on oil and water, 230 to 260 litres of the liquid were used), and must have required an unusual amount of skill, care and patience.

A striking feature of the work is the entire absence of mathematical reasoning, not a single symbol of differentiation or integration occurring throughout the whole of the book. The author has carefully avoided all theoretical discussions, and confined himself to an accurate description of experimental facts. The clearness and elegance of the language in which this description is given render it a pleasure to read the book, which will prove a source of delight to every true experimentalist.

OUR BOOK SHELF.

Indicators and Test Papers. By Alfred I. Cohn, Ph.G. Pp. ix + 249. (New York: John Wiley and Sons. London: Chapman and Hall, Ltd., 1899.)

THIS book contains an account of the source, preparation, application and tests for some scores of indicators and test papers which have been proposed for use chiefly in determining the end-point in volumetric chemical analyses. The book opens with a general discussion of the action, use, and theory of indicators, and ends with four useful tables and a good index. The first table is Trommsdorff's showing the sensitiveness of indicators to acids and alkalis, the second is R. T. Thomson's (hitherto the chief English guide), the third is Dieterich's table showing the sensitiveness of various test-papers, and the fourth is a tabular summary of the principal indicators by the author.

The compilation of this book must have demanded much patient labour, and acknowledgments are due to the author for the care and pains he has bestowed upon the work. It will prove a useful addition to analytical literature. Whilst saying this, some points of criticism cannot be withheld. In the first place it must be said that the author has not dealt in a very clear way with the theory of indicators. The subject is not an easy one, and the average operator has not hitherto troubled himself much about it. Litmus has been to him a substance provided by Nature for the discrimination between acids and alkalis rather than the means of furnishing blue alkaline salts from which a weakly acidic substance of red tint is "displaced" by the action of nearly all other acids. Again, the reasons why methyl orange is good for the titration of bases and not of acids is not usually inquired into. Such considerations make it the more desirable that the principles underlying the use of indicators should be stated very clearly. Mr. Cohn has given explanations, including the application of the ionic theory, and of the speculative mechanical theory (somewhat antiquated and unfruitful) of F. Mohr, but he has not set forth the matter with the desirable clearness and coherence.

Next with regard to the substance of the book, it is worth considering whether, in any future edition, type of two sizes might not be employed. Many of the indicators described are of extremely doubtful value, and the worker really wants to know definitely which indicators have been found meritorious by other people than those who have suggested their use. In this connection also a protest must be raised against naming indicators after their inventors. It is useful to know the composition and nine synonyms of Tropæolin OO, but there is surely no call to add to these the term "Von Müller's Indicator."

The book would have been improved by references to original papers. For example, the reflecting galvanometer is scheduled as an indicator, but there is neither a full description of its use nor a reference to Küster's paper on the subject. References would have been valuable throughout the book. A. S.

Optical Activity and Chemical Composition. By Dr. H. Landolt; translated by Dr. J. McCrae. Pp. xi + 158. (London: Whittaker and Co., 1899.)

THIS small book is a remarkably clear exposition of what is a somewhat recondite and difficult branch of chemical physics. It is well known to students of optical science that there are liquids and solid substances in solution which have the strange power of rotating the plane of vibration of a polarised ray of light that is passing through them. Familiar examples are turpentine and other essential oils, sugars, tartaric acid, quinine and albumen. But Dr. Landolt says that more than seven hundred substances, all carbon compounds, are known to exhibit this molecular rotation.

Of course the fruitful discoveries of Pasteur—the right and left-handed tartaric acids, racemic acid, molecular asymmetry, &c., are briefly described; and the more recent simultaneous discoveries of van 't Hoff and Le Bel receive fuller attention. It is shown how this property is met with only where one at least of the carbon atoms of an organic compound is united with four different atoms or radicles; and the results flowing from this kind of structure are explained and illustrated—results which form what is now called stereochemistry.

But the principal object of Prof. Landolt's book, as expressed in its title, is the connection that may be found o exist between the chemical constitution of a substance and the degree of its rotation. The fact that such relations do exist in the case of other optical properties, such as molecular refraction, dispersion, and magnetic rotation, no doubt gave rise to the expectation that some similar connection would be found in regard to this rotatory power. In the above cases the optical differences depend mainly on the nature and number of the elements composing the substance, though modified to a certain extent by the manner of combination. But here it seems to depend almost entirely on the mode of grouping. Such able experimenters as Guye, Chavanne, Walden, Tchúgaeff, Nasini, van 't Hoff, and in our own country Frankland and Crum Brown, have investigated the question. The problem has not yet been solved; but a number of suggestive results have been obtained which will no doubt lead to further research, and the clearing up of the relationships between composition and amount of rotation which unquestionably do exist.
