American notes, 27, 103, 111, 163, 172, 270, 317, 396, 412
Anglo-American Exposition, 1914, 91, 380, 418, 443
Animals and plants under domestication, lectures on, 74, 92, 112, 131, 171, 149
Annuals, 26, 84, 172, 232, 312; cultivation of, 5; dwarf, 84
Anoplantus coccineus, 401, 422
Antirrhinum for culture under glass, 396
Ants and seeds, 75, 95
Ants and woodlice, 195
Aphides, 389
Apiary, the, 71, 129, 185, 202, 315, 331, 351, 377
Apple scab, 418
Apple-sucker, spraying for, 349
Apple trees, canker in, 196
Apples: Cox's Orange Pippin, 175; Norfolk Beauty, 106; W. Crump, 206; Wolf River, 27
Aquilegia canadensis, 417
Aquilegia Sturtii, the history of, 223, 240; Aquilegias and their hybrids, 207
Arabis, hybrid, 346
Arboriculture at the Shrewsbury Show, 317; at Bayfordbury, 182
Arbutus Menziesii, 207, 241
Argentina, Grapes from, 380
Aristolochia heterophylla, 373
Arnold Arboretum in May, 413
Ashridge Park, Berkhamsted, 127
Asparagus, 216; rust-proof, 253
Asters, 432; perennial, 248
Aubergine (Egg plant), 255
Australia, a census of the genus Acacia in, 205
Avocado pears, experimental shipment of, 205

B

BAGATELLE, new Roses at, 248
Baker, Mr. John Gilbert, 40
Balls, Mr. W. Lawrence, honour for, 454
Balls Park, Hertfordshire, 205
Balmoral Gardeners' social evening, 94
Banana, the, 360; fruiting in a conservatory, 308
Banana industry, the, 238
Barnett, Mr. T. A., appointment of, 211
Basic slag, 172
Bateson, Prof. Wm. (Problems of Genetics), 90; on double flowers, 332
Bees, 71, 129, 185, 205, 235, 315, 331, 351, 377, 437; disease of, 287
Beetroots in Russia, 57
Begonia, a new winter-flowering, 319
Begonias at Cherry Hinton Hall, 73
Begonias for hanging baskets, 310
Belgian horticulturists and the St. Petersburg exhibition, 73
Belgium, fruit and Potato crops in, 399
Belvoir Castle, Grantham, spring flowers at, 286, 296
Benevolent Institution, Gardeners' Royal, 41, 63, 79, 187
Berberis aggregata, 345; B. Gagnepainii, 345; B. Sargentiana, 345; B. subcaulalata, 345; B. Wilsonae, 345
Betula, a new, 345
Biarritz, Rose congress at, 220
Biennials, hardy, 432
Bignonia Tweediana, 400
Billiard, Raymond (La Vigne dans l'Antiquité), 126
Birds, fruit-eating, 223, 241
Birmingham, new open space for, 26; public parks and other spaces at, 452

Buddleia Colvillei, 13
Bulb competition, a, 95
Bulb garden, the, 199, 239, 374
Bulb industry, the Dutch, 399
Bulbs, failure with forced, 175, 207
Bunyard and Co., Royal Warrant for George, 40
Bunyard, golden wedding of Mr. and Mrs. Thomas, 440
Burning, prevention of accidents due to, 75
Butcher's Broom (Ruscus aculeatus), 189

C

CABBAGE caterpillar, the, 82, 100, 150
Calanthe, hybrid, 28
Calceolaria John Innes, 433
Californian plants, 300
Cambridge School of Genetics, the, 57, 93
Cambridgeshire, fruit prospects in, 429
Campanula pyramidalis, 264
Canada, a garden in, 394; horticultural opportunities in, 160; importation of plants by mail in, 21; notes from, 21, 160; Plum cultivation in, 254
Candytuft, the, 312
Cannas, 276
Carduus, garden species of, 432
Carnation Robert Bruce, 402
Carnations, new, 163; perpetual-flowering, 127; soil for, 188
Cardoons, 243
Carrots in Russia, 57
Carter and Co.'s nursery, royal visitors at, 131
Carter, H. G., Genera of British Plants, 415
Casein as an adhesive, 149
Caterpillar, the Cabbage, 150
Catalpa Fargesii, 345
Cattleya Trianae, 344
Cedrela, new species of, 345
Celery disease, 95, 150, 175, 189
Celmisia, 456; C. Munroi, 440
Census of production, 111
Cercis racemosa, 345; C. chinensis, 345
CERTIFICATED FRUITS AND VEGETABLES: Apple Sandlin Duchess, 322; Citrus japonica, 46

- CERTIFICATED PLANTS:** *Adiantum gloriosum* Lemkesii, 364; *A. grossum*, 363; *Amygdalis persica rosea* fl. pl. pendula, 273; *Anthurium conchiflorum*, 257; *Anthrimum* (Dobbie's strain), 402; *Anthrimum Nelrose*, 288; *Aquilegia* (Mrs. Scott-Elliott's strain), 402; *Arabis anabrietioides* Trevor Seedling, 287; *Auricula* Gordon Douglas, 257; *A. Majestic*, 319; *Begonia* Lady Carew, 364; *Brasso-Cattleya beardwoodense*, 275; *B.-C. Menda*, 98; *B.-C. Pocahontas Undine*, 275; *B.-C. Shilliana*, 354; *B.-C. Veitchii* Leeman's variety, 275; *B.-C. Vilmoriniana* var. Centaur, 275; *Calanthe Veitchii* St. Nicholas var., 31; *Campanula cenisia* alba, 287; *C. Hohenackeri*, 425; *C. tomentosa* Maud Landale, 364; **Carnations:** *Bedford Belle*, 442; *Mr. Brotherston*, 402; *Mrs. Griffith Jones*, 402; *Scarlet Carola*, 364; *Scarlet Glow*, 442; *Cattleya Enid excelsa*, 275; *C. Magali Sander*, 355; *C. Suzanne Hye de Crom* var. *magnifica*, 242; *C. Susanae Hye grandiflora*, 176; *C. Tityus*, 258; *C. Tityus* var. *A. McBean*, 78; *C. Trianae* F. McBean, 242; *C. T. Mirabile*, 242; *C. T. Mrs. De B. Crawshaw*, 115; *C. T. Mrs. Phillips*, 115; *C. T. Walton Monarch*, 242; *C. Warneri Ardenholme*, 275; *Clematis Armandii*, 257; *C. montana superba*, 287; *C. Queen Mary*, 364; *C. Sieboldii*, 402; *Columnnea major glabra*, 257; *Cyclamen* Mrs. L. M. Graves, 45; *Cymbidium Andreana*, 275; *C. Coningsbyanum*, 46; *C. delicata*, 275; *C. Gottianum* Westonbirt variety, 115; *C. Mogul*, 154; *C. Pauwelsii*, 275; *C. P. giganteum*, 242; *C. P. maxima*, 275; *C. Schlegelii punctatum*, 46; *C. S. Southfield* variety, 115; *C. Venus*, 355; *Cypripedium Actaeus* var. *Ethel*, 31; *C. Alice Mary*, 31; *C. Carlew*, 31; *C. Desdemona*, 78; *C. Draco* "Walton Grange," 31; *C. Estella*, 31; *C. Griffin* No. 2, 242; *C. Hecla*, 31; *C. Hera Mostyn*, 31; *C. insigne* Snow Queen, 31; *C. Iona*, 98; *C. Julian*, 46; *C. Lady Evelyn James*, 31; *C. leyburnense* Fern Bark var., 98; *C. Lord Trevor* var. *Pyramus*, 193; *C. maeranthum* album, 321; *C. Nirvina*, 31; *C. Palladium*, 31; *C. Pyramus*, 115; *C. Thisbe*, 193; *C. waltonense magnifimum*, 98; *C. Zealandia*, 98; *Bulbophyllum Fletcherianum*, 320; *Calceolaria Stewartii*, 363; *Delphinium* "Henri Moissan," 442; *Dendrobium Bassattii*, 192; *D. Cybele* album, 193; *D. Lady Colman*, 115; *D. nobile* Goliath, 275; *D. superbum* Huttonii Southfield variety, 225; *D. s. Roebelenii* giganteum, 275; *Dentzia discolor* elegantissima, 402; *Erigeron* hybridus *Asa Gray*, 424; *E. hybridus* B. Ladhams, 402; *Erysimum linifolium*, 425; *Freesia Excelsior*, 153; *Hydrangea* *Lillie Mouillière*, 288; *Iris* *Cantab.*, 114; *I. chrysographes*, 402; *I. Goldcrest*, 363; *I. Iota*, 402; *I. Isolda*, 319; *I. Kashmir White*, 402; *I. laevigata* alba, 402; *I. Leucothaea*, 319; *I. sibirica* Emperor, 402; *Laelia-Cattleya*, 98; *L.-C. amabilis Fascinator*, 258; *L.-C. Ariel*, 154; *L.-C. Fascinator-Mossiae* var. *Purity*, 354; *L.-C. Dulce*, 192, 242; *L.-C. Lucasiana*, 193; *L.-C. Medina Excelsior*, 354; *L.-C. Haroldiana* Bronze King, 354; *L.-C. Sun-*
star, 354; *Lilium regale*, 364; *Lupinus polyphyllus* (Barr's strain), 402; *Lupinus Primrose Dame*, 402; *Lycaste* × *Beryl*, 98; *L. gigantea* Ashlands variety, 275; *Miltonia Adonis*, 355; *M. J. Gurney Fowler*, 354; *M. Princess Victoria Alexandra*, 354; *M. The Baroness*, 354; *M. vexillaria Laelia Sander*, 354; *M. v. Lyoth*, 273; *M. v. Solum*, 354; *Mimulus Wargrave* Fireflame, 402; *Nanodes Medusae*, 460; *Narcissus* *Admiration*, 273; *N. Bedonin*, 289; *N. Cleopatra*, 289; *N. Croesus*, 258; *N. Eastern Maid*, 226; *N. Golden Sceptre*, 273; *N. Horace*, 289; *N. Inglescombe*, 258; *N. Ivory*, 258; *N. Josine*, 290; *N. Lady Superior*, 273; *N. maximus* albus, 258; *N. Morven*, 273; *N. Nightingale*, 273; *N. Olympia*, 193; *N. Princess Juliana*, 273; *N. Queen Primrose*, 258; *N. Royal Sovereign*, 258; *N. Scarlet Gem*, 273; *N. Southern Gem*, 273; *N. Sunrise*, 226; *N. Syphax*, 226; *N. Tantalus*, 258; *N. Tita*, 226; *N. W. P. Milner*, 193; *N. Croesus*, 258; *Odontioda* Ashlands var., 98; *O. Bradshawiae* Perfection, 354; *O. Brewii* var. *niger rubra*, 193; *O. Clive*, 258; *O. Diana* Leeman's var., 193; *O. D.* var. *Gladys*, 115; *O. D.* var. *Leena*, 242; *O. Doris*, 78; *O. Graireana*, 258; *O. Hercules*, 98; *O. Joan*, 273; *O. Lucilia*, 115; *O. Margaret* Westonbirt var., 115; *O. Mrs. R. Le Doux*, 242; *O. Papilion*, 98; *O. Prince de Galles*, 355; *O. Roger Sander*, 354; *O. Royal Gem* Westonbirt var., 46; *O. Schröderae*, 460; *O. CHRONICA WILSONII.

IF we except Charles Maries, who did a certain amount of collecting in the Flowery Kingdom for Veitch more than thirty years ago, "Chinese" Wilson is the pioneer of the race of professional collectors which has sprung into existence of recent years, and has taken over the work of the Lazarist David, and other missionaries and distinguished amateurs who have done such splendid botanical work in China, and whose names are household words to all interested in the subject. With a good start of all competitors, Wilson has already introduced to cultivation a considerable proportion of the trees, shrubs and plants he came across in the tangled mass of mountain and forest, ravine and river, which seems so largely to constitute the western part of China; and though neither a Hooker nor Henry in experience or command of pen, this account* of his wanderings is the most readable that botanists and gardeners have had about a country which, thanks in no small measure to the author's own discoveries, has become of prime importance to them.

Though in all probability no one but

* *A Naturalist in Western China*. By Ernest Henry Wilson. 2 vols. (Methuen, 30s. net.)

himself is yet in a position even remotely to gauge the extent of Wilson's work in China, every year that goes by adds to our realisation of the importance of it; east, west, north, and south one can find hardly a garden in Britain in which there is not already some evidence of his first two expeditions.

In the nature of things a long time must elapse before we are able to appraise Wilson's introductions in the way of Chinese trees and shrubs at their true value; and though, as is inevitable, a proportion of these will have but little interest for us, æsthetic or economic, it seems likely that his discoveries may exer-

Tom Tiddler's ground which lies between China and Thibet. Beyond that he has followed the course of the Yangtse and its great tributary, the Min River, for over a thousand miles westward of Ichang, and yet a glance at the excellent map with which the book is provided shows that he has only scratched the country as yet.

Of late years the tendency of expert opinion has been to regard the Western Chinese flora as allied to that of the Eastern Himalaya, and as a result of the experience gained during his first two expeditions, Wilson saw no reason to question the accuracy of the generally accepted

FIG. 1.—AVENUE OF CUPRESSUS FUNEBRIS AT CHAO-CHU CH TEMPLE, CHENG TU.

(From *A Naturalist in Western China*.)

cise a decided influence on arboriculture in Great Britain.

Wilson's first expedition, undertaken for Veitch, began in 1899, and lasted till 1902; a second journey for the same firm was begun in 1903. After four years he set out again, this time in the interests of Harvard University, and 1910 saw him once more in China on behalf of the same Institution. Apart from his researches into the flora of Yunnan, as to which the book is disappointingly silent, Wilson's wanderings covered a considerable tract of remote and botanically virgin ground in North-west Hupeh, a huge slice of Szechuan, and much of that

view; indeed, he placed it on record at the time that in his judgment the flora of Western Szechuan could only be compared to that of the Sikkim Himalaya. Further acquaintance with the country generally has evidently led our author to modify the opinion he first held, for he now advances anew the interesting theory—originally conceived by Asa Gray—that the alliance is rather with the flora of Eastern North America. While admitting a considerable affinity between the Himalayan and Chinese flora, as to which there can surely be little doubt, Wilson adduces a certain amount of evidence in support of his own conclusions, while some colour:

is lent to the theory by the comparison Prof. Sargent makes, in the introduction, between the flora of Eastern North America and China. Prof. Sargent points out that the comparison cannot be regarded as conclusive, and it will no doubt be well to keep an open mind on the subject till further research into the flora of the country, stretching for several hundred miles, between the Eastern Himalaya and Western China proper reveals the relation of it to the flora of its eastern and western neighbours. Wilson considers the Chinese flora the richest of the temperate regions of the world, and as he is in a better position to judge

from 35 to 60 feet in height, and the largest is 6 feet in girth. . . . The distinctive beauty of *Davidia* is in the two snow-white connate bracts which subtend the flower proper. These are always unequal in size, the larger usually 6 inches long and 3 inches broad, the smaller $3\frac{1}{2}$ inches by $2\frac{1}{2}$ inches. . . . At first greenish, they become pure white as the flowers mature and change to brown with age. The flowers and their attendant bracts are pendulous on fairly long stalks, and when stirred by the slightest breeze resemble huge butterflies hovering amongst the trees. The bracts are somewhat boat-shaped and flimsy in texture,

gorgeous beauty of their flowers defies description. They were there in thousands and hundreds of thousands, all clad with a wreath of blossom that almost hid the foliage. Some flowers were crimson, some bright red, some flesh coloured, some silvery pink, some yellow and others pure white. The huge rugged stems, gnarled and twisted into every conceivable shape, are draped with pendant mosses and lichens. How the *Rhododendrons* find foothold on these wild crags and cliffs is a marvel. Many grow on the fallen trunks of Silver Fir, and some are epiphytic; beneath them *Sphagnum*-moss luxuriates. . . . On bare, exposed cliffs I gathered two diminutive species, each only a few inches tall, one with deep purple and the other with pale-yellow flowers."

In this book the association of limestone with *Rhododendron* is so insistent as almost to compel the conclusion that we are reading of a race of lime-tolerant *Rhododendron*, but this is too much to hope for.

Trees have their full share of the book, and the arboriculturist will envy the man who has feasted his eye on *Ailanthus Vilmoriniana* 150 feet high and 20 feet round, and the Tulip tree—dear to the heart of the Frenchmen who fashion the bird-like bodies of monoplanes—70 feet high, to mention two only at random out of a long catalogue of species, many of them new to the western world.

On the reverse of the picture one sees the remains of dense forests of *Abies Delavayi* (the Cold Fir of the Chinese), many of the trees giants of 150 feet, cut down by ruthless hands and still prone where they fell, great *Rhododendron* bushes feeding on the rotting trunks.

In all directions, apparently, wanton destruction of forests is proceeding apace, and Wilson considers that if things are allowed to go on in this fashion there will not be an acre of accessible virgin forest left in all Central, Southern or Western China in fifty years' time. He lays the blame for this deplorable state of affairs largely at the door of the charcoal burners and makers of potash salts.

In the book will be found many pages bearing on sport, agriculture, manufactures, the manners and customs of the Chinese and Thibetans, and other matters of interest to the general reader, but not coming within the province of this review. They exhibit that power of observation which is one of the attributes of the complete traveller.

Realising that the book is for general reading and not for his special delectation, even the hypercritical botanist will find little to carp at in so much of it as concerns him. Here and there a trifling misprint creeps in, while now and again the interest is allowed to flag. The index is conceived on far too narrow lines—one may even search in vain for mention of the Yangtse River—but, all said and done, it is a plain, unvarnished tale by a man of whom all Englishmen interested in horticulture or forestry have reason to be proud. *A. Grove.*

FIG. 2.—A MANDARIN ORANGE TREE IN FRUIT.
(From *A Naturalist in Western China*.)

than most, one may be content to accept his view; moreover, gardeners will rejoice to know that he is confident a great part of the Chinese flora is suitable for cultivation in temperate regions.

Much of the space in a book of this nature is necessarily absorbed by the mere enumeration of the flora met with, but in the volumes before us such catalogues are robbed of any suspicion of aridity, because of the illuminating observations the author makes on the specimens concerned. Take, for instance, his account of a clump of *Davidia* opposite which he pitched his camp one evening: "There are over a score of them growing on a steep, rocky declivity; they vary

and the leaves often hide them considerably; but so freely are they borne that the tree looks from a short distance as if flecked with snow. . . . To my mind, *Davidia involucrata* is at once the most interesting and beautiful of all trees of the north temperate regions."

Wilson gives the *Rhododendron* pride of place, and as he knows of 160 species and has himself introduced no fewer than sixty to cultivation, the genus is clearly entitled to the distinction. The species range from tiny small-leaved Alpines, growing at about 15,000 feet, and with one or two of which British gardeners are beginning to make acquaintance, to huge old bushes 40 feet high and more: "The

NOVELTIES OF 1913. ORCHIDS.

A REVIEW of the novelties of the past year in the light of the only known test, namely, the certificated plants at the Royal Horticultural Society's shows, brings prominently to the mind the fact that the great number of new Orchids presented for public inspection has been made up almost entirely of garden-raised hybrids. So much are the hopes and expectations of cultivators now based upon the superior novelties to be raised by cross-breeding that the efforts of both nurserymen and amateurs are largely concentrated upon the raising of seedlings. Nevertheless it has to be pointed out that the fact that numberless seedlings are raised each year is not necessarily a guarantee that abundant novelties of high quality will be forthcoming. In earlier days, when true species were more commonly used in crossing, better results were obtained in proportion to the number of crosses made, and greater uniformity prevailed in the character of the seedlings. Now-a-days, high-bred hybrids are more often used for crossing, and the seedlings from such parents exhibit increased variation and not infrequently a proneness to degeneration. The saving point is that in batches of quite an ordinary character exceptionally valuable seedlings appear unexpectedly and, as diamonds discovered in valueless deposits, they help to compensate for much spade work that fails to yield satisfactory results. Notwithstanding the large number of Orchid cultivators, the names of those who succeed in winning Awards at the exhibitions do not vary greatly from year to year, and most of the awards are secured by quite a limited number of growers. The work of the R.H.S. Committee continues to increase. But it cannot be said that it does not exercise the most careful discrimination in making its awards. In spite of the very large number of subjects dealt with during the past year, including those presented at the great shows at Chelsea and Holland Park, only thirty-seven secured First-class Certificates and one hundred and six Awards of Merit. Of these awards some were afterwards cancelled owing to the fact that no coloured drawings were forthcoming for the Society's collection.

Lieut.-Col. Sir GEO. L. HOLFORD, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), who has gained the highest number of awards, exhibited some of the best novelties, and the specimens presented for inspection have invariably borne the evidence of perfect cultivation, as is shown by the large number of cultural commendations awarded to Mr. H. G. Alexander. Those which won First-class Certificates were as follows:—*Odontoglossum Pescatorei* Lady Holford, the best and largest typical form; the finely-coloured *Laelio-Cattleya luminosa* "Holford's variety"; *L.-C. Britannia* "Westonbirt variety"; the fine pale yellow *Brasso-Cattleya heatonensis* Canary; *Cypripedium Roundhead*

(a model flower), and, at the last meeting of the year, the charming white *Cattleya Percivaliana* alba Lady Holford (see fig. 5, p. 10). Awards of Merit were gained for *Cattleya Leda*, a pretty hybrid between *C. Percivaliana* and *C. Dowiana* aurea; *C. Trianae* Colossal, a large flower of the best type; *C. Magnet*; *Odontoglossum Vivien*; *O. amabile* Zeus; *O. illustrissimum* "Westonbirt variety"; *O. crispum xanthotes* "Westonbirt variety"; *Odontioda Cooksoniae* "Holford's variety"; *Oncidium varicosum* "Westonbirt variety," the largest form of this useful yellow Orchid; *Cypripedium Cyclops*, and *C. Olympus*, both

worthy to rank with the other remarkable *O. Pescatorei* at The Dell, *O. P. Schröderianum* and *O. P. Veitchianum*; *O. ardentissimum* Ebor, and the noble *O. Othmarschen* shown at Chelsea; *Cattleya Trianae* The Baron; *C. Maggie Raphaël* "The Dell variety," two charming flowers; and *Brasso-Laelio-Cattleya The Baroness*, in shape and tint the best yellow hybrid of the year. The plants which received Awards of Merit were *Odontoglossum crispum* The Baroness, a noble flower, splendidly grown; *Brasso-Laelio-Cattleya Veitchii* "The Dell variety"; and *Cattleya Gaskelliana* Fairy Queen.

FIG. 3.—NATIVES CARRYING BRICK TEA TO THE MARKET.

(See "Chronica Wilsonii," p. 1.)

large and of fine shape; *Laelio-Cattleya Ganymede* "Holford's variety"; and *L.-C. Armada*.

Baron BRUNO SCHRODER, The Dell, Englefield Green (gr. Mr. J. E. Shill), by the number of good plants shown during 1913 has demonstrated that the Dell collection is one of the finest in Europe. Great improvements have been made under Mr. Shill's superintendence, and in consequence of the benefit bestowed by the newly-constructed block of Orchid houses the output of seedlings will be increased. The best plants, for which First-class Certificates were obtained, were:—*Odontoglossum Pescatorei* Sanderæ, the fine spotted form, well

The late Sir TREVOR LAWRENCE, Burford (gr. Mr. W. H. White), was a frequent exhibitor of Orchids at the Royal Horticultural Society's meetings, his plants securing for his Orchid-grower a large number of Cultural Commendations, one of the most honourable awards. The Burford collection is rich in rare and curious species; and one great attraction at the meetings of the Royal Horticultural Society were the curious and pretty so-called "botanicals," but since the award of the Botanical Certificate has been transferred from the Orchid to the Scientific Committee there has been a great falling off in such exhibits; so much so, that a return to the old order of things in this

matter may seem desirable. Two of the best of the Burford plants were *Laelio-Cattleya Fascinator-Mossiae* and *Odontoglossum Lairesei*, and these secured Awards of Merit.

PANTIA RALLI, Esq., Ashtead Park, Surrey, takes a great interest in choice varieties of particular crosses. His best exhibits of the past year were *Brasso-Cattleya Menda* (B.-C. Queen Alexandra × *C. labiata* Virginia), which secured a First-class Certificate on February 18; *Miltonia Charlesworthii* "Ralli's variety"; *Cattleya Empress Frederick* var. *Avia Clifton*; *Odontoglossum Crawshayanum superbum*; *Oncidioda Cooksoniae* and *Odontioda Cooksoniae*, both distinguished as Ralli's variety, and both securing Awards of Merit.

J. GURNEY FOWLER, Esq., Brackenhurst, Pembury, Tnnbridge Wells (gr. Mr. J. Davis), although much occupied by transferring his fine collection from the old quarters at Glebelands, South Woodford, has shown some choice novelties during the year. A large number obtained First-class Certificates, e.g., *Cymbidium Alexanderi* "Fowler's variety," a very handsome cream-white flower with rose markings; *Miltonioda Harwoodii* "Fowler's variety," of a deep cerise-rose colour; *Odontoglossum Amethyst* "Glebelands variety," and *Odontonia Brugensis Eileen*, very showy hybrids. *Cymbidium glebelandense* var. *J. Davis*, a most profuse flowerer, and very pretty, received an Award of Merit.

C. J. PHILLIPS, Esq., The Glebe, Sevenoaks (gr. Mr. Bucknell), a comparatively new cultivator, is keenly interested in Orchid hybridisation. Mr. PHILLIPS never shows an indifferent plant, and those which fail to secure awards do so generally because they are too near to a plant previously certificated. In these tests the Royal Horticultural Society's two thousand odd pictures of Certificated plants are of the highest value. His best plants were *Cattleya Adnla* "Glebe variety" (F.C.C., October 7), *Odontioda Madeline* var. *Prince of Orange*, *Odontoglossum amandum*, *Cattleya graniris*, and *Laelio-Cattleya Mrs. Temple*, which secured Awards of Merit.

Sir JEREMIAH COLMAN, Gatton Park (gr. Mr. J. Collier), received First-class Certificates for *Cymbidium Lady Colman* var. *Golden Queen*, a bright and floriferous hybrid; *Odontoglossum Queen of Gatton* (which is the best yellow ground hybrid *Odontoglossum* in its section, especially in its perfect shape); and *Laelio-Cattleya Frederick Boyle* "Gatton variety." An Award of Merit was obtained for the delicate blush-white *Dendrobium bigibbum Lady Colman*, which many would prefer to the others.

The Duke of MARLBOROUGH, Blenheim Palace (gr. Mr. Hunter), showed several pretty new *Cypripediums*. *C. Iona* (*bellatulum* × *Fairrieianum*) secured an Award of Merit, a similar award being voted for *Laelio-Cattleya Olenus* "Blenheim variety," which is one of the richest in colour in its class.

F. M. OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), has in his *Brasso-Cattleya Cliftonii magnifica*, for which a First-class Certificate was given on March 18, one of the best plants of the year. *Cattleya Tityus* "Shrubbery variety" and *Cypripedium Minnie* var. *Amazon*, also from the Shrubbery collection, secured Awards of Merit.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), seldom lets a meeting pass without sending something. His *Brasso-Cattleya Vilmoriniana* "Goodson's variety" (F.C.C.), *Odontioda Latona* "Goodson's variety," a fine scarlet flower; *Odontoglossum George Day* (a *Rossii rubescens* cross), and *O. Aireworth* "Goodson's variety," all received Awards of Merit.

DE BARRI CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), whose familiarity with *Odontoglossums* is well known, has flowered some good novelties during the past year. His *O. Queen Alexandra Theodora* (A.M., July 29), is a distinct advance on other products of this famous cross raised by him, whilst *O. Cleopatra* "Rosefield variety" received an Award of Merit at the meeting held on December 16.

E. H. DAVIDSON, Esq., Orchid Dene, Twyford, has now a large number of rare Orchids selected for cross-breeding, and a fine stock of seedlings raised by his Orchid-grower, Mr. Lakin. Among the many excellent exhibits which secured awards are the new scarlet *Habenaria Roehelenii*, *Sophro-Cattleya Saxa* "Orchid Dene variety," of a delicate salmon-rose colour; the white-petalled *Cattleya Cybele*, *Odontioda Thwaitesii Purple Emperor*, *Odontoglossum Aireworth* "Orchid Dene variety," and the richly-coloured *Laelio-Cattleya Wellesleyi* var. *Flambeau*. He has also shown a number of *Odontoglossum Rossii rubescens* crosses.

W. R. LEE, Esq., Plumpton Hall, Heywood, Lancashire, keeps the Manchester area in touch with Westminster by frequently sending exhibits. His *Brasso-Laelio-Cattleya King Emperor*, which secured a First-class Certificate on April 15, is one of the largest and best-coloured of the *B. Digbyana* crosses; and his *Cypripedium Queen Alexandra*, *C. Goliath*, and *C. Alcinida* var. *Strelsa*, which received Awards of Merit, are among the best shown during the past year.

Other amateur's exhibits which deserve mention are *Odontioda Mossiae* and *Miltonioda Harwoodii* "Moss' variety," of the late J. S. Moss, an enthusiast in *Odontoglossums*; and *Laelio-Cattleya Dominiana* "Southfield variety" (F.C.C., April 1). *Cattleya Hardyana Mrs. W. Waters Butler* secured an Award of Merit, which is evidence of its distinct character, as it had to compete with a long list of forerunners. The two last were from W. WATERS BUTLER, Esq., Southfield, Edgbaston (gr. Mr. Jones). *Odontoglossum crispum* "Cobb's variety" was shown by Mr. WALTER COBB; *O. eximium* "Warnham Court variety" by Mr. C. J. LUCAS; and some showy hybrid *Odontoglossums*

by WILLIAM THOMPSON, Esq. In our list of novelties seen in flower but not yet certificated, various promising hybrids came from F. J. HANBURY, Esq. (gr. Mr. Matthews), W. H. ST. QUINTIN, Esq. (gr. Mr. Puddle), ERNEST MOCATTA, Esq. (gr. Mr. Stevenson), Mrs. BISCHOFFSHEIM (Orchid-grower, Mr. Jones), Mrs. NORMAN COOKSON (gr. Mr. H. J. Chapman), H. T. PITT, Esq. (gr. Mr. Thurgood), G. F. MOORE, Esq., and R. G. THWAITES, Esq.

CONTINENTAL EXHIBITS.

These have not been plentiful during the past year, probably owing to the numerous exhibitions held on the Continent. Monsieur FIRMIN LAMBEAU, Brussels (gr. M. Demeuter), the leader of modern Orchid culture in Belgium, occasionally sends a few plants, and these are always of fine quality. Those shown last year were sent only in the winter and spring, the best being *Cattleya Enid* var. *F. Lambeau* (*Mossiae Reineckiana* × *Warszewiczii Frau Melanie Beyrodt*), a charming white-petalled flower, which received a First-class Certificate; *Odontonia Firminii* (*M. vexillaria* × *O. crispum*), a very interesting cross; *Laelio-Cattleya Firminii* var. *ardens*, a brilliant orange-red and purple colour; and *Cattleya intertexta Juliettae*, a pretty new form of an old Veitchian hybrid. These received Awards of Merit.

Monsieur H. GRAIRE, of Amiens, has shown some very pretty crosses of *Odontoglossum nebulosum* and *Odontiodas*, several of which received Awards.

(To be continued.)

FORESTRY.

TIMBER FOR CLOG SOLES.

CLOG-MAKING is a time-honoured industry of this country, for we learn that in 1200 the English archers petitioned the King to prohibit clog-makers using Aspen, or there would be a shortage of that wood for their bows and arrows. The best wood for the manufacture of clog soles is that of the Alder, though for inferior wear the timber of the Birch, Sycamore, Willow and Lime is occasionally used.

For ease in working, clean trees of from thirty to fifty years old are preferred, and such as are grown in close woodlands are superior to those from field and hedgerow. The price of Alder timber varies a good deal, according to the district and situation of the plantation where the trees are felled, but about 9d. per cubic foot would be a fair average. On an estate in Wales from which large quantities are annually cut the fixed price is 10d.; but in other parts of the country it may be as low as 7d. or 8d. per foot. If the roads are good, it matters but little the distance from the railway station of the plantation in which the trees are felled, for as a rule the clog soles are cut out roughly and sent for finishing in the larger centres of industry where clogs are worn. The cost of carriage of the timber in the rough is thus avoided, the roughly formed soles being carted to and despatched from the nearest rail or dock.

During the past six months many consignments of clog soles in the rough have been sent from the Bridewell and other estates to the northern parts of the country, in the factories of which the finished shape is given to the sole and the

leather tops attached. It is estimated that fully seven thousand men are employed in the clog-making industry. The making of the soles is an art which can only be successfully engaged in after years of practical experience, and the clog-maker likes his outdoor life and works with an ease and grace that is surprising, and unequalled in any other branch of timber conversion by hand. His tool resembles a stout scythe blade which is worked on a swivel joint, attached to a bench or form about a yard long and a couple of feet in height. One end of the knife is fitted with a handle for ease in manipulation, while the other is securely fixed between iron uprights to the bench, which affords room for plenty of play. It is surprising how, with a few dexterous and well-directed movements of the knife, the roughly-split block of Alder wood is converted into the clog sole. We have seen an expert clog-maker turn out twenty pairs of these soles in an hour. Generally, permission is given to make the clog soles in a convenient opening of woodland, where the timber has been felled, this resulting in a great saving of carriage, a tarpaulin-covered shed being erected and heated by the chippings from the clog soles. Nothing is wasted by the clog-maker, the refuse chips being readily sold as firewood in the neighbourhood at 3d. or 4d. a sackful.

It may seem surprising, but the best Alder—the cleanest and easiest of manipulation—comes from Germany, and this foreign wood is preferred to what is produced at home. But the German Government has for many years been planting Alder in the State forests, and a profitable speculation it is when we consider that the wood is ready for making into clog soles when twenty years planted and that from 5d. upwards per cubic foot can be obtained for the timber. Cheap German clogs are, however, also sent to this country, the soles being made of inferior and more porous wood than the Alder, but they are not in great demand and realise only low prices on the market. In this country the plantations of pure Alder are few and far between, and we have mainly to rely on mixed thinnings and isolated specimens, the timber of which is usually rough and difficult to work. Scotland produces the largest amount of timber suitable for the clog-maker, followed by Ireland and the South and West of England.

When we consider that the Alder alone is one of our hardiest trees and, moreover, one that will produce excellent timber in waterlogged ground, where few other species could succeed, it is surprising that so few plantations of the tree are to be found, and that we are dependent on foreign supplies for an industry which gives remunerative employment to upwards of seven thousand workmen. A. D. W.

ANNUALS.

FOR over thirty years I have been interested in annuals, but it was only last summer I was able for the first time to carry out an extensive trial where I could observe the plants daily. This may seem a strange statement for a seedsman to make, but I will explain. I made the trial referred to at my private residence, and that makes all the difference. On the seed farm or in regular trial grounds work is a matter of business routine, but at home one can examine one's flowers morning, noon and night, on weekdays and on Sundays, solaced by a pipe or a cigar, none daring to make one hurry over the pleasant exercise.

In the autumn of 1912 I decided to make a border for annuals out of land which had been sown down to grass for five or six years. It stretched alongside a path, and the size of the border I decided upon was over 100 yards long by 6 feet wide. I had it well manured and bastard-trenched, leaving the surface quite rough during the winter. I top-dressed the surface

just after digging with soot and lime, and it was left undisturbed until March, when it was pointed over with the digging-fork to the depth of about 4 inches. This brought the surface into friable condition and the treading tended to settle and firm the soil. Again it was left undisturbed till the beginning of May, when it was rolled, and thereafter the surface was worked as fine as possible with a rake. On the 5th and 6th of May the sowing was done, 330 varieties of annuals being sown. In ten days many of the plants had appeared above ground, notably Alyssums, Clarkias, Cyanus, Godetias, Lupinus, Candytufts, Collinsias, Leptosiphons and Virginian Stocks. It was well into June before the Hibiscus, Nicotianas, Nemesias and several of the Calliopsis appeared. Many half-hardy sorts, such as Phlox Drummondii, Lobelia and Portulaca, took three weeks to get above ground.

In the border I arranged three rows of clumps, the front row being of plants under 12 inches in height, the centre row plants from 12 to 18

over it. Larger seeds had a covering spread on carefully with the hand, and made level with the edge of a 9-inch wooden label. Then every plot was gone over and pressed rather firmly with a smooth flat piece of board. This was done to ensure that every seed was in close contact with the soil; then after this was done the whole bed got the slightest touch with a fine rake to take away the flat-pressed appearance which I dislike, and also to make the surface more easily penetrated by rain. On the whole I got good germination, many of the varieties coming up like Mustard and Cress for thickness; but then began the process which more than anything else accounted for the success I obtained. The plants were ruthlessly thinned—not once or twice, but just as often as was necessary—until I had arrived at the plan laid down. For example, Candytufts and Poppy plants stood 6 inches apart when the thinning process was completed. Strong-growing plants like Kochia, many of the Chrysanthemums, Larkspurs and Malopes, were so thinned as to

FIG. 4.—CULTIVATION OF ANNUALS.
(*Cynoglossum linifolium* after thinning)

inches, and the back row plants of over 18 inches in height. This arrangement did not work out quite correctly because, as was to be expected, many of the plants grew several inches taller than expected.

To make regular and neat work I had oval hoops made with which to mark out the spaces for the different varieties. The hoops were made of thin wood, which could be pressed into the surface of the soil, and on removal left a clear line, inside which the seeds were carefully sown. The size of the hoops for marking out the front row were 21 by 12 inches—21 inches long by 12 inches across. The centre plots marked by the same process were 24 by 16 inches, and the back row ones for strong-growing plants, like Chrysanthemums and Larkspurs, were 30 by 18 inches. The space left between the clumps was equivalent to the width of the clump. The method of covering may, I think, be referred to with advantage. I had barrowloads of sifted soil prepared. To cover the minute seeds like Lobelia a dusting of this soil was applied to the Lobelia plot by putting a handful or two of soil into a fine sieve, $\frac{1}{8}$ inch mesh, and shaking it

leave only eight to a dozen plants in the large spaces 30 by 18 inches at the back of the border. I might safely say that, as a rule, plants in the front plots were thinned to 4 inches apart, those in the centre plots to 6 inches, and those in the large back plots to 9 inches. The illustration in figure 4 shows a clump of *Cynoglossum linifolium* after the final thinning. My object in writing these notes is to endeavour to interest a wider public in annuals, which, when well treated, are not the weedy things so many people think they are. In some future notes I hope to write more particularly of varieties. W. Cuthbertson, Duddingston, Mid Lothian.

PANDANUS VEITCHII.—Plants of this variegated stove species, that have been used for decorating purposes in dwelling-rooms, and have become disfigured may be used for purposes of propagation. Select the best coloured side shoots or suckers and insert them singly in thumb pots filled with suitable soil. They will root in a gentle bottom heat in the stove or propagating pit. The old plants may be discarded. E. H., Lockinge.

The Week's Work.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

THE SEASON.—Seldom has the New Year opened more auspiciously than the present one, crops being generally plentiful. The great drought of early summer appeared as if it might ruin the vegetable crops, but very soon after the rains most of the plants developed

rapid growth, and they have given a very practical demonstration of the value of soil-drying. There will probably be some inconvenience arising from the early maturity of Cabbages, which have been fit to cut for some time, but in deeply cultivated soil it is marvellous how well the

crops come through abnormal conditions.

ENDIVE.—Batches of Endive should be placed at the cool end of the Mushroom house at five-day intervals, in order to have them always fresh and nicely blanched. Frequent transplanting enables one to lift them for the last time with nice earthy balls, and in the Mushroom house, if placed close together, with a little water under them, damping of the leaves will not occur. Those in frames should be very freely ventilated, Endive being almost hardy.

TOMATOS.—Seeds of Tomatos for early summer picking should be sown at once. A few seeds should be placed in each thumb pot, the seedlings to be subsequently reduced to one in each pot.

CAULIFLOWERS.—Seedlings left over from the late autumn in boxes may now be transplanted into large 3-inch or 4-inch pots for planting out in March. A compost of equal parts loam and manure from a spent Mushroom bed may be used; or, in a heavier soil, the addition of leaf-soil may be advisable. The plants must on no account be coddled or over-watered.

ONIONS AND LEEKS.—The first sowing of these may be made at once in boxes 4 or 5 inches in depth. Use fine loam and leaf-soil in equal proportions. Some growers allow the seeds to germinate in a cool structure, others in heat, but in the latter case the seedlings must be removed to a cool house whilst still in a small state.

CUCUMBERS.—Where plenty of heat can be obtained, seeds may be sown now for raising plants to fruit at the end of March. One seed should be sown in each thumb pot in a compost of equal parts loam and leaf-mould. Plunge the pots to the rim, and cover with glass to prevent mice from reaching the seeds. The seedlings will require transplanting a day or two subsequent to the development of the cotyledons.

SEAKALE.—If this crop is not yet lifted, it should at once be done, trenching the ground immediately thereafter to clear it of broken roots. Trim the roots of the crowns, and store the latter in clumps underground, where they can be easily got at and placed in the Mushroom house for successional cuttings. For late use arrange a

sufficient number of crowns close together in the open garden, and cover them with some light material deep enough to blanch the growth which pushes naturally in late spring. The strongest of the roots or thongs should be prepared at once for making another plantation, and be covered in the meantime with soil. Buds will form at the upper part of the thongs, and thus give the plants a longer season than if the roots were not prepared until the time of planting.

PLANTS UNDER GLASS

By C. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

HIPPEASTRUM.—Of recent years much has been done by hybridisers to improve the size, shape and colour of these valuable bulbous plants. They now range in colour from deep crimson to mottled white, and a few hybrids may be termed quite white. If Hippeastrums

are required during March and April the present date is a good time to begin forcing, assuming that the plants have had a good season's growth and a resting period. The best and soundest bulbs that show a quantity of roots round the ball of soil should be selected for

earliest forcing. Give the plants a good soaking of water to which a little manure water has been added about 24 hours before top-dressing them. With a pointed stick remove the surface soil without injuring the roots, and top-dress with a mixture of fibrous loam, leaf-soil, manure from a spent Mushroom bed, a little lime rubble and bone meal. Examine each bulb for the presence of thrips, bugs, or other insect pests, and if any are detected remove all loose material and brush the bulbs with a mixture of Gishurst Compound as directed for thrips. Select a house or pit fully exposed to the light. Make up a mild hotbed of leaves or tanners' bark to a depth of 18 inches, and plunge the pots to the rims. Maintain a temperature of 55° in the house, and a temperature in the bed of 65°. Syringe the bulbs daily to promote a moist atmosphere; very little water should be given at the roots until the growths are well advanced. When the plants are in full growth give frequent waterings of liquid manure and Clay's fertiliser; and as the flowers open remove them to a cool house and shade them from bright sunshine. When the flowering period is over return the plants to a heated pit. Encourage growth as much as possible with stimulants, and maintain a moist atmosphere by frequent syringings.

CINERARIA.—The earliest batch of these useful plants is beginning to flower, and the plants should be removed to an intermediate house. Exercise great care in watering and seeding, as plants at this stage are very liable to damp off at the neck. Plants for later flowering should be potted at once. If the plants are attacked with the leaf-boring grub they should be closely watched and each grub picked off. Fumigate the house once a fortnight, as Cinerarias are very subject to green fly.

FORCING.—To maintain a continual supply of bulbous and other forced flowers it is necessary to place a fresh batch of plants in heat every week. Daffodils should not be plunged directly in strong bottom heat, but be grown first for about a week in an atmospheric temperature of 55° to 60°. Azalea mollis, Lilacs, Viburnums and Wistaria may now be forced with satisfactory

results. Clumps of *Anchusa italica* Dropmore variety should be lifted from the open ground, potted and placed in a cold frame or vinery until they start into growth, when they should be brought into a greenhouse. Paeonies may be lifted and treated in much the same manner as *Anchusas*.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Exors. of The Late LADY DE ROTHSCHILD, Aston Clinton, Buckinghamshire.

VINES.—The houses in which Grapes are still hanging should be kept as dry as possible, and the temperature should be kept at about 45°. Each bunch should be carefully examined once a week, and all decaying berries removed. Prune the vines in houses from which the fruit has been

cut, afterwards removing all loose bark from the vines, and well wash the rods with an insecticide. White wash the walls and paint the woodwork if necessary. In any case, the latter should be thoroughly cleansed. After this has been done, the loose surface soil should be removed

from the borders, and a new mulching of turfy, fibrous loam, well-decayed manure, and lime rubble spread over the entire surface, using sufficient to bring the border up to its normal height. If it is inclined to be dry, the border should receive a thorough soaking of clear water and the vinery be kept cold until closing down time. Pot vines, now in active growth, must be carefully watched, always keeping the soil in a moderately moist condition, avoiding the slightest tendency to dryness at the roots. Where the pots are plunged in fermenting material the danger is not so great as if bottom heat is supplied by hot-water pipes. The roots are now very active, and as the vines advance in growth stimulants should be given to prevent any sudden check to the vines during the early stages of growth. Early houses may now have an extra few degrees of heat. Forcing will not be so difficult now that we have passed the shortest day. Each vine should be disbudded as soon as it is apparent which growths are carrying the best bunches. In any case avoid overcrowding the young shoots. As soon as the flowering period begins maintain a temperature of 70° to 75° by day and a minimum temperature of 65° by night. During intervals of sunshine, with a rising temperature, air may be admitted in moderation, always preventing draughts, which would cripple the tender foliage and cause rust on the berries. As soon as fertilisation is completed the borders should receive a thorough soaking with tepid water or diluted liquid manure, and a genial atmosphere should be maintained by damping the paths and staging several times a day with clear water. The evaporating troughs should be kept filled with water, to which a small quantity of strong liquid ammonia has been added, say about one tablespoonful to each gallon of water. The bunches should be thinned as early as possible, after which they will make rapid progress until they reach the stoning period. Heavy cropping must be carefully guarded against in the case of early-forced vines.

EARLY PEACHES AND NECTARINES are now well advanced in their flowering stage. Maintain a temperature of 60° to 65° by day and 55° at night, admitting air on every favourable occasion during mild weather, both day and night. Artificial fertilisation of some kind is

essential at this early period of the year, but if a hive of bees can be introduced into the house much time and labour will be saved.

EARLY STRAWBERRIES IN POTS should now be well under treatment, if ripe fruit is required during March and April. Plants that were placed in a cool house during the early part of last month will be showing signs of activity, but they must not be excited unduly, or many of the crowns will collapse during the early stages of their growth. Careful watering with tepid water only must be observed. Gently syringe on bright, fine days, and maintain a constant circulation of air at a temperature of 45° to 50° until the plants are coming into bloom, after which, with the lengthening of the days, higher temperatures may be allowed.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON, Oakwood, Wylam-on-Tyne.

EARLY-FLOWERING DENDROBIUMS.—In gardens where deciduous Dendrobiums are grown in quantities it is often found desirable to have a few of the plants in flower early in the year. To obtain this result a careful selection should be made from among plants of which the flower buds at the side of the pseudo-bulb, opposite the scars where the leaves have been cast, are in a forward state. The selected plants should be gradually removed from their resting quarters with a view to transferring them eventually to the warm house or stove. To move the plants direct

into immediate heat would probably excite too rapid growth, and instead of flowers side shoots would make their appearance. Even when plants are brought from one temperature to another by degrees, if too liberal treatment is afforded in respect to root moisture there will be growth production instead of flowers, so that considerable discretion should be exercised in watering. Only sufficient water is necessary to keep the pseudo-bulbs in a normally plump condition; very little root moisture is required when the atmosphere of the house is damp. As soon, however, as the flower buds appear more liberal treatment may be given. When selecting plants care should be observed to use those with the pseudo-bulbs thoroughly ripened. Any forcing of immature plants would lead to the production of side growths instead of flowers. The plants selected should be placed where they will be fully exposed to the light. Some of the most useful sorts for early forcing are *D. aureum* and *D. nobile* among the species, and *D. Cassiope* and *D. Ainsworthii*, with its allies, among the hybrids. If there is no demand for the plants early in the season it is more satisfactory to permit them to come on in the regular course, the flowering taking place in March or April. Not only is there less likelihood of the plants producing undesirable side growths, but the more favourable conditions of the outside atmosphere give greater substance and finer colour to the flowers. Seedling Dendrobiums and young propagated plants usually commence new growth early in the year. As soon as this commences, any repotting that may be necessary should be attended to, as the growths usually produce roots from the base in the early stages of development. Being easily damaged, repotting (or resurfacing as the case may require) should be attended to before these roots become too far advanced. A compost of finely chopped Sphagnum-moss and fibrous

peat, finely chopped and used in equal proportions, with sufficient sand to render the compost porous, is the most suitable for small plants.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl B'FAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

FOREWORDS.—My remarks each week will deal not only with work in the flower garden proper, but also with the different aspects of natural or "wild" gardening, and the many and varied purposes to which hardy and half-hardy flowering and foliage plants can be applied. The flower garden should provide pleasant surprises, and be a source of charm and delight in all seasons. In order to obtain the best effects repetitions, either in design or in planting, should be avoided, so that at each turn there will be something fresh to contemplate and new beauties to admire. It is of great importance to prepare the soil thoroughly at the start by deep cultivation; trenching to the depth of two feet is to be recommended, incorporating, at the time of digging, plenty of well-rotted animal manure or leaf-mould, with lime, rubble, or sharp sand to keep the texture open. By this means the soil will become better aerated, and the warmth of the sun's rays will penetrate to the roots.

PROTECTION FROM FROSTS AND PESTS.—Examine, at frequent intervals, half-hardy plants, such as Gunneras, Eremuri, Primulas, and *Lobelia cardinalis*, to see that birds or animals have not disturbed the protective materials placed about them, exposing their crowns to the injurious influence of frosts. Mice frequently destroy bulbs during hard weather, and pheasants are also destructive visitors to the garden—these latter are privileged, so that only preventive measures may be taken. The best plan is to surround the plants with wire netting; but the mice should be trapped, using such a trap as the "Little Nipper," baited with cheese.

SUMMER BEDDING PLANS.—Schemes and quantities of plants required for next summer's bedding should be prepared, so that the necessary stocks may be raised in sufficient quantity. The seed order should be sent to the seedsman and beds of fermenting material prepared, so that the seeds of slow-growing subjects may be raised at an early date. Many hardy herbaceous perennials may be raised from seeds in full expectation of their coming true to type and being of vigorous habits. All summer-bedding plants should be kept in a comparatively low temperature for the present, so as to discourage growth as much as may be done with safety, because all growth made during short and comparatively dark days is weakly, and unsuitable for the production of good blooms or ornamental foliage. But any stocks which are insufficient should be placed in a warmer temperature, so that propagation may be commenced at an early date. Such plants as *Antirrhinums*, *Petunias*, and *Verbenas* may now be relied upon to come true from seeds supplied by first-class seedsmen, so that it is not necessary to winter stocks of these plants. The portion of the gardens at Madresfield Court which is reserved for the cultivation of hardy and half-hardy annuals in large, irregular groups is always much appreciated and greatly admired.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

MORELLO CHERRY.—The Morello Cherry is a valuable fruit for private gardens; the tree is perfectly hardy, and thrives well in exposed positions on the north side of walls. It is a good plan to plant trees in different aspects, thus ensuring a succession of fruits; specimens on north walls furnish a supply late in the season. If the ground is in fair condition, no manure should be mixed with it at the time of planting—as a rule, healthy, young trees grow rapidly, and gross wood is of no advantage. The ground, having been trenched some time

previously, should be made firm and level on the surface. Scatter some fine soil or wood ashes amongst the roots; also mortar rubble or some other form of lime, which is necessary for all stone fruits. Trim all damaged roots with a sharp knife, and shorten any that are unduly strong, in order to encourage the development of a fibrous root-system. Fasten the trees lightly to the wall for the present; the branches may be trained more securely when the soil has settled in position. Place a mulch of some light material over the roots to protect them from extremes of weather.

PRUNING AND TRAINING THE MORELLO CHERRY.—Freshly planted Morello Cherries require very little pruning. Cut back the weak shoots to a growth bud, and shorten the strong ones, as this will lay the foundation of a good shaped tree. Established trees require to be pruned the same as Peaches and Nectarines, that is, all old fruiting wood should be cut away, and sufficient, well-ripened, young shoots trained in to furnish the wall space. The best time to do the work is directly after the fruit is gathered. The shoots of Morello Cherries are often trained too thickly.

RENOVATING OLD TREES.—Trees that have been neglected for some years should be overhauled carefully with a view to removing some of the worn-out branches, that is, those bearing few or no young shoots. When the work of thinning is completed, train the branches at suitable distances apart, and spray them thoroughly with an alkali wash, which will completely alter the appearance of the tree. Next remove some of the exhausted soil from the border, and replace with fresh loam. Feed the roots with bone-meal or other fertiliser, wood ashes, and lime rubble. If fresh soil is not available, fork the border, after applying a dressing of artificial manure and wood ashes, finishing with a mulch of farmyard manure.

MANURING FRUIT TREES.—Take advantage of frosty weather to wheel manure to trees that require feeding. Fruit trees cannot be expected to mature heavy crops year after year without manurial assistance. Bush fruit of all kinds, including Gooseberries, Red and Black Currants, and Raspberries will all be greatly benefited by a good dressing of the best manure obtainable. It is becoming a matter of some difficulty to obtain a sufficient supply of animal manure for the garden, but fish manure, bone-meal, and other concentrated fertilisers may be used instead. The garden fire will provide valuable material in the ashes for dressing fruit borders or for mixing with other manures. Collect and burn all prunings, weeds, and rubbish. Worn-out and diseased trees should be removed at once to the fire and burned.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR JANUARY.

- FRIDAY, JANUARY 2—
Dundee Hort. Assoc. meet.
- SATURDAY, JANUARY 3—
Roy. Inst. meet.
- TUESDAY, JANUARY 6—
Roy. Inst. meet. (Lecture by Prof. Turner, "Our Sun").
- WEDNESDAY, JANUARY 7—
B.G.A. Ex. Council meet.
- THURSDAY, JANUARY 8—
Roy. Inst. meet.
- MONDAY, JANUARY 12—
United Hort. Ben. and Prov. Soc. Com. meet. Surveyors' Inst. meet. (Paper by Mr. Graham Mould on "The Law of Dilapidations").
- TUESDAY, JANUARY 13—
Roy. Hort. Soc. Coms. meet. Stirling and Dist. Hort. Assoc. meet.
- WEDNESDAY, JANUARY 14—
Surveyors' Inst. Prelim. Exam. (2 days).
- THURSDAY, JANUARY 15—
Manchester and N. of England Orchid Soc. meet. Linnean Soc. meet. B.G.A. (Watford Branch) meet.
- FRIDAY, JANUARY 16—
Kew Gardeners' Social Evening.
- MONDAY, JANUARY 19—
Surveyors' Inst. Junior meet. (Paper by Mr. H. J. Smith on "The Housing and Town Planning Act in Working").
- TUESDAY, JANUARY 20—
Scot. Hort. Assoc. annual meet. Roy. Inst. meet. (Lecture by Prof. W. Bateson on "Animals and Plants under Domestication").
- THURSDAY, JANUARY 22—
Gardeners' Roy. Ben. Inst. annual meet. and election of pensioners at Simpson's Restaurant, Strand, at 2.45 p.m. Roy. Botanic Soc. meet.
- FRIDAY, JANUARY 23—
Roy. Inst. meet.
- SATURDAY, JANUARY 24—
Roy. Inst. meet.
- TUESDAY, JANUARY 27—
Roy. Hort. Coms. meet. (Lecture at 3 p.m. on "Some Aspects of American Forestry"). Roy. Inst. meet. (Lecture by Prof. Bateson on "Animals and Plants under Domestication").
- THURSDAY, JANUARY 29—
Manchester and N. of Eng. Orchid Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 37.8°.

ACTUAL TEMPERATURES:—
LONDON, Wednesday, December 31 (6 p.m.): Max. 38°; Min. 30°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, January 1 (10 a.m.): Bar. 30.2; Temp. 34°. Weather.—Fine.
PROVINCES.—Wednesday, December 31; Max. 43°, Donegal; Min. 28°, Shields.

SALES FOR THE ENSUING WEEK.

- MONDAY AND WEDNESDAY—
Rose Trees, Shrubs, Perennials, Lilies, etc., at Stevens' Auction Rooms, King Street, Covent Garden, W.C., at 12.30
- MONDAY AND FRIDAY—
Dutch Bulbs, Herbaceous Plants, Lilies and Hardy Bulbs, Fruit Trees and Roses, at 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.
- WEDNESDAY—
Border Plants and Perennials, Lilies and other Hardy Bulbs at 12, Palms and Plants at 5, at 67 and 68, Cheapside, E.C., by Protheroe and Morris.
Trade Sale of Miscellaneous Bulbs and Roots at 12 o'clock, 1,296 c/s Japanese Liliiums at 2.30 o'clock, at 67 and 68, Cheapside, E.C., by Protheroe and Morris.
- THURSDAY—
Special Sale of Roses, at 67 and 68, Cheapside, E.O., by Protheroe and Morris, at 1.

Sir Trevor Lawrence.

Our readers would receive with pained surprise the brief announcement of the death of Sir Trevor Lawrence which we printed last week. It was only in April last that he retired from the Presidency of the Royal Horticultural Society with the good wishes and the thanks of every horticulturist for the splendid services he had rendered to the Society and to horticulture. Little was it anticipated that the end would come after only a few short months. At that time it was not generally known that the late President continued to discharge the duties of his post to the last possible moment. When he intimated to the Council his wish that another President should be appointed, enfeebled health was already beginning to have its

(Photograph by Elliott and Fry.)
THE LATE SIR TREVOR LAWRENCE, BT., K.C.V.O., V.M.H.

effect. The Council at first, naturally reluctant to part with its honoured chairman, begged him to reconsider his decision to resign, and so devoted was he to the interests of the Society that he might have been led to do so had not the Council learned in time the true state of Sir Trevor's health, and ceased to press its request.

Although during his life he held several important posts, including for twelve years that of treasurer of St. Bartholomew's Hospital, it is as President of the premier Horticultural Society that he was best known. When, in 1885, he succeeded Lord Aberdare, the affairs of the Society were in a very unsatisfactory condition. The membership was small, the expenses exceeded the income, and the ship seemed to be drifting on to the rocks.

Few men could have been found unselfish enough to saddle themselves with

the responsibilities attaching to the post of President in such depressing circumstances, and fewer still to possess the first-hand knowledge of horticulture requisite to enable them to take the helm with any prospect of success.

Son of a woman who in her day was as keen a horticulturist as could be found, Sir Trevor inherited from his mother his great interest in plants and flowers, and he used to say that it was that inherited love of gardening which led him finally to accept the presidential chair.

The progress of the Society during the last twenty years is well known, and Sir Trevor Lawrence's share in bringing about such satisfactory results was dealt with so fully in our issue of April 5, 1913, last, that we need say no more than that when, after twenty-eight years, the Society again changed pilots, the fellowship numbered over 13,000, and the Society found itself possessed of ample funds.

How far the revival of the fortunes of the Society and the ever-increasing interest in horticulture have acted and re-acted on each other it is difficult to say, but there can be no doubt the Fellows owe a great debt to the late President, and it is to be hoped there may be some early and suitable recognition of his services to horticulture generally.

Until a few years ago it almost seemed as if Sir Trevor Lawrence had discovered the elixir of life, for he appeared perennially young; few men with four score years to their credit would be able, as was Sir Trevor, to spend a day in the garden with a friend, and show but little sign of fatigue at the end of it. Essentially a man of affairs, he possessed in a marked degree a sense of tact and discretion which enabled him to ride smoothly over many a difficult place; he was broad-minded and catholic in his tastes, a delightful host both in his own home and as President of the Society, and a keen practical gardener. Probably no amateur has received, and rightly received, more awards for new or little-known plants than Sir Trevor, as may be seen on reference to our April issue already mentioned.

Transpiration in Light and Darkness.

Practical gardeners and physiologists alike are agreed on the importance of water to the plant. They know that by the judicious employment of water the rate and course of a plant's development may be controlled, and they are alive to the fact that the water requirements of different plants vary to a remarkable extent. Some plants are ever-thirsty, and can never have more than enough, others are so abstemious that they are intolerant even of a few days' rain. Yet, despite the large body of valuable knowledge which we possess with respect to the relation of the plant to water, the meaning of many well-known facts remains obscure, and the significance of various practices commonly employed in gardening has not been fully elucidated. For example, it was only a short time ago that we drew attention to the interesting observation of Mr. Balls that in Egypt, the instant the sun

[*Photograph by C. P. Raffill.*]

RHODODENDRON SCHLIPPENBACHII :
COLOUR OF FLOWERS PALE ROSE WITH REDDISH-BROWN DOTS ON THE UPPER PETALS.

falls upon the cotton plant it ceases to grow owing to the fact that the loss of water outruns the uptake.

Again, who can say with certainty what is the effect on transpiration of syringing the leaves of a vine growing in a hot-house? Or, who would be prepared to state the relative amounts of water which a plant loses during day and night?

These examples of our ignorance or of the uncertainty of our knowledge suffice to show that there is ample room for further physiological investigation into the workaday processes of plants. Such investigations carried out recently by Sir Francis Darwin have brought to light a number of facts of very considerable importance. The task which Sir Francis set himself in the first place was to discover some method of measuring the amount of water which a plant subjected to certain conditions would give off if it could. The importance of this point of view will be realised when it is remembered that the stomata have the last word in controlling transpiration. Thus, imagine a plant brought into such conditions as encourage it to transpire more actively, but at the same time cause the stomata to close. Evidently if resource is had to the ordinary methods for estimating transpiration, the result would be misleading, for it would show only what the plant is doing and not what it is trying to do. In other words, the behaviour of the stomata may mask that of the plant, and it is certain that not a few cultural failures arise from the fact that conditions are sometimes imposed on a plant which encourage the cells of its leaves to give off water vapour vigorously into the air-spaces of the leaf, whilst the stomata, being closed, prevent the escape of that vapour. Sir Francis Darwin found a simple and apparently quite effective way round this difficulty in furthering our knowledge. He put the stomata out of action by smearing a layer of vaseline over the leaf-surface and then provided for the escape of water by making a number of incisions in the leaf. That this drastic treatment may be employed successfully depends on the fact that the leaf consists of an enormous number of transpiring cells all abutting on inter-communicating air-spaces. The incisions destroy but a limited number of these cells, and the remainder are free to carry on their work unimpaired during the short period of the experiment, and any water vapour which they give off escapes freely from the cut surfaces into the air.

As the result of these investigations, Sir Francis has shown, first, that the rate of transpiration is strictly proportional to the humidity of the air, and, second, that even when the air is saturated with moisture, a certain, albeit small, amount of transpiration still goes on. Having devised a method of avoiding the error due to the caprice of stomata he proceeded to examine the effect of light and darkness on the rate of transpiration of leaves. He showed that light exercises a speeding-up action on this process quite apart from its well-known action in causing stomata to open. With leaves of Laurel (*Prunus Laurocerasus*) and of Ivy the average rate of transpiration in light and darkness—

other conditions being equal—is as 130 : 100. That is to say, light, quite apart from its effect on stomata, exercises an accelerating influence on the rate at which the cells of a leaf give off water. To what this acceleration is due remains, however, to be discovered.

Coloured Supplement—The subject of the coloured plate to be published with the issue for next week is *Crinodendron Hookerianum*.

Supplementary Illustration.—Although *Rhododendron Schlippenbachii* was first discovered by Baron SCHLIPPENBACH, growing amongst other shrubs on the shores of Possjet Sound, Russian Manchuria, very long ago, and was collected by Oldham in Korea and its islands in 1863, it is, from the general cultivator's point of view, still a new plant. It is only since the introductions by WILSON, from China, where he found many species of deciduous *Rhododendrons*, mostly, however, with smaller flowers, that this type has come into wider cultivation in this country. The Japanese have this species in cultivation in the city of Jedo, where they call it *Kurofune tsutsusi*. It belongs to the type of *Rhododendron*, which markedly shows the necessity botanists found for including the garden genus *Azalea* with *Rhododendron*, for here, as with other species, we have a shrub bearing the soft, thin-textured, hairy leaves of the *Azalea* and the flowers of the conventional *Rhododendron*. The flowers are produced in loose umbels; the corolla is about three inches in diameter, and of a charming soft, rose-colour, with reddish-brown spots towards the base of the upper lobes. Our illustration is from a plant growing in the Royal Gardens, Kew, where it is quite hardy, and forms a bush three to five feet in height. This type of *Rhododendron* is distinct in character, possesses great outdoor garden value, and may easily be forced into bloom for conservatory decoration.

HAYWARDS HEATH HORTICULTURAL SOCIETY.—The executive of this society, feeling that it has become advisable to extend its scope, has decided to alter the title to "The Haywards Heath and Mid-Sussex Horticultural Society," so that the whole of the district may be included in its sphere of influence. It is also suggested that in order to concentrate its energies on the summer show the exhibition which has hitherto been held in the autumn shall be abandoned, and a sum of £200 is to be offered in prizes at the summer show. The secretary is Mr. GEO. PREVETT, The Rosary, Haywards Heath.

TOBACCO-GROWING IN BRITAIN.—In view of the interest which is being taken in the cultivation of Tobacco in this country, the Customs returns, showing the great increase in the crop, are of value. In 1906 the crops in Ireland amounted to 7,353 lbs., on which a duty of £736 was paid. In the next year the yield had increased to 20,173 lbs., and the duty paid was £2,113. During the year ending March 31, 1913, Ireland supplied 123,997 lbs. of Tobacco, whilst in Scotland, where this crop was first cultivated in 1911, last year's yield was 2,225 lbs. English-grown Tobacco did not find a place on the returns until 1912, when 319 lbs. were chargeable to duty; in 1913 the amount had risen to 8,004 lbs. In the whole of the United Kingdom 139,226 lbs. were grown, and the duty amounted to £23,963.

KEW GARDENERS' SOCIAL EVENING.—The 17th annual social evening of the gardeners at the Royal Gardens, Kew, will be held on Friday, January 16, at the Boat House Hotel, Kew. All old Kewites who intend to be present are asked to notify the hon. sec., Mr. G. E. JOHNSON, 8, Waterloo Place, Kew.

A PRECOCIOUS RHODODENDRON.—Mr. J. D. ROBERTSON, superintendent of the City of London Cemetery, Little Ilford, Essex, kindly sends a photograph taken on December 18 last of a *Rhododendron* in bloom in the cemetery, remarking that if no frosts occur many more flowers will open.

PRESENTATION TO MR. W. A. COOK.—On relinquishing his charge at Leonardslee, Mr. W. A. COOK was the recipient of mementos from the garden staff and the local public hall and cricket club.

PUBLIC PARK FOR LEIGH.—LORD LILFORD has offered to the Town Council of Leigh, Lancashire, 38 acres of land, including Bedford Wood, at a nominal rental of 10s. per annum, as a public park. The law of entail prevents the free gift of the property, which is near to the town.

NATIONAL HORTICULTURAL SOCIETY OF FRANCE.—The annual election of officers of the National Horticultural Society of France has resulted in several important changes in the constitution of the society. M. ALBERT TRUFFAUT, who has been the premier Vice-President since the death of M. HENRI DE VILMORIN, has retired on account of indisposition. His place has been filled by M. ABEL CHATENAY, who for many years has acted as Secrétaire-Général of the society. The Secrétaire-Général is M. ALFRED NOMBLLOT, of the well-known firm of NOMBLLOT-BRUNEAU AND Co., and the Assistant Secretary will be M. LEON LE CLERC. In order to give the provincial nurserymen a share in the management of the society other changes have been made. There are now two Vice-Presidents chosen from the Paris region, namely, M. PH. DE VILMORIN and AUG. NONIN, and two for the provinces, viz., MM. ALBERT BARBIER, of Orléans, and LOUIS LEROY, of Angers. Proportional representation on the Council has also been provided for the provinces, and we notice that MM. PH. RIVOIRE, of Lyons, Dr. VIDAL, of Hyères, MURNARD, of Lille, and DENAÏFFE, of Carignan, have been added to that body.

A NEW AGRICULTURAL JOURNAL.—We notice that a new weekly agricultural journal has just appeared in France called *La Terre*. It is the organ of the agricultural section of the recently established Republican Committee of Commerce, Industry, and Agriculture. It is published under the direction of M. DECKER DAVID.

SCOTTISH SOUTHERN COUNTIES GARDENERS' ANNUAL DINNER.—The annual dinner of the Scottish Southern Counties Gardeners' Association took place at Dumfries on the 19th ult., about sixty being present, under the chairmanship of Mr. W. STURROCK, Larchfield Nurseries, Dumfries. The toast of the evening, "The Gardeners," was proposed by Mr. CRAWFORD, of Messrs. LITTLE AND BALLANTYNE, Carlisle, and replied to by Mr. CRICHTON, Kinmount Gardens. Other toasts were proposed, and songs were sung by a number of gentlemen. A collection was taken on behalf of the Royal Gardeners' Orphan Fund and a satisfactory sum obtained. The committee consisted of Messrs. STURROCK, E. J. JOSS, J. BROWN, W. HUTCHINSON, T. PRITCHARD, J. CROALL, and J. McLEOD. Mr. W. TAYLOR was secretary.

HORTICULTURAL INSTRUCTION IN MIDDLESEX.—The Higher Education Committee of the Middlesex Education Committee, having considered the question of agricultural and horticultural instruction in the county, has recommended the following scheme as an experiment:—Two scholarships to be offered each year (the value to be £20 per annum for the first two years, to be increased to £50 in the third and fourth years); the scholarships to be open to pupils of 16 and under 18 years of age; and, further, that, subject to the payment of a moiety of the cost by the Development Commissioners, the Education Committee enter into an arrange-

ment with University College, Reading, for a period of three years to deal with plant diseases in Middlesex at an estimated cost of £300 per annum. These recommendations have been adopted, with the addition that the scholarships should be open to boys of parents residing in Middlesex.

THE PRODUCTION OF HAIRS ON TROPAEOLUM PERGRINUM.—All good conjuring is done by means of simple devices, and the magic of Nature is doubtless wrought by means as simple as they are obscure. Thus a simple observation led Mr. A. W. HILL to conclusions of extreme interest with respect to the production of hairs on the stems and petioles of the usually glabrous Canary Creeper (*Tropaeolum peregrinum* L.)—the "canariensis" of our gardens. Mr. HILL observed that a plant, the leaf-blades of which had been eaten by snails, produced a few hairs. Taking the hint, he experimented with seedlings of this species, removing the leaf-blades successively as they formed, and thereby compelling the plant to utilise its green petioles and stems for assimilatory and transpiration purposes. As a result of the operation, Mr. HILL found that dense tufts of hairs are

THE KEEPING OF POULTRY.—We have before us a little book with the alluring title, *Profitable Poultry Keeping*,* and it contains helpful advice and information, imparted in simple language, many illustrations of apparatus to be used on a poultry farm, and photographs of examples of the different breeds.

GLASGOW SEED AND NURSERY TRADE ASSOCIATION.—At the ninth annual dinner of this association, which was held on December 20 last, in Ferguson and Forrester's Restaurant, Glasgow, Mr. T. B. B. KERR presided over a large gathering of members. In responding to the toast of "The Seed and Nursery Trade" the chairman alluded to the great antiquity of their calling, and spoke of the climatic difficulties with which they had to contend. The great advance in popularity of the Sweet Pea could be realised when a recently published catalogue enumerated 280 varieties, whereas in 1855 only four varieties were listed, and as late as 1899 a well-known Glasgow firm mentioned in their catalogue only four named varieties and four separate colours. During the twenty-five years he had been in business in Glasgow he had seen many changes, and of the firms then in being only four now

flowers, Borage, Ericas, Aubrietia Dr. Mules, Gaillardias, Chrysanthemums, Achilleas, Berberis Darwini, Periwinkles, Veronicas, Violets, Papaver orientalis, Centaurea alba and rosea, and *Centranthus rubra*.

ANNUALS FOR 1914.—The annual output of year-books and diaries is as great this season as ever, and gardeners and farmers are provided for not less than other trades and professions.

The Gardeners' Diary, published by the Royal Horticultural Society, has quickly found a very large public, and the new edition has several advantages over the earlier issues. It contains reliable information on gardening subjects, the usual diary matter, and space for recording memoranda under each date throughout the year.

The Horticultural Directory, published by the *Journal of Horticulture*, is an indispensable guide to those who are in need of ascertaining the names and addresses of persons engaged in any department of horticulture.

Foresters' Diary.—From W. RIDER AND SON, LTD., we have received a copy of WEBSTER'S *Foresters' Diary*, a useful notebook now in its twelfth year of publication. The diary is small enough to go easily into the waistcoat pocket, but, being printed on India paper, the pages are numerous enough to contain a large amount of useful information on forestry, including a list of foresters in the United Kingdom. The diary gives ample space for notes and several pages for cash account.

Vinton's Agricultural Almanac and Diary.—We suppose that there are few farmers who now begin the year without a copy of *Vinton's Agricultural Almanac and Diary* in which to record the various operations of the year. The book forms a kind of encyclopaedia and diary in one, for the first half contains a mass of useful information, chiefly statistical and official. A diary with ample space for notes and memoranda, a carefully compiled breeders' table, and a cash account, complete this most useful work.

The Smallholder's Year Book is a compendious volume, containing information of the most varied kind and helpful illustrations. Advice is given on many subjects that will interest the small landholder, and the prospective holder is told, in the plainest and simplest way, how to obtain his land in the cheapest manner.

Live Stock Journal.—From Messrs. VINTON AND Co. we have received a copy of the *Live Stock Journal Almanac* for 1914. The almanac begins with a comprehensive breeders' table, and is followed by a series of interesting articles upon different breeds of stock by well-known experts. A number of illustrations of fat stock give variety to the work, and the last pages are occupied by a quantity of useful information of various kinds, including a directory of breeders.

Who's Who, which has issued for so many years from the well-known house of A. and C. BLACK, has become a familiar household friend. The volume is indispensable, and we wonder how it was possible to be accurate in matters which *Who's Who* treats upon when the only book of the kind obtainable was the *Peerage*—of very limited scope, naturally. From the same publishers we have the *Who's Who Year Book*, to be used with the larger volume. The information in the year book is classified under different headings, not, as in *Who's Who*, only under an alphabetical list of surnames. Messrs. BLACK also send us another handy volume, this time of a specialist nature—the *Writers and Artists' Year Book*. The book is in effect a directory of publishers classified in various ways, and gives the fullest information about each, for the use of authors and artists who wish to obtain publication for their productions. It is interesting to find a largely-increased space given to the subject of cinema plays—or "scenarios," as they are often erroneously called—a subject which has leapt to the front rank of public in-

FIG. 5.—CATTLEYA PERCIVALIANA ALBA LADY HOLFORD.

(Awarded R.H.S. First-class Certificate on December 16, 1913.) (See p. 3.)

produced by the plant in the course of a few days. Evidently, therefore, this production of hairs is connected with the arrest of growth and the abnormal condition of the plants with respect to water.

ON GRAFTING LILACS.—Mr. C. S. HARRISON, of Nebraska, has contributed to a recent issue of *Horticulture* an interesting article on the grafting of Lilacs. He observes that in the Northern States of America Privet is a poor stock, and that he uses *Syringa vulgaris* for grafting. Mr. HARRISON insists that of the two types of root of the common Lilac, that with a tap root is the softer, the type with well-developed lateral roots being liable to "sprout." Japanese and Chinese tree Lilacs may be grafted on the latter type of vulgaris; the procedure being to wait until the graft has thrown out roots of its own and then to lift the plants and remove all the vulgaris roots. The roots of the Rouen Lilac, which also do not sprout, may be used for stocks for any of the vulgaris family. The reciprocal graft may also be made. Mr. HARRISON speaks highly of the Chinese Tree Lilac, which his firm introduced into the Western States. It grows fast and blossoms in summer, bearing a mass of fragrant white blossom. These Lilacs are best grown on their own roots or as grafts on the "Western Green Ash."

remain. Referring to the early closing movement, Mr. KERR said that the one o'clock closing was a boon, but he felt that the trade required some consideration in this respect during their busy seasons, and a relaxation of the rule would be beneficial to business. The toast of "Horticultural Interests" was given by Mr. J. DOBSON, and responded to by Mr. JAMES WHITTON.

UNSEASONABLE FLOWERS.—Until Wednesday last information continued to reach us of flowers blooming out of season in various parts of the country. Mr. R. C. NORCUTT, of the Woodbridge Nurseries, sent us on the 23rd ult. two blooms of Frau Karl Druschki Rose and one of La France, which he gathered on the coast near Woodbridge, Suffolk. Mr. NORCUTT describes them as the best specimens he has ever seen out-of-doors at so late a date, and there is every reason to believe his word, for in general development they appear good enough for an N.R.S. exhibition. Another correspondent, writing from Messrs. BROWN'S nurseries at Wetherope, near Stamford, states that the following plants were in bloom out-of-doors on Christmas Day:—Pansies, Violas, Reses, Primroses (double and single), Carnations, Statice, Polyanthus, Trollius, Scabiosa caucasica, Wall-

* The Proprietors (C. Arthur Pearson, Ltd.) of the *Smallholder*, price 1s.

terest in a few short years. Another directory from the same enterprising firm is the *English-woman's Year Book and Directory*, and it may be recommended to any woman who takes an intelligent interest in matters connected with the feminist movement.

AGATHIS VITIENSIS.

IN Australasia the genus *Agathis* has great economic importance. *A. australis*, the Kauri Pine, has been described as the "monarch of the New Zealand forest," where it towers up with a straight trunk to a height of 180 feet,

a girth of 15 feet. In the interior of the larger islands of the Archipelago the resinous gum which exudes from the trunk is made into pastilles, and narrow strips enclosed by pieces of wood are used for illuminating purposes in the smaller islands. This gum is called Makadre, and from the smoke the natives obtain a pigment which they use for personal adornment. The illustration of a branchlet and cone from a tree growing in the Mexican House at Kew shows the character of this member of the Conifer family. The leaves are of a pale green colour, and vary in length from 3½ to 5 inches, and the male catkins are of cylindrical shape. The Kew tree was raised from seeds presented by Sir J. B. Thurston in 1881 whilst he was Governor of Fiji. The

NOTICES OF BOOKS.

WILD WHEATS.*

How few of us realise the antiquity and romance associated with the plant whose grains have furnished the daily bread of generations of mankind for thousands of years. Among the early Greeks and Romans Wheat was the chief cereal, and the Wheat-fields of ancient civilised races of Egypt and Western Asia must have been extensive. Some forms of Wheat were even grown by Neolithic man and the tribes who formed prehistoric settlements in Switzerland and other parts of Central and Eastern Europe.

To-day this cereal is indispensable to the most intelligent and progressive of the white races, and only in backward countries is Rye still the

FIG. 6.—FOLIAGE AND CONE OF AGATHIS VITIENSIS.

[Photograph by C. P. Raffill.

and in favourable circumstances attains to a girth of 40 feet, and lives to a great age. The timber is used for a variety of purposes, its durable nature, straight grain, strength and elasticity recommending it to ship-builders, carriage-makers, bridge-builders, carpenters, whilst it is used even for making sounding-boards for pianofortes. The sap-wood contains a deal of resin, and consequently possesses great calorific value, whilst the value of the Kauri gum is well known. Many other species of *Agathis* are natives of the Continent, and of these *A. vitiensis*, which occurs in mixed forests in the Fiji Archipelago, is valuable to the Fijians. This species becomes a tall tree, a hundred feet high, with a clean stem of some sixty feet; an occasionally fine specimen will have

plant was removed from the tropical palm house in 1897 to the newly-built Mexican house, where it has grown well and is now 25 feet high. None of the species of *Agathis* (syn. *Dammara*) may be grown satisfactorily out-of-doors in this country. The late Mr. Jonathan Rashleigh planted a small tree of *A. australis* in his very interesting garden at Menabilly, Cornwall, where it eked out a short and rather miserable existence.

bread-corn of a large portion of the population; coincident with an improvement in the standard of living comes the substitution of Wheat for Rye.

The determination of the prototypes or wild species from which our domesticated plants have arisen involves many intricate problems of variation, history and philology. Yet, in spite of the fact that not a single cereal or food plant of prime importance has been brought into use from wild stock during the last 3,000 or 4,000 years, the prototypes of the majority of our cultivated crops can be traced without much difficulty. A few there are, however, whose origin continues to baffle us, and among these Wheat occupies a

PUBLICATIONS RECEIVED.—*The Manuring of Market-Garden Crops.* By Bernard Dyer and F. W. E. Shrivell. New edition. (London: Vinton and Co., Ltd.) 1s.

* *Agricultural and Botanical Explorations in Palestine.* By A. Aaronsohn, U.S. Dep. Agric. Bur. Pl. Ind. Bull. 180. *Wild Wheat in Palestine.* By O. F. Cook, U.S. Dep. Agric. Bur. Pl. Ind. Bull. 274.

leading place. So ancient is its history that to the races who grew it 4,000 or 5,000 years ago its origin was as obscure as it is to us. Romance and legend alone supplied them with its story through the kindly services of the beneficent goddesses—Isis, Osiris and Ceres.

The Wheats in cultivation in various parts of the world fall into two groups, viz.—(1) the "Spelts," whose ears break into short fragments, each with a single spikelet attached and whose grain cannot be shaken from the glumes by thrashing; and (2) the Wheats proper, whose ears possess tough axes and readily yield their grains free from the enclosing chaff.

To the former belong:—(1) One-grained Wheat (*Triticum monococcum*), (2) Emmer (*T. dicoccum*), and (3) Common Spelt (*T. Spelta*).

The representatives of the second group are:—(1) The Macaroni and Polish Wheats (*T. durum* and *T. polonicum*), (2) the Rivet Wheats (*T. turgidum*), and (3) the Common Bread Wheats (*T. vulgare*), with which may be associated the so-called Dwarf Wheats (*T. compactum*).

The relationship of these Wheats to each other is still obscure; yet there is little doubt that the tough-eared forms were derived from the brittle-eared Spelts or from wild grasses resembling the latter.

The absence of the brittle rachis reduces their power of dissemination, and among the many hundreds of varieties of cultivated Wheats none has been found capable of maintaining itself as an "escape," and no truly wild form has been discovered in any part of the world which exhibits a close resemblance to any of the macaroni or bread Wheats.

The prototype of one-grained Wheat (*T. monococcum*) has been recognised, however, for more than fifty years in *Triticum aegilipoides* (Balansa), a wild species found in Serbia, Greece and parts of Asia Minor. *T. monococcum* was known to the ancient Greeks and is still cultivated to a slight extent in barren regions of Spain, Austria and the Balkan Peninsula. It has given rise to very few varieties, and the morphological resemblances between the wild species and the cultivated kinds are so close that the connection between them is obvious and undisputed.

T. monococcum stands somewhat alone in its distinctness from other Wheats—even from other Spelts—and its refusal to yield fertile offspring when crossed with these support the view that it is not likely to have been one of the ancestors of our bread Wheats.

It is to the unravelling of the ancestry of the bread and macaroni Wheats that so much interest has always been attached, and a stimulus and new impetus have been given to the research by the discovery of a wild Wheat in Northern Palestine by Mr. Aaronsohn, the Director of the Jewish Experiment Station at Haifa. The same species had, indeed, been collected by Kotschy in 1855 in the neighbourhood of Mount Hermon, but only a single specimen was known in the National Herbarium at Vienna. In 1906, however, Mr. Aaronsohn found it growing in abundance in the same district, and subsequently in the Jordan Valley.

The late Professor Koernicke, the German authority on cereals, who was especially interested in Kotschy's plant, named it *Triticum vulgare dicoccoides*, considering it a form of Emmer (*T. dicoccum*) and the probable ancestor of our cultivated Wheats.

The plant grows freely along roadsides and in the crevices of limestone rocks in districts away from cultivated fields, and, according to Mr. Cook, is in many places the dominant grass. There appears to be little doubt that it is a truly wild species, differing completely from any of the domesticated Wheats grown in the same region, some of which are found as "escapes."

The jointed rachis is exceptionally fragile. The glumes possess long, barbed awns and the spikelets contain one or two elongated grains. The flowers are adapted to cross-fertilisation,

and considerable variation is found among individual plants.

Although in some of its characters it bears a resemblance to *T. dicoccum* and has been named Wild Emmer, the evidence that it is the prototype of the cultivated Emmers is not clear; still more uncertain and obscure is its relationship to the bread and cultivated Wheats.

Observation of living specimens which I have grown during the last two years from grain kindly given me by Professor Biffen rather supports the view that it is a species distinct from the Emmers; it is not impossible that some forms are crosses with cultivated varieties of *T. durum* and *T. vulgare* which are grown in Palestine and Syria.

There is yet a wide gulf between this plant and any of the known varieties of macaroni, rivet or common Wheat, nearly two thousand kinds of which I am growing at Reading this year. Nevertheless, the wild Wheat of Mount Hermon, to which the suggested name of *T. hermonis* may be applied in place of *T. dicoccoides*, is of much interest and provides material for researches which may ultimately throw light upon the origin of the plants from which we obtain our daily bread. *John Percival*.

TREES AND SHRUBS.

A RARE PAMPHLET ON CONIFERS.

THE rare pamphlet, entitled *Botanical Expedition to Oregon*, is of considerable importance, as it contains descriptions of Conifers collected by Jeffrey in North America, and is the authority for the scientific names of several important trees. No account of it appears to have been published. There is a copy in the library at Kew, and another at Edinburgh.

The pamphlet is made up as follows:—An introductory page signed "By order of the Committee, Andrew Murray"; five separate plates, being drawings of cones, seeds and leaves; and pages 1 and 2 of notes and descriptions of some of the plants received from Jeffrey,* who was sent out by the Oregon Committee of Scotland in June, 1850. There is no printed date on the pamphlet, but Prof. I. B. Balfour tells me that the actual date of publication was the first week of September, 1853. There is no doubt about this date, or the fact that the publication was real, as Sir W. J. Hooker, in *London Journal of Botany*, v. 315 (1853), criticises severely the publishing of names to which were attached as authority the words "Oregon Committee." In this he was hypercritical, as on the introductory page the plain statement is made: "Figures and descriptions by Dr. Greville and Professor Balfour of the cones and seeds of the Coniferae." The figures, as mentioned on the plates, which are not numbered, were drawn by R. K. Greville; but the descriptions were written by Prof. J. H. Balfour,† and the name of the latter must be attached to the new species described.

In most books‡ on Conifers the authority "Andrew Murray" or "Oregon Committee" is wrongly given to the species in question, an unfortunate circumstance due to the introductory page of the pamphlet not having been carefully read.

* An account of Jeffrey's life is given in Lawson's *Pisietum Britannicum*, reproduced by Veitch, *Manual of Coniferae*, 1st ed., p. 166 (1888).

† Prof. J. H. Balfour, in a private letter written to Andrew Murray, dated Oct. 13, 1853, says, referring to Hooker's criticism: "All the committee was anxious to make known were the Coniferae, of which they here give drawings, along with notes by me in regard to them. The cones were all I examined." This letter was obligingly communicated to me by Prof. I. B. Balfour.

‡ The following references require correction in the cases where *Pinus Jeffreyi*, *Balfouriana*, and *Murrayana* are mentioned:—Sargent, *Silva N. America*, xi., pp. 59, 79, 91 (1897), and *Trees N. America*, p. 8 (1905); Sudworth, *Check-List of Forest Trees of United States*, pp. 15 and 16 (1898) (published as *U.S. Forestry Bulletin*, No. 17), and *Forest Trees of the Pacific Slope*, 3, 39, 47 (1908); Masters, in *Journ. R. Hort. Soc.*, xlv., 225, 231 (1892), and in *Journ. Linn. Soc. (Bot.)*, xxxv., 646 (1904); Veitch, *Man. Conif.*, 314 (1900); Beissner, *Nadelholzkunde*, 263, 272 (1891).

The following is a list of the Conifers described and figured in the pamphlet, the correct citations being given in each case:—

1. *Pinus Balfouriana*, Balfour, in Murray, *Bot. Exped. to Oregon*, I, with fig. (1853). This species is here for the first time described and named.

2. *Pinus Jeffreyi*, Balfour, in Murray, *Bot. Exped. to Oregon*, 2, with fig. (1853). This tree, here first described, is considered to be a distinct species by Sudworth and other writers; but Sargent considers it to be *Pinus ponderosa*, Lawson, var. *Jeffreyi*, Vasey, in *Rept. Dept. Agric. U.S.*, 1875, p. 179 (1876).

3. *Pinus Murrayana*, Balfour, in Murray, *Bot. Exped. to Oregon*, 2, with fig. (1853). This Pine, here first described, is kept up as a distinct species by many authors; but according to Sargent, it is *Pinus contorta*, Douglas (ex Loudon), var. *Murrayana*, Engelmann, in Brewer and Watson, *Bot. Calif.*, ii. 126 (1880).

4. *Pinus tuberculata*, Gordon, is said by Balfour, in Murray, *Bot. Exped. to Oregon*, 2, with fig. (1853), to have been collected by Jeffrey in lat. 41° at 5,000 feet elevation. The figure of the cone is excellent.

5. *Pinus lasiocarpa*, Balfour, in Murray, *Bot. Exped. to Oregon*, 1, with fig. entitled *Picea lasiocarpa* (1853) (not Hooker).

This tree, of which the cone, scale, bract, and seed are figured, is not *Abies lasiocarpa*, Nuttall, the Silver Fir of the Rocky Mountains, which was first described by Sir W. J. Hooker as *Pinus lasiocarpa*. The figure appears to represent *Abies amabilis*, Forbes, which occurs on the coast range of Oregon, where Jeffrey collected. It is interesting to note that this species, which was discovered by Douglas in 1825, seeds having been sent by him in 1830, is generally supposed not to have been seen again till Sargent and Engelmann found it in 1880. Old trees of this beautiful Fir are very rare in Britain; and there is no evidence that any of these were raised from seed sent by Jeffrey.

5. *Abies Pattoniana*, Balfour, in Murray, *Bot. Exped. to Oregon*, 1, with fig. (1853). This is identical with *Tsuga Pattoniana*, Sénéclauze, the Hemlock Spruce with large cones, which is now generally known in America as *Tsuga Mertensiana*, Sargent. The specimens here described by Balfour were collected by Jeffrey in the Cascade Mountains, lat. 42°. Specimens of the same tree, collected by W. Murray in 1854, on Scots Mountain, lat. 41°, were unfortunately published by his brother as *Abies Hookeriana*, A. Murray, in *Edin. New Phil. Journ.*, 289 (1855). Both the names, A. *Pattoniana*, Balfour, and A. *Hookeriana*, Murray, apply to the same thing, the wild tree in America, which is characterised by bluish leaves, entire in margin, and with conspicuous stomatic lines on both surfaces.

Other specimens preserved in the Kew herbarium, which were collected by Jeffrey on the Mount Baker range, lat. 49°, are identical with the preceding in all respects; but from the seeds that were sent by Jeffrey from this locality, plants were raised which differed in having green leaves, serrulate in margin, and with regular stomatic lines only on the lower surface. The peculiar variety, with green serrulate leaves, was supposed erroneously by Murray to be A. *Pattoniana*, Balfour. It has been named by me, *Tsuga Pattoniana*, var. *Jeffreyi*, Henry, in *Elwes and Henry, Trees of Great Britain*, ii. 231

§ Masters, in *Journ. Linn. Soc. (Bot.)*, xxii., 174 (1887), relying on Barron, in *Gard. Chron.*, v., 78 (1876), erroneously identifies this cone with *A. grandis*. In Barron's nursery at Elvaston the names of *A. grandis* and *A. amabilis* were reversed, as is evident from A. Murray's article in *Proc. Hort. Soc.*, vol. iii. (1863).

¶ The names A. *Pattoniana* and A. *Hookeriana* are both applied in gardens to the typical wild tree; specimens with very glaucous foliage being called by the latter name, whilst less glaucous examples are called by the former name. The typical form has always leaves more or less glaucous, never truly green as in var. *Jeffreyi*. In America, a supposed Alpine form, differing only in its stunted habit, has been identified erroneously with A. *Hookeriana*.

(1907). It has never borne cones, and is now very rare in cultivation; and, so far as I am aware, has not been observed in the wild state in America. It seems to have been either a sport or mutation, or possibly a hybrid between *Tsuga Pattoniana* and *Tsuga Albertiana*, as both these species occur on the Mount Baker range.

7. *Thuja Craigana*, Balfour, in Murray, *Bot. Exped. to Oregon*, 2, with fig. (1853). I stated in *Gardeners' Chronicle*, LIII., 325 of May 17, 1913, that this was the first description of the species, which has long been known as *Libocedrus decurrens*; and that, consequently, the correct name should be *Libocedrus Craigana*, Low, ex R. Brown, in *Trans. Bot. Soc. Edin.* ix. 373 (1868).

I have recently, however, received new information from the Arnold Arboretum, concerning the date of publication of Torrey's *Plantae Frémontianae*, which contains his description of *Libocedrus decurrens*. Mr. Rehder states that there are two sets of this paper in existence. The set, which I believe has invariably been quoted, is part of the bound Volume VI. of *Smithsonian Contributions*, which has the date 1854 on the title-page. The other set, hitherto practically unknown,* seems to have been intended for separate distribution, and bears on the title-page the following:—"Published by the Smithsonian Institution, April, 1853." As the Oregon Committee's pamphlet appeared in September, 1853, the name *Libocedrus Craigana* is invalid. Torrey's name has priority; and the correct citation of the species is *Libocedrus decurrens*, Torrey, *Plantae Frémontianae*, 7, t. 3 (1853). It is very satisfactory that this old-established name need not be changed.

8. *Pinus flexilis*, Balfour, in Murray, *Bot. Exped. to Oregon*, 2, with fig. (1853) (Not James).

This is not identical with the true *Pinus flexilis*, James, *Long's Expedition*, ii. 34 (1823); but is the same as *Pinus albicaulis*, Engelmann, in *Trans. St. Louis Acad.* ii. 209 (1863). A. Henry.

HOME CORRESPONDENCE.

JASMINE FRUITING.—Enclosed is a fruiting spray of the common White Jasmine—*Jasminum officinale*. I do not think that this creeper often matures fruit in this country. When the blossoms are visited in summer by bumble-bees, I notice that the insects insert their proboscides between the calyx and the corolla (and not down the corolla itself). This is, perhaps, the reason why fertilisation is not usually accomplished. There are several fruiting sprays upon the plant from which I picked this yesterday, and last year it fruited also comparatively freely. The fruits appear in late autumn, are pale green, and during November they turn a jet-black colour. I should like to know if the fruiting of this plant is of frequent occurrence in this country? J. E. Shaw, 23, Caledonia Place, Clifton, Bristol, December 17.

DWARF DAHLIA "MARIANNE."—I have been informed that this Dahlia was in the trials at Duffryn and that it showed up well. I cannot understand why it has been missed out of the report, because there can be no two opinions about its being the best dwarf decorative Dahlia in existence. You called attention to it in your columns last year, and in consequence I grew it largely, and found its charming apricot-coloured flowers invaluable for cut-flower work, while the plants, about 2 feet in height, were objects of beauty in the border for months. Grower.

RASPBERRY BELLE DE FONTENAY.—In Mr. Goodacre's article on "Autumn Fruiting Raspberries," in the issue for December 20, he states that no other variety can compare with *Queen Alexandra* for late and certain cropping. This may be Mr. Goodacre's experience, but in case cultivators may

be inclined to cast other varieties aside as inferior I should like to state that for the past three seasons three varieties have been grown in a large garden in Hertfordshire, namely, *Belle de Fontenay*, *Queen Alexandra*, and *November Abundance*, and *Belle de Fontenay* was easily the best for size of fruit and prolific crop. The stools are not lifted annually, but the crop last season—the third in succession—was satisfactory. A. Allen, Pond's Farm Gardens, Beaconsfield.

CHRYSANTHEMUM MADAME C. DESGRANGE.—I am interested in the statement made by Mr. Norman Davis (see vol. LIV., p. 450), that this remarkable variety originated as a "chance seedling among a batch of late varieties." This fact is as remarkable as the variety itself, and I know of no parallel to it, namely, a late variety producing an early seed sport. I suppose Mr. Davis has good grounds for his statement. It is further stated that "its raiser finds no interest in it," which, inferentially, is tantamount to saying that its raiser was known, if not to Mr. Davis, at least to the "French nurseryman into whose hands it passed." I have for years tried to find out who raised *Madame Desgrange*, and have never succeeded. Is it possible that Mr. Davis can tell us? Finally, it is stated that "*Madame C. Desgrange* eventually passed into the hands of Mr. Robert Parker, of Tooting." If by this it is to be inferred that Mr. Parker obtained possession of the whole of the stock, or even a goodly portion of it, the statement is incorrect. Mr. Parker's original stock was comprised of one plant only, which did not come by way of France. This is its history. Mr. Parker had been on a business journey to Wales, and in returning called on a friend in Bristol in whose garden there were two fine plants in full flower. Recognising its merit as an out-door variety, Mr. Parker expressed a wish to have it, and in due course one of the plants found its way to Tooting. This was not later than 1873, since in 1874 or 1875—I believe the former year—two long lines of *Madame Desgrange* occupied positions in one of the huge specimen beds for which the Tooting "Exotic Nursery" was then famous. Other lines of plants in this particular bed were of *Kniphofia aloides* (centre), then two lines of *Desgrange*, one on either side, followed by *Aster amellus*, *Rudbeckia Newmanii* and a border of *Verbena venosa*, two lines of each. These plants were all in flower together, and were the admiration of those who saw them. I had met with many erroneous statements concerning the early history of *Madame Desgrange* and when with Mr. Parker a year or two before his death I purposely enquired how he first became possessed of it. What I have stated above is in effect his own words. Moreover, the variety was grown at Tooting in my day, forty years ago, hence the statement is backed by my personal knowledge. E. H. Jenkins.

Buddleia COLVILEI.—*Buddleia Colvilei* does not often flower freely at this time of the year. There is, however, a plant growing in the open border in these gardens, carrying a quantity of blossom. On Christmas Day I counted over 20 flower-spikes fully developed, and there are numbers of branches on which the flower-buds are just showing colour. The *Buddleia* was planted about ten years ago, and has blossomed on three previous occasions, but never so freely or so late in the season as now. The flowers are distinct from those of all other *Buddleias*, and resemble the rosy-red blossoms of a *Pentstemon*. The foliage is a kind of silver-grey. It is a strong-growing subject, but unlike others of the species it does not flower until it has been established for some years. Growing in the same border with the *Buddleia* is a large bush of *Eriobotrya japonica* (the Loquat), in full flower. It has occupied its present position for about 12 years, but this is the first time it has blossomed. It is generally planted against a wall, but it makes a magnificent bush in favoured situations. The plant prefers a rather light, loamy soil, and is readily increased from cuttings or layers. F. W. Rich, Elfordleigh Gardens, Plympton.

PRIMULA OBCONICA AND SKIN IRRITATION.—I have worked among plants of *Primula obconica* for a number of years, and have never felt any ill-effects until this season, when I have suffered

irritation on two occasions after handling the plants. The first time the irritation lasted about four days, but latterly it has been more severe, and I have had to seek medical advice. W. Marsh, Markeaton Hall Gardens, Derby.

NATIONAL ROSE SOCIETY.—From the statement made at the recent annual meeting of this society it seems to be a wealthy body, and its popularity is demonstrated by the annual influx of new members. It may be assumed that the Rose is destined to be more largely grown in the future even than in the past. The introduction of so many desirable varieties increases the interest of the flower, especially to exhibitors, of whom amateurs form a large proportion. No doubt the great number of improved forms of climbing Roses, especially in the *Wichuraiana* section, has done much to popularise the flower in small gardens as well as in larger ones. This form can be employed, for instance, in providing screens to hide unsightly corners, at the same time giving a great wealth of blossom. I would like to point out to the Executive of the society that the time has come when drastic changes should be made in the arrangements for the great festival held each year in the charming grounds of the Royal Botanic Gardens, Regent's Park. Complaints are constantly made at the lack of tent room. This lack of space is particularly noticeable in the tent set apart for new Roses, which forms the centre of interest in the show. The tents are not only too small, but they are insufficiently ventilated for the reasonable comfort of visitors. Better ventilated tents, made on the principle of those used at Chelsea during the last two years, would prolong the beauty of the flowers, and provide means of inspecting them in more pleasant circumstances. Under existing arrangements the visitors are inclined to feel on a hot day that the visit to the show is hardly worth the inconvenience. A judicious expenditure in the provision of extra tent space would be welcomed by the members, and be the means of adding to the already long list of subscribers to the society. E. Molyneux.

PARMENTIER AND THE POTATO.—The centenary of the death of Parmentier has brought once again to public notice the legend that to his efforts we owe the Potato as a popular article of diet. The long continuance of this story is a remarkable comment upon certain methods of journalism and book-making. It has, however, occurred to two of the writers on Parmentier to read his book, and the following interesting passage is quoted by M. Gibault in his *Histoire des Légumes*. On page 1 of the *Examen Chimique des Pommes des Terres*, the book which was supposed to have convinced the French peasant that the Potato might be safely eaten, the following passage may be read:—"The use of this alimentary plant has been adopted for a century." Later, on p. 5, it is said that its culture was undertaken largely, and it was then (1770) a part of the poor man's food. "It is common in the markets, and is sold at the street corners, cooked or raw, as they sell chestnuts." Parmentier was doubtless interested in a certain variety of Potato, and adroitly secured a Royal advertisement for this sort, but those who eat potato "Parmentier" need not place the credit, or blame, as tastes may be, of this starchy product to his account. The wise advice, "Verify your references," was never better illustrated than in the history of Parmentier's elevation to a position he never thought of claiming for himself. Edward A. Bunyard.

GAS TAR AND MEALY BUG.—I may remind J. H. Y. (see page 427) that he has given us no new cure for mealy bug on vines, as the use of hydrocyanic acid gas was discussed in the *Gardeners' Chronicle* eight or nine years ago, and has been mentioned at intervals since, and if all who tried it had found it to be the safe, simple, and effective cure we wait for, probably there would have been very little mealy bug left in the kingdom to experiment on with gas tar or any other specific. I tried it before using gas tar, and whilst I agree with nearly all that J. H. Y. writes concerning its use for vines, I am of the opinion that to be effective on old vines the fumigation must be repeated several times to ensure the destruction of the young

* This set, with the correct date, 1853, is not cited in Sargent, *Silva*, x. 135 (1896); Veitch, *Man. Co. F.*, 253 (1900); Elwes and Henry, *Trees of Great Brit. in Ill.*, 489 (1908).

bugs, which hatch from the eggs laid in such places as the holes in the end of old spurs. It is for this reason that a really safe mixture which could be painted on the vines when they are being cleansed would be preferable. Many gardeners have to accommodate a variety of pot plants in vineries after the fruit has been cut, and I have not found the gas harmless to soft-wooded plants. I fumigated a vinery in early summer, which had been treated previously in winter, before the fruit commenced to colour, using a little under the strength recommended for bug and a little over that for greenfly; and a few *Chrysanthemums*, which were left in the vinery after the final potting, were cleared of the black fly which affected them, but the fumigation also scorched the tips of the young leaves. Another curious effect was noticed on some *Zonal Pelargoniums*. The edges of the very young leaves were scorched, and the younger flower-spikes, which had grown a few inches only, were black and withered, while the trusses which were just showing colour and the main leaves were uninjured. The Grapes on the vines were also unharmed, but the tips of the sub-laterals were affected similarly to the *Pelargonium* buds. I have used hydrocyanic acid gas for greenfly without injury to the plants, but, as is well known, mealy bug requires a stronger preparation, and it is this which causes the trouble. Will your correspondent kindly state the proportions necessary for vines, and the exact amount per 1,000 cubic feet he recommends for destroying bug on stove house plants, Cucumbers, Melons, etc., without injury to the plants? There is a similar preparation named "Hydrogas" which is said to be less dangerous, but I have not tried it. The users of gas tar do not "smear" their vines, they apply the tar with a brush, and when dry the canes look clean and glossy against the white woodwork and whitewashed walls of the vineries. *A. Shakelton, Forde Abbey Gardens, Chard.*

—Recent references in the *Gardeners' Chronicle* regarding coal gas tar as a remedy for the extirpation of this pest reminds me of a circumstance that occurred nearly fifty years ago under my own cognisance. The whole complement of vines in a large house were more or less injured by an application of gas tar and clay, inasmuch that while several of the least injured had to be cut back nearly to the base, others were supplanted by young vines. The rods in question had been subjected to the application of the insecticide in lieu of the annual dressing of "Gishurst Compound" or other remedies, which had been found more or less efficacious and had never injured the vines. In the case of the gas tar dressing, excessive peeling and scraping of the loose bark was partly responsible for the disaster, as proved by the fact that where merely the loose bark was removed, injury was not apparent; however, so far the remedy was worse than the disease. Shortly after the occurrence I was informed that had Stockholm pine tar been used instead of gas tar, little or no harm would have resulted. A small supply was procured, but as it was not required for the vines it was applied to fruit trees, such as Apples, Pears, Plums and others, with excellent results and no apparent injury to the trees. This result was obtained without the trouble of excorticating rough bark, which affords a ready shelter for the breeding and hibernation of the insects. It would be instructive if others who may have tried the wood tar remedy were to give their experiences of this as opposed to mineral tar. *William Gardiner, Horsham.*

MEALY BUG ON VINES.—Though I have used cyanide of potassium for many years as an insecticide I never employ it for plants such as *Codiaeums*. *Spider* will find vaporized nicotine an efficient and safe insecticide for bug and red spider on these and other plants. A risk always attends the use of cyanide, not only of injuring tender plants, but of poisoning any one who may inhale the gas. The latest formula I have seen gives $\frac{1}{2}$ oz. cyanide, 1 oz. sulphuric acid, and 2 oz. water per 1,000 cubic feet, the structure to be closed from dark to daylight. These amounts were to be doubled for mealy bug on vines at rest, the vines having been previously painted with wood alcohol (methylated spirits of wine). *B.*

NURSERY WAGES, PIECEWORK AND OVERTIME.—It was manifestly unfair to the Surrey nurserymen for the London daily papers to take up the so-called low wages given in that district, where for eight months in the year most of the regular hands are on piecework earning good money, and often the "hoeing men," having kept their acreage clean, have the chance of taking haying or harvest work in addition. Another point is that all the chief nurserymen keep their men on, wet or dry, in snow or frost, and thus they have that steady employment which is such a boon for the family, and far better than high wages as builders, etc., which often lead to extravagance, with liability to be dismissed at any time suddenly and no nest-egg to fall back upon. Nurserymen, too, are quick to recognise any workman who shows ability. As one of the first firms to introduce extended piecework and overtime in summer, I may say that it pans out greatly to the advantage of the men, and important work, requiring the greatest promptitude, is done quickly and carefully, the men often getting to budding at four o'clock in the morning, resting at noon, and resuming work until seven or eight at night. In my time wages have risen for nearly all grades ten shillings per week, and as we have several hands who have been all their lives with us, they know when they are well off. We are always ready to listen to any reasonable requests, consistent with the fact that the business has to pay and is not run as a charitable institution, and, like the rest of the trade, we can manage our own affairs without the assistance of any "soft-handed" agitators' interference. I enclose my card and on this occasion sign myself, *Experienced.*

JOURNEYMEN GARDENERS AND LOW WAGES.

—The remarks of *A. M.* on low wages for journeyman gardeners are interesting. It has long been recognised that the wages paid to these men are totally inadequate for the work they have to perform, and the long hours, with Sunday and weekly duty in their turn. The general wages are from 10s. to £1 weekly, and to reach the maximum sum entails quite 12 years' service. The bothy which goes with this remuneration is often not the sort of abode that appeals to a young man used to a good home. The prospects, considering the great increase in the price of necessities, are not sufficiently good to induce reliable, trustworthy men to enter the profession. *L. C., Surrey.*

—Employers must surely soon acknowledge that the wages paid to the garden staff is totally inadequate in these days of dear provisions. On all sides we hear of young men leaving the garden for service in other callings where the prospects of promotion and secure employment are the chief inducements. There are many reasons for the present low standard of wages. Many employers look no further when engaging a man than the matter of character and wages. If an excellent character is forthcoming and a low wage is asked, the candidate, be he never so poor a craftsman, stands as good a chance (if not far better) than a man who is thoroughly proficient. It has always been rather a mystery to me that the owner of an estate will spend large sums of money on trees, plants, and the equipment of a garden and then seek for a man to take charge who asks a low wage. I am well aware that through force of circumstances many excellent men are driven to accept low wages, and in such cases the employer has the advantage. There is another side, however: How often do we hear of the owners saying they have bought this, or that, spent so much on glass, so much on manure or sundries, and have only wretched results. Are they quite certain that they have a good man in charge, who is receiving a fair wage, is comfortably housed and content? Also that the members of the garden staff are receiving a fair wage and are working in conditions which are favourable? There are few professions in which more depends upon the individual engaged than in gardening. *Roamer.*

—I agree with your correspondents on p. 462. The charge laid by *A. M.*, supported by *L.*, in the issue of December 20, cannot be proved. Undoubtedly cases of too low payment exist, but they are exceptions, not the rule. My experience, extending over twenty-two years, convinces me that the journeyman's position is better to-day

than ever before. Never was his horizon larger; never, perhaps, was his ability less. With a mere smattering of knowledge he applies for posts he is unfitted to fill, and the duties pertaining to them he knows hardly anything about. Where is the head gardener who cannot point to the damage done again and again by the so-called experienced young men he has been unwise enough to place entire confidence in? Ten years ago young men knew their work, and did it thoroughly; if they did not out they went. I knew young men, strong, practical, civil, obliging, enthusiastic, devoted to the profession—qualities which scores of present-day journeymen appear never to possess. Our wages—12s., 14s., 16s.—were considered fair pay; 18s. was scarcely heard of. As for £1, 22s., 24s., with bothy, milk, etc., we never heard tell of these princely posts; Saturday half-days off, good yearly holidays, Christmas parties and boxes. Happy, some of us, if we had not to put in two or three hours most nights as overtime, for which we received nothing except the experience gained from doing the work. I am thankful to have seen an end to those bad times; they have gone because the supply of young men is limited, and those who refuse to pay fair wages must go without men or do the work themselves—which is as it should be. Between the nursery employee and the private gardener there can be no comparison. Many nurserymen and market gardeners would not take so-called experienced journeymen from private gardens if they would work for nothing; whilst many head gardeners would not employ nursery hands, even if they offered to pay for the privilege of being on the place. Every man to his trade is a good maxim for all of us. To-day 18s. is the standard wage for young journeymen—inside and out, with bothy, etc.—that brings his wage to anything from £1 up to 26s. per week. Every bothy I know of is comfortable enough for any reasonable workman. As Mr. Legg truly says, the upkeep of proper bothies is a much larger item than appears to some. Many a young journeyman is to-day better off than the head gardener. If *A. M.* and *L.* know their work and have good characters an advertisement in the *Gardeners' Chronicle* will bring them offers of good situations from all over the kingdom at 18s. and upwards. Respecting the B.G.A., there is a prejudice against it in some quarters through mistaken ideas of its aims. It was founded to protect alike the interests of the qualified gardener and the reasonable employer. This season now commenced will see the greatest scarcity of journeymen gardeners this country has ever known; the trouble will be acute both for the head gardener and his employer. Let us not shut our eyes to the fact; this is the journeyman's opportunity, and he is going to make good use of it; so much is a certainty. Having bettered his position, let us hope he will take a deeper, keener, truer interest in his work, thereby fitting himself to take the places of the old guard as they retire; many of whom they will find it difficult even to emulate. With Mr. Beeson, I appeal to them to study just a little more the interests of the employer and his head gardener, who has to teach them for nothing the secrets of a great and honourable calling. *Ed. A. Norris, Malquoits Gardens, Ewhurst, Surrey.*

—May I make a few further remarks in reply to *S. Legg* and *T. Beeson* on this subject? If Messrs. Legg and Beeson will scan the "Situations Vacant" column every week, and compare the cases where 19s. to 20s. is offered with those mentioning 16s. or so, I think they will find that two-thirds of them will offer the latter. Even if journeymen were paid 19s. on an average, do your correspondents consider that sufficient? I contend that they should be paid 25s., if good bothies are provided, or 30s. without, and duty paid 4s. extra. In what other trade, may I ask, is such a starvation wage paid? Even the roadsweepers here (Hampstead) are paid 28s., and leggings and cape are provided. Mr. Legg remarks upon the considerable expense to the employer involved by the upkeep of the bothy. How much does this cost per head in most bothies? 3s. to 4s. per week. Even when vegetables are also provided they cost the employer little or nothing. *E. L.*

SOCIETIES.

LINNEAN.

DECEMBER 18.—At the meeting held on this date, Prof. E. B. Poulton, F.R.S., President, in the chair, Mr. JOHN PARKIN, M.A., gave a summary of his paper on "The Evolution of the Inflorescence." He stated that the evolution of all types of inflorescences is to be traced from the solitary terminal flower. The first cluster to arise is a cymose group of three flowers (a simple dichasium). This comes about through the pushing out of floral shoots from the leaf-axils just below the terminal flower. Two somewhat opposing tendencies now reveal themselves:— (i.) Either the secondary floral shoots may branch repeatedly, giving rise to the compound or continuous dichasium. From this sympodial cymes, etc., can be derived. (ii.) Or the number of these secondary shoots may be increased. This eventually leads to the formation of true racemose inflorescences. Solitary axillary flowers are shown to arise in three different ways, and are all capable of being derived from the solitary terminal flower. Finally, attention is drawn to a little-recognised form of flower-cluster, which is characterised by the main axis, after emitting flowers laterally, continuing its growth vegetatively. The term *intercalary* is proposed for such. The origin of these inflorescences is indicated, and their further evolution into *pseudoterminal* inflorescences shown.

Mr. C. E. SALMON then read a short note on "Hypericum Desetangii, Lamotte, in Britain," illustrating his remarks by a series of specimens of that species and its nearest allies, together with a lantern-slide.

The next General Meeting will be held on Thursday, January 15, 1914, at 8 p.m.

EXHIBITIONS AND PAPERS.

- (1) Mrs. HENSHAW.—Lantern-slides illustrating the fauna and flora of the interior of Vancouver, from her last journey.
- (2) Mr. H. A. BAYLIS, B.A.—Some observations on the tentacles of *Blennius gattorguine*. (Communicated by Prof. G. C. BOURNE, F.R.S., Sec.L.S.)
- (3) Mr. G. C. DRUCE.—(a) Some recent additions to the British flora; (b) A note on Article 45 of the Vienna Code; (c) The Abridgment of Miller's *Gardener's Dictionary* of 1754, and Hill's *British Herbal* of 1756.

CROYDON NATURAL HISTORY.

The December meeting of the Croydon Natural History and Scientific Society was distinguished by a record attendance on the occasion of a lantern lecture on Alpine plants at home and in the garden, delivered jointly by Mr. HUGH LEWIS, of Mayfield, and Mr. W. E. TH. INGWERSEN.

After paying a tribute to Mr. INGWERSEN, to whose guidance on the subject he owed practically everything, Mr. LEWIS said that the idea of Alpine gardens or Alpinums was by no means a new one, records of at least one Alpine garden dating three centuries back. Mr. LEWIS then discoursed on the wide climatic differences experienced by the Alpine plants on being removed from their native crags to lowland gardens, and the effect produced by such changes, the plants becoming modified in structure—i.e., losing in part the very compact and tufted growth which distinguishes them in their mountain homes. The lecturer also pointed to the means of correcting this lax habit by planting many of the Alpine plants in conditions equal, as near as possible, to those appertaining to screes or moraines.

The lecturer, availing himself of the latest literature in Alpine plants and conditions (which he duly acknowledged), pointed out the actual necessity of Alpine gardens as sanctuaries for such Alpines as were threatened by the danger of total extinction in their mountain homes, by farming in Switzerland, involving draining and manuring of many of the slopes in which the mountain flora now reigns supreme. A great danger to the Alpine flora in the higher reaches above the cultivated pastures was the increased number of sheep, which, shaving the high,

stony pasture to a short, lawnlike turf, prevented many of the plants constituting this turf from seeding and increasing, and, weakened by the continued eating down of the sheep, the old plants gradually died away. He also called attention to the effect of light on growth, habit and colour.

After mentioning the advisability of expert advice in the formation and building of rock gardens and collections of Alpine plants, Mr. LEWIS left the field to Mr. INGWERSEN, who invited the company present to accompany him on the screen on a trip into the High Alps, and showed a large number of lantern-slides taken in Scotland, Switzerland, Norway, Italy, Thibet, Sikkim, Himalayas, and a number taken by Mr. LEWIS in his own garden. Commencing with the rich Alpine pastures, which presented sheets of pink, blue, purple or red according to their season, he passed to the Alpine woodlands, showing *Linnaea borealis*, and touching upon the wide distribution of this plant; the lecturer was able to show it growing in Norway, as well as in Switzerland, on both occasions under Conifers, which was the typical position favoured by this plant, although it occurred in Denmark and North Germany in Beech and Birch woods. Showing then a twisted and blasted Fir tree at the so-called tree limit to illustrate the force and rigour of the Alpine climate at high elevations, the lecturer mounted

THE LATE W. COLLINS.

to the higher and stonier pastures above the woodland belt, showing such characteristic plants as the Alpenrose, Cobweb Houseleek, *Saxifraga Cotyledon*, *Anemone sulphurea* and various forms of the stemless *Gentian*, of which the variety *G. angustifolia* (commonly grown in gardens as *G. acaulis*) was such a disappointment in many Croydon gardens by refusing to flower. After showing some more slides of *Daphnes*, *Primulas*, *Anemone vernalis* (closed and open), the lecturer demonstrated by slides the difference between the *Soldanella alpina* and *S. pusilla*, and was happy to be able to show *Soldanella alpina* actually piercing the melting snow in the Alps with its pale mauve flowers. Coming now to the high screes and moraines, the lecturer showed such typical plants as *Silene acaulis*, *Dryas octopetala*, *Saxifraga oppositifolia*, *Geum reptans*, *Campanula cenisia* and others. A number of lantern pictures from Mr. LEWIS's Alpine garden included *Silene Hookeri*, the rare *Lewisia Cotyledon* and *Saxifraga Griesebachii*.

BOTANICAL SOCIETY OF EDINBURGH.

THE second meeting for the session 1913-14 was held on the 11th ult., Mr. R. Stewart MacDougall, M.A., D.Sc., President, in the chair.

Mr. W. G. SMITH, Ph.D., gave some notes on Danish vegetation, illustrated with numerous lantern slides.

Mr. M. Y. ORR showed specimens of the leaf insect, *Pulchriphyllum crurifolium*, Serv., and gave notes on its habits.

Mr. R. S. MACDOUGALL, M.A., D.Sc., exhibited some Ceylon insects injurious to Tea, Rubber and Coffee.

Among the plants exhibited from the Royal Botanic Garden, Edinburgh, at the last two meetings were:—

Alternanthera paronychioides, St. Hil. A South American plant of creeping habit and small green foliage

Buddleia asiatica, Lour. A not quite hardy species, with fragrant, white flowers and smallish silvery foliage, from subtropical Asia.

Dracocephalum tanguticum, Maxim. This species from China is perhaps one of the best late autumn plants for its profusion of bloom, and is suitable either for the rockery or border.

Euryops virgineus, Less. South Africa. A tender shrub, hardy in Cornwall and the Scilly Islands. Flowering out of doors at Edinburgh.

Genista solditana, Pomel. An Algerian plant requiring protection in the north but perhaps hardy in the southern parts of the country.

Gentiana rhodantha, Franch. Of good, bushy habit and a vigorous grower. The flowers are of a pinky-white colour, with a fringed corolla.

Gentiana rigescens, Franch. A sturdy grower of a bushy habit, with persistent stems and foliage. The flowers are of a violet-pink colour. Very floriferous, and a late blooming species worthy of being better known. Both from Yunnan.

Hydrocotyle hirsuta, Sw. A peculiar Umbellifer from the Island of St. Domingo.

Jasminum lineare, R. Br. A rather pretty plant with fine foliage and white flowers.

Lepidium piscidium, Forst. f. A plant from the Pacific Islands, said to be used by the natives for catching fish. The plant itself was raised from seed obtained on Henderson Island.

Lobelia puberula, Michx. North America. A late-flowering species with blue flowers.

Saxifraga cinerascens, Engler et Irmischer. A doubtfully hardy species from Yunnan with yellow flowers.

Saxifraga turfosa, Engler et Irmischer. Somewhat like *S. diversifolia*, with yellow flowers, but propagating itself by stolons. Yunnan.

Spathoglottis edinensis × Rolfe. Raised at the Royal Botanic Garden from seed procured by crossing *S. Fortunei*, Lindl., and *S. pulchra*, Schlechter.

Obituary.

SIR TREVOR LAWRENCE.—The funeral of the late Sir Trevor Lawrence, Bart., V.M.H., whose death occurred on the 2nd ult., took place at Mickleham Parish Church on Saturday, the 27th ult. The church was filled with mourners, many of whom had travelled long distances to pay their respects to the memory of the late President of the Royal Horticultural Society. By special request no floral offerings were sent, and the only emblem on the coffin was a tasteful cross of *Calanthes*, *Epiphyllums* and *White Lapagerias*, made by Lady Lawrence, who was supported at the funeral by her eldest son, Sir William Lawrence, his wife, and other members of the family. Amongst those present were the Lord-Lieutenant of Surrey (Col. the Hon. Henry Cubitt, C.B.), Sir Albert Rollit, Sir Jeremiah Colman, Bt., Sir David Prain, F.R.S., Professor Bateson, F.R.S. (representing the John Innes Horticultural Institution), Mr. Thomas McRow (secretary of the Royal Agricultural Society) and a representative of the *Gardeners' Chronicle*. A memorial service was held on the same day at Holy Trinity Church, Prince Consort Road, Kensington Gore, and was attended by members of the Council of the Royal Horticultural Society. The President, Lord Grenfell, was confined to the house by illness, but the following members were present:—Baron Bruno von Schroder, Sir Harry Veitch, Sir George Holford, K.C.V.O., Sir Daniel Morris, Mr. W. A. Bilney, Mr. A. W. Sutton, Mr. Henry B. May, and the Rev. W. Wilks. There were also present Mr. David W. Thomson (Edinburgh), Mr. J. T. Bennett-Poë, Mr. F. J. Chittenden, and Mr. R. Hooper Pearson.

T. L. CHAPMAN.—We regret to record the death, at his residence in Armadale, of Thomas Learmonth Chapman, for forty-six years farmer at Wester Hillhouse, in Torphichen parish, who died on December 21, in his ninetyeth year. Deceased was a native of Beancross, Falkirk, but had resided for over fifty years in West Lothian. He was chiefly noted as a grower of seedling Potatoes, and was the raiser of such well-known varieties as the Factor, the Crofter, the Chapman, the Laird, and the Cottar.

W. COLLINS.—It is with regret that we announce the death of the late secretary of the United Horticultural Benefit and Provident Society, which occurred on the 21st ult. Mr. Collins underwent an operation in November, and was apparently progressing favourably until about ten days before his death, when he contracted a chill, which brought on an attack of pleurisy. Among the numerous floral tributes which were sent was a harp from the members of the United Horticultural Benefit and Provident Society. He leaves a widow to mourn his loss.

JOHN MATTOCK.—The death of this well-known Rose-grower at the age of 76 occurred at his residence at Headington, near Oxford, on the 22nd ult. Mr. John Mattock was born at Bath, and 40 years ago moved to Oxford. For a long time he had been a very successful exhibitor at the principal Rose shows.

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

Mr. James G. Rogers, jun., late with Mr. T. R. HAYES, Alpine Nurseries, Keswick, Cumberland, and Mr. J. WOOD, Boston Spa, Yorkshire, appointed to the SHEFFIELD HORTICULTURAL CO., LTD., Silver Hill Nurseries, Ecclesall, Sheffield, in the Alpine, Herbaceous and Landscape department.

Mr. James A. Price, as Gardener to Sir J. D. REES, M.P., Aylwards, Stanmore, Middlesex.

Mr. W. H. Jones, for the past 4½ years Gardener at Shirenewtown Hall, Chepstow, Monmouthshire, and previously 5½ years Second Gardener at Aberbalden, Abergavenny, Monmouthshire, as Gardener to N. J. McNEIL, Esq., The Rhyd, Tredegar, Monmouthshire. [Thanks for 1s. for R.G.O.F. box.—Eds.]

Mr. G. R. Nicholls, for 7 years and 9 months Gardener to ROBERT GORDON, Esq., Brockham Park, Betchworth, as Gardener to Captain SLOANE STANLEY, Paulton, Romsey, Hampshire. [Thanks for 1s. for R.G.O.F. box.—Eds.]

Mr. F. M. Folkard, late Foreman at Pett Place, Charing, previously at Orwell Park, as Gardener to H. BROCKLEBANK, Esq., Barton House, near Cambridge. [Thanks for 1s. for R.G.O.F. box.—Eds.]

Mr. George Woolly, for nearly three years Gardener to WALTER WEBB, Esq., Malquoits, Ewhurst, near Guildford, Surrey, as Gardener to Captain E. BERRY, Wycliffe Hall, Barnard's Castle, Yorkshire.

J. DAHEINFELDT, Odense, Denmark.—Seeds.

DEBATING SOCIETIES.

EQHAM DISTRICT GARDENERS.—At a meeting of this association held on the 17th ult. Mr. T. Bowser, of Ashleigh Gardens, Virginia Waters, delivered a paper on "Rock Gardens." The lecturer stated that this form of gardening has become very popular in gardens of late, and whether they are small or large a rockery was always an interesting feature of the gardens. Low-lying slopes were the best positions, avoiding large overhanging trees, for plants which re-

quire shady places can be planted on the shady side of large rocks or stones. One should try to have the rockery as natural as possible, and where streams of water are at hand these may always be used to advantage. No one particular plan should be followed but a plan that is best adapted to the site.

BRITISH GARDENERS' (Watford Branch)—A meeting of this branch of the B.G.A. was held on the 18th ult. Mr. W. Phillipa presided, and there was a record attendance. Mr. Graham, of Colney Park, St. Albans, gave a lecture on "Chrysanthemums."

ENQUIRY.

BACTERIAL DISEASE OF HYACINTH.—Can any reader inform me if the bacterial disease of the Hyacinth (*Pseudomonas hyacinthi*) has been recorded from this country? E. S. S.

BIRDS AND BUDS: Miss M. E. In order to prevent birds pecking off the buds on your Camellias, Honeysuckle and Damson trees, spray them with lime, sulphur, and a little size mixed in water.

CARNATIONS: H. T., Ireland. The plants are badly attacked by the fungus *Heterosporium echinulatum*. Pick off all affected leaves, and spray both diseased and healthy plants every third day with potassium sulphide, which may be made as follows:—Water, 2½ gallons, and potassium sulphide, 1 oz. Dissolve the potassium sulphide (or liver of sulphur as it is often called) in a quart of hot water, then make it up to 2½ gallons by adding cold water.

CINERARIA PRINCESS ALICE: S. S., Yorkshire. There is no disease present. For some reason the cultivation has been wrong. All varieties of a species do not necessarily require similar treatment.

CINERARIAS: G. W. W. Eelworm is present in the soil. The soil should have been sterilised by heating before the potting was carried out.

CYCLAMEN BLOOMS: W. P. B. The rusty appearance of the Cyclamen blooms is caused by mites. Dip the plants in an infusion of Quassia and soft soap.

FUMIGATING WITH HYDROCYANIC ACID GAS: M. A. and A. P. The proportions may be found on page 462 of the issue dated December 27, 1913.

GRAFTING OF PLUMS AND CHERRIES: Correspondent. As the grafting of Plums and Cherries is always risky, growers do not usually expect more than 75 per cent. of the grafts to succeed. Budding is better, when 90 per cent. may be expected.

NAMES OF FRUITS: W. C. Hersee. A fine specimen of Lane's Prince Albert.—A. M. 1, Beurré Diel; 2, Uvedale's St. Germain; 3, Easter Beurré; 4, Lord Burghley.—J. F. Dancer. Winter Orange.—A. C. S. M. 1, Winter Hawthornden; 2, Golden Reinette; 3, Gascoyne's Scarlet; 4, Lincoln Codlin.—J. D. 1, Beurré Diel; 2, Vicar of Winkfield; 3, Emile d'Heyst; 4, Braddick's Nonpareil; 5, Lane's Prince Albert; 6, Allington Pippin.

NAMES OF PLANTS: H. S. The Rose blooms are not in character. Send again earlier in the season.—T. W. We do not recognise the Carnation, and suggest that a bloom be sent to a grower who specialises with this flower.—T. W. R. Probably *Rhododendron racemosum*, but send again when in flower.

NEW ROSE: J. P. A deep pink-coloured sport from Rose Frau Karl Druschki which possesses rich fragrance would be a valuable addition. You should cultivate the plants and exhibit blooms at the next summer show of the National Rose Society, which will be held in Regent's Park, London, on July 7, when its merits would be adjudicated upon.

PEACH BUDS DROPPING: M. A. X. This condition may be caused by a variety of circumstances, and in the absence of a knowledge of the conditions under which the trees are grow-

ing we can only say that the chief causes are dryness at the root and too dry an atmosphere. In some of the early varieties the habit of regularly casting a large proportion of flower-buds just before growth becomes active seems to be ineradicable, and to be successful with these it becomes necessary to exercise great care in cultural detail.

PINE CONES: T. W. R. All your cones appear to be *Pinus Jeffreyi* or *P. ponderosa*. The two species are closely allied, but the former has usually larger cones and the young shoots are glaucous. We think No. 1 is *P. ponderosa*, the remainder *P. Jeffreyi*, but are not very certain about Nos. 2 and 4.

PINUS COULTERI: A. W. C. There is no disease present on the leaves. The injury is probably caused at the root, which should be exposed and examined. If white strands of mycelium are present on the surface, or there appears a white felt under the bark, dredge the plant copiously with a mixture of powdered lime and sulphur in equal quantities, and mix the same with the soil when replacing.

SHRUBS FOR SOUTH DORSET: A Dorset Gardener. Many of the rare trees and shrubs which you have admired in Cornwall would succeed in your garden, but much depends on position and aspect, and without local knowledge we can only generalise. The Magnolias you have planted will be quite hardy, and it would be worth while to add *M. Campbellii*, *M. Delavayi*, and *M. grandiflora* as standards. The most showy of the early-flowering, half-hardy *Rhododendrons* are the hybrids, of which any nurseryman who specialises in them will offer a good selection. The *Andromeda* described is probably *A. floribunda*. The following are the names of rare and showy shrubs which flower during the first half of the year and should be suitable for your purpose:—*Andromeda japonica*, *Camellia reticulata*, *C. Sasanqua*, *C. Lavinia Maggi*, *C. Donkelaaris* and others. *Berberis Bealei*, *Choisya ternata*, *Crinodendron Hookerianum*, *Daphne Cneorum* major, *Desfontainea spinosa*, *Erica ciconodes*, *E. australis*, *Embothrium coccineum*, *Escallonia exoniensis*, *Fabiana imbricata*, *Grevillea thyrsoidea*, *Lonicera sempervirens*, *Olearia macrodonta*, *Paeonia Moutan* (many varieties), and *Veronica Hulkeana*. It would also be well worth trying to grow such of the hardier *Mimosas* as *Acacia Baileyana*, *A. dealbata* and *A. longifolia*.

TOMATOS: A. N. There is no fungus disease present. The leaves are probably injured by fumes or too dry air. The lime should be powdered and dredged on when the leaves are damp, if intended to destroy caterpillars. Spraying with an insecticide is better.

TULIPS DISEASED: H. H. The bulbs are injured by the fungus *Fusarium bulbigenum*. The soil in which they have grown will be infected, and should be sterilised. No cure is possible, as the fungus is in the tissues of the bulb.

VINE DRESSING: L. T. P. The specific should be applied only to the rods, but any of the liquid which unavoidably falls on the soil will do no harm. The sulphur should be used after the vines have commenced their season's growth.

VINE ROOTS: Colonel W. B. A reply to your second query was given in the issue of December 13, p. 432.

YEW HEDGE: Gardener. Sulphate of ammonia applied at the rate of 1 oz. per square yard would be a suitable stimulant for the Yew hedge which is "becoming bare at base." If, as we suspect, it is an old hedge, it is probable that it is suffering from lack of nourishment. Too often hedges are planted, and except for periodic prunings and an occasional weeding, receive no after attention. Established hedges should receive annual top-dressings of soil and decayed manure.

Communications Received.—W. H. P.—W. R. P.—D. B. C.—W. W.—A. C. B.—R. W. C.—E. B.—R. A. M.—J. D.—J. W. M.—C. T.—E. T. C.—G. W. H.—C. R. M., New York—Mrs E. H.—H. S. T.—C. G. G.—Mrs. B.—J. H. A.—C. F. C.—J. D.—W. H. W.—A. G.—Miss E. A.—J. L. S., Washington—R. W. T.

TRICUSPIDARIA DEPENDENS (CRINODENDRON HOOKERIANUM). NAT. ORD. TILIACEAE.

A Chilean Shrub, hardy in the South-western Counties and other favourable localities.

MR. BOWLES' GARDEN.

NO one who loves plants for their own sake and endeavours to make one particular garden reflect, as in a mirror, his highest conception of beauty, can inspect the plan that is being worked out by another idealist without gaining experience. But certain gardens will always possess greater interest than others, usually because they are more characteristic of their makers. In place of slavish copying of a set pattern we want more and more liberty of design in order that every garden may possess the freshness and charm of originality, for no two need be alike, any more than the minds of those who fashion them.

For many years past Mr. Bowles has studied, handled and cultivated vast numbers of plants, making close friendships with many that specially claim his admiration or interest and getting an acquaintance with countless others. He looks upon his garden as a means of affording a home for the plants. If the garden suits their requirements, it likewise fulfils its owner's wishes, and just as any host seeks to know the characteristics and preferences of his friends, so does Mr. Bowles study his plants with minute care and absorbing interest, their affinities, peculiarities of structure, likes and dislikes and general habits.

With respect to the general conditions affecting the garden, the first thing to be

noted is that although Myddelton House is only 10 miles due north of London it is surrounded by a rural landscape, and the rustic character of the neighbourhood is proved by its rich fauna and flora. The site is 111 feet above sea level and is on the edge of a district which shares with Yarmouth the lowest rainfall in Britain. A coarse gravel subsoil drains the ground to such a degree that the garden may be classed amongst the driest in England. The New River runs through the centre of the garden, but although this artificial waterway was made some 300 years ago, the banks still carry the water through the gardens without allowing any to soak through to the benefit of adjacent plants. Moreover, the New River water is so hard that Rhododendrons have been killed

fine specimen of the hardy Palm (*Trachycarpus excelsus*) which stands in front of the conservatory is likewise in flower, the setting is very pretty, whilst on the lawn is a fine Cedar of such dimensions that one hears with something of a start that Mr. Bowles' great-grandfather brought it from Covent Garden in a pot. A fine bush of *Salvia Grahamii* in front of the conservatory must be 6ft. to 7ft. high. Across the lawn is a long border of moderate width, full of good things of herbaceous habit, and including such a colony of *Eremurus* as very few private gardens possess. There must be enough *Eremurus* plants to stock a nursery, and since most of the sorts are well represented they make a floral display of unusual attractiveness. In the border also there are many *Kniphofias*, in-

[Photograph by W. J. Tasey.]
FIG. 8.—MORNING ROOM WINDOW AT MYDDELTON HOUSE.

merely by watering them with it during periods of drought. A row of Yews on its north bank has been declared to be at least a hundred years older than the river, and it is not unlikely that there was a garden here in which the trees were planted. Mr. Bowles' ancestors settled here in the early years of the eighteenth century, but the oldest tree of which anything like a definite date of planting is known is a fine specimen of *Taxodium distichum* planted by his great-grandmother at some time prior to 1812. The present dwelling-house was built a few years later, and instead of using the good red brick of the district, the builders procured a then fashionable yellow brick from Suffolk, wherefore, says Mr. Bowles, "it has been my constant aim to smother it in creepers of all kinds." In May, when the *Wistaria* on the south front is in full bloom (see Fig. 8) and the

cluding the very beautiful *K. Northiae*. In this same part of the garden, but across another stretch of lawn, may be seen an interesting grouping of coloured foliage where grey-leaved plants and those with silver variegation are massed against bold groups of golden-leaved plants on one side and purple foliage on the other.

Mr. Bowles specially admires the large genus *Geranium*, and he collects all good hardy species that he can obtain, consequently they are to be seen in various situations, but they never seem inappropriately associated, because they mix well with other families. Turning towards a friendly wall that provides the necessary shelter for many young plants that would find it difficult or impossible to succeed in an exposed situation, a specimen of *Eucalyptus cordata*, 15 feet high and in flower, that Mr. Bowles has raised from seed obtained from an older plant, serves

to draw attention to the considerable number of species of Eucalyptus that have been grown to effective specimens. Mr. Bowles says that *E. cordata* is not an easy plant to purchase owing to incorrect nomenclature, but when it is obtained true it is one of the hardier species, far hardier than *E. Globulus* that usually does duty in gardens for the whole genus. *Olearia virgata* and its variety *lineata* produce small white, rayless flowers in July, but are rare plants, possessing much interest, and the weeping form of *Rosa rugosa*, *Eucalyptus pulverulenta*, and the choice sorts of Chinese Buddleias lately introduced, but already grown into specimens of considerable height, and many other good garden plants make the border that runs along with the wall a place of interest all the year round. *Solanum crispum* is to be seen some little distance away, scrambling over some posts and draping an old grey vase with its fes-

near Tortworth; a similarly twisted Hawthorn; a fastigiate form of the common Elder; an Oak-leaved variety of the common Laburnum; a pigmy Ash with a name almost as long as itself—*Fraxinus excelsior* var. *atrovirens nana*; *Rumex flexuosus* with very narrow, perfectly brown leaves; a viviparous form of *Poa alpina*; the Plymouth Strawberry; the one-leaved Strawberry, *Fragaria vesca* var. *monophylla*; a Hen-and-Chicken form of the common Daisy; the green Primrose; a white-flowered *Ajuga reptans*, and a form of *C. lactiflora* which grows only 1 foot instead of 6 feet, the normal height of the type. There are many other oddities in this irregular piece of ground, but sufficient have been mentioned to indicate not only the character of the plants which find a home in the collection, but also the interest such a gathering possesses for plant teratologists. These eccentrics are sheltered by standard Magnolias, *Wistaria sinensis*, *W. multi-*

cluding Irises and Tulips, are also grown in profusion. Of *Iris florentina* a word is needed to explain the beautiful belt of flowers that runs along by the side of the New River—(see fig. 11)—where Mr. Bowles made a clearing of the Laurels and *Viburnum Tinus* that formerly grew there, in order to make way for his principal collection of Irises—namely, those of the bearded section. The whole front of the bed is planted with a band some 8 feet deep and 20 yards long of *Iris florentina*, with an occasional clump of *I. germanica* amongst them, these latter for improving the dainty picture by adding touches of purple to the sheet of grey.

The Rock garden is one of the most interesting we have seen, although its owner does not claim for it superior structural effects. Its interest is more in the plants, their rarity and their flourishing, contented appearance. The design, says Mr. Bowles, would have been different had the rockery been constructed at one time, but it was not, and the first portion that was formed on a bank of stiff clay has been added to on more than one occasion by taking in pieces of meadow land for the purpose. Each and every portion has been planned, built and planted by Mr. Bowles himself, who with his own hands has helped to fix the great stones in their positions, and he, with the cunning of the true plantsman, has selected the places for the rarer and more difficult plants to occupy. He has no hard and fast rules about keeping the rockery exclusively for true Alpines, but on the contrary he plants thereon any favourite he has reason to think will thrive better there than anywhere else. Yet he has specimens of true Alpine species, really difficult plants, that make all rock-garden visitors exclaim at the wonderful success obtained. It is the success that falls only to the lot of those who have that gardening instinct by which they are able to divine with accuracy the peculiar requirements of individual plants, and the patience that never tires in the daily task of maintaining the conditions necessary to the plant's highest development. The illustration in fig. 10 represents a clump of the only American species of *Meconopsis* (*M. heterophylla*) flowering in May by the side of one of the rockery paths. The plant is an annual, and it produces its rich orange-coloured flowers, with chocolate-red, almost black centres, in the greatest abundance. But this usually happens only when it is self-sown; in other cases it is not easy to get such vigorous clumps. We must not attempt to describe the interesting plants on the rockery, however, for it would not be possible here to mention even a tithe of them, nor can we describe the collection of hardy Succulents and other features that go to the making of Mr. Bowles' charming garden. Sufficient may have been said to indicate its general character, but its peculiar charms to the plant-lover can only be fully appreciated after a visit to the garden with Mr. Bowles as guide.

(Photograph by J. A. James.)

FIG. 9.—WISTARIA MULTIJUGA IN MR. BOWLES' GARDEN.

toons of lilac-coloured flowers; truly a beautiful plant for the pleasure grounds, and particularly effective when given such a charming environment as Mr. Bowles has chosen for it. We have mentioned only a few of the trees and shrubs that recur to the memory, but they fail altogether to represent the many interesting species, including standard Wistarias and Magnolias, that are to be seen in various parts of the garden. A fine plant of *Wistaria multijuga* in full flower is shown in fig. 9, and a very graceful plant it is.

In Mr. Bowles' garden there is a small enclosure known as the Asylum. This spot has come to be known by this somewhat extraordinary name because most of its occupants are eccentrics that show some marked difference from the normal habits or appearance of their near relatives. Readers may possibly guess what some of these "demented" plants, as Mr. Bowles calls them, are like. A few may be mentioned. The first of the collection is the twisted Hazel, which Lord Ducie first found in a hedge

juga, *W. brachybotrys*, and flowering Cherries that make the surroundings pleasantly agreeable in spring even to those who have no wish to study the abnormal.

In this article it is not intended to write of Mr. Bowles' Crocuses, and for several reasons. First, our notes are chiefly of the spring garden as it appears in May, when the Crocuses are quiescent; but a stronger reason is that it would be next to impossible to deal with the Crocuses without excluding all else from notice. For Mr. Bowles' Crocuses are the Crocuses at present in cultivation. They are his special favourites, and no species, variety or form of the Crocus exists but Mr. Bowles possesses or would like to acquire it for his collection. The frame-yard tells its tale, however, for many of the frames contain the choicest and most tender Crocuses in pots, boxes, or planted out; and here, in the dark mornings of the New Year, Mr. Bowles may often be seen eagerly anticipating the opening into flower of his greatly beloved plants. Snowdrops, Daffodils and other early bulbs, in-

THE MARKET FRUIT GARDEN.

REVIEW OF PAST SEASON.

IN reviewing the circumstances of fruit-growing during the past year it is not only financial results that have to be taken into account. These have varied greatly, but, on the whole, have proved better than could have been expected early in the summer. The comparatively few growers who had even a fair crop of Plums must have had unusually good returns, for Gooseberries and Black Currants both yielded well as a rule, and the fruits sold for good prices, while the comparatively high value of Apples went far towards making up for the deficiency in the production of many varieties. But the results

NOVELTIES OF 1913.

ORCHIDS.
(Continued from p. 4.)
NURSERYMEN.

MESSRS. CHARLESWORTH AND Co., Haywards Heath, proprietors of one of the most remarkable and interesting Orchid nurseries, stand well in the matter of awards. During 1913 they obtained First-class Certificates for *Cymbidium Humblotii*, shown on April 1; *Miltonia Charlesworthii* and *Laelio-Cattleya Sylvia Princess Victoria Louise*, and the large, bronzy-red *Odontioda Brewii*, this last certificated at Holland House. The Awards of Merit were for *Cypripedium Alcinida* at the first meeting in 1913; *Oncidioda Cooksoniae*, *Oncidioda Bella*; *Odontioda Wilsonii* The President—a very pretty white and purple flower, shaped like *Odontoglossum Pescatorei*; *Cattleya Mossiae Olympia*; *Odontoglossum*

FAULTY INSTRUMENTS.

Is there any other article in common use quite as badly made as the thermometer? I have three instruments side by side, and the range of variation is 4°. The median one is taken to be the most accurate, partly because it has been tested against several other thermometers, and partly because, being a maximum as well as a minimum recorder, it marks the same temperature in the two columns of mercury. At a considerable expense a Kew-registered thermometer may be obtained; but even then, more often than not, an allowance for a detected error has to be made every time that the register is examined. Probably three-fourths of the records of frost that find their way into newspapers are erroneous.

CLEARING OFF APPLES.

Bramley's Seedling Apples left over one-eighth in bulk since they were stored, as tested by the

of the terribly wet season, 1912-13, which developed last year, are of much greater importance than the returns of that year, as they involve permanent injury to trees. Brown rot, scab, canker, and silver leaf all developed to an extent never seen before in my orchards. On the whole, brown rot has done me most harm, because it has attacked Plums extensively, as well as some varieties of Apples. To growers of Cherries for market it is a source of much loss. The scanty attention given to this disease has long been a source of astonishment to me. We hear of the "mummified" fruits which are among the results of an attack, but very little of the destroyed spurs and shoots. Until last season attacks on Apple trees had been only slight and limited in extent. But in my oldest plantation of Plums brown rot had been slowly extending for many years, in spite of the cutting-off of affected shoots and spurs; and last season the disease spread more or less all over the orchard. On Pond's Seedling and Gisborne nearly half the fruit spurs and many of the twigs are dead, as shown by the withered leaves still clinging to them. Czar and Monarch are less affected, and Prolific least of all. The first two varieties named are ruined, I think, and will probably have to be dug up after next fruiting season. We are spraying the orchard with sulphate of copper pure and simple, 4 lbs. to 100 gallons. My younger Plum orchards are not much affected, and, by spraying them with sulphate of copper, after cutting off the few affected twigs or spurs, I may check the small beginning of the disease. Domino Apple is also badly affected with brown rot, and Gascoyne's Scarlet, Early Julyan, and two or three other varieties slightly. Scab and canker are more common than they have ever been before. Multitudes of fruit spurs on Cox's Orange Pippin planted seven years ago are cankered. These are being cut off, and there are great numbers of sound spurs left.

RAINFALL IN 1913.

My total rainfall in 1913 was 30.98in., as compared with 33.23in. for 1912, and 28.73in. as the average for the twelve years ending with 1912. The monthly measurements in inches were 4.09 for January, 1.12 for February, 2.63 for March, 3.85 for April, 0.71 for May, 0.68 for June, 2.38 for July, 1.85 for August, 2 for September, 6.05 for October, 4.18 for November, and 1.44 for December. Only four of the twelve districts into which the United Kingdom is divided in the weekly reports of the Meteorological Office had over an average rainfall, and two of these are in Ireland. England south-west had 0.78in. over average, and England south-east 0.02in. over. The rest, including the Scottish districts, had less than an average rainfall.

EARLY WINTER SEVERITY.

Not since 1908 has there been weather on the last few days of December and the first days of January as severe as that which we have lately experienced. Slight frosts were registered on the 18th, 19th, and 23rd of December, while my exposed thermometer 4ft. from the ground showed 6° of frost on the night of the 24th. But a wind of arctic severity set in on the 29th, and there were 7, 6, and 8 degrees of frost on three successive nights. Sheltered thermometers in the North generally registered fewer degrees of frost than my unsheltered instruments on the 29th and 30th, because the coldness was mainly that of a wind frost. But in the night of the 31st records up to 15° of frost were registered. My object is to ascertain the temperatures to which my fruit trees and bushes are subjected, and therefore I do not adopt the usual plan of sheltering thermometers by louvres. In 1908 there was much greater severity from December 27 to December 30, inclusive. A great quantity of snow fell in the country generally, and frosts up to 16° were registered.

FIG. 10.—MECONOPSIS HETEROPHYLLA IN MR. BOWLES' GARDEN. FLOWERS ORANGE-COLOURED WITH CHOCOLATE-RED EYE.

[Photograph by W. J. Vasey.]

number of filled trays, and we began to send them to market on New Year's Day. They had been picked over twice, all unsound fruits having been removed from the sound ones. But at the end of December spots of rot began to show on a few Apples, and it was deemed advisable to pack them by instalments. The price has risen greatly, and there is a small margin of profit on the keeping of this variety. Newton Wonder is still keeping well, but will soon follow Bramley's to the market. *A Southern Grower.*

Georgius Rex; *Laelio-Cattleya Feronia* "Charlesworth's variety"; *Sophr-Laelio-Cattleya Laconia* and *S.-L.-C. Niobe*; and the distinct *Odontonia Langowoyi*. These were all finely-coloured flowers, and among species *Paphinia cristata* and *Angraecum recurvum* made a good show.

Messrs. SANDER AND SONS, St. Albans, whose enterprise in collecting Orchids is well sustained, exhibit some very showy species, as well as a number of interesting "botanicals." They secured at Holland House Show a First-class Certificate for *Miltonia Sanderiae*, one of the most delicately beautiful of hybrid *Miltonias*; an Award of Merit for the large and beautiful *Cattleya Mossiae Dreadnought*; and similar awards at Chelsea for *Odontonia Laelia*

PUBLICATIONS RECEIVED.—*My Garden Diary for 1914.* (Reading: Sutton and Sons.)—*Willing's Press Guide, 1914.* (London: James Willing, Ltd.) Price 1s.

Sander (one of a very useful decorative group raised by the firm), *Brasso-Cattleya Vilmoriniana* Etna (a very bright, purplish-rose flower), and *Oncidioda Cooksoniae illustris*, bright red. Other distinguished novelties were *Cycnoches Cooperi*, with long racemes of sepia-brown flowers, and a good companion to the new *C. Forgetianum* introduced by Messrs. Sander; *Phaius Cooperi*, a very distinct species, with chocolate-purple sepals and petals; *Maxillaria Fletcheriana*; *Cattleya Fabia* Prince of Wales, the darkest form; *Cypripedium Estella*, and other new *Cypripediums*, including the massive *C. Royal Monarch* and *C. insigne* Louis Sander. The new *Odontonia Farnesiana* and *O. MacNabiana* were also shown.

"Orchidhurst variety"; *Odontioda Seymourae*; the bright carmine-red *Miltonioda Harwoodii* "Shrubbery variety"; *Cypripedium Baron Schröder* var. *Kentore*, and many handsome hybrids chiefly flowering for the first time. A Botanical Certificate was also received for *Kefersteinia laminata*, and Cultural Commendations for *Oncidium corynephorum splendens*, and other finely-grown specimens.

Messrs. J. AND A. McBEAN, Cooksbridge, have made, perhaps, the best and most varied show of hybrid Orchids they have ever contributed to the shows. *Odontoglossum eximium* Alpha, which secured a First-class Certificate on March 4, is one of the most beautiful of the blotched *Odontoglossums* which Messrs. McBean

Exotic Nursery, King's Road, Chelsea, may be called the founders of the hybrid Orchid industry, and their original *Laelio-Cattleyas* and other showy Orchids are still standard types. *Laelio-Cattleya Olenus* var. *Ettrick* (A.M., August 26) and others were shown by this firm, together with new *Cypripediums*.

Messrs. FLORY AND BLACK, who have taken over the Laugley Orchid Nursery, Slough, formerly occupied by Messrs. Veitch, will reap the advantage attaching to work carried out under Messrs. Veitch's management, and already we have recorded in these pages some desirable novelties produced by them during their short occupation of the nursery, together with the fine new *Dendrobium Leeanum* "Langley variety," for which they received an Award of Merit on November 18.

Messrs. MANSELL AND HATCHER, Rawdon, Yorks, secured a First-class Certificate for *Cattleya Empress Frederick alba* at the Chelsea Show, and an Award of Merit for *Cattleya Magnet* var. *Serenata*.

Messrs. JAS. CYPHER AND SONS, Cheltenham, regularly show good exhibits, distinguished by their fine condition and floriferous character. The pretty *Coeloglyne intermedia* (A.M., January 21) is a very good example.

Messrs. HASSELL AND CO., Southgate, and other raisers have flowered good novelties during the year which may be accepted as worthy of awards, but the standard rises as time goes on, and it is not sufficient now merely to show a new and attractive cross; it must be strikingly distinct and sufficiently well grown to show its merits.

ILLUSTRATIONS IN GARDENERS' CHRONICLE.

The following new and rare Orchids were illustrated in these pages during 1913:—

- Angraecum Andersonii*, March 8, p. 146.
- Angraecum recurvum*, November 29, p. 374.
- Cattleya Trianae alba* Souvenir de Louis Verdenck, March 29, p. 199.
- Cattleya Lawrenceana* in Mrs. Bischoffsheim's garden (Coloured Supp.), August 30.
- Cypripedium Bourtonense*, December 27, p. 454.
- Cypripedium Demeter*, January 4, p. 3.
- Cypripedium Roundhead*, April 12, p. 230.
- Habenaria iantha*, November 1, p. 300.
- Laelio-Cattleya Nella*, December 13, p. 416.
- Lycaste Tunstillii*, December 13, p. 415.
- Megacalinium triste*, March 1, p. 131.
- Odontonia Laelia* Sander, May 24, p. 349.
- Odontioda Madeline* Prince of Orange, February 8, p. 92.
- Odontoglossum Cleopatra* "Rosefield variety," December 27, p. 456.
- Odontoglossum eximium* "Warnham Court variety," April 19, p. 246.
- Odontoglossum eximium Armstrongiae*, May 24, p. 350.
- Odontoglossum Pescatorei* Lady Holford, May 3, p. 283.
- Oncidium Lanceanum*, October 18, p. 279.
- Podandria* (*Habenaria*) *macrandra*, September 13, p. 182.
- Saccolabium glomeratum*, November 8, p. 317.

NEW OR NOTEWORTHY PLANTS.

CLEISOSTOMA SPICATUM LINDL.

A FINE inflorescence of this rare and pretty species from Borneo is sent by Mr. C. Wright, gardener to the Hon. N. Charles Rothschild. It is a strong grower, with thick, dark-green leaves 4 to 6 inches long, and 1 to 2 inches broad. The decurved rachis is stout and minutely furfuraceous, the slight downy covering extending to the ovaries and outsides of the floral segments. The flowers, which are $\frac{1}{2}$ inch across, have the sepals and petals red, with a thin, yellow line up the middle of the petals and lateral sepals. The whitish lip is prolonged into a spur $\frac{1}{2}$ inch in length, flattened at the apex. The inflorescence bears over forty flowers. *Cleisostoma* is one of the subgenera of *Saccolabium*, a genus from which there is little to distinguish it. The following references are interesting:—*Cleisostoma spicatum* Lindl. in *Bot. Reg.* sub. t. 32; Hook. f. *Flora of Brit. India* VI. 72; *Sarcanthus densiflora* Parish et Rehb. f. in *Trans. Linn. Soc.* XXX. 136; *Saccolabium densiflorum* Lindl. in *Wall Cat.* n. 7311; *Gen. et sp. Orch.* 220 and *Bot. Reg.* 1838. Misc. 56; *Aërides densi-*

FIG. 11.—IRIS FLORENTINA IN MR. BOWLES' GARDEN.
(See p. 18.)

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, are now reaping the benefit of the large block of well-appointed houses in which their fine stock has been developed during recent years. At Chelsea, on May 20, their group, illustrated in the *Gardeners' Chronicle* of June 7, p. 385, contained a wealth of new and rare hybrids. The best were the deep scarlet *Odontioda Chanticleer* "Orchidhurst variety" (F.C.C.); *Odontoglossum eximium* *Armstrongiae*, a perfect flower; *Laelio-Cattleya Aphrodite* "Orchidhurst variety"; and the deep ruby-rose *Brasso-Laelio-Cattleya Excelsior*. On other occasions Awards of Merit were gained for *Laelio-Cattleya George Woodhams*, a fine hybrid in itself and a good parent, as seen in the beautiful, new *L.-C. Armstrongae* (*L.-C. Geo. Woodhams* × *C. Iris*); and *L.-C. Marquis de Wavrin*

cultivate so well, and the large, pure white *Dendrobium Dearei* "McBean's variety" is an acquisition which, however, must always be rare. Awards of Merit were gained for *Laelio-Cattleya Smilax* var. *Prince of Orange*, *L.-C. Urania*, *L.-C. Autodon*, *Odontoglossum Phoebe splendens*, *Odontioda Keighleyensis ignifera*, *O. Charlesworthii* *Perfection*, a large, deep red form of one of the best *Odontiodas*; *Oncidium McBeanianum* (*superbians* × *macranthum*), a remarkable and pretty cross; *Cattleya Mendelii* *May Queen*, shown at Chelsea; *C. Drapsiana* "McBean's variety"; *Cymbidium Gottianum superbum*, and *Brasso-Cattleya Iris*. Messrs. McBEAN also gained a certificate of Appreciation for the remarkable *Adaglossum Juno* (*Ada aurantiaca* × *O. Edwardii*).

Messrs. JAMES VEITCH AND SONS, Royal

florum, Wall MS. Hab. Bhotan, Tenasserim, Moulmein, Penang, Perak, Borneo. It is finely figured in *Calcutta Bot. Gar. Arn.* Vol I., 85, plate 83 and Vol. VI., plate 311, the Sikkin form, which is more slender and may be otherwise different. Mr. H. N. Ridley in his excellent *Materials for a Flora of the Malay Peninsula* retains *Sarcanthus densiflorum* Lindl.

SARCANTHUS ROBUSTUM, Nv. Sp.*

THE accompanying illustration (see fig. 12) represents a very distinct and pretty *Sarcanthus* imported from Borneo by the Hon. N. Charles Rothschild, Ashton Wold, Oundle. Notwithstanding considerable pains have been taken with the plant, both at Kew and the Natural History Museum, it remains unidentified, being distinct from the many specimens examined. Consequently I propose for it the name given above. The illustration represents an inflorescence and a single flower with the sepals and petals removed, this latter showing the lip and column, both natural size; the leaf is reduced one-third. The flowers are cream-white to bluish-white and the markings claret-purple. *James O'Brien.*

NOTICES OF BOOKS.

THE ROSE BOOK.†

THIS volume contains 283 pages, and the general scheme of the book is that the first 150 pages are devoted to descriptions of various types of Roses with selected lists containing brief notes on the varieties, while the remainder of the book is for the most part devoted to details of cultivation. The descriptive portion is divided into Part I., "Roses to begin with," and Part II., "Roses to proceed with"; Part I. including the Wichuraianas, multifloras, Hybrid Perpetuals, and Hybrid Teas; Part II. Teas, Chinas, Moss Roses, Penzance Briars, Pernetiana and other types. No doubt the authors are well advised in suggesting that beginners should start with the Wichuraianas, for, as a class, they are of the easiest culture and often produce good effects in somewhat adverse conditions, but the division is arbitrary and hardly satisfactory; for instance, the Penzance Briars are surely of easier culture than many of the Hybrid Teas.

A good deal of the writing in this part is somewhat diffuse, while on the other hand the descriptions of varieties might have been amplified with advantage, and might perhaps have been more serviceable if they had been rather more critical and less generally appreciative. The observations do not always tally with that of the writer of this review. For instance, Alberic Barbier is stated to flower in June and autumn, while Coquina is only mentioned as flowering in June. In the reviewer's garden Alberic Barbier, though it has an unusually long period of flowering, produces nothing but an occasional flower afterwards, while Coquina has a considerable and well defined second flowering which is perhaps more pronounced than any other of the Wichuraiana group, unless it be François Foucard. Again, it is stated that *Avoca* blooms only in July. This is true when the plant is treated as a cut-back, but pegged down or better still allowed to grow freely on a pillar it will flower in late summer and autumn with considerable freedom. On the 16th day of October last over a dozen flowers were counted on a pillar

of *Avoca* which was about equally well furnished ever since the summer; most of the pegged down plants continued to flower almost to the end of the year. Some twenty pages are devoted to a description of Rose species, the Wild Roses of Britain and other countries. In both cases an alphabetical arrangement has been followed, with the result that the principal groups do not clearly emerge, and this is perhaps responsible for one or two rather curious omissions, e.g., *R. nitida*, *R. sempervirens* and *R. Fedtchenkoana*, while if the list is intended only for the assistance of gardeners it is perhaps a pity that little is said as to the relative merit of the species as garden plants.

The part dealing with cultural details is, in our opinion, the best part of the book, the directions are clear, simple and practical, and the style more pleasing and concise. The best time to apply the annual dressing of manure to established beds and borders of Roses is decided by the authors in favour of autumn, the manure

the well-established practice of exhibitors, and the results they obtain from watering freely with liquid manure at this period. No doubt throughout winter, especially if it be a mild one, and early spring, Roses are continually making fresh roots, but this is only in order that they may be ready for the later strain on their services when active growth commences. During winter the Roses do not want and cannot make the best use of manure, and many think they are better without it. Moreover, autumn rains are heavy, and the Rothamsted experiments show that the months of November, December and January are the periods of maximum percolation of rainfall, the drainage curve then falls rapidly, and is at its lowest through April and May, rising slightly through the three following months and rapidly in September. Manure applied in autumn, therefore, seems likely to have many of its valuable constituents washed away during the winter, and so much is this the case that it has been stated that in land occupied by cereal crops the drainage waters show that there is practically no nitrate left in the soil by the month of May.

The chief point in favour of autumn manuring appears to be its obvious convenience. It can be carried out while the beds are being tidied up, a process required in most gardens before winter sets in. Secondly, the digging in at this period may be thought less disturbing to the roots than when this is carried out while the young roots of the Roses for the coming season are delicate and easily injured.

Whether these considerations outweigh the probable loss of manurial matter carried off by the winter rains it will be for each cultivator to determine for himself. It is likely that the man on a heavy soil will think he runs less risk in this respect than his brother gardener on a light and porous formation. We admit the question is not yet settled. Interesting as are the Rothamsted experiments, we do not know that any have yet been conducted on a heavily manured Rose bed, but the arguments in favour of spring manuring seem to have some weight, particularly in the case of light soils. *White Rose.*

FIG. 12.—*SARCANTHUS ROBUSTUM*, A NEW SPECIES INTRODUCED FROM BORNEO BY MR. CHARLES ROTHSCHILD. COLOUR OF FLOWERS, CREAMY-WHITE WITH CHOCOLATE-BROWN MARKINGS.

being dug in, and any varieties that require protection receiving a mound of soil or burnt earth for the purpose. Undoubtedly the latter advice is sound, but the question whether Roses benefit most from an application of manure in autumn or spring must be considered still an open one, always assuming that if it is applied in spring it is being prepared throughout the winter by lying in a great heap well covered with soil. We may perhaps hope that our friends the meteorologists may be able to help us later on when they have perfected their experiments on the percolation of water through soil, and the contents of what we may term the filtrate. It is by no means improbable that the ultimate decision of the question will be different for light and heavy soils, and that the amount of humus in the soil may be a further element in arriving at a just conclusion. In modern conditions of Rose-growing we want to present the maximum quantity of manure in the form most readily capable of assimilation in the latter part of May and throughout June. The truth of this proposition, if it needs proof, may be gathered from

CANADA.

PROHIBITION OF IMPORTATION OF PLANTS BY MAIL.

FOR the information of those readers of the *Gardeners' Chronicle* who are accustomed to forward or may contemplate forwarding to Canada shipments of plants by mail, the following amendments to the regulations under "The Destructive Insect and Pest Act," governing the importation of plants and vegetation into Canada, will be interesting.

In Regulation 3, line 14, the words "Importations by mail shall be subject to the same regulations" have been struck out and the following new regulation (No. 18) has been passed by Order-in-Council of December 4, 1913:—"18.—The importation of all nursery stock, including trees, shrubs, plants, vines, grafts, scions, cuttings or buds, through the mails is prohibited, excepting greenhouse-grown florists' stock, cut flowers, herbaceous perennials and bedding plants, which will be admitted, provided that a detailed statement of the contents is attached to such parcels."

In order that sufficient notice may be given of this prohibition of the importation of nursery stock, etc., into Canada through the mails, this regulation will take effect on and after March 1, 1914.

Information relative to the importation of trees, plants, etc., into Canada and copies of the regulations governing the same will be gladly furnished by the undersigned, to whom communications on the subject should be addressed. *C. Gordon Hewitt, Dominion Entomologist, Department of Agriculture, Ottawa, Ont.*

* *SARCANTHUS ROBUSTUM*.—Stems $\frac{3}{4}$ inch wide, $\frac{1}{2}$ inch thick, green. Leaves $\frac{1}{2}$ to 2 inches apart, 4 to 6 inches long, about 1 inch wide, fleshy, hard, dark green, unequally bilobed at the apex. Raceme decurved at the extreme half bearing several flowers (ten or more on the imported spikes). Peduncle stout, pedicels and ovary a third of an inch long, slightly grooved. Flowers about $\frac{1}{2}$ inch across, fleshy, white to bluish, with claret-purple markings. Sepals obovate acute, the dorsal sepal concave, the laterals divergent; petals narrower, recurved. Lips stout, prolonged with spur, the callus and septate division being characteristic of *Sarcanthus*. Column fleshy, thick at the base.
† By H. H. Thomas, assisted by Walter Easlea. Messrs. Cassell. 6s.

The Week's Work.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl B AUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

THE FORMAL GARDEN.—The portion of the flower garden nearest to the residence should be made attractive by planting the beds and borders twice each year with spring and summer bedding plants respectively. Further away from the house more freedom and a more natural style of planting can be adopted. To have the garden attractive on every day of the year should be the aim of every garden lover; yet how seldom is a real effort made to have it so. Thirty years ago the gardens at Madresfield Court contained large plantations of Laurels, Box, Yew, Privet and other sombre-looking shrubs, all planted in monotonous style, and most of these have been destroyed. Their places have been planted with bold groups of evergreen and deciduous hardy flowering shrubs, and nearly every plant has room to become a fine specimen. There is a wealth of material to select from, including *Lonicera Standishii*, *L. integrifolia*, *Hammamelis* (the Witch Hazel), *Daphne Mezereum*, the Sweet Gale, *Erica codonodes*, and many others now in full bloom, which will be followed by others in succession. *Berberis Darwinii*, *B. stenophylla*, *Viburnums*, *Lilacs*, *Spiraeas*, *Choyisia ternata*, *Veronicas*, *Azaras*, *Laburnums*, *Syringas*, *Philadelphus*, *Weigelas*, *Deutzias*, *Maples* and *Hydrangeas* are a few that are suitable. In a recess may be planted a few of the choicer *Rhododendrons*, *Azaleas*, *Andromedas*, *Ericas*, and other peat-loving plants. Other sheltered corners may be selected for *Bamboos*, *Gynerium* (Pampas Grass), hardy Palms and Ferns, whilst the water-side may be planted with *Caltha palustris*, *Spiraea Aruncus*, *Lythrum*, *Iris Kaempferi*, and bog-loving plants. Room should be found for large, irregular groups, standing well back, of such plants as *Pyrethrum uliginosum*, *Helianthus* in variety, *Lychnis*, *Paeonies* and *Eupatoriums*, reserving the choicer medium-growing plants for the herbaceous border proper. Another corner may be furnished with rock plants, and still another with choice bulbs, such as *Darwin* and *Cottage Tulips*, *Hyacinthus candidans*, *Gladioli*, *Montbretias* and *Anemones*.

BANKS OF HARDY FLOWERS.—There is nothing more pleasing or effective than mounds or banks of hardy flowers, especially when seen from a distance. *Tritomas* or *Kniphofias*, *Rudbeckias*, tall *Pyrethrums*, *Indian Poppies*, the taller *Delphiniums*, *Sunflowers*, *Dahlias*, tall-growing *Pentstemons*, and *Hemerocallis* are all suitable for the purpose. The choicer *Michaelmas Daisies* are worthy a series of beds in the grass to themselves. Room should also be found for sloping banks of *Gentians*, *Lily-of-the-Valley*, *Anemones*, *Ranunculus*, and *Erythronium* (Dog's Tooth Violets). The garden should have a space set apart for annuals, which I propose to deal with later on. Bulbs are to be recommended for planting in the grass, including *Daffodils*, *Dutch Tulips*, *Grape Hyacinths*, *Chionodoxa*, *Scillas*, especially *S. hyacinthiflora alba*, *Colchicums*, and *Cyclamen europeum*, for a shady bank.

TURF AND GRAVEL PATHS.—Complete all necessary alterations to turf on lawns and repairs to grass verges where these are worn or damaged by the absence of light and the drip of dense evergreen trees and shrubs. Use the roller after rains (but not when the ground is frozen), for the more turf and grass lawns or paths are rolled the more satisfactory they become. If *Daisies* are troublesome, carefully skim off the turf very thinly, and allow it to remain in rolls for a fortnight. Afterwards prepare the soil by slightly breaking up the surface about 2 inches deep, and relay the turf. This will kill a large number of the *Daisies*, but the turf will contain seeds of the weed, and will need dressing with lawn sand, or sulphate of ammonia mixed with river sand. Scatter the lawn sand

in the same way as guano or other artificials are applied. The lawn sand will cause the leaves of the *Daisies* to shrivel, but the application must be repeated to kill the roots of the plants.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

STRAWBERRY BEDS.—If the work has not been done already, established Strawberry beds should be cleared of rubbish, the soil lightly forked, and a good dressing of farmyard manure applied. The manurial properties of the dung will be washed down to the roots by the rains, ready for the plants to appropriate in the spring, causing them to grow vigorously and develop strong trusses. Fresh plantations which have not yet furnished fruits require no top-dressing of manure, but the beds should be made clean and tidy. The present is a suitable time to prepare ground for future planting. Trench the soil deeply, enrich it with plenty of good manure and leave the surface rough and exposed to the ameliorating influence of frost and the weather generally. The site may be used for planting early Potatoes and similar crops, which will be cleared off in time for planting the Strawberries. At planting time the soil will need very little preparation, and will have become settled, so that it will be in an excellent condition for receiving the young plants.

GENERAL WORK.—In most gardens certain varieties of Apples, Pears and other fruits are not a success, and these should be marked at the time of pruning, manuring or spraying, with a view to heading back such as are in a healthy condition for re-grafting in the spring. This also applies to varieties that have been superseded by better sorts. The scions should be procured early and set carefully in damp sand or earth until required. Examine the scions occasionally to see that rats or other vermin are not causing damage to them, which may happen if frost prevails for a considerable time. During times of inclement weather labels should be made and painted for future use, stakes and poles trimmed and pointed. Examine Strawberry and other nets with a view to repairing any that are broken, and see what new ones are likely to be required. Where nails and shreds are used for fastening fruit trees the old nails should be made red-hot and the old shreds burnt. Rabbits and hares are often a source of great trouble in orchards and fruit gardens which are not enclosed by walls. They are especially troublesome during cold weather, when they will soon ruin the trees in young orchards if not checked. Wire fencing should be examined carefully and faulty portions replaced; the fence should be fairly high, and it is best turned over outwards a few inches at the top. Dress the stems of the trees with one of the preparations for making the bark distasteful to animals, and exercise a constant supervision of trees in outside gardens or orchards to see that the animals do not cause damage.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. Cookson, Oakwood, Wylam-on-Tyne.

SEED-SOWING.—Hybridisation is practised more or less extensively in almost all collections, and many of the seed-vessels are now ripening. Whilst seeds of some species may be sown at the time of harvesting (at the end of November and December) it is found desirable to save the bulk of them for sowing at the turn of the year. This method is to be recommended because, owing to the shortness of the days and the generally unfavourable conditions in winter, germination is then very slow, and the seedlings grow more or less weakly. With the turn of the year and the lengthening days the conditions gradually become more favourable, and seed germinates more satisfactorily. The methods of sowing must necessarily be governed by the facilities at hand. Where hybridisation is extensively practised it is best to have suitably-heated cases in which to germinate seeds of

Cattleya, *Laelia*, *Dendrobium*, and others of the *Epidendrum* group. By the use of these cases germination will be hastened considerably, thus shortening the time between seed-sowing and flowering. In most gardens some kind of propagating case is available, or one may easily be fixed up, which will be found of considerable advantage in maintaining an equable temperature and, with less evaporation of moisture than in the house itself, there will not be such need for waterings. It requires but very little disturbance to dislodge the seedlings from the soil in the early stages, and the least carelessness in watering is sufficient and may wash them over the sides of the pots. The method of sowing may not be generally understood; it should be done as follows: A piece of new canvas or some porous material about 4 or 5 inches square is laid flat on the palm of the hand and covered with finely-chopped Sphagnum-moss. The edges are then wrapped around the moss, forming it into a ball. This is then placed into well-drained pots, just sufficiently large to contain it. It is then watered, and when the superfluous moisture has drained away the seeds are sown on the canvas. The seeds are then transferred to the cases referred to above. *Odontoglossums* are best sown on pots in which the parent plants are growing, and the work may be done as soon as the capsules have ripened. Several pots should be chosen for seed-beds so as to ensure getting the most suitable, for, say, in half a dozen pots the seed may germinate well in one, whilst the other five may prove failures. The same is true of *Cypripediums* and *Calanthes*. It is desirable in the case of *Cypripediums* to select plants that have been recently potted, or where the compost is in a sweet and healthy condition. Most Orchids are very slow in germinating, and sometimes a year may elapse before the seedlings appear. Some of the same batch may germinate quickly and seeds of the others take a long time. Pot plants used for germinating seedlings need watering with extra care. Most of the failures are caused by careless applications of water before the seeds become attached to the rotting material, and in most cases floating them over the sides of the pots. *Calanthe* seeds ripen in about four months from the time the ovules are fertilised, and are best sown on recently-potted plants of their own kind in the spring.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of Derby, Knowsley Hall, Lancashire.

CYCLAMEN.—The first batches of these most useful plants will now be in full flower. Maintain a buoyant atmosphere of about 55°, and mix a little Clay's Fertiliser in the water applied to the roots. The later batches may be top-dressed with loamy soil, containing a little chemical manure. Remove a little of the surface soil with a stick, taking care not to damage the roots or corm. If flowers are required for house or table decoration pull the blooms in preference to cutting; the latter method leaves part of the stem, which rots and causes damage to young flowers at the base. Seedling *Cyclamen* which were sown during September and October should now have two or three leaves. Prick the strongest into pots or pans, putting the seedlings 3 inches apart, and keeping the greater portion of the corm above the soil. Use a compost of equal parts loam, peat and Oak leaves rubbed through a quarter-inch sieve, adding a little coarse sand and charcoal. *Cyclamen* are slow in germinating, so it is advisable to keep the pans on a shelf in case of young seedlings appearing later. Keep the young plants close to the glass; spray them on fine days and fumigate them occasionally.

CONSERVATORY AND GREENHOUSE.—Keep the conservatory gay with batches of forced bulbs and plants from the forcing-pit. *Azalea indica Deutsche Perle* and *A. Fielder's White* are good varieties to force and very little heat is required to bring them into bloom. Place them first in a temperature of about 60°, increasing the heat in the course of a week to 65°. Apply the syringe with force to the underside of the leaves to dislodge thrip and white fly. When the plants come into flower remove them to the

conservatory, where they will last in bloom for a long time. As the specimens pass out of flower pick off all seed-pods and return the plants to a warm pit to complete their growth.

MIGNONETTE, SWEET PEAS, CLARKIAS, SCHIZANTHUS & CALCEOLARIAS.—These plants require plenty of fresh air on all favourable occasions. Stake Mignonette neatly and stir the surface soil. Re-pot later batches and make a sowing now to produce flowers at a season just before the outdoor sowings are ready. Support Sweet Peas in pots with pieces of Birch broom and grow them as sturdily as possible.

RICHARDIA AFRICANA.—Plants of this popular "Lily" will now be in full growth and pushing up flower spathes. Give the plants a little fertiliser alternately with some diluted manure water prepared from cow-manure two or three times a week, according to the growth of the plants. Examine them for the presence of green fly, especially on the undersides of the leaves and on the half-opened spathes. Sponge the leaves with soapy water.

SEASONABLE REMINDERS.—Examine all stock plants, such as Fuchsias, Cannas, Sweet-scented Verbenas, Hydrangeas, Standard Heliotropes, Ivy-leaved Pelargoniums, Streptocarpus, and similar plants, to see that they are not too dry at the roots. If young plants of Fuchsia are required to flower in the early autumn, select some old plants of the varieties needed and start them into growth in a temperature of about 60°. Syringe them daily; take cuttings when the growths are 2½ to 3 inches long, rooting them in a frame that can be kept fairly close; pot them on as required. Stop the plants occasionally to obtain shapely specimens, and preserve them from all influences that would check growth.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

POT FIGS.—Unless bottom heat is supplied by hot-water pipes, the fermenting materials in which these are plunged should be renewed from time to time in order to maintain the bed a temperature of about 70°. The atmospheric temperature should be 70° by day and about 60° at night. A rise of 8° or 10° during the day with sun heat will do no harm, but the atmosphere must be kept moist at such times by damping the paths and brickwork with tepid water. A start should be made with successional trees; spray them to keep the bark and buds moist and grow them in a temperature of 50° to 55° by day, allowing a little less warmth at night.

FIGS PLANTED IN BORDERS.—Trees in mid-season or late houses should be pruned carefully, thinning out unripened and useless growths. Wash or paint the shoots with an insecticide (a mixture of soft soap, sulphur and warm water is suitable), to destroy scale or mealy bug. The shoots of trees trained on trellises should be fastened not closer than four inches apart, allowing six inches if there is plenty of room, for the leaves must not be crowded. Before starting the trees into growth water the border copiously. If it is considered necessary to renew the soil a mixture of fibrous loam, lime rubble and well-rotted manure—or half-decayed cow-manure—with a sprinkling of wood ashes and soot, may be employed. This mixture will be suitable also for tree in pots.

PINEAPPLES.—The temperature of the nursery house or pit should be about 65° by day, with a rise of 8° or 10° by sun heat—falling to 56° or 58° at night. During mild weather a little fresh air may be admitted to the pit. Only sufficient water will be required at the roots for the present to keep the soil moderately moist, and tepid water alone must be used at this or any other time. Plants in succession houses should be treated similarly, keeping the atmospheric temperature as near to 60° as possible; a sudden increase of heat at this season might result in the plants starting to form fruits prematurely. Water should be afforded in very moderate quantities; rather keep the plunging materials moist than to water the soil frequently, as the more

steadily the plants grow at this season the more likely are they to give better results later on. Pines in the fruiting houses should be grown in a steady night temperature of 60° to 65°, but a few degrees warmer through the day, either through the sun's rays or artificial heat, will assist in just keeping the plants growing; that is, if it is desirable that they do not show signs of fruiting before the middle or end of February. As a rule small houses have an advantage over larger ones, inasmuch as the plants can be brought into fruit in regular succession in suitable quantities. Drip, either from the condensation of moisture on the glass and roof or bad glazing, must be carefully guarded against, or the crowns of the plants may be seriously injured.

PEACHES.—A house may be started for succession. The temperature should be about 50° by day and 45° at night. Very little fire heat will be required; indeed, it is better not to hasten the trees into flower, as the buds are swelling fast under ordinary conditions, and many of them may drop if the temperature is very warm. Spray the trees lightly with clean water once or twice each day, according to the weather conditions. See that the soil in the borders is kept in a fairly moist condition, and in other respects carefully follow the instructions given in my notes printed last week.

THE "FRENCH" GARDEN.

By PAUL AQUATIUS.

COLD FRAMES.—The crops to be grown in cold frames should now be set at the earliest opportunity. On a bright day all lights can be removed, the soil well raked over, and seeds of Radish French Breakfast inserted broadcast, applying about ¼ lb. for each row of five frames. Carrot Chantenay or Guérande will also be sown, and the seeds covered with sifted soil, lightly pressed down. Six rows should be marked out for the Lettuces and the frames again covered with the lights. The two varieties of Lettuces, Little Gott and White Passion, are useful for sowing in cold frames; 108 plants of the former or 90 of the latter are sufficient for each frame. The plants required are lifted from the nursery beds and taken to the shed, where they are examined and cleansed of all bad leaves. All those showing decay on the stem should be rejected. To facilitate the handling of the lights two men should be employed for the planting, one setting the top and the other the bottom rows. Make the soil firm about the roots, but do not plant too deeply. Where little or no hot-bed is made, the paths between the frames should be filled with short and dry manure. This will hasten early growth and prevent cold winds from penetrating into the frames.

HOT-BEDS.—The making of the hot-beds will commence immediately in most gardens. The time must, however, be determined by the size of the Lettuce plants and the quantity of manure in hand. The place of the first bed (5 feet 6 inches wide) will be marked out with canes, set 8 to 10 feet apart, the manure brought in late in December being placed in a ridge. Fresh manure must then be added and well mixed with the old. Special care must be taken when making the outside, which must be very firm, utilising preferably strawy manure for the purpose. When the bed is completed the surface should be well trodden down and afterwards levelled. It should not then be more than 9 or 10 inches thick. The frames are to be set straight, allowing 1 inch between each to prevent the jamming of lights later on. A little manure can be placed in the frames to make a smooth and even surface before placing the soil. The space for the second bed is next marked out and all the black soil piled up is put inside the frames of the first bed. As soon as it is levelled and raked over Carrot Bellet can be sown very thinly. Radishes or Spinach might also be sown, but these crops hardly repay the extra labour entailed, and if they are sown in cold frames a better supply may be obtained without injuring the Lettuces. The seeds are covered with fine sifted soil and pressed down, seven rows being marked out for Lettuces Little Gott,

which will be planted (147 per frame) as soon as fermentation begins. The beds intended for Turnips are prepared in a similar way, but only Lettuces are now set (168 per frame). The seeds of Turnips are only inserted after the Lettuces are marketed, because this crop cannot thrive in a freshly-made hot-bed, and the dull, wet weather of January and February are unfavourable to the quick growth of this vegetable. The making of the hot-beds should be completed very early in February, and every bed finished on the same day as it is started, in case snow or frost involves a suspension of work.

NURSERY BEDS.—As soon as the planting of Lettuces begins the cloches at liberty can be placed on the beds prepared for Radishes and Carrots under frames. The planting is, however, postponed for another fortnight, when the soil is in a better condition. A bed of cloches should be retained to prick out a third batch of Cos Lettuces, 5 per cloche, instead of 14 as for the second transplanting. This is only done in the case of plants needed for the hot-beds in February. It produces half-grown plants, and helps to secure a very early crop. Cos Lettuce, Paris White, and Cabbage Lettuce Vauxhall Defiance are now to be sown in cold frames (½ oz. of seeds per frame) for setting outside late in April. This batch is not pricked out in nursery beds.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

HORSE RADISH.—This vegetable is usually treated with inexcusable neglect. The proper method is to lift the roots annually, storing them in sand for use in the kitchen, or merely covering them with soil in the garden. Then a new plantation is made of the number of roots annually required by the household. The ground should be dug two spits in depth, and on the top of the under spit, or about 10 inches below the surface, the roots should be arranged at 2 feet apart and covered with soil to the required level. Treated in this way nice straight even roots are produced. When the ground has been trenched some time previously to planting, the short pieces of root can be set equally well in holes, made deep enough with a dibber.

POTATOS.—It is usual to force a few Potatoes in 10 or 11 inch pots in a vinery or Peach house. The pots need not be much more than half-filled with turfy loam at present, and the tubers just covered. Very little water at the roots will be required for the first few weeks, and additions of a compost composed of half loam and half leaf-mould must be made from time to time as the haulm extends.

SEED-SOWING.—Where provision for the earliest plants of Brussels Sprouts was not made in autumn by sowing out-of-doors, seeds may be sown at once in boxes and the seedlings raised under glass. A few Cabbage Lettuces of the Tom Thumb type should be raised in the same way. Mustard and Cress should be planted every few days to keep up a supply of this salad; soak the shallow layer of soil, cover the seeds with thick brown paper, and germinate them in a hothouse. If more moisture is required rather dip the boxes than water the soil overhead. Sowings of French Beans should be made at brief intervals, but unless there is enough heat to grow these well forcing should not be attempted meanwhile.

PEAS.—In some years it is possible to make an early sowing in this month, sometimes earlier, sometimes later, according to the state of the soil and the weather. I never bury the seeds of this sowing deeply, but prefer to cover them in broad-ridge fashion with very fine soil. I thus obtain a warmer seed bed. The importance of sowing on a suitable day is very important, and the first opportunity should be embraced, for it may be well into March, if the crop is not got in this month, before the soil is again fit for working. There is, of course, a risk when sowing so early, but it is a risk well worth taking. I invariably choose a dwarf variety for the earliest crop out-of-doors.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

APPOINTMENTS FOR THE ENSUING WEEK.

- SATURDAY, JANUARY 10—
B.G.A. meet. at Richmond Hotel, Godalming.
- MONDAY, JANUARY 12—
United Hort. Ben. and Prov. Soc. Com. meet.
Surveyors' Inst. meet.
- TUESDAY, JANUARY 13—
Roy. Hort. Soc. Coms. meet. Horticultural Club Dinner; lecture by Mr. Wollaston on "Plant Collecting in New Guinea." Stirling and Dist. Hort. Assoc. Meet. B.G.A. meet. at Railway Institute, Finsbury Park.
- WEDNESDAY, JANUARY 14—
Surveyors' Inst. Prelim. Exam. (2 days).
- THURSDAY, JANUARY 15—
Manchester and N. of England Orchid Soc. meet.
Linnean Soc. meet. B.G.A. (Watford Branch) meet.
- FRIDAY, JANUARY 16—
Kew Gardeners' Social Evening.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 38.6°.

ACTUAL TEMPERATURES:—
LONDON, Wednesday, January 7 (6 p.m.): Max. 39°; Min. 31°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, January 8 (10 a.m.): Bar. 29.8; Temp. 46. Weather.—Fine.
PROVINCES.—Wednesday, January 7; Max. 47° Valencia; Min. 38°, Aberdeen.

SALES FOR THE ENSUING WEEK.

- MONDAY AND FRIDAY—
Herbaceous and Border Plants, Lilliums, Gladiolus, Begonias and other Hardy Bulbs, Roses and Fruit Trees, at 12, at 67 and 68, Cheapside, E.C., by Protheroe and Morris.
- WEDNESDAY—
Perennials, Herbaceous Plants, Gladiolus, Begonias, Lilies, Forcing Plants, etc., at 12. Palms and Plants at 5. At Protheroe and Morris's rooms.
- THURSDAY—
Special Sale of Roses at Protheroe and Morris's rooms, at 1.
- FRIDAY—
An importation of Burmese Dendrobiums; also established Orchids. At Protheroe and Morris's rooms, at 12.45.

Radium Emanations and Plant Growth.

We gave recently an account of experiments in the use of electricity as an adjunct to intensive cultivation. In the course of that account it was shown that there is reason to believe that the electrical discharge may play an important part in the horticulture of the near future, and this in several directions: First in the increase and acceleration of the growth of crops, and second in assisting the cultivator to cope with plant diseases. We have now to recount the progress which is being made with the investigation of the effects of radium emanations on plant life.

It is not surprising that our knowledge of the reactions of plants to radium emanations is still scanty, for the dis-

covery of radium is but recent, and the price of radium is all but prohibitive.

It would appear, however, that this barrier to research is about to be removed, and that processes recently invented, and referred to by Mr. Thomas Baker in his recent paper before the Royal Society of Arts, will bring radio-active substances within the purchasable reach of those desirous of experimenting with it.

Mr. Baker, in addition to holding out this prospect, has done the further service of summarising the results of his own and other recent experiments into the effects of radium on plant-development. Like the electrical discharge, radium emanations appear to act differentially on living things; that is to say they behave as though endowed with powers of good and evil—whom they will they slay, and whom they will they keep alive. Herein lies the immense possibility for the employment of the emanations in the service of mankind.

Thus Dr. Stoklasa has described recently in the *Comptes Rendus* the effects of various radium emanations on the nitrogen-fixing bacteria of the soil, and has shown that fixation of nitrogen goes on more rapidly in soil subjected to these emanations than in ordinary soil. Whether or not this property of radium of encouraging the growth and activity of certain beneficent bacteria is capable of economic application remains to be determined; but there would appear to be no valid reason—if the problem of price can be solved—why radio-active substances should not come to be used as fertilisers. Mr. Baker is emphatically of opinion that residues containing traces only of radio-active material are capable of accelerating greatly the growth of plants. He admits, however, that different kinds of plants do not respond in a uniform way to treatment with radio-active substances. For example, in one set of experiments on the use of radio-active earth Cress responded but poorly, whereas Radishes developed about three times more rapidly in a radio-active than in normal soil. The treated plants germinated much more quickly, and were already two inches high when the plants in ordinary earth were bursting through the soil. Mr. Baker is not inclined to attribute the more rapid growth of the treated plants to a sterilising effect of radium on the soil.

As an example of the minute quantity of radio-active substance required to produce a beneficent effect the following numbers and results may be cited: One part of radio-active material containing 2 m.g. (= .00035 oz.) per ton was added to ten parts of soil; Wheat was sown in the radio-active and in ordinary soil. Germination took place much more quickly in the radio-active earth, and in four weeks—the experiment was done in winter—the Wheat in the treated earth was half as tall again as that in ordinary soil. Larger quantities of radio-active material produced an adverse effect both in the germination and growth of Wheat.

Needless to say that, as is the case with the effect of the electrical discharge, nothing is known as to the manner in which radio-activity accelerates growth. Much more experimental work is required before these new instruments of husbandry can find use in our gardens and fields, but practical developments have a habit of coming quickly on the heels of scientific discovery, and therefore it behoves us to take a quick interest in the experiments which are in progress, and to facilitate them to the utmost of our power.

Like Samson in the temple of Dagon, with his hands on the middle pillars, who slew at his death more than they which he slew in his life, so the dying element Radium releases terrific forces in the course of its disintegration. To learn to apply those forces to the sustenance of mankind is one of the boldest aspirations of modern science.

Conditions Affecting Germination.

The vagaries of seeds with respect to germination are well known; but the factors

which determine the erratic behaviour are by no means understood. Seedsmen have discovered and put in practice various methods for enforcing the germination of difficult "subjects," but it is only recently that a systematic attempt has been made to investigate the causes which restrict the germination of various refractory seeds. Recent work by Messrs. Murerati and Zapparoli carried out in the experimental station for Italian agriculture, and summarised in the *Botanisches Centralblatt**, has for an object the classification of seeds according to their behaviour when exposed to various conditions of humidity. These observers find that variations in moisture have a markedly different effect on diverse seeds. In the case of such plants as *Avena fatua*, *Galium Aparine*, *Papaver Rhoeas*, and others they find that germination is greatly accelerated when the seeds are kept alternately for a long period in a dry place, and for a short period in moist air. Other seeds germinate more readily when they are exposed alternately for equal periods to dry and to moist air; but though the rate is increased the percentage of germination is reduced by this process. In this category are such seeds as those of *Rapistrum rugosum*, *Sinapis arvensis*, *Salvia pratensis*, *Abutilon Avicennae* and *Oenothera biennis*.

The germination of some seeds is uninfluenced by changed conditions of humidity—for example, *Convolvulus sepium*, *Solanum nigrum*, and others. In these cases, although the seeds remain alive, the percentage of germination is very low. The seeds of Leguminosae, *Vicia Cracca*, *V. hirta*, *Lathyrus Aphaca*, and *Daucus Carota* germinate "in gusts"—by instalments, and variations in amount of moisture do not break this habit.

Lastly, certain seeds do not germinate at all unless they are exposed alternately to dry and to moist air. If maintained in a

moist place they remain alive, but do not grow. To this class belong *Panicum Crus-Galli* and *Rumex crispus*.

Although the seeds on which these experiments were made are, for the most part, those of native "weeds," cultivators and others especially interested in the germination of garden or farm seeds may gain hints of no small usefulness by a study of this interesting work of the Italian scientists.

Coloured Supplement.—In the milder parts of the British Isles no trees and shrubs give greater interest, distinction and beauty to gardens than those of Chile, and amongst Chilean plants a place in the first rank must be given to the small tree of which we give a coloured plate. The nomenclature of the species is involved in the greatest confusion. In the *Botanical Magazine* at tab. 7160, it was figured by Sir JOSEPH HOOKER as *Tricuspidaria dependens*, a name which has been found to belong properly to a white-flowered species also in cultivation and described below. Under this name and under a synonym, *Crinodendron Hookerianum*, the plant has become widely spread in the gardens of south and south-west England, the west of Scotland, and most parts of Ireland, and the garden name is printed on our plate. At the same time the correct name is *T. lanceolata*, as was pointed out by Mr. Watson in *Gard. Chron.*, October 28, 1905. *Tricuspidaria lanceolata*, Miguel (*T. dependens* of Hooker, not of Ruiz and Pavon), is an evergreen tree 15 to 20 feet high, a native of the provinces of Valdivia and Llanquihue in Chile, and in the island of Chiloe. It is of rounded, bushy habit, and its young shoots are clothed with a soft, brown wool. The leaves, of hardish texture, are lance-shaped, rather coarsely toothed on the terminal half, pointed, $1\frac{1}{2}$ to $4\frac{1}{2}$ inches long by $\frac{1}{2}$ to 1 inch wide, dark, dullish-green above, paler beneath, and hairy on the midrib and prominent veins. The flowers, produced on stiffly pendulous stalks, need no description in the presence of the accompanying plate. They have one peculiarity, however, that should be mentioned; they form and are pushed forth from the leaf-axils on stalks an inch or more long in autumn, but the flowers do not expand or acquire their beautiful colour until the following May, or later. The finest example in the United Kingdom that is known to us is in the garden of Captain ACTON, Kilmacurragh, Co. Wicklow. According to Mr. W. J. BEAN in the *New Bulletin* for 1913, p. 110, this tree, measured by him last February, was then 20 feet high and 15 feet through. Imagine such a tree thickly laden with flowers like those portrayed on our plate! Those whose gardens are situated in a similar climate will surely need no further inducement to plant it this season. Like most Chilean trees and shrubs, it likes abundant moisture, and is benefited by a proportion of leaf-soil or peat (or both), mixed with the ordinary garden soil at the time of planting. *T. dependens* (true), Ruiz and Pavon, is distinct in nearly every respect from *T. lanceolata*. It is evergreen, but is a larger tree, and is known to reach over 30 feet in height. It is also of freer and more rapid growth. The young shoots are almost quite smooth; the leaves are ovate or oval, sometimes almost orbicular on the flowering shoots; and they are from 1 to 3 inches long by $\frac{1}{2}$ to $1\frac{1}{2}$ inches wide, the short stalk, the midrib and the chief veins minutely downy when young. The flowers are white and bell-shaped, not tapered from the base to the apex; they are borne on slender, smooth stalks 1 to $1\frac{1}{2}$ inches long, often pendulous or horizontal. Each petal is terminated by three conspicuous teeth. Cultivators in Ireland inform us that this tree is not so hardy in the open

ground there as is the red-flowered *T. lanceolata*. At Kew, however, on a wall in the garden of Cambridge Cottage, facing east, the white-flowered species is growing freely, and in July, 1912 and 1913 flowered profusely. But the plant has only been in its present situation about four years, and no very severe frost has been encountered during that time. Still, so far as present experience goes, it is a promising evergreen for walls, and it flowers at a time when shrubs in general are past. It is a native of Chile, with a rather more northerly distribution than *T. lanceolata*, and was introduced by Mr. H. J. ELWES, F.R.S., in 1901.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held on the 13th inst. in the Vincent Square Hall, Westminster.

HORTICULTURAL CLUB.—A house dinner of the club will take place on Tuesday, January 13, at 6.30 p.m., at the Hotel Windsor, Victoria Street, Westminster, when Mr. L. F. R. WOLLASTON will give a lecture entitled "Plant-collecting in New Guinea." The lecture will be illustrated with slides, reproduced from photographs taken by the lecturer. The following new members were elected at the meeting held on the 2nd ult.:—Mr. ARTHUR BATES, Mr. REGINALD CORY, and Mr. FREDERICK AMBROSE GARDINER. The Annual Meeting and Dinner will be held on February 10.

NORTH OF ENGLAND HORTICULTURAL SOCIETY.—At a meeting of this society, to be held in the Railway Institute, York, on Tuesday, January 13, at 7 p.m., a lecture will be delivered by Dr. E. J. RUSSELL (Director of the Rothamsted Experimental Station), on "The Cultivation of the Soil."

MR. W. F. GUNN.—Mr. W. F. GUNN, manager of the Dublin branch of Messrs. Alex. Dickson and Sons' seed business, has been appointed a Justice of the Peace for the City of Dublin. Mr. GUNN is president of the Dublin Naturalists' Field Club, a member of the committee of the Irish Forestry Society, and a member of the Council of the Royal Horticultural Society of Ireland.

NEW GARDENS AT GREENACRES, DISLEY.—At the conclusion of the laying out of the grounds at her Cheshire residence Miss CROSSLEY recently entertained the contractors and all the men employed on the work at dinner. The garden scheme includes a three-acre rock garden, Rose garden, wall garden, and a wild garden.

LIME CULTIVATION IN THE WEST INDIES.—The good work that has been carried on by the Department of Agriculture for the West Indies ever since its establishment is by no means diminishing under the able direction of its present Commissioner, Dr. FRANCIS WATTS, C.M.G., who has proved a worthy successor to Sir DANIEL MORRIS, and whose activities in promoting the welfare of the islands by the development of their natural resources and capabilities are exemplified, not only by the regular publication of the *West Indian Bulletin* and the *Agricultural News*, but also by the occasional issue of handy and cheap literature on distinct subjects, under the general title of "The Pamphlet Series." In many instances these are more than pamphlets, as in the case of one recently published, under the title *Lime Cultivation in the West Indies*, which runs into 136 pp., costs only ninepence, and contains not only much practical matter but also information that is interesting to the general reader. In noticing this book it is only right to say that it is the successor of one issued in 1908, under the title of *The A B C of Lime Cultivation*, which Dr. WATTS in his preface says has long been out of print, so that "the opportunity has been taken in preparing this handbook to revise and bring up to date the

information now available concerning the Lime industry," which, as he further says, "has continued to make steady progress in the West Indies, and is, at the present time, engaging a large amount of attention and undergoing rapid development." The following extracts on some of the products of the Lime, such as fresh Limes and Lime oils, will give an idea of the information to be gained from this little manual:—
"The products of a Lime estate are put upon the market in a number of different forms. That portion of the crop which is intended to be shipped as a manufactured product is allowed to ripen on the trees, the fruits, when fully ripe, dropping to the ground. For shipping as fresh or green Limes the fruits must be picked from the trees as they reach their full growth and just before the process of ripening begins. Fresh Limes are really green Limes; that is to say, they are green in the sense of not being fully ripe, and in order to be successfully shipped they must be green in colour. These fruits are generally thoroughly ripe and yellow by the time they reach the consumer in America or England. The term 'fresh Limes' is to be preferred in this connection." Under Lime oils we read:—"When the ripe fruits have fallen to the ground they are collected by women and girls and placed in heaps convenient for taking up and transporting to the mill. These Limes yield the following products, according to the method of handling and the market to be supplied. From the skins of the Lime the essential oil of Lime is obtained, a certain amount being taken from the Limes before they go to the mill, and a certain amount being obtained by distillation from the juice which comes from the mill. The oil which is obtained before the Limes go to the mill is known as 'ecuelled oil,' or hand-pressed oil (it has also received the name of otto of Limes), whilst that which is obtained by distillation is spoken of as distilled Lime oil. The ecuelled oil is more valuable and always commands a higher price on the market."

THE FLORA OF NIGERIA.*—Another interesting contribution to the flora of Nigeria has been published by the Trustees of the British Museum under the title given below. Mr. and Mrs. TALBOT are enthusiastic and successful collectors, and Mrs. TALBOT has added greatly to the value of their collections by her careful coloured drawings of the flowers of some of the more striking subjects. Mr. TALBOT contributes some introductory notes on the general character of the vegetation, which is practically the same as that of the adjoining German Cameroons region. He says: "The forests of Oban are usually described as within the evergreen belt, but though evergreens predominate, more careful study discloses the presence of a very large proportion of deciduous trees, many of which burst into leaf and flower twice every year. Several are known to flower no fewer than four times in the year, while on the other hand some cauliflorous trees only blossom every two or three years. Natives, whose information in other cases proved trustworthy, declared that certain kinds only flower once in seven years." Lianas, he states, often of the girth of our northern tree trunks, hang between giant boles 200 to 300 feet high, and, in the case of Cotton trees, over 80 feet in circumference. The collection includes upwards of 1,000 species, 195 of which are new, and there are nine new genera. Specially interesting among the new genera are:—*Crateranthus*, intermediate in structure between *Napoleonaea* and the tropical South American *Asteranthos*; *Afrohamelia* (*Rubiaceae*), *Talbotia* (*Acanthaceae*), and *Amauriella*, a member of the *Philodendroideae*. Special attention was given by Mr. and Mrs. TALBOT to cauliflorous trees, or such as produce their flowers on the trunks or on old branches, and

* *Catalogue of the Plants Collected by Mr. and Mrs. P. A. Talbot in the Oban District, South Nigeria.* By A. B. Rendle, E. G. Baker, S. Moore, and others. Printed by order of the Trustees of the British Museum. Octavo, pp. x. + 158, with 17 plates. 9s.

many new kinds were collected and drawn, belonging to such genera as *Cola*, *Napoleona*, *Drypetes*, *Tetrastemon*, *Omphalocarpum* and *Diospyros*. The *Rubiaceae* yielded the largest number of new genera (4) and species (34), though the new genera offer no very striking characteristics. *Acanthaceae* comes next with 21 new species, and there are 20 new species out of 70 of *Orchids*, mostly belonging to the genera *Bulbophyllum*, *Polystachya* and *Angraecum*. Although this book is called a catalogue, it is much more than that, for besides the full descriptions of all the new plants and the plates it contains much other information. No fewer than seven new species of *Napoleona* are described, just doubling the number previously known, and the allied new genus *Crateranthus* is among the most interesting of those figured. Kew has also received a set of the Talbot collections. W. B. H.

MR. ELWES AS A PLANT COLLECTOR.—At a recent meeting of the Cirencester Gardeners' Society Mr. H. J. ELWES, F.R.S., delivered an address on "Travels in Search of Plants." Mr. ELWES said his first real plant collecting was more or less an accident. He was going to Cyprus to collect birds, and happened to land in Asia Minor in the spring, when the country was covered with beautiful flowers, and, knowing just enough what bulbs were likely to be good and new, he filled two saddle bags with about forty different species of terrestrial *Orchids*, one of which proved to be new. When he brought it home and showed it to a committee of the Royal Horticultural Society that body said it was a worthless plant, and yet there was hardly a gardener now who did not cultivate it by hundreds. On an island he "grubbed up" two or three *Crocuses*, of which one turned out to be new, and it was then that he got rather keen about collecting. Ever since he had tried to continue the collecting of plants, birds, and insects, and he really thought the collecting of plants gave the most satisfaction. Mr. ELWES then proceeded, by the aid of lantern views, to give an account of his travels in Chili, Suakin, the Himalayas, Formosa, Mexico, the Andes, Thibet, and other places, in search of plants and to study their growth and habits.

THE PRESERVATION OF WILD FLOWERS.—The subject of "The Rehabilitation of Wild Flowers" was discussed at the dinner of the Lyceum Club on the 6th inst., and it was suggested that wild flowers should be protected from destruction by children. Sir DAVID PRAIN, F.R.S., Director of the Royal Gardens, Kew, said that it was important that an early opportunity should be taken of educating the teacher. It had been definitely stated by a member of a scientific society that the greatest enemy of wild flowers in England to-day was in many cases the schoolmaster. There had been instances of teachers who, upon discovering the existence of some rare plant, had gathered as many specimens as possible for distribution among his scholars. He appealed to all lovers of the beautiful to assist in the preservation of wild flowers. One of the speakers said that he hoped there would be established a League of Wayfarers with the object of restoring flowers to the countryside. A purpose of the League would be to stimulate the County Councils in enforcing the powers they possessed in preserving wild flowers. He suggested that planting parties should be arranged where the wastage and need of replanting were the greatest.

ENGLISH FORESTRY ASSOCIATION.—It is proposed to hold a representative exhibition of woodland and timber industries in London, under the auspices of the English Forestry Association. Invitations to co-operate are extended to all interested in the subject, and it is hoped to obtain the enthusiastic support of all concerned with English timber and under-

wood. During the course of the exhibition conferences will be held to discuss important points, and especially with a view of extending the uses of English timber or the goods manufactured from it. No information is yet given as to the place of exhibition, but we are informed that the secretary is Mr. M. C. DUCHESNE, Farnham Common, Slough.

NEW OPEN SPACE FOR BIRMINGHAM.—At the meeting of the Birmingham City Council, on the 6th inst., Mr. GEORGE CADBURY's offer of five acres of freehold land at King's Norton for use as a playing-field or recreation-ground for the scholars attending the secondary school there was accepted and the thanks of the Council accorded to Mr. CADBURY.

HORTICULTURAL EDUCATION IN PRUSSIA.—According to the *Journal of the Board of Agriculture*, Prussia possesses three centres for higher horticultural education. The Royal School for Gardeners at Dahlem (Die Königliche Gärtnerlehranstalt), which was founded in 1823; the Royal Pomological Institute at Proskau (Das Königliche pomologische Institut), opened in 1868; and the Royal School for Fruit Cultivation, Vine-Growing, and Gardening at Geisenheim-on-the-Rhine (Die Königliche Lehranstalt für Obst-Wein und Gartenbau). Dahlem demands of its students that they should have attained to the lower only of the two leaving certificates, or have had a correspondingly good education, together with four years' practical experience in gardening. At Proskau and Geisenheim the demands as to previous education are less, but both require that prospective students should have had at least two years' experience in practical gardening. In any case, however, a student who wishes to enter for the State technical examination in horticulture must possess the lower leaving certificate or its equivalent. The course usually lasts for two years; but at Geisenheim there is, in addition, a lower course lasting one year only, and open to practical gardeners of moderate education. The usual course is one or two years, the details of which differ at each of the institutions, but in each case it is so arranged as to make full use of the practical knowledge that the students already possess. There are also shorter courses for special purposes, especially at Proskau and Geisenheim. All three institutions enforce a leaving examination on those students who have completed the full two years' course. Gardeners who have passed this examination may, after they have completed seven years' practical experience, of which three years must be after leaving the institution, enter for an examination conducted under the auspices of the State, and, if successful, are granted a diploma, and the right to be termed master of their craft.

RESEARCH AND FARM INSTITUTES.—At the Conference of Educational Associations held at London University on the 6th inst., Mr. A. D. HALL, F.R.S., recently of Rothamsted, but now of the Development Commission, read a paper on the Organisation of Agricultural Education in England and Wales, wherein he stated that it had only been the advent of fresh supplies from the Development Fund that had enabled the Board of Agriculture to exercise any general co-ordinating power over agricultural education, and to lay the foundations of a scheme that should provide for all the needs of the rural community. Mr. HALL declared such a scheme did now exist in outline, but time and the co-operation of the local authorities and a desire for education were necessary to make it a real factor in national prosperity. Some ten or a dozen research institutes had been founded, generally attached to a university, and each with a subject allotted to it. These institutions were non-local, they had no educational obligations, and they were not expected to communicate their results directly to

the farmers. That function belonged to the parallel organisation of the agricultural colleges, to which end England and Wales were divided into twelve provinces, in each of which one of the colleges was situated giving long courses of instruction suitable for future landowners and large farmers, land agents, teachers, and other officials. In Mr. HALL's opinion agriculture was likely to play relatively a more important part in the national economy than it had been doing for the last century or so, and he felt that its future depended more upon the improvement of the men practising it than upon any legislative dealings with the land or its occupiers.

ANNUALS.

BEING interested in annuals for the decoration of the flower garden in summer and autumn, I was pleased to see on p. 420, Vol. LIV., Mr. Harris, of Lockinge Park Gardens, advocating their use, and still more so to see him recommending a border of annuals as a pretty feature for inclusion in the flower garden. In these gardens we have a border measuring 270 feet long by 12 feet wide, devoted entirely to annuals or plants that may be used as such, and it was quite one of the best features last season. The soil of the border was trenched and well manured at the start, and the next year it was dug and manured in the ordinary way. This season it will be trenched again, but not much manure will be added, instead a good dressing of lime, soot, and wood ashes will be applied. Whatever the weather may be, I look forward to a good display. Sweet Peas were planted for a background in two rows, in clumps at 4 feet apart, four clumps of each colour. In front of the Sweet Peas were annuals that grow from four to five feet in height, and again in front of these were others only 3 to 4 feet tall. The front row was composed of those only 2 feet high or thereabouts. Mixed *Violas* were used as an edging, and the path in front of these is grass 4 feet wide, which served to throw the colours of the flowers into greater relief. This coming season we hope to plant the Sweet Peas in large round clumps at intervals of twelve or fifteen feet apart, and also clumps of climbing *Nasturtiums*, *Tropaeolum canariense* and *Convolvulus*. Below I give a list of annuals, and also a few biennials used as annuals, which we planted last year:—*Alonsoa Warscewiczii*, *Anagallis* (blue and red), *Antirrhinum* (tall, intermediate and dwarf), *Arctotis grandis*, *Asters* (several sorts and colours), *Cacalia aurea* and *C. coccinea*; *Candytuft* (white spiral, lilac, crimson, etc.), annual *Chrysanthemums*, *Collinsia bicolor*, *Cornflower Chameleon*, *Cosmea* (early-flowering varieties), *Dianthus* of sorts, *Diascia Barberae*, *Lupinus* (blue, pink, and other colours), *Malope* (crimson), *Sweet Peas*, *Petunia Empress*, *Phacelia campanularia*, *P. grandiflora*, *Phlox Drummondii*, *Poppies* (various), *Salpiglossis* (four colours), *Abronia umbellata*, *Alyssum Snow Carpet*, *Calendula Cockade Orange*, *Clarksias Salmon Queen*, *Purple King*, *Scarlet Queen*, of the elegant type, and several of *C. pulchella* varieties; *Chirtonia pulchella*, *Eschscholtzias*, *Eutoca viscidula*, *Godetias* in various colours, *Gypsophila muralis*, *G. elegans*, *Hibiscus africanus*, *Ionopsidium acaule*, *Kaulfussia ameloides*, tall and dwarf *Larkspurs*, *Leptosiphon roseus*, *Linarias* of sorts, pink and white *Lavateras*, *Mimulus Queen's Prize*, *Nemesia strumosa* and the variety "Blue Gem," *Nemophilas*, *Ten week Stocks*, *Scabious* in four colours, *Stalice Suworowii*, *Sweet Sultans*, *Verbenas* in various colours, *Nigella Miss Jekyll*, tall and dwarf *Coreopsis*, *Swan River Daisy*, *Salvia violacea*, *Amaranthus cordatus* (Love-lies-bleeding), and *Amaranthus hypochondriacus* (Prince's Feather).

Many of these annuals were sown out-of-doors in April, and the seedlings were well thinned. During the summer the Dutch hoe was used frequently to destroy weeds and aerate the soil. This I have found to suit the young plants much better than heavy waterings, and I noticed a marked difference in the growth of the plants afterwards. The plants were thinned according to the growth I thought they would make. Some such as *Lavatera*, *Love-lies-bleeding*, *Prince's Feather*, *Cosmos* and tall *Poppies* were not closer than 1 foot or 18 inches, and in some cases this distance was not too much. To keep the tall plants from being blown about by winds neat Pea sticks were placed about some, whilst others were tied to stakes, and although this entailed considerable labour, the display of bloom was ample compensation, and the border continued in bloom until quite late in the autumn. *R. W. Thatcher, Carlton Park, Market Harborough.*

TREES AND SHRUBS.

RHODODENDRON NOBLEANUM.

RHODODENDRON NOBLEANUM is one of the oldest of the hardy hybrid *Rhododendrons*, and is still extensively cultivated, its early flowering giving it a value over the bulk of the hardy members of the genus, which flower in May or June. It was raised from the Himalayan *R. arboreum*, which has blood-red flowers, crossed with *R. caucasicum*, the blooms of which are white or pale-straw coloured. The influence of *R. arboreum* is strongly predominant in the hybrid, which takes little but hardiness from its other parent. There are several forms of *R. nobleanum* in cultivation, which are probably different seedlings from the original cross. The colours of the flowers vary from deep-crimson to a rosy-pink, but the typical form has bright, deep-crimson flowers, which are produced freely on even small plants. The leaves are 6 inches or more long by 1 inch to 2 inches wide, dark green above and covered beneath with a greyish-brown felt or tomentum, which appears smooth and shining on the surface. Others vary in the colour and quantity of this tomentum as well as in the colour of the flowers.

The variety *album* has white flowers marked with two faint perpendicular rows of dark-red spots on the upper segment. The leaves are shorter and broader than those of the type, and are also darker on the undersides. The variety *venustum* has blooms of a pleasing rosy-pink shade, freely produced in somewhat small trusses. The leaves are about the size of those of the type, but are turned downwards at the edges, which makes them look much longer and narrower. They are of light-green colour beneath, the grey or brown tomentum being practically absent. This plant must not be confounded with *R. venustum* × (*Jacksonii*), a later-blooming plant of dwarf habit and bright pink flowers.

R. nobleanum and all its forms bloom at any time from December to April, when weather conditions will allow. *J. Clark, Bagshot, Surrey.*

CULTURAL NOTE.

SALVIA SPLENDENS BOUQUET ROSE.

This variety of the Scarlet Sage is a welcome addition to gardens in winter. It differs from the older sorts in having flowers of a salmon colour, and the spikes are not so compact; but this defect will probably be overcome by selection. The majority of the plants come true to colour when raised from seeds. *W. H. Divers, V.M.H., Belvoir Castle Gardens, Grantham.*

THE VARIEGATED WILLOW WEEVIL (CRYPTORHYNCHUS LAPATHI, L.).

THE Variegated Willow Weevil has recently been reported from the North of Scotland, and it appears to be more widely distributed than has hitherto been supposed.*

Cryptorhynchus lapathi, the Alder weevil of the German forester, is in this country chiefly

FIG. 13.—VARIEGATED WILLOW WEEVIL, *CRYPTORHYNCHUS LAPATHI* (× 2).

a, Adult weevil; b, pupa, dorsal aspect; c, larva; d, pupa, ventral aspect.

an enemy of the Willow, although Alder, Birch and Poplar are also attacked by it. Both the adult beetle and its larva are injurious. The beetle gnaws the tender bark of the young shoots, causing them to wilt or die and break off. The

FIG. 14.—TUNNELINGS OF THE WILLOW WEEVIL.

a, Straight larval gallery; b, hook-shaped gallery.

larva eats into the bark of the stem and main branches, almost girdling them, and then bores into the wood itself, sometimes penetrating into the pith. It pupates there, and, as a full-grown weevil, may rest there during the winter.

* *Entomologists' Monthly Magazine*, November 1, 1913.

C. lapathi belongs to the group of long-snouted weevils. Except when it is feeding, its snout lies hidden in a furrow in the thorax. The antennae are elbowed. The adult measures rather less than half an inch in length. It is stoutly built and squat. The whole body is covered with patches of short black hairs, which give it a warty appearance. The head and basal two-thirds of the elytra are dull black, the rest of the elytra being a rosy-pink. The femora of the first pair of legs are also pink.

The larva is a white, soft-bodied, legless grub, with a well-marked, brown head and biting jaws. When full-grown it is about half an inch long. The pupa is soft-bodied and white; its abdomen ends in two short spines curving inwards.

The larval galleries of *C. lapathi* are of two types. The first is a simple, straight tunnel, bored from below upwards, about two inches long (fig. 14 A). The second type is a hook-shaped tunnel bent back on itself (fig. 14 B). At the end of this gallery the larva pupates, head downwards.

Scheidter, of Munich University, has recently worked out the life-history of *C. lapathi*.† He describes two types of generation, a one-year and a two-year. Both types may be observed in the same neighbourhood. Again, he finds that the adult weevil may remain in its pupating chamber throughout the winter, or it may leave it on emerging from its pupal state in August, and, foraging until cold weather comes, may winter in the soil or in herbage or in an unused gallery. In the last case the weevil is found head up in the gallery.

In the North of Scotland the life-history is as follows. The beetle flies in the end of April and throughout May and June, when it lays its eggs on the bark of the stems and main branches of Willows from four to fifteen years of age. For two or three weeks the young larva gnaws a tunnel in the cambial layer, almost girdling the stem. This tunnel is irregular. In July it is almost full grown, and commences to tunnel into the wood itself. In August and September it pupates and, as the adult beetle, remains in its pupal chamber until April of the next year, when it appears and commences egg-laying.

In the North the generation is a one-year one. Throughout the winter only adults are to be found in the galleries, lying head downwards. In these cases, too, the galleries are still filled with frass.

C. lapathi may do very considerable damage to Willow stems. The early work of the larva is the most serious in that the sap-flow may be stopped, and is always reduced. Stems and branches from one to six inches in diameter may be destroyed in this way.

The only remedy is to remove all infested stems and branches during the winter months and burn them. In this way the weevils are destroyed before emerging. *J. W. Munro, Aberdeen University.*

AMERICAN NOTES.

THE WOLF RIVER APPLE.

RECENT issues (see *Gardeners' Chronicle*, Nov. 1, 1913, p. 300, and Dec. 6, p. 398) have contained comments on the Wolf River Apple.

This is perhaps the largest Apple grown. Certainly it is often shown as such at the exhibitions here representing all the States where the cultivation of Apples is one of the chief industries. It possesses good eating qualities for a large fruit and invariably takes on a fine colour. The writer does not know its origin, but there is a suspicion that it is comparatively

† Scheidter, *Bunten Erlezwusler; Zoologische Zeitschrift für Forst und L. wertschaft*, April, 1913.

recent, or else it remained unknown until the revival of Apple culture in the past few years.

The soil where best results are obtained is usually strongly impregnated with iron. At a recent "land show" in Chicago, where each State strives to advertise itself by showing its best products, samples of earth were seen that represented the best Apple soil, and the dipping in of a magnet showed seemingly an enormous percentage of iron. The crops, however, are all raised by irrigation, so that the food contents of the soil are controlled by the application of water. Thus colour, flavour and size are attainable to a degree at will. Great pains are taken to ascertain when to use water. This is true also of the Citrus fruit culture, so that irrigation by no means solves all the problems of the fruit culture of the present day: it only accentuates some of them. By this mail a

In structure *C. Siebertiana* much resembles *C. Veitchii*. The spotted labellum shows the influence of the pollen-parent, and in the single flowers, taken from different plants, the variation is said to be remarkable. About thirty seedlings were raised from the cross, twenty of which have not yet flowered.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

NATIONAL DIPLOMA IN HORTICULTURE.—With reference to the details published in your issue of August 30 last, on the subject of a National Diploma in Horticulture, I notice that the fee mentioned is £4. This, to a poor man, would be a large sum; indeed, I doubt whether, if I myself desired to enter for the examination,

ture to affirm, sufficiently realised, or the subject of afforestation would receive more serious attention. As one journeys across the country how seldom it is that one comes upon any newly-planted forest trees; yet, on the contrary, how frequently one reads or hears of the gales laying some old veterans low. This denuding of the counties' best timber trees is constantly going on, but the vacancies thus caused are not made good. Six of the best counties for timber growing, if their present material is any criterion, would be Hereford, Gloucester, Worcester, Warwick, Oxford, and Chester. Mr. Hutchins rightly says 5,000 acres is an unnecessarily high limit for an experimental area. Surely 1,000 acres would make a favourable impression wherever planted, while a plantation of 500 acres of the more costly species, grown in a favoured spot where a large number could not be accommodated, would at least make a presentable appearance, beside making work and providing an ultimate reward. I wonder what is the extent of Delamere Forest, in Cheshire. It would be interesting to learn where the Coast Erosion Committee obtained the figures wherein they inform us that 1,500 acres of grass land provides employment for one man. Certainly the men are not in each other's way. There cannot be many thistles or the like to be kept under, and the grass would not be too rank from the amount of manure applied. Is it not possible for some influential body to take some step which will serve to focus public opinion on afforestation?—*C. Turner, Ken View Garden, Highgate, N.*

CHRYSANTHEMUM MADAME CASTEX DESGRANGES.

—Like Mr. E. H. Jenkins (see p. 13), I, too, am interested in Mr. Norman Davis's statement about this old-time popular early-flowering variety, but I am by no means convinced of the accuracy of that statement. Nor can I easily reconcile with information collected during many years' research Mr. Jenkins' statement, based upon his enquiry of the late Mr. Parker and probably his own memory, that the flower was in cultivation here in England so far back as 1873. The evidence gathered by me does not support, but rather contradicts, this; and I notice Mr. Jenkins has for years tried to find out who the raiser was, and perhaps the date of its original distribution, but without success. Let it be first of all understood that the proper name is Madame Castex Desgranges. An elementary knowledge of French, apart from the vagaries of proper names, suffices to show that "Desgrange" must be a mere slip of the pen or an error due to ignorance. This, however, is of little importance, for the N.C.S. in its official catalogue definitely accepted the name as given at the head of this article, and the catalogue is accepted as binding in matters of nomenclature. The chief interest in the question centres round its origin and date of distribution, and from what I know of the efforts of the French in trying to obtain a race of early-flowering Chrysanthemums, dating back to the far-off days of Lebois, I cannot agree with Mr. Davis' hypothesis—and that is all his statement amounts to—that Mme. Castex Desgranges was a chance seedling any more than I can agree with his expression of opinion that the Chinese gardeners crossed the *Chrysanthemum indicum* or *sinense* with *C. Leucanthemum* prior to the introduction of the popular autumn flower into England more than a century ago. Those who were present at the conference will remember that Mr. Davis expressed his opinion as purely conjectural. He did not attempt to substantiate it by any literary or other proof. His account of the evolution of the early race was largely his own personal experience extending over the period during which he has cultivated the flower. Valuable, of course, as far as it goes, but incomplete, at any rate, from a scientific or historical point of view. I shall show later that there is good reason for supposing that Mme. Castex Desgranges was not what Mr. Davis supposes it to have been, but for the moment we must consider Mr. Jenkins' statement about its being here in England as far back as 1873. Personal knowledge on my part I cannot invoke, for my own practical acquaintance with the flower did not begin till 1882, but my literary and historical knowledge of it goes back infinitely farther. Against Mr. Jenkins' date we have also the experience and recorded

FIG. 15.—*CALANTHE SIEBERTIANA*.

copy of an Apple issue of a Montana paper is forwarded, showing the interest taken in Apple culture in the West. *E. O. Orpet, Walden Superintendent's Office, Lake Forest, Ill.*

HYBRID CALANTHE.

We have received from Herr August Siebert, of the Palmengarten-Gesellschaft, Frankfurt-a/Main, flowers of a hybrid *Calanthe*, *C. Siebertiana* Schlechter (see fig. 15), raised in the Frankfurt garden. The hybrid resulted from a cross between *Calanthe Veitchii* hort. ♀ and *C. cardioglossa* Schlechter ♂. The first plant flowered two years and eleven months after the flower was pollinated. The plants are described as very floriferous, bulbs under 5 cm. in height showing flower spikes.

I could afford the necessary sum, let alone the extra expense of travelling, if the place of examination were some distance away. Many men would be glad to try their skill in this way, but I am afraid that a married man with a family would be entirely prevented from entering owing to the miserably low wages paid in the gardening profession. I notice that the final examination is to specialise in some one branch of horticulture. This seems somewhat of a hardship to the ordinary head gardener, who is expected to be equally proficient in all branches, and has neither time nor opportunity to specialise. *C. Robinson, St. Hilary Gardens, Cowbridge.*

THE INTERNATIONAL FOREST CONGRESS (see Vol. LIV., pp. 374, 394, 414).—What a wealth of interest and instruction the article on this subject provided. The many facts related therein should do much towards popularising this subject of vital, national concern. The importance of forestry, as one of the most valuable of national assets, is not, I ven-

facts of the greatest early-flowering specialist of his time, Mr. W. Piercy, which I quote further on. For fuller details of the early-flowering section than I can narrate here the enquiring reader may be referred to my history of the early Chrysanthemums that appeared in *The Garden* for May 16, 1891, and to my paper in the report of the N.C.S. Early-flowering Conference, held at the Crystal Palace, October 4, 1905. At other times and in other places I have more or less fully dealt with the origin of Mme. Castex Desgranges, based not upon mere speculation nor upon my own memory or experience, but from documentary evidence and personal correspondence, extending over thirty years, with the leading French Chrysanthemum growers. Of course, here again my informants on any point may be mistaken, but so far as concerns French varieties they are perhaps less likely to be inaccurate than their English colleagues. There is no doubt that Madame Castex Desgranges was like some other things in the world—it was known before it was discovered. Both Mr. Davis and Mr. Jenkins will probably peruse with interest the version of the late Mr. W. Piercy, who at the N.C.S. Conference in September, 1889, gave his life experience in early Chrysanthemums, some of which—and particularly that relating to Madame Castex Desgranges—was substantiated by reference to authentic sources—viz., the French catalogues. He says: "The most striking point to advance in general estimation these early sorts . . . was the discovery in the summer of 1879 of Madame Castex Desgrange by Mr. Robert Parker, at that time of the Exotic Nursery, Tooting, Surrey. This was found by him in a lady's garden in Wales. On March 15, 1880, he gave me two little plants of it, and from those two little plants and his stock the bulk of those now in cultivation have come. As is customary, as soon as this variety became known we had the cry common in such cases that it was known before. Old French catalogues were found in which there was the name, but no one had seen the plant. Others said they had it, but I did not find they had the stock. It was in the lists of Mons. Lemoine and Mons. Crousse, of Nancy, France, of March, 1881, but I expect they had it from England the year before or raked it up from some place in France, for we had heard nothing of it from them before March, 1881. Lemoine says it was raised by Boucharlat; Crousse spells it Desgranges." So much for Mr. Piercy's version, and although it will be seen he relies partly upon documentary evidence, he, too, becomes speculative. The chief point to which attention must be drawn is Mr. Piercy's date of 1879 as against Mr. Jenkins' 1873. To the uninitiated the case as stated entitles one to draw the conclusion that Mr. Piercy, as a practical man writing only ten years afterwards, is as likely to be correct as Mr. Jenkins writing forty years afterwards. But that will not be sufficient to settle the point, for the converse is equally likely to be the fact. It will be seen that Lemoine says it was raised by Boucharlat. My Lemoine catalogues have long since gone the way of all wastepaper, but I have what is better—I have those of Boucharlat himself. The earliest is dated 1883, and under "Chrysanthèmes Précoces" is "Castex Desgranges, Japonaise blanche pure." No raiser's name to this or any of the others is given. Apparently no general catalogue of his for 1884 or 1885 reached me, but in 1886 the variety is again included in the early section, this time adorned with the prefix of "Mme." Still no raiser's name appears. In 1887 it appears as "Mme. Castex Desgranges (B)." From what has been said by Mr. Jenkins and Mr. Piercy it is obvious that there is very little satisfaction to be obtained by referring to English catalogues between 1873 and 1879, for Madame Castex Desgranges did not become known to our growers in general till about the latter date. Mme. Castex Desgranges, between the date of its being raised and the date of its becoming commonly known in this country, is in an identical position with another variety that Mr. Davis and Mr. Jenkins probably know quite as well: I mean *Secur Mélanie*, which was raised and grown on the Continent many years prior to its introduction here. In concluding I may add that when the late Shirley Hibberd, about twenty-five years ago, gave me a commission to write a detailed history of the Chrysanthemum, which formed the principal part of a special Chrysanthemum double number of

the *Gardeners' Magazine* (October 26, 1889), I ransacked all my own sources of information, and also put myself into correspondence with every French Chrysanthemum grower I knew, to obtain definite and authentic material relating to the subject. Much original matter thus collected, having served its purpose, is now no longer at hand, but I have a very distinct recollection of enquiries made concerning the early-flowering Japanese variety under discussion. My history was followed by a number of biographical notices of the then famous French growers, compiled from notes supplied by themselves and from my own knowledge of their work. The son-in-law of Boucharlat, whom I still know personally, sent me details of his father-in-law's work, and told me that he it was who first sent out in 1873 or 1874 a set of early-flowering varieties, of which at that time (1889) only one, Mme. Castex Desgranges, had survived. He certainly ought to know; and Mr. Piercy's reference to Lemoine confirms the claim of Boucharlat as raiser. Although unknown in England, Boucharlat forty years ago was sending out new Chrysanthemums in France, and even the great Simon Délaux, when he raised his first seedlings, distributed them through Boucharlat, as he told me himself. Lemoine was then the only Frenchman that did any business of the kind in England, and he would, of course, secure any novelties Boucharlat put on the French market. Suppose we assume, for argument's sake, that Mr. Jenkins' date (1873) is correct, notwithstanding Mr. Piercy's later date, and the irresistible conclusion is that Mme. Castex Desgranges was sent out in the spring of 1873, flowered here in the autumn, and then the rest of the story is clear. *C. Harman Payne, 141, Wellmeadow Road, Catford.*

THE ABNORMAL SEASON.—I have read with interest the notes already printed on the abnormal season. In the gardens here, Royal Sovereign Strawberries, grown in pots and plunged in the open ground, have during the past two seasons pushed up their flower trusses early in December. Last year, as an experiment, I pinched out a few of these forward trusses in January, before placing the plants in the forcing house, and the result was that several weaker flower trusses were developed, which produced smaller fruits than would have been borne on the first truss. I have not found any difficulty in forcing *Freesia refracta alba* into bloom by the date mentioned. By the middle of December we had large batches of this plant in full bloom, bearing ten flowers to a spike, and with stout foliage, but the perfume is not nearly so strong as is the case with plants which flower later. *C. Robinson, St. Hilary Gardens, Coubridge, S. Wales.*

FAILURE WITH CHRYSANTHEMUMS (see Vol. LIV., p. 426).—May I suggest that Mr. Kearns' failure with his Chrysanthemums was caused in part by housing them too early in such an abnormal season? Growth was active at the time the plants were housed, and the temperature of 65° and upwards excited the plants into further growth, in which the applications of manure assisted. Mr. Kearns does not say if his plants were potted firmly; I am of the opinion that firm potting is very essential. *C. Robinson.*

SILVER-LEAF DISEASE.—The soil in these gardens is a sandy loam, not the least adhesive. I mention this fact because it would be interesting to learn whether the disease is more prevalent on trees growing on heavy or light ground. It would help towards settling his question if correspondents writing on this topic would state the nature of their soil, as I note some have done. My own experience is that it is more prevalent on light soils. According to observations of trees suffering from this serious disease I am inclined to agree with *J. F. N.*, p. 426, Vol. LIV., as to manures being favourable to the disease. In my case I put it down to inorganic manures. The trees in our second Peach house are planted in the ordinary soil that the house is built upon, but not the least trace of silvering is apparent. But three trees taken out of this same house and planted in the first house four years ago have since shown the disease. A tree of the variety Early Silver utterly collapsed through the malady spreading so quickly. The border was prepared in the usual way and enriched with

bone, wood ash and lime rubble. The same refers to outside trees. Some Plums planted in prepared soil show the disease, others planted haphazard show no signs of silver leaf whatever. In rich soils young trees make far too much wood and they grow vigorously in almost all soils. *Chas. F. Coates, Manor Park, Pottton.*

DAHLIA MARIANNE.—In reply to *Grower*, who writes of Dahlia Marianne (see p. 13), may I ask him if he has seen such varieties as Barlow's Bedder and Gluchaut growing side by side with Marianne? *A. C.*

PRIMULA OBCONICA AND SKIN IRRITATION.—My experience with this plant is very similar to that described by Mr. W. Marsh on p. 13. As has been the case with him, I was unaffected for many years, during which time I often brushed the skin of the tender underside of my upper-arm with leaves of *Primula obconica*. But one day, when working amongst these plants, I felt a stinging sensation in my right hand, which was soon followed by intense irritation. A local chemist supplied a soothing lotion, in which flowers of sulphur entered, and it allayed the irritation for the moment, but it returned for about a week. On this occasion the weather was unusually hot and I attributed the poisoning to the overheated state of my blood; so some time later I again handled the leaves of *Primula obconica* and was again poisoned. I repeated the experiment at about a year's interval with the same result, and after the lapse of several years I accidentally touched a leaf and was badly stung. It would be interesting to know if this susceptibility to *P. obconica*, after having been immune, is experienced by other persons. *A. C. Bartlett.*

JASMINUM OFFICINALE FRUITING (see page 13).—There is nothing unusual in this hardy climber perfecting its seeds in this country, but whether such seeds germinate I am unable to say, not having given them a trial, as the plant is so easily increased by cuttings or layers, propagation being best carried out during the autumn months. I was pruning a plant a few weeks ago, and noticed several well-ripened berries on the shorter shoots fairly close to the wall. This particular plant had not been pruned since it was planted some seven years ago, so readers can imagine what a tangled mass of shoots had to be cut away. The plants should be spurred back each winter, in a similar manner to *J. nudicaule*, in early spring. *J. Mayne, Buckinghamshire.*

—We have at the present time two plants of *Jasminum officinale* on a south wall, with several fruiting sprays, some of the berries green and others quite black. I have never seen ripe fruits before, but I have noticed green berries several times. I sowed some of the berries in a pot on December 20, to see if the seeds would germinate. *A. H. Chapman, Orchards Gardens, East Grinstead.*

—Although the fruiting of *Jasminum officinale* is not a regular occurrence, wall-plants in the West of England often bear a sprinkling of the fruits which Mr. J. E. Shaw describes so well on p. 13. *A.*

AUTUMN-FRUITING RASPBERRIES.—Amongst other good works, the Royal Horticultural Society is making a trial of autumn-fruiting Raspberries at Wisley, and I believe have found several varieties which promise to be superior to Alexandra, although as I saw this variety at Gunton Park last October it will "take a deal of beating," for the canes there were heavily laden with large fruits equal in flavour to the best summer produce. But may it not be with this type of Raspberry as it is with Strawberries and, in a greater degree, with Potatoes—i.e., a variety which succeeds admirably in one garden may be a comparative failure in another, so that the "best" variety for any garden can be ascertained only by experiment? *A. C. B.*

SCHIZANTHUS.—This flower, grown in most gardens in recent years, has a very pretty effect in houses, and with careful attention provides a mass of bloom for many weeks. The seed is usually sown in pans or pots and placed in a pit or other convenient place. It is not very long germinating, and seedlings when an inch or so

high are nicely rooted, and ready for thumb-pots or 60's. They should then be put into a cool frame or span-roof house, as close to the glass as possible. It is not long before they make a mass of fibrous roots and are ready to be re-potted into 48's. This plant is not so particular as a great many, but of course needs certain properties in soils. It should be potted in good turfy loam, a twelve-month-old leaf-mould, a little fine lime-rubble and sand, and any addition of patent manures helps the growth. Occasionally they are potted into 18's and 20's, making very tall plants; but if left in 32's make a much more stocky growth and the bloom is in thicker clusters *R. F. Legge.*

GAS TAR AND MEALY BUG.—The correspondence on this subject has been most interesting. There is no doubt that if hydrocyanic acid gas could be used at all times of the year it would prove a perfect cure for this pest on vines. We have here a vinery badly infested with mealy bug. I used hydrocyanic acid gas last autumn twice, with an interval of ten days between the treatment, which killed all the bugs one could see. My formula was 1½oz. sodium cyanide 130 per cent. (I believe this is about 90 per cent. stronger than the ordinary potassium cyanide), 3oz. sulphuric acid, and 6oz. water, to 1,000 cubic feet. Throughout the spring, and especially during the thinning time, I kept a sharp look-out for bugs, but saw no sign of the pest till the grapes began to colour. If one could have gone continually over the vines at this period, killing the bugs with methylated spirit, the pest could have been kept under. But few of us have time for this, and the result was that by the time we finished cutting the grapes at the end of December, the vines and grapes were as badly affected as ever. Now, if hydrocyanic acid gas could have been used at the time the grapes began to colour I am confident that we should have had no trouble from mealy bug. Are there any readers of this journal who have used the gas at that stage? If so, what was the effect on the grapes? I think no gardener would mind what he "smeared" on the vines if it would clear them of bug. Hydrocyanic acid gas has proved a great boon to many of us. Used at the rate of 1oz. sodium cyanide, 2oz. sulphuric acid, and 4oz. water to 1,000 cubic feet, it proves absolutely fatal to mealy bug, scale (especially), and other pests on Crotons, Stephanotis, Clerodendrons, Dieffenbachias, etc., with no injury whatever to the plants if necessary precautions are adopted. My plan is to select a calm day and I water any plant requiring water immediately after breakfast. I open the top and bottom ventilators to create a circulation of air, and so dry the atmosphere of the house. At this time of the year I use the gas at about 3 p.m. In the summer at about 5. But it is somewhat hard to understand why the tenderest young leaves of the plants mentioned above, and which might also include Ferns, *Gloriosa superba* and others, are quite unharmed by the gas, while the young leaves of Palms and *Pandanus Veitchii* are burned. Of course, once having found out the plants that will not stand it they can easily be removed before cyaniding. One other point is worthy of notice. Since using hydrocyanic acid gas the number of cockroaches has become less and cricket have disappeared. *F. J. Rose, South Stoneham Gardens, Swaythling.*

—In regard to the proportions of cyanide recommended by *A. J. H.* (p. 462) for fumigating dormant vines, it ought to be pointed out that these proportions are too strong for vines in active growth. The proportion I used for stove and other plants was 2 ounces sodium cyanide, 4 ounces sulphuric acid, and 6 ounces water per 1,000 cubic feet. This strength was effectual in killing the bug without injuring the plants. With reference to *Spider's* inquiry as to whether hydrocyanic gas will kill spider on Crotons without injury to the plants, I may say from experience that it has killed spider and all other insects, and did not injure the Crotons when I used it. But care must be taken that the foliage and the atmosphere of the house are thoroughly dry before cyaniding, or the plants will be injured. The proportions must be per 1,000 cubic feet as given above, and the number of generators according to the cubic space of the house. For

instance, if a house contains 3,000 cubic feet space, it is better to employ three generators, with 2 ounces cyanide in each, than to use one with 6 ounces, as the gas would in that case be more evenly distributed. Referring to Mr. Blakey's remarks (see Vol. LIV., p. 462), he states that my assertion that there is no danger in using the gas is a bold one, but he leaves out one important part of my statement, viz., "if the proper precautions are taken," which I explained. If these are strictly carried out, I still maintain there is no danger. As the head gardener is responsible he would make it his duty to understand the nature and proper use of this or any other fumigant, and would instruct his subordinates in their proper use; if this is done, the operator will soon gain sufficient knowledge of the nature of the gas to enable him to guard against any accident when using it. Your correspondent asks why vineries and other houses containing fruit should not be cyanided. It was for safety that I recommended they should not be cyanided, as many people contend that fruit absorbs poisonous gas in a confined atmosphere, but of this I have no practical knowledge, neither should I care to try it. There would be no necessity to cyanide houses containing fruit if cyaniding were done thoroughly when the trees or canes are in a dormant state, as there would not be any bug left. Fruit, too, contains more moisture (proportionately) than the foliage, in consequence of which it is more susceptible to injury by the gas. If a vinery, after being kept sufficiently warm for two or three days to hatch the eggs, is cyanided a second time, there will be no danger of the newly hatched female bugs becoming old enough to lay eggs. Your correspondent must be more clever than most gardeners claim to be if he can find every nest of eggs on vine rods to saturate them with methylated spirit, as these are often laid under the bark and in crevices where it is difficult to see and to get at them, while hydrocyanic gas penetrates every cavity. Mr. Shakelton (p. 13) reminds me that I give no new cure for mealy bug by the use of hydrocyanic gas, a circumstance of which I was fully aware, as I well know it has been recommended in the *Gardeners' Chronicle* for the last eight or ten years. I did not suppose for one moment that what I said about hydrocyanic gas would be any benefit or enlightenment to those who have a practical knowledge of the use of this gas. I wrote for the benefit of those who had no experience with this method of destroying mealy bug. What I stated I am prepared to verify, as I cleared bug by this method from a number of plant and fruit houses, and I have no doubt that if everyone who is troubled with this pest treated the pest in the same way there would be but little bug left in the kingdom to experiment on. Your correspondent appears to have been unfortunate in having plants injured by this gas, which I cannot understand, unless they were not quite dry, as, should any part of the foliage be damp, it is sure to be injured. The condition of the atmosphere of the house and the foliage of the plants is the all-important point—all must be perfectly dry for the plants to come through without injury. I have never had occasion to use this gas for the destruction of bug on Cucumbers and Melons, so cannot give the safe proportions for these plants. *J. H. Y.*

JOURNEYMAN GARDENERS.—I was very much interested in the remarks of Mr. Norris with regard to the knowledge of journeymen at the present time. I should like to hear the opinion of Mr. Norris concerning head gardeners, as all the fault is not likely to be with the journeymen, and none with the gardeners that employ them. *R.*

—The remarks made by *E. L.* in the issue of January 3 are, to my mind, ridiculous. The scale of wages he suggests is absolutely impossible, being far more than many head gardeners receive, much less under men. Supposing journeymen were paid that amount, they would be content to stop as journeymen, and would not trouble to reach higher positions. Then again, where would you find employers to pay such high wages? The majority of them would rather close their gardens, and buy what produce they required, for it would be cheaper for them. We

must not forget that gardens are hobbies, and their owners are not dependent on them for profit. As regards the conditions of other trades, some are better, and some worse. For my part, I think that 18s., with bothy, etc., is a fair wage, equal to 25s., and journeymen receiving that amount are as well off as those in most trades, besides enjoying steady employment. *E. L.* adds that vegetables cost little or nothing to grow. Then why, I ask, does he advocate such high wages for those who grow them? Many thanks are due to Mr. Norris for his letter in the same issue, who puts the case before us plainly and simply. *Contented Journeyman.*

—On the subject of *L.'s* statements in your issue of December 13 last, with reference to gardeners and their wages, I feel inclined to inform him that it is entirely the gardeners' own fault that the wages are low. He need not be downhearted over the advertisement in the columns of the gardening Press on December 13, "Members of the B.G.A. need not apply," because the members of that association were warned not to accept the situation. Members of the B.G.A. are thoroughly qualified to take any position of trust, and very many good places have been filled by the Association recently. It keeps out the unskilled and under-cutting impostor from the profession, it places good gardeners in touch with good employers, it stands out for the payment of overtime and Sunday duty. Further particulars can be obtained of the general secretary. If *L.* is not already a member, may I persuade him to join our band? *A Member of the Watford Branch.*

—If Mr. Sidney Legg refers to my previous letter on this subject (p. 426) he will see that I spoke of youths about the age of 21, and no mention was made of full-fledged journeymen. If he would take the trouble to look up the *Gardeners' Chronicle* for October 4 he would see six journeymen's situations offered at an average wage of 15s. 8d. a week, with bothy. In reply to Mr. Thos. Beeson I will give what I think are the usual hours in the majority of private gardens. In summer, 6 a.m. to 6 p.m., less ½ hour for meals. This does not include Saturday, when the hours are 6 a.m. to 4 p.m. In winter the work is usually carried on from daylight to dark; an average of nine hours a day exclusive of meals. Add to this three or four hours for Sunday morning work, and odd jobs in the evening, and the average will be found to be about 60 hours per week without duty. I know of cases where men have put in twelve hours a week extra during the busy months, for which they were not paid; and I venture to suggest that where there is one garden with eight men in the bothy there are a dozen of the same size with three or four. In consequence extra duty is more often necessary. I am ready to admit that there are employers who pay a fair wage, but they are exceptions, I am sorry to say, few and far between. In fairness I should like to say that in the garden in which I am engaged the whole staff is well paid. *A. M.*

—Mr. Legg appears to be championing the cause of the employer, by inferring that the low wages received by the average journeyman to-day represent proper remuneration for his exacting duties and long hours. I might agree with him were it true that the average journeyman with five or six years' good experience was only equal in ability to an improver. Perhaps your correspondent's reference to the respective ability of improver and journeyman concerns some one under his immediate notice. Annually we lose some of the most promising young men of our profession. Why? Because our Colonies offer far better inducements to ambitious young men in return for their labours. Men who in the future would make their mark and be a credit to horticulture are thus led to emigrate. My experience in eight bothies is that there are many so-called "good bothies" which are little better than hovels, where anything in the nature of comfort is conspicuous by its absence. The opportunities afforded bothyites of improving their knowledge by study are very inadequate in their isolated surroundings. I believe the head gardener is in many cases to blame for his indifference to the conditions affecting his subordinates, who have to endure them, or if they complain are told to go. *A Bothyite.*

STREPTOCARPUS CYANEUS.

THE *Streptocarpus* is now to be classed with the most useful greenhouse flowering plants. In recent years hybridisers have raised strains that flower abundantly and have leaves of moderate size, whilst wonderful improvements have been obtained in the form and colour of the flowers. Several new species have also been introduced recently, so that gardeners may look for still greater improvement by crossing. One of the latest of these newcomers is *S. cyaneus* (see fig. 16), discovered by Mr. E. E. Galvin in South Africa in 1891. The plant is very attractive, the rosy flowers being nearly 2 inches long and set off by handsome foliage. Already seedlings have exhibited colour variation; in some the blooms are a pale lavender or blue shade, whilst the corolla tube is blotched with yellow. Like other species and varieties of *Streptocarpus* in cultivation, *S. cyaneus* is short lived, and the plants are most

FIG. 16.—STREPTOCARPUS CYANEUS: A NEW SPECIES FROM SOUTH AFRICA. [Photograph by C. P. Raffill.]

attractive in their second year. The plant we illustrate flowered in the collection at Kew.

SOCIETIES.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 18.—*Committee present*:—Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, J. Cypher, A. G. Ellwood, J. Evans, A. Hanmer, J. Howes, J. Lupton, D. McLeod, W. J. Morgan, C. Parker, W. Shackleton, Wm. Thompson, H. Thorp, Z. A. Ward, G. Weatherby, and H. Arthur (Secretary).

Gold Medals were awarded to R. ASHWORTH, Esq., Newchurch (gr. Mr. Gilden), who staged a magnificent group of plants, and O. O. WRIGLEY, Esq., Bury (gr. Mr. Rogers), who had a large group of finely-grown *Cypripediums*. A Silver-gilt Medal was awarded to A. WARBURTON, Esq., Haslingden (gr. Mr. Dalglish), for a group composed principally of *Cypripediums*; large Silver Medals to WM. THOMPSON, Esq., Walton Grange (gr. Mr. Howes), for a group; H. J. BROMIELOW, Esq., Rann Lea (gr. Mr. Morgan), for a group;

O. x purpuratum, a massive flower of good shape, ground colour light purple heavily blotched with deep purple, white margin round sepals and petals, lip broad; *O. x rubens*, a large flower of fine broad lip, sepals and petals of a dull reddish colour shaded with purple and margined with white; *O. x Our Queen* (*crispum* *Hycanum* x *eximium*), ground colour white, sepals and petals heavily blotched; *O. amabile* var. "*Illuminator*," a large flower, of fine shape, pure-white ground, sepals and petals finely marked with bright purple, lip very broad and finely spotted; *O. crispum* *Xanthotes*, "*Walton Grange*" var., a round flower of good substance, sepals blotched with yellow, petals spotted, lip broad and blotched with yellow; *O. Bradshawae* "*Sander's* var."; *Cypripedium insigne* *Snow Queen*. All shown by WM. THOMPSON, Esq.

O. amabile "*Ashworth's*" var., a good round flower of brilliant colour; *Vanda coerulea* "*Ashlands*" var., a large flower of good colour; both from R. ASHWORTH, Esq.

Cypripedium Nivina (*Alcibiades* x *aureum* *Virginale*), a magnificent flower, good shaped and evenly marked; *Odontoglossum Arachne* (*Vuylstekei* x *eximium*), noble flower, well marked; both from W. R. LEE, Esq.

O. eximium "*The King*," from Messrs. CHARLESWORTH AND CO.

AWARDS OF MERIT.

Odontoglossum Lambeauianum Hesperum, *O. crispum* *Graphicum*, *Cypripedium Hera Mostyn*, *C. Curlew*, *C. Draco* "*Walton Grange*" var., and *C. Alice Mary*, all from WM. THOMPSON, Esq.

Odontoglossum Lady Evelyn James (*Lavertonianum* x *aureum* *Virginale*), *Cypripedium Palladium* (*aureum* *Virginale* x *villosum* *auriferum*), *Calanthe Veitchii* "*St. Nicholas*" var., all from the Hon. ROBT. JAMES.

Odontoglossum eximium Zenith, *Cypripedium Estella* (*Hindeanum* x *concolor*), both from RD. ASHWORTH, Esq.

C. Lady Evelyn James (*Lavertonianum* x *aureum* *Virginale*), and *C. Hecla*, both from W. R. LEE, Esq.

Odontoglossum x *Meteor*, from J. BUTTERWORTH, Esq.

Cypripedium Actaeus var. *Ethel* (*Lecanum* *Clinkaberryanum* x *Harefield Hall*), from Messrs. CYPHER AND SONS.

Vanda coerulea var. *Fairu Queen*, shown by Messrs. STUART LOW AND CO.

DEBATING SOCIETIES.

BRITISH GARDENERS' ASSOCIATION (North London Branch).—A special meeting will be held at the "Railway Institute," 111, Fonthill Road, Finsbury Park, on Tuesday, the 13th inst., at 8 o'clock. Speakers: Mr. Cyril Harding (general secretary), Mr. F. J. Baker, and Mr. G. W. Butcher. Members and non-members are cordially invited.

DUMFRIES AND GALLOWAY GARDENERS.—A meeting of this association was held in the Wesley Hall, Dumfries, on the 3rd inst., Mr. S. Arnott in the chair. Mr. C. G. Murray, gardener to Henry Keswick, Esq., Cowhill Town, Dumfries, read a paper on "Sweet Peas." Mr. Murray, who is a successful exhibitor of these flowers, gave full details of the cultivation he had found successful, and enumerated a selection of varieties. The next meeting will be held on January 31, when the subject of the lecture will be "Roses."

BRITISH GARDENERS' (Cardiff Branch).—At the meeting of the Cardiff branch of the B.G.A., held on the 3rd inst., Mr. W. W. Pettigrew, chief officer of the Cardiff parks, delivered a lecture on "Soils." Mr. F. G. Treseder occupied the chair.

BURNLEY AND DISTRICT HORTICULTURAL.—The monthly meeting of this association was held on the 1st inst. Mr. W. J. Hargreaves occupied the chair. Mr. J. Bayley, Queen's Park, Burnley, delivered a lecture on "Landscape Gardening." Mr. Bayley described methods of laying out large estates to secure artistic landscape effects, as well as the re-modelling of extensive grounds, and gave valuable hints concerning the formation of villa gardens.

CATALOGUES RECEIVED.

Seeds.

WM. PAUL AND SON, Waltham Cross.
EDMONDSON BROTHERS, 10, Dame Street, Dublin.
G. H. PLANT AND CO., The Eastgate, Chester.
ROBERT SYDENHAM, LTD., Tenby Street, Birmingham.
BROWN AND WILSON, 10, Market Place, Manchester.
W. DRUMMOND AND SONS, LTD., Stirling.
E. WEBB AND SONS, Wordsley, Stourbridge.

AWARDS.

FIRST-CLASS CERTIFICATES.

Odontoglossum x *fulgidum*, parentage unknown, a fine round flower with broad lip of dark bronze shade, with creamy margin round sepals and petals; *O. x The Egyptian*, sepals and petals dark chocolate colour, having a shining velvety surface margined with white, lip broad and marked with crimson brown and white front;

GARDENING APPOINTMENTS.

- Mr. Walter Bristowe, for the past five years Foreman at Madresfield Court, as Gardener to Sir HENRY LOPES, Bart., Maristow House, Roborough, South Devon.
- Mr. T. C. Grinham, for the past 2 years and 10 months Gardener to E. P. STEPHENS, Esq., Taplow Priory, Taplow, as Gardener to W. H. BUCKLER, Esq., Rocques, Taplow, Buckinghamshire. [Thanks for 1s. for R.G.O.F. box.—EDS.]
- Mr. James A. Paice, as Gardener to Sir J. D. REES, M.P., Aylwards, Stanmore, Middlesex.
- Mr. G. Weston, for the past 2 years Foreman at Bonningtons Hunsdon, near Ware, Hertfordshire, and previously at Tregwainton, Cornwall. The Friary, Old Windsor, Moor Hall, Harlow, Essex, and Stevenon Manor, Hampshire, as Gardener to Captain BANBURY, Pippingford Park, Nutley, Sussex. [Thanks for 1s. 6d. for R.G.O.F. box.—EDS.]
- Mr. Motherselse, as Gardener to A. INGHAM WHITAKER, Esq., Grayshott Hall, Haslemere, Surrey. [Thanks for 2s. for R.G.O.F. box.—EDS.]
- Mr. A. Avery, for the past twelve months Foreman, and previously Carnation Grower, to LADY GREY, Enville Hall, near Stourbridge, as Gardener at the same place. [Thanks for 1s. 6d. for R.G.O.F. box.—EDS.]

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherby), for a group of *Odontoglossum*s; Col. J. RUTHERFORD, M.P., Blackburn (gr. Mr. Lupton), for a group; Messrs. SANDER AND SONS, St. Albans; and Messrs. CYPHER AND SONS, Cheltenham, for groups. Silver Medals to the Hon. ROBERT JAMES, St. Nicholas, Yorks (gr. Mr. Benstead), for a group composed principally of *Calanthes*; A. E. PENNY, Esq., Preston (gr. Mr. Sumner), for a group of *Cypripediums*; J. BUTTERWORTH, Esq., Burnley (gr. Mr. Wilson); W. R. LEE, Esq., Plumpton Hall (gr. Mr. Branch); and a Bronze Medal to H. ARTHUR, Esq., Blackburn. Other exhibitors were Messrs. A. J. KEELING AND SONS, Bradford; Messrs. STUART LOW AND CO., Enfield; Messrs. CHARLESWORTH AND CO., Haywards Heath; and Mr. W. SHACKLETON, Great Horton, Bradford.

G. A. BUNTING AND CO., 3, Bucknall Street, New Oxford Street, London.
HARRISON AND SONS, Leicester.

Miscellaneous.

MORLE AND CO., 150, Finchley Road, London.—Liliums, Begonias, and Gloxinias.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending January 7.

A Week of Variable Temperature.—This was a week of variable temperature. The first day was very cold, both during the daytime and at night. Then came four warm days, followed by two cold ones. On the two warmest days the temperature in the thermometer screen rose to 47° and 48°, whilst on the two coldest nights the exposed thermometer registered respectively 15° and 11° of frost. The ground temperatures, which have been also variable, are now 1° colder at 2 feet deep, and 2° colder at 1 foot deep, than is reasonable. Rain fell on three days, but to the total depth of less than ¼ inch. There was still a little snow on the ground in places during the first two days of the week. Percolation through both the soil gauges recommenced after the 4th inst. The sun shone on an average for 2 hours 36 minutes a day, which is twice the average duration for the beginning of January. On the sunniest day the sun was shining brightly for as much as 5 hours 38 minutes. During the first four days calm and light airs alone prevailed, but during the remainder of the week the winds were moderately strong, and came from some westerly point of the compass. The mean amount of moisture in the air at three o'clock in the afternoon fell short of a seasonable quantity for that hour by 6 per cent.

DECEMBER.

Warm, Sunny, and Remarkably Dry, with a Rather Calm and Exceptionally Dry Atmosphere.—Taken as a whole, this was a warm December. The first half of it proved very warm. In fact, there then occurred only two unseasonably cold days, and virtually no cold nights, whereas during the last fortnight there were but three warm days and but one warm night. On the warmest day the highest reading in the thermometer screen was 53°, and on the coldest night the exposed thermometer registered 16° of frost. Neither of these extreme readings are exceptional for the time of year. Rain fell on fifteen days, and to the total depth of only ¾ inch, which is less than a third of the average quantity for the month. With only four exceptions the closing month of 1913 was drier than in any of the previous fifty-seven Decembers. The last December as dry was in 1890, or twenty-three years ago. The ground was at no time completely covered with snow. The sun shone on an average for 1 hour 24 minutes a day, which is 14 minutes a day longer than is usual in this month. It was rather a calm December, and in no hour did the mean velocity of the wind exceed twenty-one miles, direction W.N.W. The average amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by 3 per cent. We have to go back twenty-three years in order to find a December with as dry an atmosphere.

THE YEAR.

Very warm, Very Dry, and Sunless.—Taken as a whole this was a very warm year. In fact, there were only three months, April, July, and August, when the mean temperature was in any way below the average, and in only one of those months, July, did the variation from the average amount to more than a degree in temperature. The most unseasonably warm month was November, and the most unseasonably cold one July. On the hottest day, June 16, the temperature in the thermometer screen rose to 83°, and on the coldest night, February 23, the exposed thermometer indicated 20° of frost. The total rainfall fell short of the average quantity for the previous fifty-seven years by 4½ inches, making this the driest year for eleven years. The wet months were January, March, April, October, and November, and the dry ones February, June, July, August, September, and December—while in May the rainfall was about average. Taking the year as a whole, the sun shone on an average for eighteen minutes a day less than is usual. The sunniest months of the year, compared with the average, were May, June, October, November, and December, and the most sunless January, February, March, April, July, August, and September, July, considering the season, was the most sunless month of the year.

THE UNDERGROUND WATER SUPPLY.

The total rainfall for the last three months has fallen short of the average for the same period in the previous fifty-seven years by 1½ inch, which is equivalent to a loss of 26,240 gallons on each acre in this district. Last year at the same time there was a deficiency of 4,300 gallons per acre. *E. M., Berkhamsted, January 7, 1914.*

SCHEDULES RECEIVED.

County Clare Horticultural Society.—The spring show of this society will be held in Ennis, the provisional date being fixed for April 16, and the summer exhibition will be held on July 30. Secretary, Mr. H. Bill, Lifford, Ennis, Ireland.

Borough of Reigate and District Horticultural Society.—The twenty-eighth annual show of this society will be held in The Priory, Reigate, on Wednesday, July 8. Secretary, Mr. F. Phillips, The Gardens, Craigeadowie, Reigate.

Obituary.

THOMAS SAMPSON.—We regret to record the death of Mr. Thomas Sampson, who passed away in his eightieth year, after a short illness, at the residence of his son-in-law, Mr. Theo. Feilden, Stratford Lodge, Watford, at 5 a.m. on Saturday, the 3rd inst. Thomas Sampson was born at Brympton House (the present seat of Sir Spencer Ponsonby-Fane) at Brympton D'Everci, Somerset, on March 11, 1834. He was an ardent horticulturist and a Fellow of the Royal Horticultural Society. He had the finest show of flowers ever exhibited at the Bath and West of England Show, having on view many new species, when the Society visited Yeovil some forty years ago. Mr. Sampson was a prolific writer, and contributed a number of short articles and letters to the Press upon archaeological subjects. A standard little work written by him was *The History of the Holy Thorn of Glastonbury*. Mr. Sampson's eldest daughter was married in 1887 to Mr. Theodore Feilden, who is a prominent member of the London *Times* staff and a well-known newspaper man.

APPLE SHOOTS FOR EXAMINATION: *J. L.* The Apple shoots are not affected with a fungus, but are thickly covered in places with the bright red eggs of certain mites. The mites in question belong to species of the so-called "Red Spiders," and are referable to the genus *Bryobia*; they are frequently found on fruit trees, but probably are of small economic importance except in the case of the Gooseberry. The recognised treatment is in the form of a sulphur wash, and liver of sulphur has been largely used in this connection. A heavy spraying with the above wash or with strong paraffin emulsion (up to 5 gallons of paraffin in 100 gallons of wash), towards the end of February, would be beneficial.

LEAVES TUNNELLED BY GRUBS: *C. P. M. D.* The leaves are tunnelled by the larvae of a small fly, but no definite statement as to its specific identity can be made from the immature forms received.

LIME SULPHUR AND IRON SULPHATE: *Tenrab.* Lime sulphur is prepared as follows:—Take flowers of sulphur, 10 lbs.; stone lime, 10 lbs.; water, 50 gallons. Slake the lime slowly in about 3 gallons occasionally. As the heat develops add more water, and when the lime is completely slaked dilute to 50 gallons with water. Use sulphate of iron crystals dissolved in water.

MAGGOT ATTACKING PEACH TREES: *G. H. N.* Send specimens for identification. In the mean time spray the trees with an insecticide.

MICE DAMAGING SHRUBS: *A. Grant.* It is a difficult matter to prevent mice from destroying your Hollies, Laurels, and other evergreens. Clear away the Ivy that covers the ground, as this is where their nesting-places are found. If this is not practicable paint the stems of the shrubs with gas-tar, although this application may have the effect of stunting the growth of the plants until its effects wear off. Because of the presence of game it will not be safe to resort to poison, though spraying the plants with arsenate of lead paste might be useful. This should be mixed with a solution of soft soap, and syringed on the bark. In the interests of game the natural enemies of mice, such as cats, hawks, and owls, are rigorously kept down, and in consequence the mice flourish. When the balance of nature is disturbed in this way there is always a toll to be paid.

NAMES OF PLANTS: *W. H. D., Grantham.* *Ornithogalum lacteum*, native of South Africa. The

blooms last fresh for a very considerable time. The plants are often used for decoration on outgoing mail steamers at Cape Town, and arrive in England with the flowers still fresh, and capable of lasting for some weeks.—*F. F.* (1) *Pteris longifolia*; (2) *Adiantum hispidulum*; (3) *Lastrea varia*; (4) *Oncidium flexuosum*; (5) *Calanthe vestita*.—*E. S. W.* *Epidendrum fragrans*. The *Pancreatium* (*Hymenocallis*) grow well with *Eucharis*. If the plants are not in a good condition turn them out of their pots, and re-pot them in turfy loam, starting them into growth again.

ORANGE RUST OF ROSES: *H. W.* Gather all fallen leaves and burn them, as they may contain the resting-spores of the disease. Next spring drench the trees with sulphate of copper, 2 ozs. in 3 gallons of water, before the buds expand. If the disease is noticed after this treatment spray with dilute Bordeaux mixture of ammoniated carbonate of copper, 1 oz. of carbonate of copper and 5 ozs. carbonate of ammonia in 16 gallons of water, or proportionate strength.

SCORPION ORCHID: *Dummy.* The Scorpion Orchid of the Malay States is said to be *Arachnanthe moschifera*, illustrated in the *Gardeners' Chronicle*, October 13, 1894, p. 435, but the description you send does not agree with that species. The two with "gnarled roots" if leafless may be *Aphyllorchis*; but if with leaves a *Cymbidium* as you suggest. The other we cannot identify by your description. Whether terrestrial or epiphytal, it would be better to put them in pots with "corks" only until they start into growth. Place then in a warm house, and water them as other plants. If not more than a degree or two below 50° Fahr. at any time the cool house you mention would suit your *Odontoglossum Uro-Skinneri*, otherwise the cool end of the intermediate house would be safer. Do not water the plants overhead.

STRAWBERRIES: *P. S., Kamenz.* An alternative course may be followed, in accordance with the health and vigour of the plants. If the plants are strong and vigorous the spikes may be allowed to remain provided the pots be put into an intermediate house, such as one that is used for Strawberries when forcing is commenced. In such a house it will be better to place them upon a shelf, close up to the glass. Should the plants, on the contrary, be somewhat weakly, then remove the spikes at once and keep them rather dry at the roots. These adventitious trusses on the Strawberry often occur after such a season as that of 1913.

WASPS: *Correspondent.* All the wasps seen in spring are queens. All the drones or males and the workers die at the end of the year, the only survivors being the newly-born queens, and the probabilities are that the majority of the last-named build a nest and rear the first brood of worker wasps.

YEW BUDS EATEN BY PHEASANTS: *J. Verdon.* The enlarged buds on the Yews are caused by a fly which lays its eggs in the buds in the early summer. The eggs hatch, and the small grubs cause the deformation of the end of the shoot. The pheasants most probably like these grubs and take the whole bud to obtain them, with the consequence that they are poisoned by the quantity of Yew they eat. In the early autumn pick off and burn all the deformed buds you can find. In spring syringe the trees with a fairly strong solution of Quassia water, adding just sufficient soft-soap to make it stick to the foliage. The specimen enclosed is *Juniperus virginiana* (Red Cedar).

LILIES IN 1913.

HE has a longer memory than most who can recall a better year for Lilies than that just gone by. From beginning to end the previous year had brought them but few crumbs of comfort, hardly anything, in fact, but gloom and almost ceaseless deluge, and as it drew to a close, one felt—naturally enough, but quite wrongly, as it afterwards turned out—that a good many bulbs must inevitably have gone to a watery grave.

1913 led off with a month of brimful ditches, warm blustering winds from south and west, and a general preliminary voice trial by feathered friends in every bush: for two weeks February dealt out the same unseasonal fare, then, suddenly remembering itself, gave us the wonted spell of shrivelling wind.

March brought back the mild and humid days, and passed them on to April: many a trusting shrub and plant was deluded into premature activity, and just as one chuckled at the thought that winter had been beat at last, back came its tail, to lash us with the icy blast all gardeners dread once Lady Day is past, and leave the usual sorry score of blackened bud and stricken blossom in its trail.

The month sped on, and had all but run its course ere the longed-for day at last arrived when the warm west wind brought on its wings that indefinable taste, smell, feeling, call it what you will, that stirs the sluggish pulse, sends the song thrush to the topmost bough, and tells one spring is in the air.

May dipped its fingers in the wet again, and brought the Thames bank high: day followed day of rain, and one groaned at

the prospect of another soaking year of deluge. Then came summer with a burst, and while May ebbed out, gardens steamed with luscious shimmering heat. The rest of this memorable season will still be green in the grateful gardener's heart: for once in a way Lilies have had all he could wish for them, a warm wet spring, long arid flowering season, with sun enough for bloom, but not to parch the earth or scorch the flowers, and, above all, a dry and genial resting time in September and October. The only shadow on the picture has been cast by Botrytis, of which more anon.

Many gardeners will have observed that in the last two years numbers of plants have thrown the conventional time-table to the winds, choosing the most unusual season for the business of life. In no genus has this been more noticeable than *Lilium*, and the sequence of flowering which many normal years have brought one to regard as immutable seems now to have gone by the board.

In casting about for some explanation of the change, which we may suppose is only temporary, it is difficult to resist the conclusion that the tropical heat of 1911 is at the bottom of it. But whatever the unseen forces were that have been at work they brought *L. speciosum*—first as a rule to come and among the last to 'go—head-long out of the ground by the middle of February, a full month before the usual time, and at the other end of the scale these self-same forces made a sluggard of *L. chalcedonicum*, so that it did not come into flower till the second week in August.

L. testaceum found itself in bloom a fortnight before *L. candidum*, a most unusual proceeding; the characteristically twisted foliage of this Lily is well shown in fig. 17.

During the year *L. regale* has kept on its glorious career, seemingly impervious to winter wet and indifferent to the worst that our climate has yet given it: it has still to bear the brunt of a hard winter, but with that reservation one can almost say that nothing seems to matter to this accommodating Lily.

It ought not to be long before the bulbs are available for as many pence as shillings are now demanded by the dealers, for the propagation of *L. regale* is as simple as that of the homely cabbage: an average capsule will carry 500 seeds, and if these are given ordinary attention the greater part will soon germinate.

L. Sargentiae, another of the many fine plants we owe to "Chinese" Wilson, has also flourished, but does not seem so easy to manage as *L. regale*: in common with *L. sulphureum*, it is more impatient of wet when flowering is over than is the former Lily, and that means that everything possible should be done to get the autumn rains quickly past the bulbs. It cannot be insisted upon too often that neither *L. regale* nor *L. Sargentiae* will give of its best in peat or humus: they are lime- and loam-loving Lilies.

L. Sargentiae is exceptionally variable in the character of the foliage, and of a score of bulbs one may hardly find two quite alike.

FIG. 17.—LILIAM TESTACEUM. COLOUR OF FLOWERS, NANKEEN.

L. Parryi, born and bred in its English home, has proved more robust than the wild parent bulbs from California, and if intelligently managed this Lily, popularly supposed to be very difficult, need cause the gardener no concern. In common with all the Lilies of the Western United States, except perhaps *L. pardalinum*, which stands a deal of fooling, one cannot keep *L. Parryi* too dry in early autumn: this is a point seldom sufficiently appreciated by would-be growers, and as a rule is one of real practical difficulty: salvation lies in quick drainage, but this is a synonym for death in times of prolonged drought; if subterranean moisture is not available.

A well-balanced head of this splendid Westerner nodding over *L. regale* is a joyous sight, warranted to drive many a rankling garden failure away to the back shelf of memory's cupboard: incidentally it is a standing testimony to the extraordinary range and industry of the modern plant collector, and provides an object lesson in the marvellous adaptability of Dame Nature, who enables us moderns to cultivate plants from opposite sides of the earth in a climate and under conditions as different from those obtaining in their native haunts as chalk is from cheese.

Of the uncommon Lilies, *L. Kelloggii*, *Bolanderi*, *occidentale*, and *polyphyllum*, all not so very many years ago almost as rare as the hoopoe, have been hard at work reproducing themselves, and each can point to a small colony of nurslings. *L. kewense*, too, rescued from oblivion by Mr. Mallett a few years ago, is thriving apace, while the tiny Black Lily (*Fritillaria camschatcensis*) has made a welcome reappearance.

In 1913 all the American Lilies—from east and west—gave a good account of themselves, excepting only *rubescens*, a difficult plant to acclimatise and stubborn as a mule: and though one must confess to having attended the obsequies of quite a number of *L. rubellum*, drowned no doubt in the second half of the previous year, the Japanese and Chinese Lilies generally have come through the wet winters of the last two years astonishingly well.

Even *L. Brownii*, with bulb scales seemingly shaped on purpose to retain every drop of water that falls on them, has passed safely through the ordeal. This is by no means an easy Lily to keep, though not hard to propagate: in the absence of seed, which is almost unobtainable, it is readily raised from scales or by leaf-cuttings, as, indeed, are nine-tenths of the genus. As with all the Chinese Lilies at present in cultivation, lime seems essential to the true welfare of *L. Brownii*, though one may sometimes see a colony of the Dutch-grown bulbs doing well in woodland soil where the drainage is sharp.

For once in a way, *L. sulphureum* has had its opportunity, and has made the most of it: in five years out of six this Lily comes into flower too late to escape the withering effect of night frosts in mid-September, and for all the good it does,

might as well be left out of the garden altogether. Last year it was in bloom half-way through August, and the flowers remained in perfection till the end of that month. Bulbs of this Lily collected in Western China seem to be hardier than those received from Burma.

One of the most remarkable features about Lilies in a remarkable year has been the prolongation of the normal period of flowering, and the perfection of the individual flowers. In a typical English summer we have alternations of hot sun and rain, with the result that Lily blooms are seldom at their best for more than a few days at a time: they are either baked and soon spent, or else draggle-tailed and spoilt beyond

increasingly difficult to uphold the time-honoured theory that high cultivation and a sturdy constitution are factors in the power of Lilies to resist this dread disease, for while it has not yet been possible to arrive at a positive conclusion, close observation undoubtedly tends to show that the fungus attacks strong and weak alike.

That with the aid of the chemist the fungus can be kept in check is certain, but one must be ever on the watch for the smallest sign of this insidious hydra-headed plague, and act immediately. If it is once allowed to obtain a footing in the soil of the garden, even the optimist may as well ring down the curtain, at any rate for a time.

There is no panacea for this evil, which is

FIG. 18.—BULB OF *LILIUM PARRYI*, SHOWING NEW AND OLD GROWTH.

recall. In the writer's little garden hardly a drop of rain fell from beginning to end of the Lily season of 1913, and the sun was never really fierce. As a direct result of this happy combination of circumstances many individual plants of *L. Parryi*, *Roezlii*, *Hansonii*, and *Bolanderi* were in bloom for from 26 to 29 days, while numerous other species were in perfect flower for as much as three weeks.

The comparative coolness of the summer following a very wet spring, was doubtless responsible for the persistent way in which *Botrytis cinerea* marked out its victims all through the season of 1913. As the years go by it becomes

not peculiar to liliaceous plants; such remedies as are available at present take the form of spray solutions, the use of which is largely empirical: the main thing seems to be to apply the solutions in as strong a form as each plant will bear, and exactly what that strength is the gardener must ascertain for himself. If he is wise he will begin with a weak solution and gradually increase the concentration to the desired point.

In the experimental process a few of his patients will probably succumb to the treatment, and if they do he may cozen himself into a recognition of their death as a tribute to the cause of horticultural science.

Bordeaux mixture is undoubtedly of value as a preventive, and though by no means a perfect remedy, the aseptic spray solution of Evans appears to have the effect of staying the progress of the fungus in individual cases. The spray mixture, of whatever nature it may be, should never be used stone cold, and must be applied to the under side of the leaves as well as to the upper surface.

So far as the writer is aware no new species of Lily made a public appearance in 1913. At the R.H.S. meeting on October 7, Mr. Elwes exhibited a fine specimen of the wild *L. speciosum*, grown from a bulb which he himself gathered in Formosa the previous year.

Though neither the latent beauty of the specimen nor the importance of the exhibit appears to have commended itself to the authorities at Vincent Square, they will at once have been apparent to botanists and students of the genus, for the distribution of the wild plant has never yet been satisfactorily determined. Prior to the discovery of this Lily in Formosa it had only been recorded in a restricted area at Kiangiang, in Kiangsi, first by Hance and later by David, and, so far as is known, a wild plant had not been exhibited before last year.

Now one of the commonest Lilies in commerce, *L. speciosum*, is cultivated and exported in thousands from Japan and Holland, and though Japanese tradition makes Formosa the home of it, the origin of this Lily is lost in the mists of the past. It is true that a fine form, known as *speciosum magnificum*, was discovered some few years ago in the small group of islands south of Nagasaki, where it is cultivated as a vegetable, but this is not identical with the Lily exhibited by Mr. Elwes. There does not appear to be any record of it in Formosa till 1908, when, according to Mr. W. R. Price, it was discovered by Konishi and named after him by Hayata.

During the year a Korean species of *Lilium* sent by Mr. Wilson has flowered, and so has a Western Chinese species collected by Mr. Forrest (No. 692) and received from Messrs. Bees. One of a batch of Chinese Lilies sent by M. Maurice L. de Vilmorin has also bloomed, and has proved to be a remarkably fine plant, bearing in many ways a strong resemblance to *L. Sargentiae*.

A hybrid between *L. tenuifolium* and *L. sutchuenense* has flowered, but is not of much account. The following little-known Lilies are in cultivation:—*L. ochroleucum* and *L. Delavayi*, from the Edinburgh Botanic Garden; *L. Brownii* var. *kansuense*, from Professor Scheubel, a Korean species, and *L. Brownii*, of Western Hupeh, from Mr. Wilson; a species brought by Mr. Elwes from Kiushiu, a form of *L. philippinense*, as well as bulbs of the *L. speciosum* already referred to, both gathered by Mr. W. R. Price in Formosa; *L. warleyense* and several Chinese species from M. Maurice de Vilmorin. *A. Grove, Kentons, near Henley-on-Thames.*

ORCHID NOTES AND CLEANINGS.

ORCHIDS AT MESSRS. SANDER AND SONS.

It is not a light task to traverse the forty large houses devoted entirely to Orchids at the St. Albans Orchid Nursery, but the journey is rendered pleasant by the large number of showy and interesting plants, both species and hybrids, which are to be seen there. In the matter of species the establishment is exceptionally fortunate, for the famous collectors, Micholitz and Forget, who have travelled for the firm for hard on thirty years, have sent numerous collections containing a high proportion of new or rare

species, of which many, even not yet identified, have accumulated at St. Albans.

The older part of the establishment, with its broad and lofty span-roofed structures, has been reconstructed, houses of lower pitch and with modern improvements having been erected; and generally the accommodation has been increased with evident benefit to the many hybrids, which are in grand condition.

The old wood trellis work for paths placed over the natural earth in the houses has been done away with almost entirely. In order to encourage evaporation from the natural moist earth, and to provide clean, dry paths, a layer of granite chips instead of wood trellis is employed, with the result that, no matter how much water may be used on the path, a clean surface is maintained. By this means the cost of wood trellis and the unsightly appearance of partially decayed wood are avoided.

Corridors at each end of the ranges give shelter. At the one end some very fine rockeries planted with rare foliage plants, *Cymbidiums*, *Phaius* and other semi-terrestrial species, make an interesting display. In one nook there is a huge plant of *Odontoglossum coronarium* with about forty growths, which should be a fine sight when in bloom, situated as it is beneath the long, plume-like fronds of the crested *Poly-podium Knightae*. The corridors are planted with *Epidendrum O'Brienianum*, *E. Boundii*, *E. Burtonii*, *E. radicans*, and other trailing species, which give bright flowers, and the bright mauve *Bougainvillea Sanderiana*, in green and variegated forms, which have now become popular "market plants," give variety. Of plants at present in bloom the *Cypripediums* are in the majority, and many houses are filled with them. One house contains new crosses flowering for the first time, and among them are many very pretty and distinct blooms. Distinct things continue to hold their own for a great length of time, as witness a houseful of varieties of *C. insigne* in bloom, the batch of the lovely yellow-and-white variety *Sanderae*, that of the stately *Harefield Hall* variety, and a few others, each of which is in constant demand. In the same charming class as *C. insigne Sanderae*, *C. Mrs. F. Sander*, *C. Eve*, *C. aureum Surprise*, and some pretty light forms of *C. Actaeus*, are in bloom.

A batch of crosses of *C. Fairieanum* show some good things, but all have that deflected pose of the petals and the narrow outline which are evident in most *C. Fairieanum* crosses. Forms of the old *C. Hera Euryades* are still as fine as ever and not yet displaced in their sections, some in bloom here being even better than the variety *splendens*. White flowers are given by *C. niveum*; and *C. Godefroyae*, with the hybrids *C. Venus* and its ally *C. Boltonii*, are of the best clear whites. *C. Venus Rann Lea* variety is of an exceptional tint, being of a Primrose-yellow shade in the earlier stage of the flowers. Some *C. glaucophyllum* crosses in bud show an interesting peculiarity. *C. glaucophyllum* was thought by some to be a form of *C. Chamberlainianum*, but the progeny of the former are wonderfully free in growth and flower, while seedlings of the latter are not so tractable.

C. Vennel var. *Perfection* (*venustum* × *bellatulum*) is a fine, handsomely-marked flower; *C. caudatum Sanderae*, like a large form of *C. c. Wallisii*, *C. Minnie*, *C. Villebois Mareuil*, forms of *C. Thalia*, *C. Germain Opoix*, a batch of the pretty *C. callosum Sanderae* and its hybrids; a very fine *C. Miss Louisa Fowler*; *C. Alcibiades magnificum*, the finest of its section; *C. Niobe nigrescens*, a dark, claret-coloured flower; *C. Actaeus Undine*, a charming yellow-and-white; *C. Alabaster*, *C. Caruso*, *C. Gaston Bultel*, *C. Atlas*, a very large flower; and some exceptionally fine *C. Lecanum* and *C. Charlesianum* may be mentioned out of the large number in bloom.

Cattleyas, *Laelio-Cattleyas*, and *Brasso-Cattleyas*, and secondary hybrids of them,

occupy about one-third or more of the long ranges of houses, and the plants are in large batches of all sizes, the cases in the seedling house containing many thousands of seedlings in their early stages, with those in their first pot on the stages. Six houses side by side contain unflowered seedlings either of new crosses or improved old crosses to flower within the next year or two. Of favourite known hybrids much is expected from the new batch of *Laelio-Cattleya Fascinator*, in the production of which a *C. Schröderae*, better in some points than *The Baron*, was used.

In these houses but few are in bloom, but among a showy lot of *C. labiata*, including white and blush-white varieties, exceptionally good are the handsome deep-yellow *Laelio-Cattleya Charlesworthii*, still one of the best of its class; *L.-C. Golden Oriole*; *L.-C. Mauretania*, *L.-C. Minnie* (*aurea* × *exonensis*), and other pretty hybrids. In another house some finely-coloured forms of *Cattleya Maggie Raphael* have broad and richly-coloured labellums, inherited, it is said, from the *C. Trianae* used with *C. aurea* to obtain it; some *Brasso-Cattleyas*, *Brasso-Laelio-Cattleyas*, and, not in flower, a good batch of various crosses of *Sophrontis grandiflora*. A house of *Cattleya Iris* and *C. Adula*; a large batch of *C. Mantinii*, which had flowered well earlier; a house of *Laelio-Cattleyas*, with some *L.-C. Kathleen* and *Cattleya Percivaliana* in flower, with a fine specimen of the white *C. Dusseldorferi Undine*. Some *Laelio-Cattleya Britannia* and showy hybrids of the *L.-C. Ingramii* class, and, returning by the long corridor, in which large batches of *Dendrobium Wardianum*, *D. Regium*, and other showy *Dendrobiums* are resting, we come to the houses in which the imported Orchids and rare species are grown, and find in each section some attractive things in bloom. *Cymbidiums* are represented by *C. Sanderi* and its hybrids, *C. eburneum* in quantity, and most of the others, *C. Tracyanum*, *C. grandiflorum*, and *C. giganteum* being in bloom. A very large collection of *Masdevallias*, including the blackish purple *M. calura*, the white *M. tovarensis*, the very handsome *M. Bella Sander's Variety*, *M. nidifica*, and many of the botanical species in bloom. Among the *Bulbophyllums* and *Cirrhopetalums* also a number are in flower, the finest being the charming copper-orange *C. Mastersianum*. *Saccolabium acutifolium*, *S. bellinum* and *S. calceolare* were noticed; the new *Phaius Cooperi*, which is quite an acquisition to the genus; and beside it, a very fine Primrose-yellow lipped form of the handsome *Chondropetalum Fletcheri*. A small collection of *Anoectochilus*, a good house of *Vanda coerulea*; a stage of *V. tricolor* varieties, a batch of *Oncidium splendidum* in spike, and many other things promise a good show.

The *Odontoglossums* and *Miltonia vexillaria* hybrids are chiefly grown at the *Bruges* establishment, but several houses at St. Albans contain plants that are thriving well.

In one house the bright mauve-purple *Laelia Gouldiana* and some *L. anceps* are well in bloom, in another a fine lot of *Calanthes* give their pretty pink rose and white flowers, and a cool house has a fine lot of the hybrids of *Odontoglossum Edwardii*, and a fine collection of *Odontodas* with a few of their scarlet sprays still remaining.

THE MARKET FRUIT GARDEN.

ABORTIVE SPURS ON PLUMS.

A LAMENTABLE habit of growth in some varieties of Plums is that of sending out slender and elongated spurs from thick and vigorous branches. Most of these spurs are bald near their bases, sometimes for an inch or two. If they are left entire many of them die off at the end of the season, and I am not sure that those cut back to two or three buds nearest their bases do

not share the same fate. If shaved off closely the branch is made bald where they grew for all future time, as there are no signs of buds near the bases of such shoots, which emerge from tiny hollows in the branch. Last spring some of these elongated spurs on vigorous and well-furnished Presidents, then three years from the planting of them as maidens, were crowded with blossoms, but failed to bear a single fruit, whether cut back or not. The other parts of the trees were almost entirely devoid of blossom. In pruning the trees a few weeks ago nearly all these slender spurs were found to be dead, and many a branch has been thus left bald for a foot, or, in some cases, 18 inches. In addition to the elongated spurs there are large thorns; but these are less objectionable, as some of them develop a fruit bud or two near their bases. When the trees were pruned last April, the leaders of some of the best-furnished and most symmetrical trees were left unshortened. These, I notice, have not formed nearly so many of the elongated and slender spurs as those which were cut back. But a very curious result is noticeable on some of the trees. The leaders not shortened instead of continuing to grow up-

one orchard, has a great number of cankered fruit spurs, as well as many shoots affected with scab near their ends. Now, many thousands of these spurs and portions of shoots are being cut off in the pruning of nearly an acre of Cox's Orange in two parts of the orchard, and it would be a great expense, and almost impracticable, to pick every one up and burn it. Large cuttings are taken away to be burnt in the ordinary course of proceedings, but not tiny pieces, and, without being certain that these, if left on the ground, will convey infection to healthy trees or healthy portions of trees, I am not disposed to attempt the tedious task of picking up the minute pieces. My impression is that fungus infection does not arise from diseased spurs or twigs lying on the ground, or at least not in the case of scab or canker. These fungi are not saprophytes, and the cuttings at this time of year quickly die and rot on the wet ground. Mycologists recommend gathering and burning; but they recommend many things impracticable to a grower of fruit on a large scale, such as the gathering off the ground of all leaves from trees or bushes affected with leaf-spot or any other disease—an abso-

gracillipes and Mazus rugosus of the WARGRAVE Co., Roscoea cautiloides and Trollius patulus of BEES, LTD.; Paeonia l'Espérance (KELWAY AND SON); Stachys corsica (Messrs. R. WALLACE AND Co.); Crocus chrysanthus E. A. Bowles (Messrs. BARR AND SON); forms of Primula viscosa shown in spring by Mr. J. DOUGLAS; Papaver Perry's Unique, Primula Excelsior, P. Maximowiczii, P. Purdomii, Lonicera tragophylla and Androsace tibeticum of Messrs. JAS. VEITCH AND SONS; Meconopsis Delavayi, a very pretty plant shown at Chelsea from the EDINBURGH BOTANIC GARDEN, Aethionema armenum from Miss WILLMOTT; and Saxifraga Faldonside and other Saxifragas from Sir EVERARD HAMBRO.

Roses have yielded an extraordinary number of first-class novelties, and these are referred to in the *Gardeners' Chronicle* report of the National Rose Society's exhibition, July 4, and in the issues of July 12 and November 1, p. 301, November 25, p. 355, November 29, p. 377, and December 6, p. 395.

ORNAMENTAL AND FLOWERING PLANTS.

Messrs. SANDER AND SONS, St. Albans and Bruges, through their collectors have exceptional facilities for obtaining new decorative plants and Palms, and with them the past year has been specially prolific. For general utility and for growing in quantity the new brilliant-red, semi-double Camellia Fred Sander, which was so much admired at the Ghent Quinquennial, stands first. Among ornamental foliage plants *Alocasia Wartelii* with large bronzy leaves, with lighter veining; *Heliconia insignis*, Musa-like in habit; *Polypodium irioides corymbiferum*, bright green and heavily tasselled; *Trevesia elegans* and *T. annamensis*, remarkable species with ornamental foliage; *Dieffenbachia Albertii*, from Central America, with large, thick, green leaves marbled with white; *Bromelia tricolor compacta*; *Rhodospatha Forgetii*, a new Aroid of distinct habit from Costa Rica, and a very fine set of new Palms, and other ornamental plants, which were fully described in the *Gardeners' Chronicle*, May 3, 1913, and some of which will be found in the accompanying list of plants illustrated.

Messrs. JAS. VEITCH AND SONS, in their speciality of winter and spring-blooming Begonias, add *B. Julius*, a bright rose-pink double, and *B. Rosalind*, one of the best and showiest of the series. *Hippeastrum Eurasian*, a fine carmine-crimson flower, secured an Award of Merit, and the very handsome strain of *Gloxinia*, shown on July 29, was given a like Award. The reports of the special exhibitions of Dahlias, Narcissus, Carnations, Chrysanthemums, Sweet Peas and other popular flowers show that marked progress has been made in each class, and if no startling new departures have to be recorded some worthy advances have been made.

The principal novelties of the year will be found in the following list of new and rare plants illustrated in the *Gardeners' Chronicle* in 1913. It is considered desirable also to give references for the figures of destructive insect and fungous pests which have been illustrated during 1913, in continuation of the large number of illustrations of similar subjects which had been previously given. The illustrations show the pests in the various stages of their life-history, and are helpful to gardeners in their attempts to grapple with the pests in the earlier stages of development.

PLANTS ILLUSTRATED IN 1913.

Abutilon insigne (Coloured Supp.), October 4.
Abutilon roseaeflorum, October 4, p. 240.
Abutilon vitifolium, October 4, p. 241-2.
Acantholimon venustum, March 1, p. 138.
Aesculus parviflora, August 23, p. 132.
Aethionema cordifolium, January 18, p. 42.
Agave Leopoldii, January 4, pp. 10-11.
Allamanda Hendersonii (Coloured Supp.), January 11.
Althaea ficifolia, August 23, p. 140.
Alyssum alpestre, January 23, p. 52.
Amaryllis Belladonna *blanda*, June 28, p. 441.
Ananas sativus variegata, March 22, p. 182.

(Photograph by W. J. Vasey.)

FIG. 19.—PENRHYN CASTLE, CARNARVONSHIRE, SHOWING THE WEST FRONT.

(See p. 37.)

wards came to a stop at about the height at which they were left last April, and sent out crowded bunches of side-shoots from their tips. This occurred on only a few trees, and possibly the destruction of the tips of the leaders by aphides caused the deformity. But I was much surprised to find generally as much branching out from uncut as from cut leaders. Fortunately there were good laterals a little below the bunches of shoots, and the latter were cut off bodily, thus restoring the symmetry of the trees. My experience leads me to the conclusion that it is a great mistake to prune Plums severely, excepting the extra gross leaders which some varieties produce. These, if not cut back severely, rob the other branches of their due share of nourishment. Where there are smaller leaders which would replace the gross ones, I believe it is advisable to cut the latter out entirely.

DO FUNGUS SPORES RISE FROM THE GROUND?

This question has been asked in a previous pruning season; but it is of such great importance that I return to the subject. It is recalled by the pruning of Cox's Orange, which, in

lately impossible feat. Do they know for a fact that disease spores float up from the ground and infest trees? Or is their advice based simply on surmise? I suspect the latter. This is one of the many points upon which research is urgently needed. *A Southern Grower.*

NOVELTIES OF 1913.

PLANTS OF GENERAL CHARACTER.

The past year has been a good one for new and interesting additions to garden plants. Novelties in herbaceous and Alpine plants and shrubs have been shown at the Royal Horticultural Society's meetings from time to time, and many fine acquisitions have obtained awards.

THE WARGRAVE HARDY PLANT Co., Messrs. BEES, LTD., Messrs. WALLACE AND Co., KELWAY AND SONS, and other specialists have each secured honours for desirable exhibits, most of which will be found enumerated in the appended list of new and rare plants illustrated in 1913. Among those specially noteworthy are the *IRIS*

- Androsace glacialis, March 22, p. 187.
 Androsace primuloides, March 22, p. 187.
 Androsace pyrenaica, August 2, p. 78.
 Androsace tibetica, May 31, p. 362.
 Anemone narcissiflora, January 25, p. 57.
 Anemone pulsatilla rosea (Coloured Supp.), January 25.
 Arenaria purpurascens, January 18, p. 43.
 Arthropodium cirrhatum, September 13, p. 184.
 Arundo conspicua, August 9, p. 100.
 Asperula nitida (Supp.), March 8.
 Aster Climax, November 15, p. 344.
 Aster Lil Fardel, November 15, p. 338.
 Aster Miss Southall, November 15, p. 343.
 Banksia integrifolia, November 29, p. 376.
 Bauhinia variegata, June 7, p. 379.
 Begonia Apricot, November 22, p. 365.
 Begonia Emita (Coloured Supp.), November 1.
 Begonia Florence Nightingale (Supp.), August 9.
 Begonia Julius, February 1, p. 75.
 Begonia socotrana, November 1, p. 303.
 Berberis Gagnepainii, November 15, p. 335.
 Berberis Wallichiana, November 15, p. 336.
 Berberis Wilsonae (Coloured Supp.), November 15.
 Bougainvillea Sanderiana (Coloured Supp.), March 29.
 Brachyichilium Horsfieldii, January 4, p. 12.
 Camoensia maxima, September 27, pp. 214-15.
 Campanula alpina, August 23, p. 142.
 Campanula isopyllia alba, August 30, p. 150.
 Campanula spicata, March 29, p. 207.
 Campanula Stevenii nana, May 24, p. 342.
 Campanula thyrsoidea, March 29, p. 206.
 Carnation Yellow Stone, October 11, p. 260.
 Chrysanthemum Mrs. E. Luxford, January 4, p. 5.
 Chrysanthemum Wm. Turner, January 4, p. 4.
 Clematis Armandii, May 17, p. 322.
 Clematis indivisa lobata in Devon, September 20, p. 199.
 Congea tomentosa, December 6, p. 399.
 Crataegus Genesensis, February 22, p. 115.
 Crocus Fleischeri white, July 19, p. 45.
 Cyclamen latifolium St. George (Coloured Supp.), December 20.
 Cytisus supranubius, August 16, pp. 121-22.
 Dahlia Cardinal (Coloured Supp.), April 12.
 Dahlia Dungeness, September 27, p. 217.
 Dahlia Goldfinch (Coloured Supp.), April 12.
 Dahlia Mrs. Joynson Hicks (Supp.), April 12.
 Dahlia Modesty (Coloured Supp.), April 12.
 Dendromecon rigidum, August 2, p. 93.
 Dianthus, seven species of, April 19.
 Douglasia laevigata, June 7, p. 381.
 Dracaena Massangeana, March 22, p. 182.
 Echinium Bourgeauanum, January 11, p. 25.
 Echinium Pinaiana, January 11, p. 20.
 Echinium simplex, January 11, pp. 18-19.
 Edraianthus dalmaticus and Edraianthus Pumilio, July 12, p. 31.
 Erinus alpinus, January 25, p. 58.
 Eriobotrya japonica variegata, May 3, p. 293.
 Eryogonum alpinum, March 1, p. 133.
 Eryngium pandanifolium, November 1, p. 302.
 Erythraea Massonii, November 8, p. 319.
 Eucryphia pinnatifolia (single and double), October 25, pp. 284-5.
 Euphorbia Eustacei, November 22, p. 355.
 Furcraea Bedinghausii, September 6, p. 167.
 Genista horrida, March 1, p. 140.
 Globularia bellidifolia (Supp.), March 8.
 Helicrysum bellidoides, April 26, p. 266, and June 28, p. 436.
 Ipomaea rubro-caerulea (Coloured Supp.), February 15.
 Iris iberica ochracea, June 14, p. 399.
 Iris sofarana, November 29, p. 377.
 Iris trojana (Coloured Supp.), March 15.
 Kalphoia multiflora, November 22, p. 356.
 Ligustrum japonicum coriaceum, April 26, p. 265.
 Liliun auratum, October 18, p. 269.
 Liliun Martagon album, July 26, p. 63.
 Liliun regale, June 21, p. 416-17.
 Liliun sulphureum, July 19, p. 53.
 Liliun sutchuenense, August 16, p. 114-15.
 Liliun Thayerae, August 16, p. 116.
 Limonia Poggei latifolia, June 7, p. 378.
 Lindenbergia graciflora, January 11, pp. 27-8.
 Linum salsoloides, July 19, p. 42.
 Loiseleuria procumbens, May 24, p. 343.
 Matthiola pedemontana, March 8, p. 149.
 Mazus rugosus, March 29, p. 210.
 Meconopsis cambrica, July 19, p. 52.
 Meconopsis Wallichii, March 8, p. 147.
 Mutisia Clematis (Coloured Supp.), November 29.
 Mutisia ilicifolia, November 29, p. 383.
 Myosotidium nobile, July 19, p. 47.
 Myrtus Luma (Eugenia apiculata), October 25, p. 287.
 Narcissus Evangeline, May 17, p. 330.
 Narcissus St. Olaf, May 17, p. 329.
 Narcissus White Emperor, April 12, p. 239.
 Nephrolepis exaltata (plumose varieties), December 13, pp. 424-5.
 Nymphaea Conqueror (Coloured Supp.), July 19.
 Nymphaea Galatee (Coloured Supp.), December 13.
 Nymphaea gigantea Hudsoniana (Coloured Supp.), June 21.
 Nymphaea Masaniello (Coloured Supp.), September 20.
 Odontadeia speciosa, August 9, p. 106.
 Oenothera rubricalyx, March 15, p. 165.
 Olearia Chathamica, May 31, p. 363.
 Omphalodes cornifolia, June 7, p. 380.
 Pachira macrocarpa, November 8, p. 325.
 Paeonia Delavayi, June 14, p. 403.
 Paeonia l'Espérance, June 21, p. 424.
 Paeony La Lorraine, May 3, p. 296.
 Phoenix Roebelinii, March 22, p. 182.
 Polygonum polystachyum (Supp.), May 17.
 Populus Maximowiczii and P. suaveolens, March 23, p. 198.
 Primula Allionii, February 8, p. 85.
 Primula Fortunei, April 12, p. 238.
 Primula Jean Douglas, April 26, p. 267.
 Primula Listeri, April 26, p. 271.
 Primula malacoides plena, December 13, p. 428.
 Primula Maximowiczii, April 26, p. 267.

- Primula pseudo-denticulata, April 26, p. 264.
 Primula Purdomii, March 29, p. 200.
 Primula Rusbyi, September 13, p. 190.
 Primula vincaeflora, September 20, p. 198.
 Prunus cerasifera Moseri fl. pl., March 22, p. 190.
 Prunus subhirtella, May 3, p. 285.
 Puya chilensis, July 5, pp. 2-3.
 Randia maculata, August 2, p. 79.
 Ranunculus glacialis, February 22, p. 117.
 Red Sunflower, August 9, p. 108.
 Rhodochiton volubile (Coloured Supp.), May 10.
 Rhododendron Clorinda (Coloured Supp.), July 5.
 Rhododendron concinnum, May 24, p. 341.
 Rhododendron dauricum, flowering at Christmas, January 25, p. 51.
 Rhododendron yunnanense, December 6, pp. 396-7.
 Rodgersia sambuifolia, August 23, p. 131.
 Rodgersia tabularis, August 23, p. 130.
 Rosa sertata, single wh., September 6, p. 166.
 Rose Annie Crawford, August 9, p. 99.
 Rose Ellen Poulsen, May 16, p. 302.
 Rose Irish Fireflame, May 31, p. 365.
 Rose Mrs. Chas. Russell, January 25, p. 61.
 Rose Mrs. Godfrey Brown, July 26, p. 69.
 Rose Queen Mary, July 12, p. 34.
 Saxifraga ambigua, September 13, p. 183.
 Saxifraga Faldoaside, April 5, p. 214.
 Saxifraga lingulata Bellardii, August 23, p. 135.
 Saxifraga longifolia, June 7, p. 390.
 Saxifraga pyramidalis and S. longifolia in Sir Everard Hambro's Gardens, June 7, pp. 369-90.
 Socratea Forgetiana, May 3, p. 286.
 Solanum jasminoides, August 2, p. 89.
 Solanum capsicastrum Melvillii, February 15, p. 101.
 Strelitzia kewensis, August 2, p. 87.

PENRHYN CASTLE.

(See Figs. 19, 20, 21 and 22 and Supplementary Illustration.)

To those who have never visited North Wales the name may suggest perhaps a cold and mountainous region, a wild, inhospitable land, where swift mountain torrents, fed by mountain snows, speed seawards, rushing through rocky land, where only the hardiest trees and shrubs can find sustenance.

This would be a true description of parts of North Wales, but a country which is mountainous has also valleys. No richer vegetation can be grown anywhere in our islands than is produced by the fertile valleys of North Wales. With a rich soil is combined a mild and equable climate, giving full opportunities for a varied flora. Generally speaking, the climate of our country is regulated by longitude rather than by latitude, and the beneficial influence of the Gulf Stream which washes the western shores is more apparent in the West of Scotland and in North Wales than in the south-east of England.

In the broad valley at Penrhyn the wonderful variety of uncommon trees and shrubs which is usually associated with the "Cornish Riviera" may be seen growing in luxuriance. At Penrhyn many half-hardy shrubs are growing as standards in the open ground, away from the adventitious protection of walls, and their grace and beauty are enhanced by a setting of closely-mown grass or of spreading trees. These valuable shrubs are grown in several distinct sets of conditions; for example, as lawn specimens (see Supplementary Illustration) in front of the conservatories, and planted in a mature wood somewhat in the fashion of a wild garden. In the first-mentioned position specimens of Eucryphia cordifolia may be seen fully 15 feet high and bearing quantities of seeds. E. pinnata also flowers freely as a standard. There are fine examples of Styrax Obassia, Eugenia apiculata, 20 feet high and 15 feet across, Eriobotrya japonica, Camellia Sasanqua, close to a fine example of Magnolia stellata, nearly 10 feet high and as many broad. Camellia Thea, a rarer shrub, makes a broad, low pyramid, contrasting with a 25-foot-high Eugenia apiculata of more graceful outline, the brown bark peeling in sec-

tions, and disclosing the greyish-white under-bark in an effective manner. A pergola of Fuchsias (see fig. 22) strikes an uncommon note and tells how favoured is this district, for the huge bushes of *Fuchsia Riccartonii* meet overhead 9 feet from the ground. The red shoots and leaf-stalks of *Actinidia arguta*, which cling around the railings of a flight of steps (see Supplementary Illustration), give a dazzling display of colour amongst the green of the other subjects, but their hue is almost equalled by that of bushes of *Desfontainea spinosa* nearly 10 feet high, and bearing strange gold and scarlet bell-shaped flowers amongst small, Holly-like leaves. Near by a tall deciduous Cypress (*Taxodium distichum*) serves as a support for *Stauntonia latifolia*, which has climbed 50 feet towards the top, and now hangs down in graceful festoons. Magnolias of many kinds, Azaleas of sorts, and a great variety of Camellias grace the scene; and Mr. Speed, the head gardener, points out a tall *Griselinia littoralis*, which he remembers seeing grown, when it was less understood, as a stove shrub.

The formal flower garden on the other side of a broad gravel terrace is quite small. The central feature is a set of beds (see fig. 20) radiating from a sundial, bearing the date 1797 and the family crest, with the inscription "He stretcheth out the North over the empty place and hangeth the Earth upon nothing." During the summer these beds are gay with tuberous Begonias, scarlet Salvias, Pentstemons, and Heliotropes. Long, narrow beds containing central pillars of Dorothy Perkins Rose (see fig. 21) flank this centre and contrast gaily with the sober but tropical-looking leaves of the tall Australian *Dracaenas* on the opposite side of the broad walk.

(To be concluded.)

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

GARDEN ROSES.—If any planting of Roses, either in beds or groups, remains to be done, let the work be completed as soon as the conditions are favourable, for Roses planted early form roots at once, and nearly a year is gained over those planted later. A few of the newer varieties should be planted annually to keep the collection up to date, but it must be remembered that some of the newer sorts have weak constitutions and soon wear out. Select only those that have strong, healthy growth of stout, leathery foliage. Amongst red varieties I have found none equal to *Ecarlate*; indeed, had it not been for 20° of frost on December 31 we should now be gathering good, useful blooms. Up to that date several large dinner tables had been decorated nightly with that variety, and even now there are dozens of unopened buds on plants out-of-doors. Other good red sorts are General McArthur, Richmond, C. J. Grahame, Warrior, Rhea Reid, *Etoile de France*, *Avoca*, *Papa Gontier*, and *Corallina*, all of which I have proved to be first-rate bedding plants. Amongst those having pink flowers *Grand Duc de Luxembourg*, G. Nabonnand, *Prince de Bulgarie*, Mrs. E. G. Hill, *Caroline Testout*, *Madame Abel Chatenay* may all be recommended; whilst good whites are found in *Frau Karl Druschki*, *Viscountess Folkestone*, *Madame Antoine Mari*, and *Pharisaër*. Of yellow shades select *Lady Hillingdon*, *Le Progrès*, *Madame Chédane*, *Guinoisseau*, *Madame Ravary*, and *Marquise de Sinety*, for these are all well proved and good growers. Those named include Teas and hybrid Teas. They may be grouped in a series of beds on grass by themselves. The older H.P.s may also be planted in similar but separate positions, and of these Mrs.

J. W. Grant, Chas. Lefebvre, Captain Hayward, *Général Jacqueminot*, Mrs. John Laing, *Merveille de Lyon*, and Ulrich Brunner are a selection. The *Polyanthas* and *Chinas*, such as *Jessie*, *Léonie Lamesch*, Mrs. N. H. Cutbush, *Orleans*, *Madame Eugène Resal*, *Perle d'Or*, *Anna Marie de Montravel*, *Madame Laurette Messimy*, and *Hermosa* are suitable for beds. A few weeping or fountain standards, 4 to 5 feet tall, may be used as foils and trained on frames. Roses of the *Wichuraiana* type, such as *Lady Gay*, *Hiawatha*, *Lady Godiva*, and *Jersey Beauty*, may also be employed, but generally standard Roses are far less satisfactory than well-grown dwarfs, being short-lived.

CLIMBING ROSES are indispensable for covering pergolas or fences. At Madresfield Court we have an inexpensive rustic boundary screen, so simply constructed as to be worthy of imitation. It was constructed as follows:—Earthenware pipes were buried in the ground, and in these were set in cement old 3-inch iron pipes in lengths of 12 feet and upwards. These uprights were braced together with four to six ordinary wires of the same gauge as that used for cattle fencing, the wires fixed horizontally. It forms an imperishable and permanent structure. Old tree-tops or rough stakes are fastened to the wires, and on these the Roses are trained. Evergreen Roses, such as *Félicité et Perpétue*, *Dundee Rambler*, and *Bennett's Seedling*, were planted, and form a permanent and pleasing screen. Roses of another beautiful section, such as *Madame Abel Carrière* (white), N. A. Richardson (yellow), *Fellenberg* (magenta-red), and *Gloire de Dijon*, require plenty of room, and will spread themselves over old tree stumps or roots, placed roughly together in heaps, in prominent places on the turf. Where any old fences or low walls exist, these may be utilised to good effect by planting such Roses as *Grüss an Teplitz* (red, one of the sweetest and best of cluster Roses), J. B. Clark (red), and any of the multi-flora section. We have long hedges of *Rosa rugosa*. The blooms are very beautiful in the bud stage, and are useful for cutting, the foliage is very handsome, and the fruits also are beautiful in autumn.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. COOKSON, Oakwood, Wylam-on-Tyne.

DECIDUOUS CALANTHES.—When the flowering is over the plants should be rested, either on a shelf near to the roof-glass or in a dry, light position on the stage. At this season of the year space in the glasshouses is limited, and there may not be room to stage the *Calanthes*; in such circumstances it is a good plan to turn the plants out of their pots and place the pseudo-bulbs, carefully labelled, close together in shallow boxes. Cover the bottom of the box with a thin layer of materials composed of about equal parts of chopped Sphagnum-moss and broken leaves intermixed with sand. Cut away the majority of the roots, leaving only sufficient to hold the plants in position, and pack the materials about the pseudo-bulbs sufficiently firmly to secure them in an upright position. Water will not be required until the plants commence to grow again in the spring. It is not advisable to place the plants where the temperature varies much; a temperature of about 55° will be suitable until the new growths develop. Late-flowering species, such as *C. Regneri*, *C. Williamsii*, and *C. Sanderiana*, also their hybrids, should be afforded conditions that will favour the development of the flower scapes during the next two or three weeks; it is surprising how rapidly the flowers expand as soon as the days become brighter.

PHAILO-CALANTHES.—These semi-deciduous bi-generic hybrids are not the easiest plants to cultivate; as soon as they pass out of flower it is advisable to place them in a warm but rather dry house. Afford only sufficient root moisture to keep shoots plump, for an excess of moisture, either in the atmosphere or at the roots, favours the development of black "spot," that may cause rotting from the base upwards. Dry conditions and cutting out the affected parts are the best means of checking the disease.

PHAIUS.—Many early-flowering hybrids of the *P. simulans* section are producing their flower-scapes from the bases of the new growths. If it is desirable to have the plants in flower early in the season they should be hastened into growth, but if not required to flower before April or May they must be retarded. If the plants are kept cool the atmosphere must be moderately dry, especially towards evening, when the temperature declines. By the end of the present month or early in February more liberal conditions may be afforded, but the watering must be done very carefully. The plants should be examined at frequent intervals, for the presence of scale insects and red spider may prove troublesome if much fire-heat is employed. Sponging the foliage with warm soft water is the best means of destroying red spider.

PLANTS UNDER GLASS

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

STOVE PLANTS.—Fine foliage stove plants, such as *Aralia elegantissima*, *A. Veitchii* and *A. Veitchii gracillima*, *Codiaeums* (*Crotons*), *Cordylines* (*Dracaenas*), *Pandanus* and *Panax*, should not be excited into growth at this season by high temperatures, as the extra heat would encourage weak growth and the spread of insect pests, such as thrip, red spider and mealy bug. A temperature of 60° is quite sufficient on cold nights and 65° on mild nights. The temperatures during the day must be regulated in accordance with the weather conditions, but as a rule temperatures between 65° and 70° will tend to keep the plants healthy. Avoid overwatering, but do not hesitate to syringe the plants on bright mornings, remembering that on dull days only damping of the paths will be appropriate. If the plants are thoroughly sponged at this period with soapy water to which a few drops of petroleum or other insecticide have been added, it will improve the appearance of the plants and will be a check to red spider, which is troublesome if much fire heat is used. Flowering plants, such as *Coleus thyrsoides*, *Euphorbia pulcherrima* and *E. jacquiniæflora*, *Plumbago rosea*, *Begonia Gloire de Lorraine*, *B. socotrana* and its hybrids, will still be full of flower. Maintain a fairly dry atmosphere to prevent damp. As the *Euphorbias* pass out of flower the plants should be removed to a warm pit to rest. *E. jacquiniæflora* should be examined occasionally whilst at rest, as it must not be allowed to become excessively dry at the root.

TREE CARNATIONS.—Although autumn-rooted cuttings are strongly to be recommended, many do not raise their plants for autumn and winter blooming until the turn of the year. In gardens in the South of England the latter system answers well, but in colder districts the climatic conditions are not generally favourable for rooting plants in December or the early part of January, so that October is a more suitable month for inserting the cuttings. The propagation of Carnations from cuttings may be effected in various ways. Where a large stock is required I strongly recommend the sand-bed system. Arrange a frame in a house over hot-water pipes or a mild hot-bed, and place sharp sand or a sandy compost in it to the depth of about 4 inches. When the bed bottom heat is about 55° the cuttings may be inserted; greater warmth may result in the cuttings rooting quicker, but it weakens the constitution of the plant. Select strong, sturdy side shoots from the base of the flowering stems, make a clean cut below a joint, and remove the two bottom leaves. A vertical cut may be made through the joint to encourage root to form. Insert the cuttings at 2 inches apart, water the soil, and maintain an even temperature of 50°, keeping the bed uniformly moist. After a week has elapsed the lights may be taken off the frames at night and replaced in the morning. Cuttings rooted in October are filling their pots (2 inch) with roots, and should be potted on as required. Employ less leaf-mould at each successive potting, but increase the quantity of wood ash and lime rubble. The shoots of flowering plants should be tied neatly, and the surface soil stirred lightly with a pointed stick. It is not advisable to feed the plants with fertilisers until after January.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOE, Eastwell Park, Kent.

THE ORCHARD.—Many orchards are allowed to become neglected, whilst the trees in the kitchen garden receive suitable attention in such matters as pruning, training and manuring. Orchard trees that are not so old as to be altogether worthless are often thickets of growth, and, full of filth and pests, are sources of infection to all fruit trees in their immediate neighbourhood. Under such conditions the fruit is not of even medium quality. The next few weeks offer a suitable time for dealing with neglected orchards, as the work can be carried out in all but the most inclement weather. First grub up all old, worthless trees. Others that are of inferior varieties, but comparatively healthy, should be headed back, ready for grafting with better sorts at the proper time. The remaining trees should be thinned in their centres, cutting out weak and badly-placed boughs, leaving only a moderate number of clean, healthy, straight branches. Thoroughly thin the other parts of the tree to allow the sunshine and air to enter freely. The dead wood, prunings and rubbish should be burnt, mixing the wood-ashes with the top-dressing to be applied afterwards.

SPRAYING THE TREES.—When the work of pruning is completed choose a calm, mild day and spray the trees thoroughly with an alkali wash, and see that every part of the tree is wetted by the specific. There are several good spraying machines on the market, and where there are large numbers of trees to deal with it will be a good investment to purchase one. It may be necessary to spray a second time, and this should be done just before the buds expand. The spray will kill every particle of lichen and moss, and destroy the eggs of many of the insect pests. The operator should wear rubber gloves and work with his back to the wind, otherwise the fluid may be blown on to his face.

TOP-DRESSING AND MANURING.—Where the orchard is under grass the turf over the roots should be dug under the ground, and the area treated should extend as far as a yard beyond the spread of the branches. A dressing of lime will be beneficial and will help to purify the ground. This application should be followed by a mulching of farmyard manure. If the latter cannot be procured artificials may be mixed with wood-ashes and fresh soil, unless poultry, calves, or other stock are allowed the run of the orchard.

YOUNG ORCHARDS.—The pruning and spraying of trees that have always received proper attention is a much simpler task. Prune to spurs all young growths not required for extension, always remembering that the head of the tree should be kept thin of branches. Fork the ground lightly up to the edge of the grass, and afford manure according to the requirements of the trees. No general rule can be laid down with regard to manuring, as much depends on the nature of the soil and whether stock is fed in the orchard. Unless young trees have borne good crops of fruit they should not be too liberally manured, or growth may be gross and unfruitful.

THE FRUIT ROOM.—Provided a properly-constructed fruit-room is available, or even a suitably converted room, there is no great difficulty in keeping certain sorts of Apples until late in the spring. The fruits should be examined carefully at intervals, and those that show the least sign of decay removed for use at once. Fruit-rooms are often constructed as part of a scheme of buildings without the architect or builder considering the suitability of the site; sometimes they are connected with the stove-hole, or the hot-water pipes may pass under or behind them, rendering it an impossibility to keep fruit much after the New Year. In such conditions varieties that ripen late in the season shrivel and become quite useless. As a rule too many early and mid-season varieties of Apples are planted in the same garden. In selecting late culinary varieties for use after this date the following should be included:—

Newton Wonder, Alfriston, Lane's Prince Albert, Chelmsford Wonder, Annie Elizabeth, Striped Beaufin, Dumelow's Seedling (syn. Wellington) and Bramley's Seedling. Late dessert sorts include Allen's Everlasting, D'Arcy Spice, Brownlee's Russet, Cockle's Pippin, Lord Hindlip, Claygate Pearmain, Wyken Pippin and Northern Spy. Fruits of these, if stored in a cool and not excessively dry room, will furnish a supply late in the spring.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

THE ORCHARD HOUSE.—The unheated orchard house should receive a thorough cleansing. Any arrears of potting left over from October should be completed at once. Protect the roots from frost by covering the pots well over the rims with litter or other protective material. Where desirable a few of the earlier Peaches, such as Early Louise, Early Beatrice, Duke of York, Early Rivers, or Earliest of All, may be placed in a house where the temperature does not exceed 45° to 50°. The trees will develop slowly and furnish an early or second early crop. The orchard house at this season may be used for various purposes, such as growing winter saladings, either in deep boxes or planted out in the borders.

POT CHERRIES should not be too hastily dealt with in the early stages of growth. Ventilate freely during mild weather, exciting the trees very gently with artificial heat. Maintain a temperature of not more than 40° to 45° at night, and 50° to 55° by day. If through sun heat the temperature rises above 55° close down the house at that point and reduce the fire heat. Cherries should never lack moisture at the roots; during bright weather the trees should be sprayed in the morning and early afternoon, and the house ventilated to prevent a close atmosphere. Under continued favourable conditions trees so treated and started at this time of the year should mature their fruit during April or early in May. Black Tartarian, Early Rivers, Elton, Frogmore Early Bigarreau, Werders Early Black and Early Red Bigarreau are all excellent varieties to grow for early forcing.

TOMATOS.—Fruiting plants of the varieties Winter Beauty or Dwarf Red should be grown in a warm house. Let the air circulate as freely as the climatic conditions will admit, and exercise much care in watering, keeping the roots on the dry side. When roots appear on the surface, top-dress lightly with fresh soil mixed with a suitable artificial manure, and at each watering use weak manure water. Plants raised from seed late in the autumn, with a view to fruiting in the spring, should be potted into 6-inch pots, using soil of a light nature. Afterwards place the plants near to the roof-glass in a house having an atmospheric temperature of 60°. During mild weather ventilate freely, and take other measures to prevent the plants from growing spindly.

CUCUMBERS.—If Cucumbers are required early in the year make a sowing at once. Transplant the seedlings as soon as they develop their rough leaves and plunge the pots to their rims in a bottom heat of about 75° to ensure a quick root action. If the plants are plunged in hotbeds in brick pits add fresh fermenting materials directly it is seen that the heat is declining below 75°. If the bottom heat is supplied by hot-water pipes, or if the hot-bed is made in a heated structure, little or no difficulty will be experienced in this respect. January is a more favourable month for plants in bearing than November or December. Maintain a moist atmosphere and a temperature of about 75° to 80° by day, and about 65° at night. Do not pour water on the hot-water pipes, but syringe the walls and pathways frequently each day and keep the evaporating troughs filled with manure water. The shoots may be allowed to develop four or five joints before they are stopped; should the plants be in a weakly condition do not pinch the growths for the present, but remove decaying foliage.

THE KITCHEN GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

SCOTCH KALE.—This green vegetable is an excellent substitute for Spinach at this time of the year. In any case it is a mistake to cut over the tops of the Kales if the most is to be made of the crop; rather gather one or two leaves off each plant. The side-growths, which are invaluable in April, will be produced all the same, though some think it is essential to top the plants to induce their production.

JERUSALEM ARTICHOKEs.—It is my practice to lift the tubers at this time of year and store them for use. The re-planting is done at once in ground that has been recently trenched; if manured for the previous crop the soil will need no enriching for the Artichokes. Medium-sized tubers are best for planting, and they should be set in double lines at a foot apart in the rows with 3-foot spaces between the latter. The ground on which the Artichokes were grown will be much exhausted and should receive an extra large dressing of manure when it is cultivated.

MUSHROOMS.—If new beds are made up at short intervals of time very little fire-heat will be required to maintain a suitable warmth in the Mushroom house, and this system has the further advantage of lessening the amount of damping which the use of artificial heat necessitates. I prefer to have a covering of straw over the surface of the beds in order to equalise the conditions of moisture, etc. A little ventilation will keep the atmosphere sweet without lowering the temperature. There are several varieties of Mushrooms, but the most prolific that I have grown are dark-coloured. At best the Mushroom is an erratic crop, for our first bed last year came into bearing behind two later ones.

ROUTINE WORK.—We have just experienced a sharp frost accompanied with snow. As soon as the soil is dry enough to permit of working, the crops of Broccoli and Brussels Sprouts should be examined and all damaged foliage removed, so that air may circulate freely amongst the plants. The first opportunity should be taken to stir the surface of the soil in which young Cauliflowers and Lettuces are growing with either a fork or a hoe.

CARROTS.—Early crops of Carrots may be produced with facility by sowing in boxes sufficiently deep to hold a 5-inch layer of very light friable soil, germinating the seeds in a moderate temperature, and growing the plants in a well-ventilated pit. The thinnings should not be destroyed, because they succeed very well when transplanted, and provide a succession to those produced entirely in boxes.

SPINACH.—A sowing of Spinach may be made as soon as the soil is in a suitable condition. If moderately dry run a Dutch hoe just under the surface early in the day, and in a few hours, if the day continues fine, the soil will be in condition for planting.

HERBS.—Beds of Spearmint and Sorrel are much improved by a layer of soil laid evenly over the surfaces to a depth of 2 inches. Sorrel will soon be growing again, and the work should be done at an early opportunity.

LIME.—An application of lime is beneficial to the soil even where limestone abounds, and on some soils it is essential. The present month or February is suitable for applying it, and where quicklime is used it is much to be preferred to place the "shells" in a shed till they are air-slaked, after which the quantity to apply can be more easily determined, and far more equally distributed. A rough-and-ready method is to just whiten the surface, a ton going a long way towards dressing a medium-sized garden, say one of 4 or 5 acres. Besides neutralising acidity, lime disintegrates soil, making it more amenable to cultivation, destroys numbers of garden pests, and reduces the labour of weeding to some extent. Farmers who cultivate highly find lime valuable for Turnips and Potatoes, and it is a poor garden which is less highly cultivated than the very best type of farm; hence do not neglect to use lime in the garden.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the **PUBLISHER, 41, Wellington Street, Covent Garden, W.C.**

APPOINTMENTS FOR THE ENSUING WEEK.**MONDAY, JANUARY 19—**

Surveyors' Inst. Junior meet. (Paper by Mr. H. J. Smith on "The Housing and Town Planning Act in Working.")

TUESDAY, JANUARY 20—

Scot. Hort. Assoc. annual meet. Roy. Inst. meet. (Lecture by Prof. W. Bateson on "Animals and Plants under Domestication.")

WEDNESDAY, JANUARY 21—

Royal Meteorological Society meet.

THURSDAY, JANUARY 22—

Gardeners' Roy. Ben. Inst. annual meet. and election of pensioners at Simpson's Restaurant, Strand, at 2.45 p.m. Roy. Botanic Soc. meet.

FRIDAY, JANUARY 23—

Roy. Inst. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 58.7°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, January 14 (6 p.m.): Max. 36°; Min. 33°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, **Thursday, January 15 (10 a.m.):** Bar. 30.1; Temp. 40°. *Weather, —Dull.*

PROVINCES, —Wednesday, January 14: Max. 42° Shields; Min. 34° Aberdeen.

SALES FOR THE ENSUING WEEK.**MONDAY AND WEDNESDAY—**

Rose Trees, Shrubs, Perennials, Lilies, etc., at Stevens' Rooms, King Street, Covent Garden.

MONDAY AND FRIDAY—

Herbaceous Plants and Perennials, Lilliums and other hardy Bulbs, Roses and Fruit Trees, at 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.

WEDNESDAY—

Hardy Bulbs and Roots, Border Plants, Perennials, etc., at 12: 1,389 c/s Japanese Lilliums at 2.30, preceded at 12 o'clock by thousands of miscellaneous Bulbs, in lots to suit the trade; Palms and Plants at 5, at 67 and 68, Cheapside, E.C., by Protheroe and Morris.

THURSDAY—

Special Sale of Roses at Protheroe and Morris's rooms, at 1.

FRIDAY—

An importation of *Odontoglossum crispum*, also other imported Orchids, at Protheroe and Morris's rooms, at 12.45.

John Gilbert Baker.

Of the many and well-won honours which have fallen to the veteran botanist and horticulturist, John Gilbert Baker, none has been more happy than the presentation by distinguished men of science of an address of congratulation on the occasion of his eightieth birthday, which occurred on Tuesday last. The address, the felicitous terms of which we quote, was signed by the Director of Kew, Sir David Prain, the late director, Sir W. T. Thiselton-Dyer, and by his old colleagues and friends at Kew and elsewhere.

"To-day you complete the eightieth year of a long and useful life, the best part of which has been intimately connected with Kew. Enthusiasm, love, and a keen sense of duty in your work and unflinching courtesy and affection to your colleagues have been yours. You have been an example to us in our common service, and a friend whose personal charm has won our hearts. Active and vigorous through all these years, you now rest from toil with interest still unabated in the progress of our science, and with that serenity of outlook which has marked your life. May you enjoy many more years of health and happiness."

Old readers of this journal will, in particular, recognise the appropriateness of the use of the Daffodil, Crocus and Iris in the illumination of the Address, first for

the reason that among the many genera of plants which Mr. Baker studied with such luminous effect, these three were the subjects of his especial enquiries, and secondly because the results of his masterly investigations into their taxonomy were published in large part in these pages.

Mr. Baker joined the staff of the Kew Herbarium at the invitation of Sir Joseph Hooker so far back as 1866. After twenty-four years of service as first Assistant he succeeded Professor Daniel Oliver as Keeper of the Herbarium. To those of the vitality of Mr. Baker the rules made for lesser men may well appear severe, for it is now fifteen years since he retired "under the age limit" from the post which he had adorned for so long a period.

Not the least of the great services which Mr. Baker has rendered to science lies—if we may so phrase it—in the horticultural attitude which he took

JOHN GILBERT BAKER, F.R.S., V.M.H., WHOSE EIGHTIETH BIRTHDAY ON TUESDAY LAST WAS CELEBRATED BY A PRESENTATION.

up and maintained throughout his work on systematic botany. Before Ecology was invented Mr. Baker, like all the great botanists, was an Ecologist. He studied his plants as living things, and by no means confined himself to the contemplation of their remains as they appear in the "mortuary." Of him it may in truth be said that he looked at life and saw it whole.

Coloured Plate.—The subject of the Coloured Supplement to be published in the next issue is *Impatiens Herzogii*.

LAWES AND GILBERT CENTENARY FUND.—During the Christmas holidays the Lawes and Gilbert Centenary Fund Committee ceased work so as not to interfere with the ordinary Christmas appeals. The Committee has ascertained that a satisfactory laboratory can be erected and equipped for £12,000. In order to complete the

fund only £1,600 is required; and an urgent appeal is addressed to all interested in agricultural science to aid the committee to collect this amount, so that the work can be put in hand at an early date. Subscriptions should be sent to the Secretary, Rothamsted Experimental Station, Harpenden, Herts.

NURSERY FIRM'S ROYAL WARRANT.—Messrs. GEORGE BUNYARD AND CO., LTD., have been appointed fruit-tree nurserymen to Her Majesty QUEEN ALEXANDRA. The firm held the Royal Appointment as nurserymen to Her Late Majesty QUEEN VICTORIA.

LONDON NATURAL HISTORY SOCIETY.—The City of London Entomological and Natural History Society and the North London Natural History Society have amalgamated as the London Natural History Society, the first meeting of which was held at Salisbury House, London Wall, on the 6th inst. The meeting was well attended, and the retiring Presidents, Mr. A. W. MERA and Mr. A. BACOT, gave some reminiscences of the old Societies. The City of London Society dates from 1858, and was formed in Haggerston, when that district was much less in the midst of houses than it is now. The society has numbered many well-known entomologists among its members. The North London Natural History Society is of much more recent date. It was originated about 21 years ago by several young naturalists who were members of the Grocers' Company School Science Club at Hackney. Mr. F. J. HANBURY, who presided at the first meeting of the North London Society, was present at the first meeting of the London Natural History Society. Mr. L. B. PROTUE, a member of both the old Societies, has been elected President. The new Society starts with about 190 members and 60 associates; it has branches at Chingford and Woodford.

NATIONAL DIPLOMA IN HORTICULTURE.—The Secretary of the Royal Horticultural Society informs us that in view of the many arrangements which must be made in advance for the 1914 Diploma Examinations, and the necessity for fixing suitable centres, the President and Council would be glad to hear as soon as possible from all candidates wishing to register themselves for the Diploma. The 1914 examinations will be held during the week June 22 to 27. Registration, under the rules, must, therefore, be made before February 22. Holders of 1st or 2nd class Certificates in the R.H.S. General Examination in Horticulture are exempted from the qualifying examination.

LEGACY TO A GARDENER.—Under the terms of the will of the late Canon ARTHUR BARWELL, of Bletchingley House, Redhill, who died on November 15, aged 79, a sum of £100 is bequeathed to his gardener.

PERPETUAL-FLOWERING CARNATION SOCIETY.—The Perpetual-Flowering Carnation Society invites other horticultural bodies to become affiliated to it, offering to supplement the awards at shows in the provinces by placing medals at the disposal of affiliated societies of the same design and of equal value with those awarded by the society at its own shows. Particulars may be obtained from the hon. secretary, Mr. T. A. WESTON, Floradale, Orpington.

NATIONAL VIOLA AND PANSY SOCIETY.—At a meeting of Viola and Pansy growers held at Moseley on the 7th inst., it was decided to form a National Viola and Pansy Society. Mr. W. WATERS BUTLERS was elected President, and Mr. J. BASTOCK Hon. Secretary. Monthly meetings will be held, and conferences have been arranged to take place in June, July and August, when certificates will be awarded to new varieties. An exhibition will take place in June, the details of which are to be announced later. The President has offered a ten-guinea Challenge Cup for competition. Particulars may be ob-

PENRHYN CASTLE GARDENS, CARNARVONSHIRE, THE RESIDENCE OF LORD PENRHYN.

tained from the Hon. Secretary, 75, Springfield Road, Moseley.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We are requested to announce that the seventy-fourth annual general meeting of the members and subscribers of this institution will be held at Simpson's, 101, Strand, London, on Thursday, January 22, 1914, at 2.45 p.m., for the purposes of receiving the report of the committee and the accounts of the institution (as audited) for the year 1913, electing officers for the year 1914 and electing fifteen annuitants on the funds. The chair will be taken by Sir HARRY J. VEITCH, V.M.H., treasurer and chairman of committee, at 2.45 o'clock. The poll will be open at 3 o'clock and close at 4 o'clock precisely, after which hour no voting papers can be received. During the year 1913 MARTHA M. HOBBS, ANNA HUDDY, ELIZABETH SMITH and HANNAH BRYAN, widows of annuitants, were placed on the funds without election, in accordance with Rule III., 13. The voting papers were issued on December 31 last. Any subscriber not having received a copy should communicate with the secretary, GEORGE J. INGRAM, at the offices, 92, Victoria Street, Westminster, S.W. The annual Friendly Supper will be held at Simpson's, 101, Strand, London, after the annual general meeting. The chair will be taken at 6 o'clock by Sir HARRY J. VEITCH, V.M.H.

PRESENTATION TO A GARDENER.—Mr. JESSE TUCK having resigned his position as gardener at the Hengrave Estate, Bury St. Edmunds, after 43 years' service, has been presented with a souvenir by his employer, Mr. Wood, and the members of his family. Mr. TUCK is also granted a pension.

THE RAINFALL IN 1913.—Many gardeners are keen meteorologists, taking daily records of the temperature and other data concerning the weather, and, as is their custom, several have sent us the record of the rainfall in the past year. Mr. W. MANN, writing from The Observatory Gardens, Penllergare, Swansea, gives the year's rainfall as 55.75 inches, and the number of rainy days 234. From October 19 to December 11, that is 54 days, only 3 days were without rain. April, 1913, was the wettest April for 30 years past, the amount of rainfall being 6.44. But November was wetter with 8.93 inches, and there were only two days in the whole 30 that were dry. The rainfall in Davenham Gardens, Malvern, for the year was 30.87 inches. Mr. BAYFORD, the gardener, informs us that rain fell on 176 days, the greatest fall in the twenty-four hours being on September 4, when 1.28 inches were measured. October was the wettest month, with 4.76 inches, March following closely with 4.58 inches. In June, the driest month, only 0.67 inch of rain was recorded. At Osberton Gardens, Worksop, the total rainfall for the year amounted to 22.57 inches, or 10.04 inches less than in 1912. The heaviest rainfall occurred on January 11, when 1.15 inches of rain was recorded. June was the driest month, with only 8 rainy days, and a fall of .41 of an inch. In January the rainfall amounted to 3.58 inches, which was the wettest month in the year. There were 166 rainy days. Mr. ALLAN, the gardener, also gives the following interesting weather items:—The hottest day was on August 3, when the thermometer registered 88° in the shade, being 1° less than the warmest day of 1912, and the coldest day December 28, when there was 22° of frost. Mr. W. CRUMP, writing from Madresfield Court Gardens, Malvern, informs us that the total rainfall was 30.56 inches, and that rain fell on 176 days. June and July were both dry months, with 0.69 and 0.68 inch respectively, but December was only a trifle wetter with 0.87 inch. The rainfall at Rotherfield Park, Alton, amounted to 39.44 inches, spread over 202 wet days. On September 4 1.93 inches of rain fell in 24 hours, a record for the year. Mr. YATES sends a tabulated list, which shows that January was unusually wet,

with 6.49 inches. Mr. W. R. ROBERTS gives 37.05 inches as the total rainfall at Bailrigg, Lancashire. There were 208 rainy days, that is days on which .01 or more rain was registered, the wettest months being November, when rain fell on 26 days. The total rainfall at Greenhill Gardens, Warminster, was 32.68 inches, and .01 inch or more was registered on 149 days. Mr. J. B. LOWE informs us that the heaviest fall in 24 hours occurred on September 4, when 1.15 inch was registered. The wettest month was January, with 5.29 inches, and the driest June, with .66 inch, although July was only slightly wetter with .69. The records of Mr. GEO. KENT, Norbury Park Gardens, Dorking, show that 30.50 inches fell, which is about 3 inches below the average for the past six years. There were 144 rainy days, January and March being the wettest months, with rain recorded on 20 days in each. Mr. FREDERICK CLARKE states that at Lowther Castle Gardens, Westmoreland, 36.45 inches of rain fell, spread over 184 days. March with 25 wet days and November with 24 rainy days were the wettest months, and July the driest. Mr. G. BENTLEY, Shughborough Gardens, Stafford, states

crossing took place; his reply was that he did not know, but that he had received his information from Kew. It would be of very great interest to know if ever such a cross actually took place. *M. E. Mills, The Gardens, Coombe House, Croydon.*

A GARDENER'S LONG SERVICE.—During recent travels through the Midland Counties I met Mr. E. Simpson, gardener to Lord Wrottesley, Wrottesley Hall, Wolverhampton, who went to Wrottesley as gardener on August 4, 1851. He has served under three Lord Wrottesleys, and is now in his 63rd year of service. He is well preserved, and still carries out his daily duties. It would be interesting to know if this is a record. *R. Greenfield.*

CHRYSANTHEMUM MADAME CASTEX DESGRANGES.—It is but natural that Mr. C. Harman Payne, in tracing the origin of the above-named Chrysanthemum (see p. 28), should, with the evidence before him, put the "experience and recorded facts of the greatest early-flowering specialist of his time, Mr. W. Piercy," against my own. Your correspondent is, however, ignorant of, or has overlooked, the important fact that I took exception to Mr. Piercy's "1879" theory when it first made its

FIG. 21.—THE ROSE GARDENS AT PENRHYN CASTLE.

(See p. 37.)

that the total rainfall for 1913 in those gardens was 30.65 inches, March being the wettest month with 4.79 inches, and February the driest month with 0.77 inch. The heaviest rainfall occurred on October 5, when 1.44 inches was recorded.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

JASMINE FRUITING (see pp. 13, 29).—In the autumn of 1911 an old plant of *Jasminum officinale* trained on a west wall in my garden here produced a plentiful crop of berries. In the following summer several seedlings with the cotyledons still attached were noticed growing close to the stone edging in a gravel pathway, which the plant overhangs. Two of these were saved and have since made strong plants. *A. W. Darnell, Norman Lodge, New Malden, Surrey.*

EVOLUTION OF THE CHRYSANTHEMUM.—I was disappointed to see that in the report of Mr. Davis' paper at the Chrysanthemum Conference you had omitted his reference to the crossing of some variety of Chrysanthemum with the Ox-eye Daisy. I attended the conference, and asked Mr. Davis at what date this

appearance in the gardening Press. A year or two subsequently the late Mr. Richard Dean made a similar misstatement with regard to the date, which was obviously based on that of Mr. Piercy's, and this, too, I also promptly challenged in the press. Unfortunately, these challenges brought neither confirmation of the original statement nor a denial of my own; the latter then, as now, based upon facts within my personal knowledge and experience, rendering a refutation of them a somewhat difficult task. Then, so recently as the spring of 1913, a further misstatement as to the date appeared in a contemporary, with the addition—new to me at the time—that the variety in question was first "discovered" in a churchyard at Egham. These theories I also challenged, giving at the same time a correct rendering of the name of the variety as at the head of this note, by which also it was known and grown at Tooting. Further, in the early autumn of 1881 I believe. I saw in flower in a Birmingham nursery a lovely pot-grown batch of the variety under the provisional name of "Maize." Maize was, I believe, subsequently bracketed with *Madame Castex Desgranges* by the N.C.S. as a synonym, and recognising the variety at a glance I gave the owner the correct name, with the information that "the variety was grown at Tooting in my day." These plants had been raised from unlabelled stock found when the nursery changed

hands some year or two previously, and were purposely saved for proving because it was known that the former owner paid periodical visits to Continental nurseries in search of novelties. The plants in this instance, it would appear, came from France direct, and from enquiries made by me at the time it was clear that they were in Birmingham prior to 1879. From these data it will be obvious to Mr. Payne that so far from having trusted to memory for forty years I have consistently endeavoured to keep up to date. Even though I had trusted to memory, the date of the appearing of Madame Castex Desgranges in the specimen beds at Tooting could be abundantly confirmed by the fact that in the year 1875 I left Mr. Parker's employ. The conversation I had with Mr. Parker took place not less than 22 years ago. The time, also based on circumstantial evidence, while of no importance here, is also irrefutable. It is but fair to say that Mr. Parker gave me his version of finding Madame Desgranges without hesitation, and with great clearness; doubtless the finding of so important a variety having impressed itself on his memory. Then, it appears to me, there is important additional confirmation of my "1873" statement in the details sent to Mr. Harman Payne by M. Boucharlat's son-in-law, viz., that "a set of early-flowering

one has been affected with leaf disease. *George Ferrington, Cloverley Gardens, Whitechurch.*

NATIONAL DIPLOMA IN HORTICULTURE.—You have been so good as to give publicity in your columns to the National Diploma in Horticulture, which has been established by the society with the approval and authority of His Majesty's Government. The first examinations are to be held from June 22 to 27, 1914, and as candidates must register their names four months in advance, all who wish to sit in June next must send in their application before February 22. This Diploma will become recognised as the highest indication of professional ability in gardening. It is not intended for amateurs, but only for those whose life work is to be gardening, under which term we include florists, fruit growers, horticultural inspectors, horticultural instructors (not school teachers engaged in teaching other subjects), landscape gardeners, market gardeners, nurserymen, public park gardeners and seedsmen, but no amateur gardeners. The examinations will be both written and practical, and they will, so far as possible, be held at centres convenient for the candidates. As the preparations, particularly in the first year, require very careful organisation, the President and Council of the society will be glad to hear from

back wall of a Peach-house here, on a Saturday afternoon at the end of May looked the picture of health, and the following morning every leaf on a large branch of it was "silvered." On Monday the branch was cut clean off, and to this day I have never seen a single "silvered" leaf on that tree. The border, which I believe was the same age as the tree, is of a poor, sandy nature, and only received the usual annual top-dressing and two or three dustings of artificial manure throughout the season. We grow a large number of Plum trees in pots, and I have seen several trees slightly affected, but they have recovered the following season. We lost, however, a large tree of Oullin's Golden Gage, growing in a border. The evidence in the case of the Peach tree goes to prove, in this instance, that the fungus entered through a wound in the bark, and not through the roots. *H. Low, Braemore Gardens, Garve, Ross-shire.*

DECEMBER FLOWERS.—Since a second year has now closed marked until the last week by an almost entire absence of frost, a comparison with last year in this district may be of interest. This can be made by means of a record now kept for some years of flowers observed in December, and also in the fortnight from the Sunday before Christmas to that after New Year's Day. This includes anything "out," even if but a most sorry specimen. Wild flowers include any seen in the district, but the garden list is confined to the plants in my garden at Asgarth, an exposed north-east slope, dropping from about 380 feet to 340 feet above sea level. More sheltered spots would doubtless give larger numbers, but we are well above valley frosts. Hence, until New Year's morning, when a minimum of 24° cut off everything tender, plants such as Nasturtiums and Verbeena still had bloom. The values for 1910, a comparatively normal year, are added for comparison, and the number of kinds which may properly be regarded as blossoms normally belonging to the fresh season. The "½" stands for a curious case, the Red Campion. Besides last season's blossoms at the top of the stem, specimens were found on which the low-down side-shoots had developed and were in bloom, looking just like new shoots from the stock, though, as a fact, none such were found. Hazel (male), Primrose, Dog Mercury and *Lamium Galeobdolon* were the only other fresh-season wild flowers, setting aside the ordinary winter all-the-year-round bloomers. Last year ten "fresh" were recorded. Garden flowers also indicate less forward conditions. Neither Christmas Rose, Aconite, nor Hepaticas have appeared, and as yet very few Snowdrop blooms.

FIG. 22.—AVENUE OF FUCHSIAS AT PENRHYN CASTLE.

varieties, of which Madame Castex Desgranges was one, was, in 1873 or 1874, sent out by M. Boucharlat." The former date is significant, and, while confirming what is within my personal knowledge and experience, would also account for the presence in Bristol of the two plants from which Mr. Parker's original stock came, and possibly also those in Birmingham to which I have referred as being there prior to 1879, the usually accredited, if erroneous, date of the introduction of this remarkable variety. I am much indebted to Mr. Harman Payne for giving the name of its raiser, which I had long sought for in vain. *E. H. Jenkins.*

TOMATO LEAF DISEASE.—Having been troubled for about eight consecutive seasons with Tomato leaf disease, as described on p. 417, Vol. LIV., and having adopted various methods of treatment advised by different gardening friends, I had begun to despair of again being able to obtain a clean, healthy crop. But whilst looking through the *R.H.S. Diary* of last year I saw Strawsonite advertised as a specific remedy for various diseases, etc. I obtained 28 lbs., and not only did I spray the plants with it, but I also watered with it, mixing about a teaspoonful to each gallon of water, and when planting mixed about 2 ozs. with the soil in which each plant was permanently placed. The result has been that out of about 270 plants not

all wishing to register themselves as candidates as early as possible, but certainly not later than February 22. *W. Wilks, Secretary, R.H.S.*

UNUSUAL GROWTH OF CHRYSANTHEMUMS.—I have never known of a case of Chrysanthemums not blooming, as related by Mr. Kearn (Vol. LIV., p. 426), unless it were an occasional plant or two; but I noticed a curious behaviour in single-stem Chrysanthemums last season. Several varieties—*F. S. Vallis*, *Mrs. G. Drabble*, *Pockett's Crimeon* and *Reginald Vallis*—were inserted as cuttings on January 6, 1913, and allowed to make their natural "break," which they did on May 10, June 7, June 16, and July 1, in the order named. First crown buds appeared during the first ten days of September. Early summer was exceptionally wet and cold with us, hence the lateness; but instead of growths round the bud, flower buds appeared, making what should have been first crowns, terminals. It would be interesting to know if any of your correspondents have noticed a similar occurrence. *H. L.*

SILVER-LEAF DISEASE.—I have read with interest the remarks of your various correspondents on silver-leaf disease and would like to relate my experience. Nine years ago a large old Peach tree (I think it would be forty years old), of the variety *Royal George*, growing on the

Fresh season's blooms ..	15	49	39½	—	—	—

The effect of the last week of frost, chiefly that on January 1, is shown by the list of garden flowers to-day, which is now reduced to *Roses* 22, others 55. But if the mild weather now recurrent continues some further *Rose* blooms will open. Only one flower (*Red Primrose*) has come out this month by to-day. Last year nine were added for the fortnight, of which, curiously, five opened earlier this season. One, the *Laurustinus*, has been flowering this year since September. Since last year *Petit Constant* lasted just into March, and as in both years the *Banksian* began flowering in April, *Roses* ("of sorts" in the winter!) have been out in every month from April, 1912, until now. There are still a few (*Gloire de Dijon*, *Grüss an Teplitz*, *Jessie*, *Marie Parvie* and *Comtesse du Cayla*) fit for "buttonholes." *J. Edmund Clark.*

JOURNEYMAN GARDENERS AND LOW WAGES.

—Your correspondent, Mr. Norris, seems to think that because journeymen are paid better wages than he and his contemporaries were paid years ago, their present remuneration must be good. But the increased cost of living makes their 16s., 18s., or £1 of no more value to them than his 12s., 14s., or 16s. was to Mr. Norris. Therefore these times, in that respect at least, are no better than those he is "thankful to have seen an end to." His sweeping condemnation of present-day journeymen—"never, perhaps, was their ability less"—will not be taken for fact by anyone who is any judge of the quality of the exhibits at the shows, which could not be produced by the best of head gardeners without competent understudies. That damage is done by so-called experienced young men is no doubt true, but one would think that the young men "who knew their work and did it thoroughly" ten or so years ago would have developed into good enough head gardeners to be able to discriminate between good and bad men before placing entire confidence in them. It is quite true that there are plenty of situations where 18s. per week and bothy—worth say, a total of 23s.—is paid. This for skilled labour. In Birmingham last year unskilled labourers struck work for, and got, that amount per week, for fewer hours than journeymen have to work. Whatever the cost of the upkeep of bothies may be to employers, they are only worth, at most, 5s. per week to a journeyman, as equal accommodation could be obtained in lodgings for that sum. Anything over that figure must be put down to the cost of the necessity of having the journeyman near his work night and day. That head gardeners have to teach the secrets of the profession to journeymen for nothing is not correct, for if the secrets are worth anything the teaching of them must result in better produce, to the credit of the head gardener. If Mr. Norris and others were to use their influence to better the conditions in which journeyman gardeners work, they would do far more towards raising the status of the great and honourable profession of horticulture, than by writing columns of depreciation of men who are, generally speaking, of far better value than the wages given to them. *Modern Journeyman.*

—I often question the wisdom of head gardeners employing and training so many young men as is the case in many establishments. Your correspondent Mr. Beeson (page 462) evidently has eight employees under him, known as journeymen, and they all hope eventually to become head gardeners. Can one wonder that the wages are low in the gardening profession? The root of the evil is the low standard of wages paid in general to gardeners, not in the low wages paid to a journeyman, who often does the work of an average labourer. I fully admit the bothy man is a most efficient man, and keen to succeed. But let an employer advertise for a head gardener, and experienced head gardeners who apply will find competitors in a host of young men, and often those whom he has trained. The younger man is given preference. It is a case of the head gardener cutting the ground from under his feet. That is one point against too many bothy men. Many establishments only employ local men as labourers, with a trained man under glass and one or two outside, according to the size of the place. An apprentice is often trained in such places. Now, this practice does not drug the profession with a host of journeymen and foremen aspiring to be head gardeners. The Horticultural Directory enumerates over 8,000 places where a head gardener is employed, but probably only 4,000 are suitable for efficient head gardeners. Now, what number of bothy men are we training to fill the 4,000 places? Referring to Mr. Beeson's wages table, I take it 23s. is paid to his foreman, and six journeymen receive an average wage of 17s. 8d. I do not expect the bothy and other advantages are worth more than 5s. per man, making an average remuneration of 22s. 8d. Each journeyman would probably have seven or eight years' experience. What other profession or trade requiring so much exactness pays so low a wage as 22s. 8d. per week? Indoor servants or car-drivers are better paid, and get better attention, for less skillful

work than is required of the average journeyman gardener, or gardeners in general. *M. A., Co. Kerry.*

—*Contented Journeyman* raises one or two points which will bear a little discussion. I agree with him that a wage of 25s. to 30s. for journeymen is, at present, impossible. I do not agree with him when he states that gardens are hobbies. Although, of course, the owners are not depending on them for profit, I should think there are many gardens which are a source of profit to their owners. If a strict account of the garden produce is kept, and the vegetables, fruit and flowers are valued, and their respective prices entered in a ledger (as should be done in all gardens), *Contented Journeyman* would doubtless be more content to find that the result of his labours were not wasted on hobbies. Far from it. Then the value of a garden to the owner cannot be reckoned entirely in this way. A garden is, to many, a place for solace, rest and the enjoyment of pure air, amid peaceful and beautiful surroundings. It is difficult indeed to fix a value in £ s. d. upon these benefits. In reference to the note from *A Member of the Watford Branch of the B.G.A.*, if the Association can keep out the unskilled and undercutting impostor from the profession it will be a decided boon to employers and to employees. I am afraid we cannot, many of us, enter for the National Diploma in Horticulture owing to the various expenses. I maintain, however, that there are men who have served terms of apprenticeship, and who have afterward worked up through the various departments, and are holding positions of great responsibility who are not receiving a wage sufficient to meet the present high cost of provisions. *Roamer.*

—In reply to *A Member of the Watford Branch*, it is not the fault of the journeyman gardener that wages are low, but it is very often due to the head gardener, who, I believe, could, in most cases, improve the conditions of those under him. I should like to know what qualifications a man must possess before he can become a member of the B.G.A. So far as I can learn he has only to pay an annual subscription and show a reference for four years in some garden. At present I am satisfied to remain a non-member. I should like to see some examination set by the B.G.A. to prove each man's capabilities before he be accepted as a member, then, no doubt, we should all want to join. *A Non-Member.*

—As regards the rate of wages received by journeymen, I find that this varies according to the locality. A few years ago I was employed in a garden in Hampshire. There were a foreman and five journeymen living in the bothy—which, by the way, left much room for improvement. The foreman's wage was £1 weekly, and that of the journeymen from 12s. to 15s. I could name several other gardens where the wages are no better. A journeyman who accepts such a situation does so with the intention of staying only long enough to get a reference, and then passing on to a better-paid post. Can he, with such an intention, take a keen interest in his work? *A. H., Surrey.*

—The remarks which have lately been made on the subject of journeymen's wages are very interesting, but I think it is time some of our leading men had something to say—men who have been in the profession all their lives, and have had dozens of journeymen under them. It is only the veterans who can tell us whether the journeyman of to-day is as good as his prototype of twenty, thirty, and forty years ago. For my own part, I consider that young men do not now get the opportunities they formerly enjoyed of learning their work in a practical manner. They are scarcely allowed to do any Grape-thinning or Peach-tying or potting until they are well on in years; then they take a first journeyman's place, and find, naturally, that they are unable to do the work which is expected of them. As for bothies, I think it is time some of them were burnt down, for they are not fit for human beings to live in. *Foreman.*

—Mr. Norris complains of damage done by so-called experienced journeymen; but in such instances it is head gardeners who are really

to blame for giving journeymen references implying their ability to do more than they are capable of doing. *Journeyman.*

—Mr. Norris states that every bothy he has entered is fit for any reasonable workman, by which I should judge that he has entered very few. I note that there is a scarcity of journeymen; but the reason is that they are offered a mere pittance in return for their work. When they are given a living wage journeyman gardeners will again become plentiful. The sooner they begin to co-operate to obtain such a wage the better. *W. Hunt, Bicester.*

NURSERY EMPLOYEES.—I am sure most of your readers can fully endorse what has been said by *L.* and other correspondents as regards the wretched conditions existing in certain firms in the trade. There are doubtless many firms who treat their employees with fairness and consideration, but there are others which do not. I have had personal experience of one of these latter firms, in which the hours are from 6 a.m. till 6 p.m., with "duty" twice nightly every other week, and also "full" duty every other Saturday and Sunday. These hours were the same summer and winter, and we received nothing extra for such long "duty." All duty, especially Sunday work, should be paid for overtime. It seems to me that what is urgently required in our trade is an active association run on lines similar to the "National Union of Teachers," or, say, the "Merchant Service Guild." These organisations have improved the conditions of service of their members, and that without the aid of any organised strike. Such a result has been realised by agitation and the "pillorying" of the worst employers, and I believe similar results could be obtained in our trade by the establishment of a good, strong society. *P. C.*

THE ABNORMAL SEASON.—Mr. Robinson's experience with Royal Sovereign Strawberry is interesting, but up to the present no one seems to have recorded quite the same as we have in these gardens. Plants in a three-year-old bed, which will be done away with this year, have been showing bloom since October, and good-sized berries have formed. They failed to ripen, but a fruit which was picked on December 19 weighed just over an ounce and had started to colour. I am afraid that Strawberries will be very scarce next June, as practically every crown has thrown a truss, although two-year-old plants, and those put out last August, have not shown a bloom. *C. E. Bridgett, St. Helens Gardens, Hampton Wick.*

PYRETHRUM GOLDEN MOSS.—Where a bright edging is desired, gardeners should not forget to order seeds of Pyrethrum Golden Moss. The variety is a great advance on all other Golden Feathers, making a beautiful little tuft four inches high and through. The plants do not need stopping, for they only develop a few flowers late in autumn, which barely top the foliage, and many plants do not bloom at all. For that reason seed is dear, but once a stock is obtained the plants may be easily increased by division. Here we treat the plant as a perennial; during the winter it remains where planted, but it can be lifted and replanted in any odd corner. In the early spring the plants are taken up and divided. Nearly every side shoot has roots, and will soon form a specimen. *C. E. Bridgett, St. Helens Gardens, Hampton Wick.*

SKIN POISONING BY PRIMULA OBOCNICA (see pp. 13, 29).—I had been immune from the effects of this plant until last summer, when I had occasion to handle the new *Primula oboconica* variegata. My arms and wrists became covered with irritating patches, which were soon cured by applying boracic powder. As my shirt sleeves were buttoned at the wrists and my coat on, it follows that the poison worked up from the hands; so the next time I had occasion to handle the plants I made a solution of permanganate of potash crystals, and dipped my hands in it, allowing it to dry on. After handling the *Primulas* I washed my hands with ordinary soap. This precaution proved effective, and having tried it several times since in varying temperatures, I claim it as a sure preventive. Permanganate of potash may be purchased very cheaply. *E. Conway, St. Albans.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 13.—The opening meeting of the calendar year was held on Tuesday last in the Vincent Square Hall, Westminster. The exhibition was of a varied character, but there were fewer novelties and imposing groups than usual. The finest display was of Orchids, a large exhibit, principally of *Cypripediums*, shown by Mrs. RAPHAEL.

The Orchid Committee granted one First-class Certificate and five Awards of Merit.

The Floral Committee conferred one Award of Merit to a variety of *Cyclamen*, and awarded thirteen Medals for groups.

The Fruit and Vegetable Committee granted

James Hudson, R. W. Wallace, R. Hooper Pearson and W. D. Cartwright (Secretary).

Messrs. SUTTON AND SONS, Reading, contributed one of the brightest floral displays in their exhibit of *Cyclamens*, for which a Silver-gilt Banksian Medal was awarded. The plants were splendidly cultivated, and were perfect specimens of flower and foliage. In the centre of the group was a batch with ornamental leaves of the type illustrated in colours in the *Gardeners' Chronicle* for December 20. The varieties Salmon Pink, Giant White, Vulcan (deep red) and White Butterfly were shown in batches, and there were some in shades of pink. White Butterfly has more spreading flowers than the type, whilst others had fringed petals, some edged with rose or rosy-purple being exceedingly pretty.

Rev. H. BUCKSTON, Sutton Hall, Derby (gr.

Belangeri, *Nephrolepis exaltata* *superba*, *Hymenodium crinitum* and *Pteris cretica* Childsii.

Messrs. W. CUTBUSH AND SON, Highgate, showed miscellaneous greenhouse plants, both flowering and ornamental-leaved kinds, and a showy group of Carnations. White *Hydrangea hortensis* were very fine, as were also batches of *Liliums*, *Begonias*, *Ericas*, and the sweet *Daphne indica rubra*. The finest Carnations were Mrs. Lucy MacKinnon, scarlet; Lady Ingestre, salmon-pink; and Mrs. L. D. Fullerton, mauve and cerise. Although not remarkably large in size, the blooms of Mrs. Fortescue, cerise, and White Swan, white, are very pretty, and the plants exceedingly free bloomers. (Silver Flora Medal.)

Messrs. JAMES VEITCH AND SONS, Chelsea, showed many pretty flowering plants suitable for the conservatory and greenhouse. In the centre, the blue-flowered *Erlangea tomentosa*, associated with the white *Eupatorium vernale*, made a striking feature: in general appearance these plants have a strong resemblance. Another fine feature was a batch of pot plants of *Lily-of-the-Valley*, all in splendid bloom. Other subjects included *Azalea amoena* Hexe, *Freesias*, *Lindenbergia grandiflora* (like a yellow Musk) and the old, double-flowered *Primula sinensis*. (Silver Banksian Medal.)

Messrs. STUART LOW AND CO., Enfield, were awarded a Silver Flora Medal for Carnations and *Cyclamens*. The former were arranged as a very attractive group and included fine blooms of the Gorgeous, rosy-cerise, R. F. Felton, pink, British Triumph, clove-coloured, Baroness de Brien, Salmon Enchantress, Salmon King and Satin Robe. The *Cyclamens* were shown in distinct varieties in large pans, such as Giant White, Salmon King, Vulcan, crimson; Eileen Low, a charming crested variety of vinous red shade, with a white edge; and others in mauve, pink, red and other shades.

Messrs. WILLS AND SEGAR, Florists, South Kensington, showed stove foliage plants—*Codiaeums* (Crotons), *Dracaenas*, Palms, *Aglaonema*, etc. At either end was a magnificent specimen of the handsome *Phoenix Roebelinii*. (Silver Flora Medal.)

Messrs. H. CANNELL AND SONS, Swanley, were awarded a Bronze Banksian Medal for bunches of Zonal-leaved *Pelargoniums*. A new variety, named John Watts, has bright red flowers.

Messrs. W. WELLS AND CO., LTD., Merstham, showed Carnations and *Chrysanthemums*. There were several novelties amongst the former flowers, including a fine yellow variety named Yellow Prince; Philadelphia, a pretty pink variety; and an unnamed sport from Benora of brick-red colour. *Chrysanthemums* Bertha Lachaux, a pink Japanese variety, and Kathleen May, a crimson-coloured Single, were shown in good form.

Carnations were also shown by Mr. H. BURNETT, Guernsey (Silver Banksian Medal), and Messrs. ALLWOOD BROS., Haywards Heath (Silver Banksian Medal.)

Messrs. R. WALLACE AND CO., Colchester, filled a long table with dwarf conifers and shrubs, such as are valued by builders of rock-gardens. Of the very large numbers we may enumerate the following selection:—*Juniperus hibernica*, *J. procumbens*, *J. tamariscifolia*, *Cedrus Libani pendula* Sargentii, *Abies Hudsonia*, *Cupressus lycopodioides*, *C. minima glauca*, *C. argentea*, *Picea Maxwellii*, *P. Remontii*, *Pinus aviflora*, *P. a. glauca*, *P. Strobus mana*, *Taxus Cavendishii*, *Retinospora Sanderi*, *R. filicoides* and *R. obtusa gracilis*. (Silver Banksian Medal.)

An exhibit of a similar nature was shown by Messrs. PULHAM, Elsenham, Essex, and the Award of a Silver Banksian Medal was made.

Messrs. PIPERS, Bayswater, exhibited miniature shrubs and pans of *Saxifragas* and other Alpines. There was a wide selection of the choicer *Saxifragas*, including Faldonside, Boydii, S. Kotschyi, S. Burseriana Gloria, splendens, L. G. Godseff, Pauline and S. scardica. (Silver Banksian Medal.)

Mr. L. R. RUSSELL, Richmond, Surrey, filled a long table with dwarf ornamental shrubs, including some in berry, and many variegated Ivies. *Grevillea Prieisii* and *G. rosmarinifolia* were shown in bloom. (Silver Banksian Medal.)

(Photograph by R. A. Malby.)

FIG. 23.—ODONTOGLOSSUM "CANARY": COLOUR OF SEPALS AND PETALS PALE YELLOW WITH SPOTS. (R.H.S. Award of Merit, Jan. 13, 1914. See p. 46.)

one Award of Merit for a variety of Orange, a Silver-gilt Banksian Medal for a collection of Apples and Pears and a Silver Knightian Medal for an exhibit of vegetables.

Floral Committee.

Present: H. B. May, Esq. (in the Chair), Messrs. G. Reuthe, John Dickson, Chas. T. Druery, W. J. Bean, George Gordon, Chas. Blick, Wm. Howe, J. F. McLeod, Thos. Stevenson, J. W. Moorman, John Jennings, C. R. Fielder, John Green, R. C. Notcutt, E. A. Bowles, B. Crisp, W. B. Cranfield, Geo. Paul, W. J. James, E. H. Jenkins, W. P. Thomson, Chas. E. Pearson, Chas. E. Shea, W. Cunthbertson, Chas. Dixon, H. J. Jones, Arthur Turner,

Mr. A. Shambrook), showed, as in former years, a splendid exhibit of *Cyclamens*, for which a Silver Flora Medal was awarded.

Messrs. H. B. MAY AND SONS, The Nurseries, Edmonton, filled a large table with stove and greenhouse Ferns, for which a Silver Flora Medal was awarded. The collection was a very varied one, and the plants of the various kinds exhibited great diversity, not only in form, but even in the tones of green; some being almost golden, whilst others were glaucous, and still others silvery. There were numerous varieties of *Nephrolepis exaltata*, which make excellent room plants. A selection of the choicer plants included *Davallia brasiliensis*, *D. polyantha*, *D. fijiensis*, *Adiantum trapeziforme*, *A. peruvianum*, *A. reniforme*, *Asplenium nobilis*, *A.*

Messrs. BARR AND SONS, King Street, Covent Garden, showed various bulbous plants in flower, the principal subject being the Polyanthus Narcissus known as the "Jos" Lily. They were grown in howls filled with water and pebbles, and each bulb bore several fine spikes of the fragrant blooms. There was a good selection of Early Crocuses, such as *C. Imperati*, *C. chrysanthus*, of which the variety *E. A. Bowles* was conspicuous with its rich yellow cup shaded with maroon colour at the base; and *C. biflorus*. *Galanthus Elvesii*, *Cyclamen coum* and *Freesias* were also noticed. (Bronze Banksian Medal.)

Messrs. WARE, LTD., Feltham, showed numerous pans of Alpines and a few early bulbous plants in bloom, with dwarf shrubs as a background. A clump of the elegant blue-flowered *Iris stylosa* made a showy centre-piece. (Bronze Banksian Medal.)

Pans of Alpines were also shown by Messrs. WHITELEGG AND PAGE, Chislehurst, and Mr. G. REUTHE, Keston, Kent.

Mr. JAMES BOX, Lindfield, had a very vigorous and deeply-coloured plant of *Primula malacoides*, in a batch of these pretty flowers; also *Iris histrioides*, *I. Krelagei*; and sprays of *Hammamelis arborea*. The *Primula* was submitted for an Award, and the Committee desired to see the plant again. The flower stem and inflorescence are very stout, compact and rigid. The individual blooms are closely arranged, larger and of better form from the florists' point of view than the type. It has the promise of making a good garden plant.

Messrs. HERBERT CHAPMAN, LTD., Rye, showed seedlings of *Cyclamen ibericum*, many of which exhibited great improvements over the type. There were others of *C. neapolitanum* not in bloom, but the beautiful markings on the foliage shows that leaf-variegation is common in the members of this genus.

Mr. CLARENCE ELLIOTT, Stevenage, exhibited a small rock-garden, in which the beautiful *Gentiana acaulis* figured conspicuously.

AWARD OF MERIT.

Cyclamen Mrs. L. M. Graves.—A form notable for its fine colour rather than size of flower. It is a pure rich carmine: a deep shade when fresh, and especially around the eye, passing to a paler shade, but still pure, with age. It is finely matched in sheet 116 (carmine) of the *Répertoire des Couleurs*, shades 2 and 3. Shown by the ST. GEORGE'S NURSERY CO., Haslington.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the Chair), and Messrs. Jas. O'Brien (hon. secretary), W. Bolton, Gurney Wilson, S. W. Flory, W. H. White, C. Cookson, A. Dye, W. P. Bound, J. E. Shill, H. G. Alexander, W. H. Hatcher, J. Cypher, C. H. Curtis, A. McBean, T. Armstrong, Stuart Low, R. A. Rolfe, J. Charlesworth, and Sir Harry J. Veitch.

The flowering season of the *Cypripedium* having commenced, this popular Orchid occupied a prominent part in the display, which, for the season, was a good one. Sixteen entries were made of plants to go before the Committee, and five of these were given Awards of Merit and one a First-class Certificate.

The largest exhibit was a very fine group from Mrs. RAPHAEL (gr. Mr. H. Brown), Castle Hill, Englefield Green, which filled the staging at the end of the hall with admirable effect. The group was principally of well-grown forms of *Cypripedium insigne* and *C. Leeanum*, with occasional plants of other varieties. At intervals were batches of hybrid Calanthes, chiefly *C. Veitchii superba*. The whole was well-arranged, and a Silver-gilt Flora Medal was awarded.

Messrs. FLORY AND BLACK, Orchid Nursery, Slough, were voted a Silver Flora Medal for an excellent group of showy hybrids, some of them flowering for the first time, and giving great promise when developed. Among the *Cypripediums*, the finest new forms were *C. Pliny* (*Victor Hugo* × *Leeanum Clinkaberryanum*), a perfect and large flower with a fine dorsal sepal; and *C. Comorin* (*Bassano* (*Reynaldii*) × *Hera Euryades*), a fine improvement on *M. de Curie*, with distinct nearly black blotches on the dorsal sepal. *C. Snowden*, an improved form of *insigne Sanderæ* Veitch's Variety of which was also shown, *C. Aeson giganteum*, etc. Some

good *Laelio-Cattleyas*, including three plants of *L.-C. Bola*, *L.-C. Lucasiana*, *L.-C. Barbarossa*, and some good seedlings; a pretty new pink *Brasso-Cattleya*; a very large form of *Brasso-Laelia Helen*; a selection of good *Odontoglossums* and *Odontiodas*, including *Charlesworthii* and *Devossiana*, were also noted.

Messrs. SANDER AND SONS, St. Albans, were awarded a Silver Flora Medal for a fine group, in which the feature was made by 80 plants of the deep rose-purple *Laelia Gouldiana*, bearing together over 200 spikes, each of from five to eight flowers. Staged with them were two plants of *Cattleya Percivaliana Albatros*, a white form with orange coloured tube to the lip, a selection of hybrid *Odontoglossums*, *O. igneum* (*cirrhosum* ×

charming cream-white flower spotted with purple; *C. Actaeus Drewett's Variety*; *C. Gaston Bultel*; the handsome *C. Queen Alexandra*, and other fine *Cypripediums*, were also noted, and, in front, a very pretty and interesting lot of hybrid *Odontoglossums* flowering for the first time, and each with but one or two finely-blotched flowers. *Odontioda Wickhamensis* (*Odontoglossum crispum* × *Cochlodora sanguinea*), with its pretty pink-spotted flowers, was very effective.

Messrs. J. CYPHER AND SONS were awarded a Silver Banksian Medal for an effective group of *Cypripediums*, which included the best forms of *C. insigne*, *C. Leeanum*, *C. Rossettii*, *C. Curtmanni*, *C. triumphans*, forms of *C. Euryades*, the fine white *C. Boltonii*, etc. At the back were

(Photograph by R. A. Malby.)

FIG. 24.—CYPRIPEDIUM JULIAN.

(R.H.S. First-class Certificate on January 13, 1914, see p. 46.)

Wilkeanum), being an elegant white flower profusely spotted with dark red. Among *Odontiodas*, *O. Hemptinneana* was a brilliant scarlet, and a form of *O. Bradshawiae* of good shape was of very remarkable colour. Others noted were *Cattleya Trianae Princess Patricia*, white with a pink flush on the lip, *Cymbidium Mastersianum*, *C. Winnianum*, and other hybrids.

Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, had a small but select group, for which a Silver Banksian Medal was awarded. At the back were two plants of their fine strain of *Cattleya Maggie Raphael alba*, the white *C. Susannæ Hye de Crom*, and two of the true white *Laelia autumnalis alba*. *Cypripedium Holdenii* Orchid-hurst Variety (*callosum Sanderæ* × *Maudiae*) was a nearer approach to an albino than either parent; *C. Helen II. Armstrong's Variety*, a

hybrid *Calanthes* and *Laelia anceps*, and in front a selection of *Masdevallias*.

Mr. G. W. MILLER, Clarkson's Nursery, Wisbech, secured a Silver Banksian Medal for a very varied and interesting selection of *Cypripediums*, in which the forms of *C. insigne* and *C. Leeanum*, *C. Guy Gordon*, *C. Andromeda*, and varieties of *C. Hera Euryades* were noted.

Messrs. W. BAYLOR HARTLAND AND SON, Cork, were voted a Silver Banksian Medal for a group of *Cypripediums*, including *Maudiae*, *callosum Sanderæ*, *Wm. Lloyd*, *Actaeus* varieties, forms of *Leeanum* and *insigne*, *Prospero*, etc. With them were *Cymbidium Tracyanum*, and some hybrid *Odontoglossums*.

Messrs. HASSALL AND CO., Southgate, showed a very interesting selection of choice plants, which included their *Lycaste Tunstillii*, illus-

trated in the *Gardeners' Chronicle*, December 13, p. 415, a good example of their fine, white *Brassica* *Cattleya* *Menda* (Queen Alexandra \times *labiata* *Virginea*); the new *Laelio-Cattleya* *Cecilia* (*C. Trianae* \times *L.-C. luminosa*), a pretty bronze-rose flower with bright reddish purple lip; *Cypripedium* *Beryl* *Westonbirt* Variety, *Cymbidium* *Wiganianum*, and others.

His Grace the Duke of MARLBOROUGH, Blenheim Palace (gr. Mr. Hunter), showed his *Cypripedium* *Iona* (*bellatulum* \times *Fairrieanum*), which had previously secured an Award of Merit.

Lieut.-Col. Sir GEO. L. HOLFORD, K.C.V.O. (gr. Mr. H. G. Alexander), showed *Cymbidium* *Nada* (*eburneum* \times *Lowio-grandiflorum*), a large, cream-white flower, with purple spotting on the lip, and two other novelties. (See Awards.)

Baron BRUNO SCHRODER, The Dell, Englefield Green (gr. Mr. J. E. Shill), showed a very fine plant of the handsome *Cypripedium* *Moonbeam* (*Thompsonii* \times *nitens* *Sallerii*), *Cypripedium* *Maudiae* *gigantum*, a grand flower, the rich scarlet *Odontioda* *Lambeauiana* *Dell* Variety, and *Odontoglossum* *illustrissimum* *Dell* Variety. (See Awards.)

A. J. HOLLINGTON, Esq., Forty Hill, Enfield (gr. Mr. Ayling), sent *Cypripedium* *Mrs. W. R. Lang*, a hybrid of *C. Leeanum* of good variety.

PANTIA RALLI, Esq., Ashted Park, Surrey, sent *Cymbidium* *Schlegelii* *punctatum*, the pretty yellow *Odontoglossum* *Canary* (see Awards), and the brilliant dark red *Odontioda* *Keighleyensis* *Firefly*.

E. H. DAVIDSON, Esq., Orchard Dene, Twyford, showed *Odontoglossum* *Jasper* *Orchid* *Dene* Variety, a beautiful flower, profusely spotted with dark red; a very finely blotched seedling *O. crispum*, and another distinct hybrid flowering for the first time.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cypripedium *Julian* (*Vandyke* \times *Aureum* *Oedippe*) [see fig. 24], from Lieut.-Col. Sir GEO. L. HOLFORD, K.C.V.O. (gr. Mr. H. G. Alexander). A massive hybrid with the large dorsal sepal broader than long, pure white with a small Apple-green base and a median line of purple with some slighter purple spots. The broad petals and lip greenish-yellow tinged with purple, the petals having a dark line up the middle. The purplish back of the dorsal sepal showing through to the face gives a very effective tint.

AWARD OF MERIT.

Odontioda *Royal Gem* *Westonbirt* Variety (*Oda* *Vuylstekoe* \times *Odm. ardentissimum*), from Sir GEO. L. HOLFORD. Beautiful in form and bright in colour, the broad sepals and petals being rose-tinted copper colour, darker in the centre, the lip broad, reddish-rose with a well defined yellow crest. A charming flower of various tints.

Odontoglossum *illustrissimum* *Dell* Variety (*Lambeauianum* \times *ardentissimum*), from Baron BRUNO SCHRODER, The Dell, Englefield Green (gr. Mr. J. E. Shill). One of the darkest hybrid *Odontoglossums*, the sepals and petals being dark claret-red with lighter tips, and a white lip with dark red blotches around the yellow crest.

Odontoglossum *Canary* (*Oakwoodiense* \times *ardentissimum*) [see fig. 23], from PANTIA RALLI, Esq., Ashted Park, Surrey. Flowers in form and size equal to a good *O. crispum*; clear canary-yellow with a few dark spots.

Cymbidium *Schlegelii* *punctatum* (*insigne* \times *Wiganianum*), from PANTIA RALLI, Esq. Flowers large cream-white, with a slight rose tint, the lip being spotted with dark red.

Cymbidium *Coningsbyanum* (*grandiflorum* \times *insigne*), from G. HAMILTON-SMITH, Esq., Killooran, Seymour Road, Church End, Finchley (gr. Mr. Coningsby). A very fine *Cymbidium* with the wax-like sepals and petals of *C. grandiflorum* well displayed; greenish-white, the large lip cream-white with red spotting.

Fruit and Vegetable Committee.

Present: Joseph Cheal, Esq. (in the Chair), Messrs. Edwin Beckett, A. R. Allan, Geo. Kelf, J. Davis, A. Grubb, J. G. Weston, A. Bullock,

P. D. Tuckett, John Harrison, H. Somers Rivers, W. Poupart, and C. G. A. Nix.

Messrs. GEORGE BUNYARD AND CO., LTD., Maidstone, were awarded a Silver-gilt Bankers' Medal for a collection of Apples and Pears. There were 140 varieties, chiefly of Apples, and the fruits were in a remarkably fine condition for a January show. Taking dessert Apples, the pick of them were Lord Hindlip, a pretty, russet-red variety of fine flavour; Sturmer Pippin, the latest keeper of all, now greenish flushed with red, but mellowing with age until in May it becomes quite yellow; and Wagner, which will also keep good until May. Rosemary Russet, Adams's Pearmain, Claygate Pearmain, possessing good, all-round qualities; Cornish Aromatic, of excellent flavour; and Beauty of Stoke. The culinary varieties included such excellent sorts as Annie Elizabeth, Bramley's Seedling, Newton Wonder, Belle du Pontoise, Alfriston and Smart's Prince Albert.

Messrs. SUTTON AND SONS, Reading, contributed a collection of excellent vegetables attractively staged. There were New Year Savoys, Superb Early White Broccoli, Sutton's A1 Kale, Early Purple Sprouting Broccoli, Mushrooms, Scarole or Batavian Endive, Sea Kale, Matchless Spinach and Chicory.

Lady LOVELACE, Ockham Park, Ripley (gr. Mr. H. J. Towes), was awarded a Cultural Commendation for bunches of Tomatos.

AWARD OF MERIT.

Citrus japonica *Round Fruited* Variety.—This very ornamental plant appears to have more value as a decorative subject than a fruit for the dessert table. The specimens were about 9½ feet high, and bore numerous yellow fruits, about 1 inch across and perfectly round. The leaves are oblong-lanceolate, and 2½ inches long. Shown by Messrs. JAMES VEITCH AND SONS, LTD.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 10, is furnished from the Meteorological Office:—

WEEKLY REMARKS.

January 13, 1914.

Weather.—The general condition was very unstable. The sky was seldom free from cloud, and few days passed without a measurable quantity of precipitation even in the driest parts of the Kingdom. Sleet, snow, and hail showers were experienced in the North and East, and on the 5th or 6th, thunder and lightning or thunder only occurred in some Irish and Scottish localities, as well as at Southport.

Temperature was above the normal, the excess being about 2° in the West and North, and increasing to nearly 5° in the Midland Counties. The maxima were registered, at most stations, between the 8th and 10th, and ranged from 56° in the Midland Counties and Ireland S. to 50° in Scotland E. The lowest of the minima were recorded earlier, very commonly on the 7th, and varied from 17° in Scotland E. (at West Linton on the 7th), and 22° in England S.E. and N.W. to 28° in England E. and Ireland N., and to 37° in the English Channel. The lowest grass minima were 12° at Raunds and Hampstead, 13° at Newton Rigg, 15° at Wisley and Marlborough, and 16° at Buxton and Aspatria. The earth temperature readings were below the average in a large portion of the Kingdom at a depth of 1 foot, and below it in several localities at a depth of 4 feet also.

Mean Temperature of the Sea was below the normal on most parts of the coast, and in almost all localities it was lower than during the corresponding week of last year. The means for the week ranged from 48° at Scilly and Plymouth to about 40° at Scarborough and Cromarty.

Rainfall was above the normal except in England S.E. and Ireland S.; in Scotland and the North of England the excess was large. As much as 1.2 inch fell at Cally, Gatehouse, on the 4th, 1.1 inch at Burnley, 1.8 inch at Lancaster, 2.1 inch at Stonyhurst, and 1.5 inch at Poltalloch on the 8th, and 1.2 inch at Great Yarmouth on the 10th.

Bright Sunshine differed little from the average amount, being slightly above it in several English districts, but rather below it generally. In the eastern half of England the daily mean was about 1.5 hour, and a similar figure was recorded in the English Channel and Ireland S., but in some extreme northern and north-western districts it was less than 1 hour; in Scotland N. only 0.5 hour. The percentage of the possible duration ranged from 21 in the English Channel and 20 in England S.E. to 5 in Scotland N.

Barometer and Wind.—Large cyclonic disturbances moving eastward to Northern Europe and extending over these islands maintained the wind between S.W. and W. or N.W. very generally until Friday, when the development and extension south-westward of an anti-

cyclone over Scandinavia caused easterly to south-easterly breezes to set in in the East and North-East of Great Britain. Gales were experienced early in the week on many parts of the Northern, Western, and South-Western Coasts, and a similar increase of wind was reported later in the extreme North-West and North, while at the end of the week the south-easterly wind which set in on the coast of Shetland blew with the force of a gale.

THE WEATHER IN WEST HERTS.

Week ending January 11,

A Sudden Change in Temperature.—The first four days of the week were very warm, and also two of the nights, but after that a rapid fall in temperature took place. In fact, the last three days were very cold, but at night the exposed thermometer only indicated 11° of frost. On the warmest day the temperature in the thermometer screen rose to 55°—an unusually high reading at this, the coldest, period of the whole year. The sudden change in temperature was very marked, the highest reading in the thermometer screen on the 11th being 47°, and on the following day the temperature never rose above the freezing-point—a drop of 15°. The ground is at the present time 1° warmer at 2 feet deep, but 1° colder at 1 foot deep, than is seasonable. At the latter depth the ground four days ago was 5° warmer than is seasonable. Rain fell on three days, but to the total depth of less than ½ inch. On the morning of the 13th the ground was nearly covered with snow. There was some percolation through both the soil gauges on each day of the week. The sun shone on an average for 1 hour 44 minutes a day, which is about a quarter of an hour a day longer than is usual at the same period in January. The winds were as a rule of moderate strength, and the last three days have come exclusively from some north-easterly point of the compass. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 2 per cent. E. M., Berkhamsted, January 11, 1914.

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting Box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

Mr. Thomas Gamage, for the past 2 years Gardener to Sir ANTHONY WELDON, Bart., at Kilmoroney, Athy, Co. Kildare, and previously at Bowood, Curraghmore, and Ballyfin, as Gardener to the Hon. W. C. TRENCH, Clonduff Castle, Kilmallock, Co. Limerick.

Mr. S. Littleproud, for the past 3 years Second Gardener to Mrs. CLEASLEY, Cecil Lodge, Abbots Langley, Hertfordshire, as Gardener to A. BABINGTON, Esq., Densworth Cottage, Chichester, Sussex.

PUBLICATIONS RECEIVED.—*Problems of Genetics*. By William Bateson, M.A., F.R.S. (London: Humphrey Milford.) Price 17s.

ACACIA BAILEYANA: *R. McC.* There seems no reason why the leaves and flower buds of your plant of *Acacia Baileyana* should drop, as the tree usually flowers very freely. In the neighbourhood of London and other large towns fog and smoke sometimes cause the flower buds to drop, but that should not happen in country districts. Dryness at the root would have the same effect, but as your plant is growing very strongly it may be that the growths are not properly ripened. If such is the case the roots may, as you suggest, have reached the vine border, and in consequence the plant is making too gross wood. In this case the only remedy is to restrict the roots.

APPLES FAILING TO CROP: *W. M., Queen's Co.* There are three main causes of Apple trees failing to crop well, namely, excessive wood growth, unfavourable weather (including frost) during the blossoming period, and lack of pollination. As you state that the trees have not grown well the first cause does not apply. What you say of frost may indicate the cause of failure. If too many trees of one variety are in a great block lack of pollination in the cases of varieties which are not self-pollinating may be a further cause of insufficient fruiting, but from the size of the orchard this does not seem probable. The presence of a few hives of bees in the orchard, if not there or near by already, would help pollination greatly. Grass over the roots checks wood growth, but not fruiting, though it reduces size of fruit. Some of the varieties you name, including Cox's Orange Pippin, Ribston Pippin, Irish Peach, and Peasgood's Nonesuch, are shy bearers in many places. Spraying with gas lime is uncommon, and may possibly do harm. Wash made with the best quicklime from limestone, $\frac{1}{2}$ cwt. to 100 gallons of water, applied when hot immediately after slaking would be safer; or lime-sulphur of the winter strength as prescribed by the makers. You do not give details about insect or fungous attacks. The Apple Sucker (*Psylla mali*) or the aphid will often prevent fruiting to a great extent, while brown rot (*Sclerotinia fructigena*, often called *Monilia fructigena*) kills fruit spurs and twigs. For aphid spray the trees with 10 lbs. of Quassia chips and 10 lbs. of soft soap, boiled together for one hour and made up to 100 gallons, or any of the ready-made aphid washes, as soon as the pest begins an attack. The same wash will kill the sucker, if applied when the fruit buds stand well apart, shortly before they expand. The provision of shelter from the north or north-east wind, which often prevent the full setting of blossom, would be useful, and, so placed, would not shade any trees materially; but it should be on the outside of the orchard. It is doubtful whether a screen or wall no higher than 12 feet would do much good. A double row of evergreens, such as the Arbor vitae (*Thuja occidentalis*) or Cupressus Lawsoniana, or one of either and a row of Damsons inside it opposite the vacant spaces between the evergreens would make a better wind-break, but would require some time to grow.

BULBS ROTTING: *F. E., Ireland.* The rotting is caused by a bacterial disease known as yellow stripe. No cure is known. The soil in which bulb have grown should be sterilised by heat or gas-lime.

CARNATION PRINCESS OF WALES DISEASED: *R. H., Tyrone.* The Carnations are attacked by *Helminthosporium echinulatum*. As a preventive spraying with potassium sulphide is recommended. But the best results cannot be obtained from your plants unless the disease is stamped out altogether; therefore you should endeavour to pick off every diseased leaf as soon as it is seen. The plants will then appear to be disfigured by the loss of so many leaves, but if this is persisted in and the diseased leaves burned the disease will cease to trouble you. Guard against the pest being reintroduced by fresh stock.

CATERPILLARS: *A. J. J. G.* The box arrived without its contents. Send fresh specimens better packed.

GRAPE MUSCAT OF ALEXANDRIA: *Bulbo.* The wood of your Muscat vine, which lost its leaves in the summer, is very poor in quality, and not worth retaining. Cut it back to a point where there is more substance. Removing some of the glass to place the rod outside would do no good. The leaves of young vines after the roots become active should be able to bear, with advantage, all the sunshine we have in this country, provided ventilation is attended to properly. Muscat vines will grow well in a house where a shaded thermometer runs up occasionally to 95°, or even higher, if the leaves are kept clear of the glass and the atmosphere is not allowed to become too dry. You probably allowed the temperature of the house to rise considerably before affording ventilation, and after the ventilators were opened the plants suffered from a chill owing to the rapid evaporation of moisture condensed on the leaves and other surfaces. Your house with a southern aspect should be much easier to manage than one facing east.

LIME FRUIT TREES: *Paddy.* Freshly slaked lime applied to the trees profusely when they are quite wet (not otherwise) would do some thing towards killing moss and lichen; but it would be much better to spray the trees thoroughly with hot limewash, as thick as it can be got through a spraying machine or a large syringe. The quantity of lime commonly used for 100 gallons of wash is $\frac{1}{2}$ cwt. Easier stuff to spray is the lime-sulphur solution now advertised by several makers, to be applied in the winter strength which they respectively recommend. Every part of the tree should be thoroughly wetted.

MYRTLE: *Shortlands.* The larger leaf is *Myrtus communis* of the typical form; the small-leaved variety is called Jennie Reitenbach. It is catalogued by Messrs. Jas. Veitch and Sons.

NAMES OF FRUITS: *A. G.* The specimen was somewhat discoloured and bruised on arrival. It is either a small Peasgood's Nonesuch or Blenheim Pippin. We think it is a Peasgood's Nonesuch. Send earlier next season.—*G. M., Lincoln Codlin.*

NAMES OF PLANTS: *T. W. R.* *Cotoneaster rotundifolia* (also known as *C. disticha*).—*J. Clark.* *Crassula albiflora*.—*C. Robinson.* *Lachenalia Nelsonii*.—*H. T. A. 1.* *Lomaria discolor*; 2, *Selaginella laevigata*; 3, *Lygodium japonicum*; 4, *Onychium japonicum*; 5, *Woodwardia radicans*; 6, *Cyathea dealbata*.—*R. J.* *Sparmannia africana* of the order Tiliaceae, an African plant which grows well in a greenhouse or conservatory, and is often seen in cottagers' windows flowering well.—*C. S. P., Devon.* Both varieties of *Cypripedium insigne*, No. 1 being of the *C. insigne Maulei* class; 3, *Adiantum cuneatum elegans*, a garden form.—*Iris.* *Ornithogalum lacteum*, a very durable flower for decorative purposes. It may be grown in a rather dry greenhouse, or a heated pit or frame will be a suitable place. Cape bulbs, as a rule, do not like moisture. After flowering the bulbs should be rested dry and cool until the growing season. The plant seeds freely, and there is very little trouble in raising seedlings.

POTATO DISEASED: *G. M.* A typical example of potato disease—*Phytophthora infestans*.

SUB-TROPICAL AND HALF-HARDY PLANTS FOR BEDDING. *S. S. S.*—Large numbers of plants that can be raised from seed early in the year are suitable for sub-tropical or summer bedding. *Kochia trichophylla* makes a fine bed, with a carpet of *Alyssum maritimum*, or it may be carpeted with *Centaurea candidissima*. A bed of dwarf *Ageratum* with *Leucophyta Brownii* dotted over it is also very effective. *Ricinus Gibsonii* looks well with an undergrowth of *Abutilon megopotamicum variegatum*. *Abutilon Thompsonii* and *A. Savitzii* are both useful plants for producing foliage effects. A pleasing bed may be made with *Coleus Verschaffeltii*, overplanted with *Nicotiana coelestis* var. *variegata*. Another scheme is a large bed of *Nicotiana sylvestris* with an edging, if required, of a broad band of *Coleus*; but edgings to

large beds of foliage plants are often in doubtful taste, and should be used with discretion. *Polygonum lanigerum*, with silvery foliage, is a handsome plant for a large bed; whilst *Cannas*, with green or coloured foliage, are always effective; these plants may be edged with *Centaurea* or *Chlorophytum elatum* var. *variegatum*. Large beds are very effective if planted with a mixed arrangement of foliage plants. Subjects suitable for this purpose are *Solanums*—such as *S. pyracanthum*, *S. marginatum*, and *S. Balbisii*; *Melanthus major*, *Grevillea robusta*, *Albizia lophantha*, *Eucalyptus Globulus*, *Perilla nankinensis*, *Nicotianas*, *Chamaepeuce Casabonae*, *C. diacantha*, *Ricinus*, *Wigandias*, *Humea elegans*, and *Zea japonica variegata*. These, with the exception of *Humea*, can be raised easily from seed sown early in spring. Plants suitable for edgings include *Centaurea*, *Mesembryanthemum cordifolium variegatum*, *Gnaphalium lanatum*, *Pyrethrum* (Golden Feather), *Fuchsia Golden Treasure*, *F. gracilis variegata*, and *Chlorophytum elatum variegatum*. A good dark-coloured form of Beet is very effective either for an edging or groundwork. *Begonias* of the *semperflorens* type are very suitable plants either for borderings or as individual beds with other foliage plants; *Begonia semperflorens* var. *Triomphe de Lorraine* has fine dark foliage, whilst such forms as *rosea*, *alba*, *Ruby* and *Primadonna* may be raised from seed, and bedded out the same season as raised. *Veronica Andersonii variegata* is useful for edgings, and small standards of this plant are effective over a groundwork of *Heliotrope*. Some of the hardier Palms may be used, also *Cordylines*, *Phormiums*, and *Musa Ensete*. The above suggestions may be helpful to you, but without a knowledge of the situation of the garden, its surroundings, size of beds and other details we cannot give planting schemes.

TOMATO: *H. R. B.* The Tomato is a native of the warmer parts of America, and was introduced into Europe in the sixteenth century, some authorities fixing the date at 1596. An analytical chemist could furnish you with an analysis of the fruit.

VINE SHOOTS FOR EXAMINATION: *Quarterian.* Discoloured pith is attributed to an excess of nitrogenous matter in the border. Discontinue the use of nitrogenous manures and dress the border with freshly-slaked lime, using about a peck to the perch, kaint, at the rate of six pounds to this area (or a good dressing of charred vegetable rubbish or wood ashes), also a good coating of steamed bone flour or basic slag. These ingredients should be applied to the surface as soon as possible, and lightly worked in to the depth of an inch or two. Nitrogenous manure such as sulphate of ammonia or nitrate of soda should be used very sparingly during the coming growing season, say half a pound of one of these manures to the perch just before the flowers expand, and again a month later, or you might apply half the usual dose of one of the well-known fertilisers twice during the season. Apply no mulching, and do not damp excessively during the next season, but keep the surface soil stirred frequently. Ashes from coal or coke are not to be recommended for garden purposes. They contain little or no manurial properties, and when applied to a light soil especially make it less retentive and less productive.

WOODLICE IN VINE BORDER: *M. E. A. M.* To catch these pests traps should be prepared by hollowing out pieces of Potato, Turnip, etc., and placing these hollow side downwards in its haunts. When the baits are examined each morning woodlice will be found therein, which should be destroyed and the baits replaced. Similar baits may be poisoned by soaking them in Paris green or white arsenic if desired.

BRAZIL'S BOTANIC GARDEN.

ALTHOUGH the Botanical Garden at Rio de Janeiro has been in existence for over a century, it is not so well known in Europe as its merits deserve, and even among the comparatively small number of people whose travels have led them to the fascinating capital of Brazil it is only the single feature of the great central avenue of Palms which has attained celebrity.

Yet the Garden at Rio de Janeiro may justly claim to rank alongside its better-known counterparts at Peradeniya, in Ceylon, and at Buitenzorg, in Java, as one of the best botanic gardens in the Tropics. At the beginning of last year the Government of Brazil appointed Dr. J. C. Willis, who for sixteen years had been Director of the gardens at Peradeniya, to be Director of the Rio Garden, in succession to the Prefect of Rio, the previous Director. Dr. Willis is animated with the desire of spreading the fame of his new charge among all those interested in botany and horticulture, in order that the resources of the garden and laboratories may be put to the fullest use for the advancement of knowledge. In accordance with his invitation, very kindly extended through Prof. Seward, of Cambridge, the present writer spent a most delightful winter in the enjoyment of the lovely surroundings that the Garden and its neighbourhood afford.

Rio de Janeiro (which means "January River") was named by its discoverers under the false impression that the enormous bay, or rather inlet of the ocean, upon which Rio stands was the estuary of a river, and in accordance with this name the Garden is often yet entitled the "Hortus Fluminensis," or the "River Garden."

The bay itself is of great extent, running some forty miles inland, and terminated by the range of the Organ Mountains, the native home of many lovely species. Round the mouth of the bay rise a multitude of precipitous granite peaks, bare above, forest-clad below, and at the foot of these mountains, spreading itself for many a mile over hill and dale, lies the city itself, occupying what is perhaps the most beautiful, and certainly the most extraordinary, site of any metropolis in the world.

Although Rio is nearly 23° S. lat., and is consequently only a short distance inside the tropic line, it enjoys a perfectly tropical climate. This is partly owing to its sheltered position, but is chiefly due to the warm equatorial current which sweeps the coast and carries the zone of tropical vegetation far south of the actual geographical tropic. There are only two seasons in South Brazil—the dry season, which is also the cold season, and the wet season, which is hot. The climate is never really dry, but from March to September rain is decidedly less frequent, the sky is clear and the temperature lower; while in October the rain begins to increase in amount by periodical downpours, after each of which the sun comes out a little higher and a little hotter. January and February are the height of summer.

It is remarkable, however, that in tropical South America the sun, even when vertical in a cloudless sky, has nothing of that scorching power which is so inimical to plant life in Eastern lands. The atmosphere during the hot season verges continually upon saturation, and the moisture acts as a screen to the heat, without greatly diminishing the light of the sun's rays. Consequently the precautions against sunstroke which are so necessary in the East are here unneeded, and even an exposure of an hour in the sun with one's head bare hardly produces more than a slight headache. The climate is, in general, as incalculable as that of an English summer. Whatever season of the year it may be, when the wind blows off-sea clouds and rain follow—not torrential downpours either, but gentle English rain.

These moderate conditions of climate reflect themselves in the aspects of the vegetation, as well as in the habits of the population. The feature of Rio city and of the Garden which would most likely first strike the attention of an English horticulturist is the quality and extent of the lovely lawns which are to be seen everywhere. From a distance they appear smooth as the finest velvet, and of a purity which is hardly ever equalled in temperate climes, because these lawns are not sown—grass-seed will not grow at all—but actually hand-planted, each root of grass being dibbled in separately with infinite patience. It is not Poa which is used in their composition however, but Stenotaphrum, and the resulting lawns, although so beautiful, are much too soft and turfy to be of any use for games. To anyone who has ever realised the difficulty of cultivating grass outside the temperate zones, these lawns speak eloquently of mild sun and perennial moisture.

The Botanic Garden lies upon the fringe of the city, on a space of flat ground—a somewhat scarce commodity—lying at the mouth of a valley, and surrounded upon three sides by mountains, the highest of which, Corcovado, is a sharp peak about the same height as Snowdon. In front of the Garden is a lagoon, and beyond that the open ocean. All over the hills behind stretches the virgin forest, very little interfered with, in spite of its proximity to the city.

The Garden is divided into two portions by a road; the first and much the smaller portion, lies between the road and the lagoon, and remains in a wild condition. The soil is swampy and unsuited for cultivation, therefore the jungle is left standing, and the ground is covered with Bamboos, Sensitive Plant (*Mimosa pudica*), and other moisture-loving herbs and trees, which do not reach any considerable height.

The other portion of the Garden, which is much the larger of the two, is practically bisected by the main Palm avenue.

There is not much open ground, and the wonderful collection of Palms gives quite a woodland aspect to the views, an aspect which is increased by the alleys of Mango trees. These last are large and handsome, and impress the visitor with a strong sense of the prevailing magnitude of the trees. A full-grown English Elm looks insignificant if measured in imagination against one of the giants of the jungle.

The last Director but one, Dr. Barbosa Rodriguez, was a great authority on the Palmae, and the collection of specimens, comprising nearly 400 species, which he got together in the Garden is undoubtedly the finest in existence. From the spectacular point of view they are a great adornment; indeed, such another combination of grand natural surroundings and cultivated beauty as the Gardens of Rio provide could hardly be found anywhere else in the world.

The chief object of general interest in the Garden is, as has been before mentioned, the great Palm Avenue, a splendid colonnade, half a mile in length and composed of individuals of *Oreodoxa oleracea*, which are over 150 feet in height. The original Palm, from which those forming the avenue are descended, was introduced by one of the Emperors and is still in the Garden. No photograph or picture does justice to this wonderful spectacle. It is size and colouring which lend grace and dignity to the bare poles of the Palm stems, and redeem the avenue from the imputation of the ugliness with which critics sometimes charge it. This avenue runs from the main entrance right across the Gardens and terminates in a little temple, dedicated to "Dea Palmaris." From the main entrance two similar but smaller avenues diverge, so that the effect of the three combined meets the visitor immediately upon his entrance. Grouped together at one end of the Garden and approached by a special gate, stand the offices, including the library and the herbarium, the Director's new house, the laboratories, and the Director's old house, a building dating from the seventeenth century and now divided up among several families of workpeople.

It is intended that the herbarium shall soon be accommodated in a more worthy manner in a building of its own. The laboratories, including those for vegetable physiology, agricultural chemistry and bacteriology, are under competent direction, and are furnished with an equipment of apparatus, material and funds which render possible the accomplishment of the very best work. Under Dr. Willis' direction the quarterly *Contributions du Jardin Botanique de Rio* has been recommenced, therefore much more may be expected from these laboratories in the future than the past has produced.

From the hill behind there descend two little cascades, the water of which is led everywhere throughout the Garden in rippling channels which cool the air even in the height of summer. Mosquitos are rather rife, but are fortunately

not infected with yellow fever (a disease now extinct in Rio), so that no danger is to be apprehended from them.

Another feature of the Garden is the pond, rich in aquatics and surrounded by groves of Bamboos and of the huge *Ravenala madagascariensis*, the "Traveller's Tree." There is a group of the giant Bamboo, *Dendrocalamus giganteus*, and an avenue of Agaves—*Fourcroya*—striking in their rigidity, as well as the alleys of Mangos already mentioned. A numerous collection of Cycads, 22 species, has just been installed, and special sections for characteristic Orders such as Aroideae and Marantaceae have been set aside. Everywhere one is struck by the profusion of the epiphytes, some large trees being scarcely visible under their load of *Tillandsia*, *Rhipsalis*, Orchids, and other epiphytes. There are three glasshouses in the Gardens, not to keep things warm, but to keep them dry, and in one of these is housed the fine collection of Orchids made by Dr. Frazao. The Garden has, of course, a certain amount of statuary, and there is an old gateway, now the gate of the nurseries, which is one of the best remaining examples of the Portuguese Colonial period. Little has been said of the surroundings of the Garden, but in every direction, in the wonderful forests which cover every slope in gorgeous profusion, or on beach or mountain or lagoon, there is lavish interest, enough perhaps for anyone's lifetime. *R. C. McLean.*

NEW OR NOTEWORTHY PLANTS.

NEW GARDEN PLANTS FROM NEW MEXICO.

NEW MEXICO is one of the United States, bounded by Colorado on the north, Arizona on the west, Mexico and Texas on the south, Texas and Oklahoma on the east. It is a region of extremely varied topography and climate, with a remarkably interesting flora. In 1910, Mr. P. C. Standley published (*Contr. U.S. Nat. Herbarium*, vol. 13, part 6) a list of 690 species and varieties of plants described as new from material collected in New Mexico. In 1913 Messrs. Wooton and Standley published a paper (*Contr. U.S. Nat. Herbarium*, vol. 16, part 4) describing no fewer than 203 additional new species from the same State, and a few others have been added since. Among all these plants there are many which should be available for horticultural purposes, but comparatively few have as yet been utilised. I offer here a few notes on certain species which have done well in my garden at Boulder, Colorado.

ROSA STELLATA WOOTON.

This is the type of a very distinct subgenus, *Hesperhodos* (cf. *Nature*, 1913, p. 571), characterised by the large, prickly, thick-walled fruits, widely open above, the smooth non-angular seeds, and the small and very peculiar leaves. The flowers are large and very beautiful, of a deep rose-purple colour.* This is perhaps the most local Rose in the world, occurring only in a very limited area in the mountains east of the Mesilla Valley. It has grown very well at Boulder, and has been grown in England by Dr. A. R. Wallace. Probably it will only do its best in a rather dry climate. About sixty-five miles north-west of the locality for typical *R. stellata* is another limited area occupied by an apparently distinct race of the same species, *Rosa stellata mirifica* (*Rosa mirifica* Greene, 1910), which I found in fruit near the Mescalero Agency many years ago, before either species or race had been published. The behaviour of true *R. stellata* in cultivation suggests that probably some of the characters of *R. mirifica* are due to

the direct action of the environment, but it is desirable to grow the two forms side by side. It may well be that *mirifica* possesses some distinct gametic characters having to do with the size of the plant and the character of the trichomes; for although the plants live in the same general region, they are separated by a desert, and the seeds are not adapted to be carried by birds. The term "topomorph" has been suggested for isolated forms slightly different from the nomenclatural types, and seems to be entirely applicable to the present case.

ROSA PECOSENSIS COCKERELL.

Rosa pecosensis, from the Upper Pecos region, is a very pretty Rose of the *Cinnamomeae* group,

ORCHID NOTES AND CLEANINGS.

CYMBIDIUM SCHLEGELII PUNCTATUM.

The illustration in fig. 25 represents the fine variety of *Cymbidium Schlegelii*, shown by Pantia Ralli, Esq., Ashted Park, Surrey, at the Royal Horticultural Society meeting on January 13, when the Orchid Committee granted it an Award of Merit.

The original was raised by Messrs. J. and A. McBean, Cooksbridge, who received the R.H.S. Award of Merit when the cross was first shown on January 23, 1912, so that the fact of it being a winter-flowering kind is well established.

[Photograph by R. A. Mulby.]

FIG. 25.—CYMBIDIUM SCHLEGELII PUNCTATUM: PETALS AND SEPALS CREAM-WHITE TINTED WITH ROSE, LIP SPOTTED WITH RED.

the petals deep crimson, white at base. It is not yet in cultivation.

CYPRIPEDIUM VEGANUM COCKERELL AND BARKER.

This is a large form with very bright yellow lip, allied to *C. pubescens* of the Eastern U.S. Standley says of it: "A beautiful and abundant plant, common not only in the Las Vegas Range, but in the Santa Fé mountains as well. The plants often form large masses several feet across." My friend Mrs. S. Viveash kindly sent me some living plants, which have done very well at Boulder. An attempt to raise some from seed in the greenhouse was not successful. *T. D. A. Cockerell, University of Colorado, Boulder, Colorado.*

(To be continued.)

Like all other hybrids of *C. insigne* it is of elegant habit, and a good decorative plant even when not in bloom. The flowers are cream-white, with a slight blush tint, and faint rose lines on the sepals and petals, the variety *punctatum* having the labellum spotted with dark red.

CYPRIPEDIUM HANBURYANUM.

At the Royal Horticultural Society's meeting on December 16, 1913, Frederick J. Hanbury, Esq., Brockhurst, East Grinstead, showed a very large and handsome *Cypridium* under the above name, but which was said to be probably a good form of *C. Alcibiades* (*Leeanum giganteum* × *Mons. de Curte*), no trace of *C. Maudiae* being visible. Mr. Han-

* Decidedly more vinaceous than the "rose pourpré" of G. Averaux, *Manuel pour la Description des Roses*, 1906, pl. III. It is perhaps nearest to Gravereaux's "cramoisi," pl. IV.

IMPATIENS HERZOGII (NAT. ORD. GERANIACEAE)

Warm greenhouse plant from New Guinea.

bury is kind enough to write that he maintains the name and parentage as perfectly correct. It is from one of the first crosses he ever made, and at that time he had not the material from which to produce *C. Alcibiades*. Later he raised the *Alcibiades* cross, but although good, his flowers bore so little resemblance to the certificated *Alcibiades* that he should doubt the now recognised parentage of it. It is, however, probable that *C. Lee-anum giganteum* provides the dominant factor both in *Hanburyanum* and *Alcibiades*, and hence the similarity. Confirming his view that the correct parentage of *C. Hanburyanum* is *Lee-anum giganteum* × *Mandiae*, Mr. Hanbury says

bright reddish-purple, with gold lines from the base.

ODONTOGLOSSUM HYBRIDS.

WILLIAM THOMPSON, Esq., Walton Grange, Stone, Stafford (gr. Mr. J. Howes), kindly sends flowers of four very handsome hybrid *Odonto-glossums* raised at Walton Grange. Where the parentage is not known and the flowers are not positively identified Mr. Thompson simply puts a name for the purpose of identification.

O. illustrissimum Creole is of rich claret colour with white tips to the segments. *O. amaranthum* resembles it, but has a narrow

Choccensis alba), a good white flower with broader petals than *C. Trianae alba*. Disc of lip chrome-yellow.

Laelio-Cattleya Wilfrediana (L.-C. *cinnabrosa* × *C. Aclandiae*), a distinct flower with lanceolate sepals and petals nearly 4 inches across; gamboge yellow with purple spots. Lip with an expanded front lobe bright rose-purple, with yellow blotch from the base.

Laelio-Cattleya Orient (*C. labiata* × L.-C. *Adolphus*), a three-flowered inflorescence of bright copper-orange flowers with deep ruby-crimson front to the lip. L.-C. *Adolphus* was raised from *L. cinnabarina* × *C. Aclandiae*, and is usually spotted on the sepals, but no trace of the spotting appears in the hybrid.

PENRRHYN CASTLE.

(Concluded from page 38.)

MANY interesting wall plants grow against the spaces between the glasshouses, including *Camellia reticulata*, *Berberidopsis corallina*, *Lapageria rosea*, *Nerium Oleander*, *Lardizabala biternata*, *Eugenia Ugnii* (see fig. 27), *Vitis dissecta*, *Punica Granatum* (Pomegranate), the fragrant *Rhynchospermum jasmynoides*, and, most strange wall plant, an old Maidenhair tree (*Ginkgo biloba*), which develops uncommonly large leaves.

Below this charming terrace, in a little valley, a delightful bog garden has been constructed, and provides a congenial home for the huge-leaved *Gunnera manicata*, *Astilbe Davidiana*, and a great variety of Bamboos. Along the banks of the stream clumps of *Hydrangea hortensis* bear large trusses of rich, blue flowers—so blue that Maries, though well acquainted with the species in its native habitat, expressed surprise at the colour. The production of blue flowers in place of the normal rose-coloured blooms on certain bushes of *Hydrangea hortensis* has several times been the subject of discussion in the *Gardeners' Chronicle*, and in this instance the phenomenon may be attributed to the very dark bog soil on blue clay in which they are growing. Plants raised from these and planted elsewhere produce flowers of the customary pink colour. This same soil also gives an unusual intensity of colour to the blooms of *Magnolia Soulangeana*.

THE WILD GARDEN.

The scene changes from the trim yet graceful orderliness of the terrace garden, with its closely-mown grass slopes and intersecting winter garden, to a large natural wood, composed chiefly of magnificent specimens of *Pinus Laricio*, Scots Pine, Cedar of Lebanon, and broad-leaved deciduous trees. They have now developed into fine specimens, which provide shelter and protection but not dense shade. It is an ideal place for the accommodation of the large numbers of uncommon, half-hardy plants and shrubs which here find a home. Although planted in the similitude of what is termed a wild garden there is no suggestion of a wilderness, but rather of a natural garden, beautifully and thoughtfully planned. Groups of *Cordylone* (*Dracaena*) *australis* of many forms and types—one from Tresco, distinguished by very broad leaves with dark midrib and by erect flower-stalk—extend their sword-like leaves with majestic dignity. Lofty, slender, silvery-barked *Eucalyptus* (*E. coccifera*, *E. coriacea*, and *E. cordata*) add grace and lightness to the sober hues of the stalwart Conifers, and dense masses of Ghent Azaleas richly perfume the air throughout the long early summer's day. *Choisya ternata*, *Pernettya mucronata*, and various *Andromedas* are planted in bold groups, interspersed with specimens of rarer shrubs, such as *Nandina domestica*, the sacred Bamboo of the Japanese, which is richly coloured in autumn, *Caesalpinia japonica*, *Gre-*

FIG. 26.—CUPRESSUS SEMPERVIRENS AT PENRRHYN CASTLE.

that several showing the petals of *C. Maudiae* have bloomed.

LAELIO-CATTELEYA NERVA.

A FLOWER of this pretty cross between L.-C. *Nysa* (*L. crispa* × *C. Warscewiczii*) and *C. Warscewiczii* is sent by Mr. Jones, Orchid-grower to Mrs. Bischoffsheim, The Warren House, Stanmore, where it is flowering for the first time on a comparatively small plant. As is to be expected, the hybrid bears a strong resemblance to *C. Warscewiczii*, but the labellum is narrower, longer and much crimped, a feature which it gets from *L. crispa*. The flower is 7 inches across, white slightly tinged with rose, the labellum being

white margin and broad lip showing the influence of *O. Harryanum*.

O. Papilium is a grand white flower 4 inches across, and blotched over all the segments with rose-purple.

O. Hercules is still larger, very broad in all the segments, white, tinged with rose, but with quite three-fourths of the sepals and petals covered with reddish-purple blotches.

HYBRIDS FROM SCAMPSTON HALL.

Mr. F. C. PUDDLE, The Gardens, Scampston Hall, Rillington, Yorkshire, kindly sends flowers of three hybrids flowering there for the first time. *Cattleya Madonna* (*Trianae delicata* ×

villea rosmarinifolia, and *Metrosideros florida*, the bottle-brush tree, all of which flower freely in their season. A huge group, 30 feet long, of *Phormium tenax* bears numerous tall spikes of quaint flowers, and a smaller clump of the variety *atropurpureum* bears a part in the charming scene.

THE CASTLE.

Penrhyn Castle is one of the most prominent landmarks along the Menai Straits and the western road from the town of Bangor, for it stands on an eminence 150 feet above the sea-level amid luxuriously wooded surroundings. From the terrace walk entrancing views of North Wales scenery delight the eye. Along the carriage drive large bushes of Sikkim *Rhododendrons*, vividly reminiscent of Tremough and other West Cornwall gardens, are happily placed and bloom profusely. Across the park there stands an interesting group of the upright Roman Cypress (*Cupressus sempervirens*), shown in fig. 26, with bare trunks and quite distinct in character from the densely-clothed cylindrical pyramids one usually sees. Towards the

times remarks, manure is none too plentiful. The long walls which enclose six acres of the kitchen garden are covered with various fruit trees, all of flourishing appearance and trained with almost mathematical exactitude. Espaliers border many of the walks, and an uncommon feature is the long lines of large slabs of slate stood on edge for training Pears on the south side and Morello Cherries facing north. Strawberries are so largely grown that some 5,000 layers are planted annually. The Gooseberry is another fruit cultivated largely in these gardens, and to ensure regular crops in a breadth of bushes 36 yards long, wire netting has been erected over the Gooseberry quarter; this affords ample protection from birds and from spring frosts. Besides storing a large proportion of the crop of Apples and Pears in the fruit-room, such good use is made of the ice-house for prolonging the season of these fruits that Cox's Orange Pippin Apple is usually placed on the table in a fresh and plump condition so late as the second week in May. Many glasshouses are devoted to the culture of Vines, Peaches, Nectarines and other fruits, all

better than to exhibit the Penrhyn treasures to sympathetic visitors. In fig. 28 the veteran gardener may be seen on the path leading to his house.

THE ROSARY.

INDOOR GRAFTING.

This work should now be done if it is desired to increase the stock of any novelty. It is only for this purpose that grafting is to be recommended for the amateur, as plants of the older sorts may be purchased so cheaply it scarcely pays for the trouble.

Seedling Briars are the best stocks for the purpose, and although established specimens are best, the seedlings may be potted up now into small 60 sized pots. After about a week or ten days the tops of the plants may be cut off, and the stock grafted. Those with stems of about the size of an ordinary lead pencil are to be preferred. After grafting them place the stocks in a close propagating frame, where a temperature of about 83° can be maintained night and day. No ventilation should be afforded for the first six days, but after this period raise the lights one inch twice a day for half an hour. Increase the amount of air gradually until the fourteenth day, when the lights may be drawn up, and in about three weeks from the time of grafting the little plants may be placed on a stage in the same house.

Rose seed should be sown now in pots or boxes, and germinated in a greenhouse. I am using rather deep boxes—12 to 15 inches in depth—this year, as I find the soil can be maintained more uniformly moist than when shallower ones are employed. The compost consists of good fibrous loam with silver sand added.

It is essential that the seed-capsules never become dry. If they fall from the plant before opportunity affords for sowing they should be stuck in pots of silver or river sand, with the pod immersed in the sand.

When the boxes are ready break the pods and lay each seed on the surface at about 1 inch apart each way. Then push them under the soil with the blunt end of a lead pencil to a depth of not more than half an inch. Cover the surface with silver sand, and afterwards water the soil and see that it is never allowed to become really dry. The earliest seedlings will appear in about eight or twelve weeks.

SEASONABLE WORK OUT OF DOORS.

In the absence of frost or snow land intended to be planted in February and March should be dug over or trenched if needed. Digging among established Roses cannot be done too early. The ground between budded standard Briars should also be dug between the rows as soon as the side branches that were budded have been cut back.

Do not cut the shoots close up to the buds, but leave about 4 or 5 inches of the Briar growth until June.

The tops of dwarf stocks budded last summer may be cut off, close to the eye or bud, by the end of the present month.

Hedges of Roses may receive attention now; cut out the oldest wood, and tie down some of the growths to thicken the hedge where necessary. It will be an advantage to dig manure in on both sides of the hedge.

The planting of standard Briar stocks should be finished at the earliest opportunity.

Tonks' manure should be applied during February. It is slow in action and needs to be applied early if to be of use during the current season.

It is prepared as follows:—Superphosphate of lime, 12 parts; nitrate of potash, 10 parts; sulphate of magnesia, 2 parts; sulphate of iron, 1 part; sulphate of lime, 8 parts. It should be applied at the rate of $\frac{1}{2}$ lb. to the square yard, and be given in addition to the annual dressing of farmyard manure. *Experience.*

FIG. 27.—EUGENIA UGNII IN A SHELTERED CORNER AT PENRHYN CASTLE.

[Photograph by W. J. Vasey.]

old chapel there are many trees which were planted by Royalty whilst on visits to Penrhyn Castle. Of these "Royal trees" mention may be made of a vigorous spreading Turkey Oak, planted by the late Queen Victoria; a graceful Silver Birch, planted by King Edward VII. when Prince of Wales; and a companion tree of the same species, planted by his Royal Consort.

THE KITCHEN GARDEN.

The kitchen garden is of exceptionally large dimensions, and the excellence of the produce grown by Mr. Speed has long been justly famed. Onions are always of unusually fine quality, and the plot of ground devoted to this vegetable is very large. Celery also is grown extensively, and the long rows of trenches form an imposing feature of the garden. Mr. Speed is a past-master in the art and practice of crop rotation, and the observance of this, together with deep digging and frequent hoeings, is responsible for much of the success of this part of the gardens, for, as he some-

of which promise to do as well in the coming season as they have done in many past years. One vinery contains rods of Black Hamburgh Grapes, which were planted over half a century ago; they were mature rods when Mr. Speed took charge, and, thanks to skilful cultivation, still bear excellent crops.

The plant houses all evidence the same high cultivation and thoughtful management. Carnations are grown in thousands, and the condition of these, the Orchids, the stove and other plants are all worthy of this great establishment.

Mr. Walter Speed has directed the management of these gardens for fifty years. Throughout this long period he has held the full confidence of his employers and the respect of every horticulturist who has had the privilege of meeting him. Few gardens have given us greater pleasure than our summer visits to Penrhyn have provided, where every interesting feature is the result of Mr. Speed's thought and labour. He has planted most of the shrubberies and almost all the exotic trees, and he likes nothing

NOTICES OF BOOKS.

GARDEN CRAFT IN EUROPE.*

THE history of garden craft in Europe, remote as well as recent, has been the theme of many writers at different periods, but with a few exceptions the more recent records have been fragmentary compared with the comprehensive character of this latest contribution by Mr. Inigo Triggs. The present work is supplementary to the author's *Formal Gardens in England and Scotland* and *The Art of Garden Design in Italy*. That he has made an intimate study of his subject is evident from the thorough way in which he deals with the matter in his new book, and the enormous amount of historic records he has gathered from all available sources is testimony to his industry and love of the subject.

The compilation of a work such as this necessitates a great amount of research. A list of over two hundred works, many of them extremely rare, is appended to the book, and reference to these alone must have been a heavy task. The book deals purely with garden design as distinct from horticulture, although to a great extent one is intimately connected with the other. The historic account commences with the earliest times at which the decorative arts were fostered by civilisation; but these records, apart from their antiquarian interest, do not much concern us. Neither do the succeeding chapters on the gardens of the Middle Ages. The descriptions and illustrations of these gardens, though quaint and interesting, cannot in the nature of things be much more than imaginative or traditional.

The chapters that follow treat of early garden design in the Netherlands, Germany, Austria, Spain, Italy and France. Then follow chapters on English gardens from the sixteenth to the eighteenth centuries, and the concluding chapters are a dissertation on the English Landscape School and its influence on the gardens of the Continent.

When the author leaves mediæval gardens and deals with those of more recent times interest is quickened. He begins with the accounts of the French gardens, planned in the spacious days of the seventeenth and eighteenth centuries, the period during which there were more outrageous follies created in Continental (and especially French) gardens than at any other time in history. The middle of the seventeenth century saw the rise of the celebrated Lenôtre, a man who had the greatest influence on the gardens of France and the design of gardens in other Continental countries, while England also came under his influence. It was during the time of Lenôtre that French gardens displayed their greatest extravagances, and yet we owe to him a debt of gratitude for the magnificent conceptions of his brain in the many stately places that one sees to-day, albeit that many are in decay. The glory of most of these creations is a memory of the past; we all admire the broad, bold conceptions found in places like Versailles, the Trianons, St. Cloud, Chantilly, and many others, designed by Lenôtre and his followers.

The chapters devoted to French and Italian gardens comprise the bulk of the work, and are profusely illustrated by recent photographic productions as well as by copies of old prints, plans and diagrams. Indeed, the book throughout is admirably illustrated, and these illustrations serve their purpose well in elucidating the text.

In the chapters on English gardens the author has dealt in a comprehensive way with the periods of the sixteenth, seventeenth and eighteenth centuries. He describes and illustrates a selection of our English gardens which by common consent are considered the finest, and these—though less grandiose than Italian and French gardens—compare favourably with any Continental garden.

The concluding chapter, upon the "English Landscape School and Its Influence on the Continent," is of much interest to English readers. It traces the history of the art of garden design from the middle and latter half of the eighteenth century, which period saw the dawn of English landscape gardening. It was then that the first efforts were made to break away from the conventional lines of formalism, which had become the subject for ridicule and criticism, chiefly on account of the excesses in topiary work or "verdant sculpture" which had disfigured so many of the most important gardens. A violent change of taste had set in, the result being a school of practitioners who revolted against the ruling principles established by Lenôtre and his followers.

Bridgeman and Kent, an architect of eminence who laid out the gardens at Claremont and Esher, appear to have been the first to practise the new or landscape style. These were followed by "Capability" Brown, who about 150 years ago was at his zenith of popularity. Then came Repton, and these men originated what the author describes as "the ridiculous fancies of the landscape gardener." They had much to

"It is precisely because our noble mansions in the country are in a setting of their own, absolutely incomparable, of park and grove, that they are unsurpassed for loveliness anywhere. Framed as they are by evergreen and deciduous trees in every range of foliage tint, and shrubberies displaying every range of brilliant colour from early-spring to late autumn—why, the very framing makes an ugly country house look sweet and homelike."

This is the tradition that we are jealous of maintaining in our English gardens, and notwithstanding the present-day efforts to re-introduce old-time formalism, the true characteristic of a beautiful English garden will always be the blending of the natural style with the adjunct of seductive sheltered enclosures, formal or otherwise, which in this climate are so essential to the enjoyment of a garden at all seasons and so necessary for the luxurious growth of plant life. W. G.

THE MANURING OF MARKET GARDEN CROPS.*

THE new edition of this valuable work gives the results of the experiments in manuring carried out by the authors during the past 20 years.

FIG. 28.—THE GARDENER'S HOUSE AT PENRHYN CASTLE.
(See p. 52.)

answer for in their condemnation and destruction of many really fine places in their zeal to create a new style as opposed to the straight-lined and chess-board-like planning of gardens. They swept away the stately avenues, the glory of many fine places; they destroyed many charming enclosed gardens in order to carry out the natural style, as they termed it.

Without doubt Brown and his followers were vandals to a great extent in their efforts to establish a new fashion in garden-making, and probably they deserve the condemnation of present-day writers who still cling to the old-time formalism as the only possible mode of garden planning. Nevertheless, these early landscape gardeners succeeded in creating the English garden style, or what is called on the Continent the *Jardin à l'anglais*, of which we as a race of gardeners are so justly proud. The answer to the disciples of formalism is that the English style has been and is appreciated the world over, and even at the present time Continental formal gardens are being changed to the English style. We all know what is meant by the English style, which has been briefly but well described by a recent writer when he says, in allusion to the charm of English country gardens:

The prime object of these experiments is to determine how far the large quantities of stable manure purchased and used by market gardeners are necessary, and how this manure—if necessary—may be used to the best advantage. The importance of such an inquiry is manifest to everyone, and need not be insisted upon here. To those gardeners who pin their horticultural faith to an exclusive use of farmyard manure we commend a careful study of these experiments. The records can scarcely fail to convince them that a moderate use of dung, combined with applications of suitable artificials, gives better results. Take for example the results of experiments with Savoy Cabbage. Fifty tons of London dung per acre has given during eighteen seasons an average of 23 tons 6 cwt., whereas half that quantity of dung, plus phosphates and nitrate of soda, has given an average of 26 tons 16 cwt. during the same period. The costs of the two manures are respectively £10 and £8 2s. The records include the result of experiments not only with vegetables, but also with fruit trees.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

CYPRIPEDIUM.—The late autumn and winter-flowering *Cypripediums* having passed out of flower, the plants should be examined to ascertain if re-potting is necessary. Specimens in pots smaller than 6 or 7 inches diameter should be re-potted annually, but larger plants in bigger receptacles may remain for two or more seasons without affording them a shift. In re-potting large specimens the compost should be of a more durable quality than that used for those re-potted annually. All varieties with green foliage grow well in a compost consisting of two parts turfy loam and one part peat, with sufficient broken crocks and sand added to render the materials porous. For small plants it is an advantage to mix a quantity of finely-chopped Sphagnum-moss on the surface. In re-potting large specimens, especially those with matted roots or with roots adhering to the side of the pots, take care to injure the roots as little as possible. It is a good plan to water root-bound plants copiously the day before they are re-potted, for the roots adhere less firmly to the receptacles when moist. Large specimens frequently become bare of shoots in their centres, a condition which growers term hollow in the centre. Such plants should be divided carefully and the growths arranged in such a manner that their centres may be properly filled. The pots should be filled to about one-third their depth with clean, broken crocks. Press the compost moderately firmly about the roots and base of the plants, and arrange it so that the surface forms a mound, rising to the centre. The few *Cypripediums* possessing tessellated leaves flower during the winter months. These do not always thrive well when loam is included in any quantity in the potting compost. The situation of the garden as well as the locality must be taken into consideration when potting these Orchids, for evaporation of moisture is greater in a bright atmosphere and places where fogs are infrequent than, say, in the neighbourhood of London or smoky manufacturing districts, where a heavy moisture-retaining compost would be inimical to success. In damp districts and where the houses are built at a low altitude, causing less evaporation, it is desirable to employ plenty of peat or materials that does not retain moisture for a long period. The stock of any of the *Cypripediums* mentioned may be increased at the time of re-potting by cutting the rhizomes asunder between the growths and removing the back shoots, which may be placed in pots only just large enough to accommodate them.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP,
K.C.M.G., Madresfield Court, Worcestershire.

ANNUALS.—A display of annuals affords one of the brightest and most charming features of flower gardening: the various kinds offer a wide range of colours, and an assortment will provide blooms over a long period. To raise the necessary stocks preparations should be made at once. First prepare a rough plan to determine how the varieties may best be planted, and what quantities will be required. Sow the seeds thinly either in pans or in soil placed in a frame with a layer of fermenting materials 2 feet thick at the bottom. If the hot-bed and frame method is employed the plants will require very little water, as the litter will keep the soil moist, which gives them an advantage over seedlings sown in pans, for, in the latter case, should the atmosphere become very dry a second watering may be necessary before the seedlings have grown much above the surface, and this may cause damping. Admit as much air as possible whenever the conditions are favourable and grow the plants slowly to obtain healthy and sturdy specimens.

ANTIRRHINUMS.—The nurserymen have improved *Antirrhinums* from a garden point of view so much in recent years that they are almost indispensable subjects in the flower garden, and are especially valuable for colour schemes. Furthermore, the *Antirrhinum* will continue in bloom long after such subjects as *Fuchsias*, *Begonias*, *Ageratums*, *Pelargoniums* and *Calceolarias* are destroyed by frost. At Madresfield Court we utilise the taller varieties for massing in large groups, and those of intermediate height for furnishing smaller beds. Of the former Golden Chamois and Cloth of Gold, Coral (red), Carmine (pink), and White are utilised, whilst of the intermediates we select Orange King, Fire King, Crimson and White. Some obtain their best results by growing the plants as perennials, sowing the seed in July and August; but we prefer to treat them as annuals, growing them on from the commencement of the season without a check.

SELECT LIST OF ANNUALS.—Apart from the *Antirrhinums*, which cannot be regarded as true annuals, we employ *Alonsoa Warscewiczii*; *Single Asters*, which may be had in a variety of colours; *Cosmos*, crimson; *Coreopsis grandiflora*, *Dianthus Eastern Queen*, *Crimson Bell* and *Salmon Queen*; *Eschscholtzia californica* and the variety *Mandarin*; *Gaillardia grandiflora*, *Helichrysums Fireball* and *Silver Globe*, *Phlox Drummondii*, *Mignonette*, *Love-in-a-Mist*, *Nigella Miss Jekyll*, *East Lothian Stocks*, *Larkspurs*, *Lupins*, *Zinnias*, *Nemesias*, *Petunias*, *Pentstemons*, *Salpiglossis*, *Tagetes*, *Statice sinuata*, *African Marigolds Orange* and *Lemon King*, *Verbenas*, *Scabious* and *Godetias*. Those named we have proved to be most reliable kinds, and each year a few new ones are added for trial. We have a special quarter set apart for annuals only, and in the season it forms a veritable surprise garden. It is in the shape of a Greek M, and is surrounded by clipped Yew hedges 6 feet high. There are continuous borders around and against the outer hedges and a series of spaces for bedding in the middle, with grass paths 5 feet wide between them. The Yew hedge forms admirable shelter, and the flowers show to advantage in such a secluded spot.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

STRAWBERRIES.—Plants in pots must not be allowed to suffer from lack of moisture at the roots, for the trusses of bloom are developing. As the flowers expand dust them with a rabbit's tail or a fairly large camel-hair brush to assist fertilisation, and maintain a drier atmosphere whilst this operation is performed. Ventilate the house freely on all favourable occasions, as this also will assist fertilisation and prevent the fruits becoming deformed or ill-shaped. As soon as it can be determined which fruits are the strongest remove the others and use liquid manure each time the plants require watering. On warm, sunny days spray the plants overhead with warm water, and use other means to cause the fruits to develop rapidly. An atmospheric temperature of 65° or even 70° by sun heat during the daytime will be suitable, but allow it to drop to 55° or 60° at night.

CUCUMBERS.—Fresh batches of Cucumbers should be planted for a succession; where plenty of house room is available a fresh batch of plants may be started in houses, pits, or heated frames at least once a fortnight. When the latest batch of the earliest variety has been set a corresponding number of plants of a second early or mid-season variety should be started, otherwise there may be a break in the supply.

VINES IN POTS.—As soon as the bunches have been thinned and the berries started to swell, water the roots freely with liquid manure. Where roots are visible on the surface cover them with a top dressing of fibrous loam and well-decayed manure. This will form an excellent medium through which the vines may be fed until colouring of the berries commences. A fair amount of growth may be permitted beyond the bunches, but not sufficient to unduly

shade the fruit. Maintain a brisk temperature of 70° to 75° by day, allowing a rise of 5° or 6° by sun heat, and a night temperature of 65° to 70°. Unless perfectly clear rain-water is obtainable it is safer not to practise overhead syringing, otherwise a deposit from the water may disfigure the berries. The requisite atmospheric moisture should be maintained by damping with tepid water on frequent occasions.

EARLY HOUSES.—As the shoots grow they should be brought down to the trelliswork and tied, for they must not come in contact with the glass. See that cold draughts of air are not admitted into the house. At the proper time stop each growth at a suitable stage, according to the strength of each individual shoot, retaining a sufficient quantity of foliage to ensure the full development of each bunch of fruit. Severe stopping is more detrimental to early vines than a superabundance of growth; both the root and branch system should balance as nearly as possible.

MELONS.—If Melons are required early in the season sow seeds at once and get in readiness the fermenting materials for maintaining the necessary bottom heat. Sow the seeds singly in 60-size pots, using moderately moist soil, so that water will not be required before they germinate. If the plants are to be grown in large pots the latter should be got in readiness and, with the soil, placed in the pit or house beforehand to become warmed, or the plants may suffer from a chill. The soil should consist of friable, turfy loam mixed with a small quantity of leaf-mould and coarse sand, or, as substitutes for the latter, either crushed charcoal, brick, or lime rubble may be used. Perfect drainage of the pots is very essential.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY,
Knowsley Hall, Lancashire.

ROSES.—Hybrid Tea Roses under glass have started into growth, and should be fed with a little stimulant. Regulate the growths and retain only one flower-bud on each shoot. Use fire heat as little as possible, and spray the plants on fine days, closing the house early to make the most of the sun's heat. Maintain a night temperature of 55°, and regulate the ventilators so that air is admitted without causing cold draught. Dust the leaves with flowers of sulphur to prevent mildew appearing. Hybrid Perpetuals should still be grown under cool treatment, and syringed on bright days. A later batch of plants may now be housed. Examine and regulate the drainage of these plants, and if the roots are found in a good condition a top-dressing only will be sufficient. The compost should consist of good loam, lime rubble, and bone dust. Ram the soil fairly firm. When the potting is completed wash the pots and stand them in a house or pit having an atmospheric temperature of 45°. Spray the stems, but do not water the roots until growth commences.

CHRYSANTHEMUMS.—Cuttings that are rooting should be placed on a shelf near to the roof-glass, but not where cold draughts can reach them. Endeavour to have the plants as sturdy as possible. Continue to propagate decorative and single varieties.

PELARGONIUM.—Repot *Pelargoniums* as required, and admit plenty of air on all favourable occasions. Green fly is sure to appear now, and must be checked in good time.

LACHENALIA.—These plants are showing their flower spikes, and should be fed with a little fertiliser. Grow the plants under cool conditions close to the roof-glass.

FORCING PIT.—Force gradually early-flowering shrubs, such as double-flowering *Prunus*, *Kalmias*, *Azaleas*, *Rhododendrons*, *Lilacs*, *Dielytra spectabilis* and *Astilbes*. Forced bulbs passing out of flower should not be neglected, but placed in a frame to be planted out in the spring. Examine bulbs still in the ashes and remove to cold frame such as are ready. A batch of *Lily-of-the-Valley* (*Berlin* crowns) may be

placed in a gentle heat. Clumps from outdoor beds may be lifted and placed in boxes for later flowering.

ZONAL-LEAVED PELARGONIUMS.—These plants are passing out of flower and should be removed from the plant-house to an airy pit sufficiently warm to keep them growing. Let the plants become fairly dry at the roots to encourage the development of short-jointed growth. Root the cuttings singly in small pots on a shelf near to the roof-glass in a temperature of 50° to 55°. The old plants may later on be top-dressed and grown on. They can be turned to good account for summer bedding or for use as stock plants.

HIPPEASTRUM.—Prepare a second batch of Hippeastrums for forcing as advised in a previous calendar.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

THE PROTECTION OF FIG TREES.—In gardens in the colder parts of the country and in exposed situations it is advisable to afford a certain amount of protection to Fig trees out-of-doors during very cold weather. This is especially desirable in winters following a cold and wet summer or autumn, for then the points of the young shoots do not become sufficiently ripened to withstand much frost. But the protecting material must not remain on the trees during times of mild weather, as coddling will tend to make the branches excessively tender, and consequently more susceptible to damage from spring frosts after they have been trained in position. In many cases Fig trees are not properly treated in the summer and autumn to secure well-ripened shoots, which can only be brought about by an intelligent method of pinching or thinning during the growing season. Proper thinning of the shoots is the most important detail in the cultivation of the Fig, and though the evils of over-crowding are sometimes seen in the case of young trees, it is generally very old-established trees that are most neglected in this respect.

ROOT-PRUNING THE FIG.—Fine old Fig trees are to be met with in some gardens, and although they are very ornamental subjects many seldom or never produce good crops of fruit. This is the result of mismanagement on one or two most important details. The roots of these very large trees have probably found their way into a border or quarter that has been manured year after year for vegetable crops, the rich soil, combined with a free root-run, favouring the production of large numbers of strong, sappy growths. Such trees should be root-pruned at once. Take out a deep trench at a distance of 3 or 4 feet from the wall, sever all the strong roots with a sharp knife, and remove any that are growing downwards in the sub-soil. Afterwards restrict the roots to the limits of a moderate-sized border either by building a wall or by filling the trench with a quantity of chalk, stones and poor soil. The materials should be rammed firmly as the work proceeds, and this treatment will result in growth of much more moderate size the following season, which should ripen well and eventually produce fruit.

PLANTING YOUNG FIG TREES.—Where the planting of young Fig trees is contemplated the borders should be prepared now, so that there may be no delay when the time for planting arrives in the spring, when danger from severe frosts is passed. Prepare the borders in such a manner that the roots are restricted from the first, thus avoiding the evils arising from the roots getting into a rich border. Avoid the use of rank manures and rich materials generally. Ordinary garden soil is quite suitable, and this should be mixed with a good quantity of old mortar rubble and wood ash. A warm, light soil is the best rooting medium. In planting ram the soil very firmly. After the trees are planted mulch the roots with light materials and give the trees every attention, syringing and watering as required. Fig trees in a good bearing condition are best fed when carrying a plentiful crop of fruit. Such trees, with their roots restricted in narrow borders, require regular dressings of manure, and the manurial properties washed

down to the roots by copious waterings during the growing season. A warm and sunny position on a south wall is an ideal position in which to plant Figs. Varieties to be recommended as most suitable for outdoor culture are Brown Turkey, Brunswick and White Marseilles.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of Haddington, Tynninghame, East Lothian.

BROAD BEANS.—A full sowing of Green Windsor may be made without further delay. An economical method is to plant in double drills at 1 foot apart, with 3 or 4 foot spaces between, the Beans being close enough at 9 inches apart. Plants from the November sowing will be benefited by having the surface soil deeply stirred and a little earth drawn up to the stems to steady the plants. Thin them if growing closer to each other than 9 inches.

BOXING POTATOS.—Early varieties should be removed from the shelves they have occupied for some months, sorted and arranged rose end up in boxes to be prepared for planting. If medium-sized tubers from the best plants were selected in summer, these will give better results than either small "seed" or cut tubers. They must not be forced in any way. In the meantime prepare the ground by digging it thoroughly, a broad tined fork being a preferable tool to a spade. Make the soil as fine as possible, and if not manured in autumn apply a dressing of either rotted manure, old hot-bed materials, or, in the case of heavy soil, decayed leaves. When planting whiten the surface of the soil with superphosphate of lime, but do not allow the material to come in contact with the tubers. Though the soil be very deeply worked, the tubers should be planted rather shallow, say 3 inches deep, to be covered deeper with fine soil later. A position on a border near a south or west wall should be chosen for this crop.

MANURES AND MANURING.—Almost all the manure for the current year was incorporated with the soil last autumn, but every year it is not so, much of the manuring being left over until an opportunity occurs in January or February, when it is either carried in by manual labour or by horse, at once spread and dug in as soon as the soil and weather permits. I do not favour the practice of burying manure in the bottom of trenches, unless in the case of special crops, such as Leeks; consequently it is perhaps the better plan to reserve the manure until the spring. But one has to manure the ground when convenient, therefore I do not hesitate to apply it in autumn if time permits. Superphosphate of lime is of much value for garden crops, and of this I use about 4 cwt. annually, applying it just before the crop is planted, and also dissolved in water when it is necessary to irrigate. Of sulphate of ammonia 1 cwt. is, on the average, sufficient for a year for all purposes, and is used for vegetables only as a stimulant. These fertilisers and a sufficiency of animal manures, supplemented with soot, poultry manure and soils, will serve to enrich the ground in a suitable manner. Land may be improved by the addition of imported soil: clay loams by lighter material and shallow, light soils by that of a heavier kind, though in the latter case it is important not to add soil with too much clay in its composition, for it will remain in the condition of intractable clods. Soil and other material that have been superheated, as well as the ashes of the rubbish heap destructor, furnish valuable manurial substances; and even heaps of vegetable refuse that have been allowed to ferment, turned and well shaken up in the process, if limed provide plant food not to be despised by the cultivator. It has always happened that this time of the year has been that in which I have found it convenient to carry such materials into the garden, to be spread evenly on selected portions and incorporated later with the soil. For Rhubarb, Asparagus, small fruits, and some kinds of flowers it is best applied as a thin surface dressing. For Rhubarb such material is far superior to the quantities of animal manure that some consider essential for these crops.

WINTER DIGGING.—There is a pressing necessity in many instances to dig and trench ground in the winter months. I have known these opera-

tions performed with snow on the ground, and with the surface so hard it had to be broken with a pick. If the most important object gained by digging is the pulverisation of the soil, so increasing its capacity for absorbing heat, then it is clear that cultivation of this kind is not only worthless, but it is bad, and far better to wait even till crops are ready to put in, a system which has its advantages.

THE "FRENCH" GARDEN.

By PAUL AQUATIUS.

HOT-BEDS.—The weather has been very favourable for the work of making hot-beds, which should be nearly completed. The planting of Lettuces may be undertaken after the beds have been made a few days. As the weather is not exceptionally cold, placing the lining of manure in the rows between the frames may be deferred until the first week in February, but it is essential to arrange fermenting materials in the outside path around the frames at an early date. With the edge of a spade consolidate the manure, and straighten it wherever it bulges. Short manure which has been previously shaken may be put against the frame level with the top of the light and beaten with the flat of a spade or a shovel. This will in time cake and form shelter from frosts and winds. Dry, strawy manure is to be preferred for lining between the rows of frames, as it will not unduly increase the fermentation, which would cause spindly growth in the seedlings and Lettuces. Dry manure also absorbs any excess of moisture in the soil in the frame and use of excessive water is always prejudicial to tender plants at this time of the year. After having prepared the manure spread mats over the lights to prevent breaking the glass when the manure is placed by hand between the frames level with the light. The mats will not be necessary at night when the outside temperature is higher than freezing point. Keep the mats in a good condition until growth advances, when their shelter will be specially beneficial to the crops. Though growers are naturally anxious to complete their beds at the earliest possible date, they should reserve one day each week to tidy and straighten the quarter where the hot-beds are formed, and put the manure heap in order; not only will the workmen do their work in more comfort, but it will save a quantity of manure that would otherwise be rendered unsuitable for hot-beds by constant treading.

UNHEATED FRAMES.—The planting of crops in the unheated frames is now completed. It is usual to place in the paths between the frames some dry material, such as long straw, bracken, fern, or even old mats, to prevent an accumulation of mud through constantly passing over these narrow paths in all weather. These details may appear unimportant, but experience has proved that they are well worth the consideration of those who value expediency in labour. The bulk of the cloches used for the nursery beds are at liberty, and those required for cold work should be placed in their new position. The planting of Lettuces under the cloches should be arranged to suit requirements. Where Cos Lettuce have a ready sale four Lettuces Little Gott or three Lettuces Passion may be set with a Cos Lettuce in the centre. If Cabbage Lettuces are preferred five or four plants should be set respectively instead, and one Cauliflower planted in the centre early in March.

NURSERY BEDS.—As the beds are cleared of the Lettuce plants rake over the soil and cart the rubbish away. Where the ground has been manured in the autumn a thorough digging now should suffice. Spread the soil from the path evenly in the trench and replace with some from the bed. Afford ventilation freely to Cauliflowers in frames whenever the weather is favourable. The plants are tender and very liable to damage from frost, therefore precaution must be taken to spread the mats at night when necessary. If the stock of Cauliflower plants is short, a sowing may be made now in boxes, placing the latter on a shelf in a temperate house. When the seedlings appear watering must be done with extra care or "black leg" disease may appear.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are mis-directed.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

Illustrations.—The Editors will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JANUARY 27—

Roy. Hort. Coms. meet. (Lecture at 3 p.m. on "Some Aspects of American Forestry"). Roy. Inst. meet. (Lecture by Prof. Bateson on "Animals and Plants under Domestication").

THURSDAY, JANUARY 29—

Manchester and N. of Eng. Orchid Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 39.5°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, January 21 (6 p.m.): Max. 36°; Min. 33°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, January 22 (10 a.m.): Bar. 29.9°. Temp. 38°. Weather, —Dull.

PROVINCES.—Wednesday, January 21. Max. 34°, Eastbourne; Min. 44°, Valencia.

SALES FOR THE ENSUING WEEK.

MONDAY—

Herbaceous Plants, Lilliums, and other Hardy Bulbs. Roses and Fruit Trees, at 12. By Protheroe and Morris.

MONDAY AND WEDNESDAY—

Rose Trees, Shrubs, Lilies, Perennials, etc., at Stevens's Rooms, 58, King Street, Covent Garden.

WEDNESDAY—

Lilliums and other Hardy Bulbs, Perennials and Border Plants, at 12; Palms and Plants, at 5. At 67 and 68, Cheapside, E.C., by Protheroe and Morris.

THURSDAY—

Special Sale of Roses at 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 1.

FRIDAY—

Miscellaneous Plants and Bulbs. At 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 1.

The Cultivation of Flax in Great Britain.

In 1911 the Development Commissioners set on foot an inquiry into the possibility of reviving the Flax industry in Great Britain. With commendable despatch Dr. T. Vargas Eyre, who was entrusted with the inquiry, has issued his report, which is published as a supplement to the *Journal of the Board of Agriculture*.

The conclusion arrived at by Dr. Eyre is a favourable one—"there is strong reason for believing that the judicious revival of the Flax industry, managed according to improved methods, would be

productive of benefit to British agriculture, and would induce people to find regular employment in rural districts by creating a demand for skilled labour." Dr. Eyre expresses the further opinion that Flax is to be regarded as a crop particularly well adapted for the smallholder. The evidence brought forward in the Report lends support to these conclusions. Flax used to be cultivated in England on a considerable scale during many centuries. So early as A.D. 1175 it was included among produce subject to tithe. The agricultural development of other countries, and the introduction of cotton, in the early years of last century, were among the causes which led to a decrease in the area under this crop, and it so happened that when, about 1820, steam-driven Flax-spinning machinery was perfected, the farmer found in Wheat a more profitable and less troublesome crop. Dr. Eyre illustrates the rapid decadence of the industry by the records of the county of Dorset; in 1810 there were from 4,000 to 5,000 acres under Flax; in 1850 there were but 300 acres.

After the 'sixties a revival of Flax-growing took place, and in 1875 there were about 30,000 acres under this crop in Great Britain; but for various reasons—bad seasons, competition from other fibres and the high price of Wheat—the area shrunk again very rapidly.

At the present day a revival of this crop is to be desired, if only for the fact that apart from its fibre, and owing to the increase in the price of linseed, Flax appears likely to be profitable as a seed crop. Indeed, as pointed out in Leaflet No. 278 of the Board of Agriculture, linseed as food for stock may be grown more cheaply than it can be purchased at the present time. In its favour Dr. Eyre mentions that, contrary to the common impression, Flax is not a greedy crop; it makes less demands on the soil than Barley. It matures quickly, is on the land only from 10-12 weeks, and is ready for pulling between the hay and corn harvests. In a dry, early season Flax can be removed in time to allow of a catch crop being taken. It does well on light soils under climatic conditions which are not unusual in English summers—a moist atmosphere, frequent showers, and moderately low, uniform temperatures.

From remarks made by Dr. Eyre on the subject of varieties of Flax and their changes when grown in different situations, it would appear that the seed commonly used is by no means pure. Thus blue-flowered Flax (*Linum usitatissimum* vulgare) from Russia is said to give, when grown elsewhere, the white-flowered form, and short-growing, branching Flax from South Russia, when taken north, is said to yield in the course of years tall-growing plants. These statements require investigation, and although they are unimportant from the immediate point of view from which the Report is written, they may become a new nuisance if they get into the textbooks as examples of changes of form induced by changes of climate. All they mean is that the races of cultivated Flax have not been bred true to certain characters of colour and of form, which char-

acters are probably a matter of indifference to the fibre-producer. The large number of processes to which Flax has to be subjected after the crop is ripe is the chief obstacle to the re-institution of this crop in Great Britain. The plants must be pulled by hand, dried, the seed must be separated by "rippling," the stalks must be retted, the retted straw dried, the woody part got rid of by "breaking," and, finally, the fibre must be cleaned.

Although the variety and tediousness of these operations must tell against the adoption of Flax-growing by the farmer, they provide Dr. Eyre with an added reason for the cultivation of this crop by the smallholder; for in their conduct a considerable amount of employment is to be found for a rural population.

It is doubtful, however, whether under present conditions these operations are likely to be undertaken by individual growers, and it is all but certain that, if Flax is to be rehabilitated as a crop, depots—as suggested by Dr. Eyre—will have to be established wherein the preparation of the fibre is carried out. Dr. Eyre suggests that Lincolnshire, Cambridge, and Suffolk, where there is among farmers an inclination to return to Flax-growing, might form a centre for the attempt, and the fact that in the past the industry survived longest in those districts which possessed central retting depots, indicates that the establishment of such depot is advisable, or even essential, for success. Given a system of co-operation in production between growers and fibre producers Flax might well become a very useful auxiliary crop to the smaller farmers and holders of this country.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will be held in the Vincent Square Hall, Westminster, on Tuesday, the 27th inst. At the three o'clock meeting in the lecture room Professor W. SOMERVILLE will deliver an address on "Some Aspects of American Forestry."

FINSBURY PARK.—All Londoners will learn with regret that an avenue of Black Poplars, comprising some thirty-eight trees 40 to 50 feet high, has been removed at the instance of the Parks Committee from the grounds of Finsbury Park. The trees which have been cut down were about forty years old, and it is no wonder that men like Mr. SMALLWOOD, who remember their planting, should deplore their destruction. The reason which is given officially for the removal of the avenue is that more space is required for games. This raises a subject too important to be discussed in the present note; it raises broad issues with which we will deal on an early occasion.

A NOVEL OBJECTION TO GLASSHOUSES.—We have just come across an amusing campaign which is being pursued in Belgium. A society known as the Friends of the Forest (connected with the Association for the Protection of Sites) considers that the increase in Grape culture under glass is likely to spoil the beauty of the landscape around La Hulpe and Hoeylaert. They have, therefore, decided to conduct a vigorous campaign against this "pest," and have arranged a grand demonstration to take place at Hoeylaert.

NATURE RESERVES IN FRANCE.—It will be gratifying to supporters of the National Trust to learn that a society—L'Association des Parcs

Nationaux—has been formed recently in France in order to carry on work similar to that of the British Society. As the first result of the efforts of the French Society an area of some fifty square miles in the French Alps has been acquired. It is to be hoped that the success with which this movement is meeting, both at home and abroad, will encourage the National Trust to yet more ambitious efforts towards preserving the amenities of our land to the people and "to their heirs for ever."

THE PRODUCTION OF SULPHATE OF AMMONIA.—Although it has had to cede first place to Germany, this country still continues to increase its manufacture of sulphate of ammonia at a rapid rate. Thus the production has risen from 367,587 tons in 1910 to 384,976 tons in 1911, and 388,308 tons in 1912. Germany's output in 1912 was 484,000 tons, and the total world production 1,325,000 tons. Of the 388,308 tons produced by the United Kingdom in 1912, no less than 287,000, or nearly two-thirds, was exported—principally to the United States, Japan, Spain, Dutch East Indies and Italy.

CRATAEGUS IN NEW YORK.—In Bulletin 167 of the New York State Museum, Professor SARGENT summarises recent investigations into the taxonomy and distribution of *Crataegus* in the State. The list of species, with descriptions of their characters, is preceded by a key.

IRON PYRITES AS A FERTILISER.—Experiments carried out by MM. VERMOREL and DANTHONY (*Journal d'Agriculture Pratique*, Nov. 20, 1913, summarised in *The Journal of the Board of Agriculture*, No. 10, Vol. 20) indicate that sulphur has a definite and beneficial effect when applied as a top-dressing to soils. When added at the rate of 45 to 90 lbs. per acre, sulphur, so it is claimed, increased the yield from plants which received also organic manure by 30 per cent. in the case of Wheat, and by 60 per cent. in that of Beans. Encouraged by these results, the authors tried the effect of iron pyrites, which, of course, contains sulphur in combined form, and is cheaper than that element. They find that a dressing of from 90-180 lbs. of pyrites with nitrate of soda instead of with organic manure leads to increases similar to those obtained by the use of sulphur. It is interesting to observe, though difficult to explain, that when either sulphur or iron pyrites is used together with nitrate of soda instead of with organic nitrogenous manures, no increase of yield is obtained.

TO CHANGE THE SEX OF DATE PALMS.—The statements made by Mr. P. B. POPEOE in an article on the Date Palm (*Tropical Agriculturist of Ceylon*, No. 6, Vol. 41) will excite no slight interest among students of genetics. The author of this article avers that of 100 Date Palms 80 are male trees. The redressing of the balance of the sexes presents no difficulty to the ingenious inhabitants of the southern oases of Algeria. They claim that alteration of sex is readily brought about by tearing off all the leaves of the footstalks when the plants are 2 or 3 years of age; the tearing being such that the median vein is split in two from the centre of the sheath of the leaf.

"THE ORCHID REVIEW."—With the January number this well-known Orchid journal celebrates its twenty-first birthday. It now appears in a new cover, with a spray of *Odontoglossum* over the title. The number contains a review of the events of the past year, an enumeration of new plants, and a variety of interesting and cultural notes, together with illustrations of nine hybrids of *Brassavola Digbyana*.

BOARD OF AGRICULTURE LEAFLETS.—The following are among the leaflets published or revised during the past year:—No. 10, *Wireworms*; No. 20, *Maggie Moth*; No. 86, *Brown Rot of Fruit*; No. 137, *Varieties of Scab in Potatoes*;

No. 169, *Cultivation of Mangolds*; No. 242, *Bacteriosis in the Potato and Tomato*; No. 253, *Isle of Wight Bee Disease*; No. 275, *Improvement of Poor Hill Pasture*.

UNSKILFUL TREE-FELLING.—At the Clerkenwell County Court recently, an action was brought claiming compensation for damage to an Apple tree and a fowls' run by fallen boughs, which resulted from tree-felling operations in an adjoining garden. The plaintiff was awarded 30s. damages and costs.

CARBON-BISULPHIDE FOR THE STERILISATION OF SOIL IN ORCHARDS.—Writing in the *Revue Horticole* (1913, p. 493), M. L. CHASSET advocates the use of carbon-bisulphide as an agent for the sterilisation of soil in orchards. He recommends the preliminary removal of fallen leaves, and then the tracing of shallow furrows (about 1½ to 2 inches in depth) on the ground after the latter has been well worked. Carbon-bisulphide is poured into the furrows from a fine rosed watering-can, and the soil raked immediately over the furrows.

AMERICAN GOOSEBERRY MILDEW IN FRANCE.—This serious pest has recently made its appearance in the centre of France. As is now well known it first appeared in Ireland in 1900, reached Russia in 1902, Germany in 1904, Sweden in 1905, England in 1906, and Belgium in 1910. In a note on the outbreak in France, M. ETIENNE FOEX (*Journ. d.l. Soc. Nat. d'Horticulture de France*, Dec. 1913) summarises the history and modes of elimination of this pest. He points out that the remedial measures are of two kinds:—(1) autumn and winter treatment; and (2) spring and summer treatment. In the former is comprised the destruction of prunings and the digging of the soil, so as to bury deeply—8 inches or more—the spore-bearing remains of the plants. In addition autumn spraying with sulphate of iron (3 per cent.) or with Bordeaux mixture is practised, the soil as well as the plant being treated. In the spring treatment sulphur pulverisation may not be practical, as it causes the leaves to fall, but spraying with liver of sulphur (potassium sulphide, a quarter to half an ounce to the gallon of water) has proved useful. The spraying should only be done in early morning or late afternoon, lest the leaves be injured, and it must be repeated at intervals, the first spraying being undertaken when the buds burst. It is claimed also that the simpler remedy of spraying with 3 grams of soda to a litre of water (about ½ oz. to a gallon) is productive of good results. Why this pest should have been so slow in invading France is at first sight not very evident; but it is perhaps due to the fact that the French people are not fond of Gooseberries, and grow them in relatively small quantities.

"THE ORCHID WORLD."—This work is kept well up to the standard of its former excellence in the matter of Orchid lore, and well illustrated with pictures of *Odontoglossum crispum* F. McBean, *O. Thompsonianum*, *Odontonia Langoi*, and a coloured plate of Messrs. SANDER AND SONS' group at the last Holland House show. A portrait is given of Sir HARRY J. VEITCH in Court dress.

MR. W. W. NAUNTON.—Horticulturists will offer their hearty congratulations to Mr. W. W. NAUNTON, of Shrewsbury, and Mrs. NAUNTON on the celebration this week of their golden wedding. Mr. NAUNTON is well known to our readers as one of the founders of the Shropshire Horticultural Society, of which for nearly forty years he was joint hon. secretary with his business partner, Mr. H. W. ADNITT. Mr. NAUNTON has been associated with other successful undertakings in Shrewsbury, notably the Kingsland Bridge Company, which has done so much to develop the corporation's beautiful estate, alongside which Shrewsbury School is situated, and he was also one of the promoters of the Shrewsbury

Electric Light Company, which was subsequently acquired by the municipality. On Monday last the employees of Messrs. ADNITT and NAUNTON presented Mr. NAUNTON with an illuminated address and handsome gifts in celebration of the happy event. In acknowledging these Mr. NAUNTON commented with pride on the fact that amongst the employees who had subscribed were some who had been associated with the firm for close on fifty years. Mr. NAUNTON a year or two ago had a serious illness, but we are glad to be able to say that at present he is enjoying excellent health. Mr. NAUNTON is an enthusiastic amateur photographer, and some of his prints have been published in these pages.

BETROOTS AND CARROTS IN RUSSIA.—According to the *Board of Trade Journal*, issued on the 15th inst., the seed of Beetroots, which root is growing in favour as a winter food for cattle, gave a satisfactory yield and sells at 26s. 3d. per cwt. The seed of Carrots for the same use experiences difficulty in finding purchasers, which is due to considerable over-production. There is a quantity of seed over from last year, which, to a considerable extent, has lost its power of germination, and this presses on the market.

OPPOSITION TO WIMBLEDON'S PROPOSED NEW PARK.—A public meeting having opposed the suggested purchase of the Wimbledon Park Estate and adjoining lands by the municipal authorities of Wimbledon for providing an open space, a special meeting of the Town Council was held on the 19th inst. to consider the matter. The Mayor presided, and stated that a poll had been demanded by about 1,000 of the inhabitants. It was stated that many who were opposed to the scheme were not residents in Wimbledon, and it was resolved to take a poll of the electors on the 31st inst. The Council decided to issue an official statement, drawn up by the Town Clerk, explaining the scope and objects of a Bill intended to be introduced in the next session of Parliament, empowering the Council, amongst other matters, to acquire the land for the proposed park.

THE CAMBRIDGE SCHOOL OF GENETICS.—Following on the establishment of the Balfour Professorship for the study of Genetics, the announcement is made that Mr. ARTHUR BALFOUR and Lord ESHER have offered to the University certain land and buildings which have been acquired and erected to serve the purposes of genetical research. The buildings include a residence (Whittingehame Lodge) for the professor and a laboratory.

NURSERY EMPLOYEES' ANNUAL DINNER.—The employes at Mr. AMOS PERRY'S nursery, Enfield, held their annual dinner on the 3rd inst. The chair was taken by Mr. AMOS PERRY. The toast of the evening, "Prosperity to Perry's Hardy Plant Farm," was proposed by Mr. REDMAN, who stated that the annual outing of the employes will be held during the summer, when a visit will be made to Marlow, and a river trip to Windsor, where dinner will be served. He asked the company to join with him in offering best wishes for health and prosperity to Messrs. A. and W. PERRY. The chairman returned thanks for the very enthusiastic reception of the toast, and expressed the great pleasure it gave him to be present at these annual dinners.

MURDER OF A PLANT COLLECTOR.—The *Florists' Exchange* states that it is reported that Mr. C. B. ROBINSON, a botanist in the science section of the Department of the Interior of the Philippine Islands, has been put to death by the natives of Amboyna Island, in the Malay Archipelago. Mr. ROBINSON, who is said to be an Englishman, was engaged in botanical researches on the island and has done considerable work

on the flora of the Philippines, being the author of several books on the subject. He was connected with the New York Botanical Garden for more than a year.

JOURNAL OF THE R.H.S. GARDENS CLUB.—This modest little brochure, now in its sixth number, consists of some fifty pages. It is a record of the present happenings of the garden staff, including the students, of the Royal Horticultural Society's Gardens. Although the journal is read by a relatively small number, it is nevertheless of interest to all engaged in gardens and gardening. Young gardeners who may lament their present hard lot should read the reminiscences of an old Chiswickian, for they will find that long hours and unsuitable bothies are no new things, and that there are compensations in an under-gardener's life, for, although "the bothies were very ancient and considerably out of repair . . . what did that matter? we were as happy as sandboys." An excellent article on "Some South African Plants" is contributed by Mr. H. G. FORSYTH, who describes many well-known garden plants growing in their native homes, and shows how much we are indebted to the flora of South Africa for many of the finest species in cultivation. The remarks on *Gerbera Jamesonii* are particularly informative, especially on how to raise the plants from seed, and the conditions best suited to their culture. Others write of their experiences in Holland, Belgium, India, California, Switzerland, and the United States. But even the stay-at-homes have much to say that is interesting, and both Mr. MACKINTOSH's story of "Gardening in the Iron Country," and Mr. A. ATHEY on "A Day in Lakeland," will be read with pleasure. Additions to the Flora of Wisley by Mr. W. V. PITTS and the illustrated article on Earwigs will appeal especially to those of a botanical or entomological mind. The volume contains a record of the doings of the various clubs at Wisley, personal paragraphs, and much else that is concerned with the family affairs of the Guild.

AFFORESTATION.—In an article written by Major H. G. JOLY DE LOTBINIERE, and published in the *Quarterly Review* for October, the author indicates the general lines on which the work of afforestating the sixteen million acres of mountainous and heath land in this country should be undertaken, and urges the necessity for immediate action. Like other experts, Major LOTBINIERE predicts a serious shortage in our timber supply in the near future unless some such scheme is attempted.

Kew Gardeners' Social Evening.—The members of the garden staff at Kew held their 17th annual social evening on the 16th inst. at the Boat House, Kew. The company numbered close on 150, including ladies, and many old Kewites. The programme included dancing, a musical entertainment in the billiard room, a smoking concert, and a billiards competition.

POWDERY SCAB OF POTATOS.—We learn from the *Florists' Exchange* that the U.S. Secretary of Agriculture at Washington has issued two orders relating to the admission of foreign Potatos into the United States. One of these orders provides for the admission of disease-free Potatos from uninfected foreign districts under proper regulation and inspection. The other order, to protect American Potatos from the powdery scab and other diseases, temporarily extends the quarantine effective since September 20, 1912, against the importation of Potatos from Newfoundland; the islands of St. Pierre and Miquelon; Great Britain, including England, Scotland, Wales and Ireland; Germany, and Austria-Hungary, to include also the rest of continental Europe and the Dominion of Canada. This quarantine became effective on December 24, 1913, except that shipments

covered by consular invoices issued on or prior to December 24, 1913, will be admitted up to January 15, 1914. The necessary conditions governing importations are (1) freedom of the country or well-defined district from the diseases quarantined against, such freedom to be determined by adequate field inspections conducted by recognised experts of the countries concerned; (2) agreement of the country or district to maintain yearly such field inspection, and to examine and certify all Potatos offered for export, in compliance with the regulations of the Department of Agriculture.

M. ALBERT TRUFFAUT.—M. ALBERT TRUFFAUT, sen., whose distinguished services to horticulture are well known, has just received a signal mark of appreciation at the hands of his colleagues of the French National Society of Horticulture. Finding himself for reasons of health unable to continue active work on behalf of the society he determined to retire from the post of vice-president. This decision, when communicated to the meeting held for the election of officers, evoked a general expression of sympathy and regret. At the same meeting M. TRUFFAUT was elected unanimously to the

M. ALBERT TRUFFAUT, SEN.
(Late Proprietor of the Versailles Nurseries.)

office of honorary vice-president of the society. During the past thirty-four years M. TRUFFAUT has held office in the National Society as secretary of the Council, and from 1890 as vice-president. In 1899 he succeeded the late HENRI DE VILMORIN as "premier vice-president." M. TRUFFAUT has been for twenty-five years the president of l'Union Commerciale des Horticulteurs et Marchands-Grainiers de France, and is known as well in this country as abroad by reason of his services to international horticulture. In order to mark their appreciation of his remarkable services the executive of the French National Society of Horticulture has decided to give a banquet in his honour on Sunday, February 15, at 12 o'clock at the Hotel Palais d'Orsay. During the course of this function a work of art will be presented to M. TRUFFAUT. Horticulturists who wish to take part in the banquet and presentation may do so on subscribing the sum of twenty francs, or if unable to attend the banquet ten francs. Subscriptions should be addressed to the secretary, M. EMILE THIEBAUT, 30, Place de la Madeleine, Paris.

IMPATIENS HERZOGII.

(See Figs. 29, 30 and Supplementary Illustration.)

IMPATIENS HERZOGII was raised at Glasnevin five years ago from seeds sent by Dr. R. Schlechter from German New Guinea, and is the best species in cultivation. Sir Frederick Moore gave one of the seedlings to Kew, where it grew well and flowered freely in a tropical house in 1910. A figure of it was published in the *Botanical Magazine* in September, 1911, where it is described as a free-growing, free-flowering species of easy cultivation. Its nearest allies are *I. Hawkeri* and *I. Holstii* (see fig. 29), both well-known garden plants, and these species also produce large scarlet flowers. Of these three, *I. Hawkeri* is the least manageable, mite and other troubles often spoiling it; but the other two are quite as decorative and much better natured. A fourth species, *I. Sultanii*, ought to be mentioned here, as it possesses some of the qualities found in the three already named.

Impatiens is a very large and remarkably varied genus. It includes annuals and perennials, some large shrubs with fleshy stems, others wide-spreading, bushy herbs, and many diminutive, uninteresting weeds. The species occur in most parts of the world, the best-known, perhaps, being *I. balsamina*, an Eastern plant, the parent of the common garden Balsam. The largest species is *I. Oliveri*, from Uganda, which at Kew forms bushes 9 feet high and the same in diameter, with stems as thick as a man's wrist, evergreen leaves, and rose-pink flowers 2½ inches in diameter. This plant is always in flower. It has been used with fair success as a summer border plant. There is no better plant for a large conservatory, and as it is very easy to multiply by means of cuttings or seeds, which it produces very freely, it may be said to have come into our gardens to stay. Another remarkable Balsam is *I. mirabilis*, from Sumatra, which has a trunk-like stem, "as thick as a man's leg," crowned with a tuft of large, fleshy, cabbage-like leaves a foot long, and bearing erect racemes of golden-yellow flowers, curiously bellied and spurred. It was in cultivation at Kew about twenty years ago, but it did not live long, probably because it longed for the limestone rocks on which it was found by Mr. Curtis when on a collecting visit to Sumatra. Another noteworthy Balsam is *I. grandiflora* (see fig. 30), a native of Madagascar, which was in cultivation at Kew twelve years ago, when Sir Joseph Hooker described it as "by far the largest-flowered Balsam hitherto discovered." It had stout, terete branching stems, leaves 6 inches long, and axillary flowers 3 inches long and as much wide, succate and hook-spurred, rose-pink with purple blotches, not unlike a very large *tropeolum* flower, but, of course, much more fleshy. There is no end to the story of the Balsam family. Its botany occupied the attention of Sir Joseph Hooker during the closing years of his long life, and he found the genus a source of absorbing interest. Although the species (there are over 500 in Asia alone) show such a wide range of variation in stature, habit, and foliage the stamp of the family is plainly evident in the shape of their flowers, all of them having the hollow spur or sac, and the column-like arrangement of the stamens and stigma. Another peculiar character is that of the spring-like behaviour of the ripe fruit when touched.

As a garden plant first place must be given to *I. Herzogii*. When well-grown it is a bushy, leafy specimen 18 inches to 2 feet high, and the bright glistening scarlet flowers are arranged in axillary clusters, as many as six or eight of them all open together on a single branch. The pity of it is the plant is too tender to thrive out-of-doors here in summer, for it has been tried as

a bedding plant at Kew, but, like its cousins, *I. Sultanii*, *I. Holstii*, and *I. Hawkeri*, which were also tested in the same way, it could not stand the spells of low temperature which occur often enough even in summer. As a warm house plant, however, *I. Herzogii* is perfection. It only requires to be known to become generally popular.

SCOTLAND.

THE PROPOSED WINTER GARDEN FOR EDINBURGH.

THE scheme for the building of a Winter Garden in the Princes Street Gardens, Edinburgh, is meeting with a large amount of opposition in influential circles in Edinburgh, and opinion on the subject is sharply divided. The Earl of Rosebery and Lord Dunedin have both written condemning the proposal. An alternative proposal, to form a sheltered loggia, next to Princes Street, has been made, and the latest suggestion is to plant the Castle Rock with flowers. Suggestions for other sites are also being made. The opposition has had the effect of bringing again to the front the suggested removal of the fruit and vegetable market to the old gasworks site, and the conversion of the Waverley Market into a place of resort during wet weather.

EDINBURGH UNIVERSITY FORESTRY LECTURES.

THE Highland and Agricultural Society of Scotland, which has for some time given the sum of £50 per annum towards the salary of the lecturer on forestry in the University of Edinburgh, has decided to withdraw the grant, on the ground that other public bodies were taking such work out of their hands. The lectures will not be likely to suffer from this, other support being forthcoming.

TREE PLANTING IN EDINBURGH STREETS.

A PROPOSAL that trees should be planted along some of the streets in the Dalry district of Edinburgh has been favourably received, and the committee has agreed to recommend that the work be carried out.

THE HIGHLAND SOCIETY.

THE Highland and Agricultural Society of Scotland has again agreed to give two medals each to four Scottish district shows for cottage gardens. *Corres.*

M. HENRI CORREVON.—The 27th volume of our Paris contemporary *Le Jardin* is dedicated to this well-known lover of Alpine plants. M. Correvon is 59 years of age, and was born at Yverdon, Canton of Vaud, Switzerland. His family is an ancient one, dating back to the year 1142, and derives its name from the village of Correvon, near Yverdon. At 16 years of age he went to Geneva to learn gardening. From 1871 to 1874 he was at Froebel's, at Zurich, where the first Alpine plants raised for sale on the Continent were grown. In 1874-75 he went to Germany, and in 1875 to Paris, and worked at the Jardin des Plantes, returning to Switzerland the following year, where he started a nursery for Alpine plants. A hailstorm devastated the country and brought ruin in its track, and he consequently moved to Geneva. There he founded the Jardin Alpin d'Acclimatation, the first of its kind. He also started the Association for the Protection of Alpine Plants, of which he was President for 25 years. From that time his activity in his favourite pursuit developed rapidly, and he founded the Alpine Gardens at Val d'Anniviers, La Linnea, Les Rochers de Naye, La Chanousia, Le Petit St. Bernard, and La Rostania, while Champrousse and Le Lantaret were the results of lectures by him at Grenoble. About 1882 he began to contribute to various English and American journals, and as an author it may be mentioned that his eighteenth work has recently been published. In 1903 he started the Alpine garden Floraire, and last year a smaller one called Florarina, not far from and facing Mont Blanc.

VEGETABLES.

FORCING FRENCH BEANS.

FEW forced vegetables are more appreciated than French Beans, which furnish a choice dish when other vegetables are not very plentiful. Unless suitably heated houses are available I do not recommend the forcing of French Beans until after Christmas, but in January, with the lengthening days, they may be grown in a house having an atmospheric tempera-

can be afforded the plants. I have grown it with excellent results trained on wires, which afterwards supported a late batch of Cucumbers. If an upright wall is available better results would be obtained by training the Beans up strings in a similar manner to Smilax. I usually sow 8 to 10 seeds of dwarf varieties in each 9-inch pot, which is half filled with fresh loam, to which is added a little leaf-mould or well-decayed manure to keep it open. Many people use discarded potting soil in the belief that anything is good enough for Beans, but I find that few crops pay

FIG. 29.—*IMPATIENS HOLSTII*: A TROPICAL AFRICAN SPECIES WITH SCARLET FLOWERS. (See p. 68.)

ture of 60° to 65°. Pods will be ready for gathering early in March, and by making sowings fortnightly a succession may be easily maintained until the out-door plants are in bearing. The Climbing French Bean is useful where the shoots can be trained to wires or strings. The pods are long, straight, and hang in clusters, the plants continuing in bearing for a very long time. I consider this is the most economical Bean to grow if sufficient head room

better for good treatment. When the seedlings are tall enough to permit of top-dressings being applied, I thin the plants out to 5 or 6 per pot, and fill the latter with loam and decayed manure mixed. Up to this stage the climbing varieties receive similar treatment, but three plants per pot are as many as can be grown with success. After top-dressing, the tall varieties should be placed in the position they are to occupy permanently. The dwarfs, and of these I find a

batch of two dozen pots generally sufficient, should be staked either with tall Birch twigs or four sticks, around which raffia tape or string is tied. I prefer the former system as being much neater. Plenty of light and air must reach the plants, and the syringe must be used twice a day at least, and oftener on bright days. When the flowers are open a slightly drier atmosphere is advisable, but immediately the pods have set the syringing should be resumed, otherwise thrip and red spider will quickly infest the plants

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

CHRYSANTHEMUM MADAME CASTEX DES-ORANGES (see pp. 28, 41).—A few more words and I think this question may be considered as settled for all time. Since writing my former article I have communicated with Boucharlat's son-in-law and explained the question under discussion. His reply will be of great interest to Mr. Jenkins and others who know the flower and

When twenty-five years ago I gave you particulars about it, he told me exactly the facts, but he is now dead. But I remember that the seed was sved at the end of the year 1872 and sown in 1873. The plant flowered the same year (1873), and was probably sold as a novelty in the spring of 1874. It was named after the wife of the great Lyons artist, Castex Desgranges, who often came to pay M. Boucharlat a visit and to get flowers from our nursery in order to paint them. This celebrated artist is now the director of the School of Fine Arts at Lyons, and is about seventy-eight years of age." So far as is possible this seems to be the fullest and most authentic information, direct from the fountain-head, that we can obtain and should be taken note of by those who deal with historical matters relating to the Chrysanthemum. In this flower, as with others, there are unfortunately too many writers who, disregarding any attempt at original research, too often adopt previous authors' errors, and thus help to perpetuate them. In floricultural history there are many such; they are to be found repeated over and over again by writers who never take the trouble to verify dates for themselves. A glaring instance of this may be found in the oft-repeated statement that the Pompon Dahlia was originated in 1808. A little independent search through the available records would soon show that it was not known till about fifty years afterwards. But that is another story. *C. Harman Payne.*

LILIUM PARRYI (see p. 34).—The conditions under which this Lily grows in its Californian home have been admirably described by Mr. Carl Purdy and often repeated; but following Mr. Groves' interesting review of the Lily season of 1913 and his special reference to this species, the following note, which we had last year from Mr. Purdy, will be read with interest: "I am at last making *Lilium Parryi* a success. It is only light shade, a cool place and a light, loose, moist, but not boggy, soil that the plants need. After seeing them at home in South California two years ago I saw that anything like bog conditions were a mistake. I have one fine bed of young ones that was quite dry all summer." *R. Wallace and Co.*

TRICUSPIDARIA LANCEOLATA (see p. 25).—The beautiful coloured plate of this fine Chilian plant—better known perhaps by its synonym *Crinodendron Hookerianum*—published on the 10th inst., reminds me of a splendid example of it that grew in the old Parsonage garden at Ryde, and of which the late Rev. H. Ewbank was justifiably proud. While not comparable in its dimensions with the example measured by Mr. Bean at Kilmacurragh, the Ryde specimen was a particularly compact, free-flowering one, and when I last saw it, some three years ago, would be 9 feet or so in height, and a dozen or more feet through. The specimen, grown from a small plant, greatly treasured by Mr. Ewbank during his life-time, and since carefully tended by his daughters, was a picture of rare beauty when adorned with many hundreds of the drooping crimson-scarlet flowers so faithfully depicted in the coloured plate. The Ryde specimen was growing in a mixture of leaf-mould, peat, and light loam—the last in a quite small proportion—and gave no sign of a certain leaf rustiness which seems more or less inseparable from the species when cultivated in gardens more inland. Whether this rust is of a fungous nature or not I am not sure, but an apparently similar rust on *Carpenteria californica* in the same garden quite crippled the growth of this handsome flowering shrub. The *Crinodendron* at Ryde ripened seeds with comparative freedom, and I have on several occasions brought away supplies, but was never able to get them to germinate. I believe others have had a similar experience. The seeds are exceedingly hard-coated, and possibly "chipping," as is done in the case of Sweet Peas, or "bush-firing," which is said to hasten the germination of other hard-coated seeds, would have to be resorted to to bring it about. I confess, however, I have not tried either operation on the plant under notice. Seed-raising, however, is by no means an essential method of increase in this case, since every shoot that comes in contact with the soil—and many others separated therefrom by one or

FIG. 30.—IMPATIENS GRANDIFLORA.

Axils of upper leaves are bright deep rose, the petals being conspicuously blotched with deep blood red, the upper petal alone being unspotted.

(See p. 58.)

and soon ruin the crop. White fly is sometimes troublesome, but this can be destroyed by fumigating with a preparation of nicotine. From this stage onwards the roots should be fed liberally, stable dung or manure from cow-sheds being suitable. I prefer to substitute for this occasionally an artificial fertiliser. For the later batches a lower temperature is more desirable. Of the many varieties I have tried Progress stands pre-eminent. *F. A. Edwards.*

its value as the forerunner of the early-flowering Japanese section. This is what my correspondent says: "In reply to your favour, I can only confirm what I wrote to you twenty-five years ago or thereabouts. Unfortunately, it is far less easy for me to state precisely the exact date when the *Chrysanthemum Mme. Castex Desgranges* was sent out by M. Boucharlat aîné for the following reason: Between 1870 and 1875 I was doing my military service, and it was during that period that our head man, M. Jules Charton, raised it.

two inches, will develop roots from the under sides of the branches as freely as the well-known Portugal Laurel in like circumstances. Hence, seeing that the plant spreads quite near to the ground, and also in a lateral direction, there should be no difficulty in securing an abundant stock where good plants already exist. Should the above remarks on the difficulty of seedling raising meet the eye of anyone who has successfully raised the plant from seeds I should be glad to know if it has been achieved by the adoption of any special method. *E. H. Jenkins.*

MICE DAMAGING SHRUBS (see p. 32).—If Mr. Grant will procure some gin-traps and bait them with Hemp seeds he will soon catch all the mice, as they cannot resist eating the Hemp seeds. Put two traps into drain pipes, one at each end, with a few seeds between the traps and examine them night and morning. If the Ivy will cover the traps he may discard the drain pipes, as the latter are used to hide the traps and seeds from small birds. Wooden and wire traps in the open are often carried away short distances by owls, hence another value of using the drain pipes. *Jas. Hamilton, Gattonside, Melrose.*

TIMBER FOR CLOG SOLES (see page 4).—Your correspondent, *A. D. W.*, errs greatly in his prices of timber for clog-making. I have been in the trade for upwards of thirty years, and have worked in the business in Scotland, England, Ireland and Wales, but in no part have I known Alder to realise 9d. or 10d. per cubic foot. I herewith quote prices paid in my undertakings in various parts of the kingdom:—Shropshire, 6d. to 7d.; Herefordshire, 6d. to 7d.; North Wales, 6d. to 7½d.; South Wales, 4½d. to 6½d.; Yorkshire, 6d. to 8½d.; Scotland, 8s. to 10s. per ton of 30 cubic feet; Ireland, 6s. to 10s. per ton of 30 cubic feet; all wood felled and under bark. German Alder may be much more easily worked, but is too soft and spongy. It is also inferior in its lasting qualities when converted into the finished article, the "clog." As for a man making twenty pairs in the hour, I have yet to meet him. That man need never lack a situation in the trade. Twelve pairs made in the hour is good average work, and that when the lengths are cut off and roughly prepared for the dressing bench. Ireland takes second place in *A. D. W.*'s return as an Alder or suitable timber-producing country for clog-making, but in what part of Ireland could he get 3d. or 4d. per sack for refuse chips, seeing the Alder grows in bogs or in the vicinity of bogland? Finally, he over-estimates the number employed at clog-making: but I agree in stating that more attention ought to be given in planting up some of our water-logged districts with Alder, and in a decade or so there would be no demand for foreign supplies of this wood. *William Nuttall, Dromod, Drumlish, Co. Leitrim.*

—During a period of ten years I got 10d. per foot for Alder and Birch of good quality in Carnarvonshire, North Wales. At a sale in Leicestershire a similar price was obtained lately. Of course, the price varies according to the accessibility of the timber. *A. D. W.*

JASMINUM OFFICINALE FRUITING.—Your correspondent, writing in the issue of the 10th inst. (p. 29), states that he cannot tell if the seed of *Jasminum* will germinate in this country. Two years ago I sowed seeds and they produced a good pan of seedlings that grew away quickly. *Frances A. Geoghegan, Eversham, County Dublin.*

WINTER-BLOOMING ROSES.—Nothing in this anomalous autumn and winter has been more remarkable than the persistent flowering of Roses of various kinds, in spite of cold winds, frost, and a little snow. At least, in fifty years' gardening I cannot remember anything like it. The following varieties have now (January 19) really well-formed, half-opened, or even in two or three cases (such as Pharisæa) fully-opened blooms of good form: Bardou Job, General Macarthur, Laurette Messimy, China, and perhaps two or three more. And this in the open border in the very middle of Kent, and 350 feet above sea level, with the thermometer since the 11th inst. ranging from 25.3° in screen lowest to 39°

highest, and N.E. winds up to a "moderate gale." Can anybody explain this? I doubt the mild autumn being sufficient to account for it. *Alfred O. Walker, F.L.S., Ulcombe Place, near Maidstone.*

FAILURE IN CHRYSANTHEMUMS.—After careful examination of soil, plants, etc., by experts the principal trouble in the failure of my late Chrysanthemums was eelworm. I was reading Mr. C. Robinson's report under above heading, and he is right in one respect, that of housing early. I did do so—that is, in September—dreading a recurrence of early frosts, as in 1912, but I had no heat on them; on the other hand, plenty of air. The only manure used was half a load of cow manure on about 10,000 plants. While digging up the plants from the borders I find the bark is eaten clean away, causing loss of base cuttings. I may add that I am a firm believer in firm potting of Chrysanthemums, using a rammer for the purpose. We are now sterilising all soil and hope to eradicate the trouble in future. *W. E. Kearns, Horsforth, Leeds.*

ROSES IN DECEMBER.—I enclose a photograph (see fig. 31) of a vase of Edu Meyer Roses picked in a Wicktownshire garden, Corn-

FIG. 31.—ROSES GATHERED ON DECEMBER 18 LAST.

wall, on December 18 last.—*D. W. R. Carrick-Buchanan, Corsewall, Stranraer.*

THE RAINFALL IN 1913.—The total rainfall for the year at Orwell Park amounted to 22.28 inches; the number of days upon which rain was measured were 188. January, with 3.61 inches, was the wettest month, whilst August was the driest with 0.60 inch. *A. Turner, Orwell Park Gardens.*

—The rainfall in these gardens during 1913 amounted to 41.01 inches, or 3.55 inches more than the average of the past six years. January, March, April, May and October were all wet months, but December, with 2.54 inches, was drier than for six years past. Rain was recorded on 232 days, or seven more than the average. The amount of rain recorded to end of May was within 1.48 inches equal to that usually gauged in eight months. July, August and September were very favourable for harvest work. The heaviest fall in 24 hours for the past six years was recorded on October 5, when 1.86 inches fell. The range of temperature for the year, at 4 feet from the ground, in shade, was 83° on July 29 and August 3, and 14° on December 31. The last frost in May was on the 16th and the first on October 22, or ten days less than usual. The mean temperature of October, November, and to December 24 were above the average; on the last date we had snow for the first time this season. During December a large number of hardy plants were in flower, including *Cytisus multiflorus*, *C. Scoparius*, *Clematis Duchess of Albany*, *C. Jackmannii alba*; Webb's Prolific Cob Nut (female blooms expanded on the 19th); *Gentiana aculais*, *Galanthus nivalis*, *Jasminum nudiflorum*, *J. Wallichianum*, *Kerria japonica*, *Kniphofias*, *Omphalodes verna*, *O. v. alba*, *Primulas* in variety, *Papaver nudicaule*, *Pear Beurré Clairgeau* in an orchard, *Roses*, *Solanum jasminoides*, *Strawberries* in several varie-

ties, *Spiræas Marie Van Houtte* and *Reecesiana*, *Saxifraga apiculata*, *Scabiosa caucasia*, *Tunica Saxifraga* and *Mignonette*. The "Kaffir Lily," *Schizostylis coccinea* has been particularly useful and floriferous this late autumn and early winter. *John Edwards, Sylfaen Gardens, Welshpool.*

JOURNEYMAN GARDENERS AND LOW WAGES.—In reading the remarks of your correspondents on this subject in the issue for January 17, I did not notice any reference to the subject of young gardeners paying a premium to the head gardeners. To my mind this is most objectionable, and I do not believe in premiums of any kind. I have had many offers of premiums made to me during my forty-four years' experience as a head gardener, but I have never taken money from any young man who has served under me. I prefer to stand perfectly independent of any such consideration. Thus no distinction whatever enters into the question either in engaging or in the leaving of a young gardener. Premiums were more frequently paid in the past than at the present time. No doubt there are still survivals of this system, but the sooner it is abolished the better will it be for all who are concerned with the conduct of gardens. It has been the custom in some establishments to notify a young man just before he has completed his term of two years that he would be expected to leave when his two years had expired. This leaves the place open for the gardener to take another premium and a younger man with less experience is consequently engaged. I do not find any difficulty in obtaining reliable young men, and, in my opinion, the standard is quite as high, if not higher, than it was in years gone by. If our young gardeners would apply themselves more closely to thinking out various problems with which they come into contact the better would it be for them. *Jas. Hudson, V.M.H., Gunnersbury House Gardens, Acton.*

—I have been somewhat interested in the correspondence regarding the scarcity of young men for garden work. I don't think we have to look far for the cause. A friend of mine recently applied to one of our leading nurseries for a couple of young men. He received a reply saying that they had none on their books, and that young men were not such fools as to go in for gardening nowadays. If this scarcity should be the means (as I believe it will be the only means) of getting better wages and conditions for young gardeners, and also for head gardeners, then I for one hope it may long continue, for there is still plenty of room for improvements. Surely those who now complain about the scarcity of young men do not want to see a return of the days which existed a few years ago, when head gardeners put in advertisements thanking the 60, 70, or 100 applicants for the situations advertised by them? No; let us hope those days have gone, and may it be long years before they return again. For my part, I am always pleased and ready to help any young fellow that has the grit to go out and try his luck in our Colonies, for surely it is better for our Empire that our Colonies should be populated by our own countrymen than those of foreign nations. And what are the prospects for those who take up gardening as a means of living in this country? That there are some really good situations for gardeners no one can deny, but unfortunately there are not enough to go round, and for every good head place advertised to-day I venture to say there will be well over 100 applications, and most of these from good men who have had years of training and sound, practical experience. What of the majority of those young lads who start as outside garden lads? How many of these who, after years of hard and continuous work for what has been in the past scarcely a living wage, are able to secure one of these "plums"? One sometimes hears a complaint that young men are all anxious to work under glass. One of the reasons, in my opinion, is that in the past it was the one who had the best experience and knowledge of inside work who generally stood the best chance when after a head place. But I do not think myself that that will be the case in the future. The gardener whose hair turns grey early in life or happens to be blessed with five or six children will find these are drawbacks in securing a good berth in this country. Again, when a gardener reaches the age of 45 or 50

SOCIETIES.

ROYAL HORTICULTURAL

Scientific Committee.

JANUARY 13.—*Present*: Mr. E. A. Bowles, M.A., F.E.S. (in the chair), Rev. Canon Fowler, Messrs. W. Fawcett, G. Gordon, J. Fraser, W. E. Ledger, W. Hales, A. Worsley, R. A. Rolfe, and F. J. Chittenden (hon. secretary).

Hybrid Scented Pelargoniums.—Mr. J. FRASER continued his remarks regarding the origin of garden forms of scented-leaved Pelargoniums, dealing with the group to which *P. arifolium* belongs, and exhibiting specimens from the Wisley collection in illustration of his remarks.

Polypodium × Schneideri.—Mr. W. HALES showed a fruiting frond of this hybrid Fern, with three pinnae (very like those of *Polypodium aureum* in form) bearing numerous sori. This hybrid is derived from *P. aureum* × *P. vulgare elegantissimum*, and its spores, which are only very rarely produced, have hitherto proved infertile.

Variation in Galanthus Elwesii.—Mr. BOWLES exhibited several plants of *Galanthus Elwesii* in flower, selected from those shown by Messrs. Barr and Sons and Mr. G. Reuthe, and grown from imported bulbs. They showed remarkable variation in form of flower, and especially in the markings of both inner and outer perianth pieces.

Aristolochia sempervirens fruiting.—Mr. BOWLES also exhibited a fruit with ripe seeds of this plant from his garden at Waltham Cross.

HORTICULTURAL CLUB.

PLANT COLLECTING IN NEW GUINEA.

JANUARY 13.—On the above date, at the Hotel Windsor, this club held its usual monthly dinner, Sir HARRY J. VEITCH presiding over a company numbering 40. Subsequently, as is the custom of the club, a lecture was given, this time by Mr. A. F. R. WOLLASTON, who gave a most interesting account, illustrated by lantern-slides, from photographs taken by himself, of some results of plant-collecting in New Guinea. The description of the difficulties attending the exploration of an equatorial and mountainous country, densely covered by vegetation of the most luxuriant kind, plainly indicated, with the aid of the slides, the reasons why such a country remains practically virgin and unexplored. This is the more to be regretted from the botanical and horticultural point of view, since it was abundantly proved that where access was possible the flora is found to be abundant and beautiful, though mainly arboreal. The pioneer in this direction is, however, still more handicapped by the lack of transport facilities, there being no roads when once the coast was left, and, moreover, the plants or seeds collected had subsequently to suffer long periods of great heat, drought and its opposite, humidity, on the return journey, owing to the varied climatic conditions through which they had to pass en route. As one result of this nearly all seeds collected failed to germinate on arrival here. Many of the plants, however, carefully installed in Wardian cases, were preserved. Specimens for herbaria are also difficult of preservation, owing to constant humid conditions, under which they rot. The question of seed preservation became, indeed, one of the main questions involved in a subsequent discussion. Professor KEEBLE suggested that the reason of the general failure is probably that seeds produced under equatorial conditions, in which the climate was practically the same all the year round, without those marked seasonal changes which characterise other regions, are accustomed to germinate as soon as they are scattered, and hence are not endowed with a capacity for rest or dormancy during a period which permitted of their transport in a dormant state for several months. Mr. WOLLASTON himself, while recognising this possibility or probability, considered it might also be due to the scarcity, which he had particularly observed, of insect life necessary with most plants to ensure fertilisation of their seeds. Thus

his knowledge should be, and no doubt is, even greater than at 30; but I venture to say that, however thrifty he and his wife have been in the past, he will find his bank account getting near low-water mark should he by any chance get out of a place and stand out for another good "plum." I admit that this is not always the case, but these have been and still are some of the causes which make young men think twice before sticking to gardening as a means of livelihood. Again, what some of our heads do expect for their 16s., 18s., or £1 and bothy can be judged by scanning the advertisements of the garden papers. One can safely say that should these young men fulfil all the different requirements they ought to be applying for the head place. That there are indifferent under-gardeners no one can deny, but so there are indifferent head gardeners. *Agra*.

—I should like to point out that it is not only journeymen who are paid low wages, for I have found that in some cases they are paid more than responsible gardeners. I give here my own case. I was brought up in a fruit and vegetable garden, was sent out for two years' training under a good head gardener in a large establishment, for a third year under another good head, and then had two years with a landscape gardener. I have been in my present situation for six years, and am responsible for the glass, fruit, vegetables, lawns, flower borders, Roses, and rock-gardens. I hold the Royal Horticultural Society's certificate in Horticulture. My wages, be it noted, are 23s. 6d. a week, out of which I have to pay 8s. for rent. Yet I know gardeners of the most ignorant description who are getting 22s., 28s., or 30s. a week, with cottage. The only remedy for this state of affairs is for employers to insist upon all their gardeners having passed an examination in Horticulture (senior or junior, as the case may be), which will at least ensure that they have a certain knowledge of botany and chemistry—qualifications which are essential to a really intelligent grasp of the art of gardening.—*C. H.*

—If *Contented Journeyman* is contented on his wage of 18s. per week and bothy let him remain so. If a man possesses a good knowledge and is skilled in his work, and can be trusted to do it without much supervision, he is certainly worth 22s. per week at the least, with bothy. Why should young men spend their time and money from youth to early manhood studying the science and practice of horticulture for a labourer's wage on the chance some day of becoming a head gardener at 25s. to 30s. per week with house, when in the trades he can command from 25s. to 36s., and more, per week soon after he is twenty-one years of age? If *Contented Journeyman* considers that 18s. per week is equal to 25s. in other trades let him prove it; he seems to possess little or no knowledge of the condition of things in his own profession. Will he kindly show how 18s. per week is equal to 25s. in the following instances? Two or three young gardeners living in a bothy and receiving 18s. per week each (the foreman receiving 19s.) have to take duty in turn and receive nothing extra for this work, whilst a labourer receives 18s. per week and stops work at midday on Saturdays. Will *Contented Journeyman* tell us who is the better off under these conditions? He speaks of the steady employment in gardening, which is true as a rule; but employment in gardening fluctuates, as in every other profession. *Contented Journeyman* reminds us we must not forget that gardens are hobbies. In that I differ, for they are a necessity; but granted that they are kept up for a hobby, does that give the owner the right to under-pay his gardeners? I would prefer to pay men according to their ability. Some journeymen are dear at any price; some there are who lack both knowledge and enthusiasm. Take the wages of head gardeners and compare them with those paid in trades. Look at the hours of care and watchfulness, the knowledge they must possess for such miserable remuneration. Let the head gardener get thrown out of employment, then where is he? I know there are some splendid employers, but they are exceptions. Gardening is, as Mr. Norris says, a great and honourable calling, and the literature appertaining to it probably excels all others. And yet members of this great and honourable profession have little or no social standing whatever. Why? *Mayflower*.

he thought that many of the seeds might be infertile. The natives of the unexplored regions were few, and were only found in scattered villages. They constitute practically a surviving remnant of the people of the Stone Age, since they use no metals, and their weapons and tools are all of stone; fire is only obtained by friction; and their food is mainly vegetable. They cultivate the Banana, but on very primitive lines, and Tobacco also, which they utilise for smoking in a rude cigar form. Amongst the possible acquisitions of a future expedition is a magnificent climbing Rhododendron, robust and rampant, and very floriferous, bearing huge bunches of large and brilliantly coloured flowers. The collected plants, however, were accidentally lost on the return journey, and the seed failed when sown. Nearly all the photographs showed peculiarly precipitous views of densely-wooded mountains, largely of limestone, rising in some cases to over 16,000 feet. Numbers of Orchids were noted, a new *Thalictrum*, *Sarracenia*, and other plants; but, for the reasons given, the harvest of living acquisitions which reached here was unhappily but scanty. The difficulties of exploration may be imagined from the fact that the whole of the food required for the explorers and their attendants for several months had to be carried with them, and the return could only be effected by the Dutch Government arranging to send another expedition out to meet them at the end of the period fixed for return.

NATIONAL CHRYSANTHEMUM.

JANUARY 19.—A meeting of the Executive Committee was held on this date at Carr's Restaurant, Strand, Mr. T. Bevan presiding.

It was announced that the subject of Single Chrysanthemums will be discussed at the Conference to be held on December 9 in three papers, dealing (1) with the culture; (2) with the selection of the best up-to-date varieties; and (3) suggestions to future raisers of singles. It was stated that 10,060 visitors were present at the October show, held at the Crystal Palace, and 20,206 at the November show. The Floral Committee awarded 30 First-class Certificates and 19 Commendations to novelties in 1913. The annual meeting will take place on February 2 at Carr's Restaurant, Strand, at 7 p.m.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

JANUARY 12.—The monthly committee meeting of this society was held in the R.H.S. Hall, Mr. Arthur Bedford in the chair. Before the commencement of the business a vote of condolence with the widow of the late Mr. W. Collins was passed in silence. Nine new members were elected. The sick pay for the month on the ordinary side amounted to £58 14s. 8d., and on the State side £28 10s., whilst maternity claims totalled £4 10s. One member was allowed to withdraw interest from his deposit—viz., £2 12s.; the sum of £86 6s. 8d. was passed for payment to the nominee of a deceased member, and one member was allowed two weeks' pay from the Convalescent Fund. The treasurer gave his financial statement, which was very satisfactory, the trustees being empowered to invest a further sum. Owing to the date of the annual meeting falling on Easter Monday the committee decided to hold it on March 9 instead.

ROYAL CALEDONIAN HORTICULTURAL.

JANUARY 14.—The annual general meeting of this society was held in Dowell's Rooms, Edinburgh. Mr. D. W. Thomson, Vice-President, presided, and there was an attendance of 30.

The abstract of accounts submitted to the meeting showed a balance of income over expenditure of £70 16s. 3d., and that the funds had increased by £47 19s. 3d. It was announced in the report by the Council that a rock-garden competition had been introduced into the forthcoming schedule of prizes, and that the dates of the shows had been fixed for April 29 and 30, and September 9 and 10.

Reference was made to a rumour that there was an intention to abolish the section of Economic Botany in the Royal Scottish Museum, and a small committee was appointed to keep in touch with the matter and to watch developments.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

JANUARY 21.—As these pages are being passed for press we learn the result of the election of pensioners to the Gardeners' Royal Benevolent Institution.

The chair was occupied by Sir Harry J. Veitch, chairman and treasurer, and the attendance numbered twenty-four. The secretary, Mr. G. J. Ingram, having read the minutes of the last annual meeting and the annual report for 1913, the chairman referred to some of the more important items in the balance-sheet, more especially to the large donation of £1,532 1s. 7d.

RESULT OF ELECTION.

Table with columns: Name, Age, No. of Votes. Lists names like Sims, Jesse (77, 4,199) and Greenfields, William (78, 3,628).

Following the declaration of the Poll, Mr. Arthur W. Sutton kindly promised to make a donation of £20 to Walter Crossman, aged 66. Mr. Geo. Monro also made a contribution of £10 for the benefit of John E. Ellis, aged 65.

THE SPEAKER TO PRESIDE AT ANNUAL DINNER.

The Chairman announced that the Speaker of the House of Commons, the Right Hon. James William Lowther, P.C., had consented to preside at the next Festival Dinner, which will take place on Friday, June 26.

CEMETERY SUPERINTENDENTS'.

JANUARY 13.—A meeting of the above Association was held on the 13th inst. at the Hammer-smith Town Hall, the President, Mr. J. D. Robertson, in the chair.

The Secretary submitted the names of 25 applicants for membership, and these were duly elected.

The Deaths Registration and Burials Bill will come up again for further consideration in February. The Annual Convention was arranged to be held in July, at a place to be decided later.

PUBLICATIONS RECEIVED.—Maize : Its History, Cultivation, Handling, and Uses. By Joseph Brtt-Davy. (London: Longmans, Green & Co.) Price 25s. net.—Report on the Agricultural Department, St. Vincent, 1912-13. (Barbados: Imperial Department of Agriculture for the West Indies.) Price 6d.

MARKETS.

COVENT GARDEN, January 21.

Cut Flowers, &c.: Average Wholesale Prices.

Table of Cut Flowers prices including Arums, Azalea, Camellias, Carnations, Chrysanthemum, Daffodils, Gardenias, Liliun auratum, Lily-of-the-Valley, etc.

Table of Orchids and other flowers including Orchids, Pelargoniums, Poinsettias, Roman Hyacinth, Roses, Snowdrops, Spirea, Tulips, Violets, etc.

Cut Foliage, &c. Average Wholesale Prices.

Table of Cut Foliage prices including Adiantum Fern, Agrostis, Asparagus plumosus, Carnation foliage, etc.

Table of French Flowers and other foliage including Croton foliage, Eulalia japonica, Moss, Myrtle, Smilax, etc.

Guernsey and Scilly Flowers.

Table of Guernsey and Scilly flowers including Anemone fulgens, Narcissus, Ranunculus, etc.

Table of other flowers and foliage including Narcissus Continued, Ranunculus, Roses, etc.

very few Parma Violets are on sale. A few bunches of Lilac are received daily, but larger supplies are expected shortly from Holland. White Lilac is more plentiful than the coloured varieties.

Fruit: Average Wholesale Prices.

Table of Fruit prices including Apples, Apricots, Bananas, Cranberries, Dates, Figs, Grapes, Lemons, Peaches, etc.

REMARKS.—English Apples of the varieties Blenheim Pippin, Bramley's Seedling, Dumelow's Seedling (Wellington), and Newton Wonder are still available. Oregon and Wenatchee Apples in boxes continue a good supply.

Vegetables: Average Wholesale Prices.

Table of Vegetable prices including Artichokes, Asparagus, Beans, Cabbages, Carrots, Cauliflowers, etc.

Table of Potato prices including Bedford, Blacklands, British Queen, etc.

REMARKS.—Trade remains fairly good, and prices are about the same as those of last week. Consignments this week have shown a large increase, consequently stocks in London are heavy.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 17, is furnished from the Meteorological Office:—

GENERAL REMARKS.

January 20, 1914.

Barometer, Wind and Weather.—Throughout the whole of this week the weather was influenced by a large anticyclone, originally of great intensity, which advanced over the United Kingdom from Northern Europe. The region of highest pressure was situated, as a rule, over our northern districts, and the prevailing winds were therefore from some easterly quarter (north-east to south-east), gales from the north-eastward being experienced in the early part of the week on our East and South-East Coasts.

Over the country generally the weather was very dry, and in Scotland North, Ireland South and the English Channel the amount of bright sunshine was in excess of the normal. Over the more northern and eastern parts of England showers of snow or sleet, followed by cold rain, were, however, frequent, and at the close of the week rain was experienced also at most of the Scottish stations. Frost occurred in all districts, the lowest temperatures in the screen being 17° at Fort Augustus and Nairn, and 18° at Balmoral and Kilmarnock. Over a large portion of England and Ireland the sheltered thermometer did not fall below 25°, but on the surface of the grass a temperature of 17° was recorded as far south as Wisley.

THE WEATHER IN WEST HERTS.

Week ending January 21, 1914.

Ten Days of Uniformly Cold Weather.—The past week was cold throughout, and more particularly was this the case during the daytime. The present persistently cold weather began ten days ago, and has been more noticed than it otherwise would have been owing to its having been preceded by four days which were exceptionally warm for the time of year. On the coldest day of the present cold period the temperature in the thermometer screen did not rise above the freezing-point, but on the coldest night the exposed thermometer never indicated more than 11° of frost, which is 10° above the average minimum reading for that thermometer in the middle of January. The ground is still cold, being at the present time about 1° colder at 2 feet deep, and 2° colder at 1 foot deep, than is seasonable. Some rain fell on two days, but to the total depth of less than one-tenth of an inch. On one or two days a few flakes of snow fell. Up to the present time the winter has been remarkably dry, the total fall since the beginning of December only amounting to 1½ inch. There has been very little percolation through either of the soil gauges during the past week. The sun shone on an average for fifty-one minutes a day, which is three-quarters of an hour a day short of the average duration for the middle of January. Calms and light airs alone prevailed during the week, the light airs coming exclusively from some point of the compass between north and east. The mean amount of moisture in the air at three o'clock in the afternoon exceeded a seasonable quantity for that hour by 2 per cent. *E. M., Berkhamsted, January 21.*

Obituary.

D. MCGILLIVRAY.—*Horticulture*, U.S.A., records the death on the 6th ult. of Mr. Donald McGillivray, gardener and florist at Brattleboro' and Newport, U.S.A. Mr. McGillivray was trained in Scotland, and like numerous other gardeners from Great Britain who have settled in the United States built up an important florists' and nursery business.

TIMOTHY O'CONNOR.—We learn also from *Horticulture* of the death of Mr. Timothy O'Connor, one of the most widely known florists in the State of Rhode Island, who died at his home in Providence, U.S.A., on Friday, 19th ult., after a long illness. He was in his 77th year. Mr. O'Connor was born in Fermoy, Co. Cork, Ireland, and settled in Providence when he was 16 years old and began work as a gardener. Shortly afterward he entered the employ of a florist. While still a young man he founded a florist business, which at the time of his death was one of the most flourishing in the state.

ENQUIRY.

CROWN OF THE BRIDE.—Can any reader give me the name of a shrub which grows freely in Argentina and is known to the natives as *Corona di Novia*, Crown of the Bride? It was described to me by a gentleman who owns large tracts of land there as growing about 4 to 5 feet in height, with a pure white flower, something resembling in shape a crown as shown on British arms. It makes a splendid hedge there, and is magnificent when in bloom. *C. B.*

CARNATIONS: *J. W. L.* The colour of the flowers on their arrival here did not appear specially attractive. You will do well to cultivate the plants until next season, and you may find by that time that the novelty is worth sending for the consideration of the Royal Horticultural Society's Floral Committee, or you may send blooms to the Perpetual-Flowering Carnation Society's exhibition for award.

CLEMATIS MONTANA: *A Dorset Gardener.* You may cut the old plant of *Clematis montana* down to the ground in April, and it will break again strongly, unless it has a very old and thick stem, in which case it should not be cut so severely, but the straggling growths should be cut away, leaving the main stems, which will break profusely from end to end. By this treatment you will find that the plant will improve in vigour and floriferousness.

CONIFER WITH SWELLINGS: *E. Ball.* The tree is attacked by the Spruce-gall aphid, *Chermes abietis*. As only one plant is affected it will be best to grub it up and destroy it by burning. If the galls are noticed on other trees spray them next season with kerosine emulsion.

FORCING NARCISSUS PRINCEPS: *C. H.* To your enquiry as to the "earliest date to get *Narcissus Princeps* in flower," a few blooms may be had so early as January 10, regular gatherings following about a week later. In the forcing of these bulbs, however, no two seasons' results are exactly alike, even when the stock is home-grown. Lack of sunlight and sun-heat during the forcing period affects their progress enormously, and in times of fog the plants make no progress. The conditions under which the bulbs mature are important factors in forcing, and bulbs maturing in an early district may be in flower a week in advance of others from colder parts. The time of planting and the subsequent introduction of the bulbs into heat also affect the time of flowering. Much artificial heat in the very early stages of forcing not infrequently has the opposite effect to that intended, retarding instead of forcing growth. Taking a score of years for a district south of London, regular gatherings have varied between the 12th and 18th of January. In your district the first blooms should be possible some days in advance of the first-named of these dates.

FUNGUS ON LAWN: *Bulbo.* From your description we suspect that the trouble is due to "fairy rings," caused by the fungus *Marasmius oreades*. Soak the turf and ground thoroughly with strong Bordeaux mixture four times at intervals of eight days, or use sulphate of iron at the rate of 1 lb. of sulphate of iron in each gallon of water. Loosen the turf with a fork to allow the liquid to enter freely.

NAMES OF PLANTS: *J. L.* The specimens are too scrappy to properly identify. 1 and 2, Garden varieties of *Coleus*; 3, *Pelargonium*, scented variety; 4, *P.* Ivy-leaved variety; 5, *Saxifraga sarmentosa*.—*Foreman.* 1, *Pteris geraniifolia*; 2, *Adiantum formosum*; 3, *Asplenium lucidum*; 4, *Blechnum corcovadense*.—*X. Y. Z. No. 1.* 1, *Sansevieria zeylanica*; 2, *Microlepia platyphylla*; 3, *Nephrolepis rufescens*, crested form; 4, *Hibiscus rosa-sinensis* variety; 5, *Aspidium coriaceum* capense; 6, *Asparagus decumbens*. (Other matter next week.)—*V. ?.* 1, *Oncidium excavatum*; 2, *Masdevallia simula*; 3, *Pleurothallis Scapha*.

OSAGA ORANGE: *M'Head.* (1) *Maclura aurantiaca* (Osaga Orange) is not a true Orange, but belongs to the same family as the Mulberry (*Urticaceae*). Its fruit has an outside resemblance to an Orange, but is of very different internal structure, and quite inedible. The fruit is rarely seen in this country, firstly, because our climate is too dull for its development, and, secondly, because the trees are unisexual, so that if both sexes are not represented no seeds are formed. The tree is of more interest than beauty with us, the flowers

being small and green. It has, however, been recommended as a hedge plant, its armature of spines being very formidable. It is so used in the South-eastern United States, where it grows wild.

PEAR DUCHESSE D'ANGOULEME: *A. J.* This variety is classed by Mr. Chittenden and Mr. C. H. Hooper among the more or less self-fertile Pears. *Beurré Hardy* is in the same class and blossoms nearly as early, but comes into season for eating at about the same time. If you prefer a variety for much later use *Easter Beurré* is another Pear in the same class and an early blossomer. Both Pears are of excellent quality, but *Beurré Hardy* succeeds more generally than *Easter Beurré*.

PEROWSKIA AND ELAEAGNUS: *M'Head.* As to whether *Perowskia atriplicifolia* or *Elaeagnus argentea* is "the prettier and more interesting the season through," that must depend largely on the taste of the planter, but we think the latter is more effective. Its silvery foliage is good for six months of the year, and its rich yellow flowers are very fragrant. The *Perowskia* is charming at its best, flowers late, and for a good long period. But it starts late into growth, and cannot be said to have any beauty, even in leaf, until late June.

R. H. S. SENIOR EXAMINATION: *G. P. B.* The date of the examination is April 1, and it will be held simultaneously in as many different places in Great Britain and Ireland as circumstances may demand, even if only one candidate be sitting at any particular place. The time allowed for the examination is three hours and a-half, the hour fixed being generally from 6 to 9.30 p.m. Those wishing to sit for the examination, who have not attended any particular series of lectures, must send in their name and address, and also the name and address of some responsible person willing to conduct the examination, to the secretary, R.H.S., Vincent Square, Westminster, at least three weeks before the date of examination. A capitation fee of 5s. is charged for every student (for the junior general examination the fee is 2s. 6d.) Each candidate must send in the name and address of a proposed supervisor, unless he can sit in London, in which case he must say so on his entry form, and the society will make arrangements for him at their hall in Vincent Square, Westminster.

RICHARDIA (ARUM): *E. D.* The development of three spathes is unusual, but not unique. Seeing that the spathe is not part of the flower proper, but merely a bract, or modified leaf, the occurrence is not so wonderful as many imagine.

SALVIA RUHLANDI: *A. Cotton.* There is apparently no *Salvia* of this name. What is probably meant is *S. rutikaua*, a greenhouse species which requires ordinary greenhouse treatment in loamy soil. It is called the "Pineapple-scented Sage" and is of sub-shrubby habit, growing from 2 feet to 3 feet high. The origin of this plant is uncertain, but it has been in cultivation for about thirty years.

WASPS' NESTS IN NOVEMBER: *A. Shalleton.* Your record of large numbers of wasps being found in their nest on November 26 of last year is most unusual. As a rule the nest is deserted by all the wasps with the exception of the old queen or foundress of the colony, who dies in her nest at the end of the season. The males and workers also die off, the only survivors of the colony being the new queens. In the nest you had under observation most of the workers had gone, but a large number of males and nearly all the new queens were in the nest. The 300 examples you separated and placed in the box are all queens. A number of the queens were infected by a large intestinal worm belonging apparently to the genus *Sphaerularia*, a parasite which is known to infest bumble-bees and wasps.

JAPANESE LANDSCAPE GARDENS.

(See Figs. 32, 33, 34, 35, 37, & Supplementary Illustration.)

TO understand and interpret a Japanese garden of the landscape type, much more is needed than a mere aesthetic appreciation. The garden is the result of long centuries of nature-study and religious contemplation, and contains elements that carry us away to the banks of the Niranjara River in India. There it was, under a Bodhi tree, that Guatama Buddha found the truth that neither books nor penance had taught him. Truth lay in getting nearer the great loving soul of nature.

To this day a stone Buddha and a bowl carved in the shape of a Lotus flower—his favourite symbol, implying that the most exquisite life and beauty may spring out of shapeless mud—are congenial features in a Japanese garden. Like the elaborate tea ceremony, the landscape garden began in religious rites and contemplation.

It was Bodhi Dharma, twenty-eighth in descent from the great master Guatama, who carried his teachings to China, and founded Buddhism in the Middle Kingdom. There it came into contact with the newly-developed delight in tea, which was first esteemed because votaries of the Buddha cult found that it prevented drowsiness during their long hours of meditation. Fifteen centuries ago the Chinese people went into ecstatic raptures

over the soothing qualities of tea. With the Taoists it was regarded as an important element in the elixir of immortality. The southern Zen sect among the Buddhists framed an elaborate ritual of tea. These monastic people, living a secluded life, and given over to ascetic ideals, used to gather before the image of Bodhi Dharma, the Buddhist apostle of China, and drink tea out of a single bowl with the strict formality of a sacrament.

The later troubles of the great Chinese Empire destroyed any such idealistic customs and rituals; romance left for ever the drinking of the enchanting cup. But in the twelfth century these rituals were transferred to the island empire. A contemporary of Richard the Lion-Hearted, who had gone across to China to study the teachings and rituals of the Zen school, returned to the Japanese capital with a package of the celebrated Sung tea-seeds, some of which were planted at Uji in its neighbourhood. Ever since, this district has been noted for the peculiar excellence of its tea.

By the time of the Ashikaga regent Yoshimasa, who died a score of years before Columbus discovered America, the tea cult, which demanded a quaint and serene landscape for its due celebration, was established in Japan. The tea-garden became a haven of peace and relaxation to the harassed warrior and statesman. Just at the period when the country was torn asunder by rival factions, when, as in the English Wars of the Roses, every man of mettle had his sword sharpened and by his side, the cult of the garden and of the tea asserted itself as furnishing an Elysium. "Tea with us," says a charming modern writer, Okakura Kakuzo, "becomes more than an idealisation of the form of drinking; it is a religion of the art of life. The beverage grew to be an excuse for the worship of purity and refinement, a sacred function at which the host and guest joined to produce for that occasion the utmost beatitude of the mundane. The tea-room was an oasis in the dreary waste of existence where weary travellers could meet to drink from the common spring of art-appreciation."

The dust and din of the outer world were left behind as the visitors to the tea-garden entered the gate, and waited at the *machiai*, or rest-shed, until their host summoned them. From the *machiai* to the tea-room was the winding *roji*, or garden path, with its orderly but oddly-framed stepping stones, around which clustered dried pine needles. They would touch in passing some hoary moss-covered granite lantern, shaded by a gnarled evergreen tree. All conduced to serenity of spirit. A great tea-master, Kobori-Enshiu, who lived in the days of Queen Elizabeth, finds the idea of the garden path in the following verses:—

"A cluster of summer trees,
A hint of the sea,
A pale evening moon."

Absolute purity is demanded everywhere. Here is a story:—"Rikin was watching his son Shoan as he swept and dusted the garden path. 'Not clean

enough,' said Rikin, when Shoan had finished his task, and bade him try again. After a weary hour the son returned to Rikin and said: 'Father, there is nothing more to be done. The steps have been washed for the third time, the stone lanterns and the trees are well sprinkled with water, moss and lichens are shining with a fresh verdure; not a twig, not a leaf have I left on the ground.' 'Young fool,' chided the tea-master, 'that is not the way a gravel path should be swept.' Rikin then stepped into the garden, shook a tree and scattered gold and crimson leaves over the path—the wealth of autumn. Rikin demanded not only cleanliness, but also the beautiful and the natural."

Until their arrival in Japan, as a recent writer has remarked very justly, globe-trotters are under the impression that a Japanese garden means a paradise of flowers, outvying the American or European enclosure. Rather is it a paradise of rocks and stones, full of suggestion of remote valleys and hills. Flowering shrubs come in accidentally; while a blaze of colour could only appear as a background or contrast. The type of tree is that of some quaint evergreen with an individuality of its own, that seems—with its twisted roots and sinewy limbs—to tell of storms weathered successfully.

Like everything that comes from a Chinese source and retains its original flavour, there is the cult of the old and mature in the arrangement of the garden. It is our English poet Browning who speaks of the ideal man as finding truth and reality in the ripeness of his years:—

"Youth ended, I shall try,
My gain or loss thereby . . .
Young all lay in dispute,
I shall know, being old."

Every stone in the garden seems to have a meaning of its own, and the most guileless-looking rock from the river-bed may bear a name like Moon Shadow, Wild Wave or Flying Crane. The garden is an enclosure where perfect proportion reigns, and the eye is suffered to rest only upon what conveys an impression of serenity. Form and tone are everywhere; colour is merely accidental—if it be present. At no time is the Japanese garden more beautiful than by moonlight.

There are three essentials—a stone, a tree, and water or its suggestion. Thus a watercourse may be dry and yet suggest falling water. It is not necessary to have water that may be turned on when required. There is, indeed, a distinct type of garden known as the *Kare-Sunsui*, where water is not present.

The stone lantern is to be regarded as an ornamental stone, and has a place in every garden, however small. Unlike ninety-nine of every hundred Japanese articles of virtue, the stone lantern cannot be traced to a Korean or Chinese source. The first lantern we read of was erected early in the seventh century of our era by an emperor's son, Prince Iruhiko, who placed it by the side of a lake where some highway robberies had taken place. Its earliest intention was, therefore, of a social kind, to benefit

wayfarers. From the highway it found its way to the courts of temples, as a fitting decoration, and elaborate lanterns were presented to shrines by devout worshippers. At Nikko and other Buddhist centres the stone lanterns are crowded together like automobiles in Piccadilly of an afternoon. Among them are many bronze lanterns, and foreigners who have been fortunate in securing one have placed the lantern in the garden; but it does not properly belong thereto. Hanging lanterns, however, of bronze are often suspended by a chain from the verandah eaves of a house

usually hexagonal and curved at the extremities of the angles. Perhaps the best known of these pillared stone-lanterns is called the *Kasugakata*. Next comes the broader snow-viewing or *Yukimi* kind, with umbrella-like top and spreading feet. Again, there is the bracket form, where there is only one support of the nature of a leg, assuming a curved form, and allowing the fire-box to rest free over a pool. To many the appearance of instability in this form is an objection, but it can be used very effectively.

Lastly, there is the unassuming "Crouching Lantern," with neither pillar, feet, nor bracket.

This type is patterned after these fabled isles of the sea, peopled by monsters. The whole island takes the form of a tortoise, emblem of strength and longevity; on its back rests a rugged Pine tree. Stones, carefully selected, furnish the idea of the head, of the four feet, of the tail. There is also the *Fukiagejima*, or wind-swept island, with the tree branches bending to an imaginary breeze, so as to suggest mid-ocean. No fresh-water vegetation is in place with either of these forms, but a pebbly beach, sea sand and shells.

What is known as the Master's Isle is placed in

FIG. 32.—VIEW IN A JAPANESE GARDEN AT PASADENA, CALIFORNIA.

or tea-room, so as to be reflected in the garden basin, and they may be used without incongruity. Porcelain lanterns have been used on occasion, but they do not lend themselves readily to the production of the age- and weather-worn impression so desired in a garden. They are too fragile and ornamental in nature, demanding tracery and pictures of their own.

Lanterns are not much associated with actual lighting; but natural stones are often so arranged in the vicinity of standard stone lanterns as to lead up to a higher "lamp-lighting stone," often double-stepped. There are, broadly speaking, four patterns of lantern. First is the pillared lantern, with the roof over the fire-box,

It is placed upon some rude stone near a low water-basin.

The Japanese garden has also room for lamp-posts of wood. These stand on garden roads or in passages, adjacent to summer-houses or resting-sheds. The fire-boxes take a square or wedge shape, are roofed with boards or thatch, and are carried on high posts.

A garden lake of any size demands its island or islands. These are of two kinds—those that are reached from the shore by stepping-stones or bridge, and those that are out in the open, suggesting islands in the ocean. The chief of the latter kind is the *Horai-jima*, or Elysian Isle, the fairy or Brownie land of Chinese legend.

the foreground of the landscape and is reached by a bridge or a picturesque combination of bridge and stepping-stone. As often a peninsula (*deshima*) as an island, it usually has a resting-shed or rustic harbour for the visitor, as well as a Stone-of-Easy-Rest, set apart as a favourite spot for the master to take his ease. We also expect to see in the Master's Isle a Stone of Amusement (*Yukio-Seki*) on a headland convenient for angling.

Very similar to the Master's Isle is the Guest's Isle, which is placed more in the background and is likewise approached by bridge and stepping-stones. Its ornamental stones are chosen to denote hospitality. There is a

Guest-honouring Stone, which serves as a rest for an important visitor; an Interviewing Stone, of flat shape, in front of the Stone of Honour, where the host stands to salute visitors; and Water-fowl Stones for birds to rest upon.

The Master's Isle as well as the Guest's Isle may contain a Seat of Honour Stone, patterned after a sacred stone in India, and a choice old tree always grows beside it. This takes the mind back to the banks of the Niranjara River, when truth flashed upon Guatama's soul. I might also mention the *Yama-jima*, or Mountain Isle, containing two peaks, one somewhat higher than the other. Encircling this island is a stretch of flat beach with occasional rocks.

A well is an indispensable feature of a Japanese garden. While in itself useful, its chief end is often ornamental, helping to express the mood or sentiment of the whole place. The ordinary form contains a border or box-like frame of wood or stone, two buckets suspended on a pulley, one resting on the edge of the frame, the other in the water. The accessories are a drain, stepping-stones and ornamental rocks. Sometimes the pulley is of porcelain; the Oxford frame is popular for the box-frame, the sides being of artistically-grained wooden slabs.

There is a semi-religious sentiment hovering round the presence of water in a Japanese garden, as something pure and immortal, reminding us of the text in St. John's Gospel, iv., 14. "A well of water springing up into eternal life." An ornamental stone water-basin, taking the form of Fuji-yama, maybe, or, in statelier gardens, of a bronze Lotus bowl, is as common as the well. A running-water basin is also popular, the water being allowed to stream over the bowl.

There are several types of garden bridge. First comes a simple slab of granite or schist. Then there is the semi-circular Chinese arch, which, with its reflection in the water, makes a full-moon effect, giving it its name. A similar conceit is found in the name *Taiko-bashi*, or Drum Bridge, which is smaller and quaint, the circular interior combining with the reflection to suggest the head of a drum. A zig-zag bridge, with a succession of slabs at angles, is known as *Yatsubashi*, after the scenery of Yatsubashi, in Mikawa, noted for its beds of Iris flowers linked by a curious composite bridge. There are also bridges made of wattle-work covered with earth. Close to bridges of the granite-slab kind and the earth bridge it is usual to find a stone lantern.

Torii, or bird-perch gateways, come but sparingly into art gardens. In his elaborate work Conder finds space for but one passing reference to this decorative effect. It is more appropriate to temples, but can on occasion be used with good results in the private garden. The vermilion-coloured variety, with tilted cross-beam, is of later Buddhist origin; the original Shinto *torii* had straight beams of unpainted wood, white at the ends.

Let me discuss the essentials of garden construction. First comes the necessity of following and encouraging natural lines—assisting Nature, and not forcing her. Keep the geometrical and the artificial far away. Rigidly exact circles or ellipses, or rectangles, or squares—these have no place in a Japanese garden, as they have no place in actual outdoor life. Even the Parthenon, that miracle of architectural beauty, as recently shown by a capable writer, does not deal in straight lines. The apparent straight lines are delicate curves, so shaped as to give at a distance the appearance of forthrightness. And stone, it must be remembered, is not nature-life. Here must I make the exception: garden stone lanterns may always have geometrical curves, angles, and straight lines, for they come into a different category because of the material. The ease and grace of life are for the most part expressed in terms of subtle curves. To find these subtle curves demands both time and sym-

metry. Secure ease and grace of expression in the garden without the appearance of painstaking effort or studied labour. Here comes in the great principle of *Ars celare artem*, not manifest in the Dutch or Italian garden. The keynote of the Japanese garden is the spontaneity of life, which is Nature's secret that we may wrest from her by minute care and patience.

FIG. 33.—STONE JAPANESE LANTERN, SHIRA-TAYU (WHITE-ROBED CIVILIAN).

Rich design, the accumulation of ornament, savour of vulgarity. Even one graceful old Pine, with two or three *yamaji* Chrysanthemums, may make a garden of supreme taste. The garden must be given a soul.

Good taste has the effect of inspiring a feeling of truth and purity, while vulgar taste has a depressing effect. Refined taste in a garden consists not in the extent of its area nor in the

FIG. 34.—JAPANESE STONE LANTERN, YUKI-MI (SNOW-VIEW).

profusion of its shrubs and trees, but in the truthfulness of the setting or composition. In arranging the details for a garden it is well first to study the topographical features of the spot where you decide to make it. Then transplant thither the mood or aspect of some vale or stream or hill that is dear to your memory, and arrange all the single effects to suit the whole design.

Dispense with a fictitious mountain, says one good authority, if there is a fine waterfall. Eliminate a pagoda if there is an arbour. Study reticence, the "something left over," which leaves room for suggestion. A garden without suggestion is no real garden. Be ever careful to transcend artificial rules and enter as far as you can into the real spirit of Nature. *J. M. Dixon, Los Angeles.*

NEW OR NOTEWORTHY PLANTS.

NEW GARDEN PLANTS FROM NEW MEXICO.

Continued from p. 50.

SEDUM COCKERELII BRITTON.

This is a species found in the mountains near Santa Fé; it has white flowers with bright, pink styles. It prospered in the garden, and while small and not very conspicuous, it is a desirable addition to the rockery.

LEUCAMPYX NEWBERRYI GRAY.

This beautiful Composite, with large, white rays, abounds in the Las Vegas mountains, forming a conspicuous feature in the landscape. A single plant in the garden at Boulder has not as yet done itself justice, and indeed the species should be grown in masses for the best effect. The plant seems to be self-sterile like the sunflowers, as ours yielded no seed.

GAILLARDIA PULCHELLA Foug.

A well-known annual species, which I found growing in great abundance in loose volcanic soil at the Rito de los Frijoles. Very rarely a variety (*albiflora*, nov.) was found in which the yellow of the rays is replaced by white, faintly tinged with cream. Seeds from the white variety, undoubtedly crossed with normal plants growing all around, gave only the ordinary form in the garden; but next year we expect to see the recessive white again.

AQUILEGIA DESERTORUM (JONES) COCKERELL.

This is a dwarf species with red flowers of the type of *A. canadensis*, and with an enormous root. I found it growing in Santa Fé Cañon, and brought a plant home which has flowered well in the garden and produced seed. We shall use it in crosses with other species. *T. D. A. Cockerell, University of Colorado, Boulder, Colorado.*

TREES AND SHRUBS.

THE HAMAMELIS.

HAMAMELIS ARBOREA, the Japanese Witch Hazel, will, like others of the race, bloom well while still quite small. In Japan it is stated to reach a height of 20 feet, but nothing approaching this size is to be seen in this country. The species was introduced into England in 1862, but although it is one of the most characteristic shrubs we possess, it is still rare in gardens, a remarkable fact, as in the winter it is very handsome. It generally grows with a well-branched head, and, when every shoot is covered with its curiously-shaped blossoms, it is a sheet of yellow. The blossoms will endure several degrees of frost without being damaged, and are at their best during the months of January and February. The blossoms have narrow petals, which have the appearance of rolls of yellow ribbon before they are fully open, and when they are entirely expanded they suggest strips of twisted gold leaf. Each flower has four petals, and their bright yellow shows up well against the crimson sepals. The leaves, which are not perfected until the flowers are past, are very much like those of the Hazel, and in consequence Hazel has been used as a stock for the Hamamelis, but as the two plants belong to different genera this procedure has proved unsatisfactory. *H. arborea*

is seen to the best advantage when overtopping dwarf shrubs and when it is more generally grown it cannot fail to become popular. In this garden there is a specimen over 6 feet in height, every branchlet of which is studded with buds, which are now just showing yellow, so that in a fortnight or so it should be in full bloom.

H. japonica differs from *H. arborea* in being a less strong-growing shrub and a month or more later in coming into flower. The blossoms are also paler in colour. *H. Zuchariniana* much resembles *H. japonica*, but the calyces are darker in tint. These two are so much alike that, unless closely inspected, they cannot be distinguished. *H. virginica*, the American Witch Hazel, is not a winter but an autumn flowerer. The flowers of this shrub are smaller and less brilliantly coloured than those of the Japanese species. During the months of September and October, as the leaves begin to assume their golden colouring, it commences to flower. It is a robust shrub and soon attains a height of 10 feet.

and will also thrive in a peaty compost. It is naturally of a bushy habit, but can easily be pruned so as to form a small standard tree. *Wyndham Fitzherbert, Kingswear, Devonshire.*

NURSERY NOTES.

MESSRS. JAS. VEITCH AND SONS, LTD.

THE famous nurseries of Messrs. Jas. Veitch and Sons in the King's Road, Chelsea, have introduced to commerce a large number of the exotic plants which decorate our greenhouses and stoves; and hence it need scarcely be said that the nursery itself is interesting at all times. The *Nepenthes*, greenhouse *Rhododendrons*, winter-flowering *Begonias*, *Hippeastrums* and *Orchids*, in which the firm has specialised from the first, are as fine as ever, and even during the present dull season a good show of bloom may be seen.

the use of *B. socotrana* as a parent, are represented by the brightly coloured *B. John Heal* and still finer *B. Mrs. Heal*. The tints of the hybrids were at first deep rose and red, but careful breeding has resulted in the production of other bright colours in the same section. The stock is kept at the Feltham Nurseries, but examples at Chelsea show that sixteen distinct and brightly coloured varieties are now in bloom, specially bright being *Optima*, *Fascinator* and *Her Majesty*, with yellow and copper-orange tints, and *Exquisite*, of a rich rose-red.

The *Hippeastrums* are resting dry in their house, some pushing up spikes, and all in that vigorous condition which promises the fine display in spring which is one of the attractions of the nursery.

In the ornamental greenhouse is a good display of *Chrysanthemums*, *Erica hyemalis*, *E. melanthera* and other plants, with fruiting *Solanums*, etc. The warm houses have a very fine lot of *Codiaeums* (*Crotons*), their handsomely-coloured foliage being as bright as flowers. Standing above the delicate foliage of *Selaginellas*, with *Begonia Gloire de Lorraine*, both white and pink, to give flower, they are specially attractive.

Codiaeum B. Comte, with its very brightly coloured foliage of metallic lustre, is one of the best, and said to stand changes of temperature well. *C. F. Sander* has the basal halves of the leaves yellow, the tips green. *C. Thompsonii*, *C. Chantrieri*, and the different forms of *C. trilobus*, of which the variety *Disraeli*, one of the oldest, still appears to be among the best.

In the next stove house are the specimen foliage plants, the noble plant of *Dracaena Goldieana* with thirteen stems being a fine object, and the *Anthuriums* and *Alocasias* of the *Veitchiana* section are fine examples. On one side is a good collection of pretty-leaved *Marantas*, which are not now often seen.

Among good batches of decorative plants are some fine plants of *Asparagus myriocladus*, one of the best and most useful forms; a house of variegated *Aspidistras*; a fine lot of decorative Ferns, Mosses and Palms; a good lot of bushy *Otaheite Oranges* well furnished with fruit; *Dracaenas*, etc.

A feature at this nursery is the collection of stove and greenhouse climbing plants, and of pretty greenhouse plants once reigning favourites in gardens, but now scarce, owing to the needs of space for plants in batches. Nevertheless, the old species are as beautiful as ever, and are often wanted, though not in quantity. It is well to make known where they can be had.

The old *Camellia* house is now filled with Palms, which look well in the lofty structure.

THE ORCHIDS.

At the present time there is not a very great show of bloom, but some *Calanthes*, *Angraecum eburneum*, *Laelia autumnalis*, *Vanda Amesiana* and others are in flower; and in the *Cypripedium* house is a good show of bloom and bud on the forms of *C. insigne*, including the pretty yellow and white variety *Sanderae*, and the large *Harefield Hall*; forms of *C. Leeanum*, *C. Hera* and the hybrid raised here between it and *C. villosum*, named *Countess of Carnarvon*, which varies very considerably in the colour of its flowers, some being very fine; *C. Thompsonii* and others. Some plants of the handsome *Oncidium splendidum* have stout branched spikes 3 feet in height; a large lot of *Cattleya Schröderae*, *C. labiata*, *C. Trianae*, *C. Mendelii* and other *Cattleyas* are in fine condition, and well furnished with flower-sheaths, and the *Odontoglossum* house has a good show of spikes with some in bloom. The *Burmese Dendrobiums* grow very strongly, and *D. Wardianum*, forms of *D. nobile*, *D. crassinode*, etc., show well for bloom.

FIG. 35.—TAIKO, OR DRUM BRIDGE IN HUNTINGTON GARDEN, PASADENA, CALIFORNIA.

H. mollis is a native of China, and was not introduced into this country until 1898, a far later date than that of the entry of the better-known Japanese *H. arborea* and the American *H. virginica*, which were first introduced in 1862 and 1736 respectively. This new species, however, promises to take a leading place in the genus, as it is one of the most attractive of the various kinds. Owing to its recent introduction large specimens are not as yet to be seen here. Its oval, broad leaves are coated on the reverse with a dense covering of small, stellate hairs, which at once render it distinct from the other species. The golden petals of the blossoms are straight and flat, and have upturned ends, being quite unlike those of *H. arborea*. As a rule it attains the zenith of its beauty about the New Year, though it occasionally comes into bloom a trifle earlier, and is considerably in advance of the better-known *H. arborea*, which is usually not in full flower until towards the close of the month of January. A delightful feature about this plant is that its flowers have a delicate Primrose fragrance. It will succeed in light, fibrous loam,

One of the most interesting houses is that in which the famous collection of Pitcher plants is grown, the plants still bearing a fine lot of pitchers. *Nepenthes ventricosa*, *N. Mastersiana*, *N. Rafflesiana*, *N. Hookeriana*, *N. Mixta*, *N. Tiveyi* and most of the others are well set with pitchers. The very distinct *N. ventricosa*, which bears large urn-shaped pitchers, generally of a pale green colour, but often tinged with pale reddish rose, is specially attractive.

The house of greenhouse *Rhododendrons* has not been without flower for years, and the compact plants, well furnished with buds for flowering later, have among them a sprinkling of plants in bloom. A great advantage of these pretty plants is that they last a very long time in flower, and large specimens of some of the kinds continue to bloom more or less all the year. The best of those now in bloom are *Lord Wolseley*, copper orange; *Florinda*, deep rose; *Baroness Schröder*, flesh pink; *triumphans*, red; *Mrs. Heal*, white; several forms of *R. jasminiflorum*, and the deep red *Little Beauty*.

The winter-flowering *Begonias* so successfully raised and developed by Messrs. Veitch through

THE ROSARY.

CULTIVATORS NEED A GREATER VARIETY OF STOCKS.

THERE is one point in the cultivation of Roses that has always struck me as unprogressive—namely, the determined manner in which propagators stick to seedling, or cutting, Briar as stocks for budding purposes. The Rose is now grown extensively in gardens all over the country, and the nature of the soil must vary considerably. In some gardens the soil will be of a suitable character for the successful cultivation of the Rose, but in many other gardens, chiefly owing to light soils, growers have extreme difficulty in obtaining satisfactory results. Nevertheless, in face of these varying conditions, there is but one root-stock in general commerce, and that is usually derived from the seed of the Dog Rose, *Rosa canina*.

We hear a great deal, for example, about the success of a particular Rose in certain districts, while from other parts we have many complaints that the same variety will not thrive, and it is condemned as worthless. It is not the scion that is at fault, but the stock. The Dog Rose is not at home on every soil, and growing in a natural state it avoids soils of certain characters, and is rarely found upon them. When this is considered it seems strange that Briar stocks should be so largely used, and that little or no attempt should be made to discover another rooting medium for Roses that must be cultivated in gardens where the soil is not of the kind usually associated with the successful cultivation of the various types of Roses now so popular.

There are some members of the genus *Rosa* that are found in a thriving condition upon very light soils, and one of the most common is *R. pimpinellifolia*, our little native Scotch Rose. I know where thousands of plants of the Pimpernel Rose flourish most profusely in what is practically pure sand on the sea coast of the western district of East Lothian, and the Briar is comparatively rare in the immediate district. *R. pimpinellifolia*, however, is not suitable as a stock for Roses, owing to the enormous number of suckers which it produces from its roots.

Notwithstanding this, I would like to see some experiments carried out with this species of Rose as a rooting medium for cultivated varieties, and there is a natural hybrid between it and the Dog Rose that it might be possible to fix and use for budding purposes under certain soil conditions. There is no doubt, however, that *R. pimpinellifolia* and some of its natural hybrids do well upon soil on which no other Briar would thrive, and it suggests the possibility of some other species behaving in a similar way.

Such a species may be found in *R. laxa*, and an experience of three years with this stock has taught me that it may have enormous possibilities and prove of great benefit to those who must grow their Roses on light and dry soils. *R. laxa* was introduced by Retzius in 1803, and is a native of Siberia. It is not such a strong grower as the Dog Rose, and a bush that is now three years old has only attained a height of 3 feet. Its long, thin, green branches are almost devoid of thorns—one good point for the budder—and the flowers are pure white with just a suspicion of yellow at the base of the petals.

It is the wonderful root system, however, of this species which is of the greatest importance to the rosarian, and its value in this respect deserves the fullest investigation. On light soils this stock has given results of the greatest promise, and the immense quantity of fibrous roots which it produces gives the scion every opportunity to thrive and flourish. I have noted Roses upon Briar gradually degenerating upon a light, dry soil, whereas plants worked upon *R. laxa* have steadily improved. *Laxa* stock is easily worked, and on the whole is not prone to sucker. The sap rises earlier in the season than in Briar, and budding operations may be begun at an earlier date.

Apart from the question of soils, there is another matter that is of importance to the

grower. I think Major Hurst has pointed out in a recent note on the subject the heterozygous character of *Rosa canina*, and the immense variation found in a break of seedlings about to be used as stocks for budding purposes. He has drawn attention to the fact that some are strong and vigorous, while others are of a totally different character, many being weak and only producing indifferent growth and roots. The homozygous nature of *R. laxa* is very noticeable, and a batch of seedlings from this species planted up for budding will show practically no variation whatever from the type.

When it is considered that the modern cultivation of the Rose has altered considerably, and varieties that are esteemed for decorative purposes, as opposed to the old style of almost purely exhibition sorts, are now mostly in demand, it means that growers nowadays expect plants to stand and give of their best over a series of years. In this connection it is satisfactory to note that Manetti as a stock is now almost discarded, and

ORCHID NOTES AND CLEANINGS.

MESSRS. HASSALL AND CO.

IN the concluding paragraph on Orchid novelties in 1913 (p. 20) a comment on novelties in general appears in the same sentence as the appreciation of the new plants flowered by Messrs. Hassall and Co. The high reputation for good culture enjoyed by this firm, and our description of their collection published in a recent issue, make it scarcely necessary to point out that the sentence should be broken, and the latter half placed in a separate paragraph as a general comment.

ODONTOGLOSSUM AMABILE ASHLANDS VAR.

At the last meeting of the Manchester Orchid Society, December 18 last, Richard Ashworth, Esq., Ashlands, Newchurch, Manchester (gr.

FIG. 36.—ODONTOGLOSSUM AMABILE ASHLAND'S VARIETY.

no one who has the welfare of the Rose at heart will regret its disappearance. In like manner *R. rugosa* has come to the front of recent years as a stock for standard Roses. The splendid fibrous roots of this species produce and maintain enormous heads of bloom, and for plants grown in this style it seems disposed to oust the Briar. There is no doubt that Briar stocks are splendid upon certain types of soils so far as dwarfs are concerned, but there is now strong evidence that *R. laxa* is the stock of the future for those who must of necessity grow their Roses, either for exhibition or decoration, on soils that have hitherto been regarded as almost hopeless for this work. *George M. Taylor, Midlothian.*

Mr. Gilden), was given a First-class Certificate to his very handsome form of *O. amabile* (*crispum* × *crispo-Harryanum*), the plant shown having eleven flowers, each 4½ inches across, of a clear white, beautifully marked with violet-mauve colour. Mr. Ashworth kindly sends two flowers, which well demonstrate the beauty of his fine *Odontoglossum* and the correctness of the award. *O. amabile* as a second crossing of *O. crispum* shows the benefit of having a good species as a parent; and also the potency of *O. Harryanum* in giving good shape and form—a fact which is to be traced in all hybrids where it comes in directly or indirectly.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual general meeting of the members of the National Chrysanthemum Society will be held at Carr's Restaurant, Strand, on Monday, February 2, at 7 p.m. The President, Sir ALBERT ROLLIT, M.L.D., D.C.L., will occupy the chair.

PUBLICATIONS RECEIVED.—Notes from the Royal Botanic Garden, Edinburgh. October, 1913. Price 2d.—Annual Report of the Board of Regents of the Smithsonian Institution. 1912.—A Course of Practical Work in the Chemistry of the Garden. By D. R. Edwardes-Ker. (London: John Murray.) Price 1s. 6d.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

THE COOL HOUSE.—The bulk of the plants of *Odontoglossum crispum* and allied genera are in their most vigorous stage of growth; the new pseudo-bulbs are forming, and the greatest care must be exercised to get them well developed and matured. It is the same with Orchids as with fruit trees: the growths must be well ripened to obtain the best results. The modern method of cultivating *Odontoglossums* is a great advance on that of, say, a decade ago, when the plants were grown in low temperatures at this time of the year, notwithstanding the fact that this is the season of most active growth. It may be admitted that the pseudo-bulbs were hard and the flowers of generally good quality, but there was little or no increase in the size and general robustness of the plants after they were imported. A temperature of 40° or 45° at night was at one time considered suitable, but most growers now do not allow the temperature of the cool division to fall below 50° when the weather is normal. I find 53° to 55° the most suitable temperatures during the winter months, for with extra warmth the plants may be afforded a liberal supply of moisture at the roots, and the atmosphere of the house may be well charged with moisture, and, more essential still, fresh air may be admitted more liberally. A greater development of the pseudo-bulbs will necessarily entail increased care in their ripening, upon which so much depends. During periods of dull weather, when moisture evaporates slowly, water must be used sparingly, whilst the atmosphere should be kept reasonably charged with moisture, not only to assist in keeping insect pests in check, but to prevent shrinking in the pseudo-bulbs. When moisture has to be applied to the roots it must not be overdone. Let the potting compost become fairly dry before watering, which should be done, if possible, on bright days. See that plenty of light reaches the plants; soot and dirt adhering to the roof-glass must be removed by washing the outside glass on frequent occasions.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP,
K.C.M.G., Madresfield Court, Worcestershire.

SWEET PEAS.—Make a sowing of Sweet Peas in small pots, placing three to four seeds in each receptacle. Germinate the seeds in warmth and transfer the seedlings to a cold frame, where they will grow slowly and make sturdy plants. Our system is to arrange two or three clumps of each variety, setting them at 4 feet apart.

CLIMBERS.—All climbers, whether growing on walls, fences, pergolas, or other supports, should be thinned of all weak, spindly growths. Cut the foreright growths back to three buds and train some of the shoots their full length, so that the plant may extend, which is very necessary to get the best results. I am referring especially to such shrubby species as *Wistaria* and *Berberidopsis*.

BULBS IN GRASS.—Crocuses, including *C. biflorus* and *C. Sieberi*, have been attractive in these gardens all through the present month, and other bulbs are unusually forward this season. The Snowdrops and Winter Aconites will soon follow in bloom. At Madresfield Court we have large masses of Snowdrops which were planted some years ago beneath the spreading branches of Cedar trees in an avenue where the grass does not grow very rank. The plants usually continue in bloom for about a month, and they are not much damaged by severe frosts. The Winter Aconites are planted chiefly under the branches of forest trees. Next to follow will be the Dutch Crocuses, which are very effective in bright sunshine. A warm corner against a wall facing south should be selected for planting *Iris*

stylosa, and the plants must be left undisturbed for several years. It repays to soak the roots of this *Iris* in summer-time with liquid manure, as this will strengthen the plants and favour the development of the delightful lavender-coloured blooms which appear from Christmas onwards. Here we have half a dozen plants close to the windows of the mansion, and, with the above treatment, they have given splendid results.

THE PAVED GARDEN.—Irregular pieces of stone arranged as a pathway with crevices between for planting dwarf-growing subjects make an attractive feature in the garden. In order to obtain the best results it is necessary to have a stock of plants in reserve, and now is a suitable time to undertake their propagation. They may be either increased by cuttings of healthy plants or large specimens may be taken up and divided. Many of these Alpines, including the Rockfoils, *Saxifragas* (including *S. Waljisi*, *S. lantoscana* and Guildford Seedling), *Sedums*, *Dianthus* of the Alpine section, *Gentians*, *Lithospermum*, *Veronica repens*, *Aethionema grandiflora*, *Omphalodes verna*, dwarf *Campanulas*, *Androsace*, *Saponaria*, *Silenes*, *Erinus*, alpine *Phloxes*, and the Australian *Cress*, *Ionopsidium acaule*, may be raised from seed sown now. The plants of the last-named will flower next winter in the open.

PLANTS BLOOMING OUT OF DOORS IN JANUARY.—Specimens of *Daphne corallina latifolia* trained on a south wall in these gardens are in bloom and the perfume of the blossom is most delightful. Another sweet-smelling shrub, *Chimonanthus fragrans*, planted in a group of eight specimens, is largely used here for furnishing cut sprays of bloom. The bushes are planted about 9 feet apart in an irregular manner and are situated entirely in the open. We have a similar group of *Erica codonodes* planted in a mixture of peat and loam, each specimen being about 5 feet high and as much through. The plants are now masses of flowers, which are almost white. Although we had 20° of frost on the 1st inst. the *Ericas* were only slightly damaged. The *Witch Hazels*, including *Hammamelis mollis*, *H. Zaccariniana* and *H. arborea*, furnish another charming group. The yellow blossoms show up best against a background of evergreen, but specimens do well planted in grass. *Sidonia nivalis*, *Colletia horrida* and *Lonicera fragrantissima* are also in flower. A long wall planted with *Jasminum nudiflorum* has been and is at the present time a mass of golden flowers. All these shrubs may be planted now in rich, deep soil. They should receive a mulching of peat-moss litter after they are planted. If good specimens are obtained they will furnish a display next season and provide one of the most pleasing features in the flower garden in winter.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOZE, Eastwell Park, Kent.

RED AND WHITE CURRANTS.—These small fruits should be pruned on the spur system, leaving only a few buds of the leading shoots for extension, or lower down for filling up a space, caused by the decay of a branch. Cuttings of these are prepared in the same manner as those of the Gooseberry. Red and White Currants as well as Gooseberries may be planted in a shady border or trained on the north side of a wall, as fruits from these will prolong the season.

GOOSEBERRIES.—Of late years the Gooseberry has advanced in favour as a dessert fruit, but choice berries are only produced under high cultivation. New plantations are usually made in the autumn, but bushes may be planted during the next few weeks with every prospect of success provided the ground is in a suitable condition. As the plants are likely to occupy the same site for a number of years the ground should be trenched and heavily manured, for strong-growing, healthy bushes always produce the best fruit. If the work of pruning established bushes is not already completed it should be finished as soon as possible. Keep the shoots thinned well apart so that plenty of light may reach them, and remove all sucker growth, keeping the stem clear for at least 9 inches. The

centre of the bush should be sufficiently open to enable the fruit to be gathered without tearing the hands. Reserve as many of the straight, new growths as are necessary to furnish the bush, remembering that the best fruits are borne on wood of the previous year. When the work of pruning is finished spray the bushes with an alkali wash. Lightly fork the ground and apply a mulch of farmyard manure.

PROPAGATING GOOSEBERRIES.—It is a good plan to increase the stock of the best varieties each season, and the cuttings are best inserted in the autumn; but if the work was not done then it may be proceeded with now. Select strong, well-ripened shoots of the previous year's growth and make them about 15 inches long, cutting away the weak wood at the tips. Remove all the buds from the lower two-thirds of the shoot, retaining about five or six "eyes" at the top. Insert the cuttings firmly in a shady border and examine them at intervals to see if they need treading firm, for they sometimes become loosened by the action of frost. One-year-old bushes should be transplanted in open ground, allowing increased room for each bush. Cut the shoots back to a few buds to lay the foundations of a good bush.

BLACK CURRANTS.—The pruning or thinning of Black Currants is best done after the fruit is gathered in the summer, as this will favour the development of strong young fruiting growths. But the thinning is often done after other bush-fruits are pruned in the autumn and winter. All old wood should be cut clean away at the base, leaving only the strong young shoots of the previous year. It well repays to apply an annual dressing of farmyard manure to Black Currants, and this should be spread between the bushes after the soil has been cleaned and forked lightly. In propagating Black Currants all buds on the cuttings should be retained, as those set underground eventually form strong suckers and provide the best of wood for furnishing the bushes. Neglected bushes may be renovated by cutting them to the ground level and allowing new wood to develop. Every alternate bush may be cut down now, and the remainder another season.

FRUITS UNDER GLASS.

By W. HENLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

APRICOTS, CHERRIES AND PLUMS.—These fruit trees may be started slowly into growth by keeping the day temperature of the house at about 50°, allowing it to fall to 40° at night. Spray the trees twice each day with tepid water to encourage the buds to swell. With a little artificial heat fresh air may be admitted freely to the house for so long as the requisite temperature is maintained; otherwise, not too freely until the leaves are forming and the fruit is set.

PEACHES AND NECTARINES.—Some of the trees that were started early are ready for disbudding, which must be done with extra care early in the season. Remove a few of the growths daily rather than a large number at one time at longer intervals, as this would cause a check that frequently results in the young fruits dropping wholesale. The night temperature should still be maintained at about 55°, as this warmth will ensure a firm, steady growth. Ventilate whenever possible during the day, for a stagnant atmosphere is harmful. On mild nights a little air may be admitted through the top ventilators. Watch the foliage carefully, and on the first appearance of Green or Black Fly fumigate lightly, using for preference a vaporising compound. On no account must the trees be syringed with an insecticide after the fruit has formed, or serious injury to the crop may result. Cleanse the trees daily with clear water and keep all inside borders in a moderately moist condition, for if the soil is permitted to become dry Red Spider and kindred pests will speedily appear. The work of pruning the trees in late houses should be completed as soon as possible. In cleansing the trees see that the swelling buds are not damaged or rubbed out. In fixing the branches to the walls or trellis allow plenty of

space between each shoot, and see that the ties are not drawn too tightly, but allow space for the swelling of the branches. Inattention to this apparently trifling matter frequently results in great injury by strangulation of the most important parts of the tree.

VINES.—The pruning of all vines should now be completed. If Grapes are still hanging on the rods cut the bunches with as much lateral wood attached as possible, and place the stems in long-necked bottles filled with clear water to which a few small pieces of charcoal have been added. Fix the bottles in such a position that the bunches hang quite clear of them and also of the shelves. The temperature of the room or house in which Grapes are stored should be about 40° to 45° with a free circulation of air. Examine each bunch periodically, as advised in the issue for the 3rd inst. Keep the bottles filled with water, for if this is neglected the berries will quickly shrivel and spoil.

PROPAGATING VINES.—The "eyes" may be inserted singly in square pieces of turf, or in small pots or pans filled with loamy soil. Select well-formed buds from matured wood of last season's growth. Cover each bud with about half an inch of soil and plunge the turves or pots in a hotbed or propagating case with a bottom heat of about 80°. Under such conditions the buds will quickly start into growth. Keep the soil in a fairly moist condition, and as the vines need increased root room pot them on, always staging the plants close to the roof-glass. Maintain a brisk temperature and a steady bottom heat throughout the growing season, reducing the amount of warmth as the rods arrive at maturity. Young canes raised last season may be pruned back, and as they start into growth remove a portion of the old soil and pot them on into suitable-sized pots, using a mixture of good turfy loam and well-decayed manure, to which a small quantity of bone-meal has been added. Grow the plants on in exactly the same manner as advised for those raised from eyes.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

GLOXINIA AND ACHIMENES.—For early flowering a batch each of these plants should be started now. The Gloxinias may be either potted or started in boxes. I prefer the latter method on the grounds that space is saved, and it can be better determined later the size of the pot most suitable, according to the strength of the individual plants. In starting the tubers in boxes place a layer of moss or leaves on the bottom and plant them in light, peaty compost, coconut-fibre, or other quick-rooting medium, which should barely cover them. If the compost is fairly moist water will not be required until growth commences. Practise overhead spraying, maintain a moist atmosphere, and a temperature of 50° increasing to 65°. Gloxinias grow best in a compost composed of equal parts fibrous loam, peat and leaf-mould, with one peck of manure from a spent Mushroom bed for every two bushels of the compost and sufficient sharp sand and charcoal to keep the whole porous. If started in pots use those of a diameter of 4½ or 6 inches, according to the size of the tubers. Pot moderately firmly, place the pots in a light position near to the roof-glass, and grow the plants on as directed above. If seed is sown now the plants will flower in July and August. Sow in shallow pans. Use ample drainage materials and fill the pan with a light compost of sifted loam (previously sterilised), peat and sand. Soak the soil with warm water, and when the superfluous moisture has drained away sow the seeds evenly on the surface. Place the pan in a propagating case and cover it with glass. The seedlings should appear in a few days, when the glass may be removed and the pan placed on a high shelf, but protected from sunshine. In the case of Achimenes the old soil should be shaken from the roots and the latter placed at 1 inch apart in a box containing a compost as advised for Gloxinias. Cover them with ¼ inch of soil and start them into growth in a house having an atmospheric temperature of 65°. Keep the soil and atmosphere moist. The

tubers will quickly form roots, and when the top growths are 2 inches long lift several in a clump with a good ball of soil, and either pot them or arrange them in baskets to hang in the stovehouse. Syringe the plants daily, but avoid over-watering the roots. When the flowers appear remove the plants to cooler quarters.

CLIMBERS.—Allamandas, Aristolochias, Cissus discolor, Bougainvilleas, Clerodendron Balfourii, Ipomeas, Rondeletia speciosa major and Stephanotis are a few of the many climbers suitable for growing in a warm conservatory. The plants, whether growing in pots or planted out in borders, should receive attention now. The new shoots of Allamandas, Bougainvilleas and Cissus discolor should be shortened to about an inch, the soil removed from the border to a depth of about 2 inches and re-placed by rich, peaty soil. Specimens in pots should be re-potted if necessary and the drainage put in order. In planting climbers in borders restrict the roots to a space measuring from 18 inches to 3 feet square, according to the strength of the individual plant. Fuchsias, Lapageria rosea and its white variety, Passifloras, Plumbago capensis, Swainsonias, Streptosolen Jamesonii and Brachysemas are all excellent subjects for training up pillars or for suspending from the rafters of greenhouses and cool corridors. Top-dress the roots with rich, fibrous loam, thin out the weakly growths of the Swainsonias and Lapagerias, and arrange the shoots as naturally as possible. *Luculia gratissima* should be pruned severely and kept fairly dry at the roots for a week or two. Specimens planted in an enclosed area in a border thrive better than those in pots. This plant resents disturbance at the roots, but it may be top-dressed with a mixture of loam, peat and silver sand.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

SHALLOTS.—These bulbs may be planted now in well-worked soil. Arrange the sets at about 5 inches apart and wide enough between the rows to permit of the Dutch hoe being freely used, but be careful not to cover them. Where Garlic is esteemed the cloves may also be planted now.

MINT.—This herb is much used in some establishments, and a sufficient number of the long, underground stolons should be lifted, placed in boxes among light soil, and stood in one of the forcing houses, where, with an abundance of water to keep the soil always moist, a supply of shoots will soon be produced.

RADISHES AND LETTUCES.—In warm situations seeds of these salads may be sown out of doors in a sheltered border and in the same drills, which should be somewhat wider than usual. Early Radishes do not always succeed, but a row is worth trying. If a Cos Lettuce is preferred Hicks's Hardy is one of the most reliable varieties for this or perhaps for any other season. It is very hardy, grows to a large size, and "cabbages" without it being necessary to tie the leaves together.

PARSLEY.—The main crop may be sown at any time. I have an abundance of Parsley from the produce of seeds sown a year ago, the plants having been transplanted when of a suitable size to move them 1 foot apart. As a rule they continue giving us leaves till those of the succeeding year's sowing are ready, though it is safer to have another sowing to meet any losses that may occur through winter failures than to rely on the one. Dobbie's Exhibition is the finest variety for all purposes. Well-grown plants are objects of great beauty when fully matured.

LEEKs.—The main crop of Leeks should be sown at the earliest opportunity. Like Parsley, the seeds are some considerable time in germinating; and of the Leek at least it may be said that the larger it is the better it is. From the very outset Leeks should be grown in highly-manured soil, and it is a by no means bad system to enrich the spot chosen for the seed-bed with some thoroughly decayed manure, but it must be placed deeply, so that the sprouting seeds cannot

be injured by its contact. Sow either broadcast or in wide, shallow drills, and rather thinly, otherwise a great number of the seedlings will be impoverished and stunted by the more robust ones.

THE APIARY.

By CHLORIS.

SEASONABLE WORK.—In some parts of England bees will soon be gathering honey from Crocuses. These beautiful flowers supply the first pollen of the season, and on warm days the bees go out in eager search of it to provide the nitrogenous matter necessary for the successful rearing of brood. The bee-keeper can assist the bees by supplying them with artificial pollen in the shape of peafour, and for this purpose Symington's is one of the very best, as it is ground to a very fine powder. Choose a sunny nook near to the hives, well sheltered from cold winds, and sprinkle the peafour in a box of shavings. The bees will be seen loading up and revelling in the rich store of easily-obtained food. They will continue to use this until the catkins of the Hazel and Willow appear, when the apiarist should cease to use the peafour.

FEEDING.—From now until the end of April a large proportion of the winter losses among bees occur, and in most instances this is due to starvation, although these winter dwindlings are often ascribed to other causes. To feed on syrup would be to court disaster, for the liquid is stimulative in its action and would thus cause the queen to deposit more eggs than the season will warrant, and the resulting brood would perish during cold weather. This being the case use only candy made from honey and powdered loaf cane sugar. Take some honey and warm it, mixing with it the finely-powdered sugar, until the whole assumes the consistency of a very stiff putty. Allow it to stand for a few days and work in more sugar until no liquid is left. Where honey cannot be obtained, the candy must be made wholly from sugar and water, and this is made into soft candy. Take a preserving or enamelled pan, in it place 10lb. of best cane white sugar, and pour over it two quarts of boiling water. Put the pan on a bright, clear fire and stir the liquid until all the sugar is dissolved. After it begins to boil draw the vessel aside and remove the scum. When all has been skimmed off return the pan to the fire and allow it to boil as quickly as possible without any stirring for quite twenty minutes. Many are afraid to do this, as they fear that it will burn. To ascertain if the syrup has boiled long enough dip the index finger into a basin of very cold water, and immediately place it, bent, into the boiling syrup; on withdrawing it roll up the adhering sugar, and if it makes a soft ball, like plasticine, it is ready for use. There is no fear of the finger being scalded in this operation. (Those who can afford it should purchase a sugar-boiler's thermometer, which is graded from 50° to 350° F. and can be purchased for 5s. 6d.) When a ball cannot be formed the liquid must be allowed to boil for a little longer. To secure smooth candy, after removing it from the fire pour it into a shallow tin and allow it to cool. While it is cooling on no account must it be stirred (or the grain will be rough) until the finger can be held in it for quite half a minute without being scalded, then stir until the candy is white and stiff. To remove the syrup from the tin it must be warmed, and when it has reached a creamy state stir it to get out the lumps, and just before it reaches boiling point (about 200° F.) pour it into boxes or section cases and allow it to cool. The candy may be stored in a cool, dry cupboard. Should the candy be over-boiled—and hence brittle—add more water and re-boil; and to prevent the liquid boiling over fill the pan only half full.

EXAMINING THE HIVES.—No attempt must be made to make an examination of the colony as there will be a great loss of heat, and such examination may cause the bees to kill the queen. When the candy is given to the bees choose a bright, warm day, just raise the quilt sufficiently to get it under, taking care to leave no gaping corners uncovered by the quilt, or heat will escape and reduce the temperature of the lower chamber so that the brood will die.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are mis-directed.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Local News.—Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.

APPOINTMENTS FOR FEBRUARY.

- TUESDAY, FEBRUARY 3—
Scottish Hort. Assoc. meet.
- WEDNESDAY, FEBRUARY 4—
B.G.A. Ex. Council meet.
- THURSDAY, FEBRUARY 5—
Linnean Soc. meet.
- FRIDAY, FEBRUARY 6—
Roy. Gardeners' Orphan Fund Ann. Meet. and Election of Orphans at Simpson's Restaurant, Strand, at 5 p.m. Roy. Inst. meet.
- SATURDAY, FEBRUARY 7—
Roy. Scottish Arboricultural Soc. Ann. meet. Soc. Française d'Hort. de Londres meet.
- MONDAY, FEBRUARY 9—
United Hort. Ben. and Prov. Soc. Com. meet.
- TUESDAY, FEBRUARY 10—
Roy. Hort. Soc.'s Show and Ann. Meet. Horticultural Club Annual Dinner, 6.30 p.m.
- THURSDAY, FEBRUARY 12—
Manchester & N. of Eng. Orchid Soc. meet.
- TUESDAY, FEBRUARY 17—
Broughty Ferry Hort. Assoc. meet.
- THURSDAY, FEBRUARY 19—
Linnean Soc. meet.
- TUESDAY, FEBRUARY 24—
Roy. Hort. Soc. Coms. meet.
- THURSDAY, FEBRUARY 26—
Manchester & N. of Eng. Orchid Soc. meet. Roy. Botanic Soc. meet.
- FRIDAY, FEBRUARY 27—
Finchley Chry. Soc. annual meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 39.5°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, January 28 (6 p.m.): Max. 49°; Min. 40°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, January 29 (10 a.m.): Bar. 29.7°. Temp. 49°. Weather—Sunshine.

PROVINCES.—Wednesday, January 28. Max 50°, Valencia; Min. 43°, Aberdeen.

SALES FOR THE ENSUING WEEK.

- MONDAY, TUESDAY, WEDNESDAY, THURSDAY, AND FRIDAY—
First half of 10 days' Sale of Nursery Stock, at Coombe Wood Nurseries, Kingston Hill. By order of Messrs. J. Veitch & Sons, Ltd. By Protheroe and Morris, at 12 o'clock.
- MONDAY AND WEDNESDAY—
Rose Trees, Perennials, Lilliums, etc. At Stevens' Rooms, 38, King Street, Covent Garden, at 12.30 p.m.
- MONDAY AND FRIDAY—
Herbaceous and other Plants, Lilies and Hardy Bulbs, Roses, Fruit Trees, etc. At 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.
- WEDNESDAY—
Border Plants and Perennials, Hardy Bulbs, etc., at 12. Palms and Plants at 5. Trade Sale of miscellaneous Bulbs and Roots, at 12. 1,119 c/s Japanese Lilliums, at 2.30. At 67 and 68, Cheapside, E.C., by Protheroe and Morris.
- THURSDAY—
Roses, at Protheroe and Morris's rooms, at 1.
- FRIDAY—
Orchids, at Protheroe and Morris's rooms, at 12.45.

Selection and Pure Strains.

The first place in the current number of the *Journal of the Board of Agriculture** is occupied by an article which asks the question, "Can selection improve the quality of a pure strain of plants?"

To this question the authors, C. and A. Hagedoorn, of the University of Utrecht, give an uncompromisingly negative answer.

In support of their contention that a pure strain if self-fertilised will not deteriorate but will maintain its character unaided by selection, these authors point to Johannsen's well-known experiments and to the series of Wheats collected and preserved by M. Louis de Vilmorin, and recently re-discovered by a member of the firm. Johannsen's experiments, which were made with Beans, may be summarised briefly thus. By starting with single seeds "pure lines" may be obtained. The plants of each of these pure lines maintain their characters in generation after generation of their descendants, and these characters are not modified by selection. Thus Johannsen found that when he had isolated a line or race pure for a certain character—that of weight of individual seed—it made no difference to the weight of the seed of the offspring whether these offspring were obtained by sowing the somewhat larger or the somewhat smaller seeds of the previous generation. The strain had a certain range with respect to this character, and that range is maintained in successive generations. Louis de Vilmorin's observations on Wheat tend to confirm this remarkable conclusion. That distinguished horticulturist, who introduced the custom of breeding from single plants—a custom now all but universally followed—grew and preserved examples of different varieties of Wheat. From each variety a single daughter plant was preserved, and from that daughter plant in turn a single descendant was preserved. This invaluable series of pedigree plants has been discovered recently by M. Meunissier, the plant breeder to the firm of Vilmorin. The identity between the original plants and their descendants, after about 60 years of selection, is most impressive, and would seem to justify the contention of Messrs. Hagedoorn that a pure race remains pure if self-fertilised, whether selection be practised upon it or not.

Are we to assume, therefore, that all the labour of our seedsmen in maintaining and supplying us year by year with early, mid-season, and late varieties, with tall and dwarf and mid varieties, and so forth is but vain? We think not. Everything turns on the purity of the strain, and purity is an expression of constitution. Now certain characters of plants are simple. They depend on a single something present in the germ cells. Such characters are easily obtained in a pure state. Other characters are far from simple. They depend on not one or two "somethings" present in the germ cells, but upon four, five, and perhaps more of these character-bearing factors of the germ

cells. When this is the case it is probable that for one plant which is pure for this complex character there are many plants which display this character almost as conspicuously, and yet are not pure to it. The means of discrimination between the quite pure and the apparently pure are so slight that even the trained eye may be deceived.

From the practical point of view, however, Messrs. Hagedoorn's contribution is a timely one; for it will serve to emphasise to the seedsman the importance of pedigree cultivation; of starting from single seeds, and of observing the behaviour of the several families raised from these single seeds. For example, if the plant breeder discovers a desirable variety of Pea he should not only harvest and sow the seeds of that plant, but he should harvest the seeds of each first generation-plant separately in order to discover whether the desirable character is common to all the members of all the families, or whether it is confined to some families only, or even to some individuals of some families. If the character is exhibited by all the members of all the families it may be regarded as fixed. If it occur only in some families, but in all the individuals thereof, the next generation from these individuals will suffice to show whether the character is fixed. If, on the other hand, the character occur only among some individuals of certain families, the grower must be prepared for several years of "selection" before he can hope to light upon plants which are actually pure to the character. In this task isolation must again be practised.

Coloured Supplement.—The subject of the Coloured Plate to be published with the issue for next week is the Tree Lupin (*Lupinus arboreus*) from a colour photograph taken in the R.H.S. Gardens, Wisley.

HORTICULTURAL CLUB.—The annual meeting of the members of the Horticultural Club will take place in the Club Room at the Hotel Windsor, Victoria Street, Westminster, on Tuesday, February 10, at 5.45 p.m. The annual dinner will take place in the large dining-room of the hotel at 6.30. The president, Sir FRANK CRISP, Bt., will preside. The proceedings will include a musical programme, provided by the president. The following new members were elected at the last meeting: Messrs. G. NORMAN BUNYARD, A. DAWKINS, G. H. RICHARDS, and ROBERT WOODWARD, jr.

NATIONAL DIPLOMA IN HORTICULTURE.—The qualifying test for candidates wishing to take the National Diploma Preliminary Examination in June next will be held on Tuesday, March 10. Those desiring to register their names for the Diploma should make application at once on forms to be obtained from the Secretary, R.H.S., Vincent Square, Westminster, London, S.W.

THE CRYSTAL PALACE.—The proposal to devote only 20 acres of the grounds as an open space for the use and enjoyment of the public has caused disappointment, and the Metropolitan Public Gardens Association has addressed a letter to the Corporation of the City of London on the subject. It states that the Association views with serious concern the provisions of the Crystal Palace Bill, under which only 20 acres will be permanently dedicated as

GARDENS OF JAPAN.

ABOVE: SUMMER HOUSE IN THE GENKAKUJI TEMPLE GARDEN, KYOTO.

BELOW: GARDEN VIEW, SHOWING ARRANGEMENT OF STEPPING-STONES, BRIDGE, LANTERN AND PAGODA.

an open space for the use and enjoyment of the public, while access to a large area of the grounds may be curtailed by fifty days in each year; and records the opinion that the proportion of land to remain permanently open should be materially increased in view of Sir DAVID BURNETT'S pledge in his letter to the *Times* of March 11 last that the object of the scheme was to acquire the Palace and grounds for the purposes of an open space.

MUNIFICENT GIFT BY MR. LEONARD SUTTON.—At the meeting of the Council of University College, Reading, held on Tuesday, January 27, it was announced that Mr. LEONARD SUTTON, of the firm of Messrs. Sutton and Sons, had given a donation of £1,000 to the fund which is being raised for the purpose of providing adequate buildings and laboratories for the agricultural and other departments of the College.

BULBS AT HAMPTON COURT.—It is stated that the number of bulbs which have been planted this season in the Royal gardens at Hampton Court Palace exceeds one million, the weight being between two and three tons. There are 140 beds, with an average of about 3,000 bulbs to a bed; while the great 10-foot border, which extends from the river to the Hampton Court Road, takes more than all the beds.

SALE OF THE COOMBE WOOD NURSERY STOCK.—The second sale by auction at Messrs. JAMES VEITCH AND SONS' nursery, Coombe Wood, Kingston Hill, will be conducted by Messrs. PROTHEROE AND MORRIS on Monday, February 2, and nine following days. The catalogue includes Rhododendrons, Yews, ornamental, flowering and avenue trees, Roses, Clematis, Vitis, Magnolias, Bamboos and other stock. The sale will commence each day at 12 o'clock.

YORK CHRYSANTHEMUM SHOW.—Owing to the poor support which the York Florists' Society has received in the past few years in connection with the annual Chrysanthemum Exhibition, formerly one of the best shows in the North of England, the Committee has decided to discontinue the display, unless a sufficient sum is guaranteed to meet expenses. As an alternative it is proposed to hold a one-day members' show.

PROPOSED NEW PUBLIC GARDENS AT BLACKPOOL.—The Blackpool Corporation is considering the purchase of St. George's Gardens as a public open space, at a cost of £20,000. Although there are opponents of the scheme, on the score of expense, the matter has the support of the Chairman of the Finance Committee, who holds that it will not add to the burden of the ratepayers.

PROPOSED AMALGAMATION OF SCOTTISH HORTICULTURAL SOCIETIES.—If we may judge from the tone of the discussion of this subject that took place last week on the occasion of the annual meeting of the Scottish Horticultural Association, it really seems as if, after all, some practical result may come from the proposal to amalgamate the two Scottish societies. The matter has been before horticulturists for many years past, and in 1905, when the last International show was held in Edinburgh, it was thought that every means would be sought to overcome any difficulties that stood in the way of amalgamation. But the movement needed the help of a strong man, and there was none forthcoming. Directly difficulties were encountered, enthusiasm began to wane. Then or later a committee was appointed by the Scottish Horticultural Society, but it was appointed for one year only, and after discussing the matter for that period the committee left things as they were. As was pointed out by Mr. Taylor and Mr. Cuthbertson (see p. 80) the same men hold high offices in both societies, and most of them have expressed themselves on

one occasion or another in favour of amalgamation; yet nothing has been done. Neither the Scottish Horticultural nor the Royal Caledonian is remarkably strong, the Edinburgh shows are not all they might be, and Scottish horticulture is represented somewhat weakly by two voices. Amongst those who declared for union last week were Mr. KING (President of the Scottish Horticultural Society), Mr. JAMES WHYTOCK, Mr. J. W. McHATTIE, Mr. COMFORT, Mr. CUTHBERTSON, and Mr. TAYLOR. If something practical is not done soon the reputation of Scotchmen as organisers will suffer.

BEGONIAS AT CHERRYHINTON HALL.—Mr. E. DYSON, gardener at Cherryhinton, has forwarded photographs of Begonia Gloire de Lorraine, growing in a glasshouse. The plants are 8 feet in circumference and are growing in 7-inch pans suspended from the roof-rafters. They are masses of flowers, scarcely any foliage being visible beneath the great wealth of blossoms.

NEW CLASSES AT THE SHREWSBURY SHOW.—New classes have been arranged for the summer show of the Shropshire Horticultural Society, which will be held at Shrewsbury on August 19-20. One is for a collection of American Tree or Perpetual-flowering Carnations, arranged in a space measuring 15 feet by 5 feet. The first prize is a 50-guinea Silver Challenge Cup, presented by the President, ANNABELLE LADY BOUGHEY, together with £15 in money. The 2nd prize is £12 10s., the 3rd prize £10, and the 4th prize £7. The Cup will become the property of any competitor who wins it three times (not necessarily in succession). Prizes are also offered in three classes for (a) six pots of new varieties of Perpetual-flowering Carnations not yet in commerce; (b) a collection of cut Carnations occupying a space of 6 feet by 4 feet (Tree Carnations excluded); and (c) twelve vases of Picotees, white or yellow grounds, three blooms of each, staged with their own buds and foliage. A new class for nurserymen is one for a formal or informal flower garden arranged in a space 100 feet by 50 feet out-of-doors, entirely at the discretion of exhibitors, but ponds, streams and rockwork are not permitted in the scheme. The following awards will be made:—Coalport china dessert service, value £20; large Gold Medal; Gold Medal. The sum of £15 towards expenses will be allowed to each exhibitor whose exhibit the judges consider sufficiently meritorious.

THE SURVEYORS' INSTITUTION.—The annual dinner of the institution will be held at the Whitehall Rooms, Hotel Metropole, on Monday, February 23, at 7 p.m.

GIFT OF PLANTS TO THE BRITISH MUSEUM.—A second collection of Southern Nigerian plants has been presented to the Natural History Museum by Mr. and Mrs. P. AMAURY TALBOT. As stated by the *Times*, the collection comes from the Eket district, which lies along the Gulf of Guinea, stretching westward from Calabar and the Cross River. The country consists of Mangrove marsh lining the banks of creek and stream, and of fertile Palm swamp with Coconut, Pissava and oil Palms. Toward the seashore dwarf Dates fringe the low-lying lands. Mrs. TALBOT has prepared about 800 specimens of the flora of this district, and they are now being classified at the herbarium at South Kensington. Mrs. TALBOT has paid special attention to the *Napoleonas*, which belong to the Myrtle family. In some of them the flowers are about 2 inches in diameter, and white and pink in colour. The specimens include new genera of Leguminosae, whilst the Rubiaceae is represented by a number of new species. The *Randias* present interesting problems as regards insect visits for the purpose of fertilisation. *Cyclocotyla oligosperma* Wernham is a new species, hitherto known merely from a small fragment from the Congo. This, which is one of the most interesting plants in the

collection, is a member of the Apocynaceae, to which many rubber-bearing plants belong. Mrs. TALBOT has also brought back a new species of the Coffee plant and a number of Orchids, some of which are new.

OUTRAGE AT A BOTANIC GARDEN.—In the early hours of the 24th inst. a bomb exploded in the Botanic Gardens, Glasgow, breaking a number of panes of glass in the Kibble Palace, whilst a second bomb exploded near to a watchman, who fortunately escaped injury. The *Glasgow Herald* states that the Kibble Palace, or winter garden, was originally built by the late Mr. JOHN KIBBLE at his residence, Coulport, Loch Long, but was taken down and re-erected on an enlarged scale in the Botanic Gardens in 1871. It covers nearly two acres, is a handsome iron and glass structure, and comprises an entrance hall at the west end, transepts filled with flowers, and a lofty conservatory, 471 feet in circumference, which contains Palms and other tropical plants. The eastmost portion of the Kibble Palace closely adjoins the boundary of the grounds of Queen Margaret College, while a short distance to the south is the wall separating the Botanic Gardens from Hamilton Drive. Mr. JAMES WHITTON, the superintendent of parks and curator of the Botanic Gardens, who resides at Bellahouston, arrived in the gardens shortly after eight o'clock and made an examination, which revealed that twenty-seven panes of glass in the perpendicular and curved parts of the conservatory of the Kibble Palace had been shattered. Fortunately none of the plants was damaged.

REGULATING THE RAINFALL.—Sir OLIVER LODGE, in delivering the annual Kelvin lecture before the Institution of Electrical Engineers on the 22nd inst., referred to the electrification of the atmosphere, and pointed to the possibility of controlling the weather by discharging into clouds sufficient electricity to start a rainfall. Sir OLIVER said that in normal circumstances in fine weather the earth is negatively charged and the higher layers of the atmosphere positively charged. Lord KELVIN held the view that fine weather is associated with the positive condition of the upper atmosphere, and it is the fact that the electrical conditions are reversed in cloudy and rainy weather. If these things are associated as cause and effect, there is a hope that a control of the electrical conditions of the atmosphere may be the proper line of research to follow in any attempt to control the weather. Sir OLIVER thinks that the well-known influence of ultra violet light in coaxing the negative electricity of the earth into the lower air, whence it is carried by wind currents to a higher level, produces the conditions which cause thunderstorms. Experiments ought to be carried out as to the effect in countries where rain is wanted of flying kites at a high elevation and by that means discharging into the clouds sufficient electricity to start a rainfall.

BELGIAN HORTICULTURISTS AND THE ST. PETERSBURG EXHIBITION.—Belgian horticulturists, organised by their society, the *Chambre Syndicale des Horticulteurs Belges*, are busily preparing to take part in the International Horticultural Exhibition to be held at St. Petersburg next May. The Belgian Government has promised to provide the generous sum of Fs. 25,000 towards the expenses of those who wish to exhibit, out of which sum the *Chambre Syndicale* will have the disposal of Fs. 19,000, to be expended on behalf of horticulturists pure and simple. The remainder, Fs. 6,000, will be handled by a committee to be appointed to look after the interests of exhibitors of fruit and early vegetables. The money will be chiefly used in defraying railway charges (for the goods and for the fares of two delegates who will receive and unpack, etc., the exhibits), and out-of-pocket expenses at St. Petersburg. All expenses will first be paid by the exhibitors, and will be

refunded out of the grant. The two delegates who have been appointed to look after the interests of the Belgian horticultural exhibitors are M. CH. PYNART and M. FRANCOIS SPAE.

PROPOSED DEVELOPMENTS AT WISLEY.—With the annual report of the Royal Horticultural Society, which has just been posted to the Fellows, a slip is inserted containing a special notice relating to the Wisley Gardens. This notice is as follows:—"Notice is hereby given that at the annual meeting of the Society to be held on Tuesday, February 10, at 3 p.m., Sir DANIEL MORRIS, K.C.M.G., will propose, and Mr. W. CUTHBERTSON, J.P., will second a resolution to the effect that—"The Council of the Society be requested to create a Special Trust

to carry out its recommendations, there is every prospect of great developments taking place in the Society's work in the immediate future. This Report, which was only laid before the Council on December 9, will require much careful thought, for the scheme is of such magnitude and complexity, and touches so many different interests, that its mere consideration must of necessity take a considerable time before even an outline of it can be announced, so that for the present no more can be said beyond recording the fact. A new Committee has been formed to advise on the details of the Report."

ANIMALS AND PLANTS UNDER DOMESTICATION.—On the 20th inst. Professor BATESON, Director of the John Innes Horticultural Institution, Merton, gave the first of a course

only occur after hybridisation. The cross between the rock pigeon and the stock dove has now been made, and if such a cross is possible now may it not have occurred in the past? The study of the physiology of variation leads to the doubt whether there is anything to be called general variability, but variation of the type in which loss of characters occurs is very common. A case in point is that of the six-rowed Barley, which behaves as a recessive to the two-rowed form. The two-rowed form possesses a factor inhibiting the development of the six-rowed type, and it must be concluded that the latter has been derived from the wild type by the loss of this factor.

PHOSPHATIC MANURES.—Experiments carried out by Messrs. MUNTZ and GAUDECHON

[Photograph by H. N. King.]

FIG. 37.—JAPANESE GARDEN AT FRIAR PARK, HENLEY-ON-THAMES, THE RESIDENCE OF SIR FRANK CRISP, BT.

Fund to carry on and augment the Society's work at Wisley, and this meeting would approve of a part of the present surplus funds of the Society being allocated to that purpose." As bearing on the same question we extract the following paragraph from the annual report of 1913, a copy of which comes into our hands as these pages are going to press:—"The Research Committee was appointed to examine the large number of suggestions for the extension of the Society's work which are constantly being made, and to advise the Council on any reasonable ways in which the Society might assist and advance the more scientific aspects of horticulture. A very important report has been drawn up by this Committee, and, if it is found practicable

of lectures on "Animals and Plants under Domestication." He discussed the question whether the variation of domesticated animals and plants can be justly compared with that of the wild species, and considered that one grave difficulty is the fact that under domestication no new form has been known to arise which is sterile with the parent form. In the time of DARWIN but little progress had been made with the study of variation. Analysis of variation has been made possible by the Mendelian method of investigation, and the results of recent work had been to throw doubt on many of the assumptions made by earlier workers. DARWIN accepted the evidence that the numerous types of the pigeon came from a single original form. Now we would think that such variation would

(*Ann. Sc. agron. franç. et étrangère*, p. 200, 1912) have an important bearing on the application of phosphatic manures to soils. These authors find that the amounts of added phosphates absorbed by plants (Peas, Beans, Turnips, etc.), are greatest in the year during which the fertiliser is added, and that the amounts absorbed decrease markedly in the second year, and yet more in the third year. Wherefore it should be good practice to manure with small quantities of phosphates annually rather than to add larger quantities at longer intervals. The authors find, moreover, that mono-calcic phosphate is more assimilable by plants than either di- or tri-calcic phosphate, and that tri-calcic phosphate gives results slightly better than the di-calcic phosphate.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

CYANIDING TO DESTROY MEALY BUG.—The correspondence on this subject shows that the matter is both interesting and important to gardeners. Although the gas has been used in gardens for many years the process has never yet been put on a scientific basis. There are certain conditions that require definite elucidation to make cyaniding a safe and sure agent for the destruction of Mealy Bug and other pests of plants, both indoors and out. We require to know (1) how to bring about that condition of the host plant that will render it the least susceptible to the effects of the gas; (2) the life history of the pest we have to destroy; (3) to use cyanide of one uniform percentage strength; (4) to have a means of generating the gas that will not endanger human life. The first condition may, perhaps, be secured by a dry atmosphere, keeping the plants dry at the roots as circumstances will allow. A low temperature, below 55° if possible, is best, and the cyaniding should be done in the evening when light is absent or very weak. I believe it is generally known that there are two species of Mealy Bug that infest plant houses, *Dactylopius longispinus* and *D. citri*. Those who wish to know all about them should read Professor Newstead's *Monograph of Coccidae*. I have counted the eggs in many nests and have found them to be from 60 to over 200. I counted the eggs in two nests recently; one had 120, the other 145. Your correspondent, *J. H. Y.* (p. 30), seems to indicate that they hatch in two or three days, but I have not found them to hatch in so short a time, and I have known them to remain unhatched at this time of the year for a long period. Generally I have found the females are slow egg layers, when they ultimately die, if my observations have been correct. I would advise cyaniding dormant vines every ten days three or four times. I found a very fine specimen male bug last week. No doubt many of your readers will have seen the pictures from my photographs of the males and females in Professor Theobald's large book, *Pests of Orchard and Garden*, and in the practical book, by Mr. R. Hooper Pearson, *Garden Pests*, in either of which particulars are given for cyaniding. I am very pleased to say I have photographed the Mealy Bug, male and female, nests and eggs, in practically all stages, and I have a quantity of material under observation at the present time. Sodium cyanide should be used, as potassium cyanide is sold in so many strengths, whereas sodium is of one uniform strength and more soluble than the potassium salt. In the generation of the gas every precaution must be taken to ensure safety as well as the complete dissolving of the cyanide. There are cases on record where the cyanide has been dropped into the acid in paper and the cyanide has floated on the acid without dissolving. If cyanide is used at a certain strength not only will Mealy Bugs be destroyed, but their eggs also. *J. G. Blakey, Holmwood Gardens, Redditch.*

PREVENTION OF ACCIDENTS DUE TO BURNING.—In returning recently a verdict of accidental death in the case of a cook who had died from burns, the jury added a rider that all cooks should be provided with and wear unflammable aprons. To such an admirable precaution may I suggest another? One potential and not infrequently an actual factor in these distressing accidents, is the high kitchen mantel-shelf, upon which (maybe) are kept some cooking utensils. To reach these things, in a hurry probably, the cook must necessarily lean over the fire in a position so dangerous as seemingly to court disaster. The risk is undoubtedly always present; to do away with it is simple—remove the shelf. *Prevention.*

ANTS AND SEEDS.—Early last week I made a large sowing of Antirrhinums and other plants, placed the seed-pans on a stage in warm pit and covered them with paper. Some days afterwards I noticed a number of amber-coloured ants in the house, and on a closer inspection I was astonished to find that the ants were busy carrying off the Antirrhinum seeds. The insects

hunted around and when a seed was found it was lifted, carried away and eaten beneath the pan. *C. H. C.*

ROSES IN JANUARY.—With reference to the photograph of Roses reproduced in fig. 31, I am enclosing two photographs of Roses picked at Worthing on the 2nd and 6th inst. The plants are growing in the open with only a Privet hedge for protection. *G. F. Haskell.*

WAS LENOTRE EVER IN ENGLAND?—With regard to the reference to the famous landscape gardener in your last issue, p. 53, it is stated in Chalmers's *Biographical Dictionary* that Lenôtre came to England in the reign of Charles II. and laid out Greenwich Park and St. James's Park. I understand that in France no evidence has ever been found that Lenôtre visited England. Can any such evidence be found in English records of the time? *A. H.*

RAINFALL IN 1913.—The total rainfall registered in these gardens amounted to 23.80 inches. Rain was recorded on 195 days—the greatest amount on January 11, when .72 inch fell. April was the wettest month with 3.45 inches, and June the driest with .58 inch. *Alfred Wilson, Hadley Bourne Gardens, Hadley Bourne.*

TRICUSPIDARIA LANCEOLATA (see coloured plate in *Gardeners' Chronicle* for January 10, 1914).—We have found no difficulty in propagating this beautiful plant from cuttings of the half-ripe shoots; but as it is of arboreal habit, it is very desirable that it should be raised from seed, and I hope Mr. Jenkins will persevere in his endeavour. The tendency to leaf-rust which he has observed in this species may be due to excessive sun exposure. Canon Ellacombe warned me against this years ago, advising me to plant it in a north exposure, and I have realised the soundness of his counsel. Like so many Chilean plants, *Tricuspidaria* relishes moisture, rapid drainage and shelter from wind and excessive sun. Moreover, in a situation facing north or west, alternate frost and thaw are less liable to injure the flower-buds, which, forming in September, hang on long peduncles until the flowering time in June. *Carpenteria*, though a native of a very different region, seems to prefer similar conditions. *Herbert Maxwell, Monreith.*

UNUSUAL GROWTH OF CHRYSANTHEMUMS.—Many varieties of Chrysanthemums here have behaved like those described by *H. L.* (see p. 42). Both stopped and "natural break" plants of several varieties showed terminal buds instead of first crown buds with growth around the bud. The former, however, made their appearance about the proper time for taking the crown buds, opened well, and developed into excellent blooms. I think the colour of the majority of the flowers was rather better than usual, as is generally the case when terminal buds are taken. I also noticed that Chrysanthemums were more prone to sporting than usual; we had some flowers of the variety *Valerie Greenham*, one half yellow the other half its proper colour, and large blooms presented a very curious appearance. But then, many unusual things happened amongst flowering plants during the season of 1913. Annuals which dried off rather early started to grow again when the moist weather came, and flowered for a second time. A large red *Abutilon* growing here produced branches with yellow flowers which were much larger than the type. *Owen Moring, The Old House Gardens, Freshford, Somerset.*

PRIMULA OBSCURICA AND SKIN IRRITATION.—I never suffered any inconvenience from this plant until three years ago, when, in watering the plants, I was stung on the wrist and about half a dozen small pimples developed. My arm swelled up to the size of two and the irritation was dreadful, especially at night. It then infected my other arm. The doctor gave me a lotion to bathe the affected parts with, but all the skin peeled off from both arms. I was under medical treatment for four months. The next spring the complaint re-appeared in the form of a very irritable swelling in my face and arms, the attack lasting for about two weeks. Last year I had three or four attacks in the same

form; the irritation seemed to last for a week or ten days and then I got a rest, but it returned in about two months. *A. C. Thurlow, Landieu Gardens, Hartburn, Stockton-on-Tees.*

ORIGIN OF COVENT GARDEN MARKET.—The enclosed historical letter, which I contributed to the *Saturday Review*, on the origin of Covent Garden Market, may perhaps be of sufficient interest to be reproduced in the *Gardeners' Chronicle*: "It is not generally known that Covent Garden Market originated in the time of Oliver Cromwell, and at first consisted of only a few sheds, and they were temporary ones. Just eleven years after King Charles II. had been restored to the throne he made a grant of the market to William Earl of Bedford, and it has increased gradually in importance from that time. It was the fifth Earl of Bedford who was created Duke of Bedford in 1694 by William III., and this was the duke who married the daughter and sole heiress of the Earl of Somerset, who sold his house and furniture at Chiswick and nearly all he possessed at the request of the Earl of Bedford to raise a fortune for his daughter, and it amounted to nearly £13,000. But the match would not have been brought about if the King had not interposed." *B. R. Thornton, Granville Lodge, Hove, Sussex.*

JOURNEYMAN GARDENERS AND LOW WAGES.—Mr. Norris's remarks on the subject of journeyman gardeners are not very encouraging. One cannot wonder at young men not being very interested in their work, when in so many cases they receive little or no encouragement to do well. I wonder if in the former days described by Mr. Norris journeymen ever spoilt anything by inexperience? If not, they must have been unusually clever. My opinion is that if wages and conditions were better, you would not find so many young men leaving the ranks of gardeners and taking up other professions.—*H. S.*

—I read with interest the remarks of *A Non-Member* (Vol. LV., page 43), and I agree with him that an examination of some kind by the B.G.A. is necessary. But let it be some qualifying examination to run concurrently with the examination for the National Diploma in Horticulture. Surely the R.G.A. requires of its members more than an annual subscription and a reference if it is going to enrol all the gardeners in the kingdom. *C. R., Cowbridge.*

—On the subject of journeyman gardeners, *R.* (p. 30) suggests that the present generation of head gardeners does not afford enough help to journeymen, but the fact is that many places are now so inadequately staffed that the work has to be got through by the head and his foreman in as short a time as possible. Journeymen under these conditions have to keep their eyes very wide open if they are to acquire sufficient knowledge to qualify them for taking a foreman's situation, and only those who are both keen and intelligent can do this. Unfortunately, the poor conditions under which gardeners have to work have driven the best men away from gardening, into professions where their talents will meet with due reward; while those who are left are men who would probably get on very slowly in any position. With regard to the subject of wages, it is to be feared that a bad example is set by the owners of the small gardens in the residential districts just outside London. The owners (often City men) know little about gardening, but they engage one professional gardener as "head," and are satisfied to provide entirely unskilled labour to work under him, trusting to his knowledge to prevent disasters. The "under-gardeners," often mere labourers of rather more than usual intelligence, thus pick up a certain amount of rough-and-ready knowledge of gardening, and are prepared, after three or four years' work, to leave and take a place as "head" in a similar garden, at a wage much lower than that which should be asked by any gardener. I have lived in a residential district where such practices were pursued, and such cases have come within my own knowledge. *Vigornian.*

—It is interesting to read the opinion of the journeyman on the subject of his wages, but it

is also rather amusing to find how little he appreciates the difficulty which confronts the head gardener who wishes to suggest rises in the wages of the men. The head cannot say to the employer, "The men's wages must be raised." The employer pays out of his own pocket, and will not be dictated to as to what he pays. My advice to the journeymen who have written on the subject is, "Wait until you take your first place as head gardener; then we will hear what you have to say." II.

—With reference to *Modern Journeyman's* letter (p. 43), although I agree with some of his remarks, I should like to ask him where the chief interests of the young journeyman lie nowadays. For instance, does he discuss, while at work, the cultivation of plants, or the latest football match and the merits and demerits of a boxer? Which is read and studied with the greatest interest, the weekly gardening paper or the penny novelette? Far be it from me to deny these lads any pleasure outside their work—"All work and no play," etc. As regards the remarks of *M.A. Co. Kerry*, as to "head gardeners cutting the ground from under their own feet," I should imagine that the majority of head gardeners, on finding that a man of their own training had been preferred before themselves, on account of age, etc., would be the first to congratulate him and wish him well. *J. Evans, Lydham Manor Gardens, Bishops Castle, Salop.*

—I think that all fair-minded readers will agree that the present rate of pay to gardeners is too low; but how can it be remedied? There are some who think that the possession of a certificate such as the National Diploma of Horticulture will produce a better state of affairs. I am afraid, however, that success does not lie in that direction; the mere possession of certificates has never raised the wages of any body of men. I am inclined to think that until gardeners are properly organised their status and wages will remain in their present condition. *Cornubiense.*

—All praise and honour is due to your esteemed correspondent, Mr. James Hudson, for refusing to take premiums from young gardeners. It is a practice that should cease. I have myself had the offer of a premium more than once, and have served where premiums were taken from apprentices; but, curious to relate, I never knew any of those who paid turn out brilliant gardeners. Head gardeners who accept premiums are under an obligation to keep the young man, whether he is suitable or not. Enthusiastic under gardeners may not be so numerous as they were at one time; still, where good wages are paid, comfortable lodgings provided, and kind treatment afforded they are to be had. Wages have gone up rapidly and are still rising. In one of the departments in the gardens under my charge the weekly wage used to be 18s. per week, now it is 21s. If employers have a love for their gardens they will not demur at a few extra pounds per annum. My advice to young gardeners is: be diligent, studious, and exercise patience, for few, if any, have reached the top rung of the ladder without some reverses. *Forty Years' Head.*

PRESERVATION OF WILD FLOWERS.—

I have been keenly interested in this subject for a number of years, and have done my best towards bringing about the rehabilitation of wild flowers. Some time ago, when rambling with a friend, I came across a fine patch (about 200 plants) of *Paris quadrifolia* (Herb Paris), growing wild. On returning to the place some time after I was distressed to find that this patch had been ruthlessly trampled upon, and only a few specimens left alive. I found out afterwards that most of this damage had been done by school children. I was glad to see that the Director of Kew had made a public pronouncement on this subject, which I hope will result in the abolition of certificates, such as are being granted at Kew and Wisley, for 200 or more dried specimens of British flowers. There is no doubt whatever that the offering of such certificates has resulted in the disappearance of several valuable plants from districts where they were once fairly plentiful. *Cornubiense.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 27.—The most prominent exhibit at the meeting on Tuesday last in the Vincent Square Hall, Westminster, was a collection of Potatoes shown by Messrs. SUTTON AND SONS, who were awarded a Gold Medal. Another excellent exhibit in the Fruit and Vegetable Section comprised a collection of vegetables shown by Messrs. JAMES CARTER AND CO., who were awarded a Silver-gilt Banksian Medal.

The Orchid Committee granted one First-class Certificate and three Awards of Merit to novelties.

Medals were awarded by the Floral Committee for groups of Carnations, early bulbs, greenhouse plants, Ferns, and ornamental shrubs, but no award was made to a novelty by this Committee.

At the three o'clock meeting of Fellows an address on "Some Aspects of American Forestry" was delivered by Professor W. Somerville.

Floral Committee.

Present: H. B. May, Esq. (in the chair), Messrs. W. J. Bean, Chas. E. Shea, Chas. E. Pearson, John Dickson, William Bain, W. Howe,

Oranges, Hippeastrums, *Prunus sinensis alba*, with numerous *Dracaenas*, Palms, Ferns, and other fine foliage plants as a setting.

Messrs. STUART LOW AND CO., Enfield, showed Cyclamens and Carnations, for which a Bronze Banksian Medal was awarded. The Cyclamens included the novelty Mrs. Buckstone, with frilled petals of a clear salmon shade; Salmon King, and Victoria, which has waved petals stained with purple on a white ground.

Messrs. WILLS AND SEGAR, Florists, South Kensington, exhibited finely-flowered plants of Azaleas (*Rhododendron indicum*) and seedling Gerberas. Azalea purpurea grandiflora showed conspicuously with its bright lavender-coloured blossoms.

Mr. W. SEWARD, The Beeches, Hanwell, was awarded a Silver Flora Medal for a collection of finely-flowered Cyclamens.

One of the most dainty exhibits was a small group of Roman Hyacinths in fancy china bowls, staged by Messrs. SUTTON AND SONS, Reading.

Mr. W. A. MANDA, St. Albans, utilised Begonias and Ferns as a setting to an exhibit of Orchids. A new variety of *Nephrolepis* with golden-green fronds was shown under the name of M. P. Mills.

Messrs. JAMES CARTER AND CO., Raynes Park,

FIG. 33.—ODONTOGLOSSUM SANDHURSTIANUM (REDUCED). COLOUR OF FLOWERS BROWN-PURPLE.

(See p. 77.)

G. Gordon, G. Reuthe, W. P. Thomson, John Green, E. A. Bowles, W. J. James, E. H. Jenkins, R. Hooper Pearson, Charles Blick, C. R. Fielder, John Jennings, J. F. McLeod, Thos. Stevenson, F. Page-Roberts, Arthur Turner, Chas. Dixon, J. W. Moorman, James Hudson, and R. C. Notcutt.

Messrs. JAMES VEITCH AND SONS, King's Road, Chelsea, exhibited a collection of greenhouse flowering plants, for which a Silver Banksian Medal was awarded. Forced Lily-of-the-Valley, Freesias, Azaleas, *Erlangea tomentosa*, *Primula sinensis fl. pl.*, and *Kalanchoe Dyeri* were all flowering profusely.

Messrs. H. B. MAY AND SONS, Edmonton, showed 20 species and varieties of epiphytal Ferns in a groundwork of small stove and greenhouse varieties. The former included excellent specimens of *Polypodium vacinifolium*, *P. v. album*, *P. venosum*, *Drymoglossum carnosum*, *D. spatulatum*, *Davallia pycnocapa*, *D. heterophylla*, *D. canariensis*, *Asplenium obtusilobum* and *Niphobolus angustata*. (Silver Flora Medal.)

Messrs. W. CUTBUSH AND SON, Highgate, were awarded a Silver Flora Medal for Carnations and indoor plants, the latter including Azaleas, Camellias, *Daphne odora rubra*, well-fruited

exhibited Tulip William Copeland, under the name "Sweet Lavender," the only Darwin variety that forces well for flowering in January indoors. The fine purple blooms are borne on tall, stiff stems.

Messrs. R. GILL AND SONS, Falmouth, showed *Primula Winteri* and rare *Rhododendrons*. Of the latter we noticed *R. Wightii*, *R. Hookeri*, and an unnamed species raised from seeds collected in the Himalayas, having growth similar to *R. argenteum*, but with buff-coloured tomentum on the undersides of the leaves, which are 18 inches long.

Messrs. R. WALLACE AND CO., Colchester, showed dwarf Conifers and Shrubs, as at the last meeting.

Mr. L. R. RUSSELL, Richmond, Surrey, exhibited ornamental Shrubs and Ivies in pots. *Daphne Mezereum album* and species of *Hamamelis* were in flower, whilst *Aucubas*, *Pernettyas* and *Skimmias* were freely fruited and very ornamental. A red-tinted *Erica vulgaris*, named *Russelliana*, was very pleasing; a batch of this Heath would be very attractive in the rock garden in winter, whilst later, we were informed, the plant assumes a golden hue. (Silver Banksian Medal.)

Messrs. WHITELEGG AND PAGE, Chislehurst, Kent, exhibited small pot plants of Conifers, such as are used for planting on rockeries.

Messrs. ALLWOOD BROS., Wivelsfield, Haywards Heath, showed Perpetual-flowering Carnations, for which a Silver Banksian Medal was awarded. Scarlet Glow was the finest variety in the collection, which included Mary Allwood, Wivelsfield White, and White Wonder.

Mr. C. ENGELMANN, Saffron Walden, Essex, staged well-grown Carnations, which included Carola, Scarlet Carola, and Variegated Carola (rose-pink with crimson stripes and blotches), all novelties raised by the exhibitor. (Silver Flora Medal.)

Carnations were also exhibited by Mr. H. BURNETT, Guernsey (Silver Banksian Medal); Messrs. YOUNG AND CO., Hatherley, and the Misses PRICE AND FYFE, Grove Park Nursery, Lee.

Messrs. BARR AND SONS, King Street, Covent Garden, showed flowering bulbs, Primroses, Freesias and other early blooming kinds. The most striking subject was a batch of forced Tulips of the variety William Copeland (syn. Sweet Lavender). The bulbs were planted in September last, and the earliest blooms opened on January 15.

Messrs. JOHN PIPER AND SONS, Bayswater, arranged a small rock-garden, which was excellently designed. The highest point was crowned by a small plant of *Cephalotaxus pedunculata*, and down the slope was a broad band of *Saxifraga hursleriana*, whilst a "valley" was red with *Cyclamen ibericum rubrum*.

Mr. G. REUTHE, Keston, Kent, showed Crocuses, *Iris histrioides major*, *Eranthis cili-cica*, *Cyclamen Coum purpureum*, *Helleborus foetidus*, *H. corsicus* and other spring flowers.

Messrs. J. CHEAL AND SONS, Crawley, arranged a small rockery which was bright with patches of coloured Primroses, *Primula denticulata*, *Anemone blanda*, *Ericas* and *Erythronium Hartwegii*.

The WARGRAVE PLANT FARM, LTD., Twyford, Berkshire, exhibited on a rockery *Crocus biflorus*, *Iris alata*, *I. Danfordiae*, *Myosotis Ruth Fischer*, *Primula megaseaeifolia*, *Cyclamen ibericum* and other early flowers.

Mr. JAMES BOX, Haywards Heath, had uncommonly good plants of *Iris reticulata*, *I. histrioides major* and *I. Danfordiae* in a collection of Alpines which was bordered by plants of *Primula malacoides*.

Messrs. G. AND A. CLARK, LTD., Dover, showed *Polyanthuses Cloth of Gold* and *Avalanche*, together with plants in bloom of their excellent strain of coloured Primroses.

Orchid Committee.

Present: J. Gurney Fowler, Esq., in the chair; and Messrs. Jas. O'Brien (hon. secretary), De B. Crawshay, R. A. Rolfe, F. Sander, F. J. Hanbury, R. G. Thwaites, W. Waters Butler, T. Armstrong, A. McBean, W. Cobb, J. Charlesworth, J. Cypher, J. E. Shill, W. P. Bound, H. J. Chapman, H. G. Alexander, C. H. Curtis, A. Dye, W. H. White, S. W. Flory, W. Bolton, Gurney Wilson, Sir Harry J. Veitch, and Sir Jeremiah Colman, Bart.

There was a fine show of Orchids, some important groups being staged, and nineteen new Orchids entered to go before the Committee, one of which secured a First-class Certificate, and three others obtained Awards of Merit.

Mrs. NORMAN COOKSON, Oakwood, Wylam (gr. Mr. H. J. Chapman), was awarded a Silver Flora Medal for a pretty and interesting group, specially rich in showy *Odontiodas*. Among the more noteworthy were the original rich red *Odontioda Cooksoniae*; *O. Bradshawiae* Cookson's var., which, with an unrecorded *Odontoglossum*, gave the new *O. Marion* now shown, a large flower, handsomely blotched with red and tinged with rose; and with *O. ardentissimum*, the new *O. Margaret*. *Odontioda Vivienne* (Cooksoniae x amabile), a flower of good shape blotched with red and margined with rose; various other *Odontiodas*, *Odontoglossum Telemachus* var. *Esme*; a grand specimen of *Cypripedium Venus* with many flowers, and other pretty hybrids, all raised at Oakwood, were also shown.

Messrs. J. AND A. McBEAN, Cooksbridge, staged an extensive group of hybrids of *Cymbidium insigne*, for which a Silver Flora Medal was awarded. The principal feature was made of 80 plants of *C. Gottianum*, with tall spikes of blush-white flowers; *C. Alexanderi* was equally beautiful, and *C. Schlegelii*, *C. Pauwelsii*, *C. Wiganianum*, *C. Doris*, and *C. Holfordianum* were also shown.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a group composed for the greater part of hybrid *Odontoglossums*, a grand plant of *O. amabile splendens*, with a very heavy spike of large, white flowers spotted with light purple, obtaining

flowers nearest in form to those of *O. coronarium*, and with broad petals making a perfectly circular outline. The colour is deep chocolate-purple, or dark claret, the labellum having a pink tip and yellow crest. It should make a fine new break for crossing. Others noted were *Cymbidium Woodhamsianum* Orchidhurst variety; *C. Gottianum*, and a selection of hybrid *Cypripediums*.

Messrs. SANDER AND SONS, St. Albans, were awarded a Silver Flora Medal for a group in the centre of which were some well-flowered *Phalaenopsis Aphrodite*. Around them were showy *Cattleyas* and *Laelio-Cattleyas*, including very finely coloured *L.-C. Mauretania*, the light yellow *L.-C. Ernestii*, and various *Brasso-*

[Photograph by R. A. Malby.]

FIG. 39.—CYPRIPEDIUM DESDEMONA.

(R.H.S. Award of Merit on January 27, 1914, see p. 78.)

a well-merited Cultural Commendation. *O. Lambeauanum*, *O. Doris*, *O. ardentissimum*, and variety *Xanthotes*; *O. Phoebe*, a selection of finely-coloured *Odontiodas*, and other hybrids were noted. Two specially good were *Laelio-Cattleya Marcus* (*L.-C. Andromeda* x *C. Trianae*), yellow with purple markings, and the fine *Cypripedium Desdemona*. Among species were *Oncidium cheirophorum*, and *Masdevallia tovarensis*.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, were awarded a Silver Flora Medal for a fine group, principally hybrids, and which contained some very handsomely blotched seedling *O. crispum* of very fine shape, and various other hybrids, including *O. Elissa* and other *O. Edwardii* crosses. The most remarkable plant in the group was *O. Sandhurstianum* (*coronarium* x *Edwardii*) (see fig. 38), a unique cross with

Cattleyas; *Oncidium splendidum*, *Cypripedium Golden Eagle*, a very distinct hybrid; some finely blotched *Odontoglossums*, *Oncidium serratum*, *O. chrysopterum* and other *Oncidium*s.

Messrs. FLORY AND BLACK, Orchid Nursery, Slough, received a Silver Banksian Medal for a compact group of pretty hybrids, some of which were new, and notably *Laelio-Laelio-Cattleya Ariel* (*L. purpurata* x *B.-C. Mrs. J. Leemann*), a well-formed flower with cream-white sepals and petals tinged and flaked with rose-pink, the lightly fringed lip being bright rose-pink, with chrome yellow disc; and *Brasso-Cattleya Cecilia* (*C. aurea* x *B. glauca*), with cream-coloured sepals and petals and rose-coloured lip shaped like *C. aurea*, but smaller. *Odontoglossum Doris*, *O. Lambeauanum*, and a good dark seedling *O. crispum*; *Cypripedium Pliny*, *C. Elatior*, *C.*

Minos Youngii, C. Idina, and some unnamed crosses.

Messrs. J. CYPHER AND SONS, Cheltenham, were awarded a Silver Banksian Medal for a very good group of Cypripediums, remarkable for the vigorous condition and fine size of the flowers. Among the best noted were C. Bridgei, C. Thompsonianum, some handsome C. Euryades, C. Charlesianum Cypher's variety, a good, bold flower; C. Beekmannii, C. Mrs. F. Goodson, and C. Memoria Jerninghamiae, still a very fine and distinct flower. In the centre were Calanthes, and in front Lycaste lasioglossa, Oncidium cheiroporum, and Soprobronitis grandiflora.

Messrs. STUART LOW AND Co., Bush Hill Park, and Jarvisbrook, Sussex, were awarded a Silver Banksian Medal for a group of well-grown plants, in the centre being a very large and finely coloured Cattleya Percivaliana, with many flowers, and quite one of the best varieties of this pretty species. Some good Laelio-Cattleyas the brightly coloured Sophro-Laelia Psyche, good Cypripediums, including the handsome C. Beryl Westonbirt variety; Masdevallia Macrura, M. Estradae, M. tovarensis, and a fine plant of Dendrobium Wardianum album.

Messrs. HASSALL AND Co., Southgate, showed two plants of the pretty Brasso-Cattleya Menda; Odontoglossum crispum with large and finely formed flowers, and two good hybrid Cypripediums.

Messrs. W. A. MANDA, St. Albans, showed a good and varied selection of forms of Cattleya Trianae.

Messrs. SWAN AND PRICE, Keyfield Nurseries, St. Albans, staged a small group of very good Cypripediums.

FRANCIS WELLESLEY, Esq., Westfield, Woking, showed Cypripedium Westfieldiense in fine form.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cattleya Tityus, var. *A. McBean* (Enid × Octave Doin), from Messrs. J. AND A. McBEAN, Cooksbridge. A happy combination of C. Mossiae, Warscewiczii, Mendelii, and Dowiana aurea, and a model Cattleya of fine size and colour. The sepals and broad petals are deep purplish-rose, the ample lip ruby-crimson.

AWARDS OF MERIT.

Odontioda Doris (*Odontioda Cooksoniae* × *Odontoglossum amabile*), from Mrs. NORMAN COOKSON, Oakwood, Wylam (gr. Mr. H. J.

Fruit and Vegetable Committee.

Present: Jos. Cheal (in the chair), Messrs. J. Willard, Edwin Beckett, H. Markham, A. R. Allan, A. Grubb, A. Bullock, G. Reynolds, W. Poupart, C. G. A. Nix, John Basham, and James Gibson.

Messrs. SUTTON AND SONS' exhibit of Potatoes (see fig. 40), for which a Gold Medal was awarded, included 150 distinct varieties and about 50 seedlings, most of the latter being of great promise. The seedlings were arranged in the centre of the collection, and above a glass case which was filled with species of Solanum—S. etuherosum, S. Commersonii, S. Maglia, and others whose history will be found in *Gard. Chron.*, March 3, 1906, p. 129. Above the case were dishes of the Large Red Fir Apple, the Small White Fir Apple, and the Congo purple-fleshed Potatoes, whilst of more interest to growers were specimens, preserved in spirit, of various Potato diseases, illustrating wart disease or black scab, *Synchytrium endobioticum*, *Hypochnus* (*Rhizoctonia*) *solani*, and the common blight, *Phytophthora infestans*. In such an extensive collection room was found for almost all the standard and favourite varieties, many of which have originated from this famous house. The variety Windsor Castle was noticed, and it appeared to be as good as when Messrs. SUTTON AND SONS first put it into commerce; it is the forerunner of a "Castle" race, which includes such novelties as Edinburgh Castle, Dover Castle, Balmoral Castle, Stirling Castle and Carisbrook Castle. The following varieties represent some of Messrs. SUTTON AND SONS' finest Potatoes in their respective classes:—1st Early, Ringleader, Gladiator, May Queen, Harbinger; 2nd Early, Edinburgh Castle, Acquisition, Windsor Castle, Ideal; Main Crop, Superlative, Abundance, Reliance, and White City. The coloured tubers included the well-known Mr. Bresse, Reading Russet, Cardinal, and Garden Favourite. It will be seen on reference to fig. 40 that the tubers were staged in a very attractive manner, being arranged in tiers, with a ground of black drapery.

Messrs. JAMES CARTER AND Co., Raynes Park, showed a collection of vegetables representing produce from the firm's strains of seeds. There were excellent Lyon Leeks, large Cranston's Excelsior and selected Ailsa Craig Onions; Early Favourite, Snowball and other Potatoes; Cartercone Savoys, Borecoles, Chou de Russie and other winter greens; Crimson Ball, Exhibition and Long Red Beets; Silver-Skinned Jerusalem Artichokes, Incomparable Crimson Celery; Summer Favourite Carrots of the stump-rooted type, Holborn Marrow Parsnips, Batavian Endive, Brussels Sprouts, Chinese Artichokes, Spinach and many other subjects. (Silver-gilt Banksian Medal.)

The "dishes" comprising the collection were so arranged that the exhibit presented a very attractive and dainty appearance.

[Photograph by R. A. Molby.]

FIG. 40.—COLLECTION OF POTATOS SHOWN BY MESSRS. SUTTON AND SONS AT THE R.H.S. MEETING ON TUESDAY LAST.

Lieut.-Colonel SIR GEO. L. HOLFORD, K.C.V.O. (gr. Mr. H. G. Alexander), sent Cypripedium Satyr (Hera Euryades × Beryl), a very handsome Cypripedium with large, nearly black blotches on its white dorsal sepal; the broad petals and lip resembling C. Beekmannii, Indian yellow with dark purple markings. Also Sophro-Laelio-Cattleya St. Arilda (S.-L. Phroso superba × L.-C. Goldcrest), a pretty flower of a salmon-tinted yellow colour and rose margin to the lip.

G. C. ROEBELING, Esq., Trenton, New Jersey, U.S.A. (gr. Mr. Jas. Goodier), again showed the remarkable Laelia anceps Roebingiana which received an Award of Merit last year, the deeply coloured petals showing more plainly the peloriate arrangement of the segments.

H. T. PITT, Esq., Rosslyn, Stamford Hill (gr. Mr. Thurgood), showed Cymbidium Lady Colman Pitt's variety; Odontoglossum crispum Pegasus, a finely blotched seedling form; Cypripedium Talma (Charlesianum × Lathamianum), with purple-flushed dorsal sepal; and C. Proserpine (glaucophyllum × Charlesianum), with rose-spotted lip.

PANTIA RALLI, Esq., Ashted Park, Surrey, sent Cymbidium Gottianum; very fine.

Chapman). Flower of good shape, with white ground; fringed petals blotched with red, and tinged with lilac on the margin.

Odontioda Sibyl (*Odontioda Bradshawiae* Oakwood var. × *Odontoglossum dark seedling*), from Mrs. NORMAN COOKSON. A remarkable colour variation, the flower being almost wholly of a bronzy-claret tint.

Cypripedium Desdemona (Mrs. Cary Batten × *Alcibiades*) (see fig. 39, p. 77), from Messrs. CHARLESWORTH AND Co., Haywards Heath. A very distinct Cypripedium of large size. The ground colour is rich Indian yellow with small, green base to the dorsal sepal, which bears blackish-purple lines, the petals and lip being tinged and marked with the same dark hue. The surface of the flower is glossy, and very attractive.

CULTURAL COMMENDATION.

To Mr. J. E. SHILL, gr. to Baron Bruno Schröder, The Dell, Englefield Green, for three magnificent plants of Cymbidium Pauwelsii The Dell variety, two with three and one with one spike of very fine blooms.

To Messrs. CHARLESWORTH AND Co., for a magnificent plant of *Odontoglossum amabile* splendens (Harryano-crispum × crispum).

GLoucestershire ROSE AND SWEET PEA.

JANUARY 26.—The annual meeting of this Society was held at the Guildhall on the 26th inst., Mr. Michael Lloyd-Baker presiding.

The balance-sheet showed that the receipts amounted to £296 17s. 10d., and the expenditure to £327 18s. 9d., leaving a deficit of £31 0s. 11d. The Chairman, while regretting the deficit, said the kudos that accrued to them through having the National Rose Society's Show at Gloucester last year was well worth that loss, and they hoped to get it back. He moved the adoption of the balance-sheet.

Mr. Conway Jones seconded, and urged the need for more general support in the way of subscriptions. The balance-sheet having been adopted the election of officers was proceeded with.

Colonel Timms, of Watson House, was elected chairman in place of Mr. Lloyd-Baker, resigned, and Lady Holford was elected President of the Society; while Lady Cunynghame, Miss de Mont Jean, and Mrs. Buller (Norton Court) were added to the list of patrons.

The secretary and other officers were re-elected.

It was agreed to hold this year's show on Friday, July 3.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

(ANNUAL MEETING.)

The Results of the Election were recorded in our last issue.

JANUARY 24.—The following are the proceedings at the seventy-fourth annual meeting of the friends of this Institution, a note upon which was published in the last issue. There were twenty-four present, and Sir HARRY J. VEITCH presided.

The secretary, Mr. GEORGE J. INGRAM, having read the minutes of the last meeting, was called upon to read the annual report and balance-sheet for 1913, which we publish in full as follows:—

REPORT OF THE COMMITTEE.

It is with much satisfaction the Committee presents its 74th Annual Report, also a statement of receipts and payments (as audited) for the year 1913. They have again the pleasure of congratulating the friends and subscribers to the Institution on its continued prosperity and increased benefits to deserving and necessitous horticulturalists in their distress and need.

In 1913 no less than £4,593 13s. was disbursed in granting annuities of £20 and £16 a year respectively. This sum is larger by £181 than any amount hitherto expended in any one year in the history of the Institution.

At the commencement of the year there were on the funds 258 persons—145 men and 113 widows. During 1913 12 only have died, four of whom left widows who, their cases having been found eligible and necessitous, were placed on the funds for the widow's allowance of £16 a year without election, under Rule III., 13. There were, therefore, at the end of the year 250 persons receiving annuities for life, and although 8 net vacancies only have occurred the Committee recommend the election of 15 candidates from an approved list of 60 applicants, which will make a total of 265 annuitants on the funds—the highest number at any time in the history of the Charity. In thus increasing their financial obligations by adding 7 additional beneficiaries the Committee feel assured the subscribers and friends of the Charity will justify their action by a continuance of that liberality and support necessary to maintain the work.

The special funds, Victorian Era Fund and the Good Samaritan Fund, still prove to be of incalculable benefit in the relief of a large number of distressed cases.

It may be mentioned that the interest derived from the Victorian Era Fund is applied in granting aid to the unsuccessful candidates at elections who were formerly subscribers, no less a sum than £219 having been distributed amongst them during the year; whilst the income from the Good Samaritan Fund affords temporary and immediate assistance in urgent cases to deserving applicants, a sum of £246 having been disbursed from this source in 1913. The claims upon this fund are very numerous, and the Committee would be grateful for any special contributions to augment its income. Grateful letters from the recipients of aid thus rendered show how much the help was needed and how greatly appreciated.

The Annual Festival Dinner, held at the Hotel Metropole in June last, under the presidency of Leopold de Rothschild, Esq., C.V.O.—President for the second time in 25 years—was most successful. The Committee desire to place on record their deep gratitude to this warm friend of the Institution for his presence and eloquent advocacy of the claims of the Charity and for his personal generous contributions to the funds. They also take this opportunity of tendering their best thanks to those gentlemen who kindly acted as stewards or collectors, to the donors of flowers, to the horticultural Press for their liberal and gratuitous help, to those who kindly arranged the floral decorations on the occasion, and to other friends who directly or indirectly contributed to make the Festival a success.

The Committee gratefully acknowledge the help afforded by the Liverpool Auxillary by their annual concert, the Geo. Monro Concert Committee, as well as by the organisers of successful concerts at Altrincham, Liverpool, Leyton and other places. Sincere thanks are also expressed to those Clergymen who kindly allocated a proportion of their Harvest Thanksgiving offertories for the benefit of the funds.

The Committee have again to refer to the liberality of their colleagues, Messrs. Arthur W. Sutton, J.P., V.M.H., and Geo. Monro, V.M.H., for their kindness in providing a year's allowance to two unsuccessful candidates who, it is needless to say, are deeply grateful for these timely gifts.

Again the Committee sincerely acknowledge the kindness of those noblemen, ladies and gentlemen, who have opened their beautiful gardens for the benefit of the funds, amongst whom were Rt. Hon. Earl Beauchamp, Madresfield; Rt. Hon. Lord Northbourne, Betteshanger; Rt. Hon. Mary Countess of Ilchester, Holland House; the Lady Wantage, Lockinge; the Lady Battersea, Overstrand; Sir Frank Crisp, Bart., J.P., LL.B., Henley; E. J. Wythers, Esq., Epping; and C. W. Dyson Perrins, Esq., Malvern.

It is hoped that other ladies and gentlemen will follow these excellent examples.

The auxiliaries still prove valuable adjuncts to the Institution, not only in obtaining financial support, but also in creating a larger interest in its work. To the Presidents, Honorary Treasurers, Honorary Secretaries (whose names are appended), as well as to the local Committees, very grateful thanks are offered.

BRISTOL AND BATH.

Presidents. Col. H. Cary Batten | Hon. Treasurers. | Hon. Secretaries. Mr. Geo. Harris.

WORCESTER.

Rt. Hon. Earl Beauchamp, K.C.M.G. | John White, Esq. | Mr. Percy G. White.

DEVON AND EXETER.

Presidents. Trehauke H. Kekewich, Esq. | Hon. Treasurers. Mr. W. Mackay. | Hon. Secretaries. Mr. W. Mackay.

WOLVERHAMPTON.

C. T. Mander, Esq., J.P. | Mr. Geo. Bradley. | Mr. Geo. Bradley.

BERKSHIRE, READING AND DISTRICT.

Mrs. Rowland Spurling. | Arthur W. Sutton, Esq., J.P., V.M.H. | Mr. L. Castle.

LIVERPOOL AUXILIARY.

The Rt. Hon. the Earl of Derby, K.G. | Mr. A. J. Crippen. | Mr. R. G. Waterman.

The Committee are glad to be able to report that the amount received from the successful Royal International Horticultural Exhibition, 1912, was £1,532 1s. 7d., being two-thirds of the balance of the profits after all liabilities had been discharged. Part of the amount has been invested for the benefit of an Annuitant who is now in receipt of £20 a year for life. The Committee again offer their grateful acknowledgements to the directors of the Exhibition for their kindness.

The Committee have again with sorrowful regret to record the deaths of many warm friends and supporters during the past year, amongst whom they would specially refer to Sir Trevor Lawrence, Bart., V.M.H., Chairman at the Festival Dinners in 1877 and 1888, and a Vice-president of the Institution; the Rt. Hon. G. W. Palmer; Mr. Martin John Sutton, J.P.; Mr. Fred Cooper, a member of Committee for many years; Mr. R. Milligan Hogg, also a former member of Committee; Mr. Robert Sydenham, Mr. John Maulean, Mr. R. Staples, Mr. A. Porteous and Mr. Anthony Hall. The loss of these generous-hearted friends is very severely felt.

In conclusion the Committee would emphasise their gratitude for the practical aid and sympathetic help accorded to them on behalf of those who through misfortune are unable to help themselves, and earnestly appeal for additional support for this National Horticultural Charity so that the beneficent work, which has been carried on with such benefit to the poor and needy for 74 years, may be maintained and extended.

(Signed) HARRY J. VEITCH, Treasurer and Chairman of Committee. GEORGE J. INGRAM, Secretary.

The Chairman moved that the report and balance-sheet be adopted. He referred to the small attendance at the meeting, which he did not regard as a sign of indifference, but rather as showing that the subscribers had entire confidence in the way the affairs were managed. The report was in every respect satisfactory, and it was a pleasure to learn that the receipts showed an increase of £181 over those of the previous year. Because of this additional support, the Committee were enabled, said Sir HARRY, to recommend the election of fifteen candidates, notwithstanding that only eight vacancies had occurred during the year through the deaths of pensioners. The Chairman referred to the kindness of Mr. Leopold de Rothschild in presiding at the annual dinner, and for the financial support he had given on that and other occasions. The Auxiliaries had rendered valuable help, and only that afternoon cheques for more than £200 had been handed him by representatives of the Worcester and Reading branches. The sum of £1,532 1s. 7d. had been received from the Directors of the International Exhibition, to whom the Committee accorded its heartiest thanks. Thus the Institution had benefited largely on two occasions from International Exhibitions, for the sum

Audited and found correct. (Signed) THOMAS MANNING, JESSE WILLARD.

of £1,000 was contributed from the show of 1866. During the past year the Institution had lost through death many prominent patrons. The late Sir Trevor Lawrence was one of their best friends, for not only had he presided on two occasions at the annual dinners, but he was always ready to help the Institution in every way. The economical manner in which the fund was managed was a matter for congratulation, and for this they were largely indebted to their capable secretary, Mr. George Ingram. Good work was still being done by the Victorian Era Fund and the Good Samaritan Fund. After thanking the members of the Press for the assistance they had always afforded the Institution, Sir HARRY concluded his speech with an appeal for increased financial support.

The resolution for the adoption of the report and balance-sheet was seconded by Mr. WHITE, and carried unanimously.

Mr. ARTHUR W. SUTTON asked the Chairman what the Committee proposed to do with the large sum received from the Directors of the International Exhibition, and whether they could extend the benefits in consequence. In reply the Chairman stated that a sum of money had been invested to provide for an additional annuitant, and fifteen additional pensioners were included this year, although there were only eight vacancies.

The meeting then proceeded to the election of officers, and Mr. A. W. SUTTON proposed the re-election of Sir Harry Veitch as Treasurer. Every year, he said, the members became more and more conscious of the debt they owe to Sir Harry Veitch, for it was well known that he allowed the work of the Institution to take precedence of all other. Mr. BILNEY seconded, and the motion was accepted with great enthusiasm. In returning thanks, Sir HARRY announced that the Speaker of the House of Commons, the Rt. Hon. J. W. Lowther, had consented to preside at the next annual dinner, to be held on Friday, June 26.

Mr. GEO. MONRO proposed the re-election of Mr. Geo. Ingram as Secretary, and the motion was carried amidst the greatest applause.

The retiring members of the Committee were all re-appointed, and the name of Mr. Percival Etheridge added to the list to fill a vacancy caused by the death of Mr. F. Cooper. The Auditors and Arbitrators were re-elected and thanked for their services.

At this stage the scrutineers of the ballot were nominated, and the meeting was adjourned until 4.30 p.m., when the poll was declared, resulting in the election of the pensioners mentioned on p. 63 of our last issue.

THE FRIENDLY SUPPER.

The Friendly Supper was held on the evening of the same day at the same hotel. Sir HARRY VEITCH presided, and he proposed the toast of "The Gardeners' Royal Benevolent Institution." Mr. HAROLD BEALE proposed "The Committee." This toast was responded to by Mr. RUDOLPH BARR. Mr. ETHERIDGE gave "Our Country Friends," to which Messrs. CASTLE (Reading), P. M. VEITCH (Exeter), and PERCY WHITE (Worcester) responded.

The sum of £15 was offered by Messrs. W. Clement and F. Dangerfield for the benefit of the seven unsuccessful candidates who had been longest on the list, conditional on £20 more being raised to provide a consolation gift of £5 each to these candidates. The money was at once forthcoming in the form of donations from Sir Harry Veitch, Messrs. P. Etheridge, Harold Beale, Ed. Sherwood and Edmund Rochford.

Worcester and District Auxiliary.

The eighteenth annual meeting of the subscribers of the Worcester and District Auxiliary of the Gardeners' Royal Benevolent Institution was held on Wednesday, the 14th inst., at the Crown Hotel, Worcester, C. E. Pipe, Esq., in the chair.

The annual report and balance-sheet were submitted and adopted. The report stated that owing to inclement weather, the day set apart for opening Madresfield Court Gardens was not a financial success, only a small balance being the result. There was a falling off in the annual subscriptions, but this was somewhat compensated by thirteen new subscribers. The sum of £105 has been forwarded to the parent institution during the past year. The bye-

laws submitted by the committee were duly adopted, and the officers elected. The proceeds of the "Gardens" Fund being again offered to any subscribers wishing to become life members by payment of £5 5s., Messrs. J. and W. Jones, having signified their intention of accepting the same, were accordingly enrolled as life members of the institution. Mr. A. A. Preece has again kindly offered to present a piece of china to the member of the Auxiliary who shall collect the largest amount on a collecting card by the end of the year. Since the Auxiliary was started in 1896 it has contributed £1,639 to the Institution, sufficient to provide pensions for sixteen necessitous gardeners or widows of gardeners.

ROYAL OXFORDSHIRE HORTICULTURAL.

JANUARY 12.—The Mayor (Alderman the Rev. W. E. Sherwood) presided at the annual general meeting of the Royal Oxfordshire Horticultural Society, which was held on the 12th inst.

The revenue account for the year disclosed expenditure amounting to £294 11s. 7d., and receipts totalling £271 17s. 8d., this showing a loss on the year of £22 13s. 10d. The balance-sheet showed liabilities due to the bankers and secretary of £39 2s. 5d., and assets totalling £20 10s., this disclosing an adverse balance of £19 12s. 5d. The report and balance-sheet were agreed to. The President of Magdalen (Dr. Warren) was re-elected president. Messrs. Barclay and Co. were re-appointed treasurers, Mr. John Thomson and Mr. J. Morrell, hon. secretaries, Mr. W. S. Carver, auditor, and Mr. F. Lowe, acting-secretary.

SOUTHAMPTON HORTICULTURAL.

JANUARY 12.—The Mayor of Southampton (Alderman W. Bagshaw), who has been a subscriber to the society for 20 years, presided at the 51st annual meeting of the Royal Southampton Horticultural Society, held at the Council Chamber on this date.

The report showed that although the society commenced the year with a debt of £56, the net deficit is now only £10. This very satisfactory result was largely due to the kindness of Ellen Lady Swaythling in lending her beautiful grounds at South Stoneham House for the Rose show. Her ladyship had again placed her grounds at the disposal of the society for next year. The summer show did not entail any loss, but the autumn show resulted in a loss of nearly £26, largely due to unfavourable weather.

Lord Swaythling was re-elected president. The vice-presidents were also re-elected. Mr. Herbert E. Molyneux, Norton Desborough, was elected vice-chairman in the place of Mr. A. Doggrell, who had resigned. Mr. A. G. Thomson was re-elected hon. treasurer, and Mr. C. S. Fuidge was again chosen as secretary.

SCOTTISH HORTICULTURAL.

JANUARY 20.—The annual business meeting of this association was held in Dowell's Rooms, George Street, Edinburgh, on the 20th inst. Mr. King, the president, was in the chair, and there was an attendance of 140 members.

The report by the Council stated that in the beginning of last year a representation was made to the Governors of the Edinburgh and East of Scotland College of Agriculture that they considered that the time had arrived when horticulture should have direct representation on the Governing Board of that institution. This suggestion was agreed to by the Governors, and ultimately Mr. W. H. Massie was put forward as the joint nominee of the Association and the Royal Caledonian Horticultural Society, and was co-opted a member of the Board. Towards the close of the year the Council learned that there was a rumour that the authorities of the Royal Scottish Museum proposed to abolish the section of Economic Botany in that institution, and the matter was at once taken up with a view to future action should the rumour prove well founded.

At the end of 1912 the Horticultural Institution fund stood at £288 2s. 5d. During the year donations to the amount of £341 0s. 8d. had been received, and the net proceeds of the

bazaar which was held in conjunction with the Chrysanthemum Show amounted to £853 15s. 11d., the fund at December 31 last, including interest on investments, being £1,493 18s. 7d. There was a profit of £83 9s. 11d. on the Chrysanthemum Show, and the Association Fund amounted to £977 10s. 5d., an increase of £117 18s.

During the year one life and 109 ordinary members were enrolled, and the membership now stood at 1,254.

Captain Stirling, of Keir, was re-elected honorary president, Mr. King was re-appointed president, and Messrs. W. Smale and James Hay were elected to fill vacancies in the vice-presidencies. Messrs. J. Alexander, J. W. M'Hattie, W. H. Massie, W. Michie, R. T. Naismith, W. Smith and Miss Burton were appointed members of the Council; the secretary, treasurer, and auditors were all re-elected.

PROPOSED AMALGAMATION WITH THE ROYAL CALEDONIAN ASSOCIATION.

Mr. G. M. Taylor introduced the question of amalgamation with the Royal Caledonian Horticultural Society by referring to what had been done a few years ago, and asked if the matter was to rest for ever where the former committee had left it. A fresh effort should be made to bring about the amalgamation, for time, energy and money were being wasted in running two societies. The secretary, Mr. Richardson, stated that the former committee was re-appointed for one year only, and if anything fresh was to be done a new motion would have to be proposed.

Mr. Comfort thereupon proposed that the Council be authorised to enter into negotiations with the Royal Caledonian Society. It had been stated by Mr. D. W. Thomson, the chairman at the annual meeting of the Royal Caledonian Horticultural Society, that his society was prepared to favourably consider the question of amalgamation, and Mr. Comfort considered that the Scottish Horticultural Society should also be in favour of amalgamation.

Mr. Cuthbertson, in seconding, said he agreed with Mr. Taylor that it was a disgrace to Scottish horticulture that things should be as they were. The same men held high office in both societies. If there was a sincere desire for unity he was certain it could be brought about, and one strong society would be the result.

Mr. McHattie said he agreed with Mr. Cuthbertson's remarks. He was strongly in favour of a union between the two societies, and considered that every effort should be made to accomplish it.

Mr. Richardson explained that on the last occasion on which an effort was made to unite, the difficulty of the Charter of the Royal Caledonian Society was considered insurmountable. Mr. Taylor said Charter or no Charter the thing should go through. Mr. Naysmith, a new member of the Council of the Scottish Horticultural Association, said he was not prepared to commit himself to proposals for union, as he thought good work could be done by the societies separately. Mr. James Whytock strongly advocated union. Mr. King, the president, assured the meeting, after Mr. Comfort's motion had been carried unanimously, that he was strongly in favour of amalgamation, and he would see that every effort was made to bring about the desired result.

COVENTRY CHRYSANTHEMUM.

JANUARY 22.—At the annual business meeting of the above society on the 22nd inst. it was reported that the balance from 1912 was £59 16s. 1d., and the total amount on the income side of the financial statement was £218 11s. 6d. The expenditure, including £70 12s. 9d., distributed in prize money, was £150 6s. 8d., leaving a balance at the bank of £68 4s. 10d. The president, Alderman A. H. Drinkwater, J.P., congratulated the members upon the increasing popularity and success of the exhibition. The election of officers resulted as follows:—President, Alderman Drinkwater; treasurer, Alderman W. H. Batchelor; chairman, Mr. A. Scott; vice-chairman, Mr. F. Morgan; secretary, Mr. G. Griffin; auditors, Messrs. A. Hammond and F. Wilkins. The vice-presidents and patrons were re-elected, the Mayor of Coventry, Councillor S. Bettman, J.P., and Harold Twist, Esq., being added to the list.

MARKETS.

COVENT GARDEN, January 28.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

Cut Flowers, &c.: Average Wholesale Prices.

Table of Cut Flowers prices including Arums, Azalea, Camellias, Carnations, Freesias, Gardenias, Lilium auratum, Lily-of-the-Valley, and various Orchids.

Cut Foliage, &c.: Average Wholesale Prices.

Table of Cut Foliage prices including Adiantum Fern, Agrostis, Asparagus plumosus, Carnation foliage, and French Flowers like Anemones and Lillac.

French Flowers.

Table of French Flowers prices including Anemones, Lillac, Marguerites, Mimosa, Narcissus, and Ranunculus.

Guernsey and Scilly Flowers.

Table of Guernsey and Scilly Flowers prices including Anemone fulgens, Narcissus, and Soleil d'Or.

REMARKS.—The supplies of Daffedils and Tulips are gradually increasing, and the blooms are of much better quality. These bulbous flowers are the brightest subjects in the market just now, and, with Lily-of-the-Valley, the more numerous. Other kinds are very scarce, and prices remain exceptionally high, but trade is very quiet. The supply of Carnations is sufficient for the demand, but the blooms generally are small. The new crop of Roses—Richmond, Lady Hillingdon, Catherine, Mer-

ment and Sunburst—is ready, and blooms were offered for sale this week. Other sorts are expected to follow shortly. Supplies of bloom from Scilly and Guernsey are limited to Sol. d'Or and Grand Primo Narcissi and Freesias, which are all scarcer than usual at this season. A few bunches of Narcissus Poeticus were marketed this week. In the French Flower Market, Violets, Acacia (Mimesa), Anemones, White Stocks, and Marguerites are the more plentiful subjects, but the supplies are shorter than usual. Paper White Narcissus appears to be practically finished, and the quality is very poor. Prices for blooms continue very high, and there is a good demand for the class of flowers required for foundation purposes by florists; but as in the English market, the supplies are short throughout, and the salesmen have no difficulty in clearing their stocks long before the market closes.

Plants in Pots, &c.: Average Wholesale Prices.

Table of Plants in Pots prices including Aralia Sieboldii, Araucaria excelsa, Asparagus plumosus, Begonia Gloire de Lorraine, Cacti, Cocos Weddelliana, Croton, Cyclamen, Daffodils, Dracaena, Erica hyemalis, Ficus, Gleditsia, Lantana, Lilium longiflorum, Lily-of-the-Valley, Marguerites, Pandanus Veitchii, Phoenix rupicola, and Spiraea japonica.

Fruit: Average Wholesale Prices.

Table of Fruit prices including Apples, Apricots, Bananas, Cranberries, Custard Apples, Dates, Figs, Grapes, Lemons, Limes, Lychees, Nuts, Oranges, Peaches, Pears, Pineapples, Plums, and Strawberries.

REMARKS.—The supplies of English Culinary Apples are limited to the varieties Bramley's Seedling and Dumelow's Seedling (Wellington), and are about equal to the demand. All the boxed fruits from Wenatchee and Oregon are suitable for dessert purposes, and are very good, both in appearance and quality. Apples in barrels continue a good supply, the best variety being Albemarle. Pears from California and Cape Colony consist of the following varieties:—Easter Bonné, Winter Nelis, Clapp's Favourite, and Williams' Brun Chrétien. Fruits from the Cape to hand this week include Peaches, Plums, Apricots, Pears, and Nectarines. Black Grapes continue plentiful. Supplies of Tomatoes from the Canary Islands have shown an increase during the past week. Forced Strawberries from Worthing are available in limited quantities. Forced Vegetables that are obtainable include Mushrooms, Peas, Beans, Cucumbers, Asparagus, and Potatoes. Salads, such as Lettuce, Endive and Chicory are fairly plentiful. There is no shortage in the supplies of ordinary vegetables. E. H. R., Covent Garden, January 28, 1914.

Vegetables: Average Wholesale Prices.

Table of Vegetable prices including Artichokes, Asparagus, Beans, Beetroot, Cabbages, Carrots, Cauliflowers, Celery, Chicory, Cucumbers, Endive, Garlic, Horseradish, Lettuce, Leeks, Peas, Potatoes, Radishes, Spinach, Sprouts, Stachys, Tomatoes, Turnips, and Watercress.

Potatoes.

Table of Potato prices including Bedford, Blacklands, British Queen, King Edward, and Evergood.

REMARKS.—Trade is somewhat slow, and prices have a tendency to fall. Stocks in London are very large, and are accumulating. Edward J. Newborn, Covent Garden and St. Pancras, January 28, 1914.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 24, is furnished from the Meteorological Office:—

A large anticyclone maintained its position over or in the immediate neighbourhood of the United Kingdom with little modification in intensity until late in the week, and the southerly wind current on the Atlantic affected the extreme western seaboard of the kingdom only. Over the country generally the wind blew from some easterly point, and at several places in the north and east it was accompanied by slight falls of snow or sleet. By Friday the central part of the high pressure system was transferred to Germany, and the southerly current encroached gradually on the west of these islands, raising the temperature several degrees in Ireland and the most western parts of Great Britain. By Saturday, when the anticyclone had retreated still further to the south-eastward, a decided gradient for south-westerly winds embraced all our western and northern districts, while at the end of the period the change to milder weather extended to the south-eastern corner of England also. Rain now fell generally (the amount at Fort William being as large as 1.2 in.) and gales occurred at a few places in the north and north-east of Great Britain, and lightning was observed at Lerwick.

THE WEATHER IN WEST HERTS.

Week ending January 28.

A Change to Milder Weather After a Persistently Cold Fortnight.—The recent uniformly cold period which had lasted a fortnight came to an end on the 26th, since which the weather has been decidedly warmer. Just before the close of the cold period in question there were two very cold nights, when the exposed thermometer indicated 17° and 20° of frost—making these the two coldest nights as yet of the present winter. The ground temperatures are rising, but are still 1° colder than is reasonable, both at 1 foot and 2 feet deep. Rain fell on three days, but to the total depth of only about one-tenth of an inch. Since the frost came out of the ground on the 25th there has been some slight percolation each day through both of the soil gauges. The sun shone on an average for only 1 hour 9 minutes a day, which is 40 minutes a day short of the usual duration of bright sunshine at the same period in January. Calms and light airs as a rule prevailed during the week. The mean amount of moisture in the air at 3 p.m. exceeded a reasonable quantity for that hour by 5 per cent. E. M., Berkhamsted, January 28, 1914.

LAW NOTE.

THEFT AT KEW GARDENS.

RECENTLY a number of shrubs have been missed in Kew Gardens, and a special watch was set by the police, with the result that two men were captured early on Wednesday, the 21st inst. Three others, however, managed to make good their escape.

The men in custody, Allen Berrow, a labourer, of Shaftesbury Road, Acton, and Henry Wild, a flower seller, of Osborne Road, Acton, were brought before the Richmond Police Court later in the day, and charged with stealing a quantity of growing shrubs of the value of £5, the property of the Board of Agriculture and Fisheries. They were remanded for inquiries. The Curator, Mr. Watson, said that for some time past shrubs had been missed, and he identified the bag of cuttings produced as similar to the shrubs which were missing from the Gardens. He should say that the four sacks which the police had in their possession would probably be worth 10s. a sack, but to replace the shrubs which had been mutilated it would cost about £5. It was a rather difficult matter to estimate the amount of damage done.

Inspector White said the men had only been in custody for two to three hours, and the police had not had time to make inquiries.

Mr. Watson said a similar raid took place a few nights earlier, but the men got away.

Inspector White asked for a remand, which was granted.

TRADE NOTE.

Mr. E. MATTHEWS, for the past 3 years gardener to Gerard Craig Sellar, Esq., Ardornish, Morvern, Argyll, has been appointed manager to Messrs. G. Gibson and Co., Leeming Bar, Bedale, Yorkshire.

ACTION OF FROST ON CATERPILLARS: A. Wilson.

The caterpillar you have sent to us for determination is that of the common Cabbage moth, *Mamestra brassicae*. It is not unusual for this insect to pass the winter in the caterpillar stage. As a rule, however, it buries itself in the earth and pupates in the early spring. Frosts seem to have no harmful effect on this caterpillar.

AMOUNT OF LABOUR FOR A SMALL GARDEN: X. Y. Z.

You will require from five to seven men in your garden. But it is not an easy matter to answer your query, seeing that you do not state how much of the specified area of land is occupied by the kitchen garden, neither do you give the length and breadth of the glasshouses, nor the purpose for which they are used. Is the soil light, heavy, or medium in texture?

ANNUALS FOR A SHADY BORDER: Scotia.

Much depends on the density of the shade. As to the selection of kinds, if quite shady only very few plants can be expected to flower with any degree of satisfaction. The best results will be obtained by cultivating the soil well, and by early sowing, or, better still, by raising the plants elsewhere and transferring them when they are of good size. If the shade is only moderate, *Antirrhinum* (treated as annuals) would be moderately successful, and the following are also suitable. *Asperula azurea setosa*, *Bartonia aurea*, *Collinsia bicolor*, *C. candidissima*, *Candytuft* and *Hieracium*.

APPLE-STEM BORER: J. J. The insect that has made tunnells in your Apple tree is the Goat Moth (*Cossus ligniperda*). Pass a piece of stiff wire into the holes for the purpose of killing the caterpillars, or eject paraffin emulsion into the burrows. Badly-infested trees should be cut down and burned before the caterpillars escape.

CARNATION LEAVES: L. Y. The leaves have been injured by greenfly. Dip the plants in quassia extract.

CUCUMBER AND DRACAENA ROOTS: P. H. *Rotherfield*. Eelworm is present in the roots of both plants. There is no cure for specimens that are attacked, and they should be destroyed by burning. Where eelworm is present all potting soil should be sterilised by heating, or it may be mixed with gaslime.

DALBERGIA SISSOO: Wm. M. *Gossip*. *Dalbergia Sissoo* is described in *Timber Trees of India* by J. S. Gamble, and by Sir D. Brandis in *Indian Trees*. It would be of no value for planting in the British Isles, as it requires a tropical or sub-tropical temperature, and even if grown as a decorative plant indoors it would not prove very satisfactory. The timber is very valuable, and is one of the numerous kinds which are known in the timber trade as Rosewood. The heart-wood is brownish, and it possesses great strength and elasticity. It is also heavy, its weight being about 50lbs. to the cubic foot. The wood is used for all kinds of joinery and cabinet work, carving, building material, gun carriages, etc. Several other species are of similar value, more especially *D. latifolia*, from Southern India.

HORTICULTURAL COLLEGES: C. F., Switzerland.

The following are establishments where you can obtain tuition in horticulture: R.H.S. School at Wisley, Surrey; University College, Reading, Berkshire; Royal Botanic Society's School of Gardening, Regent's Park, London; South-Eastern Agricultural College, Wye; University of Leeds; Swanley Horticultural College, Kent; Devon School of Gardening, Ivybridge.

MAGNOLIAS NOT FLOWERING: A. J. L.

We assume that your inquiry as to why four Magnolias, planted more than 20 years ago against the south front of a dwelling-house, never flower, refers to *Magnolia grandiflora*. Formerly many of the plants of this species were raised from seeds, and seedlings are always very slow in coming into flower. The type is not so floriferous nor so precocious as the variety *exoniensis*, but the species and all the varieties should be raised from layers, which will flower freely at an early age. To induce your examples to flower you should remove all the side shoots on last season's growth and take care that the roots are never dry in summer.

MILDEW ON VINES: Paddy.

When pruning is completed dress the vines with soft soap, half-a-pound to a gallon of water, and as much sulphur as will make a thick paste. The vines must not be syringed during the following spring or the sulphur will be washed off. Flowers of sulphur will destroy mildew on vines while there is sufficient sun heat to raise the temperature occasionally to 80° in the shade. There are several ways of applying the sulphur. It is not sufficient to merely dust it on the bunches, for the mildew attacks the leaves and stems as well as the bunches, and although very easy to destroy when it first appears, it is more difficult to combat when it becomes firmly rooted in the skin of either the berry, the stem or the leaves, and marks of it cannot then be effaced. Sulphur may be mixed with water, using a little soapsuds first to make it into a paste. Apply the sulphured water through the nozzle of a syringe, placing the finger against the nozzle to form a spray. Half-a-pound to one gallon of water is not too much, and the mixture requires to be kept well stirred from the bottom. Or sulphur may be applied in a dry state with the Malbec bellows; but both of these plans leave some sulphur in the bunches which can scarcely be washed out. The best plan is to use Campbell's Sulphur Vaporiser: the larger size will do for a house up to 6,000 feet, using 1 ounce of sulphur to each thousand cubic feet, and attending otherwise very strictly to the directions sent out with the machine. This quantity is not likely to cause any injury if used after stoning has commenced. A coating of dust will be left on the berries, but this can be easily removed early in the following morning with a pair of strong, ordinary bellows, or it can be washed off by a thorough drenching of

soft water. If the dust remains for moisture to condense on it by rapid change of temperature it cannot then all be removed. If the fruit is cut not later than the first week in September, a fresh treatment with sulphur should then be given, and the house closed while the sun is powerful during three or four days.

MOSS ON LAWNS: A. W. M. Moss is usually found in wet, impoverished turf, and although the sea-sand would serve to lighten the soil and make it drier, we do not recommend its use. Apply a dressing of superphosphate at the end of February, which will not only feed the grass, but the acidity will help to destroy the moss. Applications of lime are also beneficial. Rake off the moss with an iron rake, working the tool across the turf after the latter has received a good raking the other way. Prepare some fine soil of a rich nature—old potting soil is suitable, and apply it evenly as a top-dressing in March.

NAMES OF FRUITS: W. J. *Bligh*. Northern Spy.—*Nita*. Siegende Reinette.—*J. Sharp*. (a) Reinette Precox; (b) Opetien pomiers; (c) Dumelow's Seedling (Wellington); (d) Brownlees' Russet; (e) not recognised; (f) Striped Beefin. K. 1, Not recognised—a very poor fruit; 2, Warner's King; 3, a very poorly grown fruit of, possibly, Bramley's Seedling; 4, Dumelow's Seedling (Wellington); 5, Alfriston; 6, Northern Greening.

NAMES OF PLANTS: H. Miles. *Arbutus Unedo*, Strawberry Tree.—*R. O.* 1, *Masdevallia Estradae*; 2, *Masdevallia polysticta*; 3, *Stelis ophioglossoides*; 4, *Bulbophyllum recurvum*.—*S. G.*, *Aigburth*. 1, One of the many garden forms of *Nephrolepis exaltata*, probably *todaoides* (see fig. 147, *Gardeners' Chronicle*, Vol. LIV., December 13, 1913). The Orchid is *Laelia Jongheana*.—*Yelch*. *Ruscus Hypoglossum*.

PRUNING NEWLY-PLANTED FRUIT TREES: G. C. V.

There is a difference of opinion as to whether newly-planted trees should be pruned in the first or the second season; but carefully managed trials have convinced many that it is desirable to prune in the April following the planting of two-year-old trees, which are preferable to older ones. As your trees were over-aged when planted, there seems to be all the more reason for cutting them back this season; otherwise they will be liable to fruit excessively at the expense of growth, and may become permanently stunted. The extent of cutting-back should be in inverse proportion to the strength of last year's shoots. The weaker they are, the more severely should they be shortened. One-third will be enough to leave in the case of moderately strong growths, a little more in that of vigorous shoots, and less in that of weak ones.

SELECT LIST OF SWEET PEAS: A. E. F. and W.

The following is a list of 18 varieties of Sweet Peas of first-rate quality and suitable for exhibition:—Maud Holmes, Elsie Herbert, Margaret Attie, R. F. Felton, Thomas Stevenson, Hercules, Mrs. Harcastle Sykes, King Manoel, Scarlet Emperor, Edith Taylor, Agricola, Elfrida Pearson, Clara Curtis, Queen of Norway, Walter P. Wright, Edrom Beauty, Barbara, King White. If two white varieties are required, do not include *Agricola* and add *Florence Wright Spencer*. If a bicolor is favoured, select Mrs. Cuthbertson in place of Mrs. H. Sykes.

WALL PLANTS FOR A CORRIDOR: Scotia.

As you do not wish to grow Roses, the best plants to train against the wall in a corridor having an intermediate temperature, for furnishing cut flowers, would be *Brunfelsia calycine grandiflora*, *Euphorbia* (*Poinsettia*) *pulcherrima*, *E. jacquimaeflora* and *Heliotropium*. You would also find *Asparagus plumosus* very useful for furnishing greenery. The *Heliotrope*, when it has covered the allotted space, should be pruned hard back about four times a year.

THE MARKET FRUIT GARDEN.

SINCE the middle of November the season has been a very favourable one for the orchards. The rainfall has been small, but there has been just enough frost to bring the soil into good condition. The rainfall of January at my station was only 0.86 inches. A better season for fruit-planting could not have been desired, and the same may be said in relation to digging in orchards. At present indications are in favour of a backward season for vegetation, which is an advantage; but there is never any certainty upon this point so early in the year. Sometimes when there are signs of premature development of fruit-buds at the beginning of February a frosty period sets in and stops progress for weeks, while at other times continuously mild weather converts a late season into an early one.

THE MORE YOU PRUNE THE MORE YOU MAY.

This might well be accepted as a fruit-grower's adage in relation to well-furnished trees. For the first three years after planting, Apple trees can hardly be pruned too severely, and it often happens that, owing to weak growth or damage done by aphid, severe treatment is needed for a year or two longer. But when enough leaders have grown to furnish the tree well, the less pruning of vigorous and sound leaders is done the better it is for results. Scabby or cankered growths, of course, should be cut back to sound

wood, whatever the age and furnishing of a tree may be, and this may be said also of very weak or misdirected shoots. But when one cuts some growths there is a temptation to cut all, and this, I think, should be resisted. A grower upon a large scale desires to avoid the necessity of extensive pruning after a good framework has been obtained. He wishes to be able then to avoid anything more than the thinning of crowding growths, the cutting out of one of any two which are crossing, whether crowded or not, and sometimes the reduction of branching tops to singles. This being the case, he needs to bear in mind that if he prunes leaders this year he will have to prune afresh next year. Below every cut made now at least two shoots will be almost certain to grow, and in the case of a tree already fully furnished with branches, all but one will have to be cut out or spurred next season, or, better still, next summer. This is what is meant by "the more you prune, the more you may." There is also another point for consideration. A tree showing scab on some of last season's growths, as already stated, must be cut back to sound wood; but it does not follow that sound shoots on the same tree should be also pruned to give it a uniform appearance. Scab attacks young wood almost exclusively, and a sound shoot present now is not likely to be attacked so far as it extends at present. Extension growth may be, but then only the extension, or part of it, will need cutting off next year, and the shoot now grown will be preserved.

Similarly in the case of a variety like Cox's Orange, liable in some places to outbreaks of canker on young wood, an observer will find that most of the outbreaks are just above where a lateral has been spurred or a leader cut back. Consequently the more cutting is done the more the canker spreads. The canker fungus finds an entrance at the cut surface unless the latter is tarred, and breaks out in the bark above the cut, sometimes close to it, and sometimes higher up the new growth.

A PRUNING PREDICAMENT.

A difficulty as to the treatment of Apple trees of a slender habit of growth has been brought home to me while pruning Cox's Orange trees eight years old from the planting. In the best part of the orchard they have made splendid growth in spite of scab and canker on many of them, diseases which have been carefully attended to from the first. Great extension was made last season, particularly near the hollow centres of the trees, many of which are 15 feet from the ground at the tips of the highest branches. These tall inside branches are very difficult to get at, either for pruning or for fruit-picking. They are not stout enough for a common ladder to be used, and, besides, they are covered with fruit-buds, which such a ladder would break off. Then, as the trees are spread widely, it is impossible to reach some of the inside branches when standing as near the top of an 8-foot step-ladder as it is safe to stand, except

by pulling them down with a crotched stiek. The necessity, therefore, has arisen for preventing any further upward growth, and the only way to attain this end is to cut back to a fruit-bud. This "goes against the grain" with the finest growths on the trees, but it is the only way out of the predicament.

DIFFICULT WORK.

In the middle fortnight of January, when frost prevailed during the whole of nearly every day, and an Arctic wind was blowing, pruning was too cold work to be endurable for long at a time. Besides, there is some doubt as to the safety of pruning in a freezing atmosphere. When the thaw set in, accompanied by a little rain, stodging around the trees produced a mass of mud, which is very objectionable. Moreover, it was somewhat dangerous to mount high steps covered with greasy mud from the boots. In each shift of the steps, which have a spiked leg opposite to the part to be mounted, they had to be wrenched with much force out of the soft soil in which they had become embedded. Under such circumstances pruning was not very pleasant work.

WINTER SPRAYING.

February is the month in which most of this work is done, though March would be preferable if one could be sure of getting through it before the buds begin to burst. But as the work is often interrupted by rain or other unfavourable weather, it is not safe to delay the start beyond the middle of February, at least in the case of Plums and Pears, and not so long in a very forward season. For the mere destruction of moss or lichen any time in the winter will do. But we hope to do something more by winter-spraying, namely, to check the development of insect and fungous pests. Many fruit-growers believe that limewash, or lime and salt, applied as late in the season as possible before the buds burst, coats over the eggs of the aphid and the Apple sucker, and prevents many of them from hatching. Entomologists, or at least some of them, doubt this, and the point is at present an uncertain one. If there be anything in it lime alone should be more effective than lime and salt, as the addition of the latter, it seems to me, must prevent the lime from drying hard upon the trees, and render it more liable to be washed off by rain. That somehow hot limewash prevents aphid infestation seemed to be indicated by the fact that one block of Plum trees seen at Pershore last season, which had been sprayed with this stuff, was quite free from the pest, while another block at a short distance was very badly blighted by it. This is no proof, it is to be admitted, but two growers said they had noticed the same coincidence. If aphid infestation always arises from eggs on the trees infested lime-sulphur is certainly not a preventive, as I have used this wash regularly for years, and no one could have worse attacks of aphid than I have had. But does an attack always arise from eggs deposited on the trees infested? I have

searched in vain for eggs on both Plums and Apples, and yet a week later the trees were badly infested. In all the pruning done this winter I have noticed only one shoot partly covered with aphid eggs. Apple-sucker eggs I have often found, and as the attacks of this pest are much less serious with me than they are in many places, it is not unlikely that the use of lime-sulphur has acted as a preventive.

MUCH-NEEDED INFORMATION.

With respect to winter spraying being a partial preventive of fungous attacks, there is great need of information as to the earliest stage in the development of each common fruit fungus in which spraying is likely to be effective and the period of the season at which it occurs. No book on mycology in my possession affords this information. Mycologists tell us to spray with sulphate of copper while the trees are dormant to prevent attacks of scab and brown rot; but one of the highest authorities states that an application of the wash before the disease gets to an active stage is useless. The question then arises as to whether either scab or brown rot is in an infectious stage before the buds burst. If not then either a fungicide is effective to some extent when the fungus is in a resting stage, or

insert them. Although the land was well prepared and the rows were well trodden immediately after the planting, the result was, if a dry period occurred, that the slits gaped open, leading to the killing of some young bushes and the stunting of others. To prevent this the plan of simply pushing the cuttings alongside of a cord into the well-prepared soil was adopted, and this proved a complete success. Since it was adopted there has been hardly a miss in a row and excellent growth has been general.

NEW OR NOTEWORTHY PLANTS.

A NEW SPECIES OF SELLIERA.

SELLIERA is a small genus of the Goodeniaceae, of which two species have long been known. One of these is endemic in Australia, and the other inhabits Australia, New Zealand and extra-tropical South America. A third species, as we learn from the *Bulletin du Jardin Botanique de Buitenzorg*, has been discovered in the rice fields of Central Java. This is named *Selliera Keningsbergeri*, and it adds one more to the southern

1867, judging from the brief account given by Dr. R. R. Gates in *American Naturalist*, 1911, p. 589. An allied species, also briefly described by Dr. Gates, is *Oenothera guttata* (*Onagra guttata* Greene in herb.), which is probably the later published *O. irrigua* Wootton and Standley. It has very narrowly-lanceolate leaves.

PRIMULA ELLISIAE POLLARD AND COCKERELL.

This is a very fine species, apparently confined to the Sandia Mountains, not yet in cultivation. It is related to *P. Rusbyi*, but has much larger flowers and a conspicuously farinose calyx. *T. D. A. Cockerell, University of Colorado, Boulder, Colorado.*

ANNUALS.

II.—ANNUALS OF DWARF HABIT.

IN proceeding to write briefly regarding a number of the annuals which I liked best among the three hundred and thirty sorts which I grew I have decided to group them according to their heights. A few annuals are so dwarf that they can with aptitude be called creeping. The very dwarfiest of all is

IONOPSIDIUM ACAULE.

Whilst endeavouring to write a description of this charming little flower last summer I turned up *The English Flower Garden*, and I see I have noted that the flowers with me are not violet, at least not deep violet. It might be permissible to call them bluish violet. Otherwise I think Mr. Robinson's description perfect. It is as follows:—"A charming little Portuguese annual about 2 inches high, whose dense tufts of violet flowers spring up freely where plants of it existed the previous season. Its peculiar beauty makes it useful for various purposes. On the rock garden associated with even the choicest of Alpine plants, it holds its own as regards beauty, and never overruns its neighbours, and it is particularly suitable for sowing near pathways or rugged steps, growing freely in such places; indeed, it would even flourish on a hard gravel walk. It flowers a couple of months after sowing, and often produces a second crop of blossoms in the autumn." This is exactly what it did with me. It was sown on May 5, and began to bloom on June 20, continuing till the end of July, coming into flower again in September. The foliage is small and neat, and forms very beautiful bright green masses.

DOWNINGIA ELEGANS OR CLINTONIA PULCHELLA.

As its name indicates, *Downingia elegans* (see fig. 41) is a very pretty annual which charms everyone, and those who have not grown it should certainly make a note to try it. With me it grew to a height of 5 inches; the flowers are not unlike a large *Lobelia* in form, the under lip or petal, which gives the character to the flower, is three-quarters of an inch across, has three distinct zones of colour, the outer one being clear blue, the middle one pure white, and the one nearest the centre of the flower bright yellow, on which there are three distinct black spots. The plant has narrow linear leaves, and branches freely near the base. It remained continuously in flower for two months in the very dry season of 1913. Its proper name is, I believe, *Downingia*. It belongs to the order Campanulaceae. The plant is a native of California. Why the name *Clintonia* should have been associated with the family I do not know. Many of my friends say that the flower is like that of a miniature Orchid.

VERONICA GLAUCA

is an annual Speedwell which I grew with care but it disappointed me. It attained a height of 4 to 5 inches, but it lacked brightness, its blue

FIG. 41.—DOWNINGIA ELEGANS, FLOWERS WHITE, WITH A BLUE EDGE AND YELLOW CENTRE.

winter spraying against it is useless. If any reader of these notes can throw light upon this point he will do good service to fruit growers.

NORFOLK BEAUTY APPLE.

This is an Apple which will probably be grown extensively hereafter, when its merits have become well known. It is a large culinary variety, the tree is a very sturdy grower, and, so far as my experience with it goes, it is free from canker and scab. At present my trees have not come into bearing to any considerable extent, and the few fruits yielded were not thoroughly tested in relation to keeping quality. I am informed that they keep till January or later. The variety was raised by Mr. William Allen, of Gunton Park Gardens, near Norwich, and sent out in 1906 or thereabouts. It has been twice before the Fruit Committee of the R.H.S. The first time it was awarded an Award of Merit, the second time a First-Class Certificate.

PLANTING CURRANT CUTTINGS.

A "wrinkle" in this connection has been derived from experience. When I began to raise Black Currants extensively from cuttings the practice was that of cutting a slit in which to

genera represented in South America, Australasia and Malaya. It is a native of Central Java.

NEW GARDEN PLANTS FROM NEW MEXICO.

(Concluded from p. 67.)

OENOTHERA HEWETTII COCKERELL.

THIS Evening Primrose, found at the Rito de los Frijoles in 1912, is one of the Lamarckiana group, with large yellow flowers. It blooms the first year from seed, but lives over, and the second year becomes a very large plant with a long flowering period. I am not sure that it is better than some of the species already in cultivation, but it is worth a trial. The buds are coloured with red as in *O. rubrinervis*. Some seed sent to Professor de Vries in 1912 has yielded him six plants, which he finds to agree exactly with my description of the type plant grown at Boulder. Two of these plants have been used by Professor de Vries for crosses with two of his mutants. From the type plant grown at Boulder I have enough seed to supply the botanic gardens of the world. It seems probable that this species was collected by Dr. W. M. Bell in the Raton Mountains so early as

being far short of that of the Germander Speedwell of our roadsides.

ALYSSUM MARITIMUM.

Here I shall only refer to the very dwarf form, which is so popular for carpeting and edging. There are many strains of it offered under many different names, such as Little Gem, White Carpet, Snow Carpet, etc. To retain the procumbent habit constant care requires to be exercised in selecting for seed, and I am sure there is room also to improve the size of the flower, as I have from time to time seen very promising heads. Most of the seed sold is grown in Germany, where the best firms give this plant much attention, raising seed by the hundredweight. The foliage of the best types is a darker, brighter green than that of ordinary maritimum. The seeds germinate in ten days, and the plants come into flower in seven weeks. They should be thinned to at least 3 inches apart.

MESEMBRYANTHEMUM CRYSTALLINUM.

The Ice Plant wants a warmer situation than Midlothian to show off its crystals. It grew abundantly, but was never what could be termed an effective border plant. On the other hand,

LEPTOSIPHON.

The Leptosiphons are surely among the most charming of all annuals. They form dense clumps of foliage, and are surmounted by numerous very bright flowers, which revel in the sunshine. The flowers of *L. aureus* (see fig. 42) are bright yellow, about half an inch in diameter. On close inspection they are seen to be lined with lemon markings, and at the base of each of the five divisions of the flower there are two tiny dark-brown spots. This lovely yellow variety was the dwarfiest of all the Leptosiphons, attaining to the height of only 5 inches.

L. roseus grew a shade taller, and the growth was rather more tufted. The foliage developed in a rosette form, from which the flowers sprang. The flowers were about half an inch in diameter, and might quite accurately be described as rose-coloured, though they are shaded or striped with blush, and have a yellow centre. In the sunshine each clump was simply a mass of beautiful flowers. The seeds came up freely in eight days after sowing, and the plants were ultimately thinned to about 4 inches apart. They remained in flower for over two months.

There is another Leptosiphon which I will

Some successful growers of winter Roses report their plants in August in a rich compost, that has been mixed for a year, and consisting of about five parts of yellow, fibrous loam and one part horse and cow manure, together with a quantity of burnt garden refuse.

The roots are shaken free of the old soil and re-potted in the fresh compost, which will supply all that is needed for the first crop of blossom. Afterwards, as soon as the flowers are over, the plants are trimmed, and when they start into growth afresh a top-dressing composed of half loam and half concentrated fertiliser is afforded.

I usually apply a handful of this mixture to each plant in an 8-inch pot, and more or less to other plants in larger or smaller receptacles.

Such feeding as this is far better than applying liquid manure, because at each watering some of the stimulant of the top-dressing is carried down to the roots, whilst the surface roots, which are always very active, derive great benefit from the stimulating properties.

Roses planted out under glass need a top-dressing applied now. In this case a mixture of two parts pulverised sheep manure, $\frac{3}{4}$ parts wood ashes, $\frac{1}{4}$ part fine bone, and four parts good, fibrous loam, should be employed.

A diligent watch must be kept for greenfly, which will be found clustering around the developing buds. I find Auto Shreds one of the simplest remedies for destroying aphides.

It will be well to place the next batch of plants in a cold house or pit, where they can be protected from frost, and they may be pruned if required to bloom in April.

A house of Roses grown without artificial heat will be very useful for furnishing blooms in late April and May. Select Hybrid Perpetuals and Hybrid Teas of the freer and hardier type, such as Prince de Bulgarie, Pharisaer, Caroline Testout and Lady Ashbourne. The blooms are usually finer than those from plants that have been forced more quickly. Such plants should be pruned now, and the shoots tied. Severe pruning gives the best results, as this ensures the development of strong, new wood, which is the basis of all good results in pot culture, provided always that the roots receive suitable nourishment.

Roses potted from the open ground last October and kept plunged outside may be utilised for greenhouse work this spring if necessary, although I prefer to allow them to grow outside for one season. Plants of Crimson Rambler potted in October and the shoots cut back at the same time to about 12 inches may be shortened now to 6 inches, and placed in gentle heat, preferably upon a bed of fermenting materials.

The plants are splendid for decorative purposes; although dwarf and bushy they will yield three or four handsome panicles of blossom, and none of the Polyantha Roses equals this old variety for brilliancy. It will pay to strike a few cuttings of this Rose every year. When one-year old they should be transplanted and cut back hard at the same time. In the following October they should be dug up and potted into 7-inch pots. Dorothy Perkins, American Pillar, Excelsa, Troubadour and Lady Godiva all make splendid dwarf pot plants treated in this way.

Polyantha Roses have become a leading feature of the spring display of flowers, and they are most useful for all kinds of decorative work. Some of the newer varieties are grand. Erna Teschendorff has blooms of a lovely rich colour; it is a much better Rose indoors than in the open; Jessie, Orleans, Susie, Jeanne d'Arc, Baby Taubenschön and Ellen Poulsen are all good novelties suitable for pot culture. Potted even so late as now these Roses would be very useful to furnish beds for a summer display where it is not possible to plant permanently this spring.

One of the best of the newer Roses for forcing is Killarney Brilliant, a variety that has caused a great impression in America, where its raisers, Messrs. A. Dickson and Sons, sent it for trial some two seasons ago. The colour is much deeper than in the old Killarney, and it has

FIG. 42.—LEPTOSIPHON AUREUS, A DWARF HARDY ANNUAL: FLOWERS YELLOW.

I can say of

MESEMBRYANTHEMUM TRICOLOR

that it did better than I expected. It was very charming on warm sunny days. The flowers then opened wide, and revealed all their beauty—brightest rose at the tips of the florets, shading off to white towards the centre, which is brown. The flowers measure $1\frac{1}{2}$ inches in diameter. The sepals and flower-stems are covered with miniature crystals. The habit of the plant is creeping, rising only 4 or 5 inches above the ground. It is said to suffer from transplanting, but of this I have no experience. It germinated twenty-three days after sowing, and bloomed in August.

SANVITALIA PROCUMBENS.

No clumps in the front of my border were more continuously effective than those of this plant. There are two forms—single and double. Both kinds grow freely and attain to a height of about 6 inches, and the plants are literally covered with their small blossoms. The single flowers are about 1 inch in diameter, ray petals clear, bright yellow, centre of the flower black. If one who does not know the plant can imagine a Sunflower so small, he has pictured a single Sanvitalia. The double form is a globular yellow flower, perhaps not quite so large as the single one. It is of the easiest annuals to grow.

refer to here, although it is taller than the preceding two. It is *Leptosiphon androsacens*. The flowers are larger, being from $\frac{5}{8}$ to $\frac{3}{4}$ inch in diameter. They are rosy lilac in colour, and open only in bright sunshine. The Leptosiphons are classed by some authorities with the Gillias, but to me I am afraid they will remain Leptosiphons. In my notes I gave them all full marks, and I know no annual more suitable or more effective for the front of borders, rockeries, steps, or path edges in positions where they are likely to get a good share of sunshine. W. Cuthbertson, Duddingston.

THE ROSARY.

SEASONABLE WORK.

ROSES under glass require much attention during the latter part of January and the early days of February.

In many establishments the varieties Richmond and Liberty are grown in considerable numbers to furnish blooms at Christmas and in the early weeks of the year. Such plants will soon be starting again into growth, and they will need a top-dressing.

many more petals. Ophelia is also gaining many admirers in America, and is confidently expected to be one of the foremost forcing varieties. The blooms possess a delicious fragrance, the buds are long and pointed, and the colour salmon-pink, with gold shading. It is to be expected that blooms will be seen largely in the English flower markets this spring.

Other good novelties are Hadley, of the General McArthur and Richmond type; Mrs.

ORANGES AND LEMONS AT STANTON HALL, DERBYSHIRE.

STANTON HALL, situated in the Peak of Derbyshire, is the country seat of Mrs. McCreagh Thornhill. Oranges and Lemons are grown under glass in the gardens with great success; the standard tree of Seville Orange (*Citrus Bigaradia*), represented in fig. 43 is planted in

from these trees has been awarded several Silver Medals from the Royal Horticultural Society and the Sheffield Chrysanthemum Society. I was informed by Mr. Harvey, the gardener, that the trees produce sufficient fruits to provide a plentiful supply of marmalade for the inmates of Stanton Hall all the year round. The average number of fruits is 150 Oranges and 100 Lemons each season. Mr. Harvey cultivates the fruits of Oranges and Lemon in a state of perfection rarely attained in this country, and they reflect great credit to his skill and care. The photograph of the Orange tree was taken after many of the fruits had been removed. F. Jennings, Chatsworth Gardens, Chesterfield.

[Photograph by J. B. Gratton.]

FIG. 43.—ORANGE FRUITING IN A VINERY AT STANTON HALL, DERBYSHIRE.

Edward Powell, Mme. Jules Bouche and Melody. The variety Prince Engelbert Charles d'Arenberg has many admirers in the United States. It is a fine, rich, crimson colour, but with me the flowers are apt to split out-of-doors.

Sunburst will be extensively grown for some time to come, even though its flowers are variable; when the petals are of a pale colour there is nothing approaching them in beauty, and when they develop the lovely rich golden colour it is absolutely the best of its special shade.

the centre of a lean-to vinery and is a fine specimen. At the time of my visit it was laden with fruits of beautiful colour and extraordinary size, the majority measuring from 15 to 16 inches in circumference. The Oranges do not ripen in one season, but hang on the tree for two years, during which time another crop of green fruit is growing, making a beautiful contrast. A Lemon tree, growing in another vinery and trained upon the back wall, was finely fruited, the individual fruits requiring the support of bags on account of their weight. Fruit

FORESTRY.

THE EDUCATION OF GERMAN FORESTERS.

IN view of the increasing interest which is being taken in the afforestation problem in England, and the consequent question of competent forestry officers, it may be of interest to consider the education of the German and more particularly the Prussian forest superintendent.

In the first case he must have a thorough higher education, which means that he must stay at school until the age of at least eighteen years and must then pass an examination considerably more difficult than the London Matriculation. He must be physically fit in all respects; that is to say, he must serve his term of military service, which in this case is one year; the man who is not fit to become a soldier is never eligible as a forester. In order that his knowledge shall be practical as well as theoretical, he must serve a kind of apprenticeship in a forest district, where he is set to do various kinds of work, such as planting, felling, measuring timber, etc., and must keep a diary of all operations or objects of interest seen during the day. This diary is of great importance, as it must be laid before the Board of Foresters, where it in a way gives an idea of the powers of observation of the candidate. The apprenticeship lasts seven months, and may be served either before or after the military service.

Now comes the most important step in the whole business—viz., the education proper at the school of forestry. For three terms—that is to say, a year and a half—the budding forester must study the natural sciences, at the end of which time he sits for a stiff examination in those subjects. If he pass this, he studies for another year and a half, this time forestry proper, with a fair amount of law, national economy, etc., and then sits for another test. Should he fail in either of these examinations he is allowed another try; but should he fail a second time, only special permission from the highest authorities can save him from being thrown out of the service.

He now receives the title "referendar," or probationer, but is by no means yet done with his education. For a whole year he must study law at some university, for six months he must manage a forest district as an under official, and for half a year more he must travel from one place to another seeing various forests and keeping a diary of everything he has seen. At the end of this time the probationer is or ought to be ready for the final examination, which is of a more practical and severe nature than the previous test. As in the former case he is only allowed to fail once. "Assessor" is now his title, and he draws his first wages, amounting to about thirty shillings per week, which, considering the time and study needed and his age (about twenty-five years), is not particularly liberal. The stipend gradually increases for about eight years to about £150-£200 a year. Up to this time he is merely an assistant in a forest area, but he is given a department of his own to manage after this eight years' ser-

vice, and his salary rises by degrees to about £500 a year.

This is very little, especially when one considers the style which such men have to live up to, and a poor man can hardly be a chief forester in Prussia. He generally needs as much money again as he earns, and thus the man without a private income is hopeless. Also from the time that the student leaves school until he passes his last examination—about six and a half years—however studious he may be, he cannot earn a penny.

There is no doubt that the German forester is the best in the world, and that the Government is doing its best to preserve this reputation by the exactitude and severity of the tests imposed on the candidates and the careful selection of individuals from a more or less personal point of view.

There are five principal schools of forestry in Germany, viz.:—Eberswalde, near Berlin; Munden, near Hanover; Aschaffenburg, near Munich; Tharandt, near Dresden; and Eisenach, near Erfurt. The two first belong to Prussia, the next one to Bavaria; the fourth to Saxony; and the fifth to Thuringia. J. G. W.

ORCHID NOTES AND CLEANINGS.

ORCHIDS AT WESTFIELD, WOKING.

THE collection of Francis Wellesley, Esq. (gr. Mr. Hopkins), although a small one, has contained from time to time more really fine things than most of the larger collections. The excellent culture of the plants affords a pleasant example of what may be done where both owner and grower are keenly interested in their subject. *Cypripediums*, *Cattleyas*, both hybrid and fine varieties of species, and *Laelio-Cattleyas* take up the greater part of the space in the neat block of houses, the most retired and warmest of which is devoted to the raising of hybrids, a most interesting lot of remarkably promising crosses being there in different stages of growth.

On the occasion of a recent visit the *Cypripediums* gave the greatest show of bloom, their house being filled throughout with showy and varied flowers. Some of the best noted were *C. Sanctaenus* Westfield variety, a model flower of attractive colour; *C. Charlesianum* Westfield variety, with a very fine white dorsal sepal with emerald green base; *C. The Premier*, with fine chocolate purple markings; *C. Waterloo*, one of the finest dark forms; *C. Memoria Mostynii* (*Actaeus Langleyense* × *aureum* Surprise), *C. J. W. Mills*, *C. Actaeus Bianca* Westfield variety, and a pretty yellow *C. insigne*, raised at Westfield. The last-named has very handsome yellow flowers with the greater part of the dorsal sepal pure white. Some very fine forms of *C. Leeanum* and *C. insigne* bore a profusion of flowers, striking examples being *C. insigne* Harefield Hall, the favourite clear yellow and white *C. insigne* Sanderae, and the distinct *C. insigne* Bohnhoffianum, which, while not so showy as some of the others, is interesting owing to the peculiarity of its sepia-brown tinted dorsal sepal. Prominent in the house, either as fine specimens or remarkable varieties, were *Cypripedium* Royal George (*Harrisianum* superbum × *Minos* Youngii), a noble flower of fine colour. The stock of this fine hybrid was originally acquired by Mr. Wellesley from the raisers, Messrs. Armstrong and Brown; *C. Delhi* of fine form, substance and colour; *C. Thalia* Mrs. Francis Wellesley, which in its early days was the coveted *Cypripedium*, realising the record price; *C. Little Gem* Westfield variety, a model flower, though not large; *C. Gaston Bultel* and *C. Germaine Opoix*, two handsome flowers of Continental origin; *C. Duchess of Argyll* (*Lecanum giganteum* × *Druryi*), and *C. Charlesworthii* *Memoria Douglasii*, two very handsome *Cypripediums* acquired from the late Mr. J. Douglas; *C. The King*, a

distinct Indian yellow flower with small chocolate purple spots; *C. Elatior Rex*, and a number of seedlings flowering for the first time.

On one side was a selection of varieties of *Cypripedium* *Thalia* and *C. Priam*, some of which have not come so fine this season as formerly.

In the *Cattleya* and *Laelio-Cattleya* houses the plants were in splendid condition, and some points in their culture may be noted with advantage. The majority of the plants were of moderate size with few back bulbs. It has been found when a rare but badly-grown specimen has been purchased that it makes little progress, even under the better conditions, unless divided, and instances of this practice were shown to us giving remarkable proof of renewed vigour. Careful watering is a great point. A too wet or sodden plant is never found at Westfield, where both in the water-supply at the root and the character of the atmosphere what is called "the dry side" is favoured. Thus the plants root most abundantly, which they never do when overwatered, *Cattleya Mossiae* and its hybrids being specially liable to damage from too much water. A very beautiful set of fine varieties of *C. Mossiae*, *C. Warscewiczii*, *C. Mendelii*, *C. labiata*, and *C. Schrödera*, with a very fine lot of albino forms in each section, show well the effects of good culture, the pseudo-bulbs being short and stout, some of them curiously so, a small plant of *C. Schrödera* Mrs. Francis Wellesley having the pseudo-bulbs almost as broad as long, and resembling those of a large *Laelia anceps*. *C. Mendelii* His Majesty the King, which secured a First-Class Certificate at the Temple Show, 1908, and Royal favour, proves a good grower, and was thriving well; and *C. labiata* alba The Empress and other albinos here seem to thrive

quite as well as the typical forms. Other remarkable plants noticed were *Laelio-Cattleya Morningtoniae* (*Pallas* × *Fascinator*), which secured a First-Class Certificate at the Temple Show, 1911; *Brasso-Cattleya Wellesleyae* (*C. Mossiae* *Wagneri* × *B. glauca*), a charming white fragrant flower, L.-C. Mr. Donald MacMaster, and L.-C. Lady Oliphant, both handsome and distinct; *Sophro-Cattleya Westfieldense* with pseudo-bulbs eight inches long, and a very bright dark-red *Sophro-Laelio-Cattleya* between *S. grandiflora* and L.-C. *Warnhamense*; *Laelio-Cattleya* Mrs. W. Hopkins (L.-C. *Haroldiana* × *L. Iona*), a very handsome flower; and several new crosses flowering for the first time, one being a finely-coloured flower, which may develop into sufficient beauty to render it desirable to retain for crossing again; but the large number of fine hybrids already raised, and the erratic behaviour of some of the promising new crosses which do not come up to expectation, render careful selection imperative.

HYBRID ORCHIDS.

THE following new or rare hybrids have recently flowered. The list is supplementary to those published in Vol. LIV., pp. 375, 385. The plants are recorded with the names of the exhibitors or of those who have sent us flowers. The names and parentage are those given by the owners of the plants. If any of our readers know of prior records, either of name or parentage, we shall be glad to make corrections where error is proved.

Orchid growers are asked to send us flowers of new crosses with particulars.

Hybrid.	Parentage.	Exhibitor.
Brasso-Cattleya Pyrrha	C. labiata × B. glauca	Flory and Black.
Brasso-Cattleya Cecilia	C. Dowiana aurea × B. glauca	Flory and Black.
Brasso-Laelio-Cattleya Ariel	L. purpurata × B.-C. Mrs. J. Leeman	Flory and Black.
Cattleya Fafner	Trianae × Enid	Flory and Black.
Cattleya Madonna	Trianae delicata × chocoensis alba	W. H. St. Quintin, Esq.
Cattleya Tityus var. A. McBean	Enid × Octave Doin	J. and A. McBean.
Cymbidium Coningsbyanum	grandiflorum × insigne	G. Hamilton-Smith, Esq.
Cymbidium Nada	eburneum × Lowio-grandiflorum	Sir Geo. Holford.
Cypripedium Alcinda var. Strelsa	insigne Harefield Hall × Alcibiades	W. R. Lee, Esq.
Cypripedium Artemis aureum	nitens × Fairrieanum	Lt.-Col. Sir G. L. Holford.
Cypripedium Bourtonense	insigne Harefield Hall × Blanche Moore	G. E. Moore, Esq.
Cypripedium Cassius	niveum × T. B. Haywood	Flory and Black.
Cypripedium Comorin	Bassano (Reynaldi) × Hera Euryades	Flory and Black.
Cypripedium Delhi	insigne Harefield Hall × Earl of Tankerville	F. Wellesley, Esq.
Cypripedium Desdemona	Mrs. Cary Batten × Alcibiades	Charlesworth and Co.
Cypripedium Floryi	Niobe × Dicksonianum var. Countess of Carnarvon	Flory and Black.
Cypripedium Frenchay	bellatulum × Lawrebel	W. Hewitt, Esq.
Cypripedium Goliath	insigne Harefield Hall × Amy Moore	W. R. Lee, Esq.
Cypripedium Hanburyanum	Lecanum giganteum × Maudiae	F. J. Hanbury, Esq.
Cypripedium Julian	Vandyke × aureum Oedippe	Sir Geo. Holford.
Cypripedium Mrs. J. Lea-Smith	Edmund Lord × aureum virginale	F. J. Hanbury, Esq.
Cypripedium Piny	Lecanum Clinkberryanum × Victor Hugo	Flory and Black.
Cypripedium Proserpine	glaucochryllum × Charlesianum	H. T. Pitt, Esq.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. COOKSON, Oakwood, Wylam-on-Tyne.

CATTLEYA.—Certain Cattleyas and allied Orchids which have recently flowered are developing new roots from the bases of the new pseudo-bulbs. Any such plants may receive attention, either re-potting or top-dressing them as is considered necessary. The work should be done before the new roots grow very long, when they would be liable to injury in the process of re-potting. Many seedlings of these Orchids commence root action at this season of the year, and any necessary potting should be done as soon as this takes place, thus enabling the plants to become re-established in the new compost with the least possible check. The choice of compost should be determined by the conditions and the situation in which the plants are cultivated. Many advocate the use of a mixture of *Osmunda* and *Polypodium* fibres, while others contend that carefully selected peat intermixed with a few broken leaves and Sphagnum-moss, with sufficient broken crocks, sand and charcoal added to render the compost porous, is the best rooting medium, using pots filled to at least one-third their depth with clean, broken crocks. Water should be afforded the roots sparingly, as in the case of all newly-potted plants. They may be sprayed overhead whenever the outside conditions permit, and this, in conjunction with damping and syringing between the plants, will provide sufficient moisture to keep the pseudo-bulbs plump until the roots can draw supplies of water from below. Many Cattleyas, *Laelias* and *Laelio-Cattleyas* have their flower-buds advancing in the sheath, and in different stages of development, and such plants should be afforded every encouragement to assist them to develop their blooms. Specimens on the point of flowering should be placed close to the roof-glass, for they will derive much benefit from the sunlight. In the early part of the year, as well as during the late autumn, unless the blossoms open in favourable conditions, they lack texture and good substance, whilst the finest colours are not developed. A more liberal treatment in respect to root moisture may also be afforded as soon as the flower-buds become well advanced. As the days lengthen it will be necessary to damp the floors and spray the plants overhead more frequently in houses where the plants are not in flower, but this work must always be regulated in accordance with the weather. Where spraying overhead is practised it is advisable to do the work sufficiently early in the day to allow the moisture to evaporate from the foliage before the evening.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

WATER AND BOG GARDEN.—Such semi-tender plants as *Gunneras* and *Spiraea Aruncus* which have been afforded protection, should be examined at intervals to see that rats, mice and other vermin are not damaging the plants by eating the crowns. If it is found that they are, traps must be set. Most of these subjects are best propagated when they start into growth, and a few should be raised each season, for it is advisable to have a stock in reserve. Water Lilies may also be increased just now.

SUMMER BEDDING PLANTS.—The propagation of *Verbenas*, *Lobelias*, *Pelargoniums*, *Fuchsias* and similar plants should receive attention. If tall plants of *Heliotropes* and similar plants are required for dot-bedding healthy, vigorous-growing specimens should be trained to single stems and grown on in a house having an atmospheric temperature of about 50°. Admit plenty of fresh air to prevent the plants from becoming drawn and spindly.

CLIMBING PLANTS.—*Wistarias*, *Loniceras*, *Jasminums*, *Vitis*, and similar subjects, should receive attention. All foreright shoots and any

of weakly growth should be removed entirely. Some extension of the plants should be permitted annually by retaining all or a portion of the leading growths. It may also be necessary to train a few new shoots arising from the lower part of the stem to take the place of worn-out branches.

CLEMATIS.—If old "butts" or large roots of forest trees are available place them in irregular clumps and plant a few specimens of Clematis—*Nellie Moser*, *Jackmannii*, or *Mons. Andre*—to ramble over them. When the plants need further support arrange roughly-trimmed tops of Larch or other trees amongst the stumps. The Clematis will soon cover the supports; they flower well in out-of-the-way parts of the pleasure grounds, for they need but little attention. We have occasionally utilised poor specimens of forest or other trees for the same purpose. The top of the tree is cut off and the branches trimmed to project irregularly. A barrowful of good soil should be provided for the plants, of which two of the same variety may be set at the foot of each tree.

SHRUBS.—Shrubberies seldom receive sufficient attention in such matters as digging, manuring and pruning. Notwithstanding the great wealth of subjects suitable for shrubberies they are usually composed of such common evergreens as *Laurels*, *Box*, *Yew*, *Aucubas*, and *Privets*, producing a monotonous and depressing effect. Such kinds are very useful to form boundaries or screens, and they are adapted for planting beneath forest trees, but only a few of these should be used where the object is to obtain a decorative effect. I purpose enumerating from time to time a few of the best shrubs in their season, and those who wish will be able to make a list for planting next season. The habit and form of each species should receive due consideration, as this will determine largely the position and space in which to plant it, for when the plant has reached maturity it should stand clear of its neighbours. This is a most essential detail, and the planter must always look ahead in this and other matters. Groups are preferable to any other system of planting, although in exceptional cases a handsome single specimen may be permitted, and there should be no repetition. A clump of nine or more, according to the size of the individuals when full-grown, and the latter at distances apart varying from 6 to 12 feet is to be recommended. In grass-land the stations for planting the shrub should be about 5 feet in diameter, using fresh soil containing good turfy loam, leaf-mould and old mortar rubble; but members of the *Heath* family, including *Rhododendrons*, *Kalmias*, *Azaleas* and *Andromedas*, which resent lime, should have peat substituted for the mortar rubble. The roots should be covered with a mulching of half-decomposed vegetable matter and the cultivated area kept clear of weeds. Pruning should be done twice a year, first after the flowers are over, when the old flowering wood and the thin, weakly spray growth should be removed, and again during the winter months, when the leaders should be shortened and the other parts pruned to preserve a proper balance in the plants.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORHCOTE, Eastwell Park, Kent.

RASPBERRIES.—Take advantage of favourable weather to complete any necessary work in the Raspberry quarters. Provided that the old fruiting canes were removed directly after the berries were gathered last summer, it will only be necessary now to cut out the superfluous rods, and tie those that are left to the wires or other supports. If the stakes are of wood these should be examined with a view to replacing any that show decay. The uprights on which the wires are strained should be 18 inches higher than the canes, after the latter are pruned, as this will permit the use of netting to protect the crop from birds. If the plants are secured to stakes in the ordinary way take care not to bunch too many canes together—four or five canes to a stake will be ample. Those trained to wires should be at least 9 inches apart. Plants that have failed should be replaced by strong, young canes, lifted with a good ball of earth. Use a

small quantity of fresh, fine soil to sprinkle amongst the roots, which grow near to the surface, consequently deep digging in established plantations is not to be recommended. Clear the ground of weeds and rubbish, and if heavy in texture fork the surface lightly in view of the treading the soil has received. When the work is completed, apply a mulch of animal manure.

PLANTING RASPBERRIES.—Ground for Raspberries should be trenched and manured heavily some time previous to planting, to allow the soil to settle. The land should be clear of such perennial weeds as *Convolvulus* (*Bine-weed*), or they will be a source of great trouble, it being almost impossible to eradicate them from established plantations. If the planting was not done in the autumn, but the canes heeled in the soil temporarily, the work should be undertaken at the first opportunity, remembering that planting too deeply is a common error. The canes should be cut down almost to the ground level, as soon as growth commences in the spring, for this will prevent them fruiting the first season, and in consequence they will grow stronger. The best varieties are *Superlative*, *Hornet*, and *Baumforth's Seedling*, whilst of the yellow sorts *The Guinea*, or *Yellow Superlative*, and *Queen of England* may be recommended.

AUTUMN-FRUITING RASPBERRIES.—In seasons such as 1913 autumn-fruiting Raspberries are a great success. *November Abundance* and *Queen Alexandra* are two good varieties, but the newer *Hailshamberry* proved much the best in these gardens. The plant is of a healthy, vigorous growth, and produces heavy crops of exceptionally large, well-coloured berries. The *Hailshamberry* should be tried in all gardens where autumn-fruiting Raspberries are appreciated. All the old canes should be cut down to the ground level.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROYSCHELD), Buckinghamshire.

PINEAPPLES.—The earliest plants will soon be showing signs of fruiting, and they should be encouraged in this by affording a brisk bottom-heat, and a temperature of 60° to 65° by night, with a rise of 10° by day, according to the weather. In times of sunshine the temperature may rise 15° higher, admitting air freely. Grow successional plants in a temperature of about 58° to 65°, with a proportionate rise by sun-heat. The roots of suckers planted in beds should be kept on the dry side, and the atmosphere kept at a temperature of about 55°.

PEACHES AND NECTARINES.—Give constant attention to the inside borders; do not allow them to become either very dry or excessively wet. When moisture is required soak the soil thoroughly with tepid manure water, or place some Peruvian guano at the rate of three to four ounces to each square yard on the border and water afterwards. This is an excellent stimulant, especially for old-established trees, or for such as have not recently received a top dressing. When the embryo fruits begin to protrude through the fading corollas the temperature, both by day and night, may be increased slightly, and more atmospheric moisture afforded.

ORCHARD HOUSE.—The pruning of all trees, and especially those in pots, should be finished without delay. As a rule, too much wood is left in orchard house trees, and the trees are allowed to produce too many flowers. Cultivators are often over-anxious to secure a plentiful show of bloom, forgetting that this involves a severe strain on the plants' energies at a critical stage, and that the more bloom is produced the less likely are the flowers to set. A Peach or Nectarine tree growing in a twelve or fourteen inch pot, for instance, with one hundred flowers, is just as good, if not better, and will produce as good a crop of fruit as one with ten times the number. In pruning, therefore, this should be borne in mind—that every flower bud, if properly developed, will produce a fruit, and that therefore a few blooms only are necessary on each shoot. The shoots of Peaches, in pots, and even those of bush

and pyramid specimens, should not be left more than 6 inches in length, and in many instances even less, unless they are required for the formation of the tree. In the case of trees that were pinched closely during the past season, the ends of the shoots only will need to be removed. Prune always to a wood bud, which may be known by its being much more slender and pointed than the flower buds. Where no wood buds are to be found the shoots should be left their entire length, if they cannot be dispensed with. Keep the ventilators open night and day for the purpose of retarding the trees as much as possible. Cleanse the trees as directed in a former calendar if insect pests are feared, and see that the roots never lack moisture. If the pots are well drained the roots can hardly receive too much moisture at this stage, but if the supply is deficient they will suffer.

STRAWBERRIES.—Plants that have been grown in slightly heated pits or frames for some weeks past should be examined frequently, and, where needed, afforded liberal root waterings. Superficial sprinklings are worse than useless, and I strongly urge that tepid water should always be used. Dispense with fire-heat as much as possible, placing mats or other coverings on the roof at night to maintain the necessary warmth, and prevent fluctuations in the temperature, an important detail in the successful forcing of Strawberries.

FIGS.—Trees breaking into growth should be grown in a moist atmosphere and a temperature of from 55° to 65°. Keep the roots plentifully supplied with water as soon as they are fairly active. In order to keep the growths short and fruitful—especially in the case of pot trees—pinch out the points of the young shoots when they are about three inches long. Now is a suitable time to propagate Figs from eyes—which strike freely—treated in much the same manner as I recommended for vines. Portions of well-ripened shoots cut into suitable pieces, one or two inches in length, and placed in small pots in strong bottom heat, will root freely in from twelve to fourteen days. Cuttings of the roots with “eyes” at the extremity will also make plants, but the process takes much longer as a rule.

THE KITCHEN GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

ONIONS.—For a very long series of years I have raised Onions under glass, sowing the seeds at this time and transplanting the seedlings in the second or third week of April. Previous to adopting this system it was impossible to protect the crop from the devastations of the Onion maggot, which since has given little, if any, trouble. Besides, the early start is responsible for a much larger bulb, there being no difficulty in obtaining an even lot of bulbs 12 inches in circumference, produced in drills at 15 inches apart, and the plants 5 inches asunder. I refer to keeping Onions such as James' Keeping, a variety probably unequalled for its reliability. Those who might be deterred from adopting this system on account of an imagined increase of labour may be assured that the labour is not more, but probably less than that required when the crop is raised from seeds sown in the open ground. Ours are sown in cutting boxes, which are placed one above another until the seed germinates, and the seeds are germinated in a temperature of 60° or so. Once the seedlings are well through the soil they are transferred to cold frames, where they remain until ready for transplanting.

CARROTS.—Sow seeds of a stump-rooted variety rather thinly on a warm border. Sparse sowing at this season obviates the need to thin the seedlings before the small roots are usable. The Carrot fly, which is very destructive in old gardens, seems less prevalent when the plants are not crowded.

CELERY.—The crop for early autumn use must be prepared by sowing a dwarf, white variety in a seed-pan. Scatter the seed very thinly over the surface of the previously moistened compost, just covering it with the finest

parts of the latter, and stand the seed-pan in a heated structure, but not near to the hot-water pipes. It is a curious circumstance that though found wild luxuriating in marshy places, Celery succeeds best in cultivation under not too moist conditions; therefore from the beginning this fact should be kept in mind and the seedlings treated accordingly.

TOMATOS.—The plants will have a tendency to make long, spindly growth, but by careful watering this will be discouraged, and a growth more favourable to the production of flower and fruit will be secured. I never syringe Tomatos and have scarcely ever been troubled with any of the diseases that are common in many gardens. Another sowing of a larger-fruited variety than Sunrise may be made. Many varieties are very similar, and the grower will do well to continue to cultivate those that he has found give the best results.

SPRING CABBAGES.—Winter Cabbages would be the more proper designation for this crop, for we commenced to cut heads in the third week of last month, the growth in late autumn having been abnormally rapid. The variety is the old but very reliable Vanack, and to succeed these we have Edinburgh Market. In most years I give early Cabbages a slight dressing of sulphate of ammonia in the beginning of March. This year they will be dressed at once, double the amount of superphosphate of lime being added. This as a precaution against “bolting.” Where a large supply of Cabbages is required during summer it would be advisable to sow seeds in a frame, or even in a box, and germinate them in heat—that is, in instances where the usual crop is ready to cut, and where there is almost a certainty of a gap occurring in the succession.

CUCUMBERS.—The plants are now growing very rapidly, and those in pots should be planted out without further delay. My system is to set each plant in a mound of soil of about one peck to start with, the material consisting of very rough pieces of semi-decayed turf, with some less rough compost to pack around the plants. Roots soon appear through the soil, and the after-treatment consists in adding fresh lumps of turf, rotted manure and a reliable fertiliser from time to time as the roots take possession of the material previously added. An abundance of moisture at the roots is essential, it being assumed that bottom heat is provided. If Cucumbers are required very early do not stop the plants until the embryo fruits are observed, and then stop the laterals just beyond each berry. Where no better means are available an early crop may be secured from plants in pots or in boxes, grown in a stove temperature. I have frequently grown early fruits under this system, starting with a small amount of compost and adding to it as required. Less water at the roots all through is needed. The plants may also be grown on hot-beds, but these involve considerably more labour than either of the methods described above.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

GARDENIA.—One and two year old plants furnish the best blooms, therefore a batch of cuttings should be inserted now to take the place of older specimens. Select strong side-shoots, make the cuttings 3 inches long, and dibble them singly in 2-inch pots containing equal parts loam, peat and leaf-soil, with a liberal sprinkling of sharp sand and charcoal. Plunge the pots to their rims in cocoanut-fibre over warmth that will provide a bottom heat of 75° to 80°. Spray the shoots overhead and grow them in close conditions until rooted. Plants in 6-inch pots with flower-buds well advanced must be watered very carefully or the blooms may grow deformed. Very weak soot-water may be afforded as a stimulant twice weekly. Spray the foliage lightly on bright mornings and examine the shoots for the presence of mealy bug, which must be destroyed. Remove the shoots at the base of the flowers as they appear, and grow the plants in an atmospheric temperature of 65° to 70°. If required for conservatory decoration

inure the plants gradually to cooler temperatures and keep them drier at the roots.

SEED-SOWING.—The raising of seedlings will demand much attention, for numerous plants are raised from seeds sown now. Shallow pans are the best receptacles for the purpose, and they should be cleansed and furnished with plenty of materials for drainage. It is advisable to sterilise the compost, which must be made smooth and firm in the pans. Soak the soil with warm water by immersing the pans. Such small seeds as those of Begonia, Gloxinia, Streptocarpus and Lobelia should be sown on the surface. Plunge the pans in fibre, cover them with glass and paper, and germinate the seeds in a temperature of 70°. When the seedlings appear remove the seed-pans to a light shelf near to the roof-glass and protect the young plants from direct sunshine. If the compost becomes dry hold the pans in a vessel of water and allow the latter to rise in the soil through the drainage hole. Larger seeds, such as those of Celosia, Schizanthus and Smilax, should be covered with fine soil to a depth of about one-sixteenth of an inch.

STOVE PLANTS.—Codiaeums (Crotons), Dracaenas, Aralias, Ficus elastica, Acalyphas, Dieffenbachias, Ixoras, and many other stove plants are starting into growth, and will need re-potting or top-dressing. The majority of stove foliage plants thrive in a compost composed of equal parts fibrous loam and peat, one quarter of the whole of half-decayed leaf-mould, with sufficient charcoal and sharp sand to keep the compost open. The more forward specimens should be attended to first. Make an examination to see if the soil is suitable to maintain the plant in a healthy condition throughout the growing season, in which case a top-dressing will suffice. See that the drainage is perfect. In applying the top-dressing remove some of the surface soil to allow space for watering, and make the new soil firm. Those re-potted must not be placed in much larger pots, remembering that good specimens can be grown in comparatively small receptacles. Use clean pots, and place some of the coarser material over the crocks. Trim the ball by removing the old pot sherds and a little of the soil. Work the new compost evenly around the ball, making it firm with a potting stick as the work proceeds. Water the roots when the work is finished, and spray the plants overhead about midday, but do not water a second time unless moisture is absolutely needed. Maintain a slightly higher temperature at night, say 65° to 68°, according to the weather; in the daytime it may rise to 75° or 80° with sun-heat. Admit air only in very favourable circumstances for the present. Stove foliage plants when used for decorations in the residence are liable to lose their lower leaves, and will not make good specimens afterwards if potted on. But they may be used for propagation; their tops should be cut off and inserted singly in thumb-pots, plunging the pots in cocoanut fibre in a propagating frame having a temperature of 75°. The ringing of Crotons, Dracaenas and Ficus elastica may be done now. Place the plants in a propagating pit or at the warmer end of a plant stove; remove a band of the bark beneath the foliage, and bind a little moss around this part. Secure the plant to a stake and syringe it daily to keep the moss moist. Roots will make their appearance in three weeks or a month, when the plants should be severed, potted up, and grown in close conditions for a few days.

PANDANUS.—Suckers taken from the base of old plants, trimmed of their outer leaves, and potted singly in small pots will root in a brisk heat. Afford water with extra care at all times. Small pot plants make dainty specimens for table decorations.

STOCK PLANTS FOR FURNISHING CUTTINGS.—Plants of fibrous-rooted Begonias, Plumbago rosea, P. coccinea superba, Coleus (foliage varieties), Thyracanthus rutilans, Clerodendron fallax and similar subjects should be placed in moist heat to produce cuttings. A few plants of Plumbago rosea may be turned out of their pots, the roots cut in small pieces, and the latter placed in pans of soil. They will quickly form useful plants.

EDITORIAL NOTICE.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

APPOINTMENTS FOR FEBRUARY.

MONDAY, FEBRUARY 9—
United Hort. Ben. and Prov. Soc. Com. meet.

TUESDAY, FEBRUARY 10—
Roy. Hort. Soc.'s Show and Ann. Meet.
Horticultural Club Annual Dinner, 6.30 p.m.

THURSDAY, FEBRUARY 12—
Manchester & N. of Eng. Orchid Soc. meet.
Preston Hort. Soc. meet. (Lecture by Mr. E. Scaplehorn on "Rock Plants and Rock Gardens.")
British Gardeners' Assoc. (London Branch) meet. (Lecture by Mr. W. J. Ing on "Hampton Court Palace and Gardens," illustrated by coloured lantern slides.)

FRIDAY, FEBRUARY 13—
B.G.A. (Kew branch) meet. Lecture by Mr. W. Hales on "British Wild Flowers for the Garden."

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 38.7.

ACTUAL TEMPERATURES:—
LONDON, *Wednesday, February 4* (6 p.m.): Max. 52°; Min. 41°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday, February 5* (10 a.m.): Bar. 29.8°. Temp. 49°. *Weather*—Sunshiny.
PROVINCES, *Wednesday, February 4*. Max. 51°, Valencia; Min. 41°, Yarmouth.

SALES FOR THE ENSUING WEEK.

MONDAY, TUESDAY, WEDNESDAY, THURSDAY, AND FRIDAY—
Continuation of the Sale of the stock at Coombe Wood Nurseries, Kingston Hill, by order of Messrs. J. Veitch and Sons, Ltd., by Protheroe and Morris, at 12.

MONDAY AND WEDNESDAY—
Rose Trees, Shrubs, Lilies, Perennials, etc., at Stevens's Rooms, 38, King Street, Covent Garden, at 12.30 p.m.

MONDAY AND FRIDAY—
Hardy Bulbs, Herbaceous Plants, etc., at 12, by Protheroe and Morris.

WEDNESDAY—
Perennials, Herbaceous Plants, Hardy Bulbs, etc., at 12; Palms and Plants at 5. At 67 and 68, Cheap-side, E.C., by Protheroe and Morris.

THURSDAY—
Roses, by Protheroe and Morris, at 1.

FRIDAY—
Orchids, by Protheroe and Morris, at 12.45.

The discoveries made by man in the domain of ideas have something in common with the

Problems of Genetics.

plants introduced from far-off countries and cultivated in our gardens. Both make their appearance suddenly, excite controversy, and having won acceptance, settle down on the shelves of our minds or of our plant-houses as inalienable parts of our mental or horticultural stock-in-trade.

Accepted, unchallenged, the idea and the plant alike pursue for a time the even tenor of their way. Then suddenly the plant begins to vary—as *Primula obconica* began to vary a year or two ago, and as *Primula malacoides* is just beginning to vary now. So is it with the idea: after it has achieved a wider acceptance and the word which expresses it has passed into everyone's mouth, suddenly it begins to vary, to take on new forms of meaning, and thereby to lose its old specific characters. For example, who, by looking upon the multitudinous varieties of Chinese Primrose could picture out a reconstruction of the original form from which they sprang? In such a way as

this the biologist's idea of Evolution is varying, and in a generation or two the new variations on this old theme will have changed men's ideas, so that none but the careful historian may be able to discover the notions and superstitions with which that idea was clothed in the nineteenth century. The great and signal merit of Professor Bateson's book on the "Problems of Genetics" is that it prepares the way for improved varieties of the idea of the evolutionary process by teaching biologists to recognise that they falter where they thought they firmly trod. By stating the problems in clearer terms Professor Bateson shows that evolutionary hypotheses which have become convictions are still awaiting proof. Nor can we think of higher praise than this, that it has fallen to the writer of "Problems of Genetics" to do for biology what the greatest dramatist of our era has done for sociology—to propound again the fundamental questions which we, good easy men, had thought were answered long ago.

To those who want clean-cut conclusions, ready for immediate use, Professor Bateson's book will not appeal. For such men his chapters have but one message—that of the poet who cried, "Ah! what a dusty answer gets the soul, when hot for certainties in this our life." But to those who are workers and want encouragement and not illusion this book will be a benefaction; for it holds out high hope that the old problems—of variation, of specific form and the like—are susceptible of solution by new methods.

The old method, which Darwin put to such masterly use, aspired to understand the mechanism of evolution by assembling in vast array the biological facts, co-ordinating them and generalising upon them.

That method failed, not by reason of lack of persistency on the part of man, but because of the obduracy of the facts. These stubborn things will not pack into our present systems, and whilst some seem to fit nicely into such a generalisation as that conveyed by the term natural selection, others will not; while some seem to proclaim the truth of the doctrine that the struggle for existence plays a part in determining the form of things, others again appear to contradict it. Till finally it has become clear that the old method has failed because it attempted to discover law and order by the contemplation of a miscellaneous collection of diverse facts of nature. The new method teaches that much sifting of these facts of nature must be practised before we can arrange them in homogeneous groups; and it shows, moreover, how this sifting may be done. Whether or not the writ of Mendelism runs throughout the realm of nature no man can say; but this may be said, that Mendelism gives to the biologist what he lacked before, namely, an experimental method for the analytical study of living things. For this method, which he has done so much to elucidate, Professor Bateson makes no extravagant claims; nor is there need, for it is unique. It stands to contemporary biology in a

relation similar to that in which the atomic hypothesis stood to the chemistry of last century.

From the point of departure provided by Mendelian analysis the bio-chemist of to-day is setting out to explore the chemical nature which determines specific form. No one can say what or how much he will find, but all will allow that a scientific inquisition holds out more hope of discovery than does an indiscriminate raid on Nature.

The impression produced by this book is that of a storm-swept landscape on which sunlight has begun to fall again. The ground is littered with the debris of the storm, but the light in the sky gives promise of trees to bud again; of a fresh and fairer landscape arising from the ruin of the old.

To those who care nothing for such fanciful impressions the book will appeal because of the array of new or neglected facts which it presents, and the searching criticism which it brings to bear on many of the statements which have been put forward in support of such hypotheses as that of the inheritance of acquired characters. In illustration of this last point reference may be made to the classic case of Schübeler's Wheats. The story goes that Schübeler imported Wheat and Maize from Central Europe to Norway, and found that in successive years the period of growth and ripening was increasingly reduced. After two generations seed was sent back to Breslau, and when grown was found to ripen more quickly than the original stock had done. Upon enquiry Professor Bateson finds that in the year (1859) during which the returned seed was grown at Breslau July and August were exceptionally hot months. . . . As Professor Bateson suggests, the elements of the weather may possibly have done something to hurry the ripening. Nor will practical growers dissent from this comment.

Supplementary Illustration.—A feature of particular interest in the Wisley gardens in June last year was a row of Tree Lupins (*Lupinus arboreus*) flowering on the margin of the lawn near to some of the glasshouses. They were just at their best when a deputation from the Floral Committee visited the gardens for the purpose of making awards to Violas in one of the best trials of Violas we have ever known. We were so impressed with the Lupins that a few days afterwards we made a second journey to Wisley for the purpose of obtaining a colour photograph of the Lupin and of several other noteworthy plants at that time in flower, including the excellent specimen of *Kalmia latifolia*, which visitors to Wisley may have noticed. The coloured plate of the Lupin will commend the plant as a standard to readers who have not hitherto made use of it in the way Mr. WRIGHT has found so satisfactory. Amongst the experts who visited the garden on the occasion to which reference has been made, there was none who had seen such fine specimens as that figured in our illustration, and all were curious to know exactly how the plants had been cultivated. A member of Mr. WRIGHT's staff has been good enough to give us the following interesting details of the method adopted:—The seeds are sown in pots or pans during July or August in cold frames or houses. As soon as the seedlings are large enough they are planted in 4-inch pots, and after they have

* *Problems of Genetics*. Silliman Memorial Lectures delivered at Yale University in 1907. By Professor Bateson, F.R.S. Pp. 258; with illustrations. Oxford University Press. 17s. net.

TREE LUPINS (*LUPINUS ARBOREUS*) IN THE R.H.S. GARDENS, WISLEY

established themselves in these pots and have been gradually hardened they are placed on a base of ashes in a sheltered position out-of-doors. In this position they are syringed frequently and induced to grow without suffering any check. The side shoots are pinched out so that a good, clear stem of 3 feet high may be formed. At this height seven or eight shoots are left to form the head. The plants are moved into 6-inch pots as soon as they are ready. The main stem is kept straight by means of bamboo stakes, and when it has attained about 3 feet in height the leading shoot is pinched out. This operation causes the shoots which have been left at the top of the stem to develop freely, eventually producing fine heads. During the winter months the plants are accommodated in a very cool house, where they are allowed to remain until danger from severe frosts is over. They are afterwards gradually hardened off for planting out-of-doors in the positions in which they will flower, generally at 10 feet apart. They grow exceedingly quickly, making heads which measure 3 feet through in little more than a year, but if proper security is not afforded them by means of stakes they will be sure to suffer injury from the winds. Seeds should be sown every season, as the plants are seldom satisfactory for more than two years. There is one word of caution that must be given in relation to Tree Lupins—namely, that they are ill-suited to places where they are likely to be subjected to the influence of winds. Some sort of protection against winds is essential; but, having stated this much, it may be further stated that when such positions have been selected for them, and the plants are grown so skilfully as the specimens at Wisley, then the Tree Lupin is certainly an object of admiration. It may well be made a feature in every garden where space is not greatly limited. In fig. 44 we reproduce an illustration of a fine white variety known as "Snow Queen."

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held on the 10th inst. in the Vincent Square Hall, Westminster. At three o'clock the annual general meeting of the Fellows will be held in the Lecture Room.

VISIT OF SECRETARY OF THE BOARD OF AGRICULTURE TO THE HORTICULTURAL CLUB.—Amongst the visitors invited to be present at the annual dinner of the Horticultural Club on Tuesday next are Field-Marshal Lord GRENFELL, G.C.M.G., President of the Royal Horticultural Society, and Sir SYDNEY OLIVIER, K.C.M.G., Permanent Secretary of the Board of Agriculture and Fisheries. Sir SYDNEY OLIVIER has already signified his acceptance of the invitation. Members intending to be present are asked to send immediate intimation to Mr. R. HOOPER PEARSON, Hon. Sec.

THE LATE SIR TREVOR LAWRENCE.—We understand that the late Sir TREVOR LAWRENCE, by his will, left all his plants to his wife, but expressed a wish that she would present to the Royal Gardens at Kew such portions of his collection as she might be advised or might consider to be mainly of botanical interest, the matter being left entirely to her decision. We understand that Lady LAWRENCE has written to Sir DAVID PRAIN, the Director of Kew Gardens, to say that she has much pleasure in informing him of her intention to carry out Sir TREVOR'S wishes, and will make the necessary arrangements in due course.

ROYAL GARDENERS' ORPHAN FUND.—In respect to the annual meeting of the Royal Gardeners' Orphan Fund, which will take place at Simpson's Restaurant, Strand, on Friday, after this issue is distributed, it may be noted with satisfaction that the Chairman will find himself in the gratifying position of being able to recommend the election of all the nineteen

candidates. Thus no poll will be necessary. We are quite sure that the subscribers to the fund will approve the Committee's recommendation. Charitable institutions exist solely for the relief of distress, and the public is always more ready to support a charity that spends its funds liberally on the purposes it is its business to fulfil than to approve a less courageous and generous policy.

MR. MARTIN JOHN SUTTON'S ESTATE.—The estate of the late MARTIN JOHN SUTTON, J.P., has been sworn for probate at £137,086 gross, the net personalty amounting to £133,831. Legacies are bequeathed to Mr. SUTTON'S widow, to each of his two sons, to his daughter, to other relations, and to certain persons in his employment. In making his bequests Mr. SUTTON observed "that, having always tried to give to religious and philanthropic objects during my life as the Lord has prospered me, rather than to lay money by for bestowal after I can no longer use it, I leave no legacies to societies." Only those most intimate with the deceased

cession:—(1) "The Desirability of holding Meetings in Provincial Fruit-growing Centres in conjunction with our Affiliated Societies"; and (2) "In what, if any, manner can the Federation extend its Scope of Utility to its Members?" A lecture will be delivered by Mr. GERALD O. SHERRARD, of the John Innes Horticultural Institution, on "Pollination Experiments with Fruit Trees," and papers will be read by Mr. W. G. LOBJOIT, on "Conditions of Tenure and Methods of Valuation"; by Professor UDALE (Worcestershire County Council), on "A Few Thoughts on Current Topics, including the American Mildew and Disposal of Garden Produce"; and by Mr. GEOFFREY F. HOOPER, on "A Few of the Little Troubles of a Fruit Grower."

ANGLO-AMERICAN EXPOSITION, 1914.—We are informed that among the British firms who have signified their intention of contributing to the horticultural display at the White City during the Anglo-American Exposition are the following:—Mr. R. H. BATH, May-flowering bulbs, quarter acre; Messrs.

FIG. 44.—LUPINUS ARBOREUS "SNOW QUEEN"

gentleman know the wide extent and fine generosity of the almsgiving which he practised all through his life.

WIMBLEDON'S NEW PARK APPROVED.—On p. 57 we referred to the opposition of some of the ratepayers to the proposal of the Town Council of Wimbledon to purchase the Wimbledon Park Estate for the purpose of an open space, and the decision to take a poll on this and other matters. The result of the poll was declared on Monday last, and the scheme approved. The number of votes cast in favour of the Bill was 2,643, against 2,086, the majority in favour being 557.

THEFT FROM KEW GARDENS.—The case of shrub-stealing from Kew Gardens, particulars of which were given in our last issue, again came before the Richmond magistrates on the 2nd inst. One of the defendants was fined 40s. and the other £6, the alternative being 14 days' and two months' imprisonment respectively.

THE NATIONAL FRUIT GROWERS' FEDERATION.—The twelfth annual meeting of the National Fruit Growers' Federation will take place at the Royal Horticultural Hall, Vincent Square, Westminster, on Wednesday, the 25th inst. The following subjects are down for dis-

CHEAL AND SONS, trees and shrubs; HOBBIES, LTD., Roses, one acre; GEORGE JACKMAN, Rhododendrons and other flowering plants; JOHN JEFFERIES AND SONS, American trees and flowering shrubs, quarter acre; KELWAY AND SON, herbaceous plots, covering three-quarters of an acre, with a display of aquatic plants covering half an acre; W. A. MANDA, American specialities, three-quarters of an acre; R. C. NOTCOTT, formal Rose garden; PAUL AND SON, flowering shrubs and Rose trees planted for effect; PIPER AND SONS, topiary exhibit, summer bedding and formal English garden; RIVERS AND SONS, trained fruit trees; L. R. RUSSELL, green and variegated tree Ivies; SPOONER AND SONS, trained fruit trees; STARK AND SON, Kniphofias and Sweet Peas, Violas and Antirrhinums; CHAS. TURNER, Conifers, Bamboos, Yuccas, Weeping Birch, Elm and Maples; R. J. WALLACE, Colchester, formal English garden; THOMAS S. WARE, Begonias; J. WOOD, 15,000 square feet of rock and water garden. Mr. LEOPOLD DE ROTHSCHILD will decorate the large central lagoon.

ERFURT PLANT AND SEED INDUSTRY.—Dr. EDMOND GOEZE, an early Kewite, contributes to the *Jahrbuch für Standen-Kunde*, 1913, an interesting review of the contents of the

catalogue of plants and seeds issued by one of the leading firms of Erfurt. His notes—historical, cultural, statistical and descriptive—are valuable and suggestive. Erfurt is the centre of the cultivation and breeding of the China Aster, among other things, and some six pages of the catalogue are devoted to the races and varieties of this old favourite garden plant, of which about 300 are enumerated.

FLORA OF NEW GUINEA.—The fifth livraison of the botany of Dr. H. A. LORENTZ's scientific expedition to New Guinea has appeared—pp. 899-988, plates 161-178. It comprises the families Amaryllidaceae, Haemodoraceae, Nyriaceae, Commelinaceae, Zingiberaceae, Pontederiaceae, Typhaceae, Hydrocharitaceae and Balanophoraceae, elaborated by various botanists. Most of the families named are represented by only one or two species; but a large number of Zingiberaceae is described and figured. *Riedelia*, Oliver, now counts fifty species; *Alpinia* is represented by thirty-seven species, and *Geanthus* by eleven. Evidently there is a great concentration of this family in New Guinea, and one wonders why so few are seen in cultivation. The Reed-maces of the world are classified under eight species.

WOOD PIGEONS AND CROPS.—One effect of the recent cold weather is the great increase in the numbers of wood pigeons from abroad, and in Devonshire especially the birds are doing much damage to crops, especially on farms. With a view to keeping the pigeons under, the Devon Farmers' Union has arranged to hold a combined shoot on the first and second Mondays in February. In one district alone it is expected that 1,600 men will take part in the shooting.

ALYSSUM BENTHAMII.—A lilac-flowered variety of this species is described by Mr. S. KARRER in MOLLER'S *Deutsche Gärtner Zeitung* (No. 1, 1914), under the varietal name of *compactum lilacinum*. It is claimed for this novelty that it is at its best in September and October.

GERMINATION OF SEEDS.—To the vagaries of germination, which formed the subject of a recent article, may be added the following, which were observed in the Munich Institute of Agriculture and reported in *Die Gartenwelt* (January 3, 1914). Fresh seeds of *Nigella sativa* sown in a seed bed exposed to the sun fail to germinate; cover the seed bed so that the seeds are in darkness, and the seeds germinate in ten days. Many species of Lily fail to germinate in darkness; but if kept for a long time (three years) in darkness and then sown in the light the seeds germinate very quickly. The statement is made that seeds of *Digitalis purpurea* require eight months for germination, but this certainly does not apply to garden strains of the plant. Some seeds germinate better after freezing; this it is said is true of species of *Primula*.

THE POLLINATION OF ENCEPHALARTOS ALTENSTEINII.—At the annual meeting of the Royal Society of South Africa, Dr. MARLOTH described the remarkable mode of pollination which occurs in the Kaffir Bread Tree (*Encephalartos Altensteinii*). As is the case with the *Yucca*, pollination is effected by an insect which gains access to the ovules for the purpose of depositing its eggs therein. In the case of *Encephalartos* the pollinating insect is a beetle (*Antliarhinus Zamiae*). That the beetle is actuated by no altruistic instinct is evident from the observation of Dr. RATTREY, that all the seeds may be destroyed by the grubs which are hatched from the eggs deposited among the ovules. Dr. RATTREY also shows that the insects are attracted to the male cones of *Encephalartos* by an odour which is perceptible in *E. Altensteinii* and powerful in *E. villosus*, Lehrs. Having paid their visit to the male, the insects visit subsequently the female cones, whither they carry pollen. Unlike *Encephalartos*, another genus of Cycads, *Stangeria* (*S. Katzeri*) is wind-pollinated.

VARIATION.—In the January part of *The Journal of Heredity* (American Genetic Association) there is a carefully written article on "Variation in Tobacco." Mr. H. K. HAYES, the writer, starts by stating the belief held by some that a change of environment often brings about the birth of new types. In 1910 an experiment was begun to develop a type similar to one of the best Cuban varieties. In that year 150 plants were grown from seed sent from Cuba. The variability was very large, and only five or six of the plants gave promise of commercial value. This is not surprising, as we are told that no attempt at seed selection had been made in Cuba. One experimenter (HASSELBRING) found that by growing pure lines, both in Cuba and Michigan, no breaking up of type occurred, and that whatever modifications he found due to change of environment appeared alike in all of the plants of a given strain. HAYES selfed the two most desirable plants in his lot of 150. These plants bore 19 and 20 leaves respectively. In the second season the produce from these two selfed plants showed great variability. Again the two best plants were selfed, two bearing 18 and 19 leaves respectively. The produce of these in the third season proved very uniform, both in number and shape of leaves, and was so far as field characters go equal to the commercial Cuban tobaccos grown on the same field. By this we presume is meant that in three years a strain was raised from Cuban seed equal to the selected strain of the same variety which was being grown in the States. To further determine whether the variations observed in generations of the foregoing experiment had any connection with change of environment, three seed-pods were picked from different plants growing in Cuba and sent to the experimental station at Bloomfield. The produce of these proved that there was no breaking up of type due to changed environment. A number of excellent illustrations is given, and it is evident that raisers of new tobaccos are finding that many of the characters of the plant follow true Mendelian lines.

NEW BOOKS.—The *Modern Gladiolus Grower*, published monthly by MADISON COOPER, Calcium, New York, U.S.A., as its title indicates, is devoted solely to the Gladiolus. It contains 32 pages of text and advertisements, and in size is 9 inches by 6 inches. The price per annum is 50 cents, or \$1 for three years. The number is well printed, and contains numerous articles of interest to Gladiolus growers, including reports of the American Gladiolus Society. Among the contents we note the Gay Gladiolus, Gladioli in a dry season, some of the newer Gladioli, testing new varieties, the Gladiolus in designs and decorative work, and among other items a page for correspondence. Such a publication should be well received by Gladiolus cultivators on both sides of the Atlantic.

ABNORMAL WEATHER IN DECEMBER.—The details respecting the weather in December that appeared over the signature of *J. Edward Clark* (see p. 42) lost part of their interest from the fact that the printer omitted to give the locality in which the notes were made. We may supply this omission by stating that Mr. CLARK'S observations related to Purley, in Surrey.

ANIMALS AND PLANTS UNDER DOMESTICATION.—In his second lecture of this course on animals and plants under domestication, Professor BATESON showed plants of the wild and cultivated forms of Parsnip, Carrot, Lettuce and other vegetables. He said that in many cases the difference between the two forms is one of size. How far this difference is due to feeding is not known, but VILMORIN, CARRIERE and BUCKMAN found that the size of the wild forms was in some cases very quickly increased under cultivation. BUCKMAN obtained the variety of Parsnip the "Student" from the wild form in

eight generations. But it must not be forgotten that probably no special precautions were taken against crossing with the cultivated types. Professor BATESON then discussed the origin of the cereals, of which the Barley has the simplest history. It is probably derived from *Hordeum spontaneum*, a two-rowed wild form found in Asia Minor. This Barley, in common with nearly all the wild forms of cereals, has a brittle rachis, so that on threshing the ear breaks in pieces. Those plants which have varied by the production of a tough rachis have been selected for cultivation. Among the wild cereals which have a brittle rachis are Rice, Wheat, and Millet. The origin of the cultivated Wheats is more complicated. The various species of Wheat differ from each other with regard to certain pairs of differences. On crossing cultivated varieties differing from each other in one or more of these pairs of characters a fertile product is obtained, and the characters introduced segregate according to MENDEL'S law. Yet when the different species are crossed together a sterile hybrid is often produced. Botanists consider that the fertility of a cross between a wild and cultivated form is a criterion of the origin of the cultivated form, but until the factors involved in fertility and sterility have been further investigated such an assumption should not be made. Photographs of wild species of Potato, lent by Messrs. SUTTON AND SONS, were also shown.

IMPORTED FERTILISERS.—The statistics of imported fertilisers indicate that basic slag is becoming more generally used as a fertiliser. Thus the amount (in tons) imported in 1910 was 16,588, in 1911 22,666, and in 1912 49,313. Guano shows a decrease from 34,124 tons in 1911 to 14,115 in 1912. Nitrate of soda is fairly stationary, and mineral phosphates show a small increase in amount imported.

A NEW USE FOR MANGROVES.—An interesting and important statement appeared recently in the French Press to the effect that the timber of species of *Rhizophora* (e.g., *R. racemosa* = *R. Mangle*) is of great value on account of its flexibility and durability. The wood, which is rich in tannin, has remarkable powers of resisting decay, and is therefore of value for railway purposes, for piles, and for mine props. Inasmuch as species of *Rhizophora* have a wide distribution in the Mangrove swamps of the tropics, the statement is worthy of the careful attention of those concerned with the development of tropical countries.

"EUCALYPTUS."—The nineteenth part of Mr. MAIDEN'S *Critical Revision of Eucalyptus* treats of *E. goniocalyx*, *E. nitens* (a new species), *E. elaeophora*, *E. cordata* and *E. angustissima*, bringing the number of species described and figured up to 105, and the number of plates to 104. It may be useful to repeat here that Mr. MAIDEN has figured forty-five species of *Eucalyptus*, on a larger scale, in his *Forest Flora of New South Wales*, a list of which is given in the part under notice. Most of the species figured in the part before us exhibit considerable variation in the size and configuration of the leaves, from the seedling stage to the adult stage. The account of *E. cordata*, as one of the hardest species, has special interest for West Country gardeners. It is figured in the *Gardeners' Chronicle* for March 12, 1910, and also in the *Botanical Magazine*, plate 7835. *E. cordata* is now known to be confined to Tasmania in a wild condition, and to the southern part of the island, growing in decomposed volcanic rock—greenstone diabase—not in recent volcanic rock basalt. It was originally described by LABILLARDIERE as an "arbor procer"; but it rarely exceeds 20 feet, and 50 feet is the extreme height recorded of wild trees. In cultivation *E. cordata* has been confused with *E. pulviger*, A. Cunn. (*E. pulverulenta* Sims). Mr. MAIDEN gives BENTHAM'S contrasting characters:—Leaves crenate, calyx obtuse at the base . . . *E. cordata*. Leaves quite

entire, calyx tapering to the base . . . *E. pulverulenta*. Among the variously shaped leaves of *E. cordata* figured by MAIDEN is a perfectly circular "perfoliate" one, 4 inches in diameter, borne by a slender branch less than a sixth of an inch in diameter. *E. nitens* Maiden was formerly classified as a variety of *E. goniocalyx*, than which it is a much larger tree, growing 200 to 300 feet high, with a trunk from "2 to 17 feet" in diameter. The dimensions are given in figures, and it seems probable that seventeen may be a misprint for seven. *E. angustissima* is an imperfectly known shrubby western species with leaves 3 to 4 inches long, and mostly less than a quarter of an inch wide, and very small globose fruits. *W. B. H.*

"THE BOTANICAL MAGAZINE."—The issue for January contains illustrations and descriptions of the following plants:—

ERYTHRINA PULCHERRIMA, tab. 8,532.—This species is closely allied to the well-known Coral Plant of gardens—*E. Crista-galli*, but is readily distinguished by the different shape of the leaflets. The history of the plant is obscure; its

of about 50 feet, with a spreading head of branches and a trunk 5 feet in girth. The leaves are marked by numerous parallel veins, one of the distinctive characters that separate *Distegocarpus* from *Eu-carpinus*. *C. japonica* is said to have been introduced by MARIES in 1879, but the specimens now in cultivation came in 1895. The tree is perfectly hardy, very graceful, grows well in stiff loam, and is stated to be an admirable subject for planting in small gardens.

PRIMULA PURDOMII, tab. 8,535.—This species was awarded the R.H.S. First-Class Certificate on March 18, 1913, when exhibited by Messrs. JAMES VEITCH AND SONS, and was described in *Gardeners' Chronicle*, March 22, of that year, p. 192. The flowers are borne in umbels from 3 to 12 inches long, and are lilac-mauve in colour. The *Botanical Magazine* plate represents them as being of a faint mauve. The leaves are covered with a white farina which adds to the beauty of this plant.

LONICERA DEFLEXICALYX, tab. 8,536.—The species is nearest allied to *L. ovalis*, but it has narrower leaves. A specimen at Kew forms a bush 7 feet in height and 15 feet across, with

ACTINIDIA CHINENSIS, tab. 8,538.—This Chinese climber first flowered in Europe in 1909 in Mr. WOODALL's garden at Brancolar, Nice. Specimens sent us by that gentleman formed the subject of the Supplementary Illustration in the issue for July 31, 1909, in which issue Mr. WOODALL gave a description of the plant.

SMILACINA PANICULATA, tab. 8,539.—This plant is a native of Guatemala and South Mexico; it was introduced by Messrs. SANDER AND SONS, in whose nursery specimens flowered in March, 1913. The blossoms, together with all parts of the inflorescence, are of snowy whiteness, and the spike is in pleasing contrast with the green foliage. The species might prove useful as a greenhouse subject, but it is not suited for growing in the open, where its more hardy congeners, such as *S. racemosa* and *S. stellata*, succeed.

RONDELETIA CORDATA, tab. 8,540.—The introduction of this plant into this country seems to have been accidental, for the first seedling appeared in soil adhering to some imported Orchid. For a long time it was grown as *Rodgiera cordata*, because it was originally supposed that the flowers were tetramerous. *Rondeletia cordata* is a good subject for the greenhouse border, forming a bush some 6 feet high and flowering freely every spring.

VIOLA GRACILIS, tab. 8,541 (see fig. 45).—This beautiful Violet has been extensively planted in gardens during recent years, especially on rockeries, where it forms delightful patches of dense growth covered in spring and early summer with purple blossoms. The species grows wild on Mount Olympus, and its habitat extends into Macedonia, and also, probably, into Montenegro.

ORANGE AND LEMON INDUSTRY IN SPAIN.—In Spain no industry has developed so rapidly as the growing of Oranges and Lemons, and none has ever proved such a source of wealth to the country. This development has been favoured, during a period of forty years, by economic conditions and the attraction of the English market. The annual value of the crops is estimated at one hundred million pesetas.

PHYTOPATHOLOGICAL CONGRESS.—An international Phytopathological Congress will be held at the International Institute of Agriculture, Rome, on February 24. The Congress will consider means for instituting an international system for the control of plant-disease. The views expressed by Professor CUIONI on the subject of expanding the present "Phylloxera" Convention into an International Phytopathological Convention, will be considered by the delegates.

GENETICS AT CAMBRIDGE.—The station for experimental investigation of problems in Genetics, to which reference was made last week, is now in working order. The ground attached to the station is about 2 acres in extent, and has been thoroughly well worked and manured. Professor PUNNETT, who has taken up his residence at Whittingehame Lodge, intends to continue his investigations on Sweet Peas, as well as those on poultry, and, as we believe, hopes also to direct his attention to the genetics of the Carnation. An excellent range of glasshouses has been erected on the station, which lies on the outskirts of the town.

FOURTH INTERNATIONAL BOTANICAL CONGRESS, LONDON, 1915.—The Nomenclature section of the Third International Botanical Congress, held at Brussels in 1910, carried towards completion the work of the Vienna Congress (1905) on the international rules governing questions of nomenclature. The combined result of the decisions reached at Vienna and Brussels has been published in the second edition of the *Rules of Botanical Nomenclature*. There remain, however, certain points which have to be settled by the Nomenclature Section of the London Congress in 1915. The pro-

[Photograph by C. P. Roffill.]

FIG. 45.—*VIOLA GRACILIS*: COLOUR OF FLOWERS VIOLET.

habitat is unknown, and it appears to have been introduced into Italian gardens, whence it has spread to various parts of the Continent. *E. pulcherrima* grows as tall as 30 feet, and the green branches are sometimes streaked with reddish-brown; the shoots are prickly, but the prickles are not so numerous as in the other species mentioned. The flowers appear in threes in the axils of the leaves, and are rosy-cerise coloured, as shown in the plate; they appear to be broader than those of *E. Crista-galli*. For a number of years a plant has been growing in the Palm house at Kew, but it does not flower freely.

GALTONIA PRINCEPS, tab. 8,533.—*Galtonia candicans* is a well-known garden plant—more commonly grown under the name of Hyacinthus; the species under notice has larger racemes and more numerous flowers, so that it would appear to be even better adapted for garden purposes than is *G. candicans*, especially because specimens flower at Kew every year under the same conditions as are afforded its congener. The flowers of *Galtonia princeps* are greenish-yellow.

CARPINUS JAPONICA, tab. 8,534.—This is a very handsome Hornbeam, growing to a height

gracefully arching branches. The rich, yellow-coloured flowers are produced in profusion on the upper sides of the twigs; as a garden subject the species is undoubtedly one of the most ornamental of the bush Honeysuckles in cultivation. Propagation is readily affected by cuttings inserted late in the summer. The plant flowers late, which is an advantage, for the blooms thus escape injury from spring frosts.

The issue for February deals with the following plants:—

AMPELOPSIS MEGALOPHYLLA, tab. 8,537.—The most remarkable feature of this Chinese species is the great size of the leaves, which are about 3 feet long. To Mr. M. L. DE VILMORIN belongs the honour of first raising specimens in Europe, from seeds received by him from China in 1894, and plants flowered in his garden at Les Barres three years later. The species was then confused with *A. cantoniensis*, which is not hardy in this country; *A. megalophylla* itself appears to be somewhat tender, for it needs a well-sheltered position in a sunny spot. The species grows well in Mr. J. HARCOURT's gardens at Nuneham, Oxfordshire, whence the material for the figure was obtained.

gramme of work for 1915 was defined by the Congress of 1910 as follows:—1. To fix the starting point for the nomenclature of (a) Schizomycetes (bacteria); (b) Schizophyceae (excepting Nostocaceae); (c) Flagellatae; (d) Bacillariaceae (Diatomaceae). 2. To compile lists of *nomina generica utique conservanda* for (a) Schizomycetes; (b) Algae (including Schizophyceae, Flagellatae, etc), new lists for groups not included in the list of 1910 and also a supplementary list; (c) Fungi; (d) Lichens; (e) Bryophyta. 3. Compilation of a double list of *nomina generica utique conservanda* for the use of palaeobotanists. 4. Discussion of motions relating to new points which were not settled by the rules adopted at Vienna in 1905 and at Brussels in 1910. The carrying out of this work has been entrusted to two committees under the direction of a rapporteur général, Dr. J. BRIQUET (Geneva), assisted by a vice-rapporteur, Prof. H. HARMS (Berlin). In the compilation of the lists of *nomina conservanda* the rapporteur général will have the assistance of a certain number of editors in each committee.

"GEO. MONRO, LTD.," CONCERT COMMITTEE.

—The eighteenth annual concert, arranged by the "Geo. Monro, Ltd.," Concert Committee, will take place at the Queen's Hall, Langham Place, on Thursday, the 26th inst. The chair will be occupied by Mr. GEO. MONRO.

SALE OF NURSERY STOCK AT COOMBE WOOD.

—The second sale by public auction of the trees and shrubs growing in Messrs. JAMES VEITCH AND SONS' Nursery, Coombe Wood, Kingston Hill, was commenced on Monday last, and will continue until the 13th inst. Coombe Wood Nursery, situated on Kingston Hill, is on a deep, rich loam. The nursery is well protected by trees from cold winds, and the plants are grown under very favourable conditions; moreover, the manager, Mr. HARROW, has a high and deserved reputation as a cultivator. In view of these circumstances it is not surprising to learn that all the lots found a ready sale, for although the attendance was not a large one the auctioneers, Messrs. PROTHEROE AND MORRIS, informed us that they had received commissions to purchase from all parts of Great Britain. The trees and shrubs included in the sale represent a wide range of subjects, and comprise Rhododendrons, golden Yews, ornamental flowering and avenue trees, Conifers in variety, Roses, Clematises, species of Vitis and other climbers, Magnolias, Bamboos and specimen plants suitable for planting in borders and "Japanese" gardens. Rhododendrons occupy a considerable portion of the catalogue, there being six thousand named varieties, besides seedlings raised from seeds sent by collectors from China. As the latter have not yet flowered many of them may prove to be new species. The Rhododendrons all met with a good demand, and we were informed that those offered on the second day were nearly all purchased by the same buyer. There have been no sensational prices. It is interesting to learn that the keenest buying was for the specimens of topiary, a fashion of gardening that is coming again into favour. The new Chinese plants also sold well. During our stay we watched the bidding for lots of the new *Ilex Perrnyi*, and these realised good prices. Standard Chestnut *Briotii* (*Aesculus Briotii*), some 10 to 12 feet high, were also in demand, and specimen standard Privets, Aucubas, *Grise-linia littoralis*, Norway Maples, *Taxus elegantissima*, Spanish Chestnuts, *Cytisus* in pots, standard Planes and *Thuja Lobbi* were soon disposed of. The catalogue includes 5,000 lots, divided into some 500 for each day of the sale.

PUBLICATIONS RECEIVED.—*Annual Report of the Board of Regents of the Smithsonian Institution, 1912.* (Washington: Smithsonian Institution.)—*An Account of the Morisian Herbarium.* By [S. H. Vines and G. Claridge Bruce. (Oxford: Clarendon Press.) Price 15s.

SCOTLAND.

THE PREMIER HORTICULTURAL SOCIETIES.

THE results of the past year have been very satisfactory to the management of the Royal Caledonian Horticultural Society and the Scottish Horticultural Association. The former society shows an increase in the funds of about £48, and this follows on a smaller increase the previous year. The attendance at the shows has improved. The Scottish Horticultural Association has a still larger increase in the funds, largely due to the success of the Chrysanthemum Show, which resulted in a profit of about £83. This was carried to the revenue account of the association, with the result that the latter showed a gain of £76, which went to capital account. The funds of the Association now amount to £951 to credit of capital account. In addition there is a sum of £1,493 standing to the credit of the Horticultural Institution Fund.

ECONOMIC BOTANY IN EDINBURGH.

THE position regarding the section of economic botany in the Royal Scottish Museum, Edinburgh, has been under the consideration of the Scottish Horticultural Association, in view of a rumour that it was to be abolished. The secretary of the Association has been in correspondence with the director of the museum, and has received an assurance that no such change was intended, but that what had been discussed was "whether it was advisable to treat the economic botany collection as a reference or teaching collection, to which students and other interested persons might have access." At present a part of the collection is open to the general public, and the Association, while favourable to anything which would make the collection more useful, would oppose anything which would restrict the access to persons desiring to consult them on application. The subject came up at the annual meeting of the Royal Caledonian Horticultural Society, when it was agreed to appoint a committee of three to watch developments in connection with it.

EDINBURGH PUBLIC PARK EMPLOYEES.

THE employees of the Edinburgh public parks have petitioned for an increase of wages and the matter is receiving consideration from the authorities. A proposal has also been made that four dwellings should be provided at the Braid Hills, as the employees there have great difficulty in obtaining houses convenient to their work. The plans under consideration provide a living-room and four bedrooms.

BALMORAL GARDENERS' SOCIAL EVENING.

THE members of the staff of the Royal Gardens, Balmoral, held their annual social evening in the Parish Hall, Crathie, recently. Nearly eighty ladies and gentlemen were present.

PROPOSED ADDITIONAL ALLOTMENTS IN EDINBURGH.

THE Parks Committee of Edinburgh has under consideration a proposal for providing allotments at Alfred Place in the city. The area selected is about two acres.

THE PROPOSED WINTER GARDEN FOR EDINBURGH.

THE Edinburgh Field Naturalists' and Microscopical Society has decided to send a memorial to the Edinburgh Town Council, protesting against the proposal to erect a winter garden or any other building in the Princes Street Gardens.

NEW PARK AT DUMBARTON.

THE Rt. Hon. Lady Overton opened a new children's park at Dumbarton on the 24th ult. The park, which is the gift of Dr. J. Douglas C. White, of Overton, and Mr. Peter Denny, is nine acres in extent, and is situated in a populous part of the town. *Correspondent.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

CYANIDING TO DESTROY MEALY BUG.

IT is as easy to clear a vinery of Mealy Bug by cyaniding as it is to destroy Greenfly in a Peachhouse by vaporising with nicotine, and it is just as safe in the hands of a careful person as any other poisonous preparation. Why your correspondent, J. H. Y., states that a vinery in fruit cannot be cyanided I am at a loss to understand. I adopted this mode of destroying Mealy Bug when it was first introduced to the public, and have continued to use it ever since, and, after long experience, I have no hesitation in recommending anyone who is troubled with Mealy Bug in the vineries to commence cyaniding as soon as the Grapes begin to turn colour, and repeat the operation at weekly intervals for four or five weeks. This can be done without the slightest harm to either fruit or foliage, and will completely rid the vinery of bug. It is much easier to destroy the young bugs than those fully developed, and the dose required to kill the young insects will do no harm whatever to either the young fruit or foliage. A much stronger dose can be used when the leaves fall, but this is hardly required, as all eggs will have hatched out and the young bugs killed before that stage. This is a very much better plan than cyaniding in winter. I do not think that the gas will destroy the eggs. I can assure those who follow this course that they will not be troubled with a single bug in a bunch of Grapes when ripe. I may add that I have cyanided a Tomato house in the middle of winter for the destruction of White Fly without injuring a single leaf, and I know of no other preparation that has such deadly effects upon this pest. Of course, the doses are very much smaller for the destruction of White Fly than for bug or thrip, etc. It is important that the materials used are of guaranteed standard quality, for if precaution is taken and the correct cubic contents of the house ascertained to get the proper quantities, success is absolutely assured. All failures in cyaniding, I am convinced, could be traced either to inferior materials or to carelessness in performing the operation. *Jas. Fulton, Grims Dyke.*

—Mr. Blakey (p. 75) seems to infer that the reason why this fumigant is not more extensively employed for the destruction of Mealy Bug is that it has never yet been put on a scientific basis. But I am of the opinion that one of the reasons why cyaniding has not been more extensively employed is that there has been too much science introduced into the method of applying the gas, instead of making it what it is, one of the simplest methods. As I described in the issue for December 13, 1913, p. 427, no special appliance is necessary. Earthenware bowls with glazed inside surfaces, holding about two quarts each, should be procured and the required quantity of water placed in them. The proper quantity of sulphuric acid is next added (it is very important to remember that the water must never be added to the sulphuric acid). The quantity of cyanide for each bowl having been weighed and placed in pieces of paper, the operator takes these in his hand, drops the contents of a paper in each bowl, walks quickly outside and closes the door after him. In about three-quarters of an hour afterwards the house must be thrown open, and no one allowed to enter for at least one hour or more. This is simple enough for anyone to perform, and I have proved it to be as safe as it is simple. To bring the plants to a condition to render them safe from injury by the gas, discontinue damping and syringing three days before cyaniding, to make certain that all moisture is dried off the stages, etc. A little air may be admitted if the weather is favourable to ensure the atmosphere of the house and the foliage of the plants being thoroughly dry. The plants should not be afforded more root-waterings than are absolutely necessary to prevent flagging; the object being to reduce the amount of moisture in the foliage and render the leaves safe from injury. I am not sufficiently versed in natural history to know if there are two kinds of mealy bug, neither do I think it desirable to make more

intimate acquaintance than I have been obliged to do with this useless, troublesome, and expensive pest. Your correspondent states there are cases on record where the cyanide has floated on the acid without dissolving. This seems to me incredible unless very thick paper were used, as the cyanide is very heavy and sinks in the acid immediately. Tissue paper may be used, and this is soon destroyed by the acid. *J. H. G.*

WISLEY IN WINTER.—When a garden gives access as much pleasure in winter as in any other season of the year one may rest assured that it has been planted with rare judgment and is placed in a spot generally favourable to vegetation. Wisley, the garden of the Royal Horticultural Society, in Surrey, was very beautiful recently after a week of hard frost, no trace of which existed in any way, and the free planting of things that contribute warm, grateful colouring in winter made up pictures of beauty that would rejoice the true artist. Looking from the rock garden, Bamboos in infinite variety, *nigra*, *aurea*, *palmata*, *invicta glaucescens*, and many others, were waving in the west wind, and here and there breaking in on the view were Himalayan Rhododendrons and such Heaths as *Erica lusitanica* (codonodes), with plummy, soft green foliage, covered over from February until May with white flowers. Here and there were groups of *E. mediterranea hybrida*, the beautiful cross between the Mediterranean Heath and *E. carnea*. The collection of Heaths, a race of shrubs that it is a pleasure to find fast becoming popular, will repay close study, and on the bank where most of them are placed each kind is well represented, showing their value in the soft light of a winter day, from the characteristic shades of green and brown. *Daphne Blagayana* will soon scent the gardens with its ivory-white flower clusters, and when it succeeds in the way shown at Wisley none of its group gives greater pleasure: shelter from the afternoon sun, and close association of stones with the roots resulting in the most bountiful growth. *Shortia galacifolia* is a great success in the peaty soil and shade from shrubs, and the warm colouring of the leaves is a pleasant break. It is also to be seen in the Alpine house which contains a collection of Saxifrages and other plants, best seen with such shelter; *S. Burseriana* and others that bloom before winter is really over asking for protection if the fresh beauty of its flowers is to be enjoyed. In the collection of scented-leaved Pelargoniums one kind stands out for brilliancy of colouring—the old favourite, *Pretty Polly*. The flowers may be described as bright vermilion, and with the fragrant foliage make a plant of rare value in the winter months. It may be hoped that these long-discarded greenhouse plants will soon come into their own. On all sides the impress of good gardening is to be seen at Wisley, and a day spent there with Mr. Wright will long remain a pleasant memory. *E. T. Cook.*

HAMAMELIS (see p. 67).—Your correspondent, Mr. Wyndham Fitzherbert, is in error when he states that *H. mollis* "was not introduced into this country until 1898." We are indebted to Maries for the introduction of this beautiful species, when collecting on behalf of Messrs. J. Veitch and Sons, 1877-1879. If the flowers of Mr. Fitzherbert's *H. Zuccariniana* resemble *H. japonica* he has not the true plant, for they are distinct. The former are coloured primrose-yellow, the latter golden-yellow, almost as much difference as there is between the colour of an orange and a lemon. *A. O., Kew.*

CELERY DISEASE.—In several issues of the *Gardeners' Chronicle* last year correspondents wrote on the subject of the disease in Celery caused by *Septoria Petroselinii*. Some suggested over-manning and the use of certain kinds of animal manure as the possible cause of the complaint, and my experience during the past three years inclines me to agree with them. In the seasons 1911-12 I lost practically the whole crop of Celery through this disease, and in each case I followed the old practice of placing 9 inches to 1 foot of rotted cow-dung in the bottom of the trenches. Last year I only used a very light dressing of dung before planting, and before earthing up I applied a good dressing of kainit—

about loz. to the square yard. A second application of the potash manure was applied before the second earthing, and in each case the soil was thoroughly well watered. The result has far exceeded my expectations. I have not seen a trace of disease on any of the "heads," most of which weighed more than 3lb. after trimming. The variety I grow for a main crop is *Standard Bearer*. I may add that, although I sprayed three times last year with the Bordeaux mixture, I did the same during the previous seasons. *H. F. Zobel, Castle Hill Gardens, Rotherfield.*

WINTER-BLOOMING ROSES (see pp. 61, 75).—Here in Dunstable, which is 460 feet above sea level, and in a garden with a south-east aspect, I gathered blooms of the following varieties of Roses on Christmas morning:—*Souvenir de Pierre Notting*, *White Maman Cochet*, *Richmond*, *Marquise de Salisbury*, *Laurette Messimy*, *S. M. Rodocanachi*, *Fran Karl Druschki*, *Mrs. R. G. Sharman Crawford*, *Hugh Dickson*, *Souvenir de S. A. Prince*, *Perle d'Or*, *Souvenir de A. Stella Gray*, *Mme. A. Carrière*, *Caroline Testout* and *Irish Elegance*. This shows that Roses can grow as well in the more northern parts as in the south. *Arthur Munt, The Priory, Dunstable, Beds.*

PRIMULA OBOCONICA AND SKIN IRRITATION.—My experiences of *Primula oboconica* have been nearly the same as those described by your correspondents. Some few years ago I could handle the plants raised from seed with impunity. The last batch that I had to deal with resulted in the well-known symptoms of poisoning. I do not know whence these plants came, but it was evident that they were of a different strain from those I had previously handled, which has made me wonder if some strains of *Primula oboconica* are not poisonous, or are at least less virulent than others. I also know of another instance where the particular strain which I first grew did no harm, whilst another did. This evidence is not sufficient to be conclusive, as the condition of the blood must be taken into consideration. It would be interesting to know if others have had a similar experience to mine. *Modern Journeyman.*

ANTS AND SEEDS (see page 75).—I have been troubled with the amber-coloured ants described by Mr. Cook, and the only method I know of preventing them from getting into the seed pans is to smear some soft soap all around the holes at the bottom, and then stand the receptacles on bricks or inverted pans. *H. Hills.*

PRESERVATION OF WILD FLOWERS (see page 76).—Many plant lovers will be gratified to see this subject raised by your correspondent. No doubt the kind of vandalism he describes is on the increase, and is largely the result of the inclusion of nature study in the school curriculum. Great devastation may also be observed at village flower shows, where prizes are usually awarded to children for bunches of wild flowers. In this case, as in the last, the schedule maker must have the blame, surely not the child. Perhaps after all the most disturbing feature in the history of the extinction of native plants is the fact that the destruction is both studied and calculated, anyone may buy a flora and arm himself with a vasculum, and it is possible that destruction may proceed according to their luck or enlightenment. There are many natural history and "Botanical Exchange Societies" of the local and "private" nature, and one would like to hear more of their enactments. At Kew the men are professional gardeners, and they are accompanied on their excursions by practised and respected botanists. *T. Sargeant.*

DAHLIA MARIANNE.—With reference to the recent correspondence about this Dahlia and the query by *A. C.* in your issue of January 10 (see p. 29) may I ask *A. C.* if he can give me any information about Barlow's Bedder, and from whom it may be procured? I should also like to know when this variety was raised. Gluchauf—not Gluchaut, as spelt by *A. C.*—is absolutely distinct from *Marianne*, but the point that many growers who are interested in Dahlias wish to arrive at is this—what is the origin of Barlow's Bedder? Can any grower tell us? There can be no question about the value of *Marianne*, and it seems extraordinary

that its merits were not recognised at the Duffryn trials. Was it considered synonymous with Barlow's Bedder? If so the question of name will require some consideration when we ascertain all the facts. *Curious.*

FAILURE OF CHRYSANTHEMUMS (see pp. 29, 61).—After carefully reading Mr. Kearns's note (Vol. LV., p. 61) I take it that he means half a load of cow-dung was used as manure water on 18,000 plants; if so, he certainly did not over-feed them. In his first letter he states that the plants were fed regularly with manure-water. I quite understood that fire-heat was not used until November, but he says he applied a temperature of 65° to 70°. I venture to suggest that Mr. Kearns will have no more trouble with his Chrysanthemums if he uses sterilised soil and does not raise the temperature too high when the plants are forming their buds. I agree with him that the deformed flowers were probably caused by a check, no doubt due to eelworms. *C. Robinson, St. Hilary Gardens, Cowbridge.*

A BULB COMPETITION.—May we appeal to your readers on behalf of a bulb competition which has been started this year in connection with many of the North Lambeth schools and several mothers' meetings, clubs and guilds? In all 1,740 bulbs have been sold to the competitors at cost price, and now we are faced with the difficulty of raising money for the prizes. It is very difficult to do this locally as the neighbourhood is a very poor one, and for this reason we wondered whether possibly any of your readers would be willing to help us. We may add that the children and other competitors are taking the very greatest interest in their bulbs. *O. Butler, M. V. Ewbank, hon. secs., Lady Margaret Hall Settlement, 151, Kennington Road, Lambeth, S.E.*

MR. J. C. MCPHERSON.—As Lord and Lady Londesborough have decided not to reside at Londesborough Park in this county (Yorkshire), the large kitchen gardens and extensive, well-arranged ranges of glasshouses have been let as a business concern. This entails the resignation of Mr. McPherson, the well-known gardener. He has served the family over forty years, first in Hampshire, then in Yorkshire. His numerous friends and confrères will be glad to know that his lordship has, with his usual kindness, granted Mr. McPherson a pension for the remainder of his life. His frank, brusque presence and his exhibits will be much missed at York and other exhibitions in the North. With his good wife, he has decided to reside in the outer London area, near to some of their family settled there. The whole of the glasshouses at Londesborough were erected under Mr. McPherson's superintendence some years ago. For producing large supplies of choice garden produce they would be hard to equal, and impossible to excel. *Yorkshire Gardener.*

JOURNEYMAN GARDENERS AND LOW WAGES.—In reply to Mr. A. Norris I should like to say that if there are any head gardeners who are worse off than journeymen they had better change their occupation and seek employment as road-men! Then, it is not quite correct to state that journeymen receive their training free of charge; many pay a premium, and those who do not pay a premium frequently work for 6s. a week. Surely, Mr. Norris would not suggest that 6s. represents fair payment for a week's work? I wish head gardeners would consider it part of their duty to use their influence with the employer to improve the wages paid to the garden staff. It was with them, and not with the employers, that most of the blame rests. *J. J., Cirencester.*

—I have read with interest the many letters on young gardeners' wages. What do they think a head gardener should receive? I applied to a nobleman one day last week for the situation of head gardener, and received a reply saying, "Apply to my agents." Then he goes on to say the wages given was 18s., cottage, and no more, and very deeply underlined *no more*. What do our young men think of this? *Nil Desperandum.*

—I quite agree that a higher wage than the present average would be very acceptable, but probably thinking about it is as far as we shall

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

JANUARY 7.—*Present:* Mr. E. A. Bowles, M.A. (in the chair), Messrs. A. Worsley, J. Fraser, J. W. Odell, W. Hales, W. C. Worsdell, and F. J. Chittenden (hon. sec.).

get at present. Young gardeners do not think of the head gardener at all. I think a journeyman receiving 18s. week, bothy, milk, and vegetables, is better off than a good many head gardeners. There are plenty of heads who have worked in some of the best gardens in the country, and have to leave through no fault of their own, who are forced to take the first situation offered them. They may be married, with a family of children, yet the majority does not receive more than 25s. week and house. The journeyman need pay only 7s. or 8s. week for his board, and a steady lad can save 10s. week. The head gardener has to provide all household goods himself, and has several mouths to feed. Who is the better off? Ask the head gardener himself, for he can speak from experience. The article by H., on page 75, puts the question in a nutshell, the fact being that gardeners are not strong enough in numbers to demand more wages. Now that other trades offer good prospects for young men, journeymen will soon again be in demand. *Journeyman.*

—It is needless to waste words on journeymen who are contented with what is at the best a very meagre existence. Everyone knows that under present conditions it is almost impossible for the average journeyman to take as much interest in his work as he would if he had the remuneration he deserves. C. H. states in the issue for January 24 that he has been in his present place for six years, at the wage of 23s. 6d., 8s. of which he pays for rent. I am surprised that a man with such qualifications as he seems to possess, and holding such a responsible position, is content to remain in a place for so long at such a very low wage. While men in charge are content to work for such low wages it is to be wondered at that the young men under them receive such a paltry reward for their labours? *R. J. D.*

—I notice that nearly all the letters published on this subject are more or less flavoured with the complaint that "conditions" are all wrong, and in need of various suggested improvements. This they undoubtedly are, and always will be from some point of view or other. My advice to the young gardener is to adapt himself to circumstances, and get all he can out of conditions as they are, and not spend his time in thinking about what they ought to be. The gardening profession is probably as good to-day as it ever was. Although we find unfavourable exceptions, there is still room and pay for the right sort of man. No doubt there are thousands of young men capable of filling good positions, but they would do well to remember that there is a vast difference between *filling* a situation and *obtaining* one. So many young men seem to think the one thing necessary for success is a thorough knowledge of horticulture, and they fill their heads with a superficial knowledge of the various subjects. But even a thorough theoretical knowledge alone is not sufficient. It is the application of knowledge that tells. My advice to young gardeners is learn how to do a job well, and by tact and politeness, as well as by thorough competence, study the art of getting the job to do. *C. H. Middleton.*

—The question of journeymen, low wages, and bothies is so complicated that no definite conclusion can be drawn. There are not two gardens in the country that are worked on the same principle. If journeymen apply for situations at 15s. or under per week, then it is entirely their own fault that they work at such low wages. They are more to be blamed than pitied, because if they did not apply for such places the head gardener would be obliged to offer more wages. On the other hand, if the head employs journeymen (not improvers) at 15s. or under, per week, he deserves all the trouble that arises from the misdeeds of unskilled men. But in many cases a gardener advertises for a journeyman "with good wages," and engages him on the recommendation of another head, who gives a glowing account of his capability just to get rid of him. Consequently, he ruins a certain amount of what would have been good produce, and the employer tells the gardener that they will not pay the wages if they cannot have better results. Who is to blame? *W. Robinson, Locks Park Gardens, Derby*

Publication of Proceedings of Scientific Committee.—Mr. WORSDELL raised the matter of the publication of the minutes of the Scientific Committee in a collected form, so that they could be more readily consulted. Many matters of great interest and value are brought before the Committee from time to time, and from the fact that the minutes were published along with so much other matter in the *Journal*, Mr. WORSDELL feared that they were frequently lost sight of. Mr. CHITTENDEN said that a complete index of the contents of the last series of the Society's *Journal* was being made, and that would at least in part remove the difficulty that certainly existed when it became necessary to consult so large a bulk as the long series of the Society's *Journal* made.

Hybrid Pelargoniums.—Mr. J. FRASER continued his remarks upon the origin of the scented-leaved Pelargoniums, dealing with plants of several sections, including P. tetragonum, P. echinatum and others. He illustrated his remarks by reference to specimens from the Wisley collection, and they will be included in full in the report on these plants upon which he is engaged.

Fertility of soil under ricks, etc.—Mr. DOWNER drew attention to the greater degree of fertility shown by soil which has been covered by a rick, and also by the spots on which shocks of Wheat have stood in wet seasons. The Committee considered that the fact that rain washed out a considerable amount of the earth salts which plants contained, especially after they were dead, accounted in part for this extra fertility, and in some cases the washing of the soil to which uncovered parts are exposed may account in part for the lowered fertility of these, while the surfaces covered with ricks, etc., while protected from drying, are also protected from the serious washing which occurs when heavy rains fall. A great amount of refuse finds its way into the soil when ricks are removed and the earth turned up, and this also may have the effect of increasing its fertility.

Report of the Council for 1913.

THE one hundred and tenth annual general meeting of the Fellows of the Royal Horticultural Society will be held on Tuesday next in the Society's hall at 3 p.m. We make the following extracts from the Report of the Council for the year 1913:—

SIR TREVOR LAWRENCE.

The year 1913 began with the shadow, as it were, of gloom cast over it by the resignation of our president, and it has ended in the great sorrow of his death, which took place on December 22, within a few days of his eighty-second birthday.

Seldom, if indeed ever, has a society been served by its president so long and so ably as the Royal Horticultural Society has been served by Sir Trevor Lawrence. Elected to the president's seat in the very difficult days of the society's history in 1885, Sir Trevor has held the reins ever since, up to the spring of 1913, and has guided the society with steadily increasing progress, out of the quagmire of difficulties in which he found it, into its present state of prosperity. Whilst thus deeply appreciating his services, most of the members of the Council have been in too close a touch with the president as contemporaries to be able to realise how great and comprehensive those services have been, and it is only the rising generation of horticulturists who in the future investigate the history of the society who will behold in clear light the vast influence and benefit to horticulture of the long and uninterrupted presidency of Sir Trevor Lawrence.

NEW PRESIDENT.

To fill the void left by Sir Trevor's resignation was the difficult task which the Council had to perform in the spring of 1913, and fortunate indeed do they consider themselves in having prevailed on Field-Marshal Lord Grenfell to accept the office.

NEW COMMITTEES.

The work of the society has increased to such an extent that, in addition to the Parliamentary Committee formed towards the end of 1912, the Council have felt it necessary to appoint two new committees—namely, (1) the Diploma Committee, and (2) the Research Committee.

The Diploma Committee is entrusted with the organisation of the examinations for the National Diploma

in Horticulture, which has been established by the society with the approval and co-operation of the Board of Agriculture. The first examination will take place in June, 1914.

The Research Committee was appointed to examine the large number of suggestions for the extension of the society's work which are constantly being made, and to advise the Council on any reasonable ways in which the society might assist and advance the more scientific aspects of horticulture. A very important report has been drawn up by this committee, and, if it is found practicable to carry out its recommendations, there is every prospect of great developments taking place in the society's work in the immediate future. This report, which was only laid before the Council on December 9, will require much careful thought, for the scheme is of such magnitude and complexity, and touches so many different interests, that its mere consideration must of necessity take a considerable time before even an outline of it can be announced, so that for the present no more can be said beyond recording the fact. A new committee has been formed to advise on the details of the report.

ORCHID REGISTER.

It has been decided to establish a register of Orchids; not only, but specially, for the sake of recording the parentage of hybrids and of securing their correct and permanent nomenclature. Mr. E. A. Rolfe has been appointed Official Recorder. The register will be carried back as far as possible by careful examination of old documents, and the Council hope that Orchid growers having private records of genera, species, and hybrids, will assist the compilation by lending them to the society to be copied for this purpose. The immediately pressing work of the Recorder, however, will be the entering up on the register of every new Orchid shown, with particulars of its parentage, raiser, owner, etc., as far as is known.

PARLIAMENTARY COMMITTEE.

The Parliamentary Committee appointed in 1912 have had the following subjects under their consideration—namely, (a) the proposed Government Seed Testing Station, (b) the Subsidies given by Government to Co-operative Organisations, which are alleged to undersell Retail Traders, (c) Railway Rates and Conditions, and (d) the Sale of Wet Coke by weight. On the two former points the Council have addressed memoranda to the Board of Agriculture; and on the question of Coke, Sir Albert Rolfe has kindly undertaken to bring the matter before the Board of Trade on the Council's behalf.

WISLEY GARDENS.

The planting of the rock garden is still proceeding, but it is necessarily a matter of time before so large an area can be well clothed with plants, especially considering the slow growing nature and rarity of some.

The Alpine house is proving a valuable addition to the rock garden, and many Fellows visit it during the earlier months of the year.

The erection of an Orchard house is at this moment proceeding. The house is being constructed with very great care, in order that exact and delicate experimental and research work concerning fruit trees may be properly undertaken within it.

A Water Lily tank, fitted with hot water pipes, is also under construction for the accommodation of Blue Water Lilies kindly presented by Mr. Leopold de Rothschild.

TRIAL OF TULIPS.

The Council issued an invitation to growers of Tulips to send bulbs to Wisley, that their correct nomenclature might be recorded and a list of synonyms made. Over 4,000 parcels of bulbs have been received and planted, and a committee of Dutch and English growers has been appointed for the work.

SPRAYING AND SUNDRIES TRIALS.

A useful trial of spraying apparatus was conducted at Wisley, in April, when awards were made.

The new system of trial of horticultural sundries, introduced this year as a means of determining the awards which such subjects as garden rollers, mowing machines, tools, insecticides, etc., should receive, has been satisfactory, and will be continued.

MR. SMITH'S RESIGNATION.

Mr. Arthur C. Smith, the assistant superintendent, resigned after six years of useful service. Mr. Blakey, who had been chief foreman, was appointed his successor, and Mr. Braddy has been raised to Mr. Blakey's position with special charge of the fruit department.

DAHLIA TRIAL AT CARDIFF.

Mr. Reginald Cory most kindly placed his garden at Duffryn, near Cardiff, at the Society's disposal for a trial of Dahlias decorative to a garden. The Council invited the co-operation of the National Dahlia Society in this trial, which co-operation was most cordially given, and the delegates from the two Societies inspected between seven and eight thousand plants, representing nearly a thousand distinct varieties, out of which 291 were selected as being desirable for garden ornamentation.

CHELSEA SHOW.

The past year has seen the first of the new series of spring shows at the Royal Hospital Gardens, Chelsea; the result in every way justified the action of the Council in transferring the Show from the Temple Gardens to Chelsea, and it is confidently hoped that Fellows will co-operate with the Council in encouraging the attendance of visitors, so that the Show may be a success in the future.

HOLLAND HOUSE SHOW.

For the second time only, in a period of ten years, the Holland House Show was favoured with beautiful weather, and was pronounced to be the most pleasant Summer Show the Society had held.

SHOWS OPEN ONE HOUR LATER.

A communication having been received from Fellows in the City, asking that the shows at Vincent Square might remain open one hour longer, the Council, after consulting the most frequent exhibitors, decided to adopt the suggestion. Fellows will accordingly find the later hours set forth on their annual tickets.

CUPS.

A standard pattern (in four sizes) for the R.H.S. Cups was adopted in 1913, and was found to be very popular with exhibitors. A cup of a different pattern has been chosen for 1914, an illustration of which will be found in the "Book of Arrangements." Mr. E. H. Davidson has again very kindly presented a cup for the best Cattleya at the Chelsea Show, and Mr. Cory a cup for the most meritorious Seedling Dahlia in the trials, which he is kind enough to allow the Society to continue for a second year at Duffryn, Cardiff.

NEW CHALLENGE CUPS.

The Council have to thank Lady Algermon Gordon-Lennox for a large silver challenge cup presented for award at the Holland House Show for hardy flowers. They have also to thank Mr. Reginald Cory, not only for the great kindness shown in placing his garden at their service for the Dahlia trial, but also for his hospitality to their delegates and for his gift of a seventy-five guinea challenge cup for a group of Dahlias for garden decoration at the Society's Show in September.

The Council have further accepted from Messrs. Clay a £75 silver-gilt challenge cup for "A Rose, not in commerce, possessing the true old Rose scent." This cup will be offered for the first time at the 1914 Holland House Show, and Messrs. Clay will furnish the Society with a smaller permanent cup to present to the winner when the challenge cup is returned.

The Council have established a silver challenge cup, value thirty guineas, to be awarded at the R.H.S. Daffodil Show. As a well-deserved compliment to by far the greatest raiser of hybrid seedlings of modern times, it is to be called the "Engleheart Cup." In 1914 it is offered at the R.H.S. Daffodil Show, on April 15 and 16, for the "Twelve Best Seedlings, distinct, which have not yet been put into commerce." The Council have accepted the trusteeship of the Barr Memorial Cup, founded in memory of the late Mr. Peter Barr, and its award will be made on the recommendation of the Narcissus Committee.

PRITZEL'S INDEX ICONUM BOTANICARUM.

The Council have also accepted the trusteeship of the sum of £250, voted by the directors of the International Horticultural Exhibition, 1912, for the revision of Pritzel's Index Iconum Botanicarum. The Council have also received a kind gift of £100 from the Veitch Memorial trustees and have themselves agreed to supplement this, and all other gifts which may be received for the purpose, by £250 annually until the fund is sufficient to pay for the revision proposed.

SAXIFRAGE CONFERENCE, 1915.

It has been decided to hold a conference on Saxifrages in 1915. Mr. Milne-Redhead has generously presented the Society with his MS. list containing nearly 1,000 entries of species, varieties, and synonyms. Further co-operation in this direction will be most gratefully accepted.

DAFFODIL YEAR BOOK, 1913.

A Daffodil year book was issued by the Society in August and found a ready sale, the copies available being rapidly bought up. The Council are greatly indebted to the Rev. J. Jacob for his assistance.

LAWRENCE MEDAL FOR 1913.

The Lawrence Medal for 1913 has been awarded to Mr. G. F. Moore, of Bourton-on-the-Water, for his exhibit of Orchids, on January 7, 1913.

DEPUTATIONS.

During the year deputations from the Society have visited the shows held at Truro, Bristol, Cardiff, Birmingham, Kendal and Maidstone, reports of which will be found in the *Journal*.

An invitation has been received from the Carlisle and Cumberland Horticultural Association, and has been accepted, for a deputation in August next.

GRAPES TO GLASGOW.

An exhibit of Wisley-grown Grapes was sent to the Glasgow and West of Scotland Horticultural Society's Show in September, where the fruit excited the greatest admiration and was awarded a special Gold Medal.

DOUGLAS' JOURNAL.

The task of editing the journal kept by Douglas when he was travelling in America nearly 100 years ago as the Society's collector has taken far longer than could have been anticipated, the writing being in places very difficult to decipher, but it is hoped to publish it early in the ensuing summer.

PLANT COLLECTOR.

The Council have arranged to share part of the expenses and of the "finds" of a collector, who is starting for the high lands between China and Tibet.

NEW HONORARY FELLOWS.

The Council felt much pleasure in appointing as Honorary Fellows of the Society Mr. H. W. Admitt and Mr. W. W. Naughton, in recognition of the remarkable ability and success with which for a long number of years they have acted as co-secretaries of the Shrewsbury Show.

OBITUARY.

It is with regret that the Council have to record the death of the following Fellows: The Duchess of Northumberland, the Earl of Pembroke, the

Countess Cowper, the Dowager Countess of Kenmare, Viscount Tredegar, Lady Darling, Lady Dorothy Neville, Colonel Archer Houlton, Alfred Austin, Esq., Martin J. Sutton, Esq., Alfred Tate, Esq., W. T. Hindmarsh, Esq., A. H. Kingsmill, Esq., J. S. Moss, Esq., Martin J. Sutton, Esq., Alfred Tate, Esq., W. T. Cily, and Messrs. Amos Perry, Robert Sydenham, Edward Webb, and A. H. Kent.

ANNUAL PROGRESS.

The following table shows the Society's progress in regard to numerical strength during the past year:—

LOSS BY DEATH IN 1913.

COMMITTEES, &c.

The Society owes a constantly recurring debt to the members of the standing and special committees, chairmen, judges, writers of papers for the *Journal*, compilers of extracts, reviewers, lecturers, and the several examiners, who, during the past twelve months, have done so much to contribute to the Society's usefulness, and to help to maintain its high standing among the practical and scientific institutions of the world. The Council also acknowledge their obligations to the Press for their invaluable assistance in reporting upon, and calling attention to, the work of the Society.

By Order of the Council,

W. WILKS, Secretary.

Royal Horticultural Society,
Vincent Square, Westminster, S.W.
January 1, 1914.

NATIONAL CHRYSANTHEMUM.

ANNUAL MEETING.

FEBRUARY 2.—The annual meeting of the members of the National Chrysanthemum Society took place on Monday last at Carr's Restaurant, Strand. The president, Sir Albert Rollit, D.C.L., LL.D., presided.

After the secretary had read the notice convening the meeting, and the minutes of the last annual general meeting, the Executive Committee's report for 1913 and the balance-sheet were read. The following are extracts from the report:—

ANNUAL REPORT.

The Great Autumn Exhibition held in November at the Crystal Palace was undoubtedly a worthy successor to the many shows which have preceded it in past years, and worthily upheld the general reputation of this society. There was a considerable increase in the exhibits of single Chrysanthemums, but, at the same time, it is satisfactory to note that there was no diminution in the number of large exhibition blooms staged. The competition was keen in the majority of the classes, although the actual number of entries was a few less than in 1912. During the October show 10,060 people visited the Crystal Palace, and during the November show the number of visitors was 20,206.

The show at Essex Hall on December 10 was held under exceptional circumstances. The exceedingly mild weather which prevailed during the whole of October and November led to the fear that it might be difficult to get a good show so late as December 10. Fortunately these fears were not realised, and after taking into consideration the nature of the season, it was generally admitted that the exhibits which were

staged, although not actually numerous, were of very fine quality. The market Chrysanthemums staged on this occasion were of outstanding merit.

A suggestion was made during the year that a special certificate should be prepared, and a copy of same awarded to the winners of the trophy in the affiliated societies' class each year in order that such society might retain a permanent record of its success. The suggestion met with the unanimous support of the committee, and the certificates are now being prepared. It has been further decided that affiliated societies who were successful in winning the trophy in past years may receive copies of the certificate upon making application to the secretary.

The annual conference was held at Essex Hall, on December 10, when the following papers were read, viz.: "The Evolution and Development of Outdoor Chrysanthemums," by Mr. Norman Davis, and "Chrysanthemums for Outdoor Garden Decoration," by Mr. T. Bevan, the latter paper being illustrated by limelight views. The attendance was again very satisfactory, over 110 members being present. A full report of the proceedings will appear in the 1913 *Transactions*.

The new volume of *Transactions* for the year 1913 is now in hand and will be published during the spring. A special supplement of photographs in natural colours will be included in this issue.

New Varieties.—Nine meetings of the Floral Committee were held during the year, when 177 new varieties were considered as compared with 249 during the previous year. The decrease in numbers was no doubt due to the fact that in 1913 a registration fee of 1s. was charged on each variety staged. The committee are of opinion, however, that the introduction of the new regulation had no detrimental effect on the general work of the committee, but rather achieved its object in keeping away varieties which only served to waste time. The following awards were made, viz.: 30 First-Class Certificates, 19 Commendations, 2 Market Certificates and 4 Market Commendations.

The usual table is set forth below showing to which sections First-Class Certificates have been awarded during the past five years:—

	1909.	1910.	1911.	1912.	1913.
Japanese	8	19	8	27	15
Incurved Japanese	—	—	—	2	2
Incurved	3	2	2	3	—
Single	7	12	21	16	13
Decorative	8	21	7	—	—
Total	26	54	38	48	30

The new classification which was introduced in 1912 is proving its value in many ways, and it is hoped that members, who have not already done so, will make themselves acquainted with the new rules bearing on this matter.

The new regulations with regard to the granting of special Market Certificates were enforced throughout the 1913 season. Ten varieties were submitted under these special regulations, and of these two were awarded Market Certificates and four were Commended as market varieties. During 1913 varieties which were staged for these special awards were judged on points as set forth in the last schedule.

During 1913 special prizes were offered for seedling plants of Anemone, Pompona and Anemone-Pompons. The committee regret to report that the Floral Committee was unable to make any award in connection with this offer of special prizes.

It has been decided to offer during 1914 a special prize of £2 2s. for the best Anemone-centred single, subject to the following conditions, viz.:—

1. That the variety must not have been placed before the Floral Committee on a previous occasion.
2. That a plant must be shown of each variety staged.
3. That the variety must obtain a First-Class Certificate in order to be eligible for the prize.

At the meeting held on December 10 the committee unanimously decided to adopt the following definition of a spray, viz.: "A spray is the last flowering growth consisting of one stem with a central flower or bud and with its surrounding flowers or buds." The Executive Committee subsequently adopted this definition as part of the society's general show regulations, and they recommend that it should be adopted by all affiliated societies.

Mr. T. Bevan, the chairman of the Executive Committee, attended the Quinquennial Exhibition at Ghent as an official delegate from this society. Mr. C. Harman Payne acted as a member of the jury, and other members were also present at this exhibition.

At the end of October an International Chrysanthemum Show was held at Ghent, when the French Chrysanthemum Society joined forces with the Belgian authorities. Exhibits were taken over from England by Mr. E. G. Mocatta (gr. Mr. Thomas Stevenson) and Messrs. W. Wells and Co., Ltd. Your committee have special satisfaction in reporting that Mr. Mocatta was awarded 1st prize in a class for 100 Japanese varieties, and also in a class for singles; and that Messrs. W. Wells and Co., Ltd., received a Gold Medal for their trade exhibit. In connection with this show, Mr. T. Bevan and Mr. C. Harman Payne acted as members of the International Jury on the special nomination of the Exhibitions Department of the Board of Trade. A report of this exhibition by Mr. C. Harman Payne will appear in the forthcoming volume of the society's *Transactions*.

The committee have pleasure in once again being able to report that the financial position of the society is good. The whole of the liabilities were paid before the close of the year, and the surplus of assets over liabilities at December 31 last amounted to £126. The audited accounts for the past year are appended to this report.

The exhibitions for 1914 have been fixed as follows: October 7 and 8, at the Crystal Palace; November 4, 5 and 6, at the Crystal Palace; and December 9, at Essex Hall.

The Conference for 1914 will be held at Essex Hall on December 9, in conjunction with the late exhibition and meeting of the Floral Committee fixed for the same date. The subject of "Single Chrysanthemums"

will be dealt with, and it is hoped that papers will be delivered under the following sub-headings, viz:—

(1) The Culture of Singles; (2) The Best Singles of to-day; and (3) Suggestions to future raisers of Singles.

In accordance with Rule 7, the following nominations have been made for elections as honorary fellows and corresponding members:—

As Honorary Fellows: Messrs. D. Ingamells, member of the Executive and Floral Committees; G. Prickett, member of the Executive and Floral Committees; and Firmin de Smet, Ghent.

As Corresponding Member: Ch. Pynaert, Ghent.

Sir ALBERT ROLLIT moved the adoption of the report and balance-sheet. He considered that the report recorded great improvements in all respects and indicated an advance in the society which was doing good work. As to finances, there was a balance of £126 surplus over liabilities. The number of Fellows had increased, and the subscriptions had materially added to the revenue. The exhibitions, he considered, had been well worthy of the society's renown. He could remember those at the Royal Aquarium, and was one of those who did not at first view with favour the Crystal Palace as a place in which to hold the shows, but he had long since been of the opinion that it was an excellent site. No society had been more loyal to the Palace than the N.C.S., and the members of it might feel that they had some share in bringing about the preservation of the great and historic building for the use of the public. After a few words relating to the affiliated societies and the good work they did in spreading abroad a love for flowers, Sir ALBERT dealt with the conferences held by the society. These fostered research and excited interest among the members, and had a decided educational value, and this was all the more important as the knowledge thus gained was widely distributed through the proceedings of these meetings being recorded in the society's publications. The society's relations abroad were of the most cordial character, and it had its part in international work. At Ghent last year many members of the society had taken part, either as jurors or exhibitors, and he would specially mention Messrs. Bevan, Wells, Stevenson, and Harman Payne in this connection. As President, he was proud of the honour of holding that position, and would always do his best to maintain the high position the society held.

The motion was seconded by Mr. T. BEVAN and carried unanimously.

A vote of thanks was proposed to the auditors.

The election of officers then followed, with the following result:—President, Sir Albert Rollit; treasurer, Mr. John Green; chairman, Mr. Thos. Bevan; vice-chairman, Mr. E. F. Hawes; foreign secretary, Mr. Harman Payne; general secretary, Mr. R. A. Witty. The auditors appointed for 1914 are Messrs. E. W. Oakley and H. C. Bridges.

The chairman spoke of the efficient services rendered by the secretary, Mr. Witty, who had helped him greatly during the year by his business-like methods.

One-third of the Executive Committee retiring by rotation an election followed to fill the vacancies. The result was as follows:—Messrs. R. Ballantine, Mills, W. Cassidy, P. A. Cragg, W. O. Hiehle, C. H. Curtis, D. B. Crane, A. J. Foster, R. J. Frogbrook, W. Newton, Thomas Smith, G. Prickett, and J. Tyler.

LINNEAN.

JANUARY 15.—A meeting of the Linnean Society took place on the 15th ult., Prof. E. B. POULTON, F.R.S., President, in the chair.

Mrs. HENSHAW gave an account of the journey into the interior of Vancouver Island, made by Mr. Henshaw and herself, illustrated with a series of photographs of the scenery and the more striking plants.

Mr. G. CLARIDGE DRUCE, M.A., F.L.S., read a paper on a Marsh Orchis, for which he proposed the name *Orchis praetermissa* (a Latin description being given), and contrasted it with the true flesh-coloured *O. incarnata* of Linnaeus, as described by C. B. Clarke in *Journ. Linn. Soc.* xix. (1881), 206, showing how it differed in the shape of the flowers and in other characters from that plant. *O. praetermissa* is the crimson-flowered plant which has a wide distribution through South and Central England. A beautiful painting of it has been executed by Miss

Trower from a seedling raised by Mr. B. Savile Ogle, who had collected the parent plant before 1903 on the borders of Berks and Hants. The seedlings obtained from it resembled each other and the parent in all the stages of their growth. The parent was figured as *incarnata* in the *Report of the Ashmolean Natural History Society of Oxfordshire* for 1904.

Mr. Druce himself collected the plants in Nottinghamshire in 1878, in Oxfordshire in 1882, in Berks and in Norfolk.

Mr. P. M. HALL and Mr. R. B. ULLMAN, who have studied the Orchids around Winchester with great assiduity, came independently to the opinion that it was a distinct species (a note on it appears in the *Report of the Winchester College Nat. Hist. Society*) and found it abundantly in Hampshire. A photograph by Mr. Bedford showed that it occurred near Lewes in Sussex.

Reference was made to another and as yet undescribed form from the Coast Sands of Britain, as well as to a northern plant, but these await further investigation.

Mr. DRUCE stated that he has as yet been unable to find any description or figure of his plant in British or European works.

Mr. DRUCE then read a note on Article 45 of the Vienna Rules, contending that the change of *Limonium* to *Statice* was either unnecessary, or, if persisted in, might open the door to other changes in nomenclature. His point was that the Linnean genus *Statice* was made up of the two Tournefortian genera, *Statice* and *Limonium*; that in his *Genera Plantarum* Linnaeus alludes to and gives descriptions of both these under *Statice*, placing first the Sea Thrifts under *Statice*. Miller and Hill correctly chose *Limonium* to represent the Sea Lavenders, leaving *Statice*, Linn., to denote the Sea Thrifts. A list of genera, in which the retained name represents a minority of the plants in the genus, had been drawn up by him; but, as the author stated, many of these were correct on the same evidence as that accorded by the example given.

He further suggested that, in order to clear up some apparent ambiguity in Art. 45, the words "has no retrospective action" might be added to it.

Mr. DRUCE's third paper gave a list of the names of genera defined by Miller, Abridgement of the *Gardener's Dictionary* of 1754, which (as wholly Tournefortian) were not included in the *Index Kewensis*: thus Miller may have to be cited for many of those genera, instead of later authors such as Adanson, Moench, Gilibert, etc.

To this was appended a note concerning John Hill's *British Herbal* of 1756, with its accidental binomials, which in some cases preceded those cited from Garsault's *Materia Medica* of 1768, which have been inserted in the fourth supplement to the *Index Kewensis*.

The next general meeting will be held on Thursday, February 5, 1914, at 8 p.m. Exhibitions and papers: (1) Mr. W. R. B. Oliver, "The Vegetation of White Island, New Zealand." (Communicated by Dr. L. Cockayne, F.R.S.). (2) Mr. W. C. Worsdell: Lantern-slides of Cape Plants, mostly in their native habitats. (3) Mr. Walter E. Collinge: On the range of Variation of the Oral Appendages in some Terrestrial Isopoda.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 15.—At the meeting held on the 15th ult., the following members of the committee were present:—Rev. J. Crombleholme (in the chair), Messrs. R. Ashworth, J. Bamber, J. Cypher, J. Evans, A. Hanmer, J. Howes, J. Lupton, D. McLeod, W. J. Morgan, C. Parker, W. Shackleton, Wm. Thompson, H. Thorp, Z. A. Ward, G. Weatherby, and H. Arthur (secretary).

R. ASHWORTH, Esq., Newchurch (gr. Mr. Gilden), was awarded a Large Silver Medal for a group composed principally of *Odontoglossum* and hybrids. The exhibit included *Odontoglossum illustrissimum* var. *Nonpareil*, *O. Janua*, *O. Arcturus*, *O. Aviator*, *O. Ethiopia*, *O. Blue Peter*, and *O. Lucy*; *Odontiodas Ashlands* var. *devoniana*, and *O. Charlesworthii*; *Cypripedium bellatulum album* and *Gomezia Barkeri*.

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish), was awarded a Large Silver Medal for a group of Orchids (a Cultural Certificate and a Bronze Medal were awarded to Mr. DALGLEISH for the excellent plant of *Cypripedium virginale*).

H. ARTHUR, Esq., Blackburn, staged various *Cypripediums* and a plant of *Oncidium serratum*, with a spike carrying 41 flowers.

Col. J. RUTHERFORD M.P., Blackburn (gr. Mr. Lupton), staged *Cymbidium Holfordianum* and *Cypripedium Actaeus major*.

MESSRS. CYPHER AND SONS, Cheltenham, were awarded a Silver-gilt Medal for a mixed collection, including *Cypripediums*, *Calanthes*, *Masdevallias*, and *Laelia anceps Sanderiana*.

MESSRS. SANDER AND SONS, St. Albans, were awarded a Silver Medal for a group containing a batch of *Laelia Gouldiana*, also choice *Odontoglossum* and *Cattleyas*.

MESSRS. A. J. KEELING AND SONS, Bradford, staged *Cypripedium keighleyense*, *C. aureum*, *Hyanum*, *Laelia anceps Sanderiana* and other Orchids.

Mr. W. SHACKLETON, Great Horton, Bradford, staged two fine varieties of *Odontoglossum crispum* and seedling *Cypripediums* of the insigne type.

Mr. D. McLEOD, Chorlton-cum-Hardy, showed *Cypripedium Boltonii* and a few cut flowers.

FIRST-CLASS CERTIFICATES.

Odontioda Thompsoniae, a fine, circular flower, 2½ inches across, coloured scarlet shaded with crimson, and having a distinct white edge around the segments; the lip is broad and margined with white; *O. × Hercules*, 4½ inches across, dark chestnut coloured with white veins and markings, the outer edge shaded with rose; *O. Papilion*, white flushed with rose, blotched and spotted with bright purple; *Cypripedium waltonense magnificum* (Rupert × Thompsonii), broad round dorsal 3½ inches across and having a clear white margin; inner portions suffused and spotted with dark rose, base green, with dark red band down the centre. The petals are light brown with dark markings and the pouch is of similar colour. All these shown by Wm. THOMPSON, Esq.

Odontoglossum illustrissimum var. *Nonpareil*, a circular flower of brilliant colouring, shown by R. ASHWORTH, Esq.

AWARDS OF MERIT.

Odontoglossum × amaranthum and *O. illustrissimum Creole*, both shown by Wm. THOMPSON, Esq.

O. illustrissimum Janua and *Odontioda Ashlands* var. (Od. *Andersonianum* × *C. Noetzliana*), both shown by R. ASHWORTH, Esq.

Cypripedium Iona (*bellatulum* × *Farrieanum*), both exhibited by the Duke of MARLBOROUGH.

C. Zealandia, shown by Rev. J. CROMBLEHOLME.

C. leyburnense Fern Bank var., shown by CHAS. PARKER, Esq.

Brasso-Cattleya Menda (*Cattleya labiata* *Virginale* × *B.-C. Queen Alexandra*), shown by R. LE DOUX, Esq.

Lycaste × Beryl, shown by Messrs. CYPHER AND SONS.

Laelio-Cattleya (*C. Trianae* × *L.-C. luminosa*), the property of Messrs. HASSALL AND Co.

LIVERPOOL HORTICULTURAL.

JANUARY 31.—The thirty-fifth annual meeting of this society was held on the 31st ult. in Hackins Hey, Liverpool, Mr. W. Mercer presiding. The balance-sheet for 1913 showed an increase both in the amount received from subscriptions and admissions to the exhibitions. The balance in hand is now £109. Mr. Leo Thomson was re-elected treasurer and Mr. G. Blackmore as sub-treasurer. Mr. Harold Sadler resigned the secretaryship after fifteen years' service and was accorded a vote of thanks. It was decided to hold a special general meeting of the society on the 18th inst. for the purpose of electing a new secretary. In the meantime a small committee was appointed to deal with applications for the office.

MARKETS.

COVENT GARDEN, February 4.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday...

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers like Arums, Azalea, Camellias, Carnations, and their prices per dozen.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage like Adiantum Fern, Agrostis (Fairy Grass), and Asparagus plumosus.

French Flowers.

Table listing French flowers like Anemones, Narcissus, Ranunculus, and their prices.

Guernsey and Scilly Flowers.

Table listing Guernsey and Scilly flowers like Anemone fulgens and Narcissus.

ties Victoria and Sir Watkin. The salesmen's stands are filling with bulbous flowers, including single and double Tulips. Larger consignments of Narcissi are arriving from the Channel Islands...

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various plants in pots like Aralia Sieboldii, Araucaria excelsa, Asparagus plumosus, and their prices.

REMARKS.—Trade is better for flowering plants—Cinerarias, Genistas, Hyacinths, Daffodils, Azaleas, Marguerites, and White Spiraea are the leading features just now...

Fruit: Average Wholesale Prices.

Table listing various fruits like Apples, Lemons, Limes, and their prices.

REMARKS.—As the supplies of home-grown Apples shorten the demand for imported fruits show a steady increase. About 40,000 cases of fruit have arrived during the past week from Cape Colony;

they include Pears, Plums, Apricots, Peaches and Nectarines. Forced Strawberries are arriving daily from the Worthing district. Black Grapes are not plentiful; the crop of Black Alicante is almost finished...

Vegetables: Average Wholesale Prices.

Table listing various vegetables like Artichokes, Asparagus, Beans, Carrots, and their prices.

Potatoes.

Table listing various potato varieties like Bedford, Blacklands, British Queen, and their prices.

REMARKS.—The conditions of trade and prices show no alterations over those of last week.—Edward J. Newborn, Covent Garden and St. Pancras, February 4, 1914.

Obituary.

E. S. Ross.—We regret to record the death of Mr. Edward Stephen Ross, gardener and bailiff to Mrs. Cordes, of Silwood Park, Ascot, which occurred on the 29th ult. from cerebral haemorrhage...

ENQUIRY.

BUCK SAVIN.—Can any reader inform me what is "Buck Savin"? Waggoners in my neighbourhood use little sprigs of it dried and powdered to mix with their horses' food...

SCHEDULES RECEIVED.

The Midland Carnation and Picotee Society.—The twenty-fourth annual exhibition of this society will be held on Thursday, July 30, and Friday, July 31. Secretary, Mr. T. Humphreys, Botanical Gardens, Edgbaston, Birmingham.

ANSWERS TO CORRESPONDENTS.

"There are few gardeners, and still fewer amateurs, who do not on occasion require immediate information upon various points of practice. But either from an unwillingness to inquire, or from not knowing of whom to make the inquiry, they too often fail to obtain the information they are in want of. And let no one be alarmed lest his questions should appear trifling, or those of a person ignorant of that which he ought to know. He is the wisest man who is conscious of his ignorance; for how little do the wisest really know!—except that they know little. If one man is unacquainted with a fact, however common, it is probable that hundreds of others in the same position as himself are equally in want of similar information. To ask a question, then, is to consult the good of others as well as of one's self."—*Gardener's Chronicle*, No. 1, Vol. 1, January 2, 1844.

ALLIGATOR PEAR: *W. C. Pendarves*. The Alligator Pear is *Persea gratissima*, known also as Avacado Pear. Specimens were illustrated in *Gardener's Chronicle*, December 26, 1908, Fig. 177. The tree is a native of the West Indies, and would not succeed in this country out-of-doors.

AMMONIACAL SOLUTION OF CARBONATE OF COPPER: *R. L.* This fungicide is prepared from copper carbonate, 5 oz.; ammonia (26° Baumé), 3 pints; and water, 50 gallons. The ammonia must be handled with care, and should be diluted to about five times its volume. Make the copper carbonate into a thin paste with water in a small vessel. Add the paste to the diluted ammonia and stir constantly. The mixture is then brought up to 50 gallons. The ammonia will evaporate rapidly, therefore ammoniacal copper carbonate should be used as promptly as possible.

BARE PATCHES IN TURF: *J. T.* Apply a dressing, as you suggest, and mix suitable lawn seeds with the fine soil.

BULBS ROTTING: *G. H.* Your bulbs are infested with bulb mite. Sterilise the soil in which the plants have been grown and burn the infected bulbs.

CAMELLIA BUDS DROPPING: *Devonion*. The most frequent causes of bud-dropping in Camellias are insufficient heat and a check to the roots, the latter either through an excess or an insufficiency of moisture. As the plant has flowered well in the same house before it cannot be due to unsuitable temperatures, and the unsatisfactory condition must be attributed to careless watering.

CARNATION PLANT: *D. M.* There is no fungus present on the leaves, but the general appearance suggests eelworm at the roots.

CATERPILLAR: *A. J. J. G.* The caterpillars are those of the common Cabbage Moth, *Plutella brassicae*. The larvae bury themselves in the earth during the daytime and feed at night when the weather is favourable.

"CLEAN CULTURE": *G. W. H.* What you describe as clean culture appears to consist in merely excluding the use of all animal and organic manures. If you ask whether such clean culture is to be recommended in all circumstances our reply is in the negative. At the same time clean culture might very often be practised by gardeners without causing any loss of cropping. Not that the exclusion of organic manures is necessary, but because the soil already contains sufficient for the needs of the plants. We have often recommended for old gardens that have been manured liberally, not to say excessively, with organic manures, the discontinuance of same for a season, applying instead dressings of lime. Further, provided the gardener can always get fresh loam from a pasture and just the amount of loam he requires for his crops, the advice which you said has been given you might be followed with advantage, but quite the contrary experience falls to most cultivators; they have to make the best of the soils available, and in doing so they frequently find that their task is materially lessened by making use of such fertilisers as your adviser condemns. As we have said, what is meant by clean culture is not to be recommended in a general way, but may frequently be found to be perfectly satisfactory for particular cases.

CHRYSANTHEMUMS: *J. W. P.* The following six varieties of single Chrysanthemums are suitable for exhibition purposes. They should be disbudded in the first week of November:—Bronze Edith Pagram, Snowflake, Sandown Radiance, Mrs. A. Middleton, Portia and Mrs. Loo Thomson. If these varieties are propagated at once, grown quite hardy in the young stage, potted into their flowering-pots (9 inch or 10 inch) during the third or last week in May, and allowed to break naturally they should show their buds about the first week in September. If they are then disbudded, leaving one bloom to each shoot, they should be at their best condition of flowering by the time stated. Mrs. Loo Thomson and Mensa, should you care to grow the latter variety in place of Snowflake, will require housing fairly early, as they are rather late varieties for shows early in November. Feed the roots liberally with manure after the buds are taken. The following six varieties are suitable for producing sprays of blossom:—Joan Edwards, Sylvia Slade, Manor House, Terra Cotta, Ceddie Mason, Mr. Tresham Gilbey and Hilda Lawrence. You might include a plant or two of Mensa, Celia and Portia, for if these bloom in time they will help you considerably. You should be able to obtain four good vases of blooms from the following seven varieties:—Mrs. W. Roots, Market Red, Heston Yellow, Mrs. R. Luxford, Mrs. G. W. Streeter, H. W. Thorpe and Phoebe.

DISEASED TREE TRUNK: *W. B. S.* Remove all dead and decaying tissue, scraping the loose rotting wood from the interior and sweeping out all the debris with a brush. When quite dry the interior of the trunk, should be painted with one or, preferably, two coats of creosote and filled up with a composition of one part of Portland cement to three of clean gravel and sand, the surface coating containing the largest quantity of cement. A coat of coal tar on top of the dry creosote goes far in making the concrete adhere firmly to the wood. When a fairly healthy tree is being operated upon, and when the bark is likely to grow over the exposed surface the concrete should only be placed on a level with the underside of the living bark. Sometimes brickbats broken small are used instead of gravel, but for various reasons cement is preferable. The concrete surface may be prevented from cracking by applying annually a coat of paint, which, for appearance sake, may be of a similar colour to that of the bark of the tree.

EXPENSES FOR REMOVAL: *Reader*. You cannot obtain compensation for expenses incurred in removing to your present situation unless your employer came to an arrangement with you by which he agreed to pay the cost. You are quite right in thinking that the expenses of removal are very frequently borne by the new employer, but this is quite the result of custom, and not due to any legal obligation. In regard to your second question, it is usual for a head gardener to give or receive one month's notice before terminating his employment, and in the absence of special circumstances this notice can generally be insisted upon in the courts. You ask: "What holiday is a head gardener entitled to during twelve months' service?" We suppose that he is not legally entitled to any absence from duty unless such absence is caused through illness. The question of holidays is another matter which rests with the parties concerned. Unless under special circumstances we should imagine that an employer would be desirous of his gardener having a week, fortnight, or even longer leave of business each year, but his power of giving such leave would depend upon all sorts of circumstances connected with the garden itself and the staff maintained to do the work and share the responsibility. If a gardener wishes to make sure of an annual holiday all he has to do is to come to an arrangement upon the question when taking up a new situation. In the event of him failing to do this he must throw himself upon the consideration of the employer.

GRUB INFECTING BULB: *J. W. B.* The grubs are those of *Merodon equestris*, the Narcissus

bulb fly (see *Gardener's Chronicle*, October 12, 1912, p. 124). This pest is widely distributed over England, and it infests Hyacinths, Tulips, Narcissi, etc. The parent fly appears from the end of April to July. We would advise you to destroy the infested bulbs. Fumigation with hydrocyanic acid gas has met with some success, but the bulbs must be thoroughly dry before exposing them to the action of this gas.

HELIOTROPE DISEASED: *R. L. F.* A parasitic fungus is attacking the "collar," and it is doubtful whether the affected plants can be saved. Water the roots with a solution of nitrate of potash at intervals of three days.

MANGOS FROM BOMBAY: *W. B.* We are informed by Messrs. Geo. Munro that they receive occasional consignments of Mangos from business people who have brought them over from Bombay. They have also had several instances where traders have endeavoured to send large quantities, but the fruits have never arrived in good condition except when they have come in small lots, brought personally. They have never heard of any large quantity being on the market, and do not think it possible that 100 cases were received here in the whole year. There is a demand for really fine Mangos from Bombay if they arrive in good condition, but the difficulty of getting suitable temperatures on board has always caused deterioration during the voyage.

NAMES OF FRUITS: Two very small Apples in blue box—Golden Harvey (syn. Brandy Apple).—*A. H.* Decayed; send again earlier next season.—*H. G.* Court of Wick.—*W. G.* Hambleton Deux Ans.—*H. F. Z.* Apple Golden Russet; Pear Olivier de Serres.

NAMES OF PLANTS: *W. T.* *Moschosma riparium*.—*V. I.* 1, *Cochloda sanguinea*; 2, *Oncidium Pubes*; 3, *Sophranotis violacea*; 4, *Brassica caudata*; 5, *Zygopetalum maxillare*.—*Correspondent*. *Dendrobium primulinum*.—*H. G.*, *Cork*. *Boronia elatior*, of the Natural Order Rutaceae. Native of South-Western Australia.—*H. R.* 1, *Pteris argyrea*; 2, *Calanthe Veitchii*; 3, *Calanthe vestita*.—

POTATO DISEASED: The trouble is due to winter-rot, which often causes the flesh to assume a red or blue colour.

PRIMULA OBCONICA LEAVES: *Scot*. No disease is present in any of the plants. The trouble is due to some error of cultivation.

VEGETABLES: *A. H. C.* It is customary for head gardeners to be allowed sufficient vegetables to satisfy the requirements of their own households, but we cannot say that they have any right to demand them. It is rather an act of grace on the part of the employer. Moreover, no reasonable gardener would think of taking supplies from vegetables that are scarce at a particular season, but he would help himself to those which were present in quantities exceeding what is necessary for his employer's establishment. We suspect there are few cases where such privileges are denied to the head gardener, especially where, as in your instance, there is no private garden attached to the gardener's residence. In any case it is a matter for arrangement between the employer and his gardener, and not one in which the gardener can make a legal demand.

VIOLET LEAVES: *F. J.* The leaves are injured by a fungus—*Cercospora violae*. Spray the plants every third day with a solution of liver of sulphur at a strength of 1 oz. in 4 gallons of water.

VIOLETS NOT FLOWERING: *Vitis*. The specimens sent were perfectly healthy, but the growth was so thin and poor, due to overcrowding, that blooms could not be expected in quantity.

MUNSTEAD WOOD.

THE home of Miss Jekyll, set high up on a ridge of Surrey hills, not far from the town of Godalming, and nestling amid a woodland of Pine and Birch, is a place loved by all who have the privilege of a close acquaintance with an English home in an exquisite setting, and made by one whose influence on "decorative" gardening has been and is far-reaching. Miss Jekyll's name is a household word to all who cultivate the gentle art which at Munstead finds full expression.

During several years the writer enjoyed the privilege of spending many hours in this woodland home, and a visit was paid recently on a misty winter day when the grey-green of Lavender and Rosemary mingled with the browns and silver of Birch and bracken. It is a garden in which lovely colour schemes and ways of planting hardy shrubs and flowers have been conceived for the purpose of surrounding the home with something more alluring and satisfying than the customary adornments, the familiar exotics, beautiful in themselves, but wearisome for their constant repetition.

Munstead has had a strong influence in fashioning the modern garden. Fashion, fickle jade though she is, certainly dictated years ago a change to

higher things in all forms of domestic art, and leaders there were to encourage this beneficent departure from mere formalism that was, in many phases, almost repulsive in its cold, forbidding attributes. And, as Miss Jekyll would tell you, the cottage garden has had a subtle, almost hidden influence in moulding the tastes of the latter part of the last century, and has yielded hardy flowers that are used in the most beautiful garden pictures at Munstead. Two occur to mind. One is that excellent garden Chrysanthemum Cottage Pink, which may be regarded—at any rate, the writer can discover no difference between the two—as identical with Emperor of China. It fills many a cottage garden in the neighbourhood with a fresh pink colour passing to a crimson shade in the centre, from early autumn until the frosts, when the leaves turn to warm, ruddy hues. When the autumn garden has lost its beauty the cottage plots that fringe the hill roadside leading to Munstead are as gay as in high summer from the bountiful planting of the Cottage Pink Chrysanthemum, which defies wind, rain and frost with surprising pertinacity; it is just this quality that gives the flower a value beyond most others for the outdoor garden.

It is not possible in a sketch of such a home as this to convey more than an impression of its beauty and interest to the garden enthusiast. When summer days are with us certain flowers stand out for their value in the border, or in some form of grouping, but an impression that will remain a pleasant memory until the end of time was the Primrose wood in the evening of a warm spring day. The flowers typify a strain brought to perfection through constant selection and crossing, and rejoice in a setting of woodland casting grateful shadows over a sea of warm orange and yellow. Many years have flown since this great lady gardener began to work at what, to use her own words, "I may now call my own strain of Primroses, improving it a little every year by careful selection of the best for seed. The parents of the strain were a named kind called the Golden Plover, and a white one, without name, that I found in a cottage garden." From these beginnings have come the glorious bunch-flowered or Polyanthus type of Primrose in roughly yellow and white colourings that have given to our gardens, large and small, much of their present spring beauty, and the variations sometimes bring forth a plant that surpasses its fellows in purity and strength of colouring and growth. All this, it is to be remembered, is the labour of an amateur, and the garden lover of to-day owes much to keen amateurs engaged in serious gardening.

Well the writer remembers the variety of Nigella damascena which Miss Jekyll raised at Munstead, and now to be seen everywhere—a mass of blue so deep that it seemed as if a bit of the heaven above had fallen to the brown earth. But on every side there is something to win the fancy and to be noted for repro-

duction. I have sometimes used this association of two things in thinking out my own plans for garden planting, Megasea and crimson tuberous Begonia. The solid foliage of the Megasea offers just that protection, so to say, that the Begonia seems to ask for, hiding ugly stems and throwing into hold and agreeable relief the full-toned flowers. Then the delightful association of Rosemary, Lavender and China Roses, which has contributed much to the gaiety of comparatively modern gardens. It is a blending of soft grey, green, and pink as clear as the pink of a sea shell, and when autumn has gone some rosebuds and open flowers will remain to carry their beauty through mild winter months.

The right placing of colours has perplexed many, and will continue to do so. Nothing is more difficult in outdoor gardening than planting well a mixed border, which, however carefully designed, is apt to go wrong somewhere. At Munstead the desire is to achieve broad and simple effects, and it is recognised there that the use of a multiplicity of things tends to the destruction of harmony in colour and all real effectiveness. Miss Jekyll points this out in her charming volume, "Wood and Garden," and the following words are well worth quoting for the suggestions they offer: "I always find more satisfaction and facility in treating the warm colours (reds and yellows) in graduated harmonies, culminating into gorgeousness, and the cool ones in contrasts, especially in the case of blue, which I like to use either in distinct but not garish contrasts, as of pale blue with pale yellow, or in separate cloud-like harmonies, as of lilac and pale purple with grey foliage. I am never so much inclined to treat the blues, purples and lilacs in associated gradations as the reds and yellows. Purples and lilacs I can put together, but not these with blues, and the pure blues always seem to demand peculiar and very careful treatment."

Miss Jekyll is emphatic in her condemnation of haphazard mixtures. Simplicity, yet a full effect, and complete harmony of colourings have been made the subject of much study for many years, and they are recorded in Munstead garden itself and in many writings. The notes on the colour grouping of Rhododendrons, shrubs too frequently ill-placed, have been of inestimable value to the writer; and though, as Miss Jekyll points out, there may be better varieties representing the colourings aimed at in the several groups, those are the ones known and will serve as well as any others to show what is meant. This scheme is recorded in the work already mentioned, and if adopted will prevent crude blunders. It is pointed out that the colourings seem to group themselves into six classes of easy harmonies, thus: (1) Crimson inclining to scarlet or blood colour grouped with dark claret colour and true pink. In this I have planted nigrescens, the dark claret colour; John Waterer and James Marshall Brook, both fine red-crimsons; Alexander Adie and atrosanguineum, good crimsons, inclining to blood colour; Alarm, rosy-scarlet; and Bianchi, pure pink. (2) Light

scarlet-rose colours inclining to salmon, a most desirable range of colour, but of which the only ones I know well are Mrs. R. S. Holford, and a much older kind, Lady Eleanor Cathcart. These I put by themselves, only allowing rather near them the good pink Bianchi. (3) Rose colours inclining to amaranth. (4) Amaranths or magenta-crimson. (5) Cool, clear purples of the typical ponticum class, both dark and light, grouped with lilac-whites, such as album elegans and album grandiflorum. The beautiful, partly-double Everstianum comes into this group, but nothing redder among purples. Fastuosum flore pleno is also admitted, and Luciferum and Reine Hortense, both good lilac-

NEW OR NOTEWORTHY PLANTS.

CALCEOLARIA × BALLII.

THIS hybrid is a pretty little greenhouse shrub, and almost intermediate in character between its two parents, *C. deflexa* and *C. Forgetii*, both natives of Peru.

Calceolaria deflexa, better known in gardens as *C. fuchsiaefolia*, is a useful winter-flowering plant for a cool greenhouse, but there is some difficulty in keeping the leaves in good condition through the winter, and this is rather detrimental to the appearance of the plant. The

makes the plant decorative. *C. Forgetii* is a small shrub with pubescent leaves, and stems. The leaves are oval, $\frac{1}{2}$ inch to 2 inches long, obtuse and serrated. The inflorescences are pyramidal, 6 inches or so long. The flowers are cream-coloured with a reddish blotch inside the lower lip, and are peculiar because of the pouch pointing upwards. The corolla is 4 to 5 inches long.

C. Forgetii was presented to the Royal Botanic Gardens, Glasnevin, by Kew in October, 1912, and during the winter its pollen was placed upon flowers of *C. deflexa*; the seed produced from the fertilised flowers was sown in March, 1913, and the first flowers of the hybrid opened in December of the same year.

The flowers of *C. × Ballii* are sulphur to clear lemon yellow, about $\frac{1}{2}$ inch in length; some are spotted red inside the lip, while others are without spots; they resemble *C. Forgetii* in shape and in the pouch pointing upwards, while the upper lobe is crenated as in *C. deflexa*. The leaves are 2 to 2½ inches long, and 1 to 1½ inch broad; the upper side is hairy, and the under surface smooth and greyish—not so white as in *C. deflexa*. The young stems are slightly pubescent.

The new hybrid seems to inherit the free-flowering properties of *C. Forgetii*, the pollen parent; the flowers last well in a cool house, and so it promises to be an attractive greenhouse subject. *C. F. Ball*, Royal Botanic Gardens, Glasnevin.

PELARGONIUM TRANSVAALENSE.

PELARGONIUM transvaalense (see fig. 47) is an extremely pretty, new and interesting plant. It grows about 2 feet high, the flowers are 1½ inch in vertical diameter, and of pale pink colour. It is new in the double sense of recent introduction to the country and also in having had the above name conferred upon it only last year. In habit it is much more like a European Geranium than a Cape Pelargonium, and the rootstock even helps the similarity; but since it has a spur adnate to the pedicel, like all other Pelargoniums, there is no question as to the genus to which it must be referred. The stems lie down completely for the resting period, and in this again the plant resembles Geranium. The rootstock, it is said, is used for dysentery by the natives of the Transvaal, and probably it has some value on account of its astringency. The name *transvaalense* is published in *Das Pflanzenreich*, of Professor Engler, vol. 53, in which the order Geraniaceae is monographed by R. Knuth. He describes this plant, but has apparently not seen leaves so large as those that are here illustrated, and some particulars from this specimen may be of use. The rootstock consists of a knotty or gnarled mass of short brown stems; the herbaceous stems with the peduncles, which are from 6 to 9 inches long, attain about 2 feet in height, they are reddish, gibbous above the nodes, and, like all the rest of the plant, except the flowers, are covered with fine, short more or less glandular hairs, thinly or thickly distributed. The leaves are few; the largest here illustrated has a stalk 10 inches long. The blades are from three to five angled, and the diameter of the largest is 7 inches. As they dry they become of very thin texture. The stipules are broadly ovate, and the bracts of the involucre are from three to six in number, broadly ovate, and acuminate very much like the stipules. The pedicels are always present, and vary from $\frac{1}{8}$ to $\frac{3}{8}$ inch long; the sepals are $\frac{3}{8}$ inch long, ovate acute, the upper rather the broader; the nectary or spur is 1¼ inch long; the petals are retuse, the upper $\frac{3}{8}$ inch wide and broader at the upper end, the lower petals are $\frac{1}{4}$ inch broad; the face of the flower measures 1½ inch vertically. There are seven stamens, all fertile, and the styles are five; the flowers have a distinctly male and female condition, and are protandrous like others of the genus. Seeds may have been set

FIG. 46.—CALCEOLARIA BALLII (*C. DEFLEXA* × *C. FORGETII*): COLOUR OF FLOWERS SULPHUR-YELLOW.

whites. But the purples that are most effective are merely ponticum seedlings, chosen when in bloom in the nursery for their depth and richness of cool purple colour.

One must leave Munstead for a while, a garden in a woodland, a garden of scents, of heath paths, nut and Michaelmas Daisy walks, Roses clambering wherever they will and beauty everywhere, a garden for the true artist, and teaching lessons that have not been unheeded by a generation of amateurs willing to learn. It is a real regret to Miss Jekyll that for reasons of health she is not able to welcome the many who, charmed by her writings, wish to visit her famous and delightful gardens. *E. T. Cook.*

leaves and stem of *C. deflexa* are glabrous and viscid; the leaves measure 2 to 2½ inches long, are ovate-lanceolate, serrated, dark green above, and whitish beneath. The flowers are drooping, and the corolla a clear yellow, $\frac{1}{2}$ to $\frac{3}{4}$ inch across the lobes, the upper lobe being nearly as large as the lower.

C. Forgetii, Bot. Mag. 8436, was introduced by Messrs. Sander in 1909 from the Andes, where it grows at an elevation of over 8,000 feet, and an illustration in *Gardeners' Chronicle*, January 27, 1912, of this plant under the name of *C. virgata*, shows how wonderfully free flowering it has been when planted out at Kew for the summer months. In very mild localities it might survive the winter in the open ground. The flowers are very small, but their profusion

by the plants own pollen, and it cannot yet be said whether it is self-sterile or not. *Pelargonium transvaalense* was received at the Botanic Garden, Cambridge, from Mr. Thorncroft, early in the year 1910, and it flowered the following November. It may be known to some as *P. Thorncroftii*, the name used for some time in the Botanic Garden of Cambridge, but Knuth's name is the first to be published. As no name at first could be given at Kew, it was intended to send an account to the *Gardeners' Chronicle* with the name *P. Thorncroftii*, but a sufficiently good photograph has only just been secured. I am now indebted to Kew for referring me to Knuth's description. This plant belongs to the section *Eumorpha* in company with *P. alchemilloides*, *P. sanciculaefolium*, *P. grandiflorum* and others. Mr. Thorncroft informs me that it grows at an altitude of 3,000 feet, and is always found in shade in the bush growing on banks in the kloofs, where the soil is loose and dry, perhaps a little damp, but never wet. *R. Irwin Lynch, Botanic Gardens, Cambridge.*

ORCHID NOTES AND CLEANINGS.

RHYNOSTYLIS GIGANTEA RIDLEY.
A FINE inflorescence of over thirty flowers each more than an inch across is sent by Mr. Tom Maltby, St. Margaret's, Woodford Wells. The flowers are fragrant, wax-like in substance, bluish-white spotted with rose-red. The broad, flatly-arranged lip is white tinged with rose, with dark rose-coloured lines from the base. It is *Vanda densiflora* Lindl. Gen. et Sp. Orch. 221, and commonly known in gardens as *Saccolabium giganteum*. It is a strong grower, requiring intermediate house in winter and the warmest house for the spring and early summer while making new growths. If kept too warm and moist in winter it gets affected with "spot," and soon declines in vigour.

LAELIO-CATTLEYA NELLA.
Two plants of this remarkably beautiful Veitchian hybrid (which was illustrated in the *Gardeners' Chronicle*, December 13, 1913, p. 416) have recently flowered with Messrs. Floy and Black, Orchid Nursery, Slough, out of the stock acquired from Messrs. Jas. Veitch and Sons, and an interesting point is raised. The recorded parentage is *L.-C. Domeniana* (*L. purpurata* × *C. Dowiana*) × *C. labiata*, but it appears that *C. Warneri* was the parent on one side and not the ordinary *C. labiata*, and that the extra beauty of *L.-C. Nella* over some of the typical *C. labiata* crosses is the consequence. This may well be the case seeing that Messrs. Veitch in their *Manual of Orchidaceous Plants* place all the section under *C. labiata*, and doubtless recorded their hybrids in the same way. It is to be hoped that other of their hybrids recorded as with *C. labiata* may have been with *C. Warneri*, which is one of the best parents for the hybridiser. It has a very distinct broad leaf, and two or three of the small lot of *L.-C. Nella* are scarcely distinguishable from small *C. Warneri*. The flowers are deep purplish-rose, with broad claret-red lip, with gold lines from the base.

E. H. DAVIDSON AND CO.

THE business established at Orchid Den, Twyford, by Mr. E. H. Davidson about a year and a half ago, for the raising and growing of Orchids, is now formed into a company, with Mr. James B. Lakin as the managing partner. A full report of this successful Orchid establishment was published in the *Gardeners' Chronicle* for November 8, 1913, pp. 3, 7, 8. Attention was drawn to the remarkably promising batches of *Sophronis grandiflora* crosses, *Odontioda* and *Odontoglossum* hybrids, *Cattleyas* and *Laelio-Cattleyas*. Mr. Davidson laid the foundation for successful hybridising by purchasing some of the best species and varieties obtainable.

AMERICAN NOTES.

HYDROCYANIC ACID GAS AS AN INSECTICIDE.

THE discussion in the *Gardeners' Chronicle* on the subject of gas tar and mealy bug is of great interest. The use of hydrocyanic acid gas is the greatest boon in our day, being the cheapest, cleanest and deadliest of all known agents for the destruction of insect pests. There is no real danger in its application to the operator, it does not go off like gunpowder, and, if the doors are locked after its liberation, there can be no danger to irresponsible individuals. Risk is, however, always present, and there seems to be no other word that fits. Atmosphere and temperature in the structure are dominant factors in that if the house is moist it is unsafe, and if the temperature exceeds 60° harm will result. There are varying qualities of cyanide, too, but the best is none too good; the grade sold as 98 per cent. pure is the most suitable.

FIG. 47.—PELARGONIUM TRANSVAALENSE. (See page 102.)

The use of this gas in vineries carries a risk also that was not stated by *J. H. Y.* for it is sure to injure Muscat varieties when the foliage is in an immature condition; but no harm results to Black Hamburgs in the same structure. It is not perfectly safe until the leaves are fully developed, which is the time the bugs are becoming active. Another error of omission is that the quantity to be used per 1,000 cubic feet was not stated. This is essential.

For the benefit of readers the following data are copied from a report recently published here, covering many kinds of greenhouse plants. The name of the author has been lost in making the clipping, and the present writer now makes due apology; but it would seem that instead of the usual dose of 1 oz. of cyanide to 1,000 cubic feet, this is a much safer base to work from, in that it shows that far less will do the work. It was found that White Fly (*Aleyrodes*) could not be killed by the gas on indoor Tomato plants without injury to same at the stated dose. Later, in

fumigating an adjoining house, the escaping gas that reached them through a partition killed the fly.

From exhaustive experiments made by the entomologist from whose results the following is cited—the dose applying in all instances to 1,000 cubic feet of air space are:—Tomatos in daytime, 1/8 oz.; at night, 3/8 oz.; Antirrhinums (Snapdragons) (very susceptible plants), 1/8 oz. in day and 3/8 oz. at night; young shoots of Roses, not more than 5/16 oz. night or day; Chrysanthemums, 3/8 oz. at night only; Carnations, not well to use more than 3/8 oz.; Lily-of-the-Valley, forced, blooms 3/8 oz., leaves 7/16 oz.; Asparagus plumosus, 3/8 oz.; Lantanas will stand 5/8 but not 7/16; Cyclamens will not be injured by 1/2 oz.; Ferns are not injured by 7/16, but stronger doses are not safe; Pelargoniums, 1/2 oz.; Lettuce was not injured by 7/16; Coleus, Hibiscus, Crotons, Begonias, Pansies, Hyacinths, Salvia, Palms and Radishes will stand a 1 oz. dose without injury; aphides will be killed with 7/16 oz.; thrips with 1/2 oz., and repeated doses of 7/16 oz.; mealy bugs not in masses by 1/2 oz., which dose repeated will kill all the pests; scale on Palms and Crotons were killed and some red spider by 1/2 oz.; this repeated will probably kill all the scales. It is advised to fumigate in as low a temperature and in as dry an atmosphere as possible, and preferably at night.

In the above report no word is said about ventilation afterwards, and it is assumed that the gas may be left in over night to dissipate before morning, but it is the most recent word for our guidance in the use of this agent, evidently made with care, and proves especially that we have heretofore used too much when adopting the usual formula of 1 oz. per 1,000 feet.

For dormant fruit trees under glass the writer has often used 2 oz. with good results for destroying both scale insects and mealy bug, but the whole thing resolves itself into using judgment. In England there would be no difficulty in getting the temperature at night below 60°; here we often have to wait for weeks, it then being too late to do the best work. An employee used two tons of cyanide in one winter in Florida in Orange groves to kill scale and white fly, but could only work at night when the temperature was low enough, and then erected tents temporarily round the trees to dose them. When the tents became wet with heavy night dews others were in reserve, and all were dried in the daytime. *E. O. Orpet, Lake Forest, Illinois, U.S.A.*

WINTER-FLOWERING IRISES IN THE ROCK GARDEN.

ONE of the charms of the rock garden is the evergreen character of most of the Alpine plants. Hence, furnished with attractive tufts and cushions of many-tinted foliage, the garden looks well all through the winter.

The miniature trees and bushes of Veronicas, Cistuses, Hypericums, Iberis, *Acaena splendens* and *Othonna* all retain their leaves. The mossy Saxifrages display mats of vivid green; the crustaceous ones provide glaucous tufts of silver-edged rosettes; the *Sempervivum* crowns show many warm tints; while the *Aubrietias* in themselves give several shades of rich verdure, intensified by the golden and silver variegations.

What more delightful setting can there be than this for the winter-flowering bulbous Irises?

Fortunately, these little Irises are easily procured and are quite hardy. When we have a succession of favourable seasons they will increase year after year; but prolonged cold, wet weather during summer plays havoc with these Eastern plants, which love to bask in the sun—that is, figuratively, for they are then underground—as much as do the Persian cats.

The earliest to flower is *Iris Vartanii*, a native of Palestine and named after Dr. Vartan, who found it at Nazareth. I have had it in blossom

on November 20; mid-December is its usual time, January 16 being the latest date I have recorded. It is a delicate, refined-looking flower about 3 inches across, pale lavender above and pale green beneath, with long, narrow standards and deeply bifid styles; the elongated falls have a white ground and darker lilac stripes with a fleshy yellow crest. The pollen is white, in blue anthers. It is deliciously scented, like vanilla. The glaucous-green quadrangular leaves grow up early and are about 10 inches long at flowering time, over-topping the scape, which is 5 inches long. This is the floral tube, for the seed-vessel is subterranean.

The small bulbs are narrowly oval with netted coats, and many tiny offsets are produced. Several bulbs should be planted in a group, facing south-east if possible, with a rock behind to shelter them from the north. The soil should be a warm loam lightened with leaf-mould and sparingly enriched with old manure.

There is a pretty pure white variety of this Iris with a pale-lemon crest on the fall. One of these produced a monstrous flower which had five styles, four falls, four standards and five anthers; three of the latter were perfect, the other two were petaloid. Monstrous forms of flowers are not uncommon in Irises, and usually consist in an extra number of parts; but sometimes they are reduced and come in twos instead of threes.

Very closely allied to the last and the most beautiful of this section is Iris *Histrio* (see *Gard. Chron.*, fig. 34, January 23, 1909), well named the play-actor from its brilliant garb. The flower is nearly 3 inches across and is carried about 4 inches above ground. The styles and standards are a pure light-blue; the oval falls have a creamy-white ground mottled over with large deep-blue spots and a line of gold down the centre. There is some slight variability in colour in individuals of this species. The soil should be similar to that for *I. Vartanii*, and a sunny, southerly position near the top of the rock garden, where it cannot be dripped upon, is essential. *I. Histrio* is an early flowerer, beginning at the end of December and continuing until the early days of March, the greatest number of flowers being produced from mid-January to mid-February. It has a slight fragrance of attar of Rose.

The leaves begin to appear in November, and, like those of all the winter Irises, they greatly need protection from the only too marked attentions of slugs and small snails. Powdered slug destroyers may be placed around the clumps, but they need constant renewal in rainy weather. The most efficient slug guard is made of strips of perforated zinc, 3 inches deep and 24 inches long, bent into a ring and fastened with wire, and then placed over the clump and pressed an inch or so into the soil. Even then the eager slug will try and force its way through the meshes if it is a very slender one. This plant is a native of Asia Minor and the Lebanon.

Iris histrioides differs from those species already described in its mode of growth. Flowers and leaves shoot up simultaneously through the frosty ground, and when the flowers open on their short scapes the leaves are but 1 to 3 inches high. It does not usually begin flowering until January 21 and then continues till the first week in March; but last winter (1913), which was a mild season, the first flower opened on New Year's Day.

I. histrioides has large flowers nearly 4 inches across of a gorgeous blue. They vary somewhat in the shape of the fall and the markings, but usually the standards and styles are an intensely bright blue, and the falls are further embellished with dark-blue spots and a gold crest down the centre on a cream ground. The species is found at Amasia in Asia Minor, and is scentless.

Iris Bakeriana (see *Gard. Chron.*, fig. 33, January 23, 1909), named after Mr. J. G. Baker, formerly of Kew, is a distinct and very pretty little flower, a native of Mesopotamia and Asia Minor, but is now increasingly difficult to

obtain. The leaves are 8 to 12 inches long at flowering time and are round in section, with eight deeply-marked furrows. The scape is 6 inches high and the flower less than 3 inches across. It makes up for its small size by its very pretty colouring. The styles and standards are deep violet-blue, while the falls are white with a yellow line and spots and streaks of deep purple ending in the rather pointed tip, which is velvety-black. It has golden pollen and a delicate fragrance of violets. The flowering season is rather prolonged—from January 19 almost to the end of March. This plant is impatient of moisture and should be placed in full sun on a well-drained plateau of the rock garden and given a light, dry soil.

After flowering the foliage of these bulbous Irises continues to grow for about two months and should be carefully preserved and tied up to a stick. The leaves of *I. Histrio* will reach 2 feet in length and those of *I. reticulata* (see *Gard. Chron.*, fig. 149, November 2, 1912) 3 feet.

The next Iris to flower is very different in colour from the other early ones. *Iris Danfordiae* (see *Gard. Chron.*, fig. 54, March 17, 1900) is golden-yellow, and, grouped with the blue ones, forms a delightful contrast. As it flowers from the end of January to the middle of March it comes in well with them. The flowers grow about 4 inches high and are 2½ inches across. The oblong golden falls have an orange crest and small brown spots on the claw. The standards are reduced to a tiny yellow bristle a quarter of an inch long, which makes this species a link with the Juno group. The species itself has been split up into two named forms, on account of the colouring of the styles; the one has green stripes on a yellow ground (*Bornmülleri*), while the other is without stripes (*Danfordiae*). This is a native of the eastern part of Asia Minor, having been brought first from the Cilician Taurus by Mrs. Danford, after whom it is named. The flower is scentless. It should be treated like the others.

After the foliage has withered all the species should have a piece of glass placed over them, supported on wires or stones, to keep the bulbs dry and help the ripening process when they are not lifted. This precaution also prevents their being planted over or smothered by encroaching vegetation. The two last Irises must be treated together, as they are two forms of one species. The blue-violet flower is named *Iris reticulata*, and the red-purple one *I. Krelagei*. *I. reticulata*, named from the netted coat of the bulb, is the hardiest and best known of this section and will flower in the ordinary border, but is at its best on the rockwork. It needs a good, well-drained loam with some lime added; and as it is addicted to a fungous disease, the bulbs should be lifted occasionally, the decayed ones removed and the offsets planted out. It is a native of the Caucasus and smells sweetly of Violets. The dark-green leaves are 8 inches long at flowering, the scape about 6 inches. The flowers are 3 inches across; the styles and standards deep violet-blue; the narrow falls dark velvety-purple with an orange crest edged with white, purple spotted. *Iris Krelagei*, named after the well-known Dutch nurseryman, differs in having broader styles and falls; the colour is a rich reddish-purple, contrasting well with the golden crest. It has only a faint Violet perfume. *I. Krelagei* begins flowering quite a week earlier, the respective dates being: *I. Krelagei*, January 25 to April 7; *I. reticulata*, February 6 to April 25.

While winter Irises are coming up they may be protected in wet or rigorous weather by glass overhead or a bell-glass, but the glass should be removed after flowering to avoid injury to the foliage.

These little Irises are very satisfactory from the length of time each blossom will last—from seven to ten days. Also, when gathered in bud, they can be packed quite easily and sent by post, and may often bring a message of cheer to a sick-room. *Eleonora Armitage*.

NOTICES OF BOOKS.

AN ILLUSTRATED FLORA OF SOUTH AFRICA.*

FEW countries have contributed so largely to European conservatories and gardens as the Cape of Good Hope. The despatch of plants from this Colony began at a very early date, before the settlement by Van Riebeeck, for we find several curious plants figured by Stapel in his edition of Theophrastus' *History of Plants*, published at Amsterdam in 1644. Some of the earliest specimens from the Cape, which are preserved in herbaria in this country, were collected about 1737 by Oldenland, who formed the *Hortus Siccus Capensis*, which was sent to Petiver, and acquired by Sir Hans Sloane. Then in 1772 came Thunberg, the father of Cape Botany, and at the same time Masson, who travelled with Thunberg, and whose plants and wonderful collection of drawings are at the Natural History Museum at South Kensington; and also about the same date Oldenberg. In 1810 Burchell, in 1815-23 Bowie, in 1825-34 Ecklon and Zeyher, and Drège, and in later years Macowan, Bolus, Schlechter, and many others.

From 1775 to 1835 Cape plants may be said to have been quite the rage. The conservatories, temperate houses, and gardens of England and the Continent teemed with Pelargoniums, Heaths, Proteas, and other handsome flowering shrubs and lovely bulbous Iridaceae, Amaryllidaceae, and Liliaceae; and as evidence of this, if other evidence were required, we may call to mind several very fine illustrated works dealing largely with Cape plants, such as the four volumes of Andrew's *Heaths* (1802-1805), and the five volumes of Sweet's *Geraniums* (1820-1830).

It is very difficult to compare the relative numbers of species of flowering plants at the Cape with any other portion of the earth's surface, but enough is known to enable us to say that South Africa ranks among the richest of regions. Dr. Bolus in his *Essay on the Flora of South Africa* in 1886, compares South Africa with Australia, which is five times larger in area, with the following result:—Australia: Orders 152, genera 1,300; South Africa: Orders 142, genera 1,255, and he considers the reason South Africa is so rich is because we have here the meeting and partial union of two, and perhaps three, distinct Floras, and that South Africa has a highly diversified surface of land and soil, and a climate with much sunlight, a condition which is favourable to the multiplication of forms.

The *Flora Capensis* was commenced by Harvey in 1859, and contains, or rather will contain when quite complete, careful descriptions of all the plants known from that region. The present work, which is to be in four large quarto volumes, will be illustrated by 180 coloured and 100 monochrome drawings, as well as 300 figures in the text. It is an introduction, and a very good one, to the charms presented by the Cape Flora. In the absence of some such work it has been most difficult for the student and traveller to understand and appreciate the variety of form that surrounds him on every side. It is the work of Dr. Rudolf Marloth, well known for his labours in connection with the Cape Flora; but its inception is due to Lady Phillips. The first volume, which has just been published, deals with the Cryptogams, Gymnosperms and part of the Dicotyledons (Piperales to Rhoeadales). The life-history of the various forms of Cryptogamic life is shortly described; and among the Gymnosperms of especial interest is the account of the curious and anomalous genus *Welwitschia*. The genus *Mesembryanthemum* is treated of in this volume, and some interesting notes are given of the mode of life of *M. rhopalophyllum*, which occurs in the sandy deserts of Southern Namib, near Pomona Island. This plant grows embedded in the sand, nothing but the slightly convex apex of each cylindrical leaf

* *The Flora of South Africa*. By Rudolf Marloth. 4 vols. 4to. 180 coloured illustrations, 100 monochrome drawings, 300 figures in text. £2 2s. per vol. net. Vol. I. Wesley and Sons.

being visible; while the buried leaf itself is fresh green, with a rather delicate skin, the exposed part is protected by a thick epidermis and cuticle and possesses few stomata. It is through this portion, which has the function of a window, that the leaf receives its light. There are 5 to 10 or even more leaves to each plant, which peep out of the sand like the eyes of the sand lizard or the sand viper. As will be gathered from this example the book abounds with information of much interest on the ecology of many of the plants. Under each family is a clavis of the genera, and descriptions of the more interesting species are appended. The area dealt with is roughly bounded on the north by the Tropic of Capricorn, starting on the west coast near Walfish Bay, and traversing German South-West Africa and Bechuanaland until the line reaches the Limpopo.

The coloured plates, though varying somewhat in merit, add much to the attractiveness of the work. The photographs of plants in their natural habitats are excellent. The type is large and clear. To the author is due the credit of producing what must be regarded as a pioneer work, for nothing similar to it, at least so far as relates to extra-European floras, has hitherto been attempted. We heartily wish for it the success it deserves, success which should encourage others in the same path, with the result of opening up one of the most fascinating branches in the domain of Natural History. Not only students of the Cape Flora, but travellers, and indeed anyone curious about the marvellous operations of Nature, will certainly be much indebted to Dr. Marloth and Lady Phillips for this most interesting and attractive work.

E. G. B.

DIERAMA (SPARAXIS) PULCHERRIMUM ALBA.

THE old name, Sparaxis, is still in general use for this plant, but owing to the marked disparity between the Sparaxis proper and Dierama in form, habit and garden value, it is necessary to recognise the tall, arching, well-flowered plants as Dierama and the dwarf, starry-flowered plants as Sparaxis. There is only one species of Dierama recognised by botanists, this being *D. pulcherrimum*, a tall-growing plant with very tough, yet slender and arching, grass-like leaves and taller racemes of delicate pendulous flowers, which sway and flutter with the least breath of wind. The bulb, which resembles that of a *Gladiolus*, but is smaller, is covered with a thick, matted tunic, and the roots are thick and evidently capable of resisting severe drought. It is said to have been introduced in 1866 by Messrs. Backhouse, of York, who described it as being very graceful in habit and as growing from 2 feet to 3 feet high; this, however, is far short of the length that the flower-stems usually attain, those shown in the illustration at fig. 48 being all over 6 feet. The type is rose-magenta in colour, a not very pleasing tint, and there is also a very beautiful and rare pure white form which is here shown and a pale pink variety. The type has been discarded here, and only the white and pale pink forms are grown. The Dierama has the greatest objection to removal, which, when it must be done, should be carried out as soon as the flowers begin to fade. Immediately after this stage stout, fleshy roots are produced from the bulbs, and if these are broken the plants are badly injured. Its general appearance would lead to the supposition that it is a water-loving plant, but it succeeds well in dry positions, provided that it is grown in porous, sandy soil, and is well watered when it commences to grow. Being a native of South Africa the Dierama cannot be considered hardy, and in the colder districts should have the protection of a wall and be mulched with leaf-mould or ashes in the winter. Deep planting is advo-

cated, and this is doubtless desirable in cold localities, but in the south-west if planted 3 inches deep and given no protection it invariably thrives. The best position for this plant is in colonies among dwarf shrubs, where its slender, arching flower-shoots rise up gracefully and are seen to the best advantage. The shrubs also afford the plants shelter. It is a subject which will well repay a little care for the first year or

seeds were collected from these plants in the past summer, all of which have been given away. The tall stems carry from eight to ten flower-pedicels, and these pedicels usually bear ten blooms. The Dierama is sometimes styled the Wand Flower, and the late Mr. Burbidge christened it the Fairy's Fishing-rod, on account of the exquisite grace and lightness of the slender flower-wands. *Wyndham Fitzherbert.*

FIG. 48.—DIERAMA PULCHERRIMUM ALBA IN A DEVONSHIRE GARDEN. (Photograph by Wyndham Fitzherbert.)

two. A deep, rich, sandy border in full sunshine will prove suitable to it, and it is a plant that all Iris lovers should grow, its beauty and grace being worthy of any little extra trouble and cultural attention. It is easily raised from fresh seeds sown as soon as they ripen in pans or boxes, and placed in a cold frame or on a shelf in the greenhouse. In the warmer districts seed sown in the open generally germinates well, and mature bulbs increase fast when once well established. To provide the finest show a group should consist of at least twenty bulbs. There are thirty bulbs in the colony shown in the illustration, and when these plants were in full bloom they provided a picture that roused the enthusiasm of visitors from far and near. Thousands of

WASPS.—I was much interested in the reply to Mr. Shakelton on "Wasps' Nests in November" in the issue for January 24, p. 64. I found three wasps' nests in a bank along a road near here (four miles south of Dublin), in December. One very strong colony was working up to Christmas. The wasps seemed rather under the usual size. On December 27 we had frost—4° to 8°—which lasted for a week, after which there was no sign of life about any of the nests. I had never seen or heard of wasps' nests at this time of year. So far as I know some of these nests had been made during the summer. We had an extraordinarily mild winter: a Laburnum had been in full bloom at the time I write of, and is now green with leaves. *Mary C. Hopkins, Robuck Hill, Dundrum, Co. Dublin.*

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

APPLE NORFOLK BEAUTY AND LIME-SPRAYING OF PLUM TREES.—I was pleased to see *Southern Grower* write so encouragingly of this Apple on p. 83. I know the original tree in the gardens at Gunton Park, Norfolk, from which Mr. Allan sent out the first stock. For several years I saw the tree heavily laden with large, even, handsome fruits, some of which I cooked in January, and found them of excellent quality, but since growing them I have not been able to keep the fruit longer than October. I consider that it is a valuable October Apple. The tree grows freely, and promises to be a good cropper when well established. With reference to the remarks on lime-spraying of Plum trees, my experience and observation of other people's practice is that lime-spraying of Plum or other trees does not prevent infestations of aphids. A grower of some 300 acres of fruit trees close here sprays his Plum trees with hot lime just at the time when the trees are bursting into bloom, and even while the blossoms are fully expanded, but while this spraying at that stage does not interfere with the fertilisation of the blossom, as many aver, it does not prevent a full crop of aphids attacking the trees just at a time when the Plums are making their first swelling. For Apples, Plums, Red and White Currants nothing but lime is employed. *E. M., Swanmore Park Estate, Bishop's Waltham.*

HAMAMELIS.—I write with reference to the paragraph on page 67 of your issue of January 31, 1914, regarding the shrub, "*Hamamelis arborea*." In it your correspondent states that this shrub attains a height of 20 feet in Japan, but nothing approaching this size is to be seen in this country. I write to state with, perhaps, interest to your readers and also to your correspondent that there are two *H. arborea* in the gardens at Tedsmore Hall, Oswestry, one of which is 18 feet high from the ground, with two branches 19 feet long. The other *H. arborea* is 16 feet high from the ground, and has a branch 17 feet 6 inches long. These have been planted about 15 years. The trees of *H. arborea* have this year flowered to an extraordinary extent, and at the present time are a mass of flowers, and a wonderful sight. The soil is sandy and on sandstone rock, 300 feet above sea level, and exposed to rough weather from the Welsh hills from the North-west. *Colonel Mainwaring Jackson, Tedsmore Hall, Oswestry.*

CYANIDING PLANT HOUSES.—*J. H. G.* (p. 94) states that it is very important to remember that the water must never be added to the sulphuric acid when cyaniding. I should be pleased to know why he is so particular on this point. During my experience I have cyanided over a hundred Fruit and Plant houses, but have always added the water to the sulphuric acid with excellent results. *J. B.* [If water be added to strong sulphuric acid considerable heat is engendered, and the liquid is apt to "boil" and splash into the face or on the hands or clothes of the operator.—*Eds.*]

CYANIDING TO DESTROY MEALY BUG.—I have read Mr. Fulton's remarks on this subject (p. 94), and have good reason to agree with his statement that failures with this fumigant may be due to inferior materials. I have been to some trouble in cyaniding two vineries, using a strength of 3 oz. potassium cyanide, 5 oz. best sulphuric acid, and 8 oz. water per 1,000 cubic feet, and almost the first thing I saw on entering one vinery after the door had been opened was a spider crawling unconcernedly down a piece of string. We found living bug in both houses after the operation. The cyanide was dissolved, but an examination of the bottles from which it had been taken showed that the potassium cyanide, which I had ordered as the strongest and best, was marked 40 per cent., which is evidently quite useless for the purpose, and should not be accepted. I have now on order sodium cyanide at 130 per cent., which I expect will give vastly different results. I can remember something similar happening when I used the cyanide many years ago. I had sodium cyanide, and when this was used up ordered some more from a local chemist, who gave me the potassium—probably a weak per-

centage—the results of which were the same as I have described above, and led me to discontinue the practice. Mr. Fulton's letter would have been of much greater value had he given the exact proportions with which he has obtained the excellent results on Grapes, Tomatoes, etc., also which cyanide and the percentage. *A. Shackleton, Forde Abbey Gardens, Chard.*

LENÔTRE.—I see that the question "Was Lenôtre ever in England?" in your issue of January 31, p. 75, has not been answered; I therefore think it may interest your readers to know that I went very carefully into the subject, which I discussed with the late M. Edouard André, and carried on a correspondence with him about it. We came to the conclusion that he did not visit England. In the third edition of my "History of Gardening in England" (John Murray: 1910) I devote several pages (178 to 193) to the question, and I give the evidence at length, including some unpublished contemporary letters, etc. Though it is clear that Lenôtre was asked to England by Charles II., and Louis XIV. gave him permission to go, I have been unable to find any contemporary record of his journey, but obtained a good deal of negative evidence which points to his not having accomplished the journey.—*Alicia M. Cecil.*

SAXIFRAGA BURSERIANA GLORIA.—Some plants possess the rare attributes of interest and beauty long before their flower-bud expands, and the subject of this note is one of them. Just now, indeed, and for days past, this Saxifrage has been conspicuous by reason of the brilliant scarlet colour of its inch-high peduncles and calyces, which, appearing above the grey of the spiny tufts, make a beautiful contrast. The charm of the plant will be enhanced as the large blossoms unfold, for it is a prince among its kind, although, perhaps, not entirely alone in size or beauty, seeing it has such peers as *Magna Tridentina* and *Major*. In the dry condition of the Alpine house the flowers last long in a good condition. Dry cold, too, would appear to be a factor in promoting the rich colour of flower-stalk, to which reference has been made, and which for a week or two is singularly bright and effective. *E. J.*

GRAFTING ROSES (see p. 52).—In his remarks on this subject *Experience* advises a temperature of 83°. I have found 70° more satisfactory, and this should be maintained both day and night. As to keeping the case closed without ventilation for the first six days, how is the superfluous moisture to escape? Apparently, it would not be able to do so, consequently the grafts would damp. I find it is necessary to wipe the glass once or twice each day to remove moisture, while on dull days it is sometimes necessary to do this three times. As is well known, damping is the Rose propagator's greatest trouble, and must be guarded against, which certainly cannot be done if the case is to be kept closed at the start, and no moisture removed. The time for taking the grafts from the case depends upon how soon there is a free flow of sap from Briar to graft, which is indicated by the pink colour assumed by the latter. This may take so few as ten days or so many as six weeks. No one can tell what time a graft will take to make growth. When the graft has assumed colour it will stand any amount of sunshine, otherwise it will fade in half an hour. *Amateur.*

JOURNEYMAN GARDENERS AND LOW WAGES.—The correspondence on gardeners' wages in your columns has been interesting and instructive. I note with pleasure that gardeners' wages have an upward tendency, and let us hope though but slow they will continue to increase, as there is still much room for improvement. As a journeyman my wage never exceeded 15s. weekly, and no extra pay for Sunday duty, and if one were fortunate enough to secure a foreman's place the increase was 3s. per week, this rate being the general pay some thirty years ago. Like Mr. Hudson, I always refused premiums. As regards the young men not taking so much interest in their work as formerly, does not this show that the majority of them are still dissatisfied with their lot? Some may retort that young men in the building and similar trades have not the same chance of promotion as a young gardener, but it must be patent to all

that not one-third of the latter can ever hope to secure a head place of any importance. In one establishment of which I had charge there were four young men in the bothy, and the highest wage paid was 14s. True there was extra money for Sunday duty, but was this a living wage for a man of 22? I believe the wage sheet has been revised during the past year or two, and not before it was necessary. Respecting bothies, it must be admitted that improvements have been made of late years, but there are still many that are not worthy of habitation. Usually these young gardeners' quarters are situated on the north side of a high wall, ill-ventilated, scantily furnished, and probably adjacent to a stoke-hole, where the smoke, fumes, and dust have a resting place. This combined with one of the youths to cook the food and clean up three or four days out of the week, and the only lavatory some couple of hundred yards away, is surely enough to damp the spirit of any youth aspiring to enter the gardening profession. There is some talk of a minimum wage being fixed for farm hands; should that come to pass, let us hope someone will plead for the underpaid gardener. *James Mayne, Slough.*

WART DISEASE OF POTATOS.

ORDER OF THE BOARD OF AGRICULTURE AND FISHERIES.

(DATED 2ND FEBRUARY, 1914.)

THE Board of Agriculture and Fisheries, by virtue and in exercise of the powers vested in them under the Destructive Insects and Pests Acts, 1877 and 1907, do order, and it is hereby ordered, as follows:—

Application of the Order.

1. This Order shall apply to England and Wales.

Definitions.

2. In this Order—
 "The Board" means the Board of Agriculture and Fisheries.
 "The Local Authority" means as regards any District the Local Authority for the District under the Diseases of Animals Act, 1894.
 "Disease" means the disease affecting Potatoes which is known as *Synchytrium endobioticum*, or Wart Disease of Potatoes, Black Scab, Cauliflower disease, or Potato canker; and "diseased" means visibly affected with disease.
 "Tubers" means tubers of the Potato plant.

Notification of Disease.

3. The occupier of any premises on which disease exists, or appears to exist, shall forthwith notify the fact by post or otherwise to the Board, or to an inspector or other officer of the Board or of the Local Authority authorised to receive such notification, and where practicable a specimen showing the disease shall accompany the notice.

Precaution to be adopted in case of an Outbreak or Supposed Outbreak of Disease.

4. No tubers shall be removed from any premises on which disease exists or appears to exist until after the investigation required by the next Article.

Investigation by Local Authority.

5.—(1) The Local Authority on receiving in any manner notice of the existence or apparent existence of disease shall forthwith take such steps as may be necessary to determine on what premises the disease exists in the crops or soil, and shall cause notice of such determination to be served on the occupier of each of such premises, which, within the limits specified in the notice, shall thereupon become "infected premises" and continue to be infected premises until the notice is withdrawn in accordance with Article 9, but the limits of the infected premises may be extended by a notice served by the Local Authority or the occupier of the infected premises.

(2) The notice shall as far as practicable include in the infected premises only those lands in which there are or have been diseased tubers.

Action to be taken after Preliminary Investigation.

6.—(1) The Local Authority may at any time and from time to time by a notice served on an occupier of infected premises require him to adopt such measures for prevention of the spread of the disease as are authorised by this Article and specified in the notice.

(2) A notice under this Article may require the occupier of the premises to adopt any one or more of the following measures:—

- (a) To destroy any part of the crop, except the tubers, by fire or such other suitable method as may be specified in the notice;
 (b) to boil thoroughly all diseased tubers;
 (c) to take such steps as the Local Authority may consider necessary to prevent the disease being conveyed to other premises.
 (3) Nothing in this Order shall prevent the destruction by the owner thereof, by fire or other effective method, of any diseased tubers.
 (4) A notice under this Article may prescribe the time within which the adoption of any measure thereby prescribed shall be completed.

Power to Prohibit the Planting of Potatoes on Infected and other Premises.

7. The Local Authority may by a notice served on the occupier of any infected premises, or any adjoining premises to which the disease is likely to spread, prohibit the planting of Potatoes in the infected or other premises except under such conditions as may be prescribed in the notice.

Provisions to Prevent Spread of Disease by Planting Diseased Potatoes.

8.—(1.) Diseased tubers shall not be used for planting or sold or offered for sale for any purpose.

(2.) No person shall use, except by licence of an Inspector of the Board or the Local Authority, or sell or offer for sale for planting tubers which to his knowledge have been grown on infected premises, whether the premises have been declared to be infected before or after the tubers were lifted.

(3.) An Inspector of the Local Authority, acting under their directions, may by a notice served on any person having in his possession or under his charge tubers which are diseased, or in a pit, bag, or other receptacle with diseased tubers, or which the Inspector has reason to believe to have been in a pit, bag or other receptacle with diseased tubers, or otherwise exposed to infection with disease, prohibit the removal of the tubers from the premises on which they are when the notice is served, except under such conditions as the Inspector, acting under such directions, may consider necessary to prevent the spread of disease and prescribe by the notice.

Withdrawal of Notices of Infected Premises.

9. A notice constituting any premises infected premises may be withdrawn by a notice signed by an Inspector or other officer of the Board. Unless there are special circumstances, a notice of withdrawal shall not be issued as regards any premises until the expiration of three years from the date of the notice declaring the premises infected.

Copies of Notices and Returns of Proceedings to be sent to the Board.

10.—(1.) A copy of every notice served under this Order shall be sent to the Board by the Inspector or officer by whom the notice is signed.

(2.) The Local Authority shall, in a form to be provided by the Board, notify the Board of any outbreak of disease.

Information to be given as to Diseased Potatoes.

11. Every person who has or has had in his possession or under his charge any diseased tubers, and every person who as auctioneer, salesman, or otherwise has sold or offered for sale any such tubers shall, if so required in writing by the Board, or the Local Authority, or an Inspector of the Board or of the Local Authority, give the Board, or the Local Authority, or the Inspector, as the case may be, all such information as he possesses as to the persons in whose possession or under whose charge they are or have been; Provided that any information given under this Article shall not be available as evidence against the person giving the same in any prosecution under this Order, except in respect of an alleged failure to comply with this Article.

Powers of Entry.

12. Any Inspector or other officer appointed in that behalf by the Local Authority, upon production if so required of his appointment or authority, may for the purpose of enforcing this Order enter any premises and examine any plant or tubers thereon.

Notification of Order.

13. This Order shall be published by the Local Authority in accordance with any direction given by the Board.

Powers of the Board and their Inspectors.

14. The powers conferred by this Order on a Local Authority or an Inspector of a Local Authority may be exercised by the Board or an Inspector of the Board respectively, and any notice served by a Local Authority or an Inspector of a Local Authority may be altered or revoked by a notice under this Order served by the Board or an Inspector of the Board.

Offences.

15. Every person shall be liable on conviction to a penalty not exceeding ten pounds, who—

- (1.) fails to give notification of disease as required by Article 3; or
- (2.) fails to adopt such measures for prevention of the spread of the disease as are specified in a notice served on him under Article 6; or
- (3.) removes any tubers in contravention of this Order or any notice served thereunder; or
- (4.) plants Potatoes in infected premises in contravention of a notice served under this Order; or
- (5.) uses tubers or sells or offers for sale tubers in contravention of this Order; or
- (6.) refuses or fails to give any information required under Article 11, or gives false information; or
- (7.) wilfully obstructs or impedes any Inspector or other officer in the course of his duties under this Order.

Execution of the Order.

16.—(1.) Each Local Authority shall carry into effect this Order within their District, and shall appoint such Inspectors or other officers for that purpose as may be necessary.

(2.) Any duty or power imposed or conferred on a Local Authority by this Order may be performed or exercised by an Inspector of the Local Authority acting under and in accordance with any directions in that behalf given by the Local Authority.

(3.) For the purposes of this Order a notice shall be deemed to be served on a person if it is delivered to him personally or left for him at his last known place of abode or business or sent through the post in a letter

addressed to him there, and a notice or other document purporting to be signed by the clerk or an Inspector of a Local Authority or an Inspector of the Board shall be prima facie evidence that it was signed by him and duly authorised by the Local Authority or the Board.

Revocation of Order.

17.—(1.) The Wart Disease of Potatoes Order of 1912 is hereby revoked; provided that such revocation shall not—

- (i.) affect the previous operation of that Order or anything duly done or suffered under that Order; or
 - (ii.) affect any right, privilege, obligation, or liability acquired, accrued, or incurred under that Order; or
 - (iii.) affect any penalty incurred in respect of any offence committed against that Order; or
 - (iv.) affect any investigation, legal proceeding, or remedy in respect of any such right, privilege, obligation, liability, or penalty as aforesaid; and any such investigation, legal proceeding, or remedy may be instituted, continued, or enforced, and any such penalty may be imposed, as if this Order had not been made.
- (2.) Every notice served under the Order hereby revoked shall have effect as if it were a notice under this Order.

Commencement.

18. This Order shall come into operation on the third day of February, nineteen hundred and fourteen.

THE WART DISEASE OF POTATOS (INFECTED AREAS) ORDER OF 1914.

The Board of Agriculture and Fisheries, by virtue of and in exercise of the powers vested in them under the Destructive Insects and Pests Acts, 1877 and 1907, do order, and is hereby ordered, as follows:

Application of Order.

1. This Order shall apply to any Area declared by Order of the Board to be infected with Wart Disease and any such Area shall be an Infected Area for the purposes of this Order.

Restriction on Planting in Infected Area.

2. No Potatoes shall be planted or sown or permitted to be planted in an Infected Area except with the authority of a licence granted by an Inspector of the Board or otherwise than in accordance with the conditions imposed by the licence. The licence may prescribe the variety of Potatoes authorised to be planted, and the source from which the Potatoes shall be obtained.

Restriction of Removal of Potatoes grown in Infected Area.

3. Potatoes grown in an Infected Area, whether before or after the declaration of the Area to be infected, shall not be removed or sown or permitted to be removed from the Infected Area except with the authority of a licence granted by an Inspector of the Board; provided that this restriction shall not apply to the removal of Potatoes not visibly diseased for the purpose of being consumed upon premises in the occupation of the person by whom they were grown.

Notification of Disease.

4. The occupier of any premises in an Infected Area on which Wart Disease exists, or appears to exist, shall forthwith notify the fact by post or otherwise to the Board, or to the person authorised by the Board to receive such reports, who will forthwith forward the report to the Board. Where this Article applies Article 3 (Notification of Disease) of the Wart Disease of Potatoes Order of 1914 shall not apply.

Precautions against Spread of Disease.

5. The following measures for prevention of the spread of Wart Disease shall be adopted by each occupier of premises in an Infected Area.

(a) The haulm, leaves and roots of each diseased plant shall be destroyed either by fire, or by some other method authorised by an Inspector of the Board, within 14 days from the date of lifting, either within the Infected Area or with the written authority of an Inspector of the Board at a place outside the Infected Area.

(b) Potatoes which are visibly diseased, if not forthwith destroyed by fire within the Infected Area, shall be thoroughly boiled as soon as possible, either within the Infected Area, or with the licence of an Inspector of the Board at a place outside the Infected Area.

(c) Litter or manure from any live stock which has been fed with Potatoes grown on land within the Infected Area shall not be used or permitted to be used as manure on any land outside the Infected Area.

Power to require Crop to be lifted.

6. An Inspector of the Board may by notice served upon the occupier of any premises within an Infected Area require him to lift any Potatoes which the Inspector may suspect to be affected with Wart Disease by a date specified in such notice.

Partial exemption from General Order.

7. No part of an Infected Area shall be declared to be "infected premises" under the Wart Disease of Potatoes Order of 1914, and any premises included in an Infected Area shall cease to be "infected premises."

Definitions.

8. In this Order—
"The Board" means the Board of Agriculture and Fisheries;

"Wart Disease" means the disease affecting Potatoes which is known as *Synchytrium endobioticum*, or Wart Disease of Potatoes, Black Scab, Cauliflower disease, or Potato canker; and "diseased" means affected with Wart Disease.

Offences.

9. Every person shall be liable on conviction to a penalty not exceeding ten pounds, who—

- (1.) plants or removes or causes or permits to be planted or removed any Potatoes in contravention of this Order; or,
- (2.) fails to give notification of Wart Disease as required by Article 4; or
- (3.) fails to adopt any measure required by Article 5 to be adopted by him; or
- (4.) fails to lift any Potatoes as required to be lifted by him under Article 6.

Short Title.

10. This Order may be cited as the WART DISEASE OF POTATOS (INFECTED AREAS) ORDER OF 1914.

POTATOS SUITABLE FOR PLANTING ON INFECTED PREMISES.

The Board of Agriculture and Fisheries desire to remind all occupiers of premises declared infected for the purpose of the Wart Disease of Potatoes Order that it is illegal to plant any Potatoes on such premises unless a licence has previously been obtained from an Inspector of the Board or of the Local Authority. The penalty for any contravention of the Order is a fine not exceeding Ten Pounds.

Such licences can, however, as a rule be obtained on application to the Board by any occupier who undertakes to obtain from a reliable dealer one or more of the varieties of Potato referred to below, all of which have been tested, some of them for several years, and have been found to resist Wart Disease under ordinary circumstances.

Should any occupier have any difficulty in finding a Potato dealer who can supply the variety he wants, the Board will, on application, send a list of dealers who have undertaken to stock these Potatoes, with a statement as to the varieties which each is able to offer.

Milecross Early.—White, round, not liable to ordinary Potato disease (*Phytophthora*), matures rapidly, haulm strong, and quality good.

Conquest.—White, round, heavy cropping, second-early Potato of good quality; must be earthed up high, as tubers are produced near surface.

Jeanie Deans.—A fine oval Potato with strong haulm and white flower. Crops heavily on light, rich soils. Stocks of this variety are not large.

Dobbie's Favourite.—A second-early, round in shape, white flower; an excellent Potato when well grown.

Abundance.—A well-known heavy cropping, late variety, oval in shape, of good quality, rather liable to ordinary disease; white flower.

Sutton's Supreme.—A second-early of pebble shape, white flower, suited to garden cultivation.

Great Scot.—A very good second-early; white and round, eyes rather deep; haulm robust; a very heavy cropper under good cultivation. Quality excellent; flower, white.

Schoolmaster.—A second-early, white-skinned and round; crops well, but is liable to ordinary disease. Not a good keeper.

Crofter.—A late oval Potato of good quality; liable to ordinary disease. Flower, white.

Culdees Castle.—A pebble-shaped variety, not quite so strong in the haulm as Crofter, and liable to produce more seed size tubers on light soil. Does well under garden cultivation. Flower, white.

White City.—A late, kidney-shaped variety. A fine Potato for garden cultivation, but not a heavy cropper. Under high cultivation tubers are frequently hollow. Of first-rate quality. Flower, lilac.

Provost.—A late, white, round Potato possessing strong haulms and white flowers; well suited to garden cultivation. "Seed" should be changed every second year.

The Admiral.—A late variety, white-skinned and round. Haulm medium, a heavy cropper and good disease-resister. Quality excellent. Flower, white.

Irish Queen.—Tubers round, eyes rather deep, haulm strong. Excellent cropper. Keeps late into season.

St. Malo Kidney.—Tubers coarse, kidney-shaped. Haulm robust. Not a good keeping variety.

King George V.—An elongated oval tuber, skin netted, eyes shallow, haulm strong. An excellent cropper. Quality moderate.

Davie's Laird.—Roundish tuber, flesh white. A robust variety that crops heavily on well-prepared medium loams. Quality excellent.

Flourball.—Well-known late variety, round and pink-skinned. Eyes rather deep, haulm straggling with bronzing on stems when exposed. Quality very good; flower, white.

Golden Wonder.—A late white-fleshed kidney with yellowish-brown tinge on skin. The "seed" should be a good size, and if unsprouted should be planted before the end of March, as the variety requires a long growing season. Liberal manuring is essential, and in gardens bastard trenching is recommended. It is possessed of excellent quality, and is one of the best late keeping Potatoes. Flower, mauve-tipped white.

Peacemaker.—Is similar to Golden Wonder.

Langworthy.—A late kidney-shaped Potato possessing white skin and flesh. Tubers that are fully developed may generally be recognised by the characteristic tapering "heel." Quality excellent. Same treatment required as for Golden Wonder. Flower, mauve-tipped white.

What's Wanted.—Shape not so constant as in Langworthy. In other respects very similar.

N.B.—The four last-mentioned varieties are, relatively speaking, light croppers, but they are probably unsurpassed as resisters of ordinary Potato disease.

This list is not exhaustive, and there are several other varieties which are resistant. They are not quoted, as the supply of Potatoes of "seed" size is believed to be small.

4, Whitehall Place,
London, S.W.

The Week's Work.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

DAHLIAS.—The old stools of all types of Dahlias should be brought out of their winter quarters—the older plants divided and placed in moist sandy soil, in warmth, to furnish cuttings. The newer Paecony-flowered type is a great acquisition, for the plants are very effective when bedded out. They throw their gorgeous flowers well above the foliage on long stems, and they are excellent as cut blooms, especially for church decoration or for placing in large vases. The Geisha is a particularly good variety. Collettere, Cactus, and Pompon Dahlias are all useful and effective plants for bedding, whilst Single varieties bloom profusely out-of-doors (provided the seed-pods are picked off regularly) until destroyed by frost.

SALVIA PATENS.—This, the finest of all blue-flowered bedding plants, may be divided, and the portions introduced in gentle warmth for propagation. The plant grows best in boxes filled with a mixture of leaf-mould, sand, and a little loam. This pretty Sage is very striking when associated with the double white Marguerite Mrs. F. Sander.

BEGONIAS.—Tuberous-rooted Begonias should be placed in shallow boxes containing moist sand and leaf-mould, in which they should be placed, but not quite covered. Ainery just started is the best place in which to grow them, but if required for bedding purposes the less fire-heat employed the more sturdy and better they grow. As soon as the shoots have grown half-an-inch long, the tubers may be cut into portions containing one or more eyes, in the same manner as seed Potatoes are divided, and replaced in similar soil and grown in a very slightly-heated structure—with just sufficient warmth to keep the atmosphere buoyant. Begonia Northiana (the Continental variety of that name) has erect scarlet flowers and an excellent constitution, and is the finest of all for bedding. This is a totally different plant from the weakly sort with drooping flowers, which is often grown under that name. Stock plants of fibrous-rooted Begonias should be pulled to pieces and placed in gentle warmth. All Begonias grow well in soil containing decayed leaf-mould, and the compost should be on the loose side. Seeds of *B. semperflorens* varieties, if sown at once, will furnish good plants suitable for summer bedding, and may be relied upon to come fairly true from seed.

SOFT-WOODED PLANTS.—The propagating houses and frames are crowded with a complement of all soft-wooded plants required for decorating the formal parterres. The closest attention must be given to prevent the young plants from becoming drawn. Where a groundwork of any special colour is attempted, with tall specimens of another kind as dot plants, the latter—such as *Heliotropes* and *Fuchsias*—should be trained with long stems. Grow them in a warm house—a temperature of 50° to 55° is suitable—where they should develop into healthy, sturdy specimens. Subjects utilised as edgings—such as *Dactylis* and *Alyssum*—should be increased either by division or by cuttings.

THE THYME WALK.—The Thyme walk is a favourite part of these gardens, and the present is a suitable time to strike a few healthy cuttings of Lemon Thyme to raise plants for filling up blank spaces. The walk may be formed as a curve to connect two points. When the plants are walked on the boots carry the pleasant perfume for hours.

HELLEBORE.—The green Hellebore *H. viridis* has been, and is at the present time, very effective in these gardens. It is an accommodating plant, for it will grow on any dry bank or slope, or under shady trees, in the poorest soils. We have also the Lenten Hellebore, *H. orientalis*, as well as the Christmas Rose, *H. nigra*, and all are worthy of extended cultivation. All of the species resent disturbance at the roots.

WATER-SIDES.—Willows and Dogwoods massed on lake-sides for winter effect, by reason of their beautifully coloured bark, should be cut close to the ground and the prunings utilised for cuttings. The latter may be dibbled in the soil to take the place of unhealthy or exhausted plants. *Salix babylonica Britzensis* has red bark, and *S. ramulus aureus* is the best of the yellow-stemmed Willows, whilst *Cornus sibirica* is the best red-stemmed Dogwood. Willows and Dogwoods should be planted somewhat closely in large, irregular masses.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON, Oakwood, Wylam-on-Tyne.

IMPORTED ORCHIDS.—Such deciduous species of *Dendrobium* as *D. Wardianum*, *D. nobile*, *D. Falconeri* and *D. Devonianum* are usually imported in large quantities at this season of the year, and the plants are in demand for private gardens, as they are useful not only for furnishing cut blooms but also for decorative purposes generally. The most useful species of all is *D. Wardianum*, and many gardeners purchase large quantities of this plant annually to furnish flowers in the spring. *D. Wardianum* does not generally remain in a good condition after it has been in cultivation for some time, and for this reason it is desirable to purchase a few fresh plants annually. Newly-imported plants should be overhauled carefully for the presence of insect pests, which may be concealed about the pseudo-bulbs, bracts, and base of the plants. All dead and decaying matter should be cut away and the plants prepared for potting. Well-drained, shallow pots or pans—they may be suspended—are suitable receptacles, for plants in bloom are seen to the best advantage when hung from the roof-rafters. The receptacles should be sufficiently large enough to accommodate the plants, but no larger. Very little compost is necessary, and it may consist of equal parts fibrous peat, *Osmunda*-fibre and finely-chopped *Sphagnum*-moss, mixed with a sufficient quantity of broken charcoal and sand to render the materials porous. The compost should be pressed firmly about the base of the plant in order to hold it in position, and the pseudo-bulbs should be secured to neat stakes. Very little root moisture will be necessary until the shoots grow some considerable distance from the base. Spraying the pseudo-bulbs, compost, etc., is the best method of applying moisture in the early treatment of the plants, for it is only necessary to retain the pseudo-bulbs in a plump condition. Those that arrive early in the season are the most satisfactory, as they obtain full advantage from our all too short summer. The directions for potting *D. Wardianum* apply also to the other species mentioned.

RENANTHERA IMSCHOOTIANA.—This plant is also imported at the present season, and no other Eastern Orchid is more serviceable in private gardens. The brilliant racemes of scarlet flowers last fresh for a long time, and they are very decorative. The plant blooms in the spring and summer and grows best in baskets or shallow pans in the warm intermediate house. The compost recommended for *Dendrobiums* is suitable for this *Renanthera*. When the plants are in active growth keep the atmosphere well charged with moisture.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOTE, Eastwell Park, Kent.

STANDARD FRUIT TREES.—Although standards are too large for planting in the majority of walled-in gardens, there is usually ground in close proximity to the kitchen garden that could be utilised for large fruit trees. Plant the hardier kinds in the colder and more exposed situations, reserving the best and warmest positions for choice varieties. Damsons may be grown in cold, windy situations, where most other fruits would fail. Thus they may be grown on the north or east side of an orchard, but if the position is a very bleak one it would be well to plant some thick-growing, hardy tree such as the Austrian or Corsican Pine, as a

wind-break. The Damsons themselves should be planted closely to act as a wind-break to the other fruit trees. The Farleigh, Bradley's King and Prune Damson are good varieties. The newer Merryweather is a good late variety; the tree is a very strong grower and bears large fruits of good flavour. Bullaces succeed under the same conditions as suit Damsons, and where they are appreciated Langley Black Bullace and the White Bullace should be planted.

STANDARD APPLES.—Although autumn planting is much to be preferred, time will be saved if the work of planting is undertaken during the next few weeks in favourable weather. If the trees arrive from the nursery when the weather is frosty, place them in a cool place where they may be unpacked with safety and the roots covered with soil until the conditions are suitable. If the ground has been previously cropped with vegetables and is in a good condition it will require very little further preparation. Do not plant fruit trees in low-lying, damp situations, as in such places spring frosts are more frequent. Well-drained ground sloping gently to the south or south-west is best suited for fruit trees, and if the soil is a rich loam success is almost assured. Inferior soils may be improved by adding wood-ash, loam, or even good garden soil. In the case of a small orchard or enclosed strip of ground it is an advantage to inter-crop with vegetables or small fruits. If the land is laid down to grass poultry or stock should be allowed on it. In any case the site for the trees should be well prepared, making stations for the trees about 6 feet in diameter. Never incorporate rank animal manure with the soil when planting young fruit trees; this is only required when the trees are bearing good crops of fruit.

STANDARD PLUMS.—Standard Plums are very useful to supplement the crop of this fruit from the wall and bush trees. Varieties of Plums suitable for planting as standards are Rivers' Early Prolific, the Czar, Belgian Purple, Gisborne, Greengage, Early Orleans, Kirke's, Monarch, Victoria, Primate, Pershore and Bonne Bouche Gage. When planting stone fruits of any kind add mortar-rubble or chalk to the soil. Tie the trees securely to strong stakes immediately they are planted and mulch the roots with some light material.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

THE VINERY.—The earliest vines should be thinned of superfluous bunches, selecting for the crop those that are the more compact, and with strong, short stems. Such bunches will be the more likely to swell their berries well, and less liable to shanking. Do not force the vines hard during dull weather. The ventilation of the vinery should receive careful attention, admitting air on favourable occasions, as nothing is more detrimental to vines in any stage than a stagnant atmosphere. See that the outside borders are protected from cold rains and snow, and keep the inside borders in a moderately moist condition. Vines in bloom should be grown in a temperature of about 65° at night, with a rather dry atmosphere, closing the house early in the afternoon when the temperature is about 80°. Newly started vines should be syringed several times daily. Any rods that are slow in breaking into growth should be bent back, and kept constantly moist. Attend to such details as disbudding and pinching to ensure the proper regulation and development of the foliage.

MELONS.—When planting Melons use the best loam obtainable, and do not allow too much room for the roots, as to do so is one of the greatest mistakes in Melon culture. Place a little powdered charcoal around the collar of each plant as a preventive of canker. The bottom heat need not exceed 70°, with an atmospheric temperature of 75° to 80°, according to the condition of the weather. If the plants are growing in pits cover the roof at night with some protective material, as this will obviate the use of much fire heat. When the atmosphere is moderately moist admit air on all favourable

occasions during the early part of the day, but close the ventilators early in the afternoon in order to take full advantage of the sun heat. Sow seeds at intervals to provide plants for successional cropping.

FIGS.—Maintain a moist, genial atmosphere in houses where the trees are already in leaf. As soon as the new growths have extended three or four inches pinch out the points, for this will favour a rapid development of the fruits. Where trees are grown in considerable numbers some of the more forward plants may with advantage be placed in another well-heated glass-house to hurry them into growth.

PEACHES AND NECTARINES.—Where more fruits have set than are required for a crop they should be thinned freely before they grow to the size of peas. Continue to disbud the shoots, taking care to retain growths that arise from the base or heel of the previous season's growth, for these mainly furnish the fruiting wood of another season, as well as being necessary for the formation of the tree. The foreright shoots, or breastwood, should be removed entirely, but if growths are required to furnish bare spaces some that are suitable may be trained in. Let the inside borders be well supplied with moisture, and keep late houses as cool as possible.

PINES.—Fruits of the Queen variety are ripening, and these will be followed by Smooth Cayenne and Charlotte Rothschild. Pay particular attention to the condition of the roots, for without good healthy roots fine fruits cannot be expected. Maintain the temperatures already advised, with a steady bottom heat. Water the soil freely whenever necessary with tepid water in which a small quantity of guano has been placed. Do not practice much syringing overhead. Successional plants should be grown slowly for the present. Where bottom heat is not provided by hot-water pipes, and a new bed has to be prepared for suckers, the present is a suitable time to get the fermenting materials ready. Some growers prefer beds of old tan mixed with a little new tan, as in this case the suckers may be plunged immediately they are potted. When potting or top-dressing the plants see that the soil is first warmed thoroughly.

CHERRIES.—The houses in which Cherries are forced should be ventilated freely during the early part of the day, for no fruit-tree resents a close, moist atmosphere more than the Cherry. Spray the trees both mornings and afternoons until the flowers expand, when syringing should be discontinued until after the fruit has set. Afford a little ventilation constantly at the top of the house as the trees come into bloom whenever there is no danger of the temperature falling below 45°; a rise of 10° or 15° may be permitted during the day by sun heat.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

TUBEROUS-ROOTED BEGONIA.—The tubers, that have been rested quite dry, should be prepared for starting again. Like the Gloxinia and Achimenes, the Begonia is best started in boxes containing leaf-mould or cocconut fibre. Shake the old soil from the tubers and arrange them just below the surface. Afford water sparingly until growth is well advanced, but use the syringe frequently. The atmospheric temperature should be 60° to 65°. Large tubers may be cut in two. Dust the cut surface with powdered charcoal mixed with slacked lime, for it should be dry before planting. Seed may be sown on the surface in well-drained shallow pans. Place a sheet of glass over the pan, and cover it with paper, for the seeds will germinate best in the dark. When the seedlings appear, accustom them gradually to the light until finally they are placed on a shelf close to the roof-glass; but they must be shaded from direct sunshine.

HERBACEOUS CALCEOLARIAS.—The earliest batch of these showy greenhouse plants growing in 5in. pots are ready for shifting into 7in. pots, in which they will flower. The compost should be open in texture. A suitable mixture

is formed of two parts sandy loam, one part leaf-mould, with dry manure and sand added. Water the soil sparingly at the start, and re-pot the plants before they become pot-bound. Aphid infests the undersides of the leaves, and should be destroyed by fumigating. Grow the plants in an airy house, close to the roof-glass, in a temperature of 55°.

CAMELLIA.—The flower-buds of these showy greenhouse plants are swelling fast, and the plants need occasional doses of weak liquid manure and syringings on frequent occasions until the flowers open. If the leaves are sponged with tepid water the plants will present a brighter appearance and it will help to promote good health in the foliage. When the flowers are over the atmosphere should be kept warm and moist. A temperature of 45° will suffice whilst the plants are in bloom.

FUCHSIA.—The main batch of these plants may be started now in a temperature of 50° to 55°. Repot them when growth commences in a compost consisting of two parts rich loam and one part well-decayed manure and leaf-mould, with a liberal sprinkling of coarse sand. Shake most of the old soil from the roots, and use small pots at the start, but as growth develops repot into larger receptacles as required. Cuttings may be struck now, and they will make good plants before the autumn. These also must be re-potted before they become pot-bound, and points of the shoots should be pinched out to obtain shapely specimens.

CHRYSANTHEMUMS.—Cuttings of Decorative and Single Chrysanthemums that are sufficiently rooted should be potted in a compost consisting of three parts rich loam and one part each of horse manure, leaf-mould, and sand. Use the syringe frequently; if the compost is fairly moist, root waterings will not be needed until fresh growth develops. Plants already established in their pots should be afforded plenty of air during mild weather. Stand them in a light position near to the roof-glass, and syringe the foliage with quassia extract to destroy green and black fly.

HYDRANGEA HORTENSIS.—A few well-established plants in pots may be placed on a shelf near to the roof-glass in a house having a temperature of 50° to 55°. When well advanced in growth, water the roots twice weekly with liquid manure. Thos. Hogg is a good white variety, and responds to the influence of a moist heat.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynningham, East Lothian.

FORWARDING PEAS.—In those years when the early crop cannot be sown out-of-doors, I make a substitutionary sowing in boxes at about this time. Earlier plants become drawn before they can be planted out. There are several ways of proceeding, but none more to be preferred than to sow the seed very thickly, almost touching each other, in ordinary cutting-boxes. The soil to be saturated with water, and the boxes placed in a warm structure for a few days until the seedlings are through the soil. Afterwards they are better grown on until two or three inches in height in a cool house. When the time approaches for transplanting into the border, allow the soil in the boxes to become quite dry, in which condition the roots can be disentangled easily without breakage. They are then set a few inches apart in rows, and so deep as to be almost covered. The crop from these is usually ready to gather at about the end of May. In the earlier localities the variety Pilot should be sown, but as yet it is too early to sow in Northern districts.

CHERVIL.—Where the leaves of this aromatic little herb are in request, a few seeds should be scattered thinly on any odd spot of ground, covering them with a little light soil and smoothing the surface with a spade. Sometimes enough to meet requirements is produced by self-sown seeds.

PARSNIPS are usually sown at about this date, but there will be ample time if they are not sown until a few weeks hence. This root-

vegetable should always be grown in deeply-trenched ground, which, if in good heart, is better not to be manured. I sow a few seeds at every 6 inches, a system which saves thinning. The rows must be at least 15 inches apart, but if too much space is allowed the roots are apt to grow very large and coarse.

BRUSSELS SPROUTS.—Another sowing, which sometimes proves the most profitable, should now be made in a cold frame, placed on a spot in the garden selected for the purpose, and in the ordinary soil. Sow the seeds broadcast, but not thickly, else the seedlings would need to be thinned. At the end of March the frames are removed and the plants exposed to harden and strengthen for planting later.

CAULIFLOWERS.—Reserve a part of the frame for a sowing of Autumn Giant or others of that type, and of a variety of the Erfurt Market type. Prepare for the Cauliflowers by incorporating some well-decayed manure into the soil a few inches below the surface. It is worth the trouble to mat the frames at night, but in the daytime expose the plants fully to the sunshine.

EARLY POTATOS.—Most of us have a spot chosen for its shelter, its exposure, and the quality of the soil in which to plant early Potatos. We, too, have our special variety—very old stagers, some of them. Myatt's Prolific, though not the very earliest sort, is still in favour, because of its high quality. Whatever the sort selected, it is important that the ground receive the most thorough preparation. It would naturally be manured when either deeply dug or trenched in autumn; and now it should be very thoroughly broken up and pulverised by means of a broad-tined fork, and a dressing of superphosphate of lime mixed at the same time—but cultivation is the main thing. Plant the tubers whole, and not too small specimens. Do not grudge a few inches of extra space. Some growers cover the sets with discarded potting compost, which is no doubt of much value to induce rapid rooting in heavy soils, but in well-prepared medium and light soils it is not needed. See that the surface of the ground is loosened after heavy rains by hoeing, which serves to warm the ground, and a careful workman will not damage the growths.

THE "FRENCH" GARDEN.

By PAUL AQUATLAS.

NURSERY BEDS.—Select a well-sheltered and sunny part of the garden for rearing seedlings in the spring. A space 30 feet wide by 25 feet long is sufficient for a garden of two acres. Make a small bed 6 inches thick for the first sowing of Cauliflower All Year Round or Half Hardy Parisian. The soil used in the frame must be in an excellent condition. Sow the seeds thinly and keep the lights close until the cotyledons appear, when a little ventilation may be afforded on every favourable occasion. The first batch of Celery should be sown within ten or twelve days on a hot-bed 6 to 8 inches thick; there have been great improvements in the strain of self-blanching varieties of Celery. Both Chemin and White American grow strong and tall, and are not so liable to disease as are some other sorts. Sow the seeds thinly, mixing them with dry sand as they are very small. Germination is slow. The seedlings must not receive any check or the plants may run to seed. Celeriac Early Parisian may be sown very early. This is a large-rooted variety and hardier than ordinary Celery, also not so liable to run to seed.

CROPS IN THE OPEN.—A sowing of Radish Sparkler or French Breakfast can be made either in drills made at 9 inches apart or broadcast. The Radishes are grown chiefly as an intercrop on ground where Lettuces or Cauliflowers will be planted in a few weeks' time, but it is advisable to sow them in a special bed by themselves in a warm corner, where the crop can be protected if necessary. Sow Spinach Monstrous of Viroflay to follow the autumn batch. When grown as a catch-crop Spinach should be sown very thinly. In heavy land sow in drills formed at 1 foot apart. The Cabbages planted in October are growing well and the ground should be well hoed and dressed with nitrate of soda.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our Correspondents would oblige by delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Letters for Publication, as well as specimens of plants for naming, should be addressed to the EDITORS, 41, Wellington Street, Covent Garden, London. Communications should be written on one side only of the paper, sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, FEBRUARY 17—

Broughty Ferry Hort. Assoc. meet.

WEDNESDAY, FEBRUARY 18—

Croydon and Dist. Hort. Soc. Annual Dinner.

THURSDAY, FEBRUARY 19—

Brighton, Hove and Sussex Hort. Soc. meet, Odd-fellows' Large Assembly Room. (Lecture by Mr. W. Giles on "Popular Vegetables for Home and Exhibition.")
Linnean Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 39.5°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, February 11 (6 p.m.): Max. 47°; Min. 45°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, February 12 (10 a.m.): Bar. 29.5°. Temp. 49°. Weather—Sunshine.

PROVINCES.—Wednesday, February 11. Max. 50°, Cornwall; Min. 43°, Aberdeen.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—

Herbaceous Plants and Hardy Bulbs, Roses and Fruit Trees, at 12, At 67 and 68, Cheapside, E.C., by Protheroe and Morris.

TUESDAY—

Fruit Trees, Ornamental Trees, and other stock, at Osterley Park Nurseries, Windmill Lane, near Hanwell, by Protheroe and Morris, at 12.

WEDNESDAY—

Hardy Bulbs and Herbaceous Plants, at 12, Trade Sale Miscellaneous Bulbs, at 12, 1.149 c/s Japanese Lilies, at 2.30, Palms and Plants, at 5. By Protheroe and Morris.

THURSDAY—

Special Sale of Roses, At 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 1.

FRIDAY—

Imported Burmese Dendrobiums, also Established Orchids, At 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.45.

MONDAY AND WEDNESDAY—

Rose Trees, Shrubs, Perennials, Lilies, etc. At Stevens's Rooms, 58, King Street, Covent Garden, London.

The annual meeting of the Royal Horticultural Society, a full report of which is published on p. 115, was of more than ordinary interest. In the first place it had to record the severe loss sustained by the Society in the death of the late President, Sir Trevor Lawrence. In deploring his loss the Society recalled the memorable and continuous services which Sir Trevor had rendered to the cause of Horticulture; services which are appreciated with admiring gratitude by all the members of the Society.

In the second place the meeting gave its sanction to a scheme elaborated by the Council for extending the work at Wisley. This extension is the natural outcome of the work which has been done during the past ten years and, as pointed out by Sir Daniel Morris in moving the motion to create a Trust Fund for the purpose, the further work to be undertaken at Wisley will involve the provision of larger facilities for each of the three kinds of activity now carried on at the gardens, namely, research, education and the carrying out of trials of flowers and vegetables. The decision of the Fellows and of the Council is a wise one; for just as a successful business must be progressive if it is to maintain its position, so must a Society which represents a progressive craft take a lead in ensuring the progress of that craft.

The suggestions received by the Council in response to its inquiry how it might best serve to advance horticultural knowledge were so numerous as to convince the Council that a bold scheme of development would meet with the support of the Fellows of the Society. This event has proved the correctness of this judgment. In perfecting the organisation for the carrying out of special investigations, for the perfecting of horticultural education and for the extension of trials the Society has taken a step which we are convinced will prove of great and lasting benefit to horticulture.

Public Parks and Playgrounds.

The wanton destruction of an avenue of Poplars in Finsbury Park raises grave issues requiring close investigation. Unfortunately, and for reasons which will be apparent immediately, the investigation of such acts as that at Finsbury Park is by no means easy. It is a simple matter for anyone who understands these things to satisfy himself that the destruction of the avenue was an act of sheer foolishness. He has only to inspect the ground to discover that the increased space available for games is so small as to fail to justify the removal of the trees.

But when we look beyond this irreparable occurrence, and, in the hope of forestalling them, endeavour to ascertain what other similar acts of destruction are contemplated by authority, we are met by a screen of secrecy, as though we were spies endeavouring to discover by guile the dispositions of an enemy. When we apply to the men who are in charge of the parks we learn that to divulge any information as to which avenue or group of trees is to fall next beneath the axe may involve the head in dismissal. Like a gaoler under the Terror, he dare not give a hint to friends of the victims which head is to fall next.

Neither, so far as we can discover, has the head of the Park any influence with the judge. The park superintendent who has a knowledge of trees, if he wish to stand well with authority, had best keep it to himself. The fiat goes forth—clear all this horticultural rubbish—trees in

avenues or groups, flower beds, shrubberies—sweep them away and erect goal posts in their place.

We protest against the absurdity of this condition of affairs. There is no state of war between the public and the Council. The Council is the servant and not the master of the public, and the public has the right to know and to criticise what the Council intends to do with the parks which it holds in trust for the people.

In present circumstances of enforced secrecy, those of us who care for parks, who know the varied part they play in public enjoyment, are confronted always with accomplished facts. This group of Planes has been cut down—it is no good crying over felled trees. That avenue of Poplars has been demolished—they are gone and grumbling will not make them grow again.

The Parks Committee is composed of well-meaning gentlemen who, as is always the case with this sort of committee, are led by the nose by the permanent officials. Hence any caprice or mistaken policy on the part of those who really determine things, if carried out swiftly and secretly, will evade criticism and, supported by the all-powerful argument of the accomplished fact, will receive the uninformed sanction of the Council. We lay stress on these facts because it is evident that without the assistance and advice of the experienced men who superintend the parks the Council is bound to continue to blunder.

That its blundering is well meant is evident. The members of the Council, like everyone else, desire that children shall have full use and enjoyment of the parks. All desire that the fullest facilities shall be provided for games. But whilst holding these common views we feel it necessary to point out that there is a very clear limit to the use of the public parks for the purpose of set games. They are frequented by thousands of tired people who are seeking rest. Men and women who have physical exercise enough in their work, and who wish to recreate themselves by the contemplation of or mere propinquity with tranquil scenes, to whom the sight of budding trees brings new life, and for whom the bright hues of flowers lighten the drab of their homes: games must not drive these people from the parks.

Wherefore the London County Council would do well to cease from its haphazard method of control and to face the fact that it has a difficult problem to resolve. That problem is to determine how far the noisy cuckoo of games shall be allowed to oust the legitimate nest-holder: to hold the balance between the park as a retreat for tired people and a sanctuary for those townsmen and women who love nature and the park as a playground. In many places these two functions are not incompatible one with another; but in the smaller parks of crowded districts they require the utmost care of adjustment. If they will take this work in hand, will call in the help of experienced advisers in horticultural affairs, and will utilise the large fund of experience pos-

Photographs by H. N. King.

LEONARDSLEE, HORSHAM, THE RESIDENCE OF SIR EDMUND G. LODER, BART.

sessed by the park superintendents, the Council will deserve the gratitude of the community. The difficulty is one which is bound to grow and the Council will be wise to face it before its administration is disfigured by more very silly acts like that of destroying the group of Planes and avenue of Poplars at Finsbury Park.

As evidence that we have not misrepresented the present state of affairs, we put on record the fact that at one of the parks which was visited in the course of our inquiry the superintendent, on learning the nature of our inquiry, ran away, lest by divulging facts of public interest he should lose his place; and this in London in 1914! To repress irresponsible chatter is to confer a benefaction: but to impose a gag on responsible officials is to proclaim oneself bankrupt in the art of government.

Supplementary Illustration.—Our Supplementary Illustration is of Leonardslee, Sussex, the residence of Sir EDMUND G. LODER, Bart. One view shows the south-east front, which slopes rather steeply from the residence. The view from the terrace includes the lake, which lies in a hollow amidst banks of Rhododendrons and other flowering and foliage plants. In the lower picture is seen the rustic bridge, which leads to the portion of the pleasure grounds beyond the lake. It is on the further side of the water that the extraordinary colonies of *Sarracenia* are cultivated. A full description of the wonderful collections of trees and shrubs contained in these gardens is to be found in the issues for October 13 and 20, 1906.

AMERICAN GOOSEBERRY MILDEW.—The Board of Agriculture and Fisheries desires to remind fruit-growers, nurserymen, market gardeners, etc., in the county of Kent that the Orders prohibiting, under a penalty not exceeding ten pounds, the movement of Gooseberry and Currant Bushes either from or within the county except by licence are still in force. The Local Authority for the county of Kent has ceased to employ an inspector for the purposes of these and other Orders under the Destructive Insects and Pests Acts, and all applications for licences should therefore be sent direct to the Board.

CENSUS OF PRODUCTION.—The Board of Agriculture and Fisheries is engaged in collecting information in connection with the census of production which is now again being taken, for the compilation of another report on the Agricultural output of the country, similar to that issued for the year 1908. A large number of forms of inquiry on various points have been sent to occupiers of land, who will, it is hoped, as on the previous occasion, assist the Board by furnishing the information required. The particulars asked for are solely for use in the Statistical Division of the Board for this purpose.

THE POTATO QUARANTINE IN AMERICA.—From statements published in the American Press it would appear that the recent establishment of the "Potato Quarantine" is having a considerable effect on prices. Thus, Mr. A. W. McCANN, writing in the *Globe* (New York), states that Potatoes which were sold wholesale at 60-65 cents per bushel in Boston, New York, Philadelphia, and Baltimore are now selling at 85-90 cents, and predicts that the wholesale price will rise to 1 dollar 50 cents before the middle of the present month. Mr. McCANN observes that New York farmers are already asking 1 dollar per bushel at the loading stations. The same writer expresses apprehension lest other countries adopt retaliatory measures, and insist that American Apples shall not be imported unless it can be shown that they are grown in districts free from such pests as codlin moth, "bitter rot," and San José scale.

HORTICULTURE AT CRAIBSTONE EXPERIMENTAL FARM.—Mr. GREENHOWE, the recently-appointed Lecturer in Horticulture in the Aberdeen and North of Scotland College of Agriculture, has submitted a proposal to the Governors to utilise the garden at Craibstone—the experimental farm acquired by the college, and situated a few miles from Aberdeen—for experimental and demonstration purposes in horticulture. It is proposed to form a model fruit plantation for supplying information as to the most suitable varieties of hardy fruits for the district, also for conducting manurial experiments and for practical demonstrations to horticulturists.

PARMENTIER AND THE POTATO.—In the last three issues of *Le Jardin* M. G. GIBAULT has contributed a series of interesting articles entitled "La Légende de Parmentier." They deal with the introduction and history of the Potato as an article of food in France.

CHICORY GROWING IN ABERDEENSHIRE.—Remarkably successful experiments in the growing of Chicory have been carried out in Aberdeenshire under the auspices of the Aberdeen and North of Scotland College of Agriculture. The districts selected were Kilblean and Culsamond, and some valuable information and results have been obtained. The variety tested was Magdebourg, which has a good reputation. The experiments demonstrated that the best soil for Chicory is a deep loam, and subsoiling previous to the crop being sown was proved to be a great advantage. To get the best-shaped roots no farmyard manure should be used, but a good dressing of artificial manures should be applied. The crop was planted early in May, and it was not ready for lifting until well into November. Had the season been late the crop might not have been a success, especially in late districts. Samples of the roots were submitted to a Coffee manufacturer on a large scale in Aberdeen, and he reported that the ground-roasted roots produced capital Chicory. The yield was, approximately, 19 cwt. per acre. The price of Chicory to the manufacturer is about £28 10s. per ton, of which the sum of £12 10s. is paid for duty, thus leaving the grower about £16 per ton. Evidently a return of 19 cwt. per acre of ground-roasted Chicory would give a profitable result. There is considerable labour and expense entailed in connection with the crop owing to the heavy dressings of manure necessary and the continuous cultivation to keep the land free from weeds in the early stages. To get the best results the leaves, when they turn yellow—that is, before lifting—require to be removed gradually. Great care must be exercised in lifting the crop, in order to prevent bleeding of the roots. Those leaves which remain green at the time of lifting make capital food for stock, thus forming another asset in the value of the crop. The college authorities purpose next season to carry out similar experiments in earlier districts within the college area, as evidently lateness in ripening is a weak point in the growing of Chicory. The growing of Chicory has been a neglected part of agriculture since the duty on the home-grown article was made practically the same as that on foreign grown. Recently attempts have been made in England, particularly in Cambridgeshire, to grow Chicory again, and it is satisfactory to learn these have met with considerable success. Meantime the further extension of the experiments in the North of Scotland will be watched with much interest.

SULPHUR AS A FERTILISER.—The most recent contribution to the discussion on the use of sulphur as a soil-fertiliser is provided by Herr W. JANICAUD, Director of the horticultural experiment station of Mülhausen, who publishes the results of his experiments in *Die Gartenwelt* (January 17). Mr. JANICAUD used the Tomato as his test plant, and carried out his culture in pots. The Tomatos (*Luculus*) were grown in various conditions; some in soil to which no manure was added; others in soil to which was added flowers of sulphur (2 grams per 1 kilo-

gram of soil = $\frac{1}{2}$ oz. to 2 lbs.), and others which received either a complete manure only or a complete manure together with sulphur. The conclusion reached is that sulphur, even in the presence of a complete manure, acts as a stimulator to the growth of the plant. Dr. HILTNER, who estimated the numbers of bacteria present in the manured and unmanured soils, finds that the effect of sulphur is to bring about a remarkable increase in the bacterial population. Thus the number of bacteria was found to be:—

Soil.	Bacteria per gram of soil.
Unmanured	12.51 millions.
Sulphured	23.59 "
Completely manured and sulphured	16.16 "
Completely manured and un sulphured	10.97 "

SMUT DISEASES OF CULTIVATED PLANTS.—Bulletin No. 73 of the Department of Agriculture, Ottawa, Canada, consists of a valuable summary, by Dr. Güssow, the Dominion botanist, of what is known of the cause and control of the smut diseases of cultivated plants. The Bulletin points out that the spores of the smut fungi are distributed by wind and by such farm instruments as threshing machines, and recommends the disinfection of the latter by means of formalin. The results of recent experiments demonstrate that though, generally, the spores are killed by passing through the body of an animal, this is not always the case; nor can it be stated with certainty that when diseased grain is fed to stock the animals run no risk of disease. As is now generally accepted, different smuts have different methods of infecting the host plants. In stinking smut of Wheat, covered smut of Barley, naked and loose smut of Oats, for example, spores distributed from diseased ears reach and lodge upon the grains, are sown with the seed, germinate in the ground, and produce secondary spores which infect the seedling. In other smuts, for example the loose smuts of Wheat and Barley, the spores, which are ripe at flowering time, are carried to the stigma of the Wheat or Barley flower, germinate like pollen grains thereon, and, sending down a germ tube into the ovary, provide for the infection of the grain which is being produced in the ovary. Evidently a knowledge of these facts must determine practice—for example, whereas dressing seed with copper-sulphate or formalin or treating it with hot water is productive of good results in the former class, it is without effect when applied to those smuts in which floral infection occurs. Early sowing of autumn wheat has been shown by Dr. MUSSERATI to result in a considerable reduction in the amount of disease. Thus Wheat sown in France on October 11 gave rise to only 1 per cent. of diseased plants, whereas in similar Wheat sown on November 22, infection took place in 90 per cent. of the plants. From these and other experiments it may be laid down that the later in autumn and the earlier in spring Wheat is sown the more the crop is likely to be affected. The gravity of smut diseases may be judged by the estimate that Oat smut alone causes a loss of 8 per cent. of the total crop, that is, a financial loss of upwards of £3,000,000 per annum. The Bulletin, which gives an excellent summary of recent work, both at Ottawa and elsewhere, concludes with an illustrated description of the chief smut diseases which attack cereals and other farm plants.

THE HORTICULTURAL BRANCH OF THE BOARD OF AGRICULTURE FIRST ANNUAL REPORT.—The report of the Horticultural Branch of the Board of Agriculture has just been issued. It is prefaced by a brief statement by Mr. T. H. MIDDLETON, who draws attention to the fact that, in addition to the horticultural subjects dealt with by Mr. ROGERS in the Report, other matters affecting horticulture are treated of in separate publications. The main body of the Report consists of an account of the scheduled

diseases of plants—*e.g.*, American Gooseberry mildew, wart disease of Potatoes, large Larch sawfly, Tomato and Cucumber canker, and others. The price of the Report is 2s. 2d.

SOCIÉTÉ FRANÇAISE D'HORTICULTURE DE LONDRES.—The annual dinner of the members of the London Society of French Gardeners will be held at the Café Royal, Regent Street, on Saturday, May 2. Mr. HAROLD BEALE, of the firm of Messrs. JAMES CARTER AND Co., will preside. The secretary is Mr. G. SCHNEIDER, 3, Meredyth Road, Barnes.

NORTH OF ENGLAND HORTICULTURAL SOCIETY.—The annual general meeting of the Fellows of the North of England Horticultural Society will be held on Wednesday, February 18, at 3 p.m., in the Queen's Hotel, Leeds.

LEGACY TO A GARDENER.—By the will of the late Miss EMILY MATILDA EASTON, of Nest House, Felling, Durham, who died on Christmas Day, aged ninety-five years, her gardener, Mr. JONATHAN MILNER, receives a legacy of £3,000.

ANIMALS AND PLANTS UNDER DOMESTICATION (see pp. 74, 92).—At the third lecture of the course Professor BATESON said that while the study of our domesticated animals and plants leads to the conclusion that many, such as the dog, the horse, and the Wheat, are of multiple origin, such a conclusion is unsatisfactory, for it only throws the problem of the actual origin of new forms a stage further back. The great antiquity of many animals and plants prevents any exact knowledge of their origin, and it is not until we come to the introductions into domesticity of the 18th century that we have good evidence of the development of forms under cultivation. A series of coloured figures by WEINMANN, published in Holland in 1740, show the state of horticulture at that date in a very complete manner. Certain plants, such as the Anemone, the Auricula, and the Balsam were fully developed, and probably no great change has since occurred in these plants. Many forms of the short-spurred *Aquilegia* existed, and it was not until the introduction of the long-spurred, Californian species that any further change occurred in this genus. The Strawberries were very poor, and their improvement is due to the introduction of the American species. A new form that has appeared quite lately is the red annual Sunflower. This plant was seen by Professor COCKERELL growing by the roadside in Colorado. Knowing that the annual Sunflower is self-sterile, Professor COCKERELL crossed this plant with the yellow form, and in the first generation obtained plants intermediate between the yellow and red type. He crossed these F_1 plants with each other, and in the second generation obtained the true red variety again, and this variety has now been put on the market. In conclusion Professor BATESON showed a number of Japanese prints (see figs. 49 and 50) illustrating the great range of variation seen in the annual *Ipomaea*. This plant is much grown in Japan, and there is great competition in the production of new forms. It is supposed that selection of the shrivelled seeds gives a larger proportion of the monstrous forms so much sought after.

PUBLICATIONS RECEIVED.—*Etudes sur la Flore du Katanga.* By Emile de Wildeman. Vol. 11. Fasc. I. (Bruxelles: Falk fils.)—*The White Gate and Other Poems.* By Lorna Leigh. (Hampstead, London: James Hewotson and Son.) Price 1s. 6d.—*Mitteilungen der Deutschen Dendrologischen Gesellschaft; und Jahrbuch für Staudenkunde.* Published by Dr. Graf v. Schwerin, Wendisch-Wilmersdorf bei Thyrow.—*Fruit and Its Cultivation.* By T. W. Sanders. (London: W. H. and S. Collingridge.) SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 10.—The meeting on Tuesday last was of more than usual importance in view of the annual general meeting of the Fellows, which was held at 3 p.m. in the Lecture Room, the

FIGS. 49 AND 50.—MONSTROUS FORMS OF *IPOMAEA*, SHOWN BY PROFESSOR BATESON AT HIS LECTURE ON ANIMALS AND PLANTS UNDER DOMESTICATION, FROM THE JAPANESE MONOGRAPH BY BUNJIRO FUJISAWA.

proceedings at which are reported below. The Hall was filled with exhibits, three of which were awarded Gold Medals, and there was an excellent attendance. A group of Orchids from the Westonbirt collection comprised the most notable floral exhibit, and it was awarded a Gold Medal.

The Orchid Committee recommended two First-class Certificates and seven Awards of Merit to novelties

The Floral Committee recommended two Awards of Merit to new plants and nineteen Medals to collections, including the Gold Medal for a comprehensive exhibit of species and varieties of *Nephrolepis* from Messrs. H. B. MAY AND SONS.

The Fruit and Vegetable Committee also awarded a Gold Medal for Oranges, Lemons and other Citrus fruits shown by Messrs. T. RIVERS AND SON.

Floral Committee.

Present: H. B. May, Esq. (in the chair), Messrs. Chas. E. Shea, G. Reuthe, W. J. Bean, Chas. T. Druery, J. W. Moorman, J. F. McLeod, Wm. Howe, Thos. Stevenson, John Green, Geo. Gordon, W. Bain, J. Dickson, Chas. Dixon, H. J. Jones, Arthur Turner, Chas. E. Pearson, W. Cuthbertson, W. P. Thomson, Geo. Paul, E. A. Bowles, A. A. Dorrien Smith, R. C. Reginald Nevill, John Jennings, C. R. Fielder, E. H. Jenkins, F. W. Harvey, Jas. Hudson and J. W. Barr.

Messrs. H. B. MAY AND SONS, Edmonton, were awarded a Gold Medal for an exhibit of Ferns, comprising 11 species and 73 varieties of *Nephrolepis*. The award was made for the educational value of the exhibit. The fronds were displayed on a white background, each was labelled plainly and arranged so that it was an easy matter to trace the evolution from the species, which included *N. exaltata*, *N. philipense*, *N. rufescens*, *N. tuberosa*, *N. acuta*, *N. pluma*, *N. Duffii*, *N. pectinata*, *N. davalloides*, *N. cordifolia*, and *N. ensifolia*. The most distinct is *N. Duffii*, the long rachis having small, round, overlapping pinnules not much larger than Peas. No varieties have originated from *N. Duffii*. *N. tuberosa* is very handsome and dark green in colour, but *N. acuta* is the darkest of all. *N. exaltata* has given the greatest diversity in foliage, and there were 40 varieties from this popular species. *N. rufescens* comes next with 13 varieties. In the whole of this collection pride of place was taken by *N. exaltata superba*, which has fronds 3 feet long, resembling ostrich plumes. Of those with "mossy" fronds, *N. e. Willmottae* has the densest and finest divided pinnae.

Messrs. JAS. CARTER AND Co., Raynes Park, filled a table with greenhouse Primulas. The finest was a stellata variety named Fairy Queen; the large flowers are white, with a tinge of violet around the yellow eye. This was grouped in a mass in association with *P. malacooides*. They also displayed choice varieties of the sinensis form of Chinese Primrose, amongst them the beautiful one named Holborn Coral. *Primula obconica* Crimson Gem and *P. obconica gigantea* pink and gigantea lilac were arranged in mounds, set round about with *Adiantum* Ferns and lightened with the pink trusses of *P. malacooides*. (Silver Banksian Medal.)

Forced shrubs, shown by Messrs. R. and G. CUTHBERT, Southgate, made a bold and striking exhibit. Clumps of Magnolias—*M. speciosa*, *M. alba superba* and others—grouped about with standard Wisterias, were arranged at either corner, and interspersed in the general collection were tall Laburnums, Lilacs, *Prunus triloba*, double-flowering Cherries and similar shrubs employed for forcing, with a ground of Japanese Maples and Azaleas. (Silver-gilt Flora Medal.)

Messrs. R. GILL AND SONS, Falmouth, exhibited Himalayan Rhododendrons, a number of splendidly-flowered plants of *Primula Winteri*, vases of *Cyclamen Coum* and Violets. The most imposing feature in the group was a plant of *Rhododendron argenteum*, carrying from 50 to 60 trusses of the large cream flowers. (Bronze Flora Medal.)

Messrs. JAS. VEITCH AND SONS, King's Road, Chelsea, filled a long table with batches of flowering plants—Azaleas, Lily-of-the-Valley, *Primula sinensis alba plena*, *Freesia*s of exceptional quality; varieties of the pretty Javanico-jasminiflorum hybrid Rhododendrons and the beautiful, blue-flowered *Tillandsia Lindenii*. The fine new Azalea Blushing Bride has very large, soft pink blossoms. (Silver Flora Medal.)

Messrs. W. CUTBUSH AND SON, Highgate, showed indoor flowering plants and forced shrubs, alpine and rock-garden plants and Carnations, for which a Silver Banksian Medal was awarded.

Messrs. STUART LOW AND Co., Bush Hill Park, Enfield, staged excellent plants of Cyclamens in pans. A new variety named Pink Pearl has rose-pink coloured blooms; it is a good companion to their fine Salmon King variety. This firm also showed hybrids of Erica Wilmoreana; the best was named King Edward VII.; E. lusitanica (codonodes), is hardy, and the flowers are sweet-smelling. Adjoining the Ericas were many vases of Carnations. A new variety named Countess of Pembroke, with salmon-red flowers, was noticed; also Gorgeous and Satin Robe. (Silver Flora Medal.)

Messrs. W. PAUL AND SONS, Waltham Cross, staged pot plants and baskets of cut flowers of Camellias, for which a Silver Banksian Medal was awarded. Many of the varieties were raised at Waltham Cross, and they included some fine singles. The well-known alba plena was shown numerous and well; another old favourite, L'Avenir, was much admired for its exquisite shape. Others of note were alba simplex, single; Apollo, large red semi-double variety; Mercury, rose; imbricata and Mars, rosy crimson.

Messrs. SUTTON AND SONS, Reading, again exhibited bowls of forced flowers, this time Freesias. They were almost as dainty as the bowls of Roman Hyacinths at the last meeting.

Messrs. ALLWOOD BROS., Wivelsfield Nurseries, Haywards Heath, exhibited fine Carnations of the perpetual-blooming type. Scarlet Glow, Wivelsfield Wonder, Mary Allwood, La Rayonnante and Empire Day are a selection of the varieties. (Silver Banksian Medal.)

Messrs. W. WELLS AND Co., Merstham, showed new Carnations, including Champion, scarlet, Yellow Prince, Philadelphia, rose-pink, and Peerless, cerise.

Carnations were also exhibited by Messrs. YOUNG AND Co., Hatherley; the Misses PRICE AND FYFE, Grove Park, Lee; Mr. J. C. JENNER, Rayleigh; Mr. C. ENGELMANN, Saffron Walden (Bronze Flora Medal); and Mr. H. BURNETT, Guernsey, who showed a novelty of crimson-maroon colour named Monarch. (Bronze Flora Medal.)

Messrs. J. PIPER AND SONS, Bayswater, arranged a large bank of Azaleas as a table group, with a rockery at one end, on which we noticed Primula Juliae, P. megasaefolia, P. Winteri, Cyclamen Coum, Saxifraga burseriana major and other Alpines in flower. Blooms of the clear yellow Richardia Elliotiana in vases were of excellent quality. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, Surrey, showed flowering shrubs, for which a Silver Flora Medal was awarded. Azaleas were all freely flowered, the best varieties being Apollo, Dutche Perle and the dwarf, red-flowered Hexe. Wistarias, Clethra arborea variegata, Kenneyda monophylla, small Orange trees in fruit, and varieties of Hamamelis were included in the exhibit.

Messrs. J. CHEAL AND SONS, Crawley, showed dwarf shrubs on a rockery, and were awarded a Silver Banksian Medal. The plants were mostly dwarf Conifers, such as Pinus Balfouriana, P. aristata, Thuya occidentalis var. Spaethii, P. obtusa pygmaea and Abies Hookeriana.

Messrs. WILLS AND SEGAR, Florists, South Kensington, again exhibited Azaleas, for which a Silver Banksian Medal was awarded. There were large plants of the pink and white President Oswald de Kerchove variety on either side of banks of Temperance (semi-double, mauve) and purpurea grandiflora.

Messrs. H. CANNELL AND SONS, Eynsford, Kent, staged bunches of Zonal Pelargoniums. A large scarlet variety named John Watts and Dr. Crawford, crimson, are both new, whilst of the older sorts the finer were Lucana, orange-salmon; Scarlet King, Mars, crimson; Sir T. Hanbury, crimson; and Venus, white.

Messrs. H. J. JONES, LTD., Hither Green, Lewisham, exhibited varieties of zonal-leaved Pelargoniums as small plants in pots.

Mr. G. REUTHE, Keston, Kent, filled a corner by the east annexe with Himalayan Rhododendrons, interspersed with Berberis Bealii, B. nepalensis, Hamamelis mollis, Drimys Winteri and Eucryphia cordata. In the annexe Mr. Reuthe showed Alpines in pots and dwarf shrubs. (Silver Banksian Medal.)

Mr. JAMES BOX, Lindfield, exhibited hardy flowers. Magnolia alba superba was conspicuous at the back, and we also noticed Iris histrioides

major and I. Danfordiae and I. Krelagei. Narcissus, Tulips, and other bulbous flowers contributed to a very showy group.

Mr. MAURICE PRICHARD, Christchurch, Hampshire, made bright patches of colour with clumps of Hepaticas, Iris stylosa, Primula denticulata in variety, Anemone St. Bavo (scarlet), Megasea speciosa rosea and other Alpines. (Bronze Flora Medal.)

Messrs. WARES, LTD., Feltham, had splendid clumps of Iris reticulata and I. stylosa in their exhibit of hardy flowers, which was backed by dwarf shrubs. Pans of Adonis amurensis, Crocus biflorus and Hepaticas were also shown well.

Messrs. R. WALLACE AND Co., Colchester, showed Crocuses, Irises, Tulips, Fritillaria citrina, F. aurea, F. armeria rubra, Cyclamen ibericum, C. Coum and other early flowers against a background of dwarf shrubs. (Bronze Banksian Medal.)

form of Cyclamen Coum, Orobus cyaneus and Primula megasaefolia are other good subjects.

A rockery was also arranged by the WAR-GRAVE HARDY PLANT FARM, Twyford, for the purpose of displaying Iris tuberosa, Omphalodes Cappadocica, with flowers of clear opal blue colour and Cydonia japonica nivalis.

Mr. CLARENCE ELLIOTT, Stevenage, also contributed a rockery, on which we noticed in flower Crocus biflorus, C. susianus, C. minimus (a little gem with violet flowers), Saxifraga Burseriana in profusion and Iris Danfordiae.

A rock-garden was also exhibited by the Misses HOPKINS, Shepperton, who showed Petasites japonica uncommonly well.

Messrs. G. AND A. CLARK, LTD., Dover, exhibited Primroses and shrubs. The former were some of the best in the Hall, especially those of blue shades. Juniperus pachyphaea elegantissima has very glaucous stems—almost blue.

[Photograph by R. A. Malby.]

FIG. 51.—IRIS CANTAB: A CHANCE SEEDLING WHICH FIRST APPEARED IN MR. BOWLES' GARDEN. (R.H.S. Award of Merit, February 10, 1914.)

Messrs. WHITELEGG AND PAGE, Chislehurst, Kent, exhibited a flat rockery brightened by patches of Iris reticulata, Houstonia serpyllifolia, Saxifraga Burseriana major and Primula denticulata.

Messrs. BARR AND SONS, King Street, Covent Garden, exhibited batches of Irises, Hyacinths, Crocuses, Tulips, Freesias in pots, Primula malacoides and varieties of P. obconica, of which Queen of Roses has rosy-crimson blooms. This firm also exhibited a rockery planted with hardy flowers in big patches. In the centre of the rockery were branched Tulips. (Silver Banksian Medal.)

Messrs. R. TUCKER AND SONS, Brookside Nurseries, Oxford, arranged a rockery in which we noticed choice and rare Alpines. The collection of Saxifragas included S. Burseriana gloria, S. Boydii alba, S. Rocheliana (a splendid clump), and S. oppositifolia grandiflora. A fine dark

Mr. G. W. MILLER, Wisbech, showed boxes of Alpines, including Primula Winteri and Hepaticas, Daffodils, Snowdrops, Christmas Roses and other early flowers.

Mr. GEO. KERSWELL, St. Thomas, Exeter, exhibited flowers of Gentiana acaulis.

The Rev. W. EARLE, Reigate (gr. Mr. Chambers), showed a variety of Cyclamen named Antarctica. The petals of the white, flattish flowers, have wavy edges.

AWARDS OF MERIT.

Rhododendron moupinense.—This is a new, white-flowered, Chinese Alpine species introduced by Mr. E. H. Wilson. The few large flowers remind one of Azalea ledifolia and the Indian Azaleas, but R. moupinense is sturdier in habit, the leaves are much more leathery and tough and the whole plant is nearly glabrous. The flowers are borne in small trusses of one to three blooms,

but they are individually very large, reaching $2\frac{1}{2}$ inches in diameter, and the rounded, overlapping, flat-expanded segments terminating the open, broadly-conical tube give the flowers a roundness and fulness that will be appreciated by florists. The corolla is pure white, of glistening, silk-like, thin and crumpled texture, with two groups of palest sulphur guide dots on the upper part of the tube. The anthers are chocolate-coloured and the stigma green. The tough, dull-green leaves which are more crowded around the tips of the shoots vary in shape from ovate to ovate-lanceolate, being from $\frac{1}{2}$ to $1\frac{1}{4}$ inch in length by $\frac{1}{3}$ to $\frac{2}{3}$ inch in breadth. Shown by Miss ELLEN WILLMOTT, Great Warley.

Iris Cantab (see fig. 51). — A pretty bulbous Iris belonging to the reticulata group, with soft amethyst-blue or pale-violet rather than Cambridge-blue flowers, which show a little white ground at the throat and the typical orange-coloured ridge. It originated as a chance seedling in Mr. A. E. Bowles' garden, and is probably derived from *I. Krelagei* or Max Leichtlin's *I. cyanea*, which were growing near to the place of origin. The flowers have the form of *I. Krelagei*, but they are a little earlier and slightly taller. The leaves overtop the flowers. The variety is especially valuable because of its constitution, for it thrives easily and multiplies rapidly, whilst the colour is very beautiful. The specimens exhibited had been slightly forced under glass. Shown by Mr. HERBERT CHAPMAN.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Gurney-Wilson, E. H. Davidson, F. Sander, R. G. Thwaites, F. J. Hanbury, T. Armstrong, A. McBean, C. H. Curtis, W. Cobb, J. Charlesworth, J. Cypher, W. H. Hatcher, J. E. Shill, W. P. Bound, A. Dye, W. H. White, S. W. Flory, W. Bolton, C. J. Lucas, R. A. Rolfe, R. B. White, C. Cookson, De B. Crawshay and Sir Harry J. Veitch.

The event of the meeting was the magnificent group staged by Lieut.-Col. Sir GEO. L. HOLFORD, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander). Both in the fine quality of the plants and in their artistic arrangement, the group was well up to the very high standard which Sir George has set at these meetings. The Society's Gold Medal was awarded as some recognition of the treat given to Orchidists and garden-lovers generally by so good a display early in February.

The exhibit was arranged with the lower line, or body of the group, composed mainly of showy Laelio-Cattleyas and hybrid Odontoglossums, the centre having the lightly-poised sprays of about 100 fine spikes of white varieties of *Laelia anceps* arching over, and the two sides made up of the elegant white and rose-coloured *Cymbidium insigne* and hybrids of it, which made a fine feature throughout the whole group. The hybrids were principally *C. Alexanderi* and *C. Gottianum*, the Westonbirt variety of which secured an Award of Merit. *C. Dryad* (*insigne* × *Parishii Sanderæ*) was a perfectly new hybrid flowering for the first time, with large, bluish-white flowers with ruby spotting on the lip. The plant bore five flowers on the spike. *C. Holfordianum*, the fine cross of *C. grandiflorum*, was well represented, and at one end stood a grand specimen of *C. Lowi-grandiflorum* with seven spikes. *Cypridiums* were in variety and all good, the Westonbirt variety of *C. Cyclops* and *C. Viking* showing them in even better condition than when they received their Awards of Merit. The many forms of *Cattleya Trianae*, including *C. T. Imperator* and *C. T. Mooreana* were very beautiful. *Laelio-Cattleya Ariel* gave rich yellow and red colour, as also did *Sophro-Laelio-Cattleya Marathon* and some other *Sophronitis* crosses. At one end a grand specimen of *Vanda Watsoniana* bore eight spikes of pretty, white flowers, and near it a batch of scarlet *Sophronitis* was a mass of bloom, and each specimen was worthy of admiration, the *Odontoglossums* and *Odontiodas* being specially fine.

BARON BRUNO SCHRODER, The Dell, Englefield Green (gr. Mr. J. E. Shill), showed four very large and handsome varieties of *Cattleya Trianae*, the best of which, *C. T. Mrs. de B. Crawshay*, secured an Award of Merit. The others were *C. T. The Premier*, a well-known,

good variety; *C. T. The Baron*; and *C. T. Goliath*, a large and finely-formed flower. *Cypridium Pyramus*, a great beauty, secured a First-class Certificate (see Awards).

H. S. GOODSON, Esq., West Hill, Putney (gr. Mr. G. E. Day), showed *Sophro-Laelio-Cattleya Herbertii* and a finely-coloured *L.-C. Charlesworthii*.

SIR JEREMIAH COLMAN, Bart., Galton Park (gr. Mr. Collier), showed a fine plant of the singular *Tainia penangiana*, a good *Miltonia Bleuana*, *Zygo-Colax Wiganianus* in very fine form and the beautiful *Dendrobium Lady Colman* (see Awards). Also a very fine *Lycaste Skinnerii*.

DE B. CRAWSHAY, Esq., Sevenoaks (gr. Mr. Stables), showed *Odontoglossum Boadicea* of good shape and well marked.

E. H. DAVIDSON, Esq., Orchid Dene, Twyford, was awarded a Silver Flora Medal for a good group of rare Orchids, all of fine quality. In the

also shown, but none could compare with the chaste beautiful seedling *O. crispum Palatine*, a model flower of the purest white, and which was superior to any typical *O. crispum* ever imported. *O. eximium Fascinator* was also fine in all respects and rich in colour. Others noted were *Miltonia Bleuana*, with eight spikes; *Odontioda Bradshawiae*, four spikes; a fine *Phalaenopsis Stuartiana*, *Dendrobium nobile virginale*, *Brasso-Cattleya Mrs. J. Leemann*, a good *Brasso-Laelia Digbyano-purpurata* and the new *Odontonia Lucillae* (see Awards).

MESSRS. ARMSTRONG AND BROWN, Tunbridge Wells, were awarded a Silver Flora Medal for a group of hybrids, some of them flowering for the first time and which will be duly recorded. *Cypridium Mrs. E. S. Rashleigh* (*Hera Euryades* × *Bassano*) was a very fine hybrid, nearest to *C. Hera* and with a similar richly-blotched dorsal sepal, but the spotting is larger

FIG. 52.—CYPRIDIUM PYRAMUS.

(R.H.S. First-class Certificate, February 10, 1914. See p. 115.)

[Photograph by R. A. Malby.]

centre was a specimen of a very fine form of the pure white *Cattleya Susanne Hye de Crom*, with handsome hybrid *Odontoglossums* around it, the best noted being a very fine and richly coloured *O. Aireworth*; *O. Louise*, a very pretty spotted flower; *O. ossulstonii*, with a seven-branched spike; a fine form of *O. ardentissimum*; and two *O. Rossii* hybrids. Some scarlet *Odontiodas*, a beautiful specimen of scarlet *Sophronitis* with twenty flowers, *Sophro-Cattleya Thwaitesii*, a good *Laelio-Cattleya Fascinator*, some white *Masdevallia tovarensis*, a very fine white *Lycaste Skinnerii*, and a handsome coloured form and other good things were also included.

MESSRS. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a select group, in which appeared two spikes of the large rose-and-white *Eulophiella Peetersiana*. Some good hybrid *Odontoglossums* were

and darker. *C. Helen II.*, *C. Venus Orchidhurst* var., *C. Beryl* and others were staged, and a good plant of the *Orchidhurst* variety of *Cymbidium Woodhamsianum*; another pretty hybrid between *C. giganteum* and *C. insigne*; some finely-blotched seedling *Odontoglossum crispum*, the brilliant scarlet *Odontioda Keighleyensis*, several *Cattleya Maggie Raphael* alba *Orchidhurst* variety from a batch which has been flowering profusely for several months, and a selection of *Laelio-Cattleyas* were also noted. One of the best plants was *Cattleya Trianae* Mrs. de B. Crawshay.

MESSRS. STUART LOW AND CO., Bush Hill Park and Jarvisbrook, Sussex, secured a Silver Flora Medal for an excellent group containing two plants of the best white *Cattleya Percivaliana* alba, *C. Trianae* alba and other white forms. Specially good also were *Laelio-Cattleya*

luminosa, L.-C. Orpetiana (C. Gaskelliana alba × L. tenebrosa), L.-C. Bella Crowborough variety and some well-flowered Brasso-Cattleyas, Sophro-Cattleyas, Phalaenopsis Schilleriana and Oncidium splendidum.

Messrs. J. CYPHER AND SONS, Cheltenham, were awarded a Silver Flora Medal for a good group of Cypripediums, with examples of Cymbidium insigne, C. Gottianum and C. Alexanderi, with which were well-flowered Calanthes, Phalaenopsis Schilleriana, Miltonia Bleuana and varieties of Cattleya Trianae. Cypripedium Bridgei was distinct and all were excellently well bloomed.

Messrs. SANDER AND SONS, St. Albans and Bruges, were awarded a Silver Banksian Medal for a small group in which were several good examples of their new strain of Odontoglossums raised at Bruges, and which, although flowering for the first time, give great promise. O. Rio-Tinto (gandavense × sceptrum) is a brownish-copper colour with narrow, primrose margin; O. Cyrus (Rolfeae × eximium) is of fine shape and tinted with rose at the back; O. Verulam (Rolfeae × Wilckeanum) is of good shape, pale yellow, heavily blotched, and with white front to the lip; O. St. Bavon (Lambeananum × gandavense) is dark chocolate-red with lighter lip; O. chryseum (Pescatorii × excellens), O. Philomene (Rolfeae × percultum), O. Desdemona (Hallii × ardentissimum) and some others displayed attractive colouring and good shape. Some fine Cattleya Trianae, bright red Odontiodas, Brasso-Cattleyas, Laelio-Cattleyas, Cymbidiums and two hybrid Lycastes were also shown.

Messrs. J. AND A. McBEAN, Cooksbridge, staged a small group of good Odontoglossums, Odontiodas, etc., their brightly-coloured O. Diana var. Gladys gaining an Award of Merit.

Mr. HARRY DIXON, Spencer Park Nursery, Wandsworth, showed some good Odontoglossum-crispum and an attractive hybrid between O. cirrhosum and O. excellens named O. aurosum.

Messrs. W. A. MANDA, St. Albans, staged a good selection of varieties of Cattleya Trianae.

Messrs. SWAN AND PRICE, St. Albans, showed a group of very good Cypripedium excellently well grown.

Mrs. THATCHER, The Manor House, Chew Magna, Somerset, sent a plant of Brassavola glauca, the greenish-white flowers having a purple spot at the base of the lip.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cypripedium Pyramus (Hera Euryades × Mrs. W. Mostyn), from Baron BRUNO SCHRODER, The Dell, Englefield Green (gr. Mr. J. E. Shill). A very fine and distinct Cypripedium with large dorsal sepal, which is white above and heavily blotched with shades of dark purple changing to rose towards the margin. The petals and lip are yellow with dark mahogany-red surface.

Dendrobium Lady Colman (Artemis × Findlayanum) from Sir JEREMIAH COLMAN, Bart. (gr. Mr. Collier). The largest and best hybrid Dendrobium, which had previously secured an Award of Merit. The flowers are white flushed with rose-pink, the large lip having a distinct maroon blotch.

AWARD OF MERIT.

Cymbidium Gottianum Westonbirt variety (churaneum × insigne), from Lieut.-Colonel Sir GEO. L. HOLFORD, K.C.V.O. (gr. Mr. H. G. Alexander). A large and finely-formed flower, white with a pink flush, and crimson spotting on the lip.

Odontioda Margaret Westonbirt variety (Odontoglossum ardentissimum × Odontioda Bradshawiae), from Lieut.-Col. Sir GEO. L. HOLFORD. Flowers of good shape, deep red with light yellow showing on the petals between the blotches and a yellow flush on the lip.

Cattleya Trianae Mrs. De B. Crawshay, from Baron BRUNO SCHRODER (gr. Mr. J. E. Shill). When well-grown, as in the present instance, one of the very finest form of C. Trianae. The broad sepals and petals are light rose-pink; the lip rose-purple in front with rich yellow disc.

Cattleya Trianae Mrs. Phillips, from C. J. PHILLIPS, Esq., The Glebe, Sevenoaks. A very remarkable and beautiful variety with the sepals bearing a distinct line of crimson up the middle, and the petals a broad feather of the same colour. Front of lip purplish-rose.

Cymbidium Schlegelii Southfield variety (insigne × Wiganianum), from W. WATERS

BUTLER, Esq., Southfield, Edgbaston (gr. Mr. Jones). A handsome large form with white flowers flushed with pink. Lip broad, white with reddish-purple spots.

Odontonia Lucelia (O. cirrhosum × M. spectabilis Moreliana), from Messrs. CHARLESWORTH AND Co. A remarkable cross; the hybrid having erect spikes of attractive flowers of stellate arrangement, rosy-lilac with attractive claret-coloured marking.

Odontioda Diana var. Gladys (O. amabile × C. Noeliana), from Messrs. J. AND A. McBEAN, Cooksbridge. Flowers of a uniform scarlet, with yellow crest to the lip. The general appearance is like O. Charlesworthii.

Fruit and Vegetable Committee.

Present: Jos. Cheal, Esq. (in the chair), Messrs. W. Bates, George Woodward, Jesse Willard, Wm. Pope, Edwin Beckett, W. E. Humphreys, J. G. Weston, A. R. Allan, W. Poupard, A. Bullock, G. Reynolds, J. Jaques, Geo. Wythes, H. Somers Rivers, C. G. A. Nix, Geo. Kelf and C. O. Walter.

FRUIT.

Messrs. T. RIVERS AND SON, Sawbridgeworth, Hertfordshire, had an imposing display of various Citrus fruits disposed in a most tempting manner. Well-grown pot plants of goodly size bore large ripe Citrons of pale golden colour or Oranges with brighter skins, whilst the centre of this magnificent exhibit was formed of an arbour of Lemons and Oranges. Such an exhibit of Citruses has probably never before been seen in this country, and it merited the Gold Medal which was bestowed by the Council.

Messrs. SEABROOK AND SONS, Chelmsford, displayed, in the east annexe, a table of brightly-coloured and plump Apples of such sterling varieties as Northern Spy, May Queen, Beauty of Kent, Newton Wonder, Gascoyne's Scarlet, Blenheim Pippin and Cox's Orange Pippin. (Bronze Knightian Medal.)

Messrs. J. CHEAL AND SONS, Crawley, showed several large dishes of their new Apple—Crawley Beauty, which well illustrated its keeping qualities.

VEGETABLES.

Messrs. SUTTON AND SONS, Reading, set up an attractive collection of high-class vegetables. The coloured Kales were very showy and served to draw attention to the adjoining stands of milk-white Broccoli, Savoys, Brussels Sprouts, Mushrooms and saladings. (Silver Knightian Medal.)

Mrs. E. H. DENNISON, Little Gaddisdon, Berkhamsted (gr. Mr. A. J. Gentle), contributed over 40 dishes of Potatoes, all of them being of typical shape and examples of first-class cultivation. (Silver Banksian Medal.)

Messrs. BARE AND SONS, Covent Garden, London, arranged a semi-circular group of coloured Kales.

ANNUAL GENERAL MEETING OF FELLOWS.

The 110th annual general meeting of the Fellows was held at 3 o'clock in the Lecture Room. Sir Harry J. Veitch presided over a large attendance, and was supported by Sir Daniel Morris, Sir George Holford, Mr. J. Gurney Fowler (Treasurer), Rev. W. Wilks (Secretary), and others.

The Chairman said: Since last we met at the annual meeting you are aware of the very grievous loss that the Society sustained in the death of our late President. It was moved at the last Council meeting, and seconded and carried unanimously, that we should ask at the commencement of our meeting to-day that every Fellow present should rise and receive in silence the following resolution.

The whole audience then rose, while the Chairman read the resolution:—

The Fellows of the Royal Horticultural Society in Annual Meeting assembled the 10th day of February, 1914, desire to express their great regret at the death of their late President, Sir Trevor Lawrence, Baronet, K.C.V.O., V.M.H., &c.

They wish also to put on record their profound appreciation.

(1) Of the most eminent services rendered by Sir Trevor to the Society during the very difficult days which beset the commencement of his Presidency in 1885 and the years that followed; and also

(2) Of the patience which he showed during the gradual building up again of the Society during the middle period of his office; and, lastly,

(3) Of the tact and wisdom with which he directed the Society's affairs during the later years of its

prosperity—a prosperity due in no small degree to the personality of its President.

It was proposed by Sir Harry Veitch, and seconded by Mr. J. Gurney Fowler, Treasurer, and carried in silence, all upstanding, "That the above Resolution be entered in the Minute Book of the Society, published in the *Journal* and communicated to Lady Lawrence and to Sir William Lawrence, together with the Address which had been prepared by the Council for presentation to Sir Trevor, but was delayed by his illness and death."

On resuming Sir Harry said: "Those members who have been behind the scenes for many years know more of the work that Sir Trevor did for our Society than those of you who only met him occasionally outside. I am one of those who remember the time when Sir Trevor was asked to take the Presidency in the very dark days at South Kensington. Sir Trevor took the Presidency at that time, when the Society was really bankrupt, but he faced the situation, and although for some years we were not able to see very great progress, we saw some eventually—due, I am sure, to the confidence that was felt in our then President. Sir Trevor was always glad to face any work. He never spared himself any trouble, but from the first, up to the time when we had the misfortune to lose him recently, he gave of his very best to the work of this Society. Sir Trevor, as we all know, was a great lover of flowers. We knew him, perhaps, best as a cultivator of Orchids. He had, without doubt, the finest collection of Orchids, as a collection, to be found in Europe, because he not only bought the more showy kinds, but added to his collection everything he could get that was distinct and beautiful. It was a pleasure to go with him into his houses, and see how he could admire a plant, however diminutive, because of its intrinsic value to him as an amateur. We knew him as an exhibitor of other kinds of plants besides Orchids. He was also fond of fruits, and had received awards for fruits at our show. He was also a keen and enthusiastic cultivator of vegetables, and at the Council table has told us that we ought to pay more attention to vegetables than we do in this country. We have lost our President, but his memory will be green for us for many years. (Hear, hear.) I am glad to think that we have upstairs the portrait, painted a year or two since, which will be a reminder to generations to come of what Sir Trevor was to this Society. We also have what is called the Lawrence Medal, which is awarded to the exhibitor who shows the finest collection during the whole year, and that also will help to perpetuate the memory of our dearly-loved President. After the loss of such a President, our difficulty was great in finding a successor, but I am thankful to say we have in his successor a gentleman who is passionately fond of flowers. I allude, of course, to Field-Marshal Lord Grenfell. Lord Grenfell came to us with a desire to do all he possibly could to maintain the prestige of our Society, and I have to express his very deep regrets that he is not able to be present with us to-day."

The Chairman then read a letter, addressed to Mr. Wilks, from Lord Grenfell, in which he said:—"I fear it is quite impossible for me to be present in the chair at the annual meeting of the Royal Horticultural Society to-morrow, as I have to be in personal attendance on the King at the opening of Parliament. I much regret that I am prevented by duty from attending the first annual meeting after I have had the honour of becoming President of the Royal Horticultural Society.—I am, yours truly, GRENFELL."

The Chairman added that, to show that Lord Grenfell's fondness for horticulture was not confined to this country, he would read a letter which the Secretary received last month from the President and Committee of the Malta Horticultural Society, asking him "to be good enough to convey to Lord Grenfell, the patron and founder of this Society, their heartfelt congratulations for his lordship's election as President of the Royal Horticultural Society. The Society remembers with pride the kind support and encouragement received from his lordship when Governor of this island."

The Chairman thought they would agree they were very fortunate to secure Lord Grenfell as successor to their lamented late President.

Proceeding to refer to the report (Paragraph 3, "New Committees"), the Chairman said that last year the Council informed the Society of the formation of a Parliamentary Committee. During the past year they had formed two

other committees, a Diploma Committee and a Research Committee. "The work of our Society," he proceeded, "is increasing rapidly, and the influence of our Society is increasing rapidly, and it is therefore necessary that those different committees should be formed. There are members of the Council on those committees, and there are also gentlemen from outside, and I am glad to say that both those and the Parliamentary Committee are doing excellent work. Of course, of one of them only the foundation has been laid, but I am quite sure before long we shall find they will render valuable assistance to our Society. The National Diploma in Horticulture is referred to, and in that case we had the assistance and help of the Board of Agriculture, which I think you will admit is a very important matter. We are not going to lose sight of the practical side of the question, and I know gentlemen over from India intending to take this examination in this National Diploma in Horticulture. Therefore its influence will be felt far and wide."

PARLIAMENTARY COMMITTEE.

The Parliamentary Committee (Paragraph 5), Sir Harry Veitch continued, had held twelve meetings between April and December. Perhaps some of them might be surprised at some of the subjects which were named—for instance, the sale of wet coke by weight. They all knew coke was very largely consumed by gardeners in this country, and if, as had been proved, it was thoroughly saturated with water and bought by weight, the purchaser was paying for the water as much as the coke, and they could understand it did not help to heat his house. (Laughter.) It had also to be taken by rail, and then carriage had to be paid for the water as well as the coke. Sir Albert Rollit kindly undertook to bring the matter before the Board of Trade on the Council's behalf, and the Chairman said he was glad to report that Sir Albert had held out hopes that day that they should be able to get something done to minimise the quantity of water that may be legally contained in coke offered for sale.

Referring to Paragraph 6 ("Wisley Gardens"), the Chairman said: "The gardens continue to exercise more and more influence on gardening every year. We had over 14,000 visitors last year. When the gardens were formed—I think some ten years ago—we had 3,000 visitors. Now we have got 14,000, and many of those visitors do not come solely as a matter of curiosity; they come so as to gain information, to ask questions, and therefore it is a thorough school of horticulture. The work is carried on in the most practical possible way. The trials which are conducted there—both for flowers and vegetables—are increasing every year." As an example of the work done, the Chairman mentioned that 217 packets of garden Peas were sent for trial, which had all to be sown, tabulated, and compared, in order to test which were the best varieties. There were so many samples of Antirrhinums that the trials occupied over half an acre. Everybody, he believed, had confidence in the work of the gardens and in the Committee. They were now building a Water-lily tank, and, thanks to the liberality of Mr. Leopold de Rothschild, it was to be stocked with blue Water-lilies from Mr. Rothschild's own collection.

Referring to Paragraph 7 ("Pelargonium Nomenclature"), the Chairman said everybody for years seemed to give names to species as they thought fit. Mr. Fraser, who was dealing with the question, had already named 124 species or varieties, and was proceeding with his task as the plants flowered.

In reference to Paragraph 8 ("Trial of Tulips"), the Chairman said over 4,000 parcels of bulbs had been received. They had arranged for a number of Dutch growers to stay at Wisley for some time, so that the whole collection might be thoroughly studied. He could not pass over this portion of the report without thanking Mr. Cory, of Cardiff, for the very great assistance he rendered to the Society last summer in connection with the trials for Dahlias. Many would think it was difficult to get 7,000 Dahlias together for examination, and the Committee from the Society found nearly 1,000 distinct varieties, 291 being selected for garden ornamentation. It showed the great ex-

tent to which the love of flowers was growing in this country.

Dealing with Paragraph 12 ("Chelsea Show"), the Chairman remarked that last year the show was a very great success, but the Council were not blind to the fact that there were certain faults in connection with the show, which he hoped would be corrected this year. In the large tent there would be no staging, except at the far end for Orchids, where beautiful sprays could be tabled and staged above the ground. The whole of the body of the large tent would have no staging, and all the groups would be staged on the ground. It struck him they would have a beautiful effect, and would be very pleased with that arrangement, which he was sure was a great improvement. No sundries would be admitted to the large tent, but would be put in another tent by themselves, and smaller pot plants would be in a tent.

The Chairman next referred to Paragraph 17 ("Pritzel's Index Iconum Botanicarum"), and said it was intended to bring this most important and valuable work up to date, as they felt the time had now arrived when this should be done. The International Horticultural Exhibition of 1912 had given the work a start by contributing £250, which was earmarked for that purpose. The Veitch Memorial Trustees had given £100, and the Council of the R.H.S. proposed out of their profits to give £250 until such time as sufficient money had been raised. Of course, the work would take a long time, but no time would be lost, and when it was completed they should have the thanks of everybody. The Secretary considered it would cost £3,000.

They had a very interesting conference last year on Primulas (Par. 18). Sir John Llewelyn very kindly came forward and took the chair. The report they had already seen in the *Journal*. Many congratulations had been received on this special report, which was considered one of the very best and most complete ever issued by the Society.

The next conference they proposed was on Saxifrages (Par. 19). It was a most interesting family of plants. They had had much correspondence with all the authorities on this family, more particularly with Dr. Engler, of Berlin, and were hoping to receive from him an advance copy of his monograph, to be published early next year. The Conference would take place in 1915, and if any lady or gentleman had any information, or could make any suggestions, the Secretary would be very glad indeed to have a communication from them.

Referring to the Lindley Library (Par. 24), the Chairman said that £600 was spent last year in purchasing books as additions to the library—money not spent without considerable thought. The Library Committee met every fortnight, and books were submitted to them. They had experts on the Committee, and they would see by the books purchased that they had added some very valuable ones. He hoped they would continue to add such rare and valuable books relating to horticulture as had been offered to them.

MR. FARRER'S EXPEDITION TO CHINA.

In Paragraph 26 it would be seen that the Council had arranged to share part of the expense of another collection. Mr. Reginald Farrer had started for China. They had not involved themselves to a large extent. They thought in fitting the rock garden at Wisley that they should try and get as soon as anyone any novelties which came over. They had spent a considerable sum of money in purchasing plants, and many thousands had been raised from seed and cuttings at Wisley. They must make some allowance for time, and he hoped it would look very much better than last summer, and next summer they would find it still further improved.

The Chairman commended the work of Mr. Wilks, remarking that none of them was aware of the work he had done for the Society. The whole staff, whether there or at Wisley, were loyal to them to the last degree. They, as a Society, could not be more fortunate, and he only hoped they would continue to work for them for many years to come. He moved the adoption of the report and accounts, which he invited the Treasurer to explain to the meeting.

Mr. Gurney Fowler, Treasurer, said the most important item in the accounts was the balance of profit, £8,938. It was not quite so much as last year, when it was £9,194, so that there was a difference of some £256 to the bad, if they might call it so. It was principally owing to the cost of the show at Chelsea, which, of course, had the International Show last year, and it was rather difficult to make any proper comparison of figures. The annual subscription list, he was glad to say, was larger by £915, which showed, he thought, life. The income from investments naturally went up as they invested other funds. The expenses, with the exception of the show expenses, were not anything more than the ordinary expenses which would be incurred in carrying on the increased business. On the capital account, £35 was spent on the hall and £217 on the garden. The account showed details of the money they had invested, he hoped well. It had not been an altogether easy time for the investment of money, but he did not think they were a great deal worse off than a great number of their fellows. All the investments were what they called first-class. Since January 1 a great change seemed to have occurred, and he thought they should find the deficiency nothing like what it was in December, 1913.

The Treasurer pointed out a clerical error in the schedule of investments, where the amount of Local Loans should be £5,800 instead of £8,500, costing £6,006.

The list of new Fellows—95 in all—was adopted earlier in the meeting, and Mr. Mark Fenwick, Stow-on-the-Wold, asked if it would not be possible to limit the number elected each year. The show was getting very crowded now, and there seemed to be a feeling that the Fellows were increasing too rapidly. He suggested that there might be a waiting-list, as in the case of a club.

The Chairman: We won't forget the question.

Mr. Fenwick: I think it might meet the case to increase the entrance fee.

The Chairman: The Council will take that into consideration.

TEMPERED CRITICISM.

Mr. R. W. Wallace, Colchester, referring to Paragraph 14, providing for shows being kept open an hour later, asked what result that was having on the attendances. If the Council were fairly satisfied on that point they would be justified in continuing the arrangement, but as one who was against the innovation, he would ask the Council to consider that there were other people to be considered, and those were the employees of the firms and the owners of the firms themselves.

Referring to the proposal that the Society should take a share in the expedition to China organised by Mr. Reginald Farrer, he asked if the Council considered it a wise move altogether that they should help to finance the expenses of an expedition run in the interests of a gentleman who was practically a trader in horticulture. He spoke as a member of the trade, especially after the remarks of Mr. Mark Fenwick that the Fellows came in such increasing numbers to the shows now. The success of the shows was made by the horticultural trade in Great Britain, and the success of the Society was due to the trade, and to those few amateurs—especially Sir George Holford—who so nobly supported the Society. Therefore he said that the trade exhibitors were deserving of the highest consideration from the Council, and he ventured to point out the restrictions placed upon the trade with regard to the most important exhibitors year by year. Some were extremely harsh, extremely hard, and extremely unfair. Outside exhibitors at Chelsea were threatened if they did not lay down a big deposit that they could not put up exhibits, and the deposit might be taken from them in the end. Those remarks were not made in any spirit of antagonism to the success of the Society. He wished to congratulate the Chairman as representing the President of that remarkable Society on the wonderful growth it had made, and the wonderful position it occupied at the present time, and the wonderful power it still had for the advancement of all sections of horticulture; let them be advanced with equal justice to all concerned.

The Chairman, in reply, said that having the fortnightly meeting open till 7 o'clock was purely tentative. Before they arrived at that decision all the exhibitors were consulted, and the majority expressed a desire that it should be open till 7 o'clock in the summer. If they found that the people did not come, it would be very easy next year to go back to the former time. They were not committed to any great expense in connection with the collector who had gone to China. They had involved themselves to the amount of £100 a year for two years, and they felt, as they were really a horticultural society, they ought to try to get the novelties which might come home as soon as any one else. People came to Wisley and expected to see the latest novelties, and it was only in that way that they could keep pace with the desire of their Fellows. If they waited until the seeds of the plants had bloomed, and until the person who had them had a stock to distribute, they should be some years behind. That was the main object they had in trying to get a portion of the collection.

In regard to a suggestion that the show might be opened an hour earlier, the Chairman said he did not think it would be possible to open an hour earlier. With regard to the Chelsea Show, they were bound to a large extent by what the authorities of the Chelsea Hospital demanded of them. They dictated certain conditions which they were obliged to comply with. When an exhibitor made an exhibit the deposit was returned. They had been disappointed a number of times by exhibitors making an entry, and getting their name in the catalogue, and a certain amount of advertisement, and then not exhibiting. The Chelsea authorities complained of the way many exhibitors left the ground. They excavated the ground, and in the majority of cases the site was not left as it was found. A considerable sum of money was required to put the ground right. They were anxious to meet exhibitors in every possible way, but they had also to please the authorities of Chelsea Hospital.

With regard to a suggestion for more seats at Wisley, the Chairman said it was a very good one.

The reports and accounts were unanimously adopted.

Referring to the elections to the Council, the Chairman said that Colonel Lockwood was appointed to succeed the late President. The elections proposed by the Council were agreed to.

PROPOSED DEVELOPMENT AT WISLEY.

Consideration was next given to the following notice of motion:—

"The Council of the Society be requested to create a Special Trust Fund to carry on and augment the Society's work at Wisley, and this Meeting would approve of a part of the present Surplus Funds of the Society being allocated to that purpose."

Sir Daniel Morris said he moved the resolution on behalf of the Council, which had taken the matter into very careful consideration. The Council wished to submit that day a proposal to the Fellows in order that certain other extensions in the work of the Society might take place. He would mention first of all that this matter of the extension of the work at Wisley was brought forward in July of last year. A committee was appointed consisting of three members of the Council and five members of the Scientific Committee, including Mr. Wilks and Mr. Chittenden. That Committee was appointed to take the matter into consideration and report to the Council. Before the Committee met a large number of circulars were sent out inviting the opinions of the Fellows of the Society on what should be done in order that the work at Wisley might be extended in such a manner as to be of advantage to the Society. About fifty replies were received, and those replies were very carefully gone into, and on the first scrutiny of them the Committee decided to avoid first of all recommending any duplication of work that was being done elsewhere—for instance, at the John Innes Institution, or at Woburn or Rothamsted. Further, they agreed that they would not undertake any work which should rightly fall to the individual. They decided that they would not

recommend any extending whatever in the case of what was not attainable. For instance, suggestions were put forward from time to time that they should undertake certain work which led to nothing definite. They decided they would not allow it. They decided they would in no case subsidise work which lay outside the actual control of the Society. Some of the subjects suggested to them were in regard to their publications. In addition, they were asked to deal with nomenclature, and bring out stud books and catalogues, and so on. They were recommended it would be very useful occasionally to have an exhibition of scientific work, and were again recommended very strongly in some instances that they should assist expeditionary work by various bodies not really connected with the Royal Horticultural Society. Further, they were asked to improve the horticultural experiments and trials at Wisley. Then they were asked to take up the work of extending education at Wisley, and also to introduce at Wisley standard methods of research. They carefully reviewed the work that had already been done or was in course of being done, but when they had had several meetings they decided to confine themselves to three different matters—first of all research; second education; and third, experimental trials of work. Anything he would say would relate to those three subjects, because those were the subjects that were of immediate interest, and those were the subjects that they thought could be taken up at Wisley at once, and results could be obtained that would be a credit to the Society. In research they were recommending that the work should be first of all upon conditions that affected the growth and treatment of plants. They had had many representations made to the Society with regard to losses that were being sustained by nurserymen and others. Those losses were due in many cases to diseases. Those diseases were often brought to the notice of the Scientific Committee. Well, voluntarily, a number of members of the Scientific Committee undertook to look into those diseases. They mentioned, when they could, the name of the disease, and they also gave some general hints as regards the best way of dealing with them. This had not gone quite far enough. They were quite convinced they must do the same as was being done in other countries. They must systematically take up the investigation of those diseases. When disease was caused by insects they must try and find out the natural enemies of those insects, and if not already in this country, it might be possible to introduce them. It was not enough to try to destroy them by insecticides. There were many other ways. Then the Committee recognised fully that, while useful work had been done and was being done at Wisley, the accommodation and the staff were quite inadequate for dealing with the questions waiting immediate attention. Then under the head of education they were now going to institute a Diploma of Horticulture. They found that the scientific work at Wisley, if they were to keep up to the standard of the Diploma, wanted revising throughout. They recommended that the Society should direct its earnest attention to promoting a National School of Horticulture at Wisley, and provide for the output of generations of practical gardeners, scientifically trained, who would be the skilled horticulturists of the future. Experimental and trial plots had been carried on for many years at Wisley, and, considering the staff and the opportunities there, he (Sir Daniel) believed the trials had been appreciated, but if they were to be placed on a thoroughly scientific footing, and if they were to command general confidence, it was necessary for the Society to increase the staff at Wisley. First of all there should be a Director appointed of proved capacity, wide knowledge of plants, and a man with a talent for administration. Under that Director there would be three experts, one for the fungous diseases, an entomologist for insect diseases, and a chemist; those three to be resident at the garden. In order to provide for the scientific staff that he had just suggested, it would be necessary to incur an expenditure of something like £2,500 a year. In addition to that, it would be necessary to have a capital expenditure which had been estimated as something between £6,000 and £7,000 for laboratories and buildings, also for equipment of labo-

ratories and for the supply of material for carrying them on. As stated in the balance-sheet, Wisley was not absolutely the property of the Society. If anything should happen that they should cease to carry on Wisley as an experimental garden, they would be liable to lose control of it. The gardens were vested in Trustees; three members of the Council were amongst the trustees, and there were three outside trustees. All the expenditure which so far had been made on the gardens had been expended on property which really belonged to the trustees. Now that they were going to increase their expenditure at Wisley, they ought certainly to make sure that they were protected, that the work there would continue, and that the Society would feel that there could not be any possible chance of the gardens being lost to the Society or to horticulture. The way that might be done would be by creating a trust fund under the terms of the resolution. In order that they might keep control of the gardens and provide for the work being carried on there permanently for horticulture, it was necessary for them to do something in the way of endowing the gardens. They were asked by the Council at that meeting to increase the expenditure in regard to the Wisley Gardens, and in order to show the reasonableness of that proposal he ought to mention that many years ago the Council held 33 acres of land at Chiswick. That was renewable from year to year at the Society's pleasure. Because the Society fell into difficulties and was unable to maintain those 33 acres, the Society gave them up and accepted an agreement for 14 acres simply from year to year on an ordinary lease. It was an extraordinary thing that at that time they had a most valuable property there and they were obliged to give it up simply because the Society fell into difficulties and could not carry it on. They had also to bear in mind that the Lindley Library, also owing to difficulties, was actually sold because they could not maintain it. Since then they had been trying to get back a library in the name of the Lindley Library, and at present, after an enormous amount of trouble and expense, they were getting back a library which was really worthy of the Society. In the case of Wisley, were they going to allow any chance of losing it to horticulture, or were they going to make an effort to save it? They had something like £80,000 surplus money. Last year there was a clear profit of nearly £9,000. They had got a Hall that cost them £40,000, and were getting a regular income from the Hall of £2,000 a year, which was practically 5 per cent. on the outlay. Taking all those circumstances into consideration, what the Council arrived at was the conclusion that they should be willing to set aside a certain portion of that large surplus as an endowment for Wisley Gardens and for the maintenance of Wisley as a first-class School of Horticulture. It was most important, he wanted them to bear fully in mind, that the reorganisation now contemplated by the Council was strictly supplementary to the work now in hand. They were spending there now £3,000 a year. They had expended £20,000 in buildings and in various improvements, so that they had really a large stake in the garden. Now the point was that the Council by the proposal that he moved that day sought to safeguard the continuance of the work at the garden, and in all its branches to make it more efficient by a higher organisation and administration as far as the experimental work and the trials were concerned. They had been told they were capable of improvement. The only way in which they could be improved was to place them under scientific control. That control would be available if this scheme was adopted. It would secure to the Society a status in the world of horticulture enjoyed by no other society, nor even any other body throughout the world. Great and wide as was the work of the Society, there was not a shadow of doubt that the alterations suggested would be great improvements, and would in every way make the work of the Society completely and thoroughly worthy of the prestige it had always enjoyed.

Mr. W. Cuthbertson, who seconded the motion, said he was interested in the matter from a different standpoint to Sir Daniel Morris. He was a practical man, and, after all, he supposed 75 to 85 per cent. of the Fellows of the

Society were practical men. They must remember that a truly scientific Society would appeal only to a minority of the Fellows. He was glad to be assured by Sir Daniel Morris that the practical side of their work at Wisley was not to be overshadowed in any respect whatever. Did he for a moment think it was, he should be a critic of a scheme instead of a supporter. For some time there had been a very insistent demand in the Press for the Society to make this forward movement, and the Committee was inundated with suggestions. It was a very difficult task to select what were thought to be the best. He quite agreed there was room for improvement in what might be termed the practical work of Wisley. All of them knew that it had been conducted very efficiently by Mr. Wright and his staff within the bounds allotted to them. They had done their utmost, but those who knew the trials best knew how much they might be improved. A number of them had been trying to get the Council to adopt better methods for some time, but immediately the professors said it was impossible to divorce experimental work from the side of scientific research, the Council accepted that doctrine, and they got forward and said they were going to achieve something. He thought it would not be out of place to say that the Committee had recommended to the Council, and he had no doubt the Committee would honourably carry it out, that in any changes which might come the position of the present heads at Wisley would not be affected. He thought that should be said straight away. When he was on the Committee he demanded that they should get an answer to that question, and they got that assurance. He thought they would have to trust the Council that the scientific men would not run away with them and overshadow the practical men, and so long as the Council was composed of men like Sir Harry Veitch, Mr. May, and Mr. Hudson he thought they could do so. They must always remember that the Society was a Society of Gardeners. He hoped that the success which had hitherto followed the action of the Council would continue to follow it. He heartily agreed with Sir Daniel Morris when he said that if these new developments were carried out on proper lines they would give the Society increased prestige and renown.

Mr. H. B. May, who supported the proposal, said he was pleased his bantling had such excellent sponsors as Sir Daniel Morris and Mr. Cuthbertson. He (Mr. May) had long cherished the hope that the society, sooner or later, would undertake such a work as that indicated in the resolution, but he thought it prudent to wait until the time when its resources would permit it to be done without detriment to existing arrangements. His friend Mr. Cuthbertson had referred to the anxiety that existed or might exist as to the practical work at Wisley being overshadowed and dominated by scientific men. If for one moment he thought such a result was probable, the present proposal would have no sturdier opponent than himself. If the proposal met with their acceptance, as he trusted it would, it would lead to the appointment of a management committee, and in appointing that committee he felt certain that the Council would not be influenced by circumstances of wealth or social position, but would select men who were qualified to carry out the important duties which would be entrusted to them. The scientific members of the committee who had formulated this scheme he felt sure entirely recognised the efforts of those lay members associated with them in their work, and it was his hope that on a similar fusion of interests on the management success would be based.

Prof. Bayley Balfour thought the proposal was a natural development of the responsibility of the Society which it accepted when it took Wisley. He did not think he need emphasise the importance of the points Sir Daniel Morris had put before the Society. He would like especially to emphasise that there was no point of antagonism between practical horticulture and science in any suggestion that had been made. They often heard of a great number of institutions doing scientific and research work for horticulture and agriculture. That was true, but he thought none of them had

the same position and the same advantages as were attached to Wisley and the property of the Royal Horticultural Society. It seemed to him that was an ideal place where practical horticulturists and scientists could meet and work together for the good of horticulture and also for the good of science. It had been pointed out that practical horticulturists had done a good deal for the Society. If the Society imported a practical access of strength on the scientific side, members could have a body of scientific opinion to which they could go and appeal with a right in a way which they could not exercise in relation to any other institution. Science itself would always benefit from the practical horticulturists. He had frequently said that the practical horticulturist was a great experimenter. A great deal of the work of the gardener was empirical, and died with him, and the practical gardener going to Wisley with some problem he could not solve, and which had occurred to him in his work, might be able to get the organised methods of science applied to it, and not only help himself, but also by giving of his empiricism to science he would directly and emphatically benefit science. He thought it was only by such a transfer of funds that the scheme could be carried out. He hoped the motion would be carried, because he was sure there was no place in the world where the opportunities were greater for benefiting practical horticulture as well as science than at Wisley.

Mr. Chas. E. Shea congratulated the Council most heartily on the step they had taken. He asked if the adoption of the scheme was to be deferred until an appeal was made to the public, or could it be done immediately.

The Chairman said there would be no appeal. Mr. Shea asked if there would be an opportunity for members to consider the scheme in greater detail, or would it be finally adopted that day. He did not like the phrase about "things not attainable" in Sir Daniel Morris's speech.

Sir Daniel Morris replied that so far as the unattainable was concerned, they thought they had better deal with the things of immediate interest that would be of practical value, and meet the demands of horticulturists first of all. He thought a society with £30,000 surplus could not very well appeal to the general public, and if it did he did not think it would get any very large return. He thought they had better accept the situation as it was now. They could not put the scheme in hand unless the meeting accepted it, so far as it had been explained to them.

The matter was put to the vote, with the result that the resolution was unanimously adopted.

HORTICULTURAL CLUB.

FEBRUARY 10.—The annual meeting of the members of the Horticultural Club was held on Tuesday last at the Hotel Windsor, the home of the Club. The President, Sir Frank Crisp, Bart., presided.

The annual report for 1913 showed that the Club continues to prosper and increase in membership. For the first time in its history it registered 200 members in November last, and the total is now 209. Thirty new members were elected during the year.

A separate report of the receipts and expenditure, prepared by the Hon. Treasurer, showed that the gross income for the year was £377 7s. 11d., including a balance brought forward of £152 13s. 8d., also the contribution of Sir Frank Crisp for the purchase of the billiard table. The expenditure was £235 6s. 7d.

Messrs. H. R. Darlington and E. A. Bunyard were elected members of the Committee in place of Messrs. C. E. Shea and A. H. Pearson, who resigned. Mr. George Bunyard retired from the office of Trustee, and Mr. H. R. Darlington was appointed to fill the vacancy.

THE ANNUAL DINNER.

Later in the evening the members assembled on the occasion of the annual dinner, at which Sir Frank Crisp presided. There was a company of about 100, including ladies. The tables were charmingly decorated with flowers and foliage plants by Messrs. James Veitch and Sons.

After the usual loyal toasts, Mr. Arthur W. Sutton gave the toast of "The Horticultural Club." He referred to the greater comfort of

the new club room and other privileges, such as the presence of ladies at the house dinners—a concession which the members greatly appreciated—and to the opportunity which the Club afforded for meeting distinguished members of the horticultural world, and learning what they were doing. They were much indebted to their President, who had not only entertained them on the occasion of the annual outing, but had contributed in many other ways to the comfort of the members.

The President, in response, said that the Club was prospering and its financial position was sound. He thanked Mr. Sutton for his kind remarks, and if he could do anything to forward the interests of the Club he would always be happy to do so.

The toast of "The Visitors" was proposed by Sir Harry J. Veitch. Miss Willmott, one of the most distinguished lady horticulturists, was with them, also Sir Sidney Olivier, Secretary of the Board of Agriculture and Fisheries, and Professor Veitch, from America, with whom he believed he could claim a common ancestry. Miss Willmott expressed pleasure at being present, and thanked Sir Harry Veitch for his kind remarks. Sir Sidney Olivier and Professor Veitch also returned thanks. Sir Sidney referred to the work of the horticultural branch of his department, which at present was mainly concerned with pests and diseases, but they hoped in time to get in touch with other branches of gardening.

The toast of "The President" was proposed by Mr. W. B. Cranfield. He referred to the many institutions and societies with which Sir Frank Crisp was connected and his great love of gardening as his beautiful gardens at Friar Park testified. Mr. A. Worsley gave the toast of "The Hon. Secretary, Mr. R. Hooper Pearson."

ROYAL GARDENERS' ORPHAN FUND. ANNUAL MEETING.

FEBRUARY 6.—The annual general meeting of subscribers to the Royal Gardeners' Orphan Fund took place at Simpson's Restaurant, Strand, on the date above named. The Chairman of the Executive Committee, Mr. Henry B. May, presided. There was no election on this occasion, as explained in these pages last week: all the candidates on whose behalf applications had been made for relief were placed upon the fund by resolution as proposed by the Committee.

The proceedings were as follows:—After the minutes of the last meeting had been confirmed the secretary read the report of the Executive Committee for 1913. This was as follows:—

It is with the liveliest sense of gratification that the Committee has once more to congratulate the supporters of the Fund on its continuously increasing prosperity and usefulness, as apart from the receipt of a one-third share of the net profits of the Royal International Horticultural Exhibition, 1912, amounting to £765 0s. 10d., the receipts from all the ordinary sources of income show an appreciable increase over the previous year's total. At the same time the amount disbursed in allowances to the children elected to receive the benefits of the fund has been increased to the extent of £62 2s. 6d., the total expenditure for the year being £1,868 12s. 6d., the largest amount yet expended in any one year since the fund was established.

The allocation to the fund by the directors of the Royal International Horticultural Exhibition, 1912, of such a substantial contribution, afforded great satisfaction to the Committee, inasmuch as its receipt enabled the whole of the twenty-five candidates at the last election to be placed on the fund, and also afforded it an opportunity for making a somewhat belated investment, enforced by the rules. Your Committee gladly embraces this, the earliest opportunity that has been afforded it, of expressing the gratitude of all supporters of the charity to the directors for their generosity.

The number of children supported by the fund at the commencement of the year was one hundred and twenty-five, and there were then twenty-three candidates waiting for election, who in their sore need of help were receiving temporary relief. At the annual meeting in February twenty-five candidates appealed for election, but at the time when the arrangements for the annual meeting were made the Committee could not see its way, prudently, to make provision for the addition of more than nineteen to the list of full-pay beneficiaries. Happily the substantial gift previously alluded to came along, and the six unsuccessful candidates at the poll were elected by special resolution, with the hearty approval of all present. During the year fifteen children ceased to receive the benefits of the fund through the operation of the age limit, and the Committee believes that it will be a source of gratification to the subscribers to know that through their generosity most of these children received extra grants to assist in providing them with much-needed outfits on entering upon the various forms of employment provided for them. Up to the close of the year only nineteen candidates had sought the aid of the Fund, and as about the same number will retire

during 1914 the Committee has pleasure in recommending that they be all placed on the Fund this day by resolution.

The annual Festival, held on May 15th, again brought together a large company to the Hotel Cecil, and with such an enthusiastic lover of his garden as Col. the Right Hon. Mark Lockwood, M.P., in the chair, it goes without saying that the function was a most delightful one socially, and financially of the most gratifying character. The genial Chairman, whose humorous sallies and pointed wit add to the gaiety and enthusiasm of any company in which he may find himself, made a stirring appeal to all present to help by their generous contributions to his list to make the Festival a great success, the more especially as the Fund was in need of wider support, and had to depend largely upon the dinner for its income. A garden, he pointed out, gave for the small amount expended a great return in providing a constant fund of pleasure, which could never fail but was always increasing. Many there were, however, who keenly enjoyed the pleasure of their gardens, and who thought when they had paid their gardeners that they had done all they were expected to do; but they should remember that many gardeners died before they were able to make any provision for their dear ones left behind, and it was the bounden duty of employers to help the Fund which conferred its inestimable benefits on so many helpless orphan children, and was so capably administered.

The response to the Chairman's appeal, which included a generous donation from himself, one hundred guineas from Mr. Sherwood and his son, fifty pounds each from Mr. Leonard Sutton and (the late) Mr. J. Newton Mappin, and one hundred and fifty-five pounds from friends in Covent Garden Market, was of a most gratifying character. Your Committee feels under the greatest obligation to Col. Lockwood for his kindness in presiding, and greatly valued help, and tenders him its most grateful thanks. It also most cordially invites the supporters of the Fund to add Col. Lockwood's name to the list of Vice-Presidents.

To the Stewards at the annual Festival: to the Honorary Local Secretaries, and especially the representatives of the Fund in the Leeds, Reading, and Westerham districts, Mr. Carver, Mr. Neve, and Mr. Rowe; and to the Committees of the Chislehurst Gardeners' Society, the Altrincham Gardeners' Association, the Bradford and District Chrysanthemum Society, the Reading Gardeners' Association, the Spem Valley Gardeners' Paxton Society, the Sevenoaks Gardeners' and West Kent Chrysanthemum Society, the Croydon Horticultural Society, the Wargrave Gardeners' Association, and the Reigate Chrysanthemum Society, one and all are most cordially thanked for their continued devotion to the charity and earnest endeavours to extend its usefulness.

For greatly valued contributions, derived from opening their private gardens—so rich in beauty and interest to all garden lovers—in aid of this and other charities, the Committee again desires to express its gratitude to the Rt. Hon. Mary Countess of Ilchester and Sir Frank Crisp, Bt.

The Fund has, alas! during the past year suffered grievous losses by the hand of death. The late Sir Trevor Lawrence, Bt., early evinced his kindly interest in the work of the Fund by becoming a Vice-President in 1890, and subsequently in 1904 by presiding at the annual Festival, which proved one of the most successful of the series which had been held up to that date. His constant support, so generously given, will be greatly missed. The late Mr. J. Newton Mappin, who was present at the last annual Festival, was a most liberal benefactor on that occasion. Of other generous supporters at various times, and some of them highly valued annual contributors, the Committee has very regretfully to include the names of the Right Hon. the Countess of Hambleton, Mr. Martin John Sutton, Mr. R. A. Milligan Hogg, the Right Hon. G. W. Palmer, Mr. Robert Sydenham, Mr. Nathaniel L. Cohen, Mr. A. Kingsmill, and Mr. Amos Perry.

To the Auditors, Mr. P. Rudolph Barr and Mr. Frank Reader, the Committee again desires to tender most hearty thanks for their careful examination of the accounts presented herewith. The retiring auditor, Mr. Reader, has so admirably filled the position so long held by the late Mr. Rowan that the Committee has the greatest pleasure in recommending his re-election.

The members of the Committee who retire by rotation at this meeting are: Mr. G. H. Barr, Mr. G. H. Cuthbert, Mr. W. Howe, Mr. J. Lyne, Mr. G. E. Messer, Mr. W. Poupard, Mr. T. W. Sanders, and Mr. W. P. Thomson, and, all being eligible, offer themselves for re-election.

In moving the adoption of the report and balance-sheet, the Chairman said that there was every reason to be satisfied with the result of the year's working. The receipts from donations and subscriptions had not only been good, but they showed an increase over the amount collected in 1912. It was very seldom indeed that the Committee found itself in the position in which it stood that day—namely, being able to recommend the meeting to place by resolution all the candidates for election—but there was no other course that would have been justifiable in the circumstances. There were reasons for knowing that there would be nineteen vacancies in the coming year amongst the annuitants, and that was the exact number of candidates awaiting election. He thought no one would regret the action of the Committee in determining to dispense with the election. The money was given them to spend upon relief rather than to hoard. The adoption of the report was moved by Mr. GEORGE GORDON, and was carried unanimously.

Mr. T. W. SANDERS moved a vote of thanks to Colonel Lockwood, M.P., for presiding at the festival dinner. He referred to Colonel Lockwood's interest in his own garden, and to his humorous and genial presence at the dinner, also to his eloquent appeal for support on that occasion. After being duly seconded the resolution was adopted. On the proposition of Mr. R. HOOPER PEARSON, Mr. Frank Reader was re-appointed auditor. The retiring members of the Committee were re-elected, and on the proposition of the Chairman Mr. B. Wynne was re-appointed secretary at the salary of £200. At this point Mr. PEARCE moved a resolution to the effect that the following candidates be elected:—Albert F. Alderman, Kathleen B. Appleford, Winifred S. L. Barnes, Marjorie Birchenough, Margaret Annie Goff, Elsie Norah Holloway, Henry Charles Holloway, Lena Phyllis Link, James George Link, Jack Perry, Ronald Perry, William Pettit, Alan Piper, Alex. Livingstone Reid, Leslie M. W. Reid, William Thomas Scott, William Slater, Philip R. Smith, Sidney A. Smith. The resolution was seconded by Mr. RIDGEN and carried unanimously.

In the evening a company of about thirty members of the Committee and their friends dined together at the same hotel.

SCOTTISH HORTICULTURAL.

ADDRESS BY THE PRESIDENT.

FEBRUARY 3.—The monthly meeting of this Association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 3rd inst. Mr. King, the President, was in the chair, and there was an attendance of 70 members. The President delivered his opening address for the session, taking as his subject "The Gardener's Education." We publish the following extracts from Mr. King's paper:—

"By the term 'gardener' I do not mean the mere student of horticulture, who may take up the subject as a pastime or a hobby, or, as is more frequently the case, with a view to the theoretical teaching of it, but the practical man, who has to take it up seriously as a means of livelihood.

"In Scotland the only organised horticultural education is to be found in the agricultural colleges. We have an excellent day course of instruction in the Edinburgh and East of Scotland College of Agriculture, and evening classes are also provided there, and there are horticultural courses in the other agricultural colleges also. But these courses are not within the reach of the working gardener. The only other institution from which the working gardener may derive educational benefit is the Edinburgh Royal Botanic Garden, into which both young gardeners and young foresters are taken for a period for the purpose of going through a course of instruction in the sciences underlying the practice of gardening and forestry, and where they are provided with subsistence in the form of work and wages. Under the Education (Scotland) Act of 1908 Burgh and County Secondary Education Committees are empowered to give assistance to such men by giving 'contributions in aid of the travelling expenses and the maintenance when residing away from home of persons selected by the Committee to attend special courses within or without their district provided by the governing body of an agricultural college, a technical college, or other central institution.' But, useful as this provision may be in many cases, it scarcely meets the case of the working gardener. These bursaries vary in amount according to circumstances from £10 to £30 per annum, and they are generally tenable for three years, but a young man could scarcely subsist on these amounts without some other means of support.

"It is highly desirable that, in the interests of the young men themselves, there should be some linking up of their work with their education, and it is, therefore, almost essential that the two things should be under the same control. Now, how is this to be accomplished? So far as I can see, the only way out of the difficulty would be to provide something in the shape of horticultural experimental areas in connection with the agricultural colleges, where the labour of the men could be utilised, and for which they would receive part payment in the form of technical instruction, as is done in the Royal Botanic Garden and in the Forest of Dean, and I can see no reason which can be urged against a plan of this sort that could not be urged against a demonstration area in silviculture or a demonstration farm in agriculture. If a sufficiently large garden were attached to each of the agricultural colleges to employ, say, a dozen to twenty young gardeners in each for a sufficiently long time to enable them to pass through a course of scientific instruction, as is done in the Royal Botanic Garden for both gardeners and foresters, it would not only bridge over the gap which separates the working gardener from the college courses at present, but it would give a steady supply of highly-trained, practical men. So far as I can see the plan would not be impracticable, and if something of the sort could be instituted in connection with the agricultural colleges it would do an immense service to horticulture, and would be an inestimable boon to a large and deserving body of men. Moreover, it would not deprive the men in any way of their independence. They would give their labour for the benefits they received, and it would give young men of exceptional ability an opportunity to place their foot on the ladder of promotion more securely than they could hope to do otherwise, while it could have no other effect than to raise the status of the gardener."

CASH STATEMENT FOR THE YEAR ENDING DECEMBER 31st, 1913.

RECEIPTS.		EXPENDITURE.

P. RUDOLPH BARR } Auditors.
FRANK READER }

January 20, 1914.

The exhibits were *Garrya elliptica* and *Helleborus guttatus*, from Mr. COMFORT, Broomfield; *Acacia Baileyana* and *Eucalyptus Globulus* (in flower), from Messrs. TODD AND CO., Edinburgh; and *Camellias* from Mr. McDONALD, Trinity Cottage, Edinburgh.

At the meeting to be held on March 3, Mr. G. M. Taylor will read a paper entitled "A Talk About Potatos."

Obituary.

MRS. W. L. CORRY.—We regret to record the death of Mrs. W. L. Corry, wife of Mr. William Longman Corry, head of the firm of sundriesmen, of Bedford Chambers, Covent Garden. Mrs. Corry passed away on the 8th inst. at St. Katharines, Caterham, Valley.

H. J. CLAYTON.—The news of the death of Mr. H. J. Clayton reaches us shortly before going to press. Mr. Clayton, who retired from the charge of Grimstone Park Gardens, Tadcaster, Yorkshire, in April, 1907, after 35 years' service, was a frequent contributor to these pages, his notes being usually signed *Yorkshire Gardener*. We hope to give particulars of Mr. Clayton's work at Grimstone Park and elsewhere next week. In the meantime we may express the very general regret that gardeners will feel for deceased, whose strong personal character and gardening skill placed him amongst the leading gardeners of his day.

ANSWERS TO CORRESPONDENTS.

COLEUS LEAVES SPOTTED: *G. R.* The injury has been caused by deleterious fumes. There is no disease of any kind present.

CLUBBING IN CABBAGE: *E. Y.* Dress the soil with lime and sulphur, applying the lime now at the rate of 15 cwt. per acre, and the sulphur later in the spring, using 5 cwt. to the acre. Do not grow Cabbages or any of the Brassica family on ground that has been recently cropped with these vegetables for at least a year.

LILIUMS WITHERING: *G. A. P.* The injury is at the roots and has been caused by a minute white worm—*Fridericella bisetosa*. The only certain remedy is injecting carbon bisulphide into the soil.

MANURE FOR POTATOS: *W. L. M.* Your query could have been better answered had you informed us if the ground has been manured with dung. If it has, and the soil has been properly cultivated, then a dressing of superphosphate of lime, 1½ to 2 lbs. per square rod, applied to the surface previous to planting would be suitable. If the soil is very poor re-dig the ground at once, first dressing it with sulphate of potash at the rate of 2 lbs. to the square rod, pulverising the soil as thoroughly as possible, and at the time of planting apply superphosphate as above. As the soil is heavy apply a slight dressing of ground lime, say ¾ lb. to the square rod, a week or two subsequent to planting. Once growth is well started, or when the haulm is 6-9 inches in height, apply a dressing of superphosphate 1½ lb. and sulphate of ammonia 1 lb. per square rod, and hoe the soil afterwards. Remember that constant stirring of the soil with the hoe, and an occasional deeper disturbance with the fork, is of the greatest value as a means of increasing Potato cropping. Plant main crop varieties well apart, as they need more room than is usually given them.

MELON: *E. Y.* The Royal Horticultural Society is conducting a trial of Melons in the Wisley Gardens this season. Send ten seeds of the variety not later than the end of the present month, addressed to the Superintendent, R.H.S. Gardens, Wisley, Ripley, Surrey. There is no fee to pay for varieties sent for trial.

MUSHROOMS: *Subscriber.* Better results are often obtained with Mushrooms when cultivated in simple sheds than when grown in up-to-date Mushroom houses. Nothing answers

the purpose better than an old shed, but draughts of cold air must be excluded. It is an advantage to thatch the portion where the bed is formed, so that a moist atmosphere and uniform temperature may be maintained. Horse manure is undoubtedly the best for the purpose, but it is not essential to have fresh droppings only; indeed a reasonable amount of short litter is beneficial, if the long straw is removed.

NAMES OF PLANTS: *D. F.* *Taxodium distichum*; Swamp Cypress.—*A. R.* *Garrya elliptica*.—*B. C.* (1) *Akebia quinata*; (2) *Eranthemum pulchellum*; (3) *Eupatorium Weinmannianum*; (4) *Dendrobium primulinum*.—*R. O. S.* (1) *Masdevallia amabilis*; (2) *Eria floribunda*; (3) *Bulbophyllum auricomum*; (4) *Tainia barbata*.—*H. C. (Surrey)* (1) *Begonia sub-peltata*, garden form; (2) *Calanthe Regneri*.—*Constant Reader.* *Billbergia nutans*.—*Lady I.* *Azara microphylla*, a Chilean shrub, hardy in this country.—*A. B. (Somerset).* *Brunfelsia (Francisca)* latifolia, the blue flower, and *Griselinia macrophylla*.—*Enquirer.* (1) *Chimonanthus fragrans*; (2) *Garrya elliptica*.—*G. C. R.* *Sparmannia africana*.—*E. A. H.* *Polystichum angulare*.

PEACH TREE: *M. P.* There is no disease present; the root system is unsatisfactory.

PELARGONIUMS DISEASED: *J. H.* Sprinkle the leaves and soak the soil once a week with a

THE LATE HENRY J. CLAYTON.

solution of sulphate of iron—½ oz. in a gallon of water. There is no disease on the Potatos.

PLANT IN A VACUUM: *Mulligan.* An active plant placed in a vacuum would die very speedily; for in the first place the gases dissolved in its sap would be given off with some violence, and hence would be apt to disorganise the living substance; and in the second place, all vital activity would be stopped owing to the absence of oxygen. Respiration, the oxidation process which results in a liberation of energy would either cease altogether or at best would be insufficient to supply the energy necessary for the plant's activity. Finally, in the absence of carbon dioxide, all manufacture of sugar and starch would cease, and hence no new material for growth would be produced. Reference to the results of growing plants under reduced atmospheric pressures will be found in Jost's *Plant Physiology* (English translation), published by the Oxford University Press.

POTASSIUM SULPHIDE: *H. W.* For destroying Orange Rust on Roses dissolve 1 oz. of the sulphide popularly known as liver of sulphur in a quart of hot water, and make this up to 2½ gallons with cold water.

ROSE ON A GREENHOUSE WALL: *Denny.* Prune some of the lower shoots severely with the object of securing strong, basal growths that will furnish the bottom part of the wall.

SCENTED FOLIAGE POT PLANTS SUITABLE FOR EXHIBITION. *W. R.* *Aloysia citriodora* (syn. *Lippia citriodora*), lemon-scented Verbena; *Myrtus communis* var. *angustifolia*, the Box-leaved Myrtle; *Pelargonium capitatum*, the Rose-scented Geranium, and *Eucalyptus citriodora*, the scented Gum Tree, would be suitable for your purpose. The plants may be obtained from the nurserymen.

SCENTED PLANTS FOR THE HERBACEOUS BORDER: *G. S. Y.* The following list of sweet-smelling plants offers a selection for planting in the hardy flower border:—*Aloysia citriodora*, Lemon-scented Verbena (tender in many localities), *Artemisia Abrotanum*, *Asperula odorata*, *Melissa officinalis*, *Ocimum Basilicum*, Carnations, Pinks, *Matricaria Chamomilla*, Wallflowers, *Santolina chamaecyparissus*, *Cytisus fragrans*, *Eucalyptus*, *Marrubium vulgare*, *Iberis odorata*, *Narcissus jonquilla*, *N. Tazetta*, *Lavandula vera*, *Lilium candidum*, *Lily-of-the-Valley*, *Malva moschata*, *Mentha odorata*, *Rosmarinus officinalis*, *Tanacetum vulgare*, *Thymus vulgaris*, *Tussilago iragrans* and Violets.

SLOW COMBUSTION STOVE: *M.* If the stove has sufficient draught to consume the coal dust it may be mixed with the coke used as fuel. Fine coal would be useful for banking up the fire the last thing at night. Try the effect of damping the coal dust before burning it.

SLUGS: *C. H.* Your plan of placing Cabbage leaves as traps is one of the best methods of combating these destructive pests, and you should continue to employ this system. Soot and lime placed around the plants act as deterrents, but we have known the slugs to reach the plants when these materials were used, probably by burrowing. The best system we know is searching for the slugs amongst the crops at night with a lamp. Slugs are very fond of Oranges, and if these fruits are halved, the pulp scooped out, and set hollow side downwards, you will trap numbers of them.

STERILISING SOIL BY STEAM: *J. B.* and *G. D.* You must first obtain a suitable boiler for furnishing the steam, which may be led through pipes made of gas-piping, furnished with a gridiron arrangement for the outlet of the steam (see fig. 54). The gridiron may be 2 feet 6 inches square, and if tyne are used

FIG. 54.—THE "HARROW" AND "GRIDIRON" METHODS OF STERILISING SOIL.

these should be about 9 inches long. You will require to construct a box without top or bottom, capable of holding a cubic yard or more of soil. The instrument is placed tyne downwards in the case, the soil is filled in, and steam at a pressure of 50 to 80 lbs. is blown in for twenty minutes. As each yard of soil is treated it should be thrown into a heap to cool gradually. By having two instruments at work the boiler may be kept constantly going. The heap should not be exposed unnecessarily to rain as valuable plant food speedily forms, and is liable to be washed out. The instrument without tyne may be used in the same manner, the steam escaping from a series of small holes drilled in the pipes.

THE TESTING OF FARM SEEDS.

IN the course of his interesting address to the Farmers' Club recently, Professor Biffen, of Cambridge, gave an account of the results of tests carried out on 2,500 samples of farm seed. Of the samples, some were sent by the members of the Royal Agricultural Society, some, which represented generally the seed sold by the small dealers in provincial towns, were received from the Board of Agriculture, and some were selected by Professor Biffen himself from casual village dealers—greengrocers and ironmongers.

The results of the tests and analyses show that whereas in the case of Wheat and Barley the seed generally has a high germination capacity, in that of Oats the seed of the last year or two has proved somewhat poor in germination.

When defects occur in the former cereals they are due rather to a mixing of varieties than to poorness in germination. Professor Biffen paid a high tribute to the quality of the seed—e.g., of Red Clover—which is distributed by the leading seed houses, and to the care with which the seed is cleaned. At the same time he observed that much of the Red Clover sold in this country is unsatisfactory and that unscrupulous dealers are apt to pass off as English Red Clover seed

grown in foreign countries. The foreign article is frequently mixed with the English, and such low-grade Clover seed is often found in small market towns and villages. Moreover, it happens not infrequently that seeds of different years' harvests are mixed, with the result that germination is faulty and growth irregular. Of weed seeds found in Red Clover the chief are: *Campion*, *Clover Dodder*, *Dock*, *Geranium* and *Plantain*. In 45 Red Clovers analysed from seed obtained by the Board of Agriculture from small dealers 29 contained seeds of *Clover Dodder*. Worst among the seed was that grown and distributed by the farmers themselves, and in such cases impurities amounted sometimes to so much as 10 per cent. Professor Biffen insisted on the importance of sale under guarantee, and stated that whereas the merchants selling thus put, in the case of *White Clover*, purity at 98 per cent. and germination capacity at 96 to 98—and are not far out—unguaranteed seed is found often to be extremely bad. Low-grade seed samples were found often to contain many weeds, much old seed and also impurities deliberately introduced.

In the case of *Lucerne* the seed tested was found to be good and adulteration rare. *Sainfoin* showed considerable variation, both in purity and germination. *Mangold* seed was generally satisfactory, and the same was found to be the case with the seed of root crops generally.

In the case of *Grasses*, *Foxtail*, *Sweet Vernal* and the finer *Fescues* and meadow *Grasses*, the seeds showed themselves generally to be good; but some of the cheap *Grass*-mixtures were among the worst rubbish that the Professor ever handled. Professor Biffen holds that the system of selling seed under guarantees has led to enormous improvements, and doubts whether a system of compulsory guarantee is necessary. Growers are becoming more and more alive to the importance of pure seeds, and the spread of agricultural education is helping to this desired state of affairs. Agricultural Institutes are also playing both a direct and indirect part in raising the standard. He advocates that use should be made of the advisory staffs attached to the Agricultural Colleges, and that they should help in the testing of the seeds of *Clovers*, *Roots*, certain *Grasses* (perennial and *Italian Rye Grass*, *Cocksfoot* and *Timothy*). He allows that from the seedsman's point of view a case of some sort may be made out for a Government seed-testing station, but does not think that the case is a strong one, observing that if a national station were really required the trade could have established one before now. He inclines to the view that such a station would not touch the small and careless dealer, nor help him to mend his ways and purify his seed. If a Government seed-testing station be founded it must be accompanied by a system of universal guarantees: but Professor Biffen holds that it should be left to the trade to decide whether it is prepared to put up with the inevitable

Government interference which such a station and system would necessitate.

Professor Biffen's paper was followed by a discussion, in the course of which Mr. Martin H. F. Sutton referred to the lecturer's statement concerning the high quality of *Red Clover* offered by the larger seed houses. He pointed out that there are nevertheless a large number of farmers who are still content to sow brown weathered seed containing a considerable number of weed seeds, and that one result of the increasing habit of the farmer to save his own seed is the inclination which he has to sow his uncleaned seed—for the necessary cleaning machinery is not and cannot be at the farmer's disposal—or to barter his seed in the local market. This fact that the farmer is tending to become a seed merchant would have to be reckoned with if any system of Government inspection were put into force. Mr. Sutton pointed out that the difficulty of hard seed in *White Clover* has been solved by the use of machinery which cracks the seed coat and thereby increases germination by 10 to 20 per cent. In referring to the subject of *Grass* seed mixtures, Mr. Sutton suggested that farmers would do well to insist upon knowing the composition of the mixture they sow. He concurred with Professor Biffen in thinking that there is no considerable demand for a Government seed-testing station, and pointed out that the seedsman has his laboratory and carries out the testing of the seeds which he sells. He agreed with the lecturer that the Agricultural Colleges could, if necessary, supplement this testing of seeds. In any case, a Government seed-testing station could not perform the whole of its task unless it were supplemented by a vigorous system of inspection.

We may add that the subject of a Government seed-testing station was dealt with editorially in our issue for September 13, 1913, p. 188, and that there is close agreement between the views expressed therein and those which were presented at the Farmers' Club.

TREES AND SHRUBS.

PROPAGATING RHODODENDRONS.

THE propagation of *Rhododendrons* may be effected in a variety of ways, each having its peculiar advantages, and a few words on the several methods may be useful.

SEEDLINGS.—Raising the plants from seeds is best for several reasons, notably because by it alone can new varieties be produced. It must, of course, be remembered that only the species can be depended upon to come true from seeds, and even these have been known to vary, but the seeds of most of the *Himalayan* species will be found reliable. For raising moderate quantities of seedlings shallow pans or boxes about one foot in diameter will be found the best receptacles to use. They should be half filled with clean materials for drainage, over which a layer of dry moss or rough pieces of leaf-mould or peat should be placed. After this a mixture of equal parts of leaf-mould, peat and sand should be prepared, and the compost strained through a fine sieve. A layer of this should bring the soil nearly to the level of the rim, and the whole will then be the better for being firmly pressed down. A thorough watering through a

fine rose should then be given and the seeds distributed evenly over the surface. A square of glass should be placed over the top and the pans stood in a shady place, the soil being kept moist. In about two to four weeks the seeds, if kept in a temperature of about 65°, will germinate. A position on a shelf near the roof-glass is well suited to the germinating seeds, which require a close, damp atmosphere. When the seedlings appear the light should be gradually

LAYERING.—The method of layering is a very simple one, and also reliable. It is a somewhat slow process, as it takes two years for a layer to form sufficient root to allow of its separation from the parent plant. A slice is pared off with a sharp knife from the underside of one of the outer branches, and the latter is pegged down to the soil. A little fine peat and leaf-mould may be placed on the surface of the soil under the layer to form a rooting medium, and it may also

and as soon as the sap is flowing freely the grafting may begin. Saddle and cleft grafting are the best methods to employ, a perfect cut in both stock and scion being essential to success. The union should be immediately bound with matting and dressed with clay, after which the plants must be placed at once in a warm frame or house at a temperature of about 60° or 65°. The worked plants will require to be kept close and moist for a time, shaded from bright sunshine, but as soon as growth begins the temperature can be lowered gradually and the plants finally placed outside. Both for seed sowing and grafting, March is the best month in the year. *W. A. C., Richmond.*

SYMPHORICARPUS RACEMOSUS VAR. LAEVIGATUS.

MANY are under the misapprehension that the attractive Snowberry exhibited at the R.H.S. meetings by Mr. Vicary Gibbs under the name *S. mollis* is new. The plant, which received an Award of Merit by the Floral Committee in 1910, a First-class Certificate last year, and is figured in the *Gardeners' Chronicle* as a Supplementary Illustration in the issue for February 18, 1911, is botanically identical with the common Snowberry of gardens, introduced, according to Aiton, in 1814. The fruits of the novelty are much larger and more freely produced, but there seems no reason to dispute the assertion that this is due to selection and superior cultivation. To make a comparison one might say there is as much difference between the Onions staged at an exhibition and those grown under ordinary garden cultivation for kitchen use. Professor Sargeant has identified the Aldenham plant as *S. racemosus* var. *laevigatus*, but this is simply a recent name given to the shrub we have so long known as *S. racemosus*. Dr. Fernald (see Gray's *Manual of the Flora of North America*, seventh edition, page 757) points out that the original type of Michaux's *S. racemosus* has leaves hairy and green on the under surface. Our common Snowberry has both leaf surfaces smooth, and the lower surface is more or less glaucous. Dr. Fernald, therefore, to differentiate it, gave the plant we grow in gardens the varietal name of *laevigatus*. It is very doubtful if the true *S. racemosus* Michaux (in Dr. Fernald's interpretation of the name) is in cultivation. *A. O.*

CIRRHOPELALUM MASTERSIANUM.

THE beautiful East Indian Orchid (see fig. 55), named in honour of the late Dr. Masters, was introduced to cultivation by Messrs. Linden, of Brussels, with whom specimens first flowered in 1890. The species formed the subject of a coloured plate in *Lindenia* of that year, the accompanying text being written by Mr. R. A. Rolfe. *Cirrhopetalum Mastersianum* is distinct from others of the genus in cultivation; it is nearest to *C. gamosepalum*, but is different in colour, whilst the cilia are much smaller. The plant under notice flowers at intervals throughout the year, and grows best in a basket suspended from the roof-rafters in a moist, warm glass-house. The best rooting medium is a mixture of peat, *Osmunda*-fibre, and *Sphagnum*-moss in equal proportions. The fleshy, recurved lip is the largest floral segment, and measures 1½ inch in length. The lip, and also the sepals and petals, are coloured yellow, shaded with umber-brown. The *Cirrhopetalums* are now included with *Bulbophyllum*; but *C. Mastersianum* and others of the genus differ in an important particular from the Burmese *Bulbophyllums*, such as *B. auricomum* and *B. hirtum*; for whereas the latter require a period of rest, the former are evergreen and need no resting period.

[Photograph by C. P. Raffill.]

FIG. 55.—CIRRHOPELALUM MASTERSIANUM: FLOWERS YELLOW SHADED WITH UMBER-BROWN.

increased, and as soon as they are large enough to handle they should be pricked out into larger pans prepared as for the seeds. For about a fortnight they may remain in the same temperature, but afterwards the atmosphere should become gradually cooler and drier until the plants can be removed into a cool frame or house, still shaded from too bright sunshine. The following season they can be placed in the nursery beds outside.

be covered with a similar mixture, making it quite firm.

GRAFTING.—This method of propagation is usually resorted to as a quick means of increasing stock, but it is not always reliable, especially in the case of the Sikkim varieties. *R. ponticum* is the stock usually employed. The stock plants should be raised from seed and potted in the autumn at the end of about three years' growth. They should be placed in frames after potting,

THE RECLAMATION OF LAND IN HOLLAND.

THERE is a charming legend in Brittany that somewhere beneath the sea a city lies submerged. In halcyon days the bells of the city of Is may be heard by the devout; but where that city is none may say. Brittany claims it, and so does Greece. For our part, we think it is in Holland, and that some day soon the city of Is will rise—like an urban Venus from the sea—and send its peal of bells, untroubled by the waters, direct to the ears of men. For whilst the learned contend, Holland is prepared to act, and to raise not a city, but a province from the sea. At least, that is the news which the *Times* special correspondent at The Hague reported recently. The Zuider Zee is to be drained, and Holland is to be presented with a

the State will establish model villages, each with 125 acres of common land, and when fully occupied the "city of Is" will provide ample room for a quarter of a million people. The land reclaimed from the sea will grow corn and roots, sugar-beet, potatoes, and vegetables. The crops are estimated to produce an annual return of £5,000,000, and will require the labour of 40,000 cultivators. The rental to the State will be £1,250,000 per annum. The remainder of the enclosed area will form a vast fresh-water lake fed by the River IJssel, a branch of the Rhine, and by other rivers. The fishermen of the Zuider Zee—some 3,000 in numbers—will sail away, with compensation for change of boat and tackle, to pursue their craft in the North Sea, and in time fresh-water fisheries will be established in the IJssel Meer. It is true that the vast scheme has yet to receive the sanction of the Dutch Parliament; but a country which reclaims

THE FERNERY.

OUR NATIVE SHIELD FERNS.

UNDOUBTEDLY there is no species of evergreen Ferns which has proved itself so prolific in "mutational" or "sport" forms as two of our three species of *Polystichum* or Shield Ferns—namely, *P. angulare*, the Soft Shield Fern, and *P. aculeatum*, the Hard Shield Fern. The third species, *P. lonchitis*, or the Holly Fern, which is only found at high levels, has not been found wanting in this respect, but it has varied to so much less a degree that we may ignore it in this article. Considerable discussion has taken place—especially among foreign botanists, but also among our own—as to the specific distinctness of the two first-named species, but no practical Fern hunter or grower can possibly feel any doubt upon this point. The two species are very often associated, and under precisely the same environments display their distinctive characters clearly. *P. aculeatum*, the Hard Shield Fern, which merits the term by being much harder in make, has a shining, lustrous and divisional character which renders it unmistakable. *P. angulare* is of much laxer habit and of softer texture and duller surface. Apart from this, there is a true specific difference of make, inasmuch as while the secondary subdivisions or pinnales of *P. angulare* have a quite distinct stalk attaching them to the rachides or secondary stalks of the pinnae, those of *P. aculeatum* are quite stalkless, the pinnales having a wedge-shaped base, by the blunt end of which they are attached, no actual stalk being formed. The two species also differ in the range of their habitats—*P. aculeatum* extending far north into Scotland, where *P. angulare* is very rare; while *P. angulare* is only found in abundance in the South and West, and in the vicinity of our warmer coasts, and also in Ireland, where *P. aculeatum*, it is true, may also be found in comparatively small numbers, but always of its specific type, as described above. In the direction of wild variation or "sports," *P. angulare*—no doubt owing to some extent to its far greater numbers in our best Fern-hunting districts—far excels *P. aculeatum*, and ranks, as we have indicated, among the Ferns of all the world, as the most generous of all the evergreen species in the way of distinct forms as regards dissection, form of subdivisions, habit, and appearance generally. It is, perhaps, the only British Fern which has become popularly familiar in the varietal way as a house-plant, owing to the beauty of its proliferous form (*P. ang. proliferum*), found very long ago, and distributed generally by the trade by reason of its easy propagation and culture. This is a much-dissected variety, with its subdivisions greatly multiplied, very slender and acutely pointed, giving its fronds quite a mossy look. Under congenial culture the stalks of the fronds break out into innumerable little buds, these sometimes even extending to the secondary mid-ribs, so that a frond, if layered and kept close, produces an abundant crop of youngsters. Hence trade growers have found it easy to raise in large quantities and distribute widely, while, as it is perfectly hardy and evergreen, its popularity as a house plant has been maintained. In addition, however, to this particular example, those who for more than half a century have devoted themselves to the search for new "sports" among our wild native Ferns have found hundreds of other forms of equal and even greater value, embracing not only forms similar to *P. ang. proliferum*, but many others of very different character. Thus we have some forms still more finely dissected, and with their subdivisions differently shaped; some which have their terminal points expanded into tassels on varied lines; some with tubular fronds; and some dwarfed and congested—so that a collector may include examples ranging from plants a few

FIG. 56.—RECLAMATION OF LAND IN HOLLAND.

new province. Eight hundred square miles of that inlet are to be converted into dry land, and the remainder, 550 square miles, is to become a fresh-water lake. The cost is estimated to be about £15,000,000, and the work is to take thirty-three years. The scheme to be adopted may be understood by reference to the accompanying map, which we reproduce by the courtesy of the *Times*. A dam or embankment 18 miles long is to be thrown across the narrow part of the Zuider Zee, leaving a canal, with locks, at the Wieringen end. To construct the dam an island is first to be built midway between Wieringen and Piaam, and from the island the embankment will run out till it joins either shore. In the enclosed region four great polders, of a total area of half a million acres, are to be formed. This reclaimed land will be ready for occupation within seventeen years after the work is begun, and it will be sold gradually by the State. On the polders

already, year by year, some 24,000 acres, may well prove bold enough to adventure on this great and splendid undertaking. If it does, and if it be brought to a successful issue, the Dutch will once again have won the title, and this time by greater arts than those of war, of Mistress of the Seas.

YOUNG PEACH TREES.—The pruning of young trees to be grown in reserve must be different from that commonly practised for established trees. Very young trees with a few strong growths only should be cut back to firm wood, training the shoots at regular intervals to form the main branches of the tree. Great care is necessary in disbudbing and pinching the new growths. Keep the centres of young trees open, and bend the stronger shoots down to retard the flow of sap, and in this way a balanced tree will be obtained. *J. G. Weston.*

inches long only, up to others of as many feet. From the wild examples of such varied types, the selective cultivator—by sowing spores and profiting by the experience that spores or seeds collected from plants which have once sported away from the normal type are apt to vary again—has been able to add another large number of “improved” types, some of which constitute undoubtedly the most beautiful Ferns the world possesses. So much, indeed, is this the case, that although our other native species—such as the Buckler Ferns, Lady Ferns, and Hartstongues—have each yielded an abundant store of wild sports producing similar results of improved offspring in the same way, the Fern specialist is apt to become in time a Polystichum specialist by preference. The Lady Fern (*Athyrium Filix-foemina*) has indeed eclipsed the Polystichum in the range of fashions which it assumes, some of which are unique among the Ferns of the world, and does its best to rival it by the feathery character of its “plumosums,”

idea of the enormous stride made, an ink-print of a pinna of this variety (*P. ang. plumosum ramulosissimum* R. Bolton), as compared with a normal pinna, is shown in fig. 55. The result of this expansion, multiplication, and repeated ramifications of the divisions is an overlapping and piling up of frondage, which transforms the normal and comparatively simple flat frond into a dense and deep triangular mossy mass of extreme beauty. Forms akin to this have been raised by H. Stansfield, of Sale, but none has gone nearly so far in its development, while the apparent exotic rivals in the mossy way—the wonderful *Nephrolepis exaltata* Marshallii compacta and *Willmottae*—are structurally on quite different lines, owing their beauty, as they do, entirely to repeated dissection.

To the finer forms of both *P. angulare* and *P. aculeatum* we have so often referred in these pages, and so many of them figure nowadays in the trade catalogues of Messrs. H. B. May, H. Stansfield, and others, that I can only

in a prepared bed in the conservatory. Such a method has been adopted here, and that it answers admirably a fine plant of *L. gratissima* bearing large trusses of flower fully testifies.

In preparing a place the position should be so chosen that it allows of being enclosed by slates or a low brick wall, so that the roots are always under control. If the bed be made about a yard square, and after ample drainage is secured room left for a 2-foot depth of soil, it will answer admirably. The compost should be turfy loam and peat, with sufficient sand to ensure porosity.

When making its growth the *Luculia* requires to be kept fairly moist at the root, but whilst the flowers are opening I find it best to be more sparing with the supply of water, and then after pruning has been done (i.e., as soon as all the flowers have dropped) only enough water is given to keep the wood in a healthy condition. At pruning time, with the exception of those growths which are required for extending the tree, the remainder should be cut hard back; in fact, in the case of an established plant, it may be pruned like the vine.

The methods of increase are by cuttings or seeds, and although plants raised from the latter are generally slow in arriving at the flowering stage, it is perhaps a safer way, as the cuttings are extremely difficult to strike. *H. Turner, Serlby Gardens, Bawtry.*

FIG. 57.—POLYSTICHUM ANGULARE PLUMOSUM RAMULOSISSIMUM R. BOLTON.
Normal pinna below to show the extraordinary development of the new variety.

but is handicapped by its deciduousness and consequent invisibility for six months in the year. The evergreen Polystichum, on the other hand, under congenial conditions, may be kept beautiful the whole year round. In the spring growth, too, the Polystichum possesses a unique charm, particularly its best plumose forms, its new crop of fronds, then clothed with almost snow-white scales, rise in a series of reflexed coils of a surpassing beauty. For all-round charm on the most varied lines, *Polystichum angulare* must therefore be recognised as an easy first among our native species, and in the foremost rank in the Fern world generally. Great as have been the achievements of the selective cultivator in connection with this species, fresh triumphs are being frequently added, an example of which has recently come before us, raised by Mr. R. Bolton, of Warton, near Carnforth, from a mixed sowing of a number of fine forms. To give an

suggest a reference thereto by those who would profit practically by the above remarks. *Chas. T. Druery, V.M.H.*

CULTURAL MEMORANDA.

THE LUCULIA.

BEAUTIFUL, sweetly-scented greenhouse shrubs, the *Luculias* comprise but two species—namely, *L. gratissima*, a native of the temperate regions of the Himalayas, and *L. pinceana*, of the Mountains of Khasia. Both are handsome plants, the former (by far the better-known species) bearing heads of rosy-linted flowers, and the latter more fragrant and larger white ones.

Whilst it responds very well to pot treatment, a better way to grow the *Luculia* is to plant it

ALPINE GARDEN.

PRIMULA WINTERI.

At the present time, and judged by the rich profusion of flower-buds calculated to endure for some weeks to come, there is no plant in the Alpine house just now more interesting or beautiful than this Himalayan *Primula*. It flowers in winter and early spring, and if afforded a little protection such as is provided by the Alpine house it yields freely of that charm of leaf and flower which knows no peer. So good, indeed, is it in the cold house, so unsullied the well-powdered leaves, and so exquisite the fringed, rosy-mauve, nearly white-throated flowers that no attempt will be made to grow it in heated structures to mar its beauty. Luckily—the word is used advisedly—the plant resents artificial heat and soon becomes a prey to red spider, hence it is more likely to be grown in its rightful place among hardy subjects. In the open a small plant has wintered quite well and the hardiness of the species is thereby proved. Grown thus, however, it is bereft of the beauty of its powdered leaves, and, like the mealy-leaved *Auriculas*, repays for the protection of a cold house or frame. *E. J.*

THE COMMEMORATION OF PARMENTIER

AMONG the men whose services to agriculture deserve to be held in grateful memory is Parmentier, whose work in the popularisation of the Potato has been recognised in a commemorative exhibition held recently in France. The following account of the exhibition and of Parmentier's work is from a communication sent to us by M. Lortel:—

The exhibition in honour of Parmentier, organised by the Society of Horticulture and the Municipality of Neuilly, under the presidency of the Minister of Agriculture, was held at Neuilly on January 25 and 26 in the Hôtel de Ville.

Peculiar interest attached to this exhibition of the “Irish Potato,” as it was called in France in the 18th century, for by a curious chance it was possible to exhibit at Neuilly the actual descendants of Parmentier's Potatoes. In 1815

the Agricultural Society of France handed over to Messrs. Vilmorin Parmentier's collection of Potatos, and entrusted to that firm the task of preserving and completing the collection. The catalogue of 100 years ago (1815) mentions 150 varieties, and it is interesting to note that up to 1856 there were added no more than 25 new kinds; whereas to-day there are upwards of 1,000.

The exhibit at Neuilly displayed by Messrs. Vilmorin included, besides Parmentier's autograph and works, some of the tubers planted by him in 1787, on the occasion of his memorable and successful effort to popularise the plant "which has saved France 20 times from famine."

Of all the varieties enumerated in the catalogue of 1815, and preserved with faithful care Messrs. Vilmorin, there remain pure at the present time only five. These are Marjolin, Vitelotte (called by Parmentier *Violette*), Shaw

cal and esculent properties of the Potato—with which, and with Meyer's daughter, he fell in love. Patriotism forbade him from marrying the latter, but for the rest of his life he was wedded to the Potato, and devoted himself to making known its economic virtues. On his return to France he put himself in communication with prominent cultivators—M. Elleraie, the Baron de Sainte-Hilaire, Lemery, and particularly with English Potato growers, such as John Howard, of Carlington, and Philip Miller.

In spite of various previous efforts, the cult of the Potato had made little progress in France. Thus the Comte de Lambertye, after a visit to England to congratulate King James on his accession, had brought back a variety of Potato much better than any in use at the time in France. The new variety was planted largely in Noirmontiers, Belle-Isle, and in the neighbourhood of Boulogne.

Again, in order to popularise the "noble

extent, the dwellers in towns, and particularly in Paris, looked askance at that vegetable.

At this point of his labours Parmentier hit upon his famous and successful method of advertising the merits of the plant. He selected as the place for his experiment the Plain of Sablons, close to Paris. On this plain the King held each year a review of his regiment of Guards, and it was famous also for its utter sterility.

After much effort Parmentier received permission and funds for his experiment. Since the review took place on May 10 he could not do his planting till the following day—that is, six weeks later than the proper time. Moreover, the weather was bad, the "seed" Potatos—Hative and La Grosse Blanche, the latter a red spotted kind, and so vigorous 'that it would grow in powdered glass'—arrived in a deplorable state, having germinated en route in spite of care in packing.

FIG. 58.—THE BOG GARDEN AT PENRHYN CASTLE, CARNARVONSHIRE, THE SEAT OF LORD PENRHYN.

(For description of the garden see the issues for January 17 and 24, 1914.)

or Chaw, Clairebonne, and Bonne-Wilhelmine. In addition to the collection of modern varieties exhibited by Messrs. Vilmorin were others by the firms of Cayeux and Leclerc, Robert, etc. Of these modern kinds *Excelsior*, an enormous yellow-fleshed variety, was exhibited by M. Hyacinthe Rigaut.

It was during the Seven Years War that Parmentier's attention was first directed to the value of the Potato as an article of food. In his capacity of 'pharmacien en chef' he observed that many of the French soldiers saved themselves from starvation by digging up, cooking by the camp fires, and devouring Potatos found in the fields. Taken prisoner, Parmentier remained in Germany, where he was lodged with a well-known doctor—Meyer, of Frankfurt. He used his enforced leisure in studying the chemi-

tuber" in France, the Duke of Hamilton (as Chevalier Binet) invited sundry great personages to dinner, and served them with morue and Pomme de Terre (cod and Potatos), as being one of the finest of English delicacies. The attempt was not particularly successful, and only led to the planting of a few acres.

Parmentier likewise attempted to popularise the tuber by means of dinner parties, at which the fare consisted of nothing but Potatos; but, needless to say, the device was fruitless of result except that in consequence of these Potato feasts he failed to be elected Representative of the Government—the electors fearing that he might, if appointed, attempt to feed them exclusively on this unpopular diet.

Although the cost of living compelled the peasants of that day to grow Potatos to some

The Parisian crowd, which had watched the planting of this barren land with amused contempt, was stupefied. All day the crowd thronged to see the luxuriant vegetation springing up, and all day the ripening crop was guarded by regiments of soldiers. But at night the guard was withdrawn in order to encourage pilfering, as the surest, if not the most moral, means of popularising the Potato. The yield from 35 arpents was 8,880 kilograms, or nine-fold the weight of the tubers used as seed.

Louis XVI. appeared at Court with a Potato flower, presented by Parmentier, in his button-hole, and the King's gardeners were commanded to plant Potatos in the Royal domain of Rambouillet—the Potato had arrived! *Translated and abridged from a special article by M. J. Lortel.*

NOTICES OF BOOKS.

THE JAPANESE CHRYSANTHEMUM.

At the Paris Autumn Show, held by the National Horticultural Society of France in November, 1908, there was organised by the committee what was called a Retrospective Chrysanthemum Exhibition. Old books, pamphlets, prints, engravings, photographs, and every conceivable literary and artistic curiosity relating to the Chrysanthemum, were exhibited. The exhibition was in every way a success—so much so that two years afterwards a Retrospective Rose Exhibition was held by the same society and at the same place. At the Chrysanthemum exhibition the walls were covered with many choice engravings and portraits, not the least attractive being an original oil painting of Captain Blancard, the introducer of the flower into Europe. In the numerous glass cases were enclosed bibliographical treasures and literary rarities, all having some special reference to or bearing upon the flower in honour of which the show was held.

We are reminded of this most interesting event by the receipt of a large octavo brochure from the pen of M. René Momméja, entitled *Le Chrysanthème au Japon*. It is apparently a reprint of an article that has appeared in the *Bulletin* of the Société Franco-Japonaise de Paris. Although quite complete and an independent publication in itself, no price appears upon it, and we do not know even if it is on sale. If so, as the brochure bears the imprint of the library of the society, any applications must probably be made there for copies.

M. Momméja's work is neatly printed and occupies twenty-three pages of text; the illustrations—most of them extremely quaint, as is usual with Japanese pictures—are full-paged and *hors texte*.

The story opens with a history of the Chrysanthemum in Japan, including its culture, the Emperor's fête, the Feast of Happiness, and the introduction of the flower into Europe. There is then a botanical chapter, which is followed by another dealing solely with the Japanese method of classification. Exhibitions, amateur and imperial, are dealt with descriptively. It is, on the whole, an interesting contribution to the literature of the Chrysanthemum, and only an enthusiast such as M. Momméja is could have produced it.

A word may be given to the illustrations, of which there are thirty-six in black-and-white and one in colour. In some cases there are six different types of flowers on a page. The first we notice is the reproduction of a kakemono, entitled "To En Mei," a great Chinese poet and lover of the Chrysanthemum. We wonder, in our sublime ignorance of the Japanese vernacular, whether this is the same man whose name has been given in Chinese as Fao-yüan-Ming, and who is recorded to have lived about the year 365-427 A.D., and to have given up his official cares so that he might devote himself to versification and the pleasures of the wine cup, coupled with the growing of the Chrysanthemum (see p. 5 of *Chrysanthemums*, in the Present Day Gardening series). There are some Japanese drawings of Chrysanthemums grown in 1736, sketches by the great artist Hokusai about 1815, and examples of the various types according to Japanese classification. A picture, full-paged, of a wonderful trained specimen plant on a single stem, bearing 1,083 blooms, is also given, as are views of exhibits in the shows. But we must conclude with just a bare mention of the only coloured illustration, which represents the seven varieties originally introduced from Japan into Europe by Robert Fortune in 1862.

HISTORY OF THE GRAPE VINE.*

The literature of the vine at the present day is probably unequalled by that of any other fruit, and it might seem at first that no part

had been left unexplored. The work before us fills, nevertheless, a distinct gap in this literature, and will be welcomed by all students of pomological history. The author has certain qualifications which render him especially well-equipped for his task. His experience as a practical Grape-grower in the district of Beaujolais has been of inestimable service in his study of the ancient history of the vine. It is not always that the wide culture and patient enthusiasm of the savant is superadded to the intimate knowledge of culture which comes from a lifelong experience with one particular plant. M. Billiard is, however, an example of this happy combination, and his book therefore stands out from the usual kind of pomological history.

The work treats with the utmost detail all aspects of the vine, beginning with its geological history and following its culture through historical periods, and the making, storing and selling of the wine are also fully described. We will therefore notice briefly these subjects in the order in which they appear.

Recent developments of paleontological botany have considerably modified opinions as to the "native home" of the vine. Older writers generally placed this in the country lying between the Black and Caspian Seas. M. Billiard, however, brings forward the evidence of Saporta, Heer, Zittel and others as to its existence in Central Europe in very early times. In the eocene deposits in champagne many species of *Vitis* have been found, some of which bear considerable resemblance to *V. rotundifolia* of Central Asia.

Coming to later times, there is proof of the use of the Grape by the Lake Dwellers, seeds having been found in various stations extending as far north as Belgium, though, of course, more frequently in southern latitudes. Whether the fruit was then used for wine-making is a moot point, but the author views its probability with some favour.

In historic times the matter becomes naturally more certain, and the great outpouring of the Aryan peoples into Europe had probably much to do with the progress of vine culture and the use of wine. The remarkable similarity between words of the Armenian, Greek, Attic and Romance languages proves the westward progress of the conquering vine. The large part it played in the lives of the Greeks and Romans is too well-known to need repetition, and those interested will find much information as to the worship of Dionysos and Bacchus in these countries.

A particularly interesting chapter is that upon the vicissitudes which viticulture has undergone from many varied causes. The unlimited powers of the Roman Emperors had much to do with these fluctuations, and to read of the purchase of uncultivated lands and their plantation with vines by Aurelius, and the gratuitous distribution of wine to the people reminds one of the frequency with which history repeats itself!

The second part of the work is concerned with the history of the culture and maladies of the vine, and is of the greatest interest. Those who consider plant diseases to be a scourge of modern times will find material here to bring about a change of view; even in the tenth century washes were used as preventives against these troubles.

Of the interesting details of the wines of various localities, their manufacture, storage and usage this is not the place to dwell. The pages of Athenaeus and memories of Trimalchios' banquet will be recalled and many interesting sidelights thrown upon them.

Not the least important feature of the work is the numerous pictures of sculptures, pictures and ceramics which illustrate in a manner generally lively the large part which the Grape played in the early days of civilisation. From Egypt to Europe museums have been ransacked for these evidences, and they form a unique collection.

On the format of the work no adverse criticism can be passed, except the regrettable necessity of the heavily-loaded paper, which makes it too weighty for armchair reading. Type and spacing are alike excellent, but the work, as is usual with Continental productions, is unbound.

La Vigne dans l'Antiquité is of the type of work usually called "standard," and it is certainly one which must be included in every pomological library. So thoroughly has the author explored his field that it will, we venture to think, be long before a successor will be needed, and probably still longer before an author so gifted as M. Billiard will be found. E. A. Bunyard.

THE DISEASES OF TROPICAL PLANTS.*

Dr. Cook, the author of this volume, has had considerable experience of the subject of disease in tropical plants, and, although he recognises that much work remains to be done in this field of investigation, has published his work in the hope that it may prove of use to the planter, and may lead to the filling up of the present gaps in the knowledge of tropical fungous diseases. Dr. Cook has rendered a service of considerable value to the tropical agriculturist. His labours must have been severe, for the descriptions of tropical diseases are to be found scattered in a hundred periodicals, and, moreover, the descriptions themselves are often anything but precise.

In illustration of the need for the thorough investigation of the diseases of tropical plants is the fact that not one of the crop-yielding plants of the tropics is free from the attacks of serious fungous pests. Thus Rubber suffers from canker—which, like that in our Apples, is due to a species of *Nectria*; from bark disease, due to *Corticium* sp.; from stem disease (caused by *Diplodia rapax*); from die back; from fruit disease, due to a species of *Phytophthora*; from seedling disease (caused by *Pestalozzia guelpini*); and other pests almost too numerous to mention.

Dr. Cook introduces his subject by a short account of the structure and functions of plants.

Following this chapter are others on classification of fungi, and the rest of the book is taken up with a description of the diseases of the chief tropical food-plants, and with an account of methods of prevention and control. Investigators of tropical fungous diseases will be particularly grateful to Dr. Cook for including as an appendix a carefully drawn up list of references to original papers. So far as we have been able to test it, this list is remarkably complete; one omission may, however, be noted—that of Mr. Ball's interesting observations on sore shin disease of Cotton. We hope that those of our readers who reside in the tropics will bring Dr. Cook's useful work to the notice of planters and others concerned with the incidence of fungous diseases on tropical plants.

FORESTRY.

AVONDALE FORESTRY STATION.

In the *Journal of the Department of Agriculture, Ireland*, for October, 1913, pp. 102-125, there is an account, with a plan, by Mr. A. C. Forbes, of the progress of the Avondale Forestry Station from its foundation in 1906 to the end of 1912. The greater part of the report is devoted to a detailed description of the forestry plots, which are 104 in number and cover an area of 121 acres. Each plot is composed of a main crop of one or of two or three species, which will remain as a pure or mixed group when the nurses have been gradually removed. Of the nurses employed the common Silver Fir was a complete failure, while Larch, Spruce and Scots Pine have been successful for this purpose. All the Silver Firs suffer severely from frost at Avondale, except *Abies grandis*, a plot of which is very thriving. Of the Maples, the Norway

* *La Vigne dans l'Antiquité*. By Raymond Billiard. Lyon: Librairie H. Lardanchet. English agents: Messrs. Wesley and Co.

* *The Diseases of Tropical Plants*. By Melville Thurston Cook, Ph.D. (London: Macmillan and Co., Ltd.) Price 8s. 6d.

Maple plot is the best, this tree keeping pace so far with the Larch nurses. Sitka Spruce is growing vigorously, but many plants were attacked last year by aphid and lost most of their needles in spring. The *Picea rubra* plot is also very thriving.

The species which have proved most difficult to transplant are *Pinus insignis*, Maritime and Corsican Pines. With these there have been repeated failures, but the best results were obtained by using three-year-old plants, which had been transplanted in the nursery during the previous year, and planting out in the plots in late spring. A few *Pinus insignis* were killed by frost in winter when under 12 inches high, and this species is difficult to establish unless raised in pots and planted out with balls of earth.

Larix sibirica was tried, but all the plants died in two years. This plot has now been filled with *Larix occidentalis*, which was raised from seed obtained from Montana in 1910. Of the different kinds of European Larch, the Silesian variety is much superior to that raised from Tyrolean seed.

There are numerous notes on the different species, and an estimate, based on the experience gained in forming the different plots, of the approximate cost of planting the various species will be found useful, as it includes labour, trees and replacing the failures during the first three years.

FLORISTS' FLOWERS.

PENTSTEMON.

THE value of Pentstemons for massing in beds or borders or for filling gaps in the hardy flower border is greater each year owing to the high qualities of the newer varieties. They are easy of propagation, require but little attention during winter, and grow freely in spring when transferred to their flowering quarters. The following varieties are all to be recommended. John Ruthven, growing fully 3 feet high, has a handsome flower spike which develops extra large blooms with a shade of rich pink, a delicate edging of the same colour and a pure white throat. Thomas Heron has a dwarf, compact habit of growth and is extra free in flowering, making a first class bedding variety; the colour is rose with crimson stripes in the throat. William Goodman produces handsome spikes fully a yard high; the salmon-scarlet flowers have a white throat. Mrs. N. F. Barnes is pink in colour with a white throat. Mrs. Lockett Agnew has large violet flowers thickly set on tall spikes. Lady Hamilton has dark purple blossoms with a white throat, a very effective variety. Albert J. Smith is deep pink with an open throat of white. Hilda Stevenson has a rose-coloured tube and white throat. Miss Lella Stewart Peter is scarlet except for the white throat. There are in addition Lord Granard, crimson with scarlet stripes; Mrs. Robertson, rose pink with white throat; Louis Paulham, bronze-chocolate with white-feathered throat; Mrs. Alexander Brown, rich rose with white throat; Lady Forbes, the strongest-growing variety, producing spikes 4 feet long, deep pink with white throat; Parachute, with blossoms 2½ inches in diameter, scarlet, with white throat; République, bright vermilion, and Thomas H. Cook, a variety with flowers 2½ inches in diameter, produced on a short spike, colour rich rose flushed with red. *E. Molyneux.*

PERPETUAL-FLOWERING CARNATIONS.

PERPETUAL-FLOWERING Carnations are grown extensively and most successfully at the Lynwood Nurseries, Raleigh. The glasshouses are situated on high, open ground, and slope sharply to the west. They are 200 feet long, 50 feet wide, and proportionately high, and provided with ample front and top ventilators. All the flow 4-inch pipes are fixed on brackets at about

8 feet above the floor-line of the houses, the returns being nearer to the ground-line. The plants are growing on benches 4½ feet wide, fixed 3 feet from the ground, seven centre and two side benches with eight narrow paths between them, and one wide central path with double doors at each end. The plants in one house are planted in a suitable compost on the benches, 1,500 plants, consisting of Rose Pink Enchantress, White Enchantress, May Day, and Windsor, and the growths are trained to an almost invisible network of wire running lengthwise and crosswise over the individual benches. Fifteen thousand plants in 32-size pots occupy the benches in No. 2 house. All the plants in every stage of growth, from the cutting upwards, bear evidence of good cultivation, being sturdy, perfectly clean, and floriferous. They are propagated from selected stocks of the best varieties and grown in ideal conditions. In one of the propagating houses 33,000 cuttings of perpetual-flowering Carnations are being rooted. The varieties include, among others, Lady Alington, Lady Northcliffe, Mary Allwood, Mrs. G. F. Dutton, R. F. Felton, Empire Day, Scarlet Glow, Carola, Mikado, and Fairmount. In four large houses *Asparagus plumosa* is grown for cut foliage. *H. W. Ward.*

ASHRIDGE PARK.

ASHRIDGE PARK, the residence of the Rt. Hon. Earl Brownlow, is about four miles from Berkhamsted, separated therefrom by a wide common. The mansion may be described as one of "the stately homes of England"; the style of building is massive, the proportions ample; and the gardens around the house are well suited, in size and magnificence, to adorn this handsome edifice. At each end of the house a fine avenue runs forward, one of Limes the other of Elms. The trees are of noble proportions, being of considerable age and well developed. Beyond the avenues a beautiful view stretches out as far as the eye can see; the home park lies just beyond the shrubberies and gardens, and beyond that again miles of well-wooded, undulating country.

The park is extremely rich in matured timber. Spreading Oaks, tall Beeches and Ashes, gigantic Chestnuts and all the other trees to be found in English woodlands are here represented. The famous "Queen" Beech formed the subject of the Supplementary Illustration in the issue for January 27, 1912. The companion tree, the "King" Beech, fell a victim a few years since to a severe storm; it is said to have been even larger than the "Queen," though the bole of this latter tree was officially stated by the Royal Arboricultural Society to be 80 feet from the ground to the lower branches. Some of the Chestnuts are hardly less remarkable, the branches of one of them spreading over an area of 108 feet in diameter. There are numbers of fine Cedars, among them some good specimens of *C. atlantica glaca* (the largest 45 feet in height), *Abies nobilis* (50 feet), *A. grandis*, American Scarlet Oaks, *Quercus Ilex*, and *Q. suber* (the Cork Tree).

Ancient Yews, both green and golden, adorn the terraces and flower garden. They blend well with their younger kindred. Close by is the Italian garden, which contains a number of Irish Yews, planted as a relief to the main design, which is carried out in Box, round a massive fountain in the centre. Last year a bold design in blue, scarlet, yellow and white was carried out, each of the large beds containing masses of one colour only. The ordinary annuals and bedding plants were used, and the effect was very fine.

The spacious lawns are broken here and there by groups of evergreen and flowering shrubs. Rhododendrons and Azaleas grow well, in spite of the chalky formation of the soil. There are some fine plants of Sweet Bay, particularly large specimens, which have come safely through many

winters; some good examples of *Cupressus sempervirens*; and a very fine bush of *Ceanothus dentatus*.

A picturesque waterway intersects the grounds and forms a boundary to the lawns, opening out at one end into a skating pond. The pond is surrounded by clipped Yew hedges, which form on the other side a background for the Old English garden, the fragrance of whose herbs extends far beyond the confines of the garden. The waterway is spanned at one point by a bridge, from which a number of fine avenues radiate. The central avenue is planted with trees of *Sequoia gigantea*, nearly fifty years old—they stand from 50 to 55 feet high. The rest of the walks are planted with *Quercus Ilex*, *Juniperus chinensis*, Walnut and *Cupressus nootkatensis*. Close to the last-named avenue is a circle of *Libocedrus decurrens* about 25 feet high. A stone pedestal in the centre of the circle, bearing an inscription on an open book, denotes the intention of the planter to make of the circle a kind of open-air temple.

There are many good specimen Conifers, such as *Cryptomeria elegans*, from 18 to 20 feet high; *Juniperus Youngii aurea*, 18 feet; *Pseudotsuga Hookeri*, 16 feet; *Retinospora filicoides*, 14 feet; *Sciadopitys verticillata*, "Weeping" Spruce, *Picea pinsapa*, and a number of *Cupressus erecta viridis*, 30 feet or more in height.

Several groups of *Cotoneaster frigida* are to be seen, covered in winter with brightly-coloured berries. *Magnolia*, *Catalpa*, *Liriodendron*, *Ginkgo biloba*, Black Walnut, and a large spreading *Cedrus* help considerably in presenting a fine effect; and a rare evergreen Beech—*Fagus betuloides*—is about 24 feet high.

The Rose garden is secluded and restful, with an old-world charm and grace all its own. The middle bed contains a basin, surmounted by a stone figure; it is encircled by Venetian pillars. The garden is surrounded by a Yew hedge, and has four entrances. The beds all radiate from the centre, each bed containing one variety; Richmond, Corallina, Madame Ravary and Caroline Testout were four of the varieties specially noticeable.

The Monks' Garden (so called on account of its being on the site of an old monastery), the Main Terrace, and the Italian Garden are arranged in a formal style, and the unconventional methods employed in the bedding present a very pleasing effect. The flowers chiefly used are tuberous and fibrous Begonias (notably "Crimson Gem"), dark Coleus, dwarf Tropaeolums, *Gnaphalium latifolium*, Antirrhinum (a white variety), and various annuals; and also standard Heliotropes, Fuchsias and Lilies.

On the Main Terrace are some magnificent standard Bays, the heads measuring 9 feet in diameter, and the stems 4 feet high. There are also some large plants of scented Verbena—pyramids 5 feet high, and standards with 4 foot stems, their conical heads measuring 3½ feet to 4 feet across the base.

On the south front of the house several good climbers are doing well, among others *Magnolia grandiflora* (30 feet high) and *Ceanothus azureus*; while over the Orangery a Fortune's Yellow Rose and a plant of *Vitis Cointetiae* are growing together.

Inside the Orangery, Camellias, Oranges and Myrtles grow in profusion; on the inside of the roof a rare plant, *Billardiera longiflora*, occupies a place with other climbers. There is a conservatory, also well filled with climbing and other plants. A well-stocked fernery near the conservatory contains a good specimen of *Angiopteris erecta*; and the outside wall of this house is covered with *Vitis heterophylla variegata*, *Schizophragma hydrangeoides*, *Tecoma grandiflora*, *Berberidopsis corallina*, etc.

Most of the glasshouses (which have been recently renovated) lie near the kitchen garden. In both these departments the same skill and care is observed as elsewhere in the gardens; and the indoor and outdoor crops can only be described as excellent. *G. Arden.*

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

ODONTIODA.—Many of these beautiful Orchids are developing their flower-scapes grown during the winter. When the plants have grown actively during the winter the pseudo-bulbs are usually in a more or less sappy condition at this time, and it is desirable to harden them before the inflorescences develop. Odontiodas may be exposed to considerably more light than may Odontoglossums without detrimental effects to the foliage; therefore plants that are producing their flower-scapes should be suspended from the roof-rafters or staged within a reasonable distance of the roof-glass. Plenty of sunlight will not only favour the ripening of the pseudo-bulbs, but plants that are suspended will be out of the reach of slugs and small snails which damage the young flower-scapes and roots. As the plants pass out of flower they may be repotted or top-dressed according to their several needs. Like *Cochlioda*, one of the parents, *Odontiodas* resent root disturbance, and should not be shifted unless re-potting is absolutely necessary. For this reason a compost with lasting qualities should be used. A mixture comprising two parts fibrous peat and one of broken Oak leaves with chopped Sphagnum-moss and coarse silver sand is suitable; sometimes the tips of the leaves die if a compost of a heavier nature than this is used. Press the materials firmly about the roots, and more firmly than in the case of *Odontoglossums*. Use clean pots filled to about one-half their depth with chopped Bracken rhizomes and place a few crocks in the bottom—just sufficient to cover the drainage-hole. Shade newly-potted plants from strong light and keep the atmosphere humid until the roots grow into the fresh compost.

SHADING.—In view of the lengthening days and increasing power of the sun's rays get the roof-blinds ready for use whenever required. Lath and other wooden blinds are very serviceable during cold, winter nights, for when lowered they obviate the use of much fire heat; but when employed on lofty structures in which the plants are staged at a considerable distance from the roof-glass they have a tendency to cause growth to become drawn and weak. It is therefore preferable to use No. 5 canvas blinds for lofty houses. All gable-ends facing south should be covered during the hottest part of the day. A piece of old shading material may be used for this purpose, cut to shape and furnished with eyes so that it may be hung on hooks, to be taken down quickly as required.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

STRAWBERRIES.—Successional plants that have been growing slowly will now be sufficiently advanced for introducing into the forcing pit. Admit air freely for the first week and until the flower trusses show, when the amount of ventilation should be reduced gradually, and the temperature raised to aid the blossoms to develop sturdily. At this stage apply liquid manure at alternate waterings, and damp the plants once or twice daily during bright weather.

CUCUMBERS.—The beds that were prepared last month are in a suitable condition, and by this time the young plants will be nearly or quite ready for re-potting. This is a most trying time of the year to keep the young plants in a growing state. The roots should be plunged in bottom heat until growth is strong, and the latter sprayed overhead—as well as the surface of the bed—daily as required. Allow the sun to shine direct on the plants, and admit air daily when the outside conditions are favourable.

MELONS that were planted last month are growing freely. Water the roots thoroughly whenever moisture is required. It is a mistake to use too small a quantity of water whilst the plants are growing rapidly or carrying a crop of fruit. Increase the amount of ventilation as the days lengthen, as this will favour the development of healthy foliage. High temperatures at night and an atmosphere surcharged with moisture are both harmful. Aim at obtaining foliage that will withstand the brightest sunshine—for Melons should never be shaded—and this can only be obtained by a moderate degree of moisture, plenty of air, and the smallest amount of artificial heat compatible with the health of the plants. Allow the leader of each plant to run nearly to the top of the wires or trellis, then pinch out the tops and train the laterals horizontally.

VINES.—The airing of the vinery should receive careful attention. The amount of moisture in the atmosphere should be in accordance with the weather and the ventilation afforded. Vines that have been started recently should be syringed several times daily until the buds burst. If ripe Muscat Grapes are required during August and September the vines should be started now. Maintain a night temperature of 48° or 50°, allowing a rise of 10° or 15° by sun heat. Always remember that Muscat Grapes require a higher temperature from the start than other varieties. Use the syringe daily until the vines are well advanced in growth, when damping the walls, staging and pathways frequently will suffice to maintain the necessary atmospheric moisture, and the syringing may be discontinued. When the borders require moisture use water warmed to a temperature 5° or 10° higher than that of the house. Cold water would give a severe check to the vines, which would probably affect them throughout the remainder of the season. Early pot vines in an advanced stage of growth, and on which the fruit is setting freely, will soon be in a condition for the bunches to be thinned. On no account touch the berries with the hand during the process of thinning, or they will present an unsightly, rusty appearance later on. A thin piece of wood, or a stick with a forked end, is all that is required to manipulate the bunch whilst it is being thinned. Do not thin too severely at the first time; it is safer to examine and treat each bunch a second, or even a third, time for the removal of seedless or undesirable berries.

THE KITCHEN GARDEN.

By R. P. BROTHERTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

SEAKALE.—The planting of Seakale need be delayed no longer. The ground, no doubt, has been prepared for some time, and, if in the rough, should be either broken down or re-dug. Mark off the lines and plant the sets with a dibbler at one foot apart, and just so deep as to be covered with a quarter of an inch of soil. Finish by running a Dutch hoe through the surface to leave it smooth for subsequent hoeings.

INTERCROPPING.—A large number of vegetables may be grown on ground which otherwise would lie idle for the time being. Thus, between rows of Peas running 4 to 6 feet apart the supply of Spinach, Turnips, Lettuces, and Radishes for summer can be grown, two or three lines of each between every two rows of Peas. In like manner with Broad Beans, slow-growing crops such as Artichokes and Horse Radish planted recently, an early crop can be secured without doing any harm to the permanent one. But one must discriminate. A fine crop of Broad Beans can be produced by having a single plant at the end of every second row of Potatos, but in this case the Potatos close to the Beans will suffer injury. In like manner I have seen splendid samples of Cabbage and Brussel Sprouts produced, but always at the expense of the Potatos, so that intercropping to pay can be profitably pursued only where there is sufficient space for both vegetables.

FRENCH BEANS.—This crop may from now be forced easily wherever there is space to spare in a structure not over-ventilated and

somewhat warmer than a greenhouse. I do not advise growing the plants in pots, but in deep boxes well drained and three parts filled with a very fertile compost, say, of two parts loam and one part old Mushroom-bed manure, with fertiliser added as required later. A few days are gained by swelling the Beans in water previous to sowing, but this must not be carried to the bursting of the skin or the protrusion of the radicle. Sometimes French Beans are placed in vineries, which is always a highly risky proceeding owing to the susceptibility of the foliage to red spider infestation. I have grown the running type planted out at this season, but, though an enormous crop was secured, it was so late that I should not care to repeat the trial.

JERUSALEM ARTICHOKEs.—It is time that the tubers were planted. I set them in double rows one foot apart, with 3 or 4-foot spaces between. The white-skinned is the more handsome tuber, but the old purple variety is the more profitable.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

IRIS FOETIDISSIMA.—This is a good plant for poor soil, thriving where little else will grow. The capsules open in winter, and display the beautiful scarlet seeds.

PLANTS FOR SHADY SPOTS.—*Hypericum calycinum*, *St. John's Wort*, is a valuable subject for planting in shady situations. *Polypodium vulgare* may be used for the same purpose. *Daphne pontica* and *D. laureola* are two valuable dwarf shrubs for dry, shady banks. All these plants retain their foliage and produce excellent effects in winter.

HERBACEOUS BORDERS.—Certain kinds of herbaceous plants require to be divided and replanted every year or every second year, either in early autumn or in the spring, just as growth commences. It is a great advantage to have a reserve garden where the plants may be propagated and grown. A sufficient number of healthy, vigorous plants should be set this spring in the reserve garden to meet the requirements for next autumn or spring planting. The stock plants should be removed to their permanent quarters and planted in well-prepared ground. Lift the plants with good balls of soil filled with healthy roots, and they will become established in their new quarters and give better results than those propagated straight away by divisions of old stools. The latter plants receive a considerable check at the start and half the season is lost before they recover, consequently they do not always flower at the proper season, the flowers are of inferior quality and the plants are less satisfactory generally. Moreover, when there is a good selection of plants in the reserve garden it is possible to make changes and improvements in arrangement of the flowers every year. This applies especially to such plants as *Spiraea*, *Pyrethrum*, *Hemerocallis*, *Inula*, *Helenium*, *Geum*, *Funkia*, *Achillea*, *Betonica*, *Erigeron*, *Gentiana*, *Linum*, *Oenothera*, *Coreopsis*, *Trollius*, *Rudbeckia*, *Salvia*, *Campanula*, and *Armeria*.

ARRANGEMENT OF THE PLANTS.—Plant in bold, irregular groups of from 5 to 50 plants, according to the height, habit and colour of the species, and, as far as possible, take into consideration the period of flowering. If a little of the exhausted soil is replaced by fresh loam mixed with bone meal and well rotted animal manure so much the better, and the extra labour will be well repaid. Plants that resent disturbance at the roots, including the herbaceous *Clematis*, especially *C. Davidiana* and *integrifolia*, members of the *Eryngium* family, *Monarda*, *Delphiniums*, *Anemone japonica*, *Paeonies*, and others, must be left alone until re-planting is absolutely necessary. At Madresfield we find it most satisfactory to avoid repetition in planting, and to have only one group, large or small, of any one variety of herbaceous plant. And we do not plant any bulbs in any part of the herbaceous borders. Strong-growing, tall-flowering herbaceous plants, such as *Pyrethrum uliginosum*, *Helianthus*, *Miss Mellish*, *H. lactiflorus*, *H. scaber major*, *H. rigidus*, *H. multi-*

florus, *Lythrum Salicaria superbum*, and others, should be planted in open spaces, or clearances in shrubberies, in ground that has been trenched and cleared of tree roots. It is now a suitable time to divide these tall growers; the flowers will light up the sombre tones of the evergreens all through the late summer, when flowering shrubs are mostly over.

LILY-OF-THE-VALLEY.—A few beds of Lily-of-the-Valley should be broken up every year at this season, utilising the strong crowns for forcing, and the smaller ones for re-planting in fresh, well-manured ground. Under generous cultivation the spikes will develop large "bells" that will amply repay for the extra trouble, as compared with those from crowded beds or in exhausted soil.

MONTBRETIA.—These beautiful border flowers should be lifted every third year and re-planted in a fresh site. Select young, vigorous corms and discard the old ones that are exhausted. Do not use fresh manure, especially if the animals have been littered with peat-moss. A sandy loam, with the addition of pure leaf-mould, free from animal manure, suits the Montbretia to perfection.

VIOLETS.—Make preparation for forming new beds in readiness for re-planting the young runners as soon as flowering is over.

SPRING FLOWERS.—We have in bloom out-of-doors Snowdrops, Dutch Crocuses, *Scilla sibirica* (these in the grass), *Spiraea Thunbergii*, *Berberis Aquifolium*, *B. grandiflorum*, *Daphne Mezereum*, including the white variety; *Cydonia japonica nivalis*, *Hamamelis Zuccainiana*, *H. virginica*, and *H. arborea*, also in the wild garden, *Pulmonaria officinalis*, *P. maculosa*, and *Petasites fragrans*. The last-named should be planted in the very poorest soil, or, like all other Colts-foot, it will spread to where it is not wanted. The perfume of the "Winter Heliotrope," as the *Petasites* is called, scents the whole place where it is growing. We have also on banks Primroses, Violets, and *Omphalodes nana*, and, on slopes set apart for peat-loving plants, *Erica lusitanica*, *E. Veitchii*, *E. carnea*, and *E. mediteranea hybrida* in bloom.

THE HARDY FRUIT GARDEN.

By J. C. WESTON, Gardener to Lady Northcote, Eastwell Park, Kent.

PEACHES AND NECTARINES.—The trees having been loosened from the wires in the autumn, and allowed to hang away from the wall all the winter in order to retard the flower-buds, should now be trained in position again or the expanding buds will be liable to damage when the trees are being cleansed. Well-trained specimens that have been disbudded and pinched as required last season will require but little pruning at this stage. It is a usual practice to go over the trees after the fruit is gathered with a view to removing all old wood that has borne fruit, in order that the energies of the tree may be directed to the development and ripening of the young wood. All weakly or badly-ripened wood that has been previously overlooked should be removed entirely now, cutting the shoots back to a healthy growth-bud. After this is done cleanse the trees and train them to the trellis. After fruit trees have been trained on walls for a number of years the brick-work becomes full of holes, and these should be filled in with cement. I prefer training the trees to wires fastened along the walls, for they are neater and permit the work of training to be done more quickly than when nails and shreds are used. First fasten the main branches securely in their places with strong twine, then fill the intervening spaces with the young wood, which should be disposed thinly and regularly over the wall space. A common error in Peach culture out-of-doors is to leave too much wood in the trees. The shoots should be about 9 inches apart. First twist the twine or matting around the wire, as this will prevent the bark being in immediate contact with the wire and allow room for the wood to swell when making the ties. When the training is completed spray the plants all over with an insecti-

cide to ensure perfect cleanliness both in the trees and the wall.

TOP-DRESSING OLD TREES.—After Peach and Nectarine trees have borne regular crops for several seasons they show signs of exhaustion, and the roots need to be top-dressed. The present offers a suitable time to carry out this work. Remove some of the old soil by means of a fork, taking care not to injure the roots, and replace with compost consisting mainly of sweet loam mixed with lime or mortar rubble, and a little charcoal. Work in fine soil amongst the small roots, and tread or ram the whole firm. Afford a copious watering if the weather is dry, and finish off by mulching with material from a spent Mushroom bed or peat-moss litter. Do not employ a thick layer of heavy animal manure. This will keep the soil cold.

PLANTS UNDER GLASS

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

CALADIUMS.—The plants, having been rested, may be started into growth again. Shake the old soil from the tubers and scrape away any decayed portions of the latter. Large specimens may be cut in halves, dusting the wound with powdered charcoal. If the plants are started into growth in boxes of peat and leaf-mould see that each variety is labelled carefully, and only just cover the tubers. Stand the boxes on a hot-bed in a Cucumber house to promote a quick, vigorous growth. Use the syringe on frequent occasions and keep the atmosphere well charged with moisture. If pots are used from the start the receptacles should not be larger than will just accommodate the tubers. The compost should be open in texture, and may consist of equal parts turfy loam, leaf-mould, lumpy peat, a little well-decomposed manure, some charcoal and sharp sand. After they are potted stand the plants in a house with a temperature of 65°; slight bottom heat is an advantage. Use the syringe two or three times each day, but afford water to the roots sparingly until growth is well advanced. As soon as the pots are filled with roots the plants may be afforded a shift into larger receptacles, using the same compost. Use plenty of materials for drainage, as the plants will require an abundance of water when in full growth. The dwarf, small-leaved *C. argyrætes*, employed as an edging to other stove plants, should be potted in 60's.

CANNA.—The old stools should be removed from their winter quarters, divided and placed in boxes containing leaf-mould and well-decomposed manure on a mild hot-bed. The atmospheric temperature should be about 60°. As soon as the leaves develop the portions may be potted in a rich, porous compost. Grow the plants in an intermediate house and remove them to the conservatory when in bloom.

COLEUS.—Insert cuttings of foliage varieties singly in small pots and root them quickly in a brisk heat.

PALMS.—It is not necessary to re-pot Palms every year, but any that need attention in this respect may be seen to now. It is surprising for how long a period Palms will keep in a good condition in the same pots if the roots are fed during the summer months with manure water. *Cocos Weddelliana*, *Kentia* and *Phoenix Roebelinii* are the best kinds for indoor decoration. They should be grown at the warmest end of the stove or Palm house. Specimens in small pots that are root-bound should be placed in slightly larger pots. Remove the old crocks from amongst the roots and fill the cavity made in doing this with soil. Place the ball of roots whole in another pot and press the added soil firmly. The compost may consist of three parts turfy loam, one part each of leaf-mould, sand and charcoal, with a 6 inch potful of bone-meal added to every barrowload of the materials. A little peat may be used for seeding Palms, but it is not necessary for established plants. Syringe the leaves twice daily from now onwards to promote a moist atmosphere and maintain a mean temperature of 60° to 65°. Seeds sown now will germinate readily if placed in a brisk bottom heat and kept moist.

THE APIARY.

By CHLORIS.

MANAGEMENT.—Draw up a scheme of work for the coming season, for although much of the success with bees depends on the weather, the flow of nectar and the working capacity of the bees, skilful management also tells. Every careful beekeeper is aware that one strong stock well cared for is more productive than half a dozen weak colonies. Occasionally a hive of bees will yield an excellent supply of honey with scarcely any trouble on the part of the beekeeper, but such cases are exceptions. If all or nearly all the nectar-bearing flowers are growing some distance from the apiary remove the hives to the source of honey and thus reduce the length of the journeys, for this will save much valuable time, because the honey season is always a very short one. Again, see that the colonies are each headed by a young and vigorous queen. Should any stock be ahead or behind its companions in the quantity of brood, then a wise apiarist will equalise matters. A watch, too, must be kept upon the wants of every hive, and above all see that swarms, after they are hived, have a good supply of food, because during the swarming season the weather often prevents the bees from going out in search of food and the larder is often empty.

WARMTH.—See that the quilts are ample and place layers of newspaper between them or under chaff or other cushions to conserve the heat, taking care to leave no gaping corners. Breeding has already commenced. Where a number of hives are kept nail a stout card—a postcard is suitable—on the roof of each hive for recording notes instead of trusting to memory, for mistakes are often made through confusing one colony with another.

THE "FRENCH" GARDEN.

By PAUL AQUARIAS.

HOT BEDS FOR CLOCHES.—These beds are formed in the same manner as those for frames. As Cos Lettuces do not thrive in very high temperatures the beds should not be more than 8 inches thick when well trodden, and they should be composed of one-third fresh and two-thirds dry manure. Black soil should be placed in the centre of the bed to form a ridge 4 or 5 inches deep when pressed down. Where only 6 or 8 beds are required it is preferable to make them at the same time and to complete the levelling and sowing on a bright day. When the beds for cloches are adjoining those for frames a 3-foot path should be left between. A similar path, formed half-way along the cloche beds, where there are more than 10 or 12 beds, will also be useful. When ready for levelling the soil mark out the position of each bed, which should be 4ft. 6in. wide. Place a peg at each corner, and stretch a line down both sides. Level the soil with the rake, and throw all lumps on the next bed to be covered. A sowing of Carrot Chantenay should be made very thinly, covering the seeds with sifted soil and pressing them down. It is not advisable to sow short-stumped varieties of Carrot at present, as long-rooted sorts are more saleable when this crop is ready in June. After sowing place the cloches in position. The line should be next placed against the pegs on one side, setting the cloches touching the line, and allowing a space of 1½in. between each to facilitate tilting the glasses when cleaning the crop. To set the middle row place a cloche at each end to determine the room needed. The line should be brought over against these end cloches on the outside, and the whole row is set as in the case of the first one. The same method is adopted for the third row, and it will be found there are about 2 inches of the width of the bed to spare, which becomes part of the path. The planting should be undertaken as soon as the beds are completed. Set two plants of Lettuce Little Gott on the south side only, for although many growers plant one also on the north side it is not to be recommended, as it does not thrive owing to the shade from the Cos Lettuce growing in the centre. Only the best Cos Lettuces are used for this batch. They are cleansed of all decayed leaves, and are set deeply and very firmly at the roots.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are mis-directed.

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, FEBRUARY 21—
B.G.A. (Godalming branch) meet.
TUESDAY, FEBRUARY 24—
Roy. Hort. Soc. Coms. meet.
THURSDAY, FEBRUARY 26—
Manchester & N. of Eng. Orchid Soc. meet. Roy. Botanic Soc. meet.
FRIDAY, FEBRUARY 27—
Finchley Chry. Soc. annual meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 40°.

ACTUAL TEMPERATURES:—
LONDON, Wednesday, February 18 (6 p.m.): Max. 45°; Min. 42°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, February 19 (10 a.m.): Bar. 29.8°. Temp. 46°. Weather—Dull.
PROVINCES.—Wednesday, February 18. Max. 43°, Mayo; Min. 37°, Aberdeen.

SALES FOR THE ENSUING WEEK.

MONDAY AND FRIDAY—
Herbaceous Plants and Hardy Bulbs, by Protheroe and Morris, at 67 and 68, Cheapside, E.C., at 12.
MONDAY, TUESDAY, WEDNESDAY, THURSDAY, AND FRIDAY—
The whole of the Nursery Stock at the Palace and Beaufort Nurseries, Stapleton, Bristol, re Parker and Sons (Bristol), Ltd., in voluntary liquidation. By Protheroe and Morris, at 12.
TUESDAY AND WEDNESDAY—
Nursery Stock, at Turners Nursery, Uxbridge (Land to be offered for sale shortly), by Protheroe and Morris, at 12.
WEDNESDAY—
Hardy Bulbs and Forcing Plants, Perennials, Border Plants, etc., at 12, Palms and Plants, at 5. By Protheroe and Morris, at 67 and 68, Cheapside, E.C.
THURSDAY—
Special Sale of Roses at Protheroe and Morris' rooms, at 1.
FRIDAY—
Sale of 1 acre 3 rods 7 poles Freehold Land at the Nurseries, Buckwell, Somerset; also the whole of the Nursery Stock. By Protheroe and Morris, at 12.
MONDAY AND WEDNESDAY—
Rose Trees, Perennials, Bay Trees, Lilies, etc. At Stevens's Rooms, King Street, Covent Garden, at 12.30.

Classification of Roses.

The National Rose Society is considering the advisability of revising the present classification of Roses. The questions to be determined are: Is any alteration desirable, and if so, upon what lines should the revision proceed?

Neither question can be satisfactorily answered until the object to be achieved by any new classification or arrangement has been settled and a definite decision arrived at as to the purpose for which the work is primarily intended to be used. Taken all round the method of arrangement at present adopted by the Society has worked wonderfully well, and on the principle of *beati pascidentis*, or, in other words, that every presumption should be made in favour of a system which time has sanctioned, it should not be disturbed unless there is something better to put in its place, and by better perhaps we should be understood to mean something not merely theoretically an improvement, but

which will be of practical service to the persons likely to make use of the new system.

The Society issues from time to time a catalogue of such Roses as are thought most worth cultivation. Under the present arrangement the statement of the raiser, or, in default of him, of the introducer, of any new Rose is accepted, practically without inquiry, as to the class in which it should appear, regard being had to the desirability of not increasing classes unnecessarily. Thus the Roses introduced as Pernetiana have been temporarily classed with Persian Yellow and Austrian Copper under the head Austrian hybrids, and in like manner all the Wichuraiana hybrids have been grouped under the name Wichuraiana, and the multiflora hybrids under Multifloras.

Then for purposes of exhibition only another classification has been made. A select list of Roses, considered specially suitable for exhibition, has been arbitrarily drawn up, and in some cases the class in which any amateur may show is dependent on the number of plants of Roses contained in this list and cultivated in his garden. Moreover, Roses in this list cannot, except in certain specified cases, be shown in the classes for decorative Roses. We believe entry into this list depends almost entirely on the frequency with which a Rose has been shown in a winning box, records of all the winners being carefully preserved. This list is revised annually, it serves an eminently practical purpose, and it does not seem clear how the method of dealing with it is likely to be altered with advantage.

Another list of new Roses for the purposes of certain classes in the exhibitions is issued annually, and should the requirements of the schedule makers cause it hereafter to become desirable, these lists intended purely for the use of exhibitors can at any time be extended, altered, or restricted.

The classification contained in the biennial official catalogue issued by the N.R.S. seems to stand on rather a different footing from that of the purely exhibition lists, and should the Society think fit to issue a more extended catalogue for purposes of classification, then the same remark would apply to this also.

Now the chief, if not the only, object of a classification is to give as compendiously as possible certain information about the plants or groups of plants contained in its several compartments, the various plants being so arranged that those in each compartment may be, so far as practicable, more like the others in that compartment than like those in any other compartment. What is the information that we desire chiefly to convey? In the task proposed we might proceed on one of two lines: we might attempt to proceed on the lines of a purely scientific classification, arranging the different varieties so as to give as much information as possible of the scientific position of each, examining for that purpose all the different organs, stems, thorns, leaves, and flowers, and grouping them accordingly; or, ignoring these methods, we might endeavour to arrange the varieties

according to the purposes for which they are most suitable for use in the garden. We might direct our efforts to obtain either a scientific or a garden classification. A scientific classification would involve much work of great value, and would quite probably be of much interest to many rosarians, bringing into prominence, as no doubt it would, many characters that down to the present have been passed over unnoticed by the majority, and though likely to raise many difficulties, it would settle some doubtful points, and would, it may be hoped, be of some practical value. To the great majority of the members of the Society, however, it is almost certain that a garden classification would be the more useful of the two, and therefore such a classification is the one that ought to be adopted.

Whichever basis were adopted, there are many difficulties that would be common to the two. Hybridisation has been practised to such an extent that in our garden forms there is often no clear line of demarcation between any two neighbouring groups. Moreover, as Darwin long ago pointed out,* the Rose naturally lends itself to the production of new groups in a comparatively short period, and even in the wild state intermediate forms connecting the different species together by natural links are common.

Let us illustrate this from the group *Villosa*. We have at the one end of the scale *R. pomifera* Herrm, then *R. mollis* Sm., *R. omisssa* Déségl. and at the other end *R. tomentosa* Sm. Now there is no difficulty in finding in nature plants the characters of which accurately correspond to those assigned by botanists to each of these types, but there are also found numerous variations or forms intermediate between these typical plants, which it is extremely difficult, and in some cases impossible, to refer with certainty to either of the two typical plants between which they are interposed.† Exactly the same thing occurs in our garden varieties, and in the last resort recourse must be had to a more or less arbitrary arrangement if some doubtful plant is to be placed in one rather than another division.

Places where such a difficulty is sure to occur lie in the dividing line between the Teas and H.T.s, the Chinas and H.T.s, and between the H.T.s and H.P.s, while the division between the Wichuraiana hybrids and some of the ramblers is in some cases not too easy to distinguish. In such cases those entrusted with the proposed revision will do wisely to be guided when possible by well-established custom, even when the solution of the doubt might seem to lie equally well on the side of change.

Another question not free from difficulty will be the treatment of those Roses now coming into use for bedding purposes, which include the *Polyantha* Pompons, the perpetual flowering dwarf Wichuraianas introduced by Messrs. Paul and Son, and the more dwarf of the hybrid Musk Roses. For the purposes of our gardens it is not unlikely that the employment

* See *Variation of Animals and Plants under Domestication*. Second edition, p. 461.

† *Cl. Crépin Bull. Soc. Roy. Bot. Belg.* Vol. 34, pp. 110, 113.

of these varieties may prove to be somewhat alike, and means might be found of grouping them as subdivisions of some class intended to include many of the bedding Roses.

Whatever scheme of classification is decided upon it will be desirable to be on our guard against attempting too great subdivision of the principal groups. The French have split up the Hybrid Perpetual section into something like thirteen different groups, which for the most part are headed each by the Rose from which the group has sprung or which it is supposed to resemble. Interesting though this is historically, it appears out of place in an arrangement intended primarily to give information as to the garden value of the varieties. That a large group like that of the H.T.s might with advantage be subdivided may be admitted, but subdivision should be carried out cautiously, and only employed where it can be shown to be a means of conveying definite information of the habit or capabilities of the different sub-sections.

The classification of Daffodils attempted a few years ago by the R.H.S. is worth study by those who undertake the proposed revision of Rose classification. The circumstances were in some respects similar, such arrangement as there was had grown up in reliance on the class assigned by the raisers to their introductions. No doubt this classification has certain points of merit, but perhaps the greatest is that it is definite, and on the other hand it affords more than one admirable illustration of what it is generally best to avoid. Two lessons to be drawn from it may be suggested. One is the danger of creating new sections for novelties that have not yet, and possibly may never, become established in gardens, and the other is the necessity for deciding clearly the object in view in working out the proposed arrangement and of adhering closely to it when it is determined.

Should it ultimately be decided to proceed with the proposed revision of a classification of Roses, it may be desirable that it should embrace a larger area than that to which the official catalogue is confined. It is even a question whether advantage might not be taken of the opportunity to make it comprehensive, and bring down the work of the "Noms des Roses" to the present day.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held in the Vincent Square Hall, Westminster, on Tuesday, the 24th inst. At three o'clock a lecture on "The Use of Explosives and of the Blow-lamp in the Garden" will be given by Dr. H. E. DERRHAM, Sc.D., in the lecture room.

NATIONAL DAHLIA SOCIETY.—A conference, under the auspices of the National Dahlia Society, will be held at Carr's Restaurant, Strand, on Monday, the 23rd inst.; at 7 p.m. Mr. GEO. GORDON, V.M.H., will preside. The following papers will be submitted: (1) "Observations on the Trials at Duffryn in 1913," by Mr. REGINALD CORY; (2) "The Modern Dahlia," by Mr. H. SHOESMITH.

* The *Noms des Roses* (Paris, 1906) is a complete list compiled by Messieurs Léon Simon and Pierre Cochet of the Roses introduced down to that date. It contains the names of 11,016 varieties, and is a most useful work of reference.

ROYAL VISITORS AT RAYNES PARK.—Their Majesties the KING AND QUEEN OF PORTUGAL honoured Messrs. JAMES CARTER AND Co. with their presence at Raynes Park on Friday, the 13th inst. The Royal party, whose visit extended over an hour, were conducted round the buildings by Mr. HAROLD BEALE, and were particularly interested in the extensive seed-cleaning machinery, and in the various germination tests in the laboratory. Messrs. CARTER have for many years held the appointment as seedsmen to the Royal House of Portugal.

ANIMALS AND PLANTS UNDER DOMESTICATION.—At his fourth lecture of the course, Professor BATESON discussed the origin and development of the Chinese Primula and of *Cyclamen persicum*. The origin of the Chinese Primula is not clear, but the botanists of the present day are in general agreement in ascribing it to the Primula found growing in the Tchang gorge by HENRY, WILSON, and others (see fig. 59). Nevertheless, all efforts to cross this plant with our Chinese

which occurred, and hybridising with them. With regard to the history of *Cyclamen persicum*, Professor BATESON said that it had been thought by many that our cultivated varieties had all come from one form, the *Cyclamen persicum* found wild in Palestine and Asia Minor, which was probably introduced into Europe in the beginning of the eighteenth century. But in the horticultural literature of the first half of the nineteenth century there are many records of attempts made to hybridise this plant with the European species of *Cyclamen*, and some of these claim to have been successful. At least, it is noteworthy that such attempted hybridisations were followed by the appearance of many new forms.

TRADE BANQUET AT LEICESTER.—The National Federation of Fruit and Potato Trades' Associations (Incorporated), Ltd., will hold important meetings at the Grand Hotel, Leicester, on Tuesday next, the 24th inst. There will be a meeting of the Executive Committee in the

FIG. 59.—PRIMULA SINENSIS GROWING ON THE ROCKS AT PING-SHAN-PAI, WESTERN CHINA (NAT. SIZE).

Primula have failed, and Professor BATESON considers it impossible that it has anything to do with our cultivated forms. It is known that the Chinese Primula introduced into Europe in 1821 had been already in cultivation in China, and in a Chinese book of the date 1828 a plant resembling our Primula is figured, and is said to have been grown in the gardens of Yunnan. The plant originally introduced and figured in the *Botanical Magazine* was of the pyramidalis type, and we now know that this is a hybrid form, which does not breed true, but throws plants with star-shaped flowers, and also plants with fimbriated flowers. Besides the plant introduced in 1821, seeds were imported in 1824 and distributed by the Horticultural Society. Between the years 1837 and 1842, nine varieties are said to have arisen, and this appears to have been the first break. Professor BATESON discussed in detail the behaviour of the different types on hybridising. He pointed out that these types have not been produced by a slow process of selection of one form from another, but by choosing the large variations

morning, from 12 noon until 1.30, a public conference in the afternoon from 2.30 to 6 p.m., and a banquet at 6.30 for 7 p.m. The secretary is Mr. HENRY W. GOODALL, Tavistock Hotel, Covent Garden, W.C.

THE KEW FLAGSTAFF.—The recent lowering of the flagstaff owing to decay removes for the time being one of the most conspicuous objects in the garden. The pole, a fine specimen of the Douglas Fir, *Pseudotsuga Douglasii*, came from Vancouver Island. It was brought to the London Docks slung to the side of a large vessel, towed up the river and erected in 1861. Its possession by Kew is due to the generosity of Mr. EDWARD STAMP, of the firm of Messrs ANDERSON, ANDERSON AND Co., who were at the time engaged in the timber trade of British Columbia. Commercially, the wood of the Douglas Fir is known as the Oregon Pine. The spar was originally 159 feet high and 20 inches in diameter at the base, the age of the tree from which it was cut being about 250 years and the total height 180 feet. When high up in the air

the top of the pole looked thin, but when lowered the apex was found to be as thick as a scaffold pole. Once previously, in 1896, it was found necessary to take down the spar, remove the base and splice on a piece of Pitch Pine. As might have been expected, the evidences of decay are now more serious. Even if it is decided to re-erect the sound portion, the pole will not form such an imposing feature as formerly, towering, as it did, above the tallest trees in the Gardens. We hope it may be possible to obtain an equally fine specimen from British Columbia. *Kew Guild Journal*, Vol. III., No. XXI.

FATAL ACCIDENT TO A GARDENER.—JOHN DONSON, a gardener, aged 65 years, living at Highbury, was killed on the 10th inst. whilst engaged in felling trees. The unfortunate man was sawing a branch at a height of 33 feet from the ground, whilst another person was holding a rope attached to the branch. It appears that the wood commenced to crack suddenly, and he was knocked from his position and fell to the ground, being killed instantaneously.

"THE BAZAAR, EXCHANGE AND MART" is going to issue one of its three weekly editions, namely, that published on Saturday, at a penny. The *Bazaar* has been a great public favourite for the past forty-six years, and this development should greatly increase its popularity.

TRANSIT OF FRUIT.—MR. WILLIAM RAWSON, a representative of the fruit importers in the Hull district, laid a grievance before the Railway Commission on the 6th inst., as to the practice of railway companies owning steamships giving foreign fruit-growers a preference on the sea which enabled them to send their fruit right through and undersell the English importers, who had to import their goods and then ship them on from Hull.

MR. KENNETH GRAY, a director of JAMES GRAY, LTD., horticultural builders, Chelsea, has this year been elected President of the Institution of Heating and Ventilating Engineers. Our contemporary *The Ironmonger* prints an appreciative notice and portrait of Mr. Gray in the issue for the 7th inst.

COCAINE IN INDIA.—The discovery, development, uses and, what is worse, the abuses of drugs, many of which are of vegetable origin, have in recent years followed each other in rapid succession and have been greatly assisted by the advent of the patent medicine vendor. So important, indeed, has the matter become that a select committee was appointed some time since to inquire into the present state of the law affecting the sale and advertising of patent or proprietary medicines. The important part taken by Kew in years past in the successful introduction into our oversea possessions of valuable economic plants, is exemplified by the success of the Cinchona cultivation in India, which has resulted in India producing her own quinine and selling it in penny packets at any post office. Another important medicinal plant which received attention from Kew was the Coca (*Erythroxylon coca*), the active principle of which is cocaine. The plant has been long known in Bolivia and Peru as a valuable nerve stimulant, and is used to prevent hunger, for which purpose the leaves are chewed by those undertaking long and arduous journeys. The chief use of cocaine with us, however, is as a local anaesthetic, but in India it has become a scourge, and an outcry is being made for more stringent penal legislation against smuggling and the illicit sale of the drug. The maximum penalty for cocaine smuggling in Bengal is three months' imprisonment, which is declared to be altogether inadequate considering the evils arising from the traffic. It is suspected that smuggling is largely carried on through Goa or other of the French settlements, and cocaine is also brought into the country from Germany by Austrian steamers.

PANAMA-PACIFIC INTERNATIONAL EXPOSITION, SAN FRANCISCO, CALIFORNIA.—MR. LEWIS L. SANDER, of Messrs. SANDER AND SONS, St. Albans, has recently visited the Exposition Grounds at San Francisco as the guest of Mr. GEORGE A. DENNISON, chief of the Exposition's department of horticulture. Messrs. SANDER intend to exhibit Begonias and Orchids. We are informed from San Francisco that already a large representation in the department of horticulture is assured from England, the reasons being, according to Mr. SANDER, that the opening of the West as a market for English shrubs and other products of the horticulturist is full of promise for the future. Mr. SANDER is reported to have expressed his appreciation of the preparations that are being made in the following terms: "This horticultural scheme is alone worthy of a visit from Europe. No exposition that I have attended—and I have seen them all during more than a decade—has ever approached your present undertaking, either in magnitude of conception, comprehensiveness of scheme, or grandeur of setting. This is the biggest exposition that was ever attempted."

"KEW GUILD JOURNAL."—The *Journal* of the Kew Guild for 1914 maintains the interest of former numbers. The frontispiece is a portrait of Mr. W. J. BEAN, the Assistant Curator, who entered Kew in 1883. Mr. BEAN's connection with the arboretum at Kew is well known, and he has seen it practically replanted. His first position was as sub-foreman in the Palm house, and he afterwards held a similar office in the Orchid department. Kew "Notes" give many interesting details connected with the Gardens. Many will be surprised to learn that no fewer than 3,792,581 persons visited Kew in 1913, the largest number on one day (August Bank Holiday) being 107,085. Members of the permanent staff have received substantial additions to their salaries during 1913, whilst the constables, labourers, and some others have also been granted concessions, but the young gardeners appear to have been overlooked. Two cottages have been purchased on the south side of Kew Green and will be used by the herbarium staff, chiefly for microscopic work.

BIRMINGHAM FLOWER SHOW.—The Birmingham Horticultural Society, which, it will be remembered, was formed three years ago from the nucleus of the old Handsworth Horticultural Society, has decided to hold a three days' show this year instead of two days, and the dates are fixed for Thursday, Friday and Saturday, July 16, 17 and 18. Money prizes are offered of the value of £600, and the awards include nine challenge cups, of the total value of 130 guineas, besides gold, silver-gilt, silver and bronze medals. The secretary is Mr. WM. G. CARRADINE, 36, Hamstead Road, Birmingham.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting of the members of the Surveyors' Institution—an afternoon meeting arranged for the convenience of country members—will be held in the lecture hall of the Institution on Monday, the 23rd inst., when a paper will be read by Mr. CHRISTOPHER TURNOR, entitled "Comments on the Land Enquiry Committee's (Rural) Conclusions." The chair will be taken at 4 o'clock.

TOMATO GROWING IN CEYLON.—Experimental plantings of Tomatos in the gardens at Peradeniya indicate (see *Topical Agriculturist*, 42, No. 1) that the crop may prove a paying one. The chief trouble in cultivating the Tomato in Ceylon is due to its liability to attack by *Bacillus solanacearum*, which causes a large amount of disease.

NEWSVENDORS' BENEVOLENT AND PROVIDENT INSTITUTION.—The attendance of subscribers, the Press, the trade generally, and all interested in the objects of this institution is

particularly desired upon the occasion of the seventy-fifth annual general meeting of the friends and supporters of this fund, which will be held at 15, Farringdon Street, London, on Thursday, the 26th inst., at 7 p.m. The President, Col. the Hon. HARRY L. W. LAWSON, M.P., will occupy the chair.

OLD GLASGOW GARDENS.—In a lecture delivered recently to the Junior Imperial and Constitutional League on "Glasgow in the Eighteenth Century," says the *Glasgow Evening Times*, Mr. THOMAS LUGTON made special mention of gardens and orchards. Till the middle of the eighteenth century Glasgow was a big village remarkable for its gardens. In 1683 HUGH WOOD, gardener at Hamilton, could supply the following fruits:—Gooseberries of three kinds, Red and White Currants, Strawberries, Apricots, three sorts of Plums, Black and Red Cherries, Swanegg, Achans, Wardens and Bergamot Pears, Peaches, and nine varieties of Apples. In vegetables WOOD could supply varieties of the following:—Beans, Peas, Shallots, Onions, Lettuce, Parsnips, Beets, Asparagus, Spinach, Kale, and Cabbages. In 1740 Baillie AUSTIN had for sale grass and garden seeds, flowers, and small fruit bushes at his nursery in Trongate, north side. In 1752 WILLIAM BOUCHER, nurseryman and seedsman, Edinburgh and Camlachie, Glasgow, could send, carriage free by carriers, a large assortment of shrubs, fruit and forest trees from his large nursery at Camlachie. Stobercross Mansion, at Anderston—removed about 1870—had a garden producing a great variety of fruits, roots, and flowers in 1750. The still well remembered Park House in Paisley Road had in the same year an orchard containing 1,000 fruit trees and half an acre of Asparagus.

TIGRIDIAS.

(See Supplementary Illustration.)

SEVEN species of Tiger Iris are known to science, and they are natives of Mexico, Central America, Peru, and Chili. Only three are in cultivation, whilst those generally grown are all forms of *T. Pavonia*, the Peacock Tiger Iris. Few flowers are more gorgeously coloured or more beautiful than the members of this genus, and they make a brilliant display during the months of July and August. Although the blossoms soon fade, numbers of fresh ones are produced in succession over a long period, which compensate for this fugitive character.

T. PAVONIA has scarlet flowers, with an orange-yellow basin, also spotted scarlet, whilst other forms have darker markings. It is a native of Mexico, and has been in cultivation since 1796. Of the numerous varieties, *Conchiflora*, which is one of the three reproduced in the coloured plate, has pale-yellow flowers, the centre depression being covered with crimson blotches. Although such a charming variety, it is of somewhat weaker constitution than the others. *Grandiflora* is a large-flowered form, with rich colouring, while the variety *alba* has white segments and cup spotted with ruby; flowers of *Immaculata* are often from 6 inches to 7 inches in diameter, and nearly pure white throughout. An exceptionally fine variety known as *Lilacea*, and sometimes as *Ruby Queen*, has large flowers of a vivid clear rose-colour.

Although generally considered to be only half-hardy, *T. Pavonia* is very easy of cultivation, provided the plants are grown in a warm, sheltered border or recess where they are protected from cold winds. They grow best in open, well-drained soils, and in warm districts the bulbs may remain in the ground all the winter, especially if planted deeply and afforded a thick mulching of leaves and litter. In heavy soils they are

VARIETIES OF TIGRIDIA PAVONIA (NAT. ORD. IRIDEAE).

best lifted in the autumn and stored in moist sand in a cool, frost-proof shed. The best time to plant is early in March, and the bulbs should be placed at least 4 inches below the surface. The plants need a plentiful supply of moisture at the roots, and if this and other details of cultivation are attended to, the plants will furnish an abundance of large flowers. *Tigridia Pavonia* has been much improved during recent years. "Le Geant Rose" has large flowers of a clear, unspotted rose colour, whilst "Le Geant Rouge" is similar in habit, but with intense orange-red coloured flowers with an unspotted rose-tinted cup.

T. PRINGLEI.—This species was introduced in 1883 from South Mexico, and is less hardy than *T. Pavonia*. The flowers are scarlet, the cup blotched with crimson. The stem is slender, and grows from 1 to 2 feet high.

T. VIOLACEA.—This species is also from Southern Mexico; it is less hardy than the forms of *T. Pavonia*. The perianth is coloured violet and

little affected by the inclement weather usually experienced at this time of year. It will thus be seen that *Rhododendron moupinense* is a most welcome addition to our gardens. *E. Willmott, Warley, Essex.*

A FASCIATED TROPAEOLUM.

ONE of the most remarkable examples of the very common phenomenon of fasciation is illustrated in fig. 61. Mr. Charles Prentis, who sends the specimen, states that the malformed plant (*Tropaeolum tuberosum*) produced the ribbon-like stem (E and C in the figure) to a height of 12 feet, and then threw up more normal growths, which reached to about 40 feet and flowered profusely.

The specimen is interesting, not only because of the fasciation which it exhibits, but also because of the tuber-like growths which occur along the course of the stem—for example,

fasciation, and we have seen a row of *Euonymus* in which most of the plants were fasciated, and have satisfied ourselves that the malformation was called forth by the persistent attentions of cows, which gained access to and browsed upon the young shoots. With respect to the formation of the aerial and monstrous tubers, it may be observed that many climbers—*c.g.*, *Dioscorea* sp.—form aerial tubers normally, and that Sachs, as recorded by Goebel in *Organography of Plants*, found that it is possible by artificial means to induce the roots of *Cucurbita* to form tubers. By removing all the growing points of the shoot Sachs showed that the root rudiments which lie right and left in the stem, close by the stalks of the leaves, grow out into short tubers, each about the size of a hazel nut. Inasmuch as a study of the abnormal is calculated to throw light upon the course of events which determines normal growth, it is to be hoped that botanists will devote attention to phenomena such as those presented by the *Tropaeolum* here illustrated, and generally carry on the interesting studies in teratology which Dr. Masters did so much to advance.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

MANAGEMENT OF THE L.C.C. PARKS.—It is with feelings of satisfaction that one who has been in touch with the inner working of the parks finds the *Gardeners' Chronicle* calling attention to the methods of management of the public parks under the control of the London County Council. We have seen not only an avenue of trees disappear at Finsbury Park, but also flower-beds abolished from several other parks. The excuse offered is that either a playground for children or extension of football ground is necessary. Surely the best place for children to play is under the shade of trees, where grass or plants will not grow. Again, we find, contrary to the usual practice, that football or other grounds are now allowed to be used when quite "unplayable." One can realise how costly such grounds are to keep up. The position of the superintendents must seem untenable, even from an outsider's point of view. Interference with the work of practical men by those with little or no knowledge of horticulture has of late years greatly lowered the prestige of our London parks. I, in common with several others, left the service of the L.C.C. several years ago, because it was increasingly evident that gardeners wishing to rise in their profession were not wanted. Just recently it has come to my knowledge that the men probably required for responsible positions in the future will only be those of fine physique, and soldiers will possibly have priority over all others. Perhaps other readers will know if my informant was right. *Private Gardener.*

PLANTS AT BITTON VICARAGE.—I send a photograph of a specimen of *Clematis cirrhosa* covering a tall holly, which I think you may like to see; but the picture does not do justice to its great beauty. I also send fruiting spray of *Zanthoxylum planispinum*, very pretty and a mass of red berries the size of pepper-corns. Also spray of male flowers of *Parrotia*. There is a promise of an abundance of flowers this year. *H. N. Ellacombe, Bitton Vicarage, Bristol.*

HORTICULTURAL REPORT OF THE BOARD OF AGRICULTURE.—I notice on p. 111 that the first report of the Horticultural Branch of the Board of Agriculture has just been issued, and that the price of this report is 2s. 2d. The price seems hardly fair to horticulturists, seeing that the *Journal* of the Board of Agriculture may be had monthly at the nominal price of 4d. *C. Frankish, Waltham Hall Gardens, Grimsby.*

CHICORY GROWING IN ABERDEENSHIRE (see p. 111).—I cultivated a fairly large quantity of Chicory last season of the variety Witloof, the seeds sown in deep soil on May 2; this variety must not be sown too early, as a number of my plants bolted. I should be glad to know

FIG. 60.—RHODODENDRON MOUPINENSE: FLOWERS WHITE (NAT. SIZE).
(Photograph by R. A. Malby.)

the outer segments are rosy-purple. The flowering season is a short one, for the plant usually produces only a few blossoms towards the end of May. *W. Irving.*

RHODODENDRON MOUPINENSE.

RHODODENDRON MOUPINENSE, which I exhibited at Vincent Square last year, and again last week, when it was given an Award of Merit, was raised at Warley from seed sent over by E. H. Wilson, whilst collecting in Western China for the Arnold Arboretum.

This *Rhododendron*, briefly described in the *Gardeners' Chronicle*, February 14, p. 113, is a very beautiful plant, whether grown as a pot plant or in the open. Its neat and compact habit renders it especially well suited to the rock garden, and the fact that it flowers the third year from sowing is an additional point in its favour. The beautiful, fragrant white flowers are of considerable substance, and are in consequence but

at F. The habit which in the normal plant results in the formation of periform, irregular tuberous roots manifests itself in the fasciated stem in true stem-tubers. That these structures are true tubers is clear; for, as illustrated at A in the figure, transitions occur between the thin lateral shoots and the extraordinary massive tuber-like shoot A. As shown in A, the base of such a transition shoot is swollen, and the leaves around the swollen part of the stem are reduced to mere scales. Imagine this swelling of stem and reduction of leaf to go further, and the result is a tuber shown at F in the figure.

As to the cause which has led to the fasciation we can say but little. Excess of nourishment is sometimes responsible for this form of "over-growth." For example, fasciation occurs not infrequently on shoots from stools and suckers, and it is said that it may be induced by pinching out the main shoot of seedling beans and allowing one of the cotyledonary buds to develop. Injury of the growing point may also lead to

if the roots of this particular variety are of use for making Chicory, as my plants had roots as large as big Parsnips. Our plants were grown for salad purposes. Witloof Chicory must not be grown in a very damp soil, as the foliage is very subject to damping. *C. R., St. Hilary Gardens.*

THE RUCKSACK.—There seems to be a doubt in the minds of some readers of the *Gardeners' Chronicle* as to the correct way of spelling the word "rucksack," and also as to the derivation of the word itself, so it may be useful to state the facts a little fully, and to indicate the conclusions which appear to

the terminal syllable sack (or sac) is of Latin origin (*Fr. saccus*), and as rucksack is a German and not a French word, sack is to be preferred. But it is in connection with the first syllable that controversy has arisen. There is no doubt but that rucksack (or rücksac) is wrong. It is etymologically incorrect, and in any case it could hardly convey the intended meaning of "a sack carried on the back." It remains, then, to consider what is the origin and historical meaning of the word written as rucksack. Some ingenious people have endeavoured to save the notion of "back" by appealing to a dialect—or archaic form of rücken (back)—namely, *ruck (-e)*. But there seems to be little real evidence for this

of that jumbling together of the contents of the bag, such as actually occurs in the ordinary rucksack. Moreover, this view of the derivation is that taken by German authorities most competent to form an opinion (*cf. Muret-Sanders, Encyclop. Wörterbuch, IV., p. 1681*). The original meaning of this word ruck is well seen in the expressions, "Einen kräftigen ruck geben" (give a good push), "Ein ruck am zügel" (pulling the reins). Anyone who has carried a heavy rucksack weighing 40 to 50 lbs. will vividly realise the aptness of the meaning embodied in the word ruck. It is not the position on the back of which one thinks, but of the load itself; and it is the shoulders, not the back, that really feel the strain. It appears, then, that the latter solution of the problem is probably the right one. *J. B. Farmer.*

ORIENTAL LILIES AND THEIR CULTURE IN SCOTLAND.—I have read with much appreciation the admirable article of Mr. A. Grove, entitled "Lilies in 1913," on pp. 33, 34 and 35 of the *Gardeners' Chronicle*. My own experience of the Lily season of last year—so memorable for its unusually long continuance of sunlight—almost entirely coincides with his. It is indeed seldom, as your correspondent has so clearly indicated, that we have such a uniquely beautiful period and of such comparatively extended duration, for the maturation of their resources and the revelation of their utmost powers. Not often have I seen such Lilies of commanding aspect as *Lilium giganteum*, longiflorum, Wilsonii, Henryi (a Lily of vigorous growth, of enduring character and much floral fascination), auratum platyphyllum, vars. Witte and virginale; *Lilium excelsum*, an exquisitely graceful garden hybrid, between the beautiful Madonna Lily and the scarlet Martagon; Brownii, Hansonii, a variety of distinctive attributes, or speciosum magnificum and Kraetzeri, grander in growth or more impressive in aspect than they were last year. *Lilium candidum*—one of the finest of Levantine Lilies, which is never more effective than when grown in borders among bright pink and crimson Roses (such as the incomparable Hugh Dickson and Mrs. Sharman Crawford)—I have seldom seen in Scotland to greater advantage, and its fragrance in the calm evenings of last summer was simply exquisite—"Like odours rapt from remote Paradise." The noblest specimen of *Lilium giganteum* I had the gratification of seeing last autumn was grown in the famous "wild garden" of the Viscountess Dalrymple at Lochinch Castle. I recently received a communication from Her Grace Millicent Duchess of Sutherland asking me to select Oriental Lilies of a vigorously growing and floriferous description for the garden and orchard of her new residence at Roehampton, consist chiefly of varieties that flower contemporaneously in June and July. Among others of hardly less beauty and reliability I have suggested *Sovizitanum*, *giganteum*, *Hansonii*, *candidum*, longiflorum, *Wilsonii*, the various beautiful forms of *Lilium elegans*, with auratum virginale and rubro-vittatum, and Brownii, Sargentiae, and Henryi, to flower somewhat later in the season. It is much to be regretted, in connection with this subject, that the speciosums so often delay, especially in shady gardens, their appearance till October, as they are, perhaps, the fairest and most fragrant of all. *David R. Williamson.*

A DICTIONARY OF HARDY PLANTS.—Writing in the *Gardeners' Chronicle* (Vol. LIV., November 29, p. 386) on the above subject, in my remarks concerning the plates I was so anxious that these should be the best possible that I was led to criticise somewhat severely the plates in Mr. Thompson's book on *The Alpine Plants of Europe*. In justice to Mr. Thompson, I wish to say that my criticism was indeed very severe, and did not allow sufficiently for the good figures that certainly are present in the book, and also to point out that I criticised equally severely the plates in Mr. Farrer's volume *The Rock Garden*. Owing to the omission of the latter remarks, I seemed only to be commenting on Mr. Thompson's book, which was not the case. I take this opportunity of reiterating my remarks as to the value of Mr. Thompson's book to all interested in Alpine plants. *E. B. Anderson, Dublin.*—[We append the words omitted. The reason they were de-

FIG. 61.—FASCIATION IN TROPAEOLUM TUBEROSUM.

A, B, tuber-like shoots of different strength; C, section of fasciated stem; D, section through swollen apex shown at F; E, ribbon-like stem; F, swollen apex. (See page 133.)

follow legitimately from them. The word rucksack originated among the German-speaking people in the Alps, and it has spread of late years through Germany, England, and other nations accustomed to visit the Alps. The word has largely displaced knapsack in this country, and also the corresponding word ränzen (satchel or knapsack) in Germany. As the rucksack is a bag slung across the shoulders, and rests on the back, the forms rücksack (or rücksac), from rücken (back), have been used, especially by English people, instead of rucksack (or rucksac), as the word is written on the Continent. Now,

view. Rücken is the current word meaning the back, even among the people who commonly carry, and speak of, the rucksack. It is not obvious why two different forms of the word should continue to be used, even if it could be shown that the article itself is old enough to render such a derivation historically probable. A more likely origin is, however, to be sought in another word, ruck, which has nothing to do with rücken, but means a push or pull, with a secondary implication of jerking or jostling, as well as expressing the notion of hauling a load. At the same time, it excellently conveys the idea

leted was that Mr. Anderson's criticism and recommendation rested on inaccurate assumptions. The "excellent plates of the *Gardeners' Chronicle*," are not reproductions from paintings, but from colour photographs taken by the same artist who took the photographs for Mr. Farrer.—Eds. "If there must be a coloured plate or so, let them be from actual paintings, such as the excellent plates of the *Gardeners' Chronicle*, and not from colour photographs, or such rather poor reproductions as the plates in Mr. Farrer's *The Rock Garden*; plates for which, I am sure, Mr. Farrer is not responsible, and which must have maimed and bruised his artist's soul when he saw them."]

BUCK SAVIN (see *Gard. Chron.*, Feb. 7, p. 99).—Waggoners here use the Juniperus Sabina to mix with horses' food. They are very particular to inquire for the male or "buck" variety. *A. Hillman, Hailsham.*

CROSSING THE CHRYSANTHEMUM.—Since the publication of my letter in the *Gardeners' Chronicle* of January 17 last, I have tried to get information from Kew Gardens, and the correspondence received from there has led me to believe they hold no records of a cross between the single Chrysanthemum and the Ox-eyed Daisy, or they will not inform gardeners upon the matter. I think this is a great pity when horticulturists are seeking for knowledge. I am also extremely disappointed that my letter had no response from your readers, and especially from some of those who attended the National Chrysanthemum Society's Conference. Mr. Norman Davis has made a suggestion that the cross was made. Is it possible? *M. E. Mills, Coombe House Gardens, Croydon.*

"CLEAN CULTURE."—In the *Gardeners' Chronicle* of November 29, 1913, there is an article entitled "The Philosophy of Manuring," which contains the following paragraph:—"The gardener must build up a soil of such constitution that it will both hold water and part with it readily to the plant, since decaying or organic matter, farmyard manure for example, imparts this property to the soil. This class of substance is looked upon as an ideal manure." In the answer which you give to *Clean Culture* in your issue of the 7th inst. you say "clean culture" appears to consist in "merely excluding the use of all animal and organic manure." As I understand "clean culture," it consists not in the exclusion, but in the use of all kinds of vegetable organic matter rotted down to a suitable consistency, but in the entire exclusion of animal matter. The question, therefore, seems to resolve itself into this: What does the animal matter in stable-dung or dung from the cow-house or pig-sty contain, which assists in "building up a soil of such a constitution that it will both hold water and part with it to the plant," and what advantage is derivable from animal manure which cannot be better obtained from chemical manure, especially as to the times and mode of applying the same? For garden purposes (and it is with regard to these that I write) chemical manures can generally be kept in solution and be applied whenever required as well as be applied in their original condition as a top-dressing. The question is of importance, for, even supposing stable dung to be an "ideal manure," it is becoming every year more difficult and expensive to obtain. *Clean Culture.*

DAHLIA "MARIANNE."—In reply to *Curious* (p. 95), who asks for the origin of Dahlia Barlow's Bedder, I believe that Messrs. Ware, Feltham, Middlesex, are the raisers, or at any rate they introduced the variety to commerce. When asking *Grower* if he had ever seen this variety and Gluchauf growing side by side with Marianne I did not intend to convey the idea that they were synonymous varieties. Far from it; for, as he states, Gluchauf is quite distinct, though classed with Marianne as a dwarf bedding Cactus, whilst Barlow's Bedder is scarlet, and described in Messrs. Ware's catalogue as a dwarf bedder rivalling *Salvia Zurich* in colour. My reasons for asking was because of *Grower's* emphatic statement that "there can be no two opinions about its being the best dwarf decorative Dahlia in existence." Waiving my own opinion, I can assure him that, to my knowledge, the varieties I named have found more admirers than his favourite. I thank *Curious* for correct-

ing my spelling of Gluchauf. Purchased from three sources, the name was spelled differently in each instance. *A. C.*

THE PRESERVATION OF WILD FLOWERS.—I believe there are in certain counties by-laws prohibiting the digging up of wild flowers and Ferns for sale. If these were in force in every county much destruction of our native flora would be prevented. I have in mind a district in North Staffordshire where thirty years ago every hedgerow and coppice was packed with Primroses. Now they are nearly exterminated, and only a few plants here and there are to be found. Hart's Tongue Ferns, too, were fairly common; at the present time I can only find one plant in the countryside. They have all been dug up and sent to the towns by the country people. The same thing is happening in the Nottingham district. Ferns and Primroses are being dug up wholesale and sold by hawkers in the streets. *W. Parker, Superintendent's Office, Nottingham Corporation Public Parks.*

PROPOSED AMALGAMATION OF THE ROYAL CALEDONIAN HORTICULTURAL SOCIETY AND THE SCOTTISH HORTICULTURAL ASSOCIATION.

—I am not aware of the source from which the latter part of the report of the annual business meeting of the Scottish Horticultural Association which appeared in the *Chronicle* of January 31 emanated, but the statement that I "explained that on the last occasion on which an effort was made to unite, the difficulty of the Charter of the Royal Caledonian Society was considered insurmountable" is incorrect. I made no such statement. What I said was, that the Crown would not agree to accept surrender of the Charter, and that were amalgamation to be brought about without this the Crown could appropriate the funds of the Caledonian Society. I trust this correction will receive the same prominence in the paper that the allegation has received. *A. D. Richardson, Secretary of the Scottish Horticultural Association.*

GRAFTING ROSES (see pp. 52, 106).—In my experience 65° is the most suitable temperature to start with under the propagating frames, with bottom heat, of course, a degree or two higher. The amount of warmth may be increased gradually after the first week or two up to 70° and 75° on bright days, and I have always found a few degrees lower to answer best during the night. I agree with *Experience* that for the first few days the frames should be kept closed, as the grafted plants requiring little moisture at the start there would not be sufficient condensation for the time being to cause any injury through damping. If after the fifth day there is too much moisture the lights can be tilted for a couple of hours in the morning, or the ventilation may be graduated according to the weather, closing the frames early in the afternoon. The best time to take the grafts from the frame is when there is a good callus at the junction of stock and scion and the top growth begins to be active. The plants will not be all ready at the same time, and it is usual to pick out the more forward specimens daily and place them on the stage of the house close to the roof-glass. The difference in the flow of sap arises from several causes. The kind of stock used is one factor. Again, plants worked on established stocks that have been stood outside during the summer will respond differently from those that have been lifted from the ground a few weeks before being brought under glass with little or no root action to start with. The former will be quite a fortnight in advance of the latter, which, probably, as *Amateur* observes, might take six weeks before being ready to work. On established stocks the earliest grafts would be ready to take out of the frames by that time. I am referring now to dormant grafting, which is usually finished early in February. *J. D. G.*

—When I advised that no ventilation should be afforded for the first six days after grafting, I did not imagine any gardener would refrain from wiping the glass each morning to remove condensed moisture, which is necessary whether in the case of a cloche or any other covering. The few moments occupied in doing this cannot be considered ventilation in the strict sense of the

term, such as I indicate later in my remarks by placing a label under the light for half-an-hour twice a day. In the short space of five days there can be no damage by damping provided dormant, well ripened wood be used as scions. I know there is a difference of opinion about temperature for grafting Roses, but most experts will agree with me that, provided a stock is established, the quicker it can be induced to form a callus the better. *Amateur* states that it sometimes takes six weeks before some grafts commence to grow, but if delayed until this time the chances of ultimate success are very remote, and on the contrary no propagator would, I think, remove the grafts from the case in a few days, no matter how promising they appeared. *Experience.*

CYANIDING TO DESTROY MEALY BUG.—Mr. James Fulton criticises on p. 94 the remark of your correspondent, *J. H. Y.*, that a vinery in fruit cannot be cyanided, and that he cannot understand why. But Mr. Fulton says nothing to show *J. H. Y.* or any of your readers how it can be done. I consider that it is useless for anyone to write in the strain of Mr. Fulton's letter unless he is prepared to state definitely the exact quantities of potassium or sodium cyanide used per 1,000 cubic feet by himself. I have used here Edward's cyaniding apparatus for the last three years, but, like *J. H. Y.*, I do not as yet approve of cyaniding a vinery whilst in fruit, and this conclusion is the result of actual experience. Three years ago I cyanided a house of Muscat Grapes when the berries were beginning to colour. I used $\frac{3}{4}$ oz. of sodium cyanide, 130 per cent. per 1,000 cubic feet, with the following proportions of water and sulphuric acid:—6 oz. water and 2 oz. sulphuric acid to each oz. cyanide, the sulphuric acid being that known as commercial acid. All the young leaves and points of the lateral growths were killed, consequently the Grapes did not swell to their usual size. If Mr. Fulton would state clearly the quantities of cyanide he uses per 1,000 cubic feet, and whether sodium or potassium, and the percentage of same, he will assist many. There is not the slightest doubt but that cyanide is most dangerous to the operator unless handled very carefully. In cyaniding a late vinery which adjoins a plant house, several plants were damaged by the gas getting through the crevices of the partition, and our houses are all in first-class condition, being as good as new. I paste paper around the crevices of the door in this house, and also over any crevice where the gas might get through, and still some plants have to be removed for safety. *James Colville, Epsley Hall.*

—When Mr. Fulton (p. 94) is so emphatic in stating that a vinery can be safely cyanided when the fruit begins to colour, and he repeats the operation for four or five weeks, I hope he is right. Although it is hard to believe that the fruit does not become contaminated by the fumes, I may give the following instances of fruit being affected by other fumes. Some time previous to taking charge of these gardens every glasshouse here was put in thorough repair, and it so happened that a vinery in fruit was painted inside. Those who partook of some of the grapes afterwards suffered severe intestinal disorder. On another occasion the same effects were produced after lightly fumigating a few Nectarine trees with X.L.A.I. compound; therefore I say be careful of subjecting fruit approaching maturity to fumes of any kind. Of course, the effect of the fumes is not apparent after the fruit has been allowed to hang for any length of time afterwards. Mr. Fulton also states that cyaniding is certain death to white fly. It will be a benefit if it is. I have tried nicotine vapouring compounds at different strengths, and I notice that, although the flies fall down as if completely dead, they are only dazed and most of them rise again, some soon after, others after many hours. I find it best to well syringe the pests with an insecticide when they are down in this dazed condition. *Chas. F. Coates, Manor Park, Potton.*

—Mealy-bug is present in the vineries here, and we cannot get rid of the pest. I read with interest the article by Mr. Fulton (p. 94), and I would very much like him to give the full particulars of bowls and quantities of cyanide and water he uses; also the quantities accord-

ing to the size of house. Is there no danger of cyanided fruit causing poisoning? *T. P. Colvin.*

JOURNEYMEN GARDENERS' WAGES.—*Journeyman* (page 96) says, "A journeyman receiving 18s. per week, with bothy, etc., is better off than many head gardeners. The journeyman need only pay 7s. or 8s. a week for his board, and if steady can save 10s. a week." That may be the case with himself, but what about those in lodgings, and how many journeymen get 18s. a week, with bothy, etc.? I think, take it on the whole, the average wage for journeymen nowadays is 16s. or 17s., with bothy. The cost of living being so high, how many can save 10s.? But one cannot wonder at wages being low, for those advertising for journeymen require applicants to state experience and wages required, and, nine times out of ten, the man that states the lowest wage is engaged. What have the head

a week. I am glad to see that in many establishments the staff is allowed the Saturday half-holiday; and why not, considering that the men have to undertake Sunday duty and work overtime in many places without extra remuneration? *Journeyman* (p. 96) says a steady lad can save 10s. a week out of 18s., but to do that one must possess a very contented disposition to remain always in the isolated bothy in the country. Much of the blame rests with gardeners themselves, and I urge upon young gardeners, especially those taking responsible positions, to demand a wage equal to meet the increased cost of living. *Another Journeyman.*

—The correspondence on journeymen's wages seems to have drawn from several of your correspondents the fact that to obtain better wages and better conditions it is necessary to be unanimous on the point at stake. Several, too,

mittee the benefit of his views, we should get on towards his ideal and ours a little faster. How many bothies are not fit to live in? The B.G.A. endeavours to point out existing evils, trusting to get them righted, by using common-sense methods and not force. The Association wants employers to grant their men a half-holiday on Saturday, and a living wage. Surely, too, we need protection against the influx of unskilled labour to responsible positions. The B.G.A. has encountered apathy, fought it, and is winning; and if the gardening profession as a whole breaks down this barrier not only wages but the status of our honourable calling will be raised to its proper level. *A Member of the London Branch.*

—Thanks are due to Mr. Hudson for his remarks on the abilities of present-day journeymen. Mr. Hudson, being at the head of a first-class establishment, would naturally be able to obtain the pick of the available men, and it may be argued by some that his opinions on this subject are therefore inaccurate. But Mr. Hudson does not employ all the good men, and those he does employ do not serve all of their time as journeymen with him. I agree with Mr. Hudson's remarks about apprenticeship at a premium, but he does not say whether such a system tends to keep wages down or not. Probably it does do so, but the practice appears to be dying out, and has no appreciable effect on wages to-day. In reply to *Agra*, may I point out that we may, without being unduly pessimistic, count on the present prosperity in trade being followed by the inevitable slump, and the concomitant result will be that our profession will again be over-crowded. We must therefore search at once for a remedy for the admittedly bad state of affairs. In my opinion, the only thing that will provide a remedy is combined action. This can only be brought about by some form of union. There is some doubt as to whether the B.G.A. is proceeding on the right lines, but, at any rate, it is a beginning, and as such deserves encouragement. Another of your correspondents says that the practice of journeymen accepting a low wage for the sake of getting a reference is not conducive to the production of the best work, but I should think that the reverse is more likely to be the case, as the better the work is done the better will be the reference. But I believe this practice tends to keep down the standard of wages, as the heads of some establishments may take advantage of it to secure good men at a comparatively low wage, with the certain knowledge that the men will do their best for the sake of the reference and the chance of getting a good job when they leave. Mr. Evans seems to insinuate that the chief interests of journeymen nowadays lie in sport and penny novelettes; but I think I showed in my last letter that this is not so, and my view is supported by Mr. Hudson and *Forty Years' Head*. I may also add that I do discuss my work whilst doing it, and also after work hours, and I find most journeymen are ready to do so. Only last evening five of us discussed horticultural subjects for several hours, and that is no infrequent occurrence. Personally, I never read a penny novelette. With reference to *H.*'s remarks, I can assure him that we do appreciate the head gardener's difficulties. If he approaches the subject in the manner he suggests, he will most certainly put his employer's back up; but if wages are low in his establishment he may point out that he can only get indifferent men in consequence. *Modern Journeyman.*

—One would think, after reading the correspondence on this subject, that a gulf—more or less wide—existed between head gardeners and journeymen. Experience, based on a number of years in the profession, has proved to me the contrary, their interests being comparatively identical; therefore any effort intended to improve their lot must be a united one. That both are inadequately paid is only too evident; indeed, a number of cases brought to my notice would only be described as "sweating." Young gardeners would do well to supplement their horticultural studies with the study of legislation likely to affect them, such, for instance, any proposed Housing Bill, as it would affect the abominable hovels called bothies where the young gardeners are housed. In other branches of legislation the young gardener especially might be indirectly, if not directly, affected. *J. T.*

FIG. 62.—CATTLEYA TRIANAЕ MRS. PHILLIPS: SEPALS AND PETALS WHITE WITH CRIMSON SHOWING IN THE CENTRE OF EACH SEGMENT.
R.H.S. Award of Merit, February 10, 1914. See p. 115, ante.

gardeners to say about that? Can journeymen expect to get a working wage while this sort of thing goes on. I think head gardeners getting 25s. a week and house are as well off as journeymen getting 18s. *C. H.* states in the issue for January 24 that he has been in his present place six years, and gets 23s. 6d. and has to pay 8s. rent. While head gardeners work for such a wage as that the employer is not going to pay under gardeners a good wage. Who is to blame? One cannot wonder at journeymen sticking up for a working wage. I quite hold with what *R. J. D.* said on page 96. *J. H.*

—I have read with great interest the discussion on journeymen's wages, and I hope it will have good effect. It is indisputable that not only journeymen, but gardeners in general, are underpaid. But we are told the employment is steady and constant. I quite agree—seven days

have urged combination, and yet no one seems to point to the British Gardeners' Association as an effective remedy for the admitted weakness of an unorganised profession. Teachers, lawyers, journalists, and many other craftsmen have combined and formed associations which rightly guard their several professions. These are not trade unions in the general sense, and do not work on quite the same lines as trade unions. They exist for the object of ensuring adequate remuneration for their services, to keep out unqualified men, and to raise each profession to a certain status. Who will argue against such? I contend that the spirit of the B.G.A. is similar. I often wonder why gardeners take their lot so quietly, for many have a hard life. The B.G.A. is out to better it, if possible, and I make bold to say that if every gardener who "sits on the fence" and picks holes in the B.G.A. would join, and give the Executive Com-

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 10.—Present: Mr. E. A. Bowles, M.A., F.E.S. (in the chair); Dr. A. B. Rendle, M.A., F.R.S., Sir J. T. D. Llewellyn, Bart., Messrs. A. Rolfe, W. C. Worsdell, A. Worsley, R. H. Curtis, W. Fawcett, C. E. Shea, W. E. Ledger, G. Wilson, J. Fraser, E. M. Holmes, G. Gordon, and F. J. Chittenden (hon. sec.).

Hybrid Pelargoniums.—Mr. FRASER continued his remarks upon the origin of scented Pelargoniums, and illustrated them by specimens from the Wisley collection. He dealt principally with Pelargonium zonale, P. inquinans, P. betulinum and P. cucullatum.

Odontoglossum sp.—Mr. ROLFE exhibited on behalf of Mr. H. S. Goodson, of Fairlawn, Putney, a rare species of Odontoglossum from Peru. Mr. ROLFE took a specimen to examine and report upon it.

Odontonia × Luciliae.—A plant of this new hybrid was submitted to the Committee from the Orchid Committee. It was raised from seed of Odontoglossum cirrhosum fertilised by pollen of Miltonia spectabilis Moreliana. It has apparently proved difficult to raise a cross the other way, and the result has given a remarkable purple flower. A Certificate of Appreciation was unanimously recommended to Messrs. CHARLESWORTH, the raisers.

Fusarium bulbigenum.—Mr. SHEA referred to this parasite of Narcissus and other bulbs, and the Secretary recounted its history in England. It was described some years ago by Messrs. Cooke and Masee, and was apparently lost sight of for about twenty years until in the hot summer of 1911 specimens were shown before this Committee, and in that year the fungus proved troublesome also in Holland. There are grounds for supposing that rather high temperatures are necessary for the development of this fungus, and that therefore it is likely that the disease will be evident only in certain seasons, at any rate to a harmful extent. It was again found in several places in the past summer, and in both seasons rotting of the bulbs was brought about by it. It is important, of course, that bulbs showing any sign of the attack should not be planted, and it might be well to plant, at least for a year or two, newly imported bulbs, whether grown in England or abroad, quite apart from those already in the garden.

Crocus aerius.—Mr. BOWLES showed a Crocus which has recently been imported under the name of C. Tauri, but which appears to be only C. aerius, a species native in Persia and described by Herbert in the *Journal of the Society* in 1847.

Violets with two or three flowered stems.—Mrs. ALMA BAKER, of Newton Abbot, sent specimens of Violets with two or three flowers on a stem. This mode of flowering occurred in several gardens a few years ago, and was recorded in the Minutes of the Committee, since when it has been observed in many parts of the country.

Propagation of Hemionitis.—Mr. CHITTENDEN showed young plants of this fern growing from the junction of leaf-stalk and blade after they had been removed from the plant and inserted in sand in a propagating pit, much as is done with Begonia leaves. Young plants are quickly formed, and grow rapidly. In one case a young plant had been found in this position while still attached to the parent plant.

NATIONAL CHRYSANTHEMUM.

FEBRUARY 16.—A meeting of the Executive Committee was held at Carr's Restaurant on this date. Mr. Bevan presided. To commemorate the twenty-first year of the Stoke Newington Chrysanthemum Society it was resolved to offer that body the N.C.S. large Silver Medal for competition at their next show. The Derby Gardeners' Association was admitted in affiliation. The interim financial statement, which was submitted by the secretary, showed a satisfactory working balance. The vacancies on the Floral Committee, necessitated by the retiring of one-

third of the members according to rule, were filled by the election of Messrs. C. H. Curtis, Emberson, Prickett, Springthorpe, T. Stevenson, H. J. Jones and R. Ballantine. The members of the Finance, Schedule and Publications Committees were also elected. It was decided that the annual outing should be a river trip, and take place on Monday, July 20, or failing that date, July 27. Mr. Leach was thanked for his kind invitation for the committee to visit Woodhall on June 22. Subject to the President's approval, the annual dinner will take place at the Holborn Restaurant on November 26.

ROYAL METEOROLOGICAL.

JANUARY 21.—The annual general meeting of this society was held on Wednesday the 21st. ult. at the Institution of Civil Engineers, Great George Street, Westminster, Mr. C. J. P. Cave, M.A., president, in the chair.

The Council's annual report referred to the various branches of work which had been carried on by the society during the past year. These included researches in the upper atmosphere, meteorological lectures, the collection of phenological observations, and the commencement of the preparation of a series of normal values of the climatological elements of the British Isles.

The Council awarded the Symons Gold Medal for 1914 to Mr. W. H. Dines, F.R.S., in recognition of his distinguished work in connection with meteorological science.

Mr. CAVE in his presidential address dealt with the subject of upper air research. He pointed out that research in the upper air may be by means of manned balloon with observer and instrument, or by self-registering instruments sent up in kite, captive balloon, or free balloon. Kites were first used for this purpose by Dr. Wilson, of Glasgow, 1749; and also in Arctic expeditions in 1821 and 1836. The box kite and the use of steel piano wire instead of line enabled greater heights to be attained; and both were adopted by the Blue Hill Observatory in 1895. The use of kites was not taken up in England till 1902, when Mr. Dines flew them from a steamer. After referring to the use of balloons and the ascents made by Glaisher and others, the President said that danger to life in high ascents caused M.M. Hermite and Besancon to use a registering balloon in 1893; a free balloon carried a recording instrument, the recovery of the instrument being dependent on the balloon being found after its descent; a height of nine miles was reached in France, and thirteen miles in Germany soon after. He next referred to the various types of instruments used in the research, and described Mr. Dine's meteorograph, which is an extremely simple and light instrument. Rubber balloons are usually used, and as they ascend they record the winds above the surface, a special theodolite being used for observing the balloons. The International Commission for Scientific Aeronautics directs the studies for upper air research, and special days are arranged for international ascents of balloons and kites, stations in various parts of the world taking part in the work. The first great result of these researches has been the discovery that the atmosphere is divided into the Troposphere, where the air is in constant movement, horizontal and vertical, and the Stratosphere, where turbulent motion seems to cease. The Stratosphere begins at about 7.5 miles in these latitudes. The method of investigation is new, but many other results are beginning to come to light, and it seems as though changes of weather do not begin at the surface of the earth, but are dependent upon movements taking place about 7.5 miles up.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

FEBRUARY 9.—The monthly Committee meeting of this society was held at the R.H.S. Hall on Monday the 9th inst. Mr. Chas. H. Curtis in the chair. Three new members were elected. Three members were assisted from the Distress Fund, and two members were allowed to withdraw double the amount of interest, viz., £3 12s. 8d and £2 1s. 2d. respectively. The Secretary reported that the accounts on the State Section of the Society had been passed by the

Government auditors. The annual meeting will be held on March 9 at the R.H.S. Hall at 7.30 p.m.

ABERDEEN CHRYSANTHEMUM.

FEBRUARY 14.—The annual meeting of the members of this Society was held in the Young Men's Christian Institute Hall, Aberdeen, on Saturday, the 14th inst. There was a good attendance, and ex-Baillie Middleton, chairman of the Society, occupied the chair. The chairman moved the adoption of the report and financial statement for the past year, which were considered very satisfactory, and they were cordially approved. Lord Provost Maitland, Aberdeen, was re-elected hon. president, and ex-Baillie Middleton was appointed as hon. vice-president. Ex-Baillie Allan, Aberdeen, was unanimously elected chairman, Mr. David Ritchie vice-chairman, Mr. Magnus H. Sinclair secretary and treasurer. The committee was also elected. It was decided to hold the next annual exhibition in the Music Hall Buildings, Aberdeen, on Friday and Saturday, November 20 and 21.

ABERDEEN NATURAL HISTORY.

JANUARY 16.—A largely-attended meeting of the members of this society was held in the Botanical Classroom, Aberdeen University, on Friday, the 16th ult., when Dr. JAMES W. H. TRAIL, Professor of Botany in Aberdeen University, delivered an illustrated lecture on the "Arctic-Alpine Flora of Scotland." Dr. Gibb, Lecturer in Geology, occupied the chair, and in introducing the lecturer said Dr. Trail was the first president of their society. Most of the plants, said Dr. Trail, were found at an altitude of 2,500 feet above sea-level, and he proceeded to show numerous illustrations of Alpine plants, including the Dryas, the Snow Gentian, Saxifragas, Willows, Silene and Whortleberry. The lecturer pointed out that many of the Alpine plants have beautiful flowers and flourish in great profusion during the short summer season.

Professor J. Arthur Thomson, Aberdeen University, in moving a vote of thanks to Dr. Trail, referred to the excellent lessons which the doctor had pointed out as to the way in which Alpine plants overcome difficulties and suited themselves to the conditions in which they flourished. In acknowledging the heartily-given vote of thanks, Dr. Trail mentioned that those present might have an opportunity of examining the collections of Alpine plants made by the late Professor Macgillivray and the late Mr. John Roy, who was for many years a head schoolmaster under the Aberdeen School Board. Dr. Trail mentioned that Mr. Roy had prepared a flora of the north-east of Scotland, but had handed it to the Rev. Dr. Ferguson, of Fearn, with instructions to his executors to have all papers burned. That had, unfortunately, been only too faithfully carried out, but his collection of plants had been saved by Mrs. Roy and presented to the Aberdeen University, where it was likely to remain as a worthy memorial of one who was a most conscientious worker, and one whose memory they would ever hold in high esteem.

ST. GERMAN'S HORTICULTURAL.

FEBRUARY 7.—The fifth annual dinner of this excellent local society took place on the 7th inst. at the Victoria Mansions Restaurant, when, owing to the indisposition of the President, Sir Edward Coates, Bart., M.P. for Lewisham, Mr. W. E. Robinson took the chair. The toast of the evening, "Success to the St. German's Horticultural Society," was proposed by Mr. T. W. Sanders. The Chairman of Committee, Mr. W. H. Collins, replied. Among other speakers were Mr. Harman Payne, who replied for the visitors.

PUBLICATIONS RECEIVED.—*One and All Gardening, 1914.* (London: Agricultural and Horticultural Association.) Price 2d.—*Wild Flowers.* By Macgregor Skene. (London and Edinburgh: T. C. and E. C. Jack.) Price 6d.—*Transactions and Proceedings of the Botanical Society of Edinburgh.* Vol. xxvi. Part II. Secretary, Mr. W. W. Smith, Royal Botanic Gardens, Edinburgh.

MARKETS.

COVENT GARDEN, February 18.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—EDS.]

Cut Flowers, &c.: Average Wholesale Prices.

Table listing cut flowers and their wholesale prices, including Arums, Daffodils, Gardenias, Lilies, and various orchids and roses.

White Freesia, and Anemone fulgens are arriving in good condition from Sicily and Guernsey. There is a good supply of Carnations, Azalea, Arums, Lilium Harrisi, Tulips, Lily-of-the-Valley and Forget-me-Nots. There are exceptionally fine blooms of Violet Princess of Wales on sale. Snowdrops and Wallflowers are very plentiful. Roses show an increase in numbers, especially the varieties Richmond and Niphotos; there are also some fine blooms of Lady Hillingdon, Sunburst, Mrs. Ward, and Liberty. Roses are selling freely, and at reasonable prices. In the foreign flower market Violets are the most plentiful subject, but many baskets of these flowers are arriving in an unsaleable condition, pointing to the finishing of the season. Pink, Red, and single varieties of Anemones, similar to the St. Bridget varieties, but with larger blooms, are on sale. There is a fair supply of Mimosa, Yellow Marguerites, White and Pink Stocks, and Freesias. Parma Violets are more plentiful, but they show the effects of the long journey sooner than the singles.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing plants in pots and their wholesale prices, including Aralia Sieboldii, Asparagus plumosus, and various ferns and cacti.

Continental growers are lessening, and the prices have risen. Tomatoes from the Canary Islands are a full supply, but trade in them is slow. Mushrooms are sufficient for the demand. Asparagus is arriving from the Evesham district. Forced Beans from Guernsey have been scarcer, also Peas. The quantities of Seakale are more than sufficient to meet the demand. Ordinary vegetables are plentiful.—E. H. R., Covent Garden, February 13, 1914.

Vegetables: Average Wholesale Prices.

Table listing average wholesale prices for various vegetables such as Artichokes, Asparagus, Beans, Cabbages, Carrots, Cauliflowers, Celery, Chicory, Cucumbers, Endive, Garlic, Horseradish, Lettuce, Leeks, and Onions.

Potatoes.

Table listing prices for different varieties of potatoes including Bedford, Blacklands, British Queen, and Kent.

REMARKS.—In the plant market flowering subjects form the leading feature just now. Some very fine Cyclamen are still on sale. The other subjects include Cinerarias, Genistas, White Marguerites, Erica Willmorei, E. persoluta, White Spiraea, Hyacinths, Tulips and Daffodils. Azaleas are very plentiful.

Fruit: Average Wholesale Prices.

Table listing average wholesale prices for various fruits including Apples, Lemons, Limes, Lychees, Mangoes, Nectarines, Oranges, Pears, Pineapples, Plums, and Strawberries.

REMARKS.—A few fruits of Bramley's Seedling are the only home-grown Apples obtainable. Supplies of Apples from overseas in boxes and barrels are sufficient for all demands. The first shipment of Australasian Apples is in course of transit. Arrivals of Cape fruits to hand comprised 12,000 boxes of Plums, Peaches, Nectarines, Pears, Grapes, etc. Another boat with fruit is expected to arrive on Saturday next. Forced Strawberries from the Worthing district are arriving daily. Supplies of Grapes (Black) from English and

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending February 14, is furnished from the Meteorological Office:—

THE WEATHER IN WEST HERTS. Week ending February 13, 1914.

The Wettest Twelve Days as Yet of the Present Winter. —This was another very warm week, and the third week in succession in which both the day and night temperatures have been as a rule unusually high for the time of year. On the warmest day the highest reading in the thermometer screen was 57°, making this, with three exceptions, the warmest day recorded here in February during the last twenty-eight years, and on the warmest night the thermometer exposed on the lawn only fell to 46°, making this, with three exceptions, the warmest night recorded here during the same period. There were no cold days, but on the one cold night the exposed thermometer registered 11° of frost. The ground is at the present time 4° warmer at 2 feet deep, and 5° warmer at 1 foot deep, than is reasonable. Rain fell on five days during the week, and to the total depth of 1½ inch. During the last twelve days 2 inches of rain has fallen, which is rather in excess of the average quantity for the whole of February, and more than fell during the two previous months of the present winter. Of that amount, 8½ gallons has already come through the bare soil percolation gauge, and 7 gallons through that on which short grass is growing. The sun shone on an average for 2½ hours a day, which is about the average duration for the same period in February. The winds were, as a rule, moderately high, and on one day the mean velocity for the windiest hour reached twenty-one miles—direction S.S.W. Since the beginning of the present month there has been a great prevalence of winds from some point between south and west. The mean amount of moisture in the air at three o'clock in the afternoon fell short of a reasonable quantity for that hour by 8 per cent. A selected patch of yellow Crocuses in my garden first showed an open flower on the 14th inst., or ten days earlier than its average date for the previous twenty-seven years, but ten days later than last year. E. M., Berkhamsted, February 13, 1914.

REMARKS.—The supplies generally show an increase on those of last week. Trade has improved a little, and prices are lower. Except for a few best varieties of English-grown Daffodils the value for these flowers is higher. Supplies of Narcissus Poeticus are sufficient for the demand. Yellow and White Daffodils, Poet's Narcissus,

TRADE NOTE.**MESSRS. ROBINSON BROTHERS, LTD.**

WE are informed that Messrs. Robinson Brothers, Ltd., manufacturers of Carmona garden-alities, West Bromwich, are opening a London office and warehouse at 101, Long Acre, W.C. Mr. A. J. Macself, until recently a member of the staff of the *Gardeners' Magazine*, will take charge of this branch of the business.

NEW INVENTIONS.**HORIZONTAL THERMOMETER.**

WE have received from the Harrow Speciality Co. a specimen of their "Max-Min" horizontal thermometer, which is so constructed that no magnet is required to move the pointers that register the maximum and minimum temperatures. By the simple movement of tipping the thermometer on one end the small floating pointers fall into position again. It is said also that should the mercury itself become separated it is only necessary to lift the scale out of the case and give it a sharp shake downwards, when the mercury will at once unite. The thermometer is contained in a strong metal case, which is enamelled, and it is fitted with a folding rain and sun shield.

THE "STANDALONE" FOOT SCRAPER.

FROM the Gripper Manufacturing Company, Leicester, we have received a bi-prong foot scraper and brush for use in gardens. It consists of a wooden shaft 4 feet high, the lower end being inserted in a galvanised steel frame with two prongs, the feet of which insert into the ground and hold the scraper erect. By grasping the staff with one hand the sole of the boot can be scraped and the sides brushed with the greatest convenience, and the creosoted wood handle by drawing attention to the scraper tends to the preservation of clean paths.

LAW NOTES.**LIABILITY OF A RAILWAY COMPANY FOR DAMAGED GOODS.**

A JUDGMENT of importance to traders was delivered by Mr. Justice Banks, in an appeal by a Railway Company against the decision of the Judge of the City of London Court, in a case of action to recover damages for injury to a machine carried by them. The machine—a milling machine—was delivered to a van sent by defendants to convey it to their station at Smithfield, en route for Minehead. The plaintiff's servant handed the carman who was sent to collect the goods a consignment note containing no restrictions exempting the defendants from liability for damage during transit. The carman refused to take the machine without a special contract note, and asked the plaintiff's servant to write O.R. (owner's risk) upon the note tendered to him and to initial it. This was done. The machine was carted to Smithfield Station, where afterwards it was found with its steel bore cracked. The Judge held that the effect of the above-described special contract was that the owners took the ordinary risks of transit, but that the defendants remained liable for injury resulting from negligence of their servants; that the broken condition was not conclusive evidence of such negligence. He gave judgment for defendants, but in case the Divisional Court should hold that there was evidence justifying the inference that the injury was caused by negligence, he assessed the damages provisionally at £50. The plaintiffs appealed, and the Court allowed the appeal. In giving judgment Mr. Justice Banks said that there was no evidence that anything which occurred between the plaintiff's servant and the carman justified the inference that the former agreed to any special stipulations or conditions as to the liability of the defendants. It was not disputed that under an owner's risk contract the defendants would be liable for the negligence of their servants. On the question of evidence of negligence a witness called by plaintiff had given his opinion that the damage was caused by a severe blow. The blow must have been given whilst the machine was in the custody of the railway company. There was *prima facie* evidence that the damage could only have re-

sulted from improper treatment of the machine whilst in the custody and control of the railway company. The appeal was allowed, and judgment entered for the plaintiff for £50.

SALE OF LILY-OF-THE-VALLEY CROWNS.

ON appeal, Sheriff Gardner Millar has adhered to the decision of Interim Sheriff-substitute Macdonald given in an action brought in Glasgow Sheriff Court by Messrs. Eugen Schaffeniuss (Limited), London, against Messrs. J. and R. Thyne, nurserymen, Glasgow, for £36 3s. 8d., the cost of Lily-of-the-Valley crowns sold to defenders in 1911. The terms of the contract were disputed, defenders contending that the order given was for prime quality crowns of similar quality to those supplied to them the previous season and seen in bloom by pursuers' representatives who took the order. Defenders further averred that the crowns supplied proved to be of inferior quality and worthless to them. The Sheriff-substitute found for pursuers, and granted decree for the sum sued for, as well as for £1 9s. 11d., also due by defenders.

In the course of a note affirming that decision, Sheriff Millar said it seemed to him clear that defenders were to get first-quality Berlin Lily-of-the-Valley crowns. Their agents argued that that meant Lily-of-the-Valley crowns of the same quality as the previous season, but it was explained that as the crowns vary in different years the quality may be of less excellence in one year than another, and be thought that what was meant was that it was the first quality of the particular year. Pursuers averred that they sent first-quality crowns, and if there was a failure in the crop it must have been due to lack of proper cultivation of them. Probably the most serious question was, could the quality be discovered at the time they were sent? If defenders could have discovered the quality of the goods by examination when they received them, and failed to do so, but proceeded to plant them, then he thought they were liable for the price. The case seemed to him to be distinguishable from the cases of seed, the quality of which could not be discovered till after the crop was raised from it.

Obituary.

HENRY J. CLAYTON.—Mr. Henry James Clayton, whose death was announced in our last issue, served his apprenticeship in the Earl of Wharnclyffe's gardens at Wortley Hall, Sheffield. After leaving Wortley he served for a time in the gardens at Strathfieldsaye, the seat of the Duke of Wellington, and later was foreman at Hackwood Park. He was appointed head gardener to Lord Bolton at Hackwood Park in 1866, and remained there for six years, removing in the autumn of 1872 to Grimston Park as gardener to Mr. John Fielding, who had just purchased the Grimston Park estate from Lord Londesborough. Lord Londesborough and his gardener, Mr. William Denning, removed to Norbiton. Mr. Clayton remained at Grimston until 1907, and he served under three different owners—Mr. John Fielding, Mr. Tom Fielding, and Mrs. Fielding. Many important alterations and improvements were carried out in the large establishment at Grimston during the long period of years the place was under the care of Mr. Clayton. He set to work to convert the Orchid houses into serviceable houses for growing Pines and Melons. The houses being span-roofed, the centre beds lent themselves splendidly for Pines, and slate boxes took the place of the side stages for growing Melons in, the arrangements answering splendidly. Then he grew in another wide lean-to house most excellent pot vines. The vines were grown the first season in 10-inch pots. They were then cut back to 6 or 9 inches from the surface of the soil and shifted on into pots 2 feet in diameter by about 1 foot deep. Gros Colmar, which was somewhat new at that time, was exhibited quite ripe at York Show in June, but the variety grown was chiefly Black Hamburgh. He managed every department of the garden with the utmost credit to himself and satisfaction to his employers. Many gardeners now holding responsible positions in the profession have served at one time or another under Mr. Clayton, and one and all bear testimony to the general respect in which he was held. He

was a strong man, big in frame. He stood head and shoulders above most of his companions, whilst his intelligence appeared to be in proportion to his build. He found it easy to influence the minds of others, and the young men who came into association with him benefited very much from his influence during their training at Grimston. Mr. Clayton's name will always be associated with the Royal Gardeners' Orphan Fund. He not only assisted in establishing the scheme, but it is a question whether the idea of creating such a fund originated first in the mind of Mr. Clayton or Mr. Penny, who was then head gardener at Sandringham. At any rate, the suggestions of both these men came before the public at practically the same moment, and Mr. Clayton followed up his proposal by maintaining an unflagging interest in the welfare of the fund. Many a time since 1887 has the committee received helpful suggestions and practical advice from Mr. Clayton, and he has always been a missionary for the cause in the great county. He was a member of the Ancient Society of York Florists, in which he took much interest; indeed, he was in the habit of sending us notes on the shows promoted by that society and those of the York Gala. He was one of the founders of the North of England Horticultural Society. He was twice married, and leaves four sons and three daughters. One of his sons is manager to Messrs. Daniels Brothers, Norwich. The remains were buried on the 11th inst. in the churchyard of Kirkby Wharfe, the parish where Mr. Clayton was Vicar's Warden up to the time of his death.

Mr. E. Mines, Abbey Gardens, Bury St. Edmunds, has sent us the following note:—"It was with regret I read on p. 120 of the death of Mr. H. J. Clayton. As one who had the pleasure of serving under him from August, 1899, to August, 1901, I can testify to his abilities as a gardener and instructor. Although in working hours he carried a rather stern appearance, he had a very kind heart, and was always ready to listen to any request for advice, which was freely given. Mr. Clayton wanted no "slackers," but when duty was over he encouraged us in our games, especially cricket, of which he was very fond. I cannot let the present occasion pass without recording the great respect and admiration I had for him."

JAMES JOHN COMONT.—There are many in the seed trade who will learn with regret of the death of Mr. J. J. Comont, who was for over half a century a representative of Messrs. James Carter and Co., of High Holborn, London, and Raynes Park. Few men were more widely known, or more highly respected in certain seed-growing circles, as the deceased gentleman always proved himself a straightforward and honourable business man. He was for many years an annual visitor to Canada and the United States of America, where his knowledge was eagerly sought after by those in the trade. Those of his immediate associates who enjoyed the pleasure of his close acquaintance for a great number of years mourn the loss of an open-hearted and generous comrade. He died on February 13 at Acton, London, after a long illness borne with great fortitude.

ANSWERS TO CORRESPONDENTS.

AMOUNT OF LABOUR REQUIRED TO WORK A SMALL GARDEN PROFITABLY: P. A. Bearing in mind all the particulars given in your letter regarding the size of garden, number of glasshouses, and the character of the subjects grown therein and the fact that you are expected to make the place pay by the sale of surplus garden produce, you will require at least five men to keep the garden and grounds in good order and to do the extra work which the growth and sale of surplus produce incur. Two guineas per week, with house rent free, coal and vegetables, together with a commission of 5 per cent. on profits, would be a fair wage for the person supervising the work.

BUD-DROPPING IN PEACHES: W. P., Notts. The reason Peaches cast their buds in the spring is because of an unequal balance of growth

between root and shoot. It is not met with to any great extent in trees grown out-of-doors, where the plants enjoy a complete rest in winter, and, when growth develops, it occurs concurrently in root and shoot, but is very slow at the start. In glasshouses it is not an easy matter to regulate top and bottom growth, for the conditions may at one time favour root development and at another time that of the buds. The experienced cultivator endeavours to regulate the conditions of the border and house to ensure equal growth by seeing that the trees receive a sufficient supply of water at the roots during the resting season and keeping the house cool, attending especially to the ventilation when the sun is shining, for this may cause the temperature to rise many degrees in a few minutes.

EXPIRATION OF ENGAGEMENT: Gardener. You state that the employee refused to work after 12 p.m., although the proper time for leaving is 3 p.m. The man ought to have stayed his full time, and technically his employer could sue him for damages for not serving the proper hours, but the damages would be so small that it would not be worth his while to bring an action.

FRUIT TREES AND CANKER: Anon., Weston. We thank you for the extract from the volume on market fruit growing relating to the prevention of and cure of canker in Apple trees by means of pruning. This advice is sound enough so far as it goes, and we believe the reasons for the pruning are pretty generally understood by cultivators. The fungus (*Nectria ditissima*) causing canker is usually a wound parasite, that is, a parasite the spores of which find a lodgment in shoots on which the bark has been injured by some cause or another. When immature wood is left upon the trees there is always the liability that frost will injure such wood during the winter, in some cases causing the bark to crack. Its connection, therefore, with the spread of canker is close enough to be easily understood, and most gardeners know better than to leave immature wood upon trained trees, their efforts on the contrary being directed towards preserving the bark of the tree from injury, so that lodgments are not provided either for fungous diseases or pests, such as American blight and others. We do not think it of general interest to print the extract in full.

HOOF-PARINGS: A. C. This material forms a valuable nitrogenous manure. The parings should be divided finely, and they will be better used after having been kept for some time.

KENTIA PALM ROOT INFESTED WITH WHITE INSECT: E. W. R. The insects affecting the roots of your Kentia Palm are *Ripersia terrestris*. The plants should be removed from the pots, spraying the exposed roots and soil with carbon bisulphide, using a small glass spraying apparatus. Scald the pot and have it in readiness for replacing immediately after spraying. The carbon bisulphide will not kill the eggs of the insect, therefore the process must be repeated. Shade the plants from bright sunshine for a week after treatment.

LILY BULBS SPLITTING: W. F. B. The trouble is not due to disease, but to an excess of moisture in the soil.

"MALMAISON" CARNATION: W. R. B. Both the plants have been injured by insect punctures earlier in the season. There is no fungus present to cause disease. Keep the plants clear of pests by the use of an insecticide.

MELONS: C. C. Melons may be grown in a minimum temperature of 60° to 70°, without bottom heat, but you must be careful in the distribution of moisture in the house until the temperature has risen to 70°. In some market nurseries Melons are grown successfully without bottom heat on mounds placed 2 feet apart on the floor of span-roofed houses pretty close to the flow and return hot-water pipes. As you intend growing your plants on the staging, which is 18 inches above the hot-water pipes, place about half a bushel of the fermenting material you mention at intervals

of two feet, and over this about one peck of good loam. The soil should not be mixed with the fermenting material, but simply placed on the top of it, and should be in the house at least 24 hours previous to planting, in order that it may become fairly warm before setting the plants therein. If you intend training the plants to a trellis fixed under the roof-glass, it will be advisable to shift the young Melon plants out of the 3-inch pots into 32's (6-inch pots), and grow them on until about 15 inches high before transferring them to the mounds. Press the soil firmly about the roots in planting, watering through a rosed can to settle the soil. When the roots push through the mounds or hillocks, top-dress them with a compost consisting of one part horse-droppings, or short manure, quite free from worms, and four parts loam, well mixed, and which should be in the Melon-house for the period indicated to become slightly warm. Continue to apply top-dressings as the roots appear and until the intervening spaces are filled nearly level with the summit of the mounds.

NAMES OF PLANTS: T. B. 1, *Lonicera*, but cannot identify the species without flowers; possibly *L. japonica*; 2, *Azara microphylla*; 3, *Cotoneaster microphylla*; 4, *Ceanothus dentatus*; 5, *Pyracantha* (*Crataegus*) *coccinea*.—*J. A.* *Juniperus bermudiana*.—*W. D.* 1, *Lopezia miniata*; 2, *Solanum jasminoides*.—*W. J. M.* *Nandina domestica*.—*T. B.* *Dendrobium tortile*.—*R. J. W.* 1 and 2, *Dendrobium nobile*; 3, *Cypripedium Numa*; 4, *C. Calypso*; 5, *C. nitens*; 6, *C. Argus Hybrid*; 7, *C. (Selenipedium) Sedenii*; 8, *C. villosum*; 9, *C. Prospero*; 10, *C. Harrisianum*; 11, *C. Ashburtonae*.—*J. L.* *Billbergia nutans*, a Bromeliaceous plant generally epiphytic. Native of Brazil.—*W. B.* *Cornus Mas*.

PLUMBAGO ROSEA: A. R. Eelworm is present at the roots. The infected loam should be sterilised by heating, or it may be mixed with gaslime, but this must be done about two months before it is used for plants.

PRIMULAS FOR MOIST PLACES: Dorset Gardener. The following species of *Primula* will grow in the mud of ditch-bottoms or on pond edges, and are indifferent to actual inundation at times: *P. japonica*, *P. pulverulenta* and its cream-coloured form *Mrs. Berkeley*; *P. Poissonii*, *P. rosea* and *P. involucrata*. For planting in spongy ground just above the water-level select *P. sikkimensis*, *P. Bulleyana*, *P. rosea*, *P. involucrata*, *P. sibirica*, *P. frondosa*, *P. farinosa*, and *P. capitata*. The following species will grow in damp woodland soil, where deep leaf-mould overlies loam:—*P. Bulleyana*, *P. Veitchii*, *P. cortusoides*, *P. Sieboldii* vars. *P. Juliae*, *P. denticulata*, *P. malacoides* (which is flowering now after 18° of frost three weeks back), *P. luteola* and *P. elatior*. We cannot say if any of the species is rabbit-proof.

QUANTITIES OF SEEDS FOR SOWING ½ ACRE: Amateur. The following quantities of seeds will be sufficient for raising half an acre of the respective crops:—Mangold, 4 lbs.; Swedes, 1 lb.; Turnips, 1 lb.; Carrots, 4 lbs.; Parsnips, 3½ lbs.; Cabbage, 2 lbs.; Potatoes, 12 bushels of "seed" tubers, weighing 1½ to 2 ozs. each; Lucerne, 12 lbs.; Clover, 8 lbs.; Oats, 2 to 2½ bushels (some may consider this too much, but rooks devour some and the Oat does not tiller so much as Wheat, and hence does not require so much space); and Barley 2 bushels.

STERILISING SOIL: Mulligan. Sterilise the soil as you suggest, and also that used for seedlings. There is no need to sterilise the water.

TOMATO-SICK SOIL: Grower. Remove the soil which has been in the house for several years, and replace it with fresh, rich loam. If this is not obtainable fork a good dressing of freshly-slacked lime or soot into the old soil before planting.

TREES FOR A SCREEN: Beta. The following is a list of evergreen and deciduous trees which will suit the conditions named in your letter.—*Deciduous.* *Acer Pseudo-platanus*, *Betula*

alba, *B. lutea*, *Fagus sylvatica*, *Fraxinus excelsior*, *Juglans nigra*, *Larix leptolepis*, *Populus deltoidea aurea*, *Ulmus cornubiensis* and *U. montana*.—*Evergreen.* *Abies grandis*, *A. Nordmanniana*, *A. nobilis*, *Cupressus Lawsoniana*, *C. macrocarpa*, *Picea Engelmannii*, *P. excelsa*, *Pinus Cembra*, *P. Laricio*, *P. sylvestris*, *Pseudotsuga Douglasii* and *Quercus Ilex*. The best ultimate effect would be obtained by planting selected species in groups, twenty to twenty-five feet apart, and closely planting deciduous forest trees between them as nurse plants, these latter to be thinned as circumstances require. The row of established Spruce would not make a satisfactory permanent hedge.

TREATMENT OF JAPANESE PYGMY TREES: L. M. When the trees commence to grow in the spring afford manure twice a month—say, in March, April, May and June, and again in September and October; in the hot days of July and August no manure should be afforded, nor in winter and early spring, the plants then being at rest. The best kind of manure is finely-powdered oilcake and bone-meal, and to a jardinière 1 foot in diameter three or four large teaspoonfuls, not heaped, of this dry manure should be spread evenly around the edge of the jardinière. Re-potting should be done once in two or three years as follows:—Lift the plant out of the receptacle and, with a sharply-pointed stick, remove about one-third of the old soil around the edges and bottom, cutting away a portion of the old, fine roots, but none of the strong roots; then replace the plant in the same jardinière, first seeing that the drainage is in order. For a small, shallow bowl use a flat piece of tin or a flat crock over each hole, and over this spread some rich, fresh soil, filling up with rich soil to within ½ in. of the rims. In the case of large plants, concave crocks should be employed for drainage. The work should be done in February or March, just before growth re-commences. To maintain dwarfness in the trees, pinch the young growth from April to the middle of June. In the case of *Thuja obtusa* pinch out the points of the young growth all over the plant, to maintain the correct form; and this practice is also applicable to *Cryptomeria* and all other Conifers except *Pinus*. *Pinus* should have the points of the irregular growth pinched out simply to maintain the shape of the plant. In *Pomegranates*, *Lagerstroemia indica*, and the flowering Peach and Cherry, pinch back the non-flowering shoots either before or after blooming. *Wistaria* is best pinched in July and August so far as regards the young shoots, leaving only four or five leaves on each. Maples and other deciduous trees are pinched back at the same time as *Thuja obtusa*, leaving two to four leaves, as may be necessary to maintain the desired shape of the plants. Should a second growth be made the same rule is followed of pinching out the points.

VINE ROOTS: T. D. S., Ireland. The roots are injured by the presence of stagnant water in the soil, showing that the drainage of the border is in an unsatisfactory condition.

VIOLETS DISEASED: Oxonia. The fungus *Cercospora violae* is causing the injury to the leaves. Spray the plants with liver of sulphur—1oz. to four gallons of water—also soak the soil with the same specific.

WARTY EXCRESCENCES ON VINE STEMS: H. B. Excrecences, such as those you send, are sometimes produced in vines by high feeding and a close, moist atmosphere. It is a condition of growth known as intumescence, and is akin to the warty excrecences found sometimes on the undersides of the leaves. Ventilate the vinery more freely, and promote less atmospheric moisture.

ROSES THAT FLOWERED AT CHRISTMAS.

IN a well-known passage in his *Animals and Plants under Domestication*, the late Mr. Darwin, when treating of the Rose, wrote: "From the effects of crossing and variation Mr. Rivers enthusiastically anticipates that the day will come when all our Roses, even Moss Roses, will have evergreen foliage, brilliant and fragrant flowers, and the habit of blooming from June to November. A distant view this seems, but perseverance in gardening will yet achieve wonders, as assuredly it has already achieved wonders."

The first edition of Darwin's book was brought out in 1868, and Rivers' *Rose Amateur's Guide*, from which he quoted, in 1837, while to-day, after a mild autumn such as we have just experienced, we may say that, with the exception of the Moss Roses, in which little advance has been made, the prophecy has been to a large extent fulfilled and even surpassed; for in 1913 we gathered fair Roses up till Christmas, and, notwithstanding the cold weather which then set in, a few stray blossoms were picked till nearly the close of January.

It may be interesting, after the exceptionally mild yet dry autumn, to notice the varieties that were specially useful during November and December. I think the three that provided us with most flowers were Richmond, Lady Hillingdon, and Mme. Léon Pain. Richmond

was wonderful and produced an almost constant succession of flowers, in quantity almost equalling all the rest together right up to Christmas. It is very curious that in my own garden General McArthur gave me very few flowers during this period. My garden is on a Middlesex hill-top, with from 8 to 4ft. of gravel or stony soil, and a friend some few miles off at the bottom of a Hertfordshire valley had a similar experience. On the other hand, about as many miles away in the opposite direction, in a nursery on a clayey slope, General McArthur flowered finely, as the nurseryman said, just as if it were summer. This is very puzzling and illustrates the danger of assuming that the results of one garden can be relied on in one of a different character. Now in North Middlesex all the hill-tops are cut off with gravel and the slopes and valleys are heavy clay, while in Hertfordshire, speaking very generally, the conditions are almost precisely reversed, the valleys being gravel or alluvial soil, and the higher ground very often more or less heavy clay, though seldom so heavy as that of Middlesex. It looks as though one might provisionally assume that Richmond is the better suited for a light and General McArthur for a heavy soil. I am, however, experimenting further with these two Roses, and for this purpose have planted a bed of Richmond and another of the General close together, in another part of the garden from that in which I have grown either of them before. I am inclined to think soil has a good deal to do with it and not merely climate, and in this connection I remember noticing a bed of Richmond and Hugh Dickson in the extreme North of Scotland, not a great many miles from Thurso, in which, to my surprise, Richmond had proved far more vigorous in growth than Hugh Dickson.

Lady Hillingdon is another Rose that seems much affected by soil, and though I have little to complain of in the behaviour of this Rose, it has often seemed to me that on the stiff loams of the Midlands and the stony, clayey slopes of this district it produces a larger proportion of highly-coloured flowers than it does with me.

It was, perhaps, somewhat unexpected to find Mme. Léon Pain so good last autumn, for it is a Rose which, though producing plenty of autumn buds, is often spoilt by the wet, and so usually suffers from autumn rains, but its unusual excellence is accounted for by the dryness of the weather, which gave the flowers the opportunity of opening.

Next to these three Roses I think I am inclined to place Edu Meyer, which has flowered abundantly and well, though the blossoms have not had the intense colouring of their summer showing.

Very good, too, have been Mme. Abel Chatenay, Pharisæe, Frau Karl Druschki, Mme. Alfred Carrière, Lady Roberts and Camoens, while it is no surprise to pick many flowers of Mrs. E. G. Hill through November. We had also a very late burst of blossom on Antoine Rivoire and G. Nabounaud, though both of these naturally lacked the freshness and delicacy which are so attractive in their summer blooms.

Leaving for a moment the fine-shaped Roses, the Common Pink China was full of flower all the autumn, while Jessie, Orleans and Mrs. Cutbush went on very late; in fact they continued to flower for a time after they had lost a good deal of their foliage, and the bright pink flowers, of the two latter on stems gradually becoming more naked each day, produced rather a weird effect.

Roses which gave us a few pretty flowers at intervals but not in quantity are Dorothy Page Roberts, Lady Pirrie and, curiously enough, the hybrid rugosa Daniel Leseuer. We have also had many flowers from G. C. Waud, which, however, though cheerful in the garden, are really of little use, being too full to open well in winter. The same observation may be made of Mrs. A. E. Coxhead, which produces plenty of flowers, though they are not of much value late in the year.

It is, in fact, a necessary character of a good late autumn or winter flowering Rose that it should be much less full than those Roses which are the joy of the exhibitor's heart. Roses with tightly-packed petals in the sunless time of the year are apt to rot before they can expand properly. Even Frau Karl Druschki, the only n.p. in my list, is rather full for this purpose, but the late flowers are, of course, much thinner than those we get in the summer.

A friend living between this place and London has kindly sent me a list of Roses that flowered well after November. I am interested to find this list very nearly confirms our experience here, and contains most of the Roses I have named, and, in addition, Joseph Hill, Betty, Mme. Ravary, Princesse Marie Mertchersky, Gustave Régis and Marquise de Salisbury.

In addition to the quality of late flowering, one of the characters to which Darwin looked forward in the passage I have quoted was that of evergreen foliage. Several of our modern Roses possess this to a remarkable degree, especially among the Tea group. Last spring, at pruning time, Mme. Antoine Mari and Medea were both covered with the previous year's foliage, Marie van Houtte had retained a large proportion of it, and my beds of these Roses seem as though I should find the same state of affairs this year. The mild autumn, of course, allowed the foliage to remain on in many cases unusually long, but in most cases the bitter east winds of the latter half of January killed the remaining leaves. Coming as it did on leaves that were not ripened but still in active work, it has killed them before they were ready to fall; but the Teas I named above seem to have resisted even those icy blasts.

What the precise effect of this will be I am a little uncertain, and I rather fear it to be an indication that much of the wood is not well ripened and that careful selection at pruning time and the rigorous cutting out of sappy or frosted wood may be called for.

It is rather curious that practically no advance in the Moss Roses has taken place of recent years. The last edition of the official catalogue of the N.R.S. contains only six varieties. These are Common Moss (1596), White Bath (Salter, 1810), De Meaux (Sweet, 1814), Crested Moss (Vibert, 1827), Perpetual White (Laffay, no date), and Blanche Moreau (Moreau Robert, 1830). The date of Laffay's Perpetual White is apparently unknown, as it is not given in the *Noms des Roses*. Laffay, however, was a horticulturist at Auteuil, in France, and brought out most of his Roses between 1835 and 1845. He brought out Gloire des Mosseux, however, as late as 1853, and we may probably place Perpetual Moss somewhere between these dates.

In *Les Plus Belles Roses*, M. Charles Annet gives a more extended list of Mosses, and he mentions six later than 1830, namely, Mousse-line, 1831, Oeillet panaché, 1838, Capt. Basroger and Crimson Globe, 1890, Zenobia, 1892, and

Mme. Louis Lévêque, 1904. The fact that none of these obtained a place in the official catalogue indicates they have not yet become popular. This may be due to Moss Roses being for the moment out of fashion. It is, however, to be hoped that the public will not let this beautiful class altogether drop out in the rush for the more striking and brilliant novelties of to-day. Wichmoss, a mossy hybrid of *Wichuriana* of climbing habit, introduced in 1911, is a new break in this class. *White Rose*.

ALPINE GARDEN.

SPRING-FLOWERING CYCLAMEN.

THE two varieties of *Cyclamen* named *C. europaeum* and *C. hederacifolium* (or *neapolitanum*) are well known; and are cultivated, especially the latter, in many English and Continental gardens. The delicate white flowers are generally admired, and the varieties enjoy considerable popularity. They are, however, both autumn-flowering kinds, and not quite so popular as those which blossom in the spring.

The varieties of the *C. repandum* type are less well known. They are all indigenous to the south and the east of Europe. The first of the white-flowered kinds is *C. coum* (syn. *vernum*), from Greece and Armenia. At Floraire it flowers in January and February, sheltered beneath the shrubs, and at the same time as *Erica carnea*, *Viola Florairiensis* and *Iris stylosa*. The winter Aconite, which flowered last year so early as December, has not yet (beginning of February) made an appearance this season, having been retarded by severe frost; but my small *Cyclamen coum* flowers well, in spite of the cold.

C. ibericum (*C. caucasicum* or *elegans*) is a nearly allied species which might be considered a large form of *C. coum*. The most brilliant variety is the English *C. Atkinsii*; it bears a pretty white flower, with a deep crimson spot at the base of each petal. *C. repandum* (*C. romanum*), from South Europe, is a pretty variety with a sweet scent; the two before-mentioned kinds have little or no scent. *C. repandum* or *romanum* bears deep crimson flowers, with long, narrow, often spirally incurved petals. It blossoms from March until May. The variety, very common in the vicinity of Rome, is found everywhere between stones and rocks. It is quite hardy with us, but cannot stand much damp.

C. latifolium, the *C. persicum* of horticulture, is not hardy with us.

There is a charming variety very seldom met with in gardens, which is known as *C. balearicum*. It was found by a countryman of mine, Mr. William Barbey, thirty years ago, in the island of Majorca. He gave me a specimen, but I lost it many years ago; nor did he himself keep the original plant for long. I was very anxious to replace it in my collection, and ordered it several times from different nurserymen in Italy and elsewhere, but I always got instead the common *C. repandum* or *C. hederacifolium*. Finally, I managed, only last year, to obtain it from Palma, and hope to be able this time to keep it. I have tried growing it in several different places and under various conditions. It seems to do best under wood in good leaf-mould mixed with stones, and in a dry position. It flowers in March and April. This variety differs from *C. repandum* in that the leaves are more deeply indented and are spotted with white, and that the flowers are only half the size of those of *repandum*, and a very light colour. It is a very fragrant variety.

All the sorts I have mentioned are spring-flowering, and are all easily cultivated, except, perhaps, the last named, which is a little tender. I was obliged to cover it up during the late severe winter, but it seems to be going on well, and I have great hopes that it will flower before long. *H. Correvon, Floraire, Geneva.*

TENDER PLANTS IN A WIGTOWNSHIRE GARDEN.

THE sub-tropical scene represented in fig. 63 is in the garden of K. McDonall, Esq., of Logan, Wigtownshire. Many will be surprised to learn that the Club Palms (*Cordyline australis*) and Tree Fern (*Dicksonia antarctica*) grow luxuriantly out-of-doors in this Scottish garden, but

the plants admirably—young specimens planted in 1910 have attained to a height of 9 feet. *Dicksonia antarctica* was planted in 1907, and has made remarkable growth for a plant of this kind in the open. At the time of writing (February 19), the fronds are as fresh and green as they were in the autumn. They measure about 12 feet in diameter. In favourable seasons two new sets of fronds are produced, one in May and another in August or September. The site where the Fern is now growing is a hole

FIG. 63.—CORDYLINES AND TREE FERN IN A WIGTOWNSHIRE GARDEN.

this part of the Rhins of Galloway is very favourably situated, and many other tender shrubs may be grown in the open. The *Cordylines* were planted in 1905, and are now about 18 feet high. More than twenty of the plants flowered freely during the summer of 1912, and their small white, delightfully fragrant flowers made a charming picture in the garden. One head of flowers may be seen in the illustration. These noble plants give a fine sub-tropical effect to the garden during summer, and are also a great acquisition during the winter, when most trees and shrubs are bare of leaves. The soil, a black sandy loam resting on rock, seems to suit

quarried out of the solid rock, which was filled with suitable compost.

Mr. McDonall, who is an ardent horticulturist, has, during recent years, planted many tender plants and shrubs in his garden, and all are growing with equal success. Among the many may be mentioned *Abutilon vitifolium*; *Chamaerops Fortunei*, the Chusan Palm; *Drimys Winteri* (the plant receives no protection and is now covered with seeds); *Embothrium coccineum*, the South American Fire Bush, most appropriately named from the wonderful colour of its fiery-red flowers, which appear in clusters in May; *Solanum jasminoides*; *Solanum*

crispum, too seldom seen as a bush, for in this form only can its real beauty be appreciated; *Calceolaria integrifolia*; the curious violacea; with small helmet-shaped flowers; and Himalayan *Rhododendrons* in great variety. Not one of these plants is protected in average winters, with the exception of the Tree Ferns, which as a precaution have their trunks covered with straw. *A. Findlay, The Gardens, Logan.*

NOTES ON IRISES.

THE RETICULATA GROUP.

THE first sight of the confused fragments of a puzzle which have to be fitted together is apt to be disheartening. Scarcely any two pieces seem to belong together, and the majority, indeed, appear to be so detached from the rest as to be quite meaningless. Such has hitherto been my feeling with regard to the disconnected facts that have constituted our knowledge of the group of early-flowering bulbous Irises, of which *I. reticulata* (see fig. 64) is the best-known example. It cannot be pretended that all the fragments can yet be made to fit together into a complete picture, but it is, perhaps, possible to suggest some definite arrangement and to ask whether facts within the knowledge of others who are interested in the group seem to them to fall into their places in the scheme.

The chief difficulty lies, of course, in obtaining specimens of wild plants from known localities. Importers and collectors are only too inclined, perhaps not unnaturally, to be reticent as to the precise localities from which their supplies come, and herbarium material is not always sufficiently carefully prepared to enable us to see clearly the somewhat minute points of difference.

Anyone who has grown *I. reticulata*, *I. histrio* and *I. histrioides* must have noticed that there are marked differences in the methods of increase of these plants. Flowering bulbs of the two latter species form round their bases a cluster of as many as twenty or thirty small bulblets, no bigger than, and not unlike in outline to, grains of wheat. *I. reticulata*, on the other hand, forms a much smaller number of relatively large bulblets differing considerably in size one from another. The smallest, however, is usually three or four times the size of the bulblets formed by the other two species. As far as my information goes, *I. reticulata* is confined to the Caucasus region, and it is only there that Irises are found which increase in the same way. All the other members of the group form the innumerable bulblets already mentioned, and come from further south. The only exception is *I. Bakeriana*, which is easily distinguished by the character of its foliage, as we shall see later.

There can, I think, be little doubt that the deep violet-blue *I. reticulata* of our gardens is not the commonest form of that species in its native home. Indeed, I have so far failed to find any scrap of evidence to prove that it is not merely a colour form of garden origin. Bieberstein's original figure (*Cent. Plant. Rar. Taur. Cauc.* I. t. 11, 1810) does not even justify the assumption that this is his type. On the contrary, his drawing represents much more faithfully the red-purple flowers, which have always been the product of any bulbs which I have received direct from the Caucasus, and also of those plants that I have raised from seeds from the same source. The actual shade of red-purple is apt to vary and the blade of the falls is usually more or less conspicuously veined; the style-branches are broader than the haft of the falls, and the standards, also, are broad and tend to curve inwards to meet each other instead of pointing outwards at nearly the same angle as the style-branches as do those of *I. reticulata*.

The view that a red-purple flower is the com-

mon wild form is supported by the fact that self-fertilised seed of the type has never given me anything but red-purple forms. This has also apparently been the experience of others, and yet it is a result which no Mendelian theory seems able to explain.

There is yet another tone of colour, which is found among the forms of this Caucasian Iris. It is a peculiar slaty blue, sometimes quite dark, and sometimes so pale that one sturdy example has even received the name of Cantab.

As we leave the Caucasus region and go further south, we come to the home of *I. histrioides* in the neighbourhood of Amasia or Amas. Its habit suggests that it is an inhabitant of mountainous districts where the winters are severe, for the flowers come up almost simultaneously with, and sometimes even before,

is carried all along the haft, as was also the case in Leichtlin's *purpurea*. The latter does not now seem to be in cultivation, but this feature and its short leaves are perhaps enough to justify us in assigning it to this group of plants. We seem also to have lost the colour-forms of *sophenensis*, which Foster tells us (*Bulbous Irises*, p. 7) may vary from red-purple to a lightish blue. The only form which I know, and which comes true from seed, is of a pale blue colour, with a lemon-yellow central ridge, much resembling a rather small pale *histrioides*. Among seedlings of the latter, variation in the exact shade of colour occurs both in the flowers as a whole and in the yellow ridge on the falls.

Going still further south, we come to the region where *I. histrio* (see fig. 65) is native. Our difficulty here lies in the fact

FIG. 64.—IRIS RETICULATA : FLOWERS RED-PURPLE IN THE CAUCASIAN FORM : DEEP VIOLET-BLUE IN THE GARDEN FORM (SEE TEXT).

the leaves. The flowers are flatter and less funnel-shaped than those of the Caucasus group, and of a vivid blue colour, except in the upper part of the blade of the falls, where there occurs a triangular white patch veined and dotted with blue. All these characteristics are found in home-raised seedlings of this species, and, as has been already observed, it differs sharply from the Caucasus plants by its method of increase.

With *I. histrioides* I am inclined to connect somewhat closely the plant to which Michael Foster gave the name of *sophenensis*, in memory of the fact that it came to him from the neighbourhood of Kharput, a district which in ancient times bore the name of Sophene. This Iris has flowers of the same shape as those of *I. histrioides*, but smaller. In neither does the central ridge on the falls fade away, as in *I. reticulata*; in both it

that it is no longer possible to say with certainty to which of two distinct plants the name was originally given. It is, perhaps, rather more probable that it was bestowed on a plant with upright standards and very conspicuously blotched falls, which seems to be confined to Palestine, if not indeed to Lebanon. This Iris has been distinguished as *histrio orthopetala*, and it is evidently closely allied to the form with divergent standards and less conspicuously blotched falls, which is common in the neighbourhood of Marash, and which is now commonly supplied by the trade for the more showy orthopetala. Both produce numbers of minute bulblets, but they differ from the two groups we have already considered by the fact that their foliage, though longer, is more slender and less erect. It is far less rigid, and seems always to begin to curve as soon as it emerges from the

soil. The prevailing colour of the flowers is a blue-purple, and the falls are either dotted or veined more or less distinctly.

It is interesting to notice that of this Iris, too, there is now known a red-purple form, *atropurpurea*. As *reticulata* and *Krelagii* only differ in colour, so does this plant resemble what is probably the northern form of *histrion* in every respect but that of colour, except that the central ridge is here non-existent, though the black tubercles that dot the low ridge in *histrion* are here conspicuous as raised points along the central line of the haft of the falls.

Further south still, we come to *I. Vartani*, which is hardly more than another development of *I. histrion*. It is distinguished by the length of its style-crests, and for us in the north by its inability to survive our climate for more than a year or two at the most. Of the white form of *I. Vartani*, some examples are beautifully

describing a new species under the name of *I. Bornmülleri*.

Definite dates for the flowering of these plants are most misleading. This year *I. reticulata* is in full flower in the middle of February, while I have known it so late as the last days of March. And yet, if, as seems not improbable, all our stock of *I. reticulata* has arisen by division from a single bulb, we might reasonably expect it to be much more constant in its time of flowering than any other of these species, where seedlings are innumerable and differ considerably in their time of flowering. For instance, this season I had some *I. Krelagii* in flower in the last days of November, though this is no doubt exceptional, while others have yet to open their buds at the end of February. Much depends, I believe, on the date at which the growth of the previous year was ripened off, and on the weather during the late autumn and early winter. The embryo

interest of the plant is that there are now considerable differences among the flowers produced by the different bulbs in the extent of the triangular white patch at the throat and of the arrangement and number of the dark-violet blotches upon it. Seeing that such differences, small though they are, do undoubtedly arise among the individuals obtained by vegetative increase, we can form some idea of the possibilities of variation among the forms of these Irises which nature has evolved by sexual reproduction. *W. R. Dykes, Charterhouse, Godalming.*

THE PRUNING AND TRAINING OF FRUIT TREES.

In passing through an otherwise fairly well managed garden last October I observed that trees of Apples and Pears in bush, pyramid and espalier forms had made a large amount of second growth, nearly all the buds on some of the shoots having started and formed thickets of weakly twigs. The leaves were still green and the growths very soft. But on coming to the orchard trees no second growths were to be seen; those which were made in the spring and allowed to remain unchecked had ripened very well. Then in another establishment were some well-trained Pears which had their shoots pinched in the spring. These had made a second growth, which was also pinched in early summer, and there was no further attempt at elongation, while there were good, plump buds on the earlier growths to cut back to at the winter pruning. Here, then, are three distinct systems of treatment, and it is worth while before another growing season arrives to consider the merits and demerits of each. It may be said by the advocates of summer pruning that the first-mentioned case is an extreme one; but I have seen many such, and I have noticed that such fruit as there was on trees so managed was mostly on scraggy spurs out of the reach of sunlight. I am no advocate of summer pruning, not yet for growing fruit trees for the purpose of supplying flower-sticks; but I believe in stopping the shoots with the finger and thumb nails in the spring and again in early summer, and those which are likely to become strong should be stopped some days before the weakly ones. Large orchard trees are best left unshortened and kept severely thinned. If we take the trouble to measure the rapidity of growth of the fruit of an Apple or Pear tree during the week preceding the amputation of growing shoots, called summer pruning, and also during the week following, we find a vast difference between the two rates. And it would be strange if it were not so. We know that if we attempt to bud a stock a few days after beheading it, or even after trimming its side-shoots, the bark will not rise and our efforts will be vain. The same thing happens to a tree bearing fruit. The channel of communication between the leaves and the fruit is blocked, and the fruit for a time is starving, because it has little or no power in itself to draw nourishment from the soil or from the atmosphere, but is dependent on the leaves both for the supply and the preparation of that nourishment. The unskilled man will tell you to cut off some of the leaves and throw strength into the fruit, but the skilled grower knows that this will have the opposite effect. Superabundant leafage will prevent light and air reaching the fruit and the primary buds. But why allow such leafage to be formed, using up energy which could be turned to better account? In a dry summer, such as was experienced last year, there is another reason for preventing unnecessary leafage. Every leaf exposed to the light is taking its part in drawing up water from the soil, through the roots, stems and branches, the greater part of this water being discharged into the atmosphere, and is thus making the soil drier than it otherwise would be.

FIG. 65.—IRIS HISTRION: FLOWERS COLOURED BLUISH-PURPLE.

spotted with blue, and we can only regret that this Iris has such a poor constitution.

There remain two outlying species, which are easily separated. To the west, in Asia Minor, occurs *I. Danfordiae* (see fig. 66), which is distinguished by its minute bristle-like standards and by its yellow colour; while to the East is found *I. Bakeriana*, whose eight-ribbed leaves divide it at once from all the other Irises we have considered. That *I. Danfordiae* has been described under more than one name is due not to the variation of the olive-green markings which sometimes occur on the blade of the falls and on the backs of the style-branches, but to the fact that the first-described herbarium specimens had lost their outer bulb-coats, with the result that the description did not mention their reticulated structure. Baker was thus led to class this Iris among the Junos on account of its minute standards, and it was only when the plant was re-discovered by Bornmüller that Haussknecht, seeing the reticulated bulb-coats, thought he was

flower is already in the bulb when we plant it in the autumn, and it is not difficult to imagine that external conditions have great influence on the flowering-time of bulbs which develop their flowers with such amazing rapidity as do these small Irises. My experience is that imported bulbs and those that have been lifted flower earlier than those left in the ground, and this is probably to be explained by the fact that the ripening has been more complete.

There is one other point that may be of some interest. *I. Bakeriana* is admittedly of poor constitution, and apparently nowhere in England does it do really well. For several years now I have grown it side by side with a beautiful hybrid form, of which the late Max Leichtlin sent me a single bulb under the name of *Bakeriana melaina*. The latter increases regularly by offsets, and this year there have appeared ten flowers, though the type has been flowerless. *Melaina* has six-ribbed leaves, and is probably a hybrid of *Bakeriana* and some *reticulata* Iris. Its falls are of the richest velvety-violet, and the

We see many trees which twice in the year—i.e., after winter and summer pruning—are so neatly cut into shape that one might suppose the form of the tree and not the production of fruit was the primary object.

But the neatness is of short duration, for as both weak and strong growths receive very much the same treatment from the knife, the inequalities are speedily made manifest by the stronger and upper growths taking the lead, whereas, by timely pinching the strong shoots you divert the supplies to the weakly ones, which in time become strong, and very weakly ones, such as those which occur near the base of the tree, where the branches are almost horizontal, can be left to grow still longer, and they will at the same time increase in diameter.

It is found that root pruning is seldom necessary when trees are kept pinched in the way recommended, because all shoots inclined to be rampant are checked very early, and in some cases are entirely removed, as are also very weakly ones which can be spared, and it is the rampant growths which encourage corresponding growths of the roots.

Another question arises in connection with late growths forced into existence by summer pruning. In a dry season, where does this growth come from and of what does it consist? The ground was so dry last season that trees on surface-rooting stocks, such as the Quince, could not possibly draw water or anything else from it; yet after the atmosphere became humid, and before the water from the clouds had penetrated the soil, growth was very rapid. The inference is that all mineral matters as well as nitrogen and hydrogen supplied to these useless and harmful shoots were robbed from the permanent parts of the trees. We know that stored-up material can be transferred without root action by the fact that a felled tree will sometimes produce shoots 2 or 3 feet in length.

We had evidence of the almost total absence of moisture in the soil when lifting Chrysanthemums in October after there had been a considerable fall of rain. The surface was damp, but half an inch below there did not seem to be a particle of moisture, and all the lower roots were dark-coloured and hard, those only near the surface, and some actually above it, had new growths. Yet these same plants which had remained dwarf and hard during the summer had afterwards made a large amount of growth and became very tall. They subsequently produced flowers which were soft and thin in texture.

Wm. Taylor.

NOTICES OF BOOKS.

SCHOOL GARDENING.*

THE object which Mr. Brewer has in view in writing this book is expressed succinctly in the introduction, which is written by the Rt. Hon. Henry Hobhouse. This object is to show how the school garden may be used so as to give a less "bookish" form of education than that now prevalent. To this end the author is at pains to indicate how lessons in many subjects—arithmetic, drawing, mensuration, etc.—may be made more real by relating them with the work of the school garden. In accordance with this ruling idea Mr. Brewer recommends that lessons in woodwork—now given in many schools—should take the form of exercises in the making of the simpler garden implements.

With these views we are in fullest sympathy, but we must take serious exception to the author's assertion that "A schoolmaster should not mind if he is not an expert at gardening; he should be an expert at teaching, and it is the teaching that is the thing." The fallacy underlying the statement italicised is responsible for half the evil in modern education. The cry goes up for a change from the old book subjects to more real subjects, and teachers ignorant of

these subjects are obliged to teach them. The result is deplorable, and chiefly in this, that in ignorant hands the "real" subjects soon became as unreal as those which they have displaced.

It is true that a teacher in a school garden need not know the practice of hot-house cultivation of Grapes and Pines; nor need he be conversant with the intricacies of Orchid hybrids; but if he be not an expert in school gardening he will be bound to fail. As Falstaff exclaimed: "I am not only witty in myself, but a cause of wit in others." So a real teacher in any subject must be able to declare: "I can not only tell my scholars how to do this thing, but I can do it." This fundamental fallacy excepted, we are in general agreement with Mr. Brewer's thesis. His purpose is to make the scholars use their eyes and hands and wits, and he succeeds in demonstrating that this may be achieved by making full use of the school garden as a school teaching instrument.

Teachers who find themselves in charge of school gardens and who wish to make the fullest use of them will find in Mr. Brewer's book much useful help. We like particularly the introduction of simple experiments—e.g., in seed sow-

FIG. 66.—IRIS DANFORDIAE: COLOUR OF FLOWERS YELLOW. (See page 144.)

ing—into the ordinary school work, for among too many people there still lingers the idea that an experiment is a mode of mystification instead of a method of getting an answer to a precise question. The help which such teachers may derive is both direct and indirect; not only may they adopt Mr. Brewer's suggestions, but they will be led themselves to conceive of others which they can put into practice in the lessons in the school garden.

PLANTING IN UGANDA.*

THIS very readable book may be commended not only to the planters for whom it is written, but also to the wider public of persons interested in the natural features and fortunes of greater Britain beyond the seas.

The authors, who have had considerable experience in Uganda plantations, possess a firm and apparently well-founded belief in the future of this remarkable country. For in truth Uganda is a remarkable country. Lying on the equator, it nevertheless has a far from tropical temperature and rainfall. The mean maximum temperature is only 80°. and the annual rainfall is from 40 to 51 inches. The relatively low temperature is due first to the highness of the land, Uganda forming an undulating and in parts hilly plateau of from 3,000 to 4,000 feet above

sea level; and secondly, to the presence of a great body of water—the Victoria Nyanza. In the daytime breezes always blow, but at night the air is still. Like that of other tropical regions, the range of temperature is but small (mean maximum 80°, mean minimum 62°) and the relative humidity is high.

One conspicuous advantage possessed by that part of the Protectorate known uneuphonesously as Buganda is that the land is not covered with dense forest. It is dotted with little hills with easy slopes, giving good drainage and running down into swamp or stream fringed with forest. The good land is under a growth of Elephant Grass (*Pennisetum setosum*) so dense as to kill out all other plants except an occasional tree of Muvule (*Chlorophora excelsa*) or of Acacia.

Two rainy seasons with no very set terms occur each year, but although little rain falls in December, January, and February, or in June, July and August, it is rare for a month to pass without any rain. Analyses of soil from various planting centres in the two provinces, Buganda and Busoga, indicate a high degree of fertility, although the soil in certain districts is somewhat deficient in lime.

The rubber industry dates from 1901, in which year a single tree (of *Hevea brasiliensis*) was received from Kew. From consignments of seed received in 1904, 300 trees were raised and planted out in the gardens at Entebbe. The growth of those trees indicates that tapable size—viz., 16 inches girth at 3 feet from the ground—is reached in five years.

The first planting of Cocoa was also made in 1901, Kew again supplying the trees.

Coffee (*Coffea arabica*) was introduced about the same time and has been found to produce its full crop three years after sowing. The plant yields two main crops each year, and, since there are intermediate flowerings, picking is in progress from February to November. The seed takes eight months to ripen. The chief harvest is in September, and the heavier the crop in one season the smaller it is in the next; hence in each year there is one big and one small crop.

Records of the yield from tapping *Hevea brasiliensis* (Para rubber) are somewhat meagre, but lead the authors to estimate that eight-year-old trees will average 2lb. of rubber per tree. Yields of Coffee appear to be remarkably good, reaching so much as 2lb. per tree, and the authors are sanguine of the promise of this crop. Unfortunately, as is pointed out by Prof. Dunstan in the introduction, the Coffee disease, due to the fungus *Hemileia vastatrix*, has made its appearance in plantation Coffee. As everyone knows, this pest was the direct cause of the abandonment of the once flourishing Coffee industry in Ceylon, and it is to be hoped that it may not prove so destructive in Uganda. Those in charge of the administration of Uganda are doubtless taking steps to control this most serious of pests; but it is curious that no reference to the subject is to be found in the body of this book. There would appear to be a good prospect of producing an immune strain, for Coffee (*robusta*) is indigenous, and hence there is ample opportunity for seeking for naturally immune strains, and for experimenting with the object of producing resistant hybrids by cross-breeding. In this connection those interested in the planting industry should note the account given in this journal (March 6, 1909, p. 153) of a new species of Coffee that has been discovered in Central Africa which has so far remained immune to *Hemileia vastatrix*. The species in question is *C. congensis*, and was discovered by Mr. Dybowski on the shores of Oubangi.

The maps accompanying the text show that there is ample room for the further expansion of the planting industry, and any young man with the necessary capital might well make a tour of inspection and enquiry of the Protectorate with a view to settling. The work is abundantly and well illustrated, and concludes with an account by Mr. George Massee of the chief diseases caused by fungi.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

VANDA.—The different species and varieties of Orchids allied to *Vanda tricolor* are commencing to grow, therefore it is a suitable time to undertake the work of potting them. It is not desirable to re-pot these plants unless a shift is absolutely necessary, but even in the case of very healthy specimens the compost on the surface requires renewing after the long season of rest. Where top-dressings of this kind are necessary it is desirable to ascertain that the drainage is satisfactory. Plants that have become leggy through loss of their lower leaves should be reduced by cutting away a portion of the stem. The length to which the stems may be shortened must be governed by the condition of the roots. Some plants root freely along the stems, whilst others have roots at considerable intervals, and this fact must be taken into consideration. Fasten the growths to strong sticks. Use scrupulously clean pots, and place a few suitable crocks over the drainage holes. The plant should be arranged in position, as many as possible of the lower roots placed carefully inside the pots, and the space filled in with a mixture of clean crocks and charcoal to about two-thirds the depth of the receptacle. The remaining space may be filled with finely-chopped Sphagnum-moss intermixed with silver sand and broken charcoal. Press the compost firmly about the plant, and arrange it in the centre to form a slight mound. Some may prefer to use a compost of *Osmunda* or Peat intermixed with Sphagnum-moss; but it is immaterial which compost is used, provided suitable conditions are afforded the plants. After the work of re-potting is finished soak the roots with rain-water. Shade newly-potted plants from strong sunlight until the roots are re-established, and maintain a humid, warm atmosphere at all times.

AERIDES.—Many of these Orchids require a treatment similar to that recommended for *Vanda*. But the thicker-leaved species, such as *A. crassifolium*, *A. crispum*, *A. Fieldingii*, *A. Lobbii*, and *A. maculosum*, do not grow so rapidly as many of those of a more compact habit. They grow best during the summer in a warm, intermediate house; a shady position in the *Cattleya* house is suitable. The roots are thicker and more fleshy than those of *A. odoratum* and others of its type, therefore good drainage is essential, and a small amount of the potting compost should be used. The dwarfier-growing species, such as *A. Lobbii*, *A. crassifolium*, and *A. maculosum*, grow best in baskets or shallow pans, in which they may be suspended close to the roof glass. During the plant's period of most active growth the roots require an abundance of moisture. Overhead spraying will be beneficial whenever the outside conditions are favourable for doing this.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to EARL BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

THE PINETUM.—Keep an observant eye on the leading shoots of all choice young specimens of coniferous trees, and if from any damage—by squirrels or other cause—to the central shoot there are more than one top growth struggling for the mastery select the best-placed and most healthy shoot and shorten the others by means of long-handled pruning shears. Keep the trunks of all Conifers and forest trees free from Ivy excepting an occasional forest tree that has seen its best days: In such cases the Ivy, when laden with its winter berries, will not only be an ornamental feature in the landscape, but furnish a pretty evergreen for Christmas decorations. A small colony of specimen hush Ivies in variety planted by the margins of shrubberies and laden with various coloured berries gives a charming winter effect.

THE IRIS GARDEN.—How seldom do we see the members of this handsome family of flowering plants given the attention in cultivation they merit! We have a corner of about half an acre set apart for Irises, chiefly the German Flag Iris. There are between forty and fifty irregularly shaped beds of various sizes arranged in the grass, each planted with one variety. When the plants are in flower the Iris garden is one of the loveliest features of Madresfield Court. *I. pallida* and its varieties, *Madame Pacquette*, *Gracchus*, *Victorine*, *Mrs. Darwin*, *Purple King*, *Jacquelineana*, *Madame Chereau*, *Maori King*, and many others, are all excellent plants for furnishing cultivated beds on lawns, whilst many of the commoner varieties may be utilised with good effect in woodland paths. One of the chief details in the successful cultivation of Irises is care in planting; do not cover the rhizomes with soil. If necessary plants may be divided, but this will be at the expense of this season's flowers. The best method of propagation is to spall off side-shoots as soon as the flowering is over and plant them in the reserve garden until autumn.

LILIES may be associated with the Irises, especially *L. candidum*, and *L. speciosum* [*lancifolium*]. Mr. C. Maries, the celebrated plant collector, once informed me that he often found Lilies growing wild in association with a foster plant, such as prairie grasses, a hint I at once acted on by planting *Iris germanica* and the Lilies I have enumerated together. Irregular blocks or groups of *Tulip Gesneriana* major were already dotted about in the grass, and by adding a few more Tulip bulbs to the Iris beds we are able to secure a triple period of consecutive or successional flowering, making this quarter a pleasing or attractive section of the pleasure grounds. *Iris Kaempferi* is best grown by the water's edge, where the gorgeous blossoms are reflected in the water. *I. Monnierii*, *I. ochroleuca* (syn. *gigantea*) and other tall growers are suitable for planting in odd corners, along the margins of lakes, or in the water-garden proper.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the EARL OF DERBY,
Knowsley Hall, Lancashire.

HUMEA.—Plants in 6-inch pots should now be shifted into their final pots—8 or 9 inch. Rich, fibrous loam, leaf-mould, a little manure from a spent Mushroom bed, some charcoal (broken small), and a dash of sharp sand will provide a suitable compost. Watering must be done with extra care, as damping is a frequent cause of trouble.

HANGING BASKETS.—Baskets of foliage or flowering plants are always attractive in the greenhouse and conservatory suspended from the roof rafters. Amongst the foliage plants we utilise for this purpose are *Asparagus Sprengeri*, *A. deflexus*, *Davallia bullata* and other *Davallias*, whilst of the flowering subjects we employ varieties of Ivy-leaved *Pelargoniums* largely, as these make a pretty show during the summer. *Schizanthus Wisetonensis* is also suitable. By twisting the growths and tying them loosely round the baskets the plants will appear like balls of flower. Prepare the baskets by lining the interior with Moss to prevent the soil from falling through the sides. Use an open, loamy compost for the flowering plants and peaty materials for the foliage subjects.

BOUVARDIA.—The plants, having rested for a period of about six weeks, should be prepared for another season's growth. If it is desired to increase the stock an old plant may be utilised to provide root cuttings. Shake the old soil from the roots, cut the latter in small pieces, and place the portions in a pan of light, peaty soil. Plunge the receptacle in bottom heat, and the cuttings will quickly form roots, at which stage they may be potted and grown on in a moist atmosphere with a temperature of 65°. The shoots of old plants should be pruned to prominent buds, and whilst the latter are still dormant thoroughly wash the wood with Gishurst compound, using a brush on the hard, old wood to dislodge mealy bug. Grow the plants in a temperature of 60°, syringe them daily until they show their new growths, when

the old soil should be shaken from the roots and the plants re-potted in slightly smaller pots. Afford a shift when the receptacles are full of roots. Use the syringe freely and fumigate the house on the first signs of aphids.

TUBEROSE.—Successional batches of this sweet-scented bulbous flower should be potted as required. Remove the side bulbs to throw all the strength of the plant into the flowering shoots. One bulb may be planted in each 5-inch pot or three in each 7-inch pot, but the single planting is preferable. Use rich fibrous loam mixed with leaf-mould as compost and pot firmly. Plunge the pots in bottom heat (60° to 70°). Light spraying with clear water will suffice to supply moisture until growth is advanced, when the roots should be watered freely. As the flower spikes appear secure them to neat stakes and remove the plants to an intermediate house. Bulbs for later batches may be kept in a dry place until required for use.

AZALEA.—Remove the old seed vessels from specimen plants of Indian Azaleas that have finished flowering and grow the plants in a temperature of 60°. Syringe them twice daily, regulating the second syringing so that the foliage becomes dry before night-fall. Azaleas do not require re-potting every year; established plants, if in a healthy condition, require only top-dressing. Remove some of the surface soil with a pointed stick and replace with a mixture of three parts peat, one part loam, enriched with a little fertiliser. Ram the soil hard. Young plants should not be over-potted. Pick some of the soil from the ball with a sharp stick, remove the crocks, and press the compost very firmly with a potting stick as the work of potting proceeds.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

PINEAPPLES.—Continue to grow the plants in a steady bottom heat and pay careful attention to watering the roots. As the weather brightens allow the temperature to rise and admit plenty of air when the conditions are favourable. Successional plants may be grown in a temperature of 60° to 65° at night, increased to 70° to 75° by day. Plants that were potted last autumn will soon be growing freely, and the path, brickwork and staging should be kept moist, but do not syringe the plants. Suckers should receive every attention at this stage. Get the bed, pots and soil ready, and pot them without delay, using rich, turfy loam only as the rooting medium. Pots 7 inches in diameter should be used for large offsets, and 5-inch pots for the smaller ones. Let the receptacles be well drained and plunge them at once without watering the soil. The temperature should be 55° to 60° at night and 65° to 70° by day. As the suckers possess no roots much warmth will cause them to become drawn and weakened. Afford shade on bright days from the midday sun.

PEACHES AND NECTARINES.—Syringe the trees in the early house freely, as early as the sun will permit in the afternoons of bright days. Keep the house closed for two or three hours afterwards, when the ventilators at the top of the house may be opened for an inch or so, and a little air permitted at night during mild weather, for this will cause the air to circulate. Hasten with all despatch the work of preparing the successional and late houses for forcing. Take advantage of sunny weather to ventilate the house freely where the trees are in bloom, and pollinate the flowers of shy-setting varieties by dusting a camel hair brush or rabbit's tail gently over the stamens and stigmas.

ORCHARD HOUSE.—Keep the roots in a proper condition as regards moisture, whether pot plants or specimens planted out, for nothing causes the fruit to drop more than dryness at the roots. Apricots and Cherries on the point of blooming should be afforded an abundance of fresh air in mild weather, for plenty of ventilation will assist the flowers to set. In late houses admit air to the fullest extent to retard the flowering of the trees.

FIGS.—In houses where the fruit is swelling maintain a genial, humid atmosphere and a temperature of about 65° by night, rising by day to 75° or 80° and higher by sun heat. A few more pot trees may be started to furnish a succession. Finish any pruning that is required to be done and follow the advice given for the earlier trees.

TOMATOS.—Plants with fruit fast maturing should be fed by top-dressing the roots occasionally with loam mixed with a small quantity of bone meal, also by watering on frequent occasions with liquid manure. Gather the fruits as soon as they are ripe, or even at a little earlier stage. Maintain a buoyant atmosphere by artificial heat and afford an abundance of air during mild weather. A sowing of seed for the main crop plants may be made now. As soon as the seedlings are in the rough leaf pot them singly into 60-sized pots and grow them on as advised in the issue for January 17.

FORCING PITS.—Admit an abundance of air to Strawberry plants in bloom and do not sprinkle them with water overhead as heretofore, but give more frequent and copious supplies of liquid manure to the roots to strengthen the plants.

THE HARDY FRUIT GARDEN.

By J. C. WESTON, Gardener to Lady NORTHCOPE, East-west Park, Kent.

MULBERRIES.—This fruit is frequently grown in unheated houses, where the soil and climate conditions are not favourable for the trees maturing their fruits in average seasons out of doors. The trees may be grown either in pots, tubs, or in a narrow border against a wall. During the growing season afford an abundance of water to the roots, or the fruit will drop. When once the trees have reached average size, little, if any, pruning will be required. Short fruiting spurs will at that stage develop throughout the entire length of each branch. The variety Large Black is the best and most generally grown. The Mulberry, being one of the latest of all fruit trees to start into growth, may be potted, or transplanted late in the season, but care must be taken not to damage the fleshy roots during the operation.

WINTER-SPRAYING.—It is generally found most convenient to apply winter washes as soon as the work of pruning and training is completed. Old, neglected trees may need a second application of the wash in order to cleanse them thoroughly, the first time early in the winter, and again just before the buds open in the spring. The work of spraying with caustic washes should no longer be delayed, the sap being already on the move, and, once the buds commence to open, such washes would cause much harm to the trees. Do the work on a mild, calm day, as much of the spray fluid will be wasted if the weather is windy, and at such times there is a danger to the operator through the wash blowing on to the face. Rubber gloves and old clothes should be worn, as it is difficult to avoid being splashed. Not only does an annual winter spraying keep the trees perfectly clear of lichens and fungous growths, but it also destroys dormant insects and their eggs. For a small or moderately-sized garden a knapsack sprayer is probably the most convenient appliance to use, but in large fruit gardens or orchards, one of the larger spraying machines is of more service. See that the fluid reaches every part of the tree, especially the trunk and main branches, which should be saturated, in order that the wash may penetrate in crevices and rough places of the bark, as these are the lurking places of insects and their eggs.

CONCENTRATED ALKALI WASH may be purchased in tins of small quantities, and after using it for a number of years I can strongly recommend it.

AMERICAN BLIGHT.—Wherever this pest is noticed on fruit trees, measures should be taken at once to destroy it, for the blight spreads very rapidly, and will quickly infect a plantation. Pure paraffin oil is one of the best specifics, and should be worked in thoroughly in all the crevices where the pest is seen by means of a paint brush. This should be done as soon as the leaves have fallen, and again before the trees burst into leaf.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

HERBS.—Any work requiring to be done in the herb garden should be proceeded with when convenient. Chives, if overgrown, should be sub-divided into little clumps and planted a few inches apart, and Sorrel, which is commencing to grow, should be treated in the same manner, but only if it has been too long a time in the same position. The broad-leaved is the preferable variety. Lavender, rooted in frames, should be transplanted into a sheltered spot at a few inches apart for re-planting in the autumn, and Sage should be treated in like manner. Sage, however, roots readily at this time of year from rather long shoots set deeply into the ground. Thyme lasts only a few years here, and has to be raised anew from seeds sown about the middle of March. Where Basil is in request, seeds may be sown now. A moderate heat is essential, and the seedlings are all the better if pricked out into boxes to strengthen them before planting in the open garden. Sweet Marjoram may also be sown now, but for this herb there is time enough, only it saves in labour to grow together as many of these herbs as will succeed under the same treatment.

EDGINGS.—It contributes largely to the pleasure of the garden of vegetables to have the edging to walks trim and neat. Therefore trim Box or relay it, and see to other material before the rush of work comes on.

SPRING BROCCOLI.—Should the plants be small and not growing freely, spread a dressing of horse droppings or Peat Moss litter between the rows and around the plants to give them a much-needed start, and thus favour the production of good heads. The above manures are to be preferred to nitrogenous salts, which, however, may be substituted where the former cannot be had. White Sprouting Broccoli is turning in, and if carefully gathered, that is, just the little white buttons, others will develop on the same stalks.

SEEDS TO SOW.—A small sowing of early Milan Turnip may be made on the chance of the crop succeeding. Also some more Turnip-rooted Radishes, dropping the seeds very sparsely. Turnip-rooted Beet, where required for summer use, is another crop that should be sown now, also Cabbage and Cos Lettuces, with a fair-sized breadth of Spinach. I have grown nine or ten varieties of the last-named, and have found none generally so satisfactory as Viroflay. Lente-à-Monter is very slow to run, and might be substituted in naturally dry soils. Sow also another breadth of Broad Beans.

POTATOS.—The tendency of growers in recent years is in the direction of early planting, and no doubt there is much to be said in its favour, one of the most important reasons being the production of roots while the growths are making comparatively little progress. Early sorts must be selected to secure early crops, and at the other extreme late varieties, unless planted early, yield reduced crops. In garden culture quality is before everything, hence only varieties of the best flavour should be grown, and the selection to be choice need not be large. None has here excelled Puritan for early summer eating. It requires the best culture. Midlothian Early succeeds it, but is less good in quality and less exacting in its wants. Duke of York and British Queen are very largely grown, too, but neither is equal to the last-named. King George V. gave very good results as a mid-season variety, and is one worth a trial, but Nonsuch or Windsor Castle ought also to be planted. From the beginning of September no variety excels Golden Wonder, the best of the Langworthy type, and perhaps the best late variety in existence; but, like others of the class, the tubers run small unless the cultural treatment be of the best, viz.: ground trenched, moderately manured, and further enriched with artificials, with wide-spaced rows, three feet at least, and half that distance between the sets. Among others grown for the first time in 1912 Arran Chief gave no small but an enormous crop of very large tubers, fit only for baking. A lower-class culture would therefore be suitable for

this variety. Baronet, a new Kidney variety, has tubers even larger. Whole tubers of moderate size are preferable to cut sets, though one sometimes has to use the latter, which give better results than the very small "seed" which is not infrequently supplied when bought in. The worst kind of set of all is that which is produced from tubers which are cut to single eyes, sometimes having only a small portion of the tuber attached. The crop from these is never large, and the tubers are small and often unshapely.

THE "FRENCH" GARDEN.

By PAUL AQUATIUS.

HOT-BEDS.—The crops in the frames are making good growth, and should be gone over at least once within the next fortnight, with the object of removing decayed leaves. The Radishes should be marketed as soon as they are ready, removing at the same time those growing wiry or too close to the Lettuces. As soon as the Cauliflowers are well forward they may be set amongst the other crops, 24 of such varieties as Snowball, or 15 of a bigger sort, like Driancourt or All Year Round, to each frame. Plant the roots deeply, burying the bottom leaves, and make the soil very firm. The paths between the frames should again be filled with dry manure within the next ten or twelve days. Spread mats over the lights in frosty or stormy weather, taking care that they overlap one another on the side opposite that from which the wind is blowing. It is advisable to place them in position when they are wet during a clear and breezy night, even though there be no danger from frost, for this will dry them. Afford ventilation to the Cos Lettuces under the cloches by making two apertures with the closed fist, or a triangular block of wood, under the rim of each bell-glass. Take care to keep these openings clear during the season. Another batch of Cos Lettuce may now be planted to each row of cloches, in the spaces between two glasses, on the south side.

MELONS.—The first sowing of this important crop should be made in boxes filled with loam and black soil. Germinate them in a house having a temperature of 65° to 70° Fahr. The soil will not need to be watered if it is used sufficiently damp at the time of sowing. If a greenhouse is not available, make up a bed 14 to 18 inches thick, composed of three parts of fresh and one part of dry manure, to accommodate one frame of one light. As soon as the materials become warm from fermentation place the seed boxes in the centre of the light. Spread mats on the light and round the bed as soon as the temperature falls in the afternoon, and allow them to remain in position until 8 or 9 a.m. the following morning. Some growers instead of raising Melons so early, sow a batch of Vegetable Marrows, and set these plants in the frames during the second week of April, when the frames will be at liberty from the crops grown without heat. Early in June the Marrows will grow without shelter, and the frames will be again available for a late batch of Melons. This method is to be recommended, especially where a big selection of produce is required, and where the staff is a small one.

CROPS IN THE OPEN.—The work of manuring and digging the ground for open air crops is completed. The surplus black soil left from the hot-beds should be well broken with the fork, to be used either for covering seeds or mulching beds previous to planting. Its use increases the amount of food for the plants, favours earlier cropping, because dark soils are always warmer, and prevent clogging of the soil in wet weather. Animal manure, especially when well decayed, is preferable to artificials in the intensive culture of vegetables, as most of the crops grown are of a very sappy nature, and it is essential to use only manure which helps to retain moisture in the ground. Should the weather remain genial, Lettuces, Passion and Palatine, may be planted outside within ten or twelve days. They are set 10 inches apart each way, and made firm at the roots. If the plants are not very strong, or should the garden be an exposed one, it is preferable to defer planting until a little later.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher.—Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Special Notice to Correspondents.—The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

APPOINTMENTS FOR MARCH.

- TUESDAY, MARCH 3—
Scottish Hort. Assoc. meet.
- WEDNESDAY, MARCH 4—
B.G.A. Ex. Council meet.
- THURSDAY, MARCH 5—
Linnean Soc. meet. British Gardeners' Assoc. meet. at Bush Hotel, Carlisle—
- FRIDAY, MARCH 6—
Dundee Hort. Assoc. meet.
- SATURDAY, MARCH 7—
British Gardeners' Assoc. meet. at Pearith. Société Française d'Hort. de Londres meet.
- MONDAY, MARCH 9—
United Hort. Ben. and Prov. Spec. Com. meet.
- TUESDAY, MARCH 10—
Roy. Hort. Soc. Coms. meet., Special Bulb Show (2 days). (Lecture at 3 p.m. on "Adaptive Degradation the Cause of Many Cases of Evolution Among Plants.")
- THURSDAY, MARCH 12—
Manchester and N. of Eng. Orchid Soc. meet.
- MONDAY, MARCH 16—
Surveyors' Inst. Exam.
- TUESDAY, MARCH 17—
Broughty Ferry Hort. Assoc. meet.
- WEDNESDAY, MARCH 18—
Stevenage and District Hort. Soc. Sh.
- THURSDAY, MARCH 19—
Linnean Soc. meet. Roy. Soc. of Arts meet. Paper by Mrs. Villiers-Stuart on "Indian Water Gardens."
- TUESDAY, MARCH 24—
Royal Hort. Soc. Coms. meet. (Lecture at 3 p.m. on "Pruning Shrubs.")
- THURSDAY, MARCH 26—
Manchester and N. of Eng. Orchid Soc. meet. Roy. Botanic Soc. meet.
- TUESDAY, MARCH 31—
Cornwall Daffodil and Spring Fl. Sh. at Truro (2 days).

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 40.7°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, February 25 (6 p.m.); Max. 44°; Min. 34°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, February 26 (10 a.m.); Bar. 29.5°. Temp. 45°. Weather—Dull.

PROVINCES.—Wednesday, February 25. Max. 47°, Valencia; Min. 38°, St. Ives.

SALES FOR THE ENSUING WEEK.

- MONDAY AND FRIDAY—
Hardy Bulbs and Herbaceous Plants, Roses, Fruit Trees, etc., at 67 and 68, Cheapside, E.C. by Protheroe and Morris, at 12.
- WEDNESDAY—
Perennials and Border Plants, Hardy Bulbs, etc., at 12. Special sale miscellaneous Bulbs at 12. 1,000 c/s Japanese Lilliums at 2.45. Palms and Plants at 5, at Protheroe and Morris's rooms.
- WEDNESDAY AND THURSDAY—
Nursery stock, at Horsell Nurseries, Woking, by Protheroe and Morris, at 12.
- THURSDAY AND FRIDAY—
Clearance Sale of Nursery Stock, at the Cemetery Road Nurseries, Hitchin, by Protheroe and Morris, at 12.
- THURSDAY—
Roses at Protheroe and Morris's rooms, at 1.
- FRIDAY—
Orchids, at Protheroe and Morris's rooms, at 12.45.
- MONDAY AND WEDNESDAY—
Shrubs, Roses, Perennials and Lilies, at Stevens' Rooms, King Street, Covent Garden, at 12.30.

The Riddle of Species.

Systematic plant-breeding and the analysis of the results thereof, have led to the discovery of such a vast array of new facts that it is by no means astonishing to find the more adventurous-minded among biologists attempting to apply these discoveries to the elucidation of the origin of species. It is true, of course, that among living biologists there are some who maintain that the last words on this subject were said by Darwin. Of these orthodox naturalists some pin their faith to those sections of the tables of the Law of Evolution, which ascribe the appearance of new species to the accumulated effects of environment. Others of them maintain that the source of the origin of species is to be found in the instability of species. Just as *humanum est errare*, so variability is the property of all living things. They do vary, for better and for worse. The better variations survive. The better of these survive again, and so at last the surviving forms are so manifestly dissimilar from the parent form and from one another that the supreme arbiter in these things—the systematist—pronounces them to be so many distinct species. Controversy has ranged round those opposing opinions for so long, the champions of these opposing views have annihilated one another so often and so completely that the dispute has died down—as though it were a Shakespearean tragedy—because there are no performers left. A third group of biologists has tended more and more to stand aloof from the quarrels of the Montagues and the Capulets—the exponents of the doctrine of the inheritance of acquired characters, and of that of the selective accumulation of chance variations. They stand aloof and wonder, applying to the origin of species, it may be regretfully, the aphorism that the mystery of life endures—the closer it is approached the greater it becomes. Such doubting apostles of evolution will greet with mixed feelings the attempt made by Dr. J. P. Lotsy to apply the results of Mendelian discovery to the elucidation of the origin of species. Translating the words of Brutus into the language of a more decorous day, they may be inclined to exclaim—"There is tears for his love, joy for his fortune, honour for his valour, and death for his ambition." Dr. Lotsy's thesis is that new species arise by the crossing of species. Though the thesis is not new, the arguments which the author advances in its support are both novel and weighty. Briefly these arguments are as follow: A species is a thing of infinite variety. It is an assemblage of forms which may be ranged into a larger or smaller number of lesser groups—the petites espèces of Jordan. If the sorting process be carried far enough the species may be separated into a number of micro-species, each of which is unique and immutable. A true micro-species might be grown for ever and anywhere, and it would first and last and always to itself be true.

If, however, one micro-species with one

set of characters be mated with another possessing a different set of characters, an unstable hybrid is produced.

The hybrid characters of this first generation plant or animal are dealt out among its offspring in all manner of combinations. The several characters of the parents are recombined in new and varied ways in the offspring. Some of these combinations are such that the forms which possess them breed true. They are petites espèces or genotypes, and, in so far as they differ from one another and from the parental forms, they are new micro-species. If the two parents belong to different species the assemblage of micro-species which segregate in the second or later generation constitute a new species in the ordinary sense of that heavy-laden word.

To do justice to the argument and to the wealth of illustration which Dr. Lotsy brought forward in its support is not possible within the limits of space at our disposal. We will, therefore, confine ourselves to examining what must be regarded as the fundamental postulate on which the argument is based. This postulate affirms that a genotype or true micro-species is, like the laws of the Medes and Persians, unalterable. Like the germ plasm of Weissman, a genotype cannot change. It is the unit of life. Circumstance, climate, may play upon the individual and may make it tall or short, fleshy or meagre, but such passing influences have no lasting effect, and the progeny of the genotype shows no trace of the changes which circumstances beget in the parent.

This is a hardy proposition to which those who are best informed will neither assent nor object. They will ask for proof. This proof Dr. Lotsy offers in the results of Johannsen's famous experiments on the inheritance of size and weight of Beans. As is now well known, Johannsen discovered that it is possible to sort out from a race of Beans a number of pure lines. In each pure line the seeds have a certain range of weight and size, and for each pure line that range is fixed, so that although seeds are chosen from either end of the range—a large seed and a small seed, for example—the range of size in the seeds which they produce is the same in the produce of the small and of the large seed and identical with that of the pure line from which the seed was selected: or, expressed axiomatically, all the members of a pure line give rise to identical offspring. Selection in the seedman's sense means, therefore, the picking out of those pure lines which best serve his purpose.

We are not prepared to assert that Dr. Lotsy is wrong in ascribing this un-deviating permanence to the germinal factors on which a plant's manifest character depend. We are inclined to think, however, that Dr. Lotsy ascribes to these factors a too rigid unchangeableness. The factors which determine characters must grow. Therefore, it is possible that in some circumstances the rate of growth of a factor may be so increased that a germ cell may receive "two factorial doses"

Supplement to the "Gardeners' Chronicle."

VIOLA "WALTER WELSH" IN THE R.H.S. TRIALS, WISLEY, 1913

instead of one, and this doubling of a factor may be expressed in the plant by a "new" character — a giant, a brighter flower, or even a change of form. If this be proved to occur, Dr. Lortsy's conclusion that species originate solely by crossing must be regarded as untenable; but even so, the author will have performed a notable service in compelling the wandering or reluctant attentions of biologists to the greatest—or almost the greatest—of biological problems.

Coloured Plate.—The Supplement this week illustrates a plant of the well-known bedding Viola Walter Welsh, as grown in the trial of Violas carried out in the Royal Horticultural Society's gardens at Wisley last season. The culture of the plants at Wisley left nothing to be desired, and the deputation of the Floral Committee that judged the varieties on the ground had rarely if ever seen a better display of these popular flowers. The illustration is reproduced from a photograph taken on the spot, after means had been taken to isolate the plant from the neighbouring specimens. The habit shown is perfectly natural, and nothing had been done in the way of supporting the growths. Amongst the tallest plants were Maggie Mott, Virgin White and Kittie Bell, which grew to a height of 16 inches. The variety Walter Welsh came into the next category, which included plants growing to a height of 12 inches, such as Archibald Grant, W. Robb, Primrose and King Cup. For further particulars of the trial our readers may turn to the *Gardeners' Chronicle* for July 5, 1913, pp. 11 and 18.

R.H.S. DAFFODIL YEAR BOOK, 1914.—Secretaries of Daffodil societies, or of horticultural societies which hold spring shows where Daffodils form a speciality, are asked to send as soon as possible a copy of their schedule for 1914 to the Rev. JOSEPH JACOB, Whitewell Rectory, Whitchurch, Salop, in order that notices of such shows may appear in the *Daffodil Year Book*.

THE TRADE AND THE R.H.S. SHOWS.—It will be remembered that Mr. WALLACE made some remarks at the annual meeting of the Royal Horticultural Society respecting the hour of closing the fortnightly exhibitions at the Vincent Square Hall. We understand that steps are being taken to present a petition to the Council in favour of closing the shows at the usual time, 6 p.m., instead of at 7, the hour now proposed. The firms represented at the Hall on Tuesday last were asked to sign the petition, and most of them did so, the latter hour being very unpopular with exhibitors. In the afternoon an informal meeting of traders was held in the Horticultural club room to consider certain regulations that have been arranged in connection with the forthcoming show at Chelsea, and it is likely that representations on the matter will be made to the Council.

BARON BRUNO SCHRÖDER AND THE ROYAL GARDENERS' ORPHAN FUND.—Supporters of this excellent fund will learn with pleasure that Baron BRUNO SCHRÖDER has consented to preside at the next festival dinner of the Royal Gardeners' Orphan Fund, which will take place at the Hotel Cecil on Thursday, May 21.

ANIMALS AND PLANTS UNDER DOMESTICATION.—At the sixth lecture of the course at the Royal Institution, Professor BATESON said that the study of the histories of those plants introduced during the eighteenth and nineteenth centuries showed that in the majority of cases development had proceeded along very similar lines. A "break" had occurred, generally as the result of a definite cross

between two species, and all the possible re-combinations of the new characters thus produced have then been made by repeated hybridisations. There is, however, one case—that of the Sweet Pea—which forms a definite exception to this rule. So far as is known, all the varieties of the Sweet Pea have been derived from the species found wild in Sicily, and there is no evidence that a cross with any other species has occurred. There is no other case so clearly established of a large number of forms arising from one species without hybridisation with another species. It had been supposed by some that all our garden varieties of the Cineraria had come from *C. cruenta*, without the introduction of any other species. But it is now evident that at least one other species, *C. lanata*, had been crossed with it, giving rise to many hybrid forms in the early part of the nineteenth century. In recent years Mr. LYNCH had crossed the garden varieties back with *C. cruenta*, producing the graceful star forms. Two more "breaks" had been caused by putting in *C. lanata* again, and by crossing with *C. primulinus*, a yellow-flowered species from the Cape. It has been observed that when a change of type occurs it is usual to find that many new forms appear almost simultaneously. Such simultaneous changes may be caused by the introduction of a new species, or they may be attributed to the appearance of a new variety due to the loss of a single factor and the combination of the new character with previously existing varieties. The history of the Rose forms a striking series of periodical "breaks." The whole race of Hybrid Perpetuals was derived from crosses made with a Rose found growing in a hedge in the Ile de Bourbon. The Noisette Roses were obtained by M. NOISSETTE by crossing *R. indica* with *R. moschata*. Similar cases were mentioned as occurring in Dahlia, Calceolaria, and Fuchsia.

NATIONAL CARNATION AND PICOTEE SOCIETY.—Mr. CHAS. HENWOOD has been appointed secretary of the National Carnation and Picotee Society in succession to his father, Mr. T. E. HENWOOD. The new secretary's address is 21, Clifton Road, Maida Vale.

INTERNATIONAL INSTITUTE OF AGRICULTURE, ROME.—Sir JAMES WILSON, K.C.S.I., has been appointed to act as delegate for Great Britain and Ireland, the Dominions of Canada, Australia, New Zealand, the Union of South Africa, and the Government of Mauritius on the Permanent Committee of the International Institute of Agriculture at Rome. Lieut.-Col. Sir DAVID PRAIN, C.M.G., Director of Kew Gardens, Sir JAMES WILSON, K.C.S.I., and Mr. A. G. L. ROGERS, Head of the Horticulture Branch of the Board, have been nominated by the President of the Board of Agriculture and Fisheries to represent the Department at the International Phytopathological Conference to be held at Rome on the 24th inst.

SIR RONALD MUNRO FERGUSON.—Scottish horticulturists and arboriculturists deeply regret that his appointment as Governor-General of Australia necessitates the departure of Sir RONALD and Lady MUNRO FERGUSON from Scotland. Sir RONALD FERGUSON has long been one of the most active and energetic advocates of afforestation, and at his estate of Novar gives a practical demonstration of his deep interest in the subject. He is also a keen horticulturist. The local flower show at Raith has been held annually in the grounds attached to his residence.

SUGAR AND COTTON CROPS.—The Board of Agriculture and Fisheries have received the following telegram from the International Institute of Agriculture:—"The total production of raw Beet sugar during the current season in the following countries was, for the four months ended December, 126 million cwts., or 2.3 per cent. below last season's production in the corresponding period—Germany, Austria, Belgium,

Denmark, France, Italy, Netherlands, Roumania, Switzerland, and the United States. The estimated production of raw cane sugar in Cuba is 49,573,000 cwts., or 10.2 per cent. above last season's production. Final returns show the production of cleaned cotton in India as 18,575,000 cwts., or 12.8 per cent. above last season's production."

ROBBERY FROM A GARDENERS' BOTHY.—The gardeners' bothy at the Moffat Hydropathic Institute was recently entered by burglars, and money belonging to the two gardeners who occupied it taken. Some banknotes were left, but £8 in gold belonging to one and £4, the property of another, was stolen.

AMERICAN CARNATION SOCIETY.—It is interesting to note that the Committee of the American Carnation Society, reporting at the annual meeting held in Cleveland, expressed doubt that Carnations are losing either in fragrance or in keeping qualities. The Committee observes (see *American Florist*, February 7, 1914) that flowers produced during the comparatively sunless winter months are naturally less fragrant than those produced in more sunny seasons. The Committee is of opinion that deterioration where it occurs is largely due to bad and over-cultivation and particularly to improper selection and handling of cuttings. The Burki prize for the best keeping Carnation as tested by its endurance in the cut state during the show was awarded to Mr. S. J. GODDARD, Framingham, Mass., for a vase of Pink Delight. Other varieties which kept well were Rosette, Beacon and Benora. Among new Roses exhibited at this show, our contemporary comments very favourably on Hadley, a bright red rose, shown by Mr. A. N. PIERSON, Inc., of Cromwell, Conn. It is said to be a fine flower and a good keeper, with good stem and foliage.

CASEIN AS AN ADHESIVE.—Experiments carried out by Messrs. VERMOREL and DANTHONY indicate that casein serves well for increasing the adhesiveness of Bordeaux mixture. To dissolve the casein mix thoroughly $3\frac{1}{2}$ ozs. of powdered burnt lime with $1\frac{1}{2}$ oz. of powdered casein. Add the mixture to a little wafer, and work it into a paste. Make up to a quart by adding water a little at a time. This amount will serve to mix with 100 gallons of Bordeaux mixture. As an adhesive for Paris green or for acid Bordeaux mixture gelatine may be used at the rate of 3 to 8 ozs. per 100 gallons.

MAY-SICK LAND.—Here and there, in parts of certain fields on farms in Warwickshire, Cheshire and Nottinghamshire, crops, whether of Wheat, Oats, Mangolds, or Potatos, show year after year symptoms of disease. The leaves turn yellow and growth is arrested. Land producing this effect is said to suffer from May-sickness. The cause of the malady is obscure, but Mr. W. E. COLLINGE, who has published recently (*Journal*, Board of Agriculture, XX., No. 10, 1914) an account of his investigations on the subject finds that May-sickness may be remedied by dressing the land with sulphur at the rate of 6 cwts. to the acre, the cost of which is about 30s. per acre.

THE ORIGIN OF SPECIES BY CROSSING.—The above subject was introduced by Dr. Lortsy at the meeting of the Linnean Society, held on Thursday, 19th inst. A general account of Dr. Lortsy's paper will be found in our leading article, and hence reference need be made here only to the more interesting examples which Dr. Lortsy brought forward in support of his theory. Of these examples the most striking from a horticultural standpoint was his account of the re-making of Petunias with green-bordered petals. It appears that these Petunias arose soon after the introduction of *Petunia violacea* (in 1830). This species was crossed with *P. nyctaginiflora*, and the races with green bordered petals arose as a result of the cross. In course of time these fancy Petunias disappeared from cultivation, as

did also the true *Petunia violacea*. The latter species was, however, rediscovered recently in Messrs. VILMORIN'S establishment at Verrières. Crossed with *P. nyctaginiflora* it yielded in the second generation large numbers of the green-bordered race which had been lost so long. Dr. LORSY also mentioned as a contribution to the controversy as to the real nature of *Oenothera Lamarckiana*—the plant rendered famous by DE VRIES—that by crossing *Oe. grandiflora* and *Oe. biennis* plants are obtained which though not identical with, yet resemble greatly, *Oe. Lamarckiana*. Moreover, among the offspring of the cross are some which throw abnormal plants in the same way as *Oenothera Lamarckiana* throws "mutating forms." Thus the view that *Oe. Lamarckiana* is a hybrid receives considerable support. As an example of the pitfalls which await the naturalist over-eager to explain things, Dr. LORSY cited the case of a glabrous form of *Viola* growing in association with *Viola palmata*. It would seem natural to assume that the glabrous form had arisen as a subtractive mutation from *V. palmata*; that it owed its origin to the loss of a factor for hairiness. Yet it has been shown by BRAINERD that this glabrous form has arisen from the descendants of a cross between *Viola palmata* and *V. papilionacea*. The paper gave rise to an animated discussion, in which the following, among others, took part:—M. PHILIP DE VILMORIN, SIR FRANCIS DARWIN, MAJOR HURST, PROFS. BATESON, FARMER, WEISS, MACBRIDE, DENDY, KEEBLE, DRs. RENDLE, SLAFF, and GATES, and Miss SAUNDERS. In the course of the discussion Mr. ARTHUR SUTTON exhibited an interesting slide illustrating the various types of Beet—Garden Beet, Mangel, Spinach Beet, and others, as well as the wild Beet (*Beta maritima*), from which species these cultivated forms are held to be derived.

A CINERARY URN.

An interesting discovery was made recently on Messrs. J. Carter and Co.'s seed farms at Dedham, not far from Flatford Bridge, made famous by Constable's picture.

While digging gravel out of a pit on the estate, a cinerary urn (see fig. 67) of the Bronze Age was unearthed. It contained human bones, and experts ascribe it to a date from 900 to 1,000 years B.C., or nearly 3,000 years ago. An examination of the gravel pit is interesting as it shows that the interments were made in V-shaped graves some 5 feet below the present ground level, and in several cases a curious layer of charcoal or charred wood near the top gives evidence that funeral feasts were prepared on the improvised hearth. Investigations are still going on under the directions of Mr. A. G. Wright, the Curator of the Colchester Museum, and care will be taken to preserve any other rare specimens that may be there. An authority on the subject writes:—The type of cinerary urn found at Dedham is that known to archaeologists as the overhanging urn type. According to the Hon. John Abercromby, who has made a special study of the Bronze Age ceramics, this type of urn began to make its appearance somewhere about 1400 B.C. in the S.W. of England, and lasted to about 650 B.C., with certain variations in its form.

Urns of this type are generally of thick, coarse ware, made entirely by hand of the local clay mixed with sand and small stones, and vary in colour from pale ochre to a rich brown. At the time of their beginning cremation was the popular form of burial, but inhumation had not entirely ceased. It was customary, too, to raise a barrow (a mound of earth) over the burial site, but about 900 B.C., owing perhaps to the increase of the population, the barrow was discarded and interments were made in small, flat

cemetaries. At Dedham there is no trace of a mound; but the burials appear to have been made in the top of a small hillock or rising ground. If this surmise is correct, we have an approximate date of about 900 B.C. Messrs. Carter intend to place the urn, with any others that may be found, in their entrance hall at Raynes Park.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

DIERAMA PULCHERRIMUM (see p. 105).—I have cultivated this plant since 1907 in heavy clayey loam at an altitude of more than 600 feet, and have had racemes of flowers from 4½ to 5 feet in length. When planted in masses *Dierama* is a beautiful object in bloom, for although the colour of the type is not very pleasing, those of pink and white shades are charming, and the only quality lacking is perfume. Among several hundred seedlings I have only raised one with pure white flowers; I have hope of obtaining a red or scarlet variety. After the flowers have faded the plants are attractive for several weeks

FIG. 67.—CINERARY URN FOUND ON MESSRS. CARTER'S SEED FARM, DEDHAM.

while carrying their seed vessels, and it is interesting to note that, while the first flower to expand is at the bottom of the raceme, the first seed to ripen is usually at the apex, and this appears to be the case with those illustrated in fig. 48, p. 105. Seed ripens in considerable quantities, and if sown as soon as ripe in a cold frame, germinates freely; the seedlings are fit for planting out the following April. As to the hardness of *Dierama*, I have known the plants to withstand 20° of frost, and frost which lasted for 116 hours, without any apparent injury. The rainfall here is about 37.00 inches, and we have registered as much as 25.12 inches during the six winter months, but this great amount of moisture did not appear to harm the plants in any way. They are, however, liable to be killed by eelworm. *John Edwards, Cefn-garthmyl, Berriew, Montgomeryshire.*

CELERY DISEASE (see p. 95).—Regarding manuring of Celery, I will give methods adopted by me in the past two seasons with very different results. In 1912 my Celery trenches were enriched with a 6 to 7 inch layer of well-rotted farmyard manure, cow and horse manure mixed. The material was dug into the bottom of the trenches, and a light dressing of slacked lime was placed in the bottom of part of the trenches. The crop was planted about ten days after the trenches were prepared. After planting a heavy fall of rain occurred, which suited the plants.

I occasionally dusted them with soot and lime, and I fed the roots with liquid manure about once in eight or nine days, always after rainfall. When preparing the soil for earthing up I mixed a little Vaporite with it, generally in the morning, and by the afternoon the ground and plants were in a good order for applying the earth by hand. The summer of 1912 being very wet I had no cause to water the plants, which furnished a fine crop of Celery without the slightest sign of disease. I followed the same methods in 1913, with the exception that lime was used. The ground was adjoining that which was used for the previous year's crop. But the weather of 1913 being dry and warm I had to water the crop, with the result that disease appeared early in August. I sprayed the plants on the first signs of disease with copper compound. The first spraying seemed to check the disease, but further spraying seemed to have very little effect. I picked off leaves that were affected, and that further weakened the plants. After this experience can it be said that manuring has any bearing on the disease? I am more inclined to think in my case that the watering was responsible. Therefore weather and season have more to do with the disease than manure. *M. A., Co. Kerry.*

THE CABBAGE CATERPILLAR (see pp. 82, 100).—You state that the caterpillars of the Cabbage Moth "not unusually" pass the winter in that state, but I think you are probably mistaken in the species. So far as I am aware, as a collector of some thirty years' standing, the larvae of that species always pupate before the winter, as do those of the closely allied species *Mamestra persicaria*, and other pupae are often dug up in the garden during the winter months. On the contrary, the larvae of the Large Yellow Underwing (*Triphaena pronuba*) do live through the winter and pupate in the spring, and these are probably the ones sent. Your reply on p. 82 is in itself contradictory, for you say: (1) It is not unusual for this insect to pass the winter in the caterpillar stage. (2) As a rule, however, it buries itself in the earth and pupates in the early spring. One gathers that these are supposed to be opposite statements, but as a matter of fact they are just two ways of saying the same thing, because, according to (2) if the caterpillar pupates in the spring then it must live through the winter as a caterpillar. This is what the first statement says. If you get any more of the larvae in question I shall be glad to set the matter right for you, and in any case I should like to see "hibernating" larvae of *Mamestra brassicae*. *C. Nicholson.* [Our expert informs us that he has proved that the larvae of the moth in question often pupate in spring. He has reared a number of adults from larvae which had passed the winter in a herbaceous border in the city of Chester.—Eds.]

CHICORY - GROWING IN ABERDEENSHIRE (see pp. 111, 133).—The Witloof is a sub-variety of the Chicory Magdeburg, and could be utilised for the purpose of making commercial Chicory. Roots intended for the purpose must not be forced first to produce salading. The yield per acre would be inferior to the Magdeburg Chicory, which gives roots weighing as much as 18 ozs. each. Sowings of the Witloof variety, made early in May, are liable to bolt in dry seasons such as 1913. *P. Aquatias.*

PISTACIA VERA AND ELEAGNUS ANGSTIFOLIA.—I should be obliged if you would state in the *Gardeners' Chronicle* that I shall be happy to send seed of *Pistacia vera* and *Eleagnus angustifolia* to anyone forwarding a stamped addressed envelope to *A. C. Bartholomew, Park House, Reading.*

THE LATE H. J. CLAYTON.—I had the privilege of serving under the late Mr. Clayton for a period of twelve years, during which time I held five different positions, including five years as general foreman. He has been rightly described as one of nature's nobelmen; a man of broad views, not only on horticultural matters, but on things in general. I have seen more of Mr. Clayton than I have of my own father. I had a letter from him about a couple of weeks before he died, when he wrote

in his usual cheery way. We corresponded at frequent intervals during the whole of the fifteen years since I left him. I cannot express adequately the regret I feel in having lost one of my best friends and tutors. *J. Snell, Briery Gardens, Sunderland.*

THE PARMENTIER MYTH.—(see p. 124).—The recent celebrations in honour of Parmentier have caused this story to pass the round of the daily papers, and even, it must be confessed, of many horticultural journals. I venture, therefore, once again to point out a few facts, which totally contradict this generally accepted idea. It was in 1773 that Parmentier published his *Examen Chimique des Pommes de Terre*, and in 1785 he planted the famous 35 arpents which stupefied the Parisian crowd and enrolled Louis XVI. as advertising agent of the astute Parmentier. The facts of history, however, remain. The Potato was generally grown all over France, from the early days of the eighteenth century, and thousands of sturdy peasants had probably fed upon it long before Parmentier "discovered" it. It is not possible here to give many extracts which prove this statement, but I may mention that Leopold, Duke of Lorraine, in 1719, decreed that certain of his tithes should be paid in Potatoes, and, to come to later dates, in the *Pratique du Jardinage*, by the Abbé Roger Schabol, the Potato is mentioned in a gardening calendar, amongst other vegetables, without any comment as to its rarity or any recommendations as to its uses. In an early catalogue in my possession, namely, that of Messrs. Vilmorin, dated 1771, Potatoes are offered for sale amongst other vegetables. Even more interesting are the remarks of Parmentier himself, in his book above quoted, where he says, on page 1: "The use of this plant has been adopted for a century," and on page 5: "It is so widely spread that there are provinces where Potatoes have become a part of the nourishment of the poor, and one sees the entire fields covered with it in the neighbourhood of the capital, where it is so common that all the markets are filled with it, and it is sold at the corners of the streets, cooked or raw, as they sell chestnuts." The idea of reading Parmentier's book has apparently never occurred to his eulogisers. One may imagine, without unduly exercising that faculty, that the Potato was a new article of diet to the higher circles of France, and that Parmentier's discovery consisted in introducing it to them. In his enthusiasm he recommended it for making bread, an idea which had been tried long before his time; but he was not chemist enough to know that starch without gluten will not make bread. It is somewhat amusing to read that Parmentier's attention was first directed to the Potato as an article of food by the French soldiers digging it up during the Seven Years' War. One asks who can have been the planters of these Potatoes, so unknown at the time? It has also been already pointed out that for 35 arpents seed must have been obtainable in large quantity, and the astute device of withdrawing the guard round these valuable Potato fields, in the light of the above facts, loses its point. It is probable that Potatoes were stolen for the same reason for which they are stolen nowadays. Parmentier, therefore, claims remembrance as a predecessor of the astute dealers who in times not far distant exploited the credulity of Potato growers by offering a variety which would turn the poorest sand into gold. The whole history is an interesting contribution to the study of psychology rather than horticultural history. *Edward A. Bunyard.*

THE MOON'S EFFECT ON PLANTS.—Talking with a fellow-gardener on a variety of subjects a short time back, he made the following (to me) surprising statement. At his previous place as journeyman, in a large establishment, it fell to his lot on one occasion to insert a batch of *Chrysanthemum* cuttings, which he did in the usual way. When the head saw them some time afterwards he told him the cuttings would not be much of a success owing to the fact that they had been inserted when the moon was on the decline, and advised him to take another lot of cuttings directly there was a new moon. On my inquiring whether there was any noticeable difference between the two batches of cuttings my friend said that the second batch *did* appear

to root and make headway more quickly and healthily than the first. Previous to this statement I met a Sussex man who said his father would only sow seeds, plants, etc., when the moon was in the ascendant—to do so when on the wane would be courting failure. There is a similar idea held in some parts of the country by farmers with respect to the birth of animals, lambs in particular, the inference being that those born with a new moon have a much more successful outlook than those born after the moon has reached its full. But the foregoing are the only two cases where I have heard of gardening operations and the moon being associated in present-day practice. *C. Turner, Ken View Garden, Highgate.*

CYANIDING TO DESTROY MEALY BUG.—Mr. Shakelton's remarks on page 106 go to prove conclusively my assertion that the failures in cyaniding are due to using cyanide of an inferior quality, together with an improper graduation of the other requisites. I would warn your correspondent not to put too much faith in the 130 per cent. cyanide of sodium, as this is a meaningless quantity and

reward of 25s. per week, and a free house. Strange it is, but true, that, although the gardener is so poorly paid, the employer frequently consults him upon many important matters connected with the establishment, subjects entirely foreign to horticulture. I think this fact proves that the gardener is looked upon as being an intelligent, observant, capable servant. Personally, it is the deep interest that horticulture possesses that has induced me to remain in the ranks, and I venture to say many others are in a similar position. What is more deplorable than to find an unskilled man in charge of a garden in which he takes no interest. I am inclined to think this fact, with its disastrous results, is the chief cause of the present unsatisfactory conditions. I write from experience. What can we do to remedy this state of affairs? *Roamer.*

—I was very pleased to read the remarks made by Mr. Hudson, on p. 61, on the habit of head gardeners of taking premiums from journeymen, as I think the practice very objectionable. Years ago it was more prevalent than it is at the present time, but it still exists, and I know several

(Photograph by R. A. Malby.)

R.H.S. Cultural Commendation February 24, 1914. (See p. 153.)

is no guarantee whatever of its purity. If he insists on being supplied with a guarantee stipulating that there is 98 per cent. of pure cyanide of potassium, he would then be more than half way on the road to success. I have never found it necessary to use a dose of 3 ozs. cyanide of potassium to the 1,000 cubic feet of space (not even in a vinery in winter). Half that quantity will not only kill mealy bug, red spider and thrips, but also mice, toads, woodlice, cockroaches, snails, slugs, and worms. In fact, no animal life can survive a strong dose of hydrocyanic gas. I should like to warn beginners of the great danger they incur of pouring water upon a strong solution of commercial sulphuric acid. *Jas. Fulton, Grims Dyke Gardens, Harrow Weald.*

GARDENERS' WAGES.—The discussion upon this subject is doing a vast amount of service, in so far as it is showing the younger generation the true facts of the case. Doubtless many a youth will "throw up the sponge," and small wonder. We find that after ten or fifteen years' struggling along in unsanitary bothies, working long hours, with often additional unpaid duty, we may, with luck, reach the position of head, with a

instances where it is in force. In one case the premium paid was as high as £25. I have been head gardener for a good many years where a large staff is employed, and I could take premiums if I wished, but my conscience would not permit me to do so. I know that the wages the journeyman will receive and his opportunities for advancement will not warrant it. I am of the same opinion as your correspondent *Forty Years Head* (p. 76), that by taking a premium from a young man, the head gardener is under an obligation to keep him for the term, whether he has an aptitude for gardening or not. In many instances a man would thus be brought into the profession who is not adapted to it. *Thirty-eight Years Head.*

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 24.—The usual fortnightly meeting of the Committees of this society was held on Tuesday last in the Vincent Square Hall, Westminster. An excellent exhibit from the Weston-birt collection included enormous plants of *Cattleya Trianae*, *Cymbidium eburneum* and *C. Lowianum*, the Lindley Medal being awarded for excellence of culture. The Orchid Committee recommended two First-class Certificates and three Awards of Merit.

The most imposing exhibit before the Floral Committee was a collection of Tulips, for which a Gold Medal was awarded. There were also bright groups of forced trees and shrubs, Primulas, Carnations, Camellias, Daffodils, Hyacinths and other bulbous flowers, and numerous rock-gardens. The Floral Committee recommended two Awards of Merit to novelties.

The Fruit and Vegetable Committee made no award to a novelty, but four collections were

exhibited on the bulbs. A large mound of *Lachenalias* made a pretty feature in the centre, and these were as praiseworthy as the Tulips. (Gold Medal.)

Lady TATE, Park Hill, Streatham Common (gr. Mr. W. Howe), contributed a great bank of flowers with well-grown pot specimens of Tulips, Daffodils and Hyacinths, relieved with Ferns and Palms. (Silver-gilt Banksian Medal.)

Messrs. SUTTON AND SONS, Reading, filled a table with their fine novelties in *Primula sinensis* set in a ground of *Adiantum* Ferns, which threw the flowers in relief. One corner of the exhibit was composed of the yellow *Primula kewensis* associated with the new White Queen stellata variety, and this led on to rows of Coral Pink, Giant Salmon Pink, The Duchess, Giant Crimson, The Czar, lavender blue; and Reading Blue, a paler shade than the last, with a centre-piece composed of Dark Blue stellata variety intermingled with *P. malacoides*, with a ground of Ferns. Two pretty novelties in star Primulas were seen in Coral Pink and Silver Star, the latter having no colouring in the eye. This firm also showed a batch of fine white

flowering shrubs, but very suitable for arranging along the walls of a conservatory or greenhouse. They had also a rockery which showed great taste in its method of arrangement and planting. (Silver Banksian Medal.)

Messrs. WM. PAUL AND SON, Waltham Cross, filled the corner by the east annexe with Camellias, flowering Cherries, double crimson-flowered and white Peaches, *Pyrus Malus floribunda* and other beautiful flowering trees of this character, making a delightful exhibit, for which a Silver Flora Medal was awarded.

Messrs. STUART LOW AND CO., Bush Hill Park, were awarded a Silver Banksian Medal for Carnations, Cyclamen, and other greenhouse plants.

Messrs. JAMES VEITCH AND SONS, LTD., Chelsea, were awarded a Silver Banksian Medal for an exhibit of Azaleas and other greenhouse flowers.

Messrs. WILLS AND SEGAR, South Kensington, made big banks of flowers with *Cinerarias* and *Cyclamens* in a variety of colours. (Silver Banksian Medal.)

Mr. Geo. PRINCE, Oxford, showed a small group of Roses, for which a Bronze Flora Medal was awarded. Two big vases of Fortune's Yellow were at the back, and in front were such varieties as Mme. Edouard Herriot and Sunburst.

Messrs. H. B. MAY AND SONS, Edmonton, were awarded a Silver Banksian Medal for Pansies, Polyanthuses, and Ferns, the last including a dozen or more excellent plants of the densely plumose variety of *Nephrolepis exalata*, named after Miss Willmott.

Messrs. H. CANNELL AND SONS, Swanley, showed Zonal-leaved *Pelargoniums*, *Cyclamens*, and varieties of *Primula sinensis*.

Varieties of Zonal-leaved *Pelargoniums* growing in small pots and carrying large trusses of blooms were shown by Messrs. H. J. JONES, LTD., Rycroft Nurseries, Hither Green.

Messrs. ALLWOOD BROS., Wivelsfield, Hayward's Heath, had some of the best Carnations in the show, for which they were awarded a Silver Banksian Medal.

Other exhibitors of Carnations were Mr. J. C. JENNER, Rayleigh, Essex; Mr. H. BURNETT, Guernsey. (Silver Banksian Medal); Mr. C. ENGELMANN, Saffron Walden (Silver Banksian Medal); Messrs. YOUNG AND CO., Cheltenham; and Messrs. W. WELLS AND CO., Merstham.

Messrs. R. GILL AND SONS, Falmouth, again showed *Rhododendrons*, *Violet Princess of Wales*, and *Cyclamen coum*.

Mr. J. J. KETTLE, Wimborne, Dorsetshire, showed varieties of single and double Violets. Mr. MAURICE PRICHARD, Christchurch, Hampshire, was awarded a Silver Banksian Medal for a dainty rock garden planted with Alpines.

Messrs. BAKER'S, Wolverhampton, showed several boxes of Alpines, having in fine condition *Primula denticulata*, and its white variety.

Mr. G. REUTHE, Keston, Kent, exhibited Shrubs and Alpines. The two most interesting plants were *Tecophilaea cyanocrocus*, with clear blue petals; and the lovely *Crocus aeneus*, the gem of the genus and very rare. The flowers of the *Crocus* are coloured light blue, passing to white, with gold in the interior at the base, against which the bright red stigma shows conspicuously. The foliage develops after the blooms are over. (Silver Banksian Medal.)

The WARGRAVE HARDY PLANT NURSERY, Twyford, were awarded a Silver Banksian Medal for Alpines exhibited on a rockery.

Messrs. BARR AND SONS, King Street, Covent Garden, contributed a pleasing group of bulbous and other hardy flowers, together with a rock-garden exhibit. They had charming pans of *Iris reticulata*, pots of *Primula malacoides*, hybrid

FIG. 69.—FREESIA EXCELSIOR: FLOWERS DEEP CREAM BLOTCHED WITH ORANGE COLOUR. R.H.S. Award of Merit, February 24, 1914. (See page 153.)

[Photograph by R. A. Maiby.]

awarded Medals. At the three o'clock meeting in the lecture room, an address on "The Use of Explosives and of the Blow-lamp in the Garden" was delivered by Mr. H. E. DURHAM, Sc.D.

Floral Committee.

Present: H. B. May, Esq. (in the chair), A. A. Dorrien Smith, George Paul, G. Reuthe, Chas. E. Shea, E. H. Jenkins, Thos. Stevenson, W. J. Bean, F. W. Harvey, H. J. Jones, C. Dixon, W. H. Page, John Dickson, C. E. Pearson, R. C. Nevill, Wm. Howe, J. F. McLeod, J. W. Moorman, C. Blick, C. T. Druery, E. Bowles, W. A. Bilney, R. Hooper Pearson, George Gordon, W. Cuthbertson, F. Page Roberts, R. C. Notcutt, Jas. Hudson, T. W. Barr, J. Jennings, W. G. Baker, R. W. Wallace, B. Crisp, W. B. Cranfield and W. P. Thomson.

Messrs. R. AND G. CUTHBERT, Southgate, had the largest exhibit in their collection of Tulips, which ran the entire width of the building at the end opposite to the clock. There were some 60 distinct varieties, and each sort was shown by itself in a round basket in a setting of greenery. The blooms were in the very best condition of freshness and colouring and were

Freesias and *Hyacinths* in art bowls. (Silver Flora Medal.)

Messrs. J. CARTER AND CO., Raynes Park, showed their new star *Primula Fairy Queen* and *Princess Mary*, a pretty blush-pink variety of the older type. It was a very dainty exhibit, and showed how well these beautiful greenhouse flowers appear when massed. At either end were banks of Tulips, which gave additional interest and colour. This firm also showed a new Trumpet Daffodil named *Sir Francis Drake*. The big trumpet is of deep yellow colour, being set off by a perianth of Emperor type, with old gold shading. The foliage is most vigorous.

Messrs. W. CUTBUSH AND SON, Highgate, arranged a very large floor group of forced shrubs, and, as a separate exhibit, Carnations and Alpines. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, staged, in a mass, profusely-bloomed plants of Azaleas, with standard Lilacs rising amongst them at intervals and backed by a row of Palms. (Silver Flora Medal.)

Messrs. PIPERS, Bayswater, exhibited espalier trees of *Pyrus floribunda*, *P. atro-sanguinea*, double-flowered Peaches and Cherries, a system of training not often practised with ornamental-

Gerberas, numerous fine Daffodils, and a big batch of Tulips. A prominent feature was a bank of the fragrant Narcissus Poeticus Grand Soleil d'Or. (Silver Banksian Medal.)

Messrs. WARES, LTD., Feltham, were awarded a Silver Banksian Medal for Alpines. Their Irises were good, especially *I. sindjarensis*, *I. reticulata*, and *I. histrioides*.

The GUILDFORD HARDY PLANT NURSERY were awarded a Bronze Flora Medal for hardy flowers and Alpines; Mr. JAMES BOX, Hayward's Heath, received a Silver Banksian Medal for an exhibit of a similar nature, and Messrs. R. H. BATH, LTD., showed bowls of bulbous flowers.

Hardy flowers were shown well by Messrs. GEO. JACKMAN AND SON, Woking. We noticed the rare *Androsaco carnea alba*, *Morisia hypogaea*, *Helichrysum bellidioides*, numerous fine *Saxifragas*, and *Megasea ciliata* in this exhibit.

Messrs. WHITELEGG AND PAGE, Chislehurst, Kent, exhibited a long, flat rockery on a table, but it had not sufficient depth to appear effective. It was brightened with many well-flowered *Saxifragas*. (Bronze Flora Medal.)

Messrs. G. and A. CLARK, LTD., Dover, were also the exhibitors of a rockery on which coloured Primroses were well displayed.

The rock garden that pleased us most was shown by Mr. CLARENCE ELLIOTT, Stevenage. The stones were of old grey limestone, and the blocks were disposed in a natural manner. (Bronze Flora Medal.)

Rock gardens were also shown by Messrs. THOMPSON AND CHARMAN, Bushey, Hertfordshire; the BURTON HARDY PLANT NURSERY, Christchurch; R. TUCKER AND SONS, Brookside Nurseries, Oxford; R. WALLACE AND CO., Colchester. (Bronze Flora Medal.)

AWARDS OF MERIT.

Freesia Excelsior (see fig. 69).—A new variety characterised by its great substance and vigour. The colour is rich cream blotched with orange, very much like the variety *Leichtlinii*. The outside of the tube was also in some cases lightly shaded with purple. The flowers, however, are larger in size and stouter in substance than any of the varieties in commerce, and the foliage showed such extraordinary vigour that it was nearly an inch in breadth, though grown in ordinary conditions. The remarkable constitution of the plant promises great things in the hands of the hybridist, and may well lead to a new strain. We were informed that under identical conditions it blooms three weeks earlier than *F. refracta alba*, which was displayed with it. Shown by Messrs. SUTTON AND SONS.

Sparaxis King George V.—This is a variety raised some years ago from seed by Mr. W. Barr, who finds that every year it blooms at this early period for a *Sparaxis*. It is also notable for its very rich colour, the brightest tints in which are the deepest shade of blood-red (of the *Répertoire de Couleurs*), and this passes insensibly towards the centre into a dark maroon, which gives a definite edge to the usual light-yellow eye. Shown by Messrs. BARR AND SONS.

CULTURAL COMMENDATION.

To Mr. F. LLOYD, Croydon, for pan of *Saxifraga Burseriana* (see fig. 68). The pan was about 3 inches in diameter, and there were more than three hundred expanded flowers, which were so densely placed as to hide the foliage.

OTHER NOTEWORTHY PLANTS.

Crocus Thomasianus (sativus) Weaveri.—A distinct purple-red variety, shown by the WAR-GRAVE HARDY PLANT NURSERY.

Freesia Robinella.—Mr. F. H. CHAPMAN showed this new variety of Messrs. Van Tubergen's. The flowers are a deep shade of old rose, the darkest of the red shades that we have seen in these flowers.

Orchid Committee.

Present: Sir Harry J. Veitch in the chair, and Messrs. Jas. O'Brien (hon. sec.), F. Sander, R. G. Thwaites, F. J. Hanbury, F. M. Ogilvie, T. Armstrong, C. H. Curtis, W. Cobb, A. McBean, J. Charlesworth, J. Cypher, W. H. Hatcher, J. E. Shill, H. G. Alexander, W. P.

Bound, A. Dye, E. H. Davidson, S. W. Flory, W. Boltou, Gurney Wilson, F. J. Chapman, de B. Crawshay, Stuart Low, R. A. Rolfe, and Sir Jeremiah Colman, Bart.

In the main building Lieut.-Col. Sir GEO. L. HOLFORD, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), occupied the same space as on the occasion of the last show, when his group secured for him the Society's Gold Medal.

On this occasion the exhibit was equally interesting, but confined mainly to grand forms of *Cattleya Trianae*, and some huge specimens, marvels of high cultivation. The award was divided, a Silver-gilt Flora Medal being awarded for the group, and a Lindley Medal for the three wonderful specimens, viz., *Cattleya Trianae*, var. *Hydra*, with 96 beautiful flowers (the same specimen which, when smaller, was illustrated in the *Gardeners' Chronicle*, February 18, 1911, p. 108); *Cymbidium Lowianum*, with 15 spikes, bearing together 278 flowers; and *C. Lowie-eburneum*, with 26 spikes of 101 flowers; these three giants being in tubs. A batch of the Westonbirt *Cymbidium Dryad* (insigne \times *Parishii Sanderæ*), with 10

example, in those with labellums spotted all over with rose colour. Messrs. Sander state that they take every precaution to record their seedlings accurately, and with better parents have gone over the well-known Continental crosses with the result that in many cases the reputed parentages have been proved to be incorrect. A finely formed flower (*Rolfeae* \times *Pescatorei*) is a great improvement on *O. Rolfeae* (*Pescatorei* \times *Harryanum*), but it ought to be known by that name, as no new element is introduced except in degree. *O. St. Andre* (*Rio Tinto* \times *ardentissimum*) is a very handsome flower with yellow ground colour heavily blotched, and with the lip covered with rose spotting.

Messrs. STUART LOW AND CO., Bush Hill Park, and Tarvisbrook, Sussex, were awarded a Silver Flora Medal for a very fine group of splendidly grown Orchids, excellently well staged. Most of the showy Orchids of the season were represented, including fine forms of *Cattleya Trianae* and other *Cattleyas*, with a plant of the pretty white-petalled *C. Percivaliana* Little Gem. *Odontiodas*, *Odontoglossums* and *Cypri-*

FIG. 70.—CYMBIDIUM ALEXANDERI HAMILTON-SMITH'S VARIETY; SEPALS AND PETALS WHITE; LIP MARKED WITH CRIMSON.

R.H.S. FRS. Class Certificate, February 24, 1914. (See page 154.)

spikes of fine white flowers, the lip spotted with purple, stood at one end, and a fine lot of the pretty yellow L.-C. Ariel (*C. aurea* \times *L. Cowanii*) at the other. Sixteen distinct forms of *C. Trianae*, with very fine blooms, were included, and among them the large variety *Colossal*, *Madame Louise Hemptinne*, with blush-white sepals and petals; *Lowii*, white with a pink tint on the lip; *Ampliata*, of a pale peach-blossom colour like *C. Schroderae*; *Nooreana*, one of the finest in colour; *The Premier*, *Chrystobel*, white with sulphur yellow in the tube of the lip; and *Perfecta*, a large bloom with crimped edge to the labellum, were prominent. Two exhibits gained Awards of Merit (see Awards), but the fine *Laelio-Cattleya Aureole* (L.-C. *luminosa* \times *C. Iris*), with a strong spike of eight brightly-tinted flowers of a peculiar magenta-red colour on yellow ground, which many visitors admired, was passed without award.

Messrs. SANDER AND SON, St. Albans, were awarded a Silver Flora Medal for a fine group, the most interesting feature in which was the excellent selection of new hybrid *Odontoglossums*, which, while being all of fine size and shape, exhibited great variety of colour, with some novelty in the arrangement of it, as, for

pediums were in variety, and specially attractive were *Brasso-Cattleya Madame Chas. Maron* and other *Brasso-Cattleyas*, and a very bright reddish-rose hybrid between L.-C. *Ophir* and L.-C. *Charlesworthii* flowering on a very small plant.

Messrs. CHARLESWORTH AND CO., Haywards Heath, were awarded a Silver Flora Medal for a small but very select group, all good specimens. The best noted were *Phalaenopsis Schilleriana alba*, the unique snow-white form; *Brasso-Laelia-Cattleya Joan* (*C. Octave Doin* \times *B.-L. Mrs. Greatrix*), a good yellow flower with fringed lip; *Sophro-Laelio-Cattleya Electra* (*S.-L. heatonensis* \times *C. labiata*), ruby-red in colour; *Cattleya Trianae The Baron*, a noble white flower; *Odontonia Langowoyi*, the pretty hybrid of *Miltonia Schroderiana* which recently received an Award of Merit; some bright red *Odontiodas* and showy *Odontoglossums*; the elegant *Angraecum citratum*; and a singular pink-tinted form of *Cattleya Susanno Hye de Crom* (*Gaskelliana alba* \times *Mossiae Wageri*), out of a batch which give white and tinted varieties.

Messrs. ARMSTRONG AND BROWN, Orchidhurst, Tunbridge Wells, were awarded a Silver Banksian Medal for a group, principally hybrids,

some of which were new, and the seedling *Odontoglossum*, flowering for the first time, specially attractive; crosses between *O. illustrissimum* and *O. eximium*, and one between *O. Lambeaunum* and *O. excellens* being distinct. A singular *O. Pescatorei*, with a few violet spots, and some hybrids of it, were also remarked. *Cymbidium Iona* (insigne × giganteum), and a finely marked *C. Lady Colman*; *Cypripedium Venus* Orchidhurst variety; *C. Holdenii*, *C. Leander* Cambridge Lodge variety; *C. Florida* (Fowlerianum × glaucophyllum), a new cross of remarkable features, the broad dorsal sepal and broader lower sepals having blackish lines and greenish margin, the very dark petals a strongly ciliate margin, lip rose-colour.

Messrs. J. CYPHER AND SONS, Cheltenham, were awarded a Silver Banksian Medal for a good group, principally of fine *Cypripediums*, *Phalaenopsis Schilleriana* and *P. Stuartiana* were finely in bloom; a selection of pretty *Masdevallias* included *M. ignea*, *M. caudata* *Shuttleworthii*, *M. Courtauldiana*, *M. Hincksiana*, etc., and the bright scarlet *Epiphronitis Veitchii*, and *Sophronitis grandiflora*, were arranged in front.

Messrs. FLORY AND BLACK, Orchid Nursery, Slough, were awarded a Bronze Banksian Medal for a small group in which were two good varieties of *Odontodia Schroderi*, several *O. Sibyl*, *O. Graireana* and two unnamed *Odontodias*. The best of the *Odontoglossums* were *O. amabile*, *O. Lambeaunum* and *O. Doris*, pretty forms of which were shown. Among *Cypripediums* were a very fine *C. Dicksonianum*, Countess of Carnarvon, with rich rose-purple dorsal sepal, with white tip. New *Cypripediums* were *C. Marcus* (Dicksonianum × Leeanum), *C. Trincolo* (insigne *Harefield Hall* × *Victor Hugo*), and *C. Marina* (aureum × *Lord Wolmer*).

Messrs. HASSALL AND CO., Southgate, were voted a Bronze Banksian Medal for a small group in which were the new *Odontocidium Southgatense* (*Odontoglossum Edwardii* × *Oncidium macranthum*), a very singular hybrid with flowers having broad sepals and petals of a dark purple colour and rose lip with ovate front and yellow disc. The pretty *Odontodia St. Fuscien*, *Brassocattleya Langleyense* albens, good *Cattleya Trianae*, *C. Empress Frederick*, *Cypripedium villosum Stanleyi*, a very large form, *Cymbidium insigne*, and *C. eburneo-Lowianum* were also shown.

Messrs. SWAN AND PRICE, St. Albans, were awarded a Bronze Banksian Medal for a group of *Cypripediums* in great variety and good quality, with *Cattleyas*.

Messrs. E. H. DAVIDSON AND CO., Orchid Dene, Twyford, showed a selection of rare Orchids, including the very large and handsome *Cattleya Trianae* Orchid Dene variety, *C. Harrisoniana* alba, with a good show of pure white blooms; the fine white *Odontoglossum crispum* *Princess May*; and the deep rose and claret-red *O. Twyford Gem*, the most beautiful of *O. Rossii* hybrids; also *Sophracattleya Warnhamensis*, and a charming pan of *Odontoglossum Oerstedii*, with 18 white flowers.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), again showed the pretty and floriferous brown and yellow *Odontoglossum Boadicea* (triumphans × *ardentissimum*), *O. Damaris* (Rolfæ × *Waltonense*), fine forms of *O. harvengtense* and *O. Hallio-crispum*, and *Odontodia Bella* (*Cochlioda Noezliana* × *Odontoglossum bellatulum*).

Monsieur JULES HYE DE CROM, Ghent, (gr. Mr. Coen), sent *Cypripedium Tracyanum maximum* (aureum *Hyeaunum* × *Leeanum* *Clinkerberryanum*), a very large light-coloured flower.

C. J. LUCAS, Esq., Warnham Court, Horsham (gr. Mr. Duncan), sent the large-flowered *Cypripedium Harlequin*, and *C. Robsonii* (exul × *insigne* *Sanderæ*), first flowered by Messrs. Sander in 1905.

Miss HELEN F. M. SIDNEY, Moreton, Holly Place, Hampstead, showed a finely-flowered *Dendrobium splendidissimum*.

Mr. L. LAWRENCE, Shoreham House Gardens, Shoreham, showed a good specimen of *Selenipedium Sedenii candidulum*.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum Colossus (parentage unrecorded), from Baron BRUNO SCHRODER,

The Dell, Englefield Green (gr. Mr. J. E. Shill).—A noble *Odontoglossum* with probably the largest flowers of any yet shown, and a fine example of good culture. The greater part of the broad segments was covered with large purple-red blotches, the margins and a few irregular lines between being white. The colour was heightened by the rich purple back of the segments.

Cymbidium Alexanderi *Hamilton-Smith's variety* (insigne × *eburneo-Lowianum*), from HAMILTON SMITH, Esq., Seymour Road, Finchley (gr. Mr. A. Coningsby).—A very beautiful variety, differing from others in its white, wax-like flowers having an irregular band of crimson on the lip as in *C. Lowianum*.

AWARD OF MERIT.

Cypripedium Mogul (Mrs. Wm. Mostyn × *chrysotozum*).—From Lieut.-Colonel Sir GEO. L. HOLFORD. A very beautiful *Cypripedium* of fine shape and thick texture; yellow, tinged with purple, the ivory-white dorsal sepal having a purple band in the middle.

Laelio-Cattleya Ariel (*C. Dowiana aurea* × *L. Cowenii*), from Lieut.-Colonel Sir GEO. L. HOLFORD.—A very floriferous and pretty hybrid as seen in the small batch shown. Spikes tall, with six to ten flowers, reddish golden yellow or copper colour, with ruby-red lip.

Phalaenopsis Ariadne (*Aphrodite* × *Stuartiana*), from Messrs. SANDER AND SONS, St. Albans.—A very interesting and beautiful plant introduced by Messrs. SANDER as a natural hybrid and quite intermediate, the large white flowers bearing some of the spotting of *P. Stuartiana* on the lateral sepals. It was first flowered and home-raised by Messrs. JAS. VEITCH AND SONS in 1896, *P. Aphrodite* being the seed-bearer.

Fruit and Vegetable Committee.

Present: Jos. Cheal, Esq. (in the chair), Messrs. C. G. A. Nix, W. Poupert, W. H. Divers, J. Jaques, W. Crump, A. Bullock, A. R. Allan, A. Grubb, W. Bates, Edwin Beckett, Jesse Willard, and John Harrison.

Messrs. JAMES CARTER AND CO., Raynes Park, were awarded a Silver-Gilt Banksian Medal for 73 varieties of Potatoes. The dishes were arranged on a green velvet cloth, and Palms were employed to enhance the effect. The tubers were clear of skin, evenly matched and very attractive generally. Varieties of the firm's introduction were conspicuous, and of these the more notable were *Advancer*, *King of the Russets*, *Long Keeper*, *Invicta*, *Snowball*, *Early Favourite*, and *Goldfinder*. The old Scotch Regent variety was included for its excellent flavour, although it is not popular with some on account of having deeply set eyes. Another variety of excellent table quality was seen in *Excelsior*, but in this again there is the defect of small size.

Mr. W. E. SANDS, Hillsborough, Co. Down, exhibited 21 baskets of Potatoes, for which a Bronze Knightian Medal was awarded. Many, such as *Emerald Queen*, *Edina*, *Leinster Wonder*, *Irish Hero* and *The Gardener* bore names unfamiliar to growers in this country.

Mrs. DENNISON, Little Gaddesden, Berkhamsted, showed excellent root vegetables and Potatoes, including *Large Record*, *Ailsa Craig*, and *Rousham Hero* Onions; *Summer Favourite* and *Early Market* Carrots; *Early Milan*, *Round Red* and *Jersey Lily* Turnips; splendid *Maltese Parsnips*; good *Musselburgh* and *Holborn Model* Leeks. (Silver Knightian Medal.)

The Duke of RUTLAND, Belvoir Castle, Grant-ham (gr. Mr. W. H. Divers), showed a collection of Apples and bunches of *Black Alicante* Grapes, for which a Silver Banksian Medal was awarded.

Mr. H. HEMSLEY, Crawley, showed fruits of the new Apple *Crawley Beauty*.

NATIONAL FEDERATION OF FRUIT AND POTATO TRADES' ASSOCIATIONS.

FEBRUARY 24.—The eleventh annual general meeting of the members of the National Federation of Fruit and Potato Trades' Associations (Incorporated), Limited, was held on the 24th inst. in the Grand Hotel, Leicester. There was a large attendance of delegates. On being elected President, Mr. Wm. Cann (Manchester)

occupied the chair. The annual report was presented, of which we print the following extracts:—

ANNUAL REPORT.

The hope expressed in the last Report that if the Federation were reorganised on the lines suggested, all the trade associations would become affiliated, has been fully realised. We are glad to be able to report that all known associations connected with the wholesale fruit trade are now members of the Federation, and, in addition, we now have 189 individual members.

It has been decided to form a Foundation Fund to provide a reserve against special contingencies, and up to the present time £337. 18s. has been subscribed. This amount is quite inadequate for the purpose—the reserve should be at least £1,000—and we trust that all members who have not yet contributed will send a donation to the secretary.

In order to relieve the Executive Committee of some of the detail work, a Northern division has been formed to deal with all matters of special interest to the North. The country has been divided by the line of the 55th degree, and all Great Britain north of this line, together with all Ireland, has been allotted to the Northern Division. A Northern committee has been formed of all the executive members resident in the Northern division, Mr. Wm. Cann being appointed chairman, and Mr. Ernest Farrington, of Manchester, secretary.

The members of the Northern Committee have done a very large amount of useful work during the year. They have held committee and sub-committee meetings, and, in addition, have addressed meetings in various parts of the country, with the result that several associations which had broken up or become moribund have been re-formed, and have joined the Federation. They have also been successful in obtaining a large number of individual members. It is hoped, during the coming year, to form other associations where there are sufficient wholesale traders to render this possible.

Railway matters have also taken up considerable time. On May 22 a deputation waited on Mr. Marriott, of the Lancashire and Yorkshire Railway, to lay certain grievances before him. Messrs. Crouch and Bellis attended on behalf of the Federation. Mr. Marriott promised to improve the service, and a number of claims for delay were settled satisfactorily.

The Federation was asked to take up the question of flower cartage in London. The rates had been increased from 4s. 2d. to 6s. 8d. per ton, and the minimum raised from 2d. to 6d. As a result of representations from your committee, the minimum charge was reduced to 3d., but the Metropolitan Conference refused to reduce the tonnage rate.

The demurrage charges came up for consideration owing to the companies issuing new regulations allowing only two days before demurrage was charged. We communicated with the companies in an endeavour to get a longer time allowance, but without any result. It therefore seems that we shall have to make use of our legal remedy under the Railway Rates and Charges Order Confirmation Acts of 1891-2. These Acts provide that if the trader is dissatisfied with the time allowed, or the rate charged, he can create a difference—that is, raise a formal objection—when the company must submit the matter to the arbitration of the Board of Trade.

A Royal Commission on Railways has been appointed to inquire into the relationship between the railway companies of Great Britain and the State in respect to matters other than safety of working and conditions of employment, and to report what changes, if any, are desirable in that relationship. Your committee have applied to be heard by the Commission, and have appointed Messrs. Cann, Dennis, Larsen, Meek, and the two secretaries as witnesses. The chief points on which evidence will be given are late deliveries, classification, owner's risk conditions, delivery of empties, increased rates and reduced facilities.

The report was adopted.

During the afternoon a Conference was held to discuss matters relating to the transit of produce.

The President said that so far as the railway companies were concerned the trade was subjected to the same expensive and irritating treatment as formerly, and that in face of the 4 per cent. increase in the rates. They did not object to the 4 per cent. increase, but they strenuously objected to the inefficient service they got in return; there was no certainty of reaching the market in proper time. In asking for a better service they were only asking for what they were accustomed to get before the railway companies entered into working arrangements, thus doing away with competition. In addition to bad delivery, they had also to complain of demurrage charges and indifference to complaints. Offering suggestions in the way of remedies, the President mentioned the issuing of time-tables for traffic to traders, which he thought would be exceedingly useful. If railway companies broke contracts by running late they should be penalised. They wished to work amicably with the railway companies, realising they could be mutually helpful, and to that end he suggested quarterly conferences between representatives of the companies and local associations to consider suggestions for improvements.

Mr. Major (London) thought it ought not to go forth from the President's remarks that they entirely agreed with the increase in railway

rates, which were most oppressive in many cases.

On behalf of the Leicester Association Mr. Tomlin (Chester) moved a resolution that the question of demurrage be considered by the Federation, the time allowed for unloading trucks of loose Potatoes being totally inadequate.

This was seconded by Mr. Dent (Manchester). The resolution was carried, and on the suggestion of Mr. Eatough (Blackburn) it was also decided that a list of grievances be sent to the Railway Clearing House for consideration.

Mr. Rhodes (Liverpool) moved the following resolution, which stood in the name of the Liverpool Market Tenants' Association:—"That the attention of the Federation be directed to the question of late deliveries on the part of the railway companies, with a view to ascertaining what is considered a just and reasonable delivery." He contended that since the rates were increased deliveries had been later.

In seconding, Mr. John Martin (Liverpool) said that what they wanted to know was what really constituted reasonable delivery.

The resolution was carried.

Another resolution dealing with the same subject was moved by Mr. Shipley on behalf of the Leicester Association. The resolution indicated habitual late delivery to Leicester of goods from Liverpool and Manchester, amounting to two and three days' delay.

Mr. Charles Wilson (Leicester) seconded, and the resolution was agreed to.

Other matters dealt with were signing for goods before receipt, the grouping of small consignments, charges for empties, and propaganda work.

THE BANQUET.

The annual banquet was held in the evening at the Grand Hotel, all the delegates being present. It was decided to hold next year's meeting in London.

NATIONAL DAHLIA.

FEBRUARY 23.—This Society held its annual conference at Carr's Restaurant, Strand, on Monday last. Mr. Geo. Gordon, the President, occupied the chair. The Chairman, in his opening remarks, referred to the trial of Dahlias carried out last year by Mr. R. Cory at Duffryn, and the competition for the Cory Cup and Veitch Memorial Medal. These events should forward the interests of the flower. Raisers were endeavouring to secure varieties that will be as useful in the garden as for exhibition, and he trusted that everyone would take a broad view of the possibilities of the flower and encourage every type. In the absence of the author, Mr. R. CORY, Mr. J. A. JARRETT read the paper on the Duffryn trial, and a second paper on "The Dahlia of To-Day" was read by Mr. H. SHOESMITH. We are compelled to hold over our report until next week.

EDINBURGH BOTANICAL.

FEBRUARY 12.—The fourth meeting for the session was held on the 12th inst., Dr. R. S. MacDougall, President, in the chair.

Mr. MONTAGU DRUMMOND gave an account of a summer vacation in Jamaica, with lantern illustrations, with special reference to the Botanic Gardens at Hope, near Kingston, at Castleton, twenty miles inland, and at Cinchona, in the Blue Mountains, at an altitude of 5,000 feet. He pointed out the special advantages of Cinchona as a tropical station for research, and drew attention to the project which is on foot to make that station more fully available to British students, and in aid of which the British Association for the Advancement of Science has already granted £25.

MISS LAMONT read a paper on "The Ecology of an Argyllshire Area (the Estate of Knock-dow)," with lantern illustrations, in which she indicated the distribution of various types of vegetation taken as representative of the flora of the district.

Dr. R. S. MACDOUGALL exhibited the Citrus white fly (*Aleyrodes citri*), parasitised by the red fungus (*Aschersonia aleyrodidis*) and the black fungus (*Aegerita Webberi*).

Mr. WHYTOCK showed a collection of plants from out-of-doors at Dalkeith Palace.

The following plants in flower were shown from the Royal Botanic Gardens:—*Cullumia squarrosa*, R. Br., a peculiar South African composite; *Rhododendron moupinense*, Franch.; and *Rhododendron oleifolium*, Franch., a hardy species with whitish flowers, tinged sometimes with lilac. Introduced from Western China by Mr. Wilson.

DEBATING SOCIETIES.

WARGRAVE AND DISTRICT GARDENERS'.

At the meeting of the above association held on the 11th inst. Mr. W. H. Scott gave a lecture on "The Evolution of Vegetable Culture." He referred to the vegetables mentioned by Parkinson as being cultivated at the end of the seventeenth century, and showed how by careful elimination of worthless kinds and hybridisation of the best varieties our present-day vegetables have been brought to a high state of perfection. The use of manures was carefully pointed out, and the great advantages of glasshouses in lengthening the season of many vegetables were referred to. The improvement is very marked, said Mr. Scott, if one remembers the quality, size and appearance of the vegetables exhibited at any large show of twenty years ago and those of the present day.

BIRMINGHAM AND DISTRICT GARDENERS'.

At the meeting of this society, held on Monday, the 26th ult., a lecture on "Edible and Poisonous Fungi" was delivered to a large audience by Dr. Jessie Bayliss Elliott, Lecturer on Botany at the University of Birmingham. Miss Elliott emphasised the importance of a knowledge of fungi to gardeners and horticulturists in general as there was no definite rule as to whether a fungus is edible or not. She stated that many more fungi are edible than is commonly supposed, and many could be utilised for food. After giving some receipts for cooking fungi the lecturer proceeded to explain the method of mushroom culture in Paris, the details of which she had gathered from personal investigation. The lecture was illustrated by lantern slides.

READING GARDENERS'.

The first fortnightly meeting of the winter session was held on the 26th ult. in the Abbey Hall, Mr. J. T. Tubb, chairman of the committee, presiding over a large attendance. Mr. J. A. Murray, B.Sc., of the University College, Reading, delivered a lecture on "Farmyard and Stable Manures." Mr. Murray based his opening remarks on the well-known bias of practical gardeners toward farm and stable manure for the cultivation of garden crops generally, and said that the preference was well founded. No artificial manure could or ever would take the place of stable or farm manure. It was quite possible to supply to the soil all the soluble or even insoluble food that a given quantity of stable manure contained by compounding various artificial manures, but their action on the soil in other respects was totally different from that of stable manure. Artificially supplied no organic matter, and the great value of farm or stable manure lay, not so much in the soluble manurial substance it contained, as in the many-sided effect that the organic matter had on the soil itself. The lecturer pointed out the relative values of various kinds of farm and stable manure and how such value was greatly affected by the age and food of the animals, and the treatment the manure received. Where the urine was allowed to drain away, or insufficient litter used to retain it, by far the most valuable portion of the manure was lost. Again, washing by rains would waste nearly, if not all, the immediately available plant food, and some time must elapse before manurial matter less soluble could, by the aid of fermentation, be brought to a condition when it could be taken up in the soil water by the plant.

The evening devoted to "ten minute" papers by the younger members last April proved so successful that a similar gathering was held on Monday, the 2nd inst. Papers were contributed by Messrs. C. Goodchild ("Greenhouse Plants"), J. Lloyd ("Starting a Business"), P. Kaye ("Melons"), R. Baker ("Stove and Greenhouse Plants"), C. Reader ("Violets"), and F. Barnes ("Malmesbury Carnations").

The annual tea and entertainment took place on the 18th inst. About eighty members and friends were present, the president (Mr. F. S. Parfitt) being in the chair. After the tea and during the time the hall was being cleared those present were afforded an opportunity of inspecting Messrs. Sutton and Son's stores and offices. At 7.30 an audience of about 600 assembled at an entertainment, and an excellent programme was provided by the kindness of Mr. Leonard Sutton.

BRISTOL AND DISTRICT GARDENERS'.

The fortnightly meeting of this association was held on the 12th inst. the president, Colonel Cary Batten, J.P., occupying the chair. Two papers were read by Mr. Barrow and Mr. Estence on "Tomatos" and "Decorative Chrysanthemums" respectively. The prizes offered by the president for two Cypridiums were won by Mr. Jennings (1st) and Mr. Curtis (2nd).

BRITISH GARDENERS' ASSOCIATION (Leamington Branch).—A meeting of the members of the Leamington branch of the B.G.A. was held on the 31st ult. Alderman A. Holt, chairman Leamington and County Show, presided. A lecture was given by Mr. J. H. Hays, superintendent of the local public park, on "Propagation by Seed."

BRITISH GARDENERS' (Edinburgh Branch).—The monthly meeting of the Edinburgh branch of the B.G.A. held on the 9th inst., Mr. W. H. Morland presid-

ing. A lecture on "Hybridising," illustrated by lantern slides, was delivered by Mr. Hosking, horticultural lecturer at the Glasgow and West of Scotland College of Agriculture. The next meeting will be on March 9, when the subject of the lecture will be "The Formation and Maintenance of Herbaceous Borders," by Mr. A. McDonald, Darnhall Gardens, Eddlestone.

DUMFRIES AND GALLOWAY GARDENERS'.

The monthly meeting of this association was held in the Wesley Hall, Dumfries, on the 31st ult. Mr. S. Arnott, president, occupied the chair. A paper on "The Rose: its History and Cultivation," was read by Mr. W. Sturrock, manager of the Larchfield Nurseries, Dumfries. Mr. Sturrock dealt briefly with the history of the flower, and more fully with its cultivation. He gave a selection of the best varieties for planting.

SOUTHAMPTON AND DISTRICT GARDENERS'.

The first monthly meeting of the new session was held on the 29th ult., the president, Mr. H. E. Molyneux, in the chair. Mr. Montague Allwood, of Wivelsfield Nurseries, Haywards Heath, gave a lantern lecture on "The Perpetual-Flowering Carnation." Twenty-four new members were elected—a record number for any one meeting.

KILMARNOCK AND DISTRICT GARDENERS'.

The monthly meeting of this society was held on the 11th inst., Mr. R. K. Sillars presiding. Mr. D. Vallance, of Dunakin, delivered a lecture on "Beekeeping," illustrating his remarks with the aid of various sections of hives, etc. The intimate connection of beekeeping with horticulture, and the methods to adopt to ensure the most profitable return of honey, were clearly explained.

BATH GARDENERS'.

Mr. T. Parrott presided at the fortnightly meeting of the Bath Gardeners' Debating Society, held on the 9th inst. There was an excellent attendance. A paper on "Apple Cultivation" was given by Mr. Strugaell.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS'.

At the meeting held on Monday the 9th inst. two papers were read. Mr. Brotschneider, of Compton Nurseries, first gave a paper "On the Propagation of Roses." After giving full details of the methods of cleft, tongue, and whip grafting he closed his lecture by briefly answering questions raised. The second paper was by Mr. Brown, proprietor of Compton Nurseries, King's Norton, and he dealt with "The Best Varieties of Roses." Amongst the twenty-four best Roses for general purposes, said Mr. Brown, were Hugh Dickson, Frau Karl Druschki, Mrs. John Laing, and General McArthur. He gave lists of the best bedding Roses; the best for standards; the best varieties for pillars—chief of which were the American and Blush Ramblers—varieties for pot culture; and the twelve best suited for town gardens, together with the twelve best Teas and twenty-four best varieties for exhibition.

CHESTER PAXTON.—At the opening meeting of the winter session, under the chairmanship of Mr. A. W. Armstrong, a lecture entitled "Cultivation of Chrysanthemums" was given by Mr. A. Calderbank, Chief Instructor in Horticulture at Holmes Chapel College, Cheshire. The lecturer dealt very fully with his subject under the heads of propagation, composition of soils, manures, their value and method of application, and gave numerous cultural hints. He emphasised the need of fresh air and sunshine, and gave explicit directions as to the composition of soils and liquid and other manures. He gave an extensive list of varieties which he recommended for cultivation, and explained the method of raising new varieties.

At the usual bi-monthly meeting held in the Grosvenor Museum on the 21st inst., Mr. Montagu Allwood delivered a lecture on "Perpetual-Flowering Carnations" to a large audience over which Mr. N. F. Barnes, Eaton Gardens, presided. Mr. Allwood illustrated his lecture with a series of lantern slides (a number of which were coloured), and which gave added interest to what the chairman described as one of the best lectures they had listened to.

BURNLEY AND DISTRICT HORTICULTURAL.

A meeting of this association was held in the Mechanics' Institute, Burnley, on the 5th inst. Mr. W. J. Hargreaves occupied the chair. Mr. H. Jackson, of Ightenhill Park, gave a lecture on "Summer Bedding."

WATFORD HORTICULTURAL.

A well-attended meeting of this society was held on the 13th inst. The president, R. H. Comyns, Esq., occupied the chair. Mr. H. Newman was presented with a marble time-piece as a mark of esteem and recognition of his services as secretary from 1910 to 1912. A lecture on "Potato Culture" was delivered by Mr. R. A. Ayre, of Bushey Lodge Farm. He dealt with the subject under the following heads: Seed, manure, cultivation, profitable side, healthful side, and beautiful side.

BRITISH GARDENERS' (Watford Branch).

The monthly meeting of the Watford branch of the B.G.A. was held on the 19th inst. Mr. W. Phillips presided. Mr. H. Curtis, superintendent of Parks, Northampton, gave a lecture on "Old-fashioned Flowers for Spring Bedding." He dealt exhaustively with the raising of the plants from seeds, their general cultivation and flowering periods. At the next meeting, to be held on March 19, Mr. W. R. Phillips, Kennels, Stanmore, will deliver an address on the "Cultivation of Root Crops."

LIVERPOOL HORTICULTURAL.

A special general meeting of this society was held on the 19th inst. for the purpose of electing a secretary in succession to Mr. H. Sadler, who has filled the office for the past 15 years. Mr. W. Mezer, occupied the chair. The name of only one candidate was submitted, Mr. W. S. Peet, 36, Dale Street, Liverpool, a chartered accountant, and he was unanimously appointed.

GARDENING APPOINTMENTS

Mr. B. Savage, for the past 18 months with Messrs. CUTBUSH AND SON, The Nurseries, Barnet, and previously for 12½ years with Mrs. E. RIDER COOK, Woodford Green, as Gardener to W. H. BROWN, Esq., Harts, Woodford Green, Essex. [Thanks for 1s. for R.G.O.F. box.—EDS.]

Mr. H. C. Lewis, for the past 2 years Second Gardener at Derryswoad, Womersley, Surrey, and previously at Greenlands, Henley-on-Thames, as Gardener to A. D. HART, Esq., Charnwood, Melbourne, Australia.

Mr. C. Brookes, for nearly 3 years Foreman at St. Osyth Priory, Colchester, Essex, as Gardener to Mrs. FAUDEL PHILLIPS, Mapleton, Edenbridge, Kent.

Obituary.

JOSEPH TOWELL.—The *Florists' Exchange* records the death of Joseph Towell on January 26, who was born in County Down, Ireland, May 24, 1848. He left school at the age of fourteen and worked three years in the gardens of the Marquis of Downshire; thence he went to East Hempstead Park, and later worked in many private and commercial establishments. Mr. Towell settled in the United States in 1872 and engaged himself as a gardener for several years, holding positions in New York, Newport, Long Island, Staten Island and Canada. In 1878 he secured employment in the Bellevue Nursery, U.S.A., which he managed until 1880, when he bought the business, operating the same until about 1910. As a wholesale grower he shipped largely to New York, and he held at one time the best retail store in Paterson.

JOSEPH FELS.—Our readers who are familiar with the work of the Vacant Land Cultivation Society will learn with regret of the unexpected death at the age of 61 years of the founder and president, Mr. Joseph Fels, who succumbed to an attack of pneumonia on the 15th inst. at Philadelphia, U.S.A. In our issue for May 15, 1909, p. 312, will be found particulars of the operations of the society in the Metropolitan area, where there are numerous instances in which vacant land awaiting the enterprise of the builder has been brought into a state of cultivation under the direction of the superintendent, Mr. R. Lewis Castle. Not only have the sites been much improved in appearance, but the gardening operations have provided remunerative employment for men who would otherwise be out of work. In 1905 Mr. Fels acquired an estate of 1,300 acres at Hollesley Bay, which he placed at the disposal of the Central (Unemployed) Body for the formation of a labour colony for the unemployed; and he afterwards bought 600 acres of land at Maylands, Essex, for a similar colony.

APRICOT TREE ATTACKED BY MAGGOTS: A. G. S. P. The caterpillars are those of the magpie moth, *Abraxas grossulariata*; all of them are immature. The best remedy for this pest is to spray with either Paris green or arsenate of lead.

BONE MEAL: A. P. This manure would benefit the Tomatoes and Chrysanthemums. It should be used at the rate of 1lb. to each barrowful of the potting soil, or 14lb. to a cartload.

ERRATUM.—In the note on perpetual-flowering Carnations at Lynwood Nurseries, Rayleigh (p. 127), the number of plants in one house grown on benches should read 15,000 instead of 1,500, as printed.

GLASS FOR A GREENHOUSE: T. G. The clear glass would suit the plants best, but if the untinted, rolled glass is not too dense this may be used. One advantage of the latter is that during very bright weather it would not need to be shaded, but you must remember that there are more dull days in a year than sunny ones.

LADY GAY ROSE: E. P. It is very natural to find a difficulty in accepting Crimson Rambler as a parent of Lady Gay. There seems little or nothing about the plant to render this probable, though in dealing with hybrids it is often the unexpected that happens, and this parentage is believed to have been stated with authority; at least, it is given by Mr. Daniel, who has made a special study of the parentage of Roses. The distinctive characters botanically of *Rosa multiflora* and *R. Wichuraiana* are as follows:—

<i>ROSA MULTIFLORA.</i>	<i>ROSA WICHURAIANA.</i>
Thorns frequently in pairs.	Thorns almost always scattered.
Leaflets rather rough, usually more or less pubescent, lighter green than in <i>R. Wichuraiana</i> .	Leaflets always glabrous, smooth and shining, smaller than in <i>R. multiflora</i> .
Stipules very characteristic, deeply pectinated, the teeth longer than the leaf-like part of the stipule is broad.	Stipules, with fine teeth, not longer than the leaf-like part of the stipule is broad.
Stylar column usually glabrous.	Stylar column often hairy.
Stems upright at first, arching later, strong, rigid and brittle.	Stems, creeping along the ground, lax and flagellate, and easily bent or twined in any direction.

Tried by these tests no one would connect Lady Gay as it has been distributed in this country as a multiflora, but it would be placed without hesitation among the *Wichuraiana* group. We must not expect to find any of our garden forms, which are mostly hybrids, possessing exactly the typical characters of the species; it will always be a case of greater or less. For instance, in *Crimson Rambler*, a multiflora hybrid, and not very far from the type, thorns are seldom noticed in pairs. Lady Gay, however, possesses so many of the qualities of the *Wichuraiana* type that Dr. Williams was justified in classing it among the *Wichuraiana* hybrids. We believe that he has now admitted *Hiawatha* and *Excelsa* to the same group.

NAMES OF FRUITS: W. Manning. Apple New Bess Pool.—J. A. J. B. Apple Royal Somerset.—G. W., Brandon. Ashmead's Kernel.—H. A. Gros Fenouillet.—J. I. S. 1, Reinette du Canada; 2, Calville St. Sauveur; 3, D'Arcy Spice syn. Spring Ribston; 4, Waltham Abbey Seedling.

NAMES OF PLANTS: A. J. W. *Brunfelsia calycina* var. *Macrantha*, also known in gardens as *Franciscea*. Insert cuttings of the ripened growths at once, using only those which have not started into new growth, as these form the best plants. Cuttings are also easily rooted in the autumn if ripened growths are placed in a sandy, peaty soil in a close frame furnished with brisk heat. *Brunfelsias* are best treated as stove plants during their growing period, and may be transferred to an intermediate house during the late summer and autumn.—J. W. R. *Dendrobium Pierardii*.—Constant Reader. The Orchid is *Dendrobium speciosum*, an Australian species, which may be grown in any warm, sunny greenhouse, fruit-house or conservatory. The tree is *Cornus Mas*. *Asparagus plumosus* grows well in almost any situation, and should be potted in turfy loam.—I. M. 1, *Dendrobium cretaceum*; 2, *Dendrobium Parishii*; 3, *Dendrobium sauguiolentum*; 4, *Odontoglossum Lindleyanum*.—Constant Reader (J. C.). 1, Probably a leaf of *Asarum canadense*. Send when in flower; 2, *Anemone Hepatica* varieties; 3, *Libonia Penrhosiensis*; 4, *Nepeta (Glechoma) hederacea variegata*; 5, *Pelargonium Little Trot*; 6, *Hibiscus Rosa-sinensis Cooperi*. G. H. S. 1, *Cupressus filifera plumosa*; 2, *C. Lawsoniana lutea*; 3, *C. filifera plumosa aurea*; 4, *C. pisifera squarrosa*; 5, *Cryptomeria elegans*.

OPPORTUNITIES FOR GARDENERS IN AUSTRALIA: G. Howell. We submitted your enquiry to our valued correspondent, Mr. Gilbert Errey, of Victoria, Australia, who replies as follows:—"The possibilities of gardening employment in Australia depend largely upon the qualifications and tastes of the applicant. The general demand is for men accustomed to the climatic conditions, which differ greatly from those in England. The main features of outdoor gardens in Sydney are shrubs—par-

ticularly Roses—and bedding annuals or foliage plants, such as *Iresine* and *Alternanthera*. Hardy herbaceous perennials, as known in England, are grown in a "bush" house or greenhouse. Bulbs for spring flowering are popular, but Tulips and a few others requiring cooler conditions are seldom grown. The members of the *Amaryllidaceae* are much in evidence. Wages vary from £3 or £4 per week for a very limited number of head gardeners, who are also expert propagators; to '20s. per week and found' for labouring work in the garden. Many gardens are managed entirely by 'jobbing' gardeners, who work for four hours upwards per week at one garden and elsewhere for the rest of the week, frequently keeping six gardens in order by giving one day per week to each. Wages for these 'jobbers' usually average about 8s. to 8s. 6d. per day of eight hours, with no board or lodging—an occasional popular and expert jobber commands 9s. and 10s. per day. Should a good grower of vegetables and flowers consent to go several hundred miles out of Sydney and endure the bush life of a squatter's homestead (10 to 25 human beings centred in an area of perhaps 50 to 1,000 acres) he usually receives good treatment, with £80 to £100 per year with board and lodging. I would advise those who land to make personal application to the secretary of the Horticultural Society of N.S.W., to the Curator of Botanic Gardens, Sydney, or to such a firm as Messrs. A. Yates and Co., 184, Sussex Street, Sydney. You could insert an advertisement in the Sydney daily papers stating your qualifications, experience generally, and the position desired. The cost would be from 2s. 6d. to 5s., according to the space taken and the number of insertions."

PARADISE STOCKS: Constant Reader. These are shallow rooting and more or less dwarfing stocks, obtained from layers, as distinguished from seedling Crab and free stocks, which have tap roots, and are conducive to more vigorous growth in the trees grafted or budded upon them. There are several types of the Paradise stock. The French Paradise is of too dwarfing a character for commercial plantations, and is to be recommended only for use in gardens where space is limited. The less dwarfing English broad-leaf Paradise is recommended for bush trees in large orchards, though for some varieties of Apples and for standards the Crab or free stock is preferable. The English Paradise is a selection, probably from the *Doucin*, a stock intermediate in vigour of growth between the French Paradise and the Crab or free stock. The Crab is the wild Apple, and the free stock is raised from the pips of Apples, usually obtained from cider mills, but sometimes from a particular variety.

POTATO: S., Stepney. No disease is present in the tubers. The superficial scab on the surface would not account for the smell when the Potatoes are cooked.

PRIMULA OBCONICA UNHEALTHY: W. B. The injury is caused by a fungus. Spray the plants at intervals of four days with a solution of liver of sulphur—1 oz. in 6 gallons of water.

RICHARDIA (ARUM) LEAVES UNHEALTHY: C. H. The injury to the leaves is not due to fungous disease or insect pests. The cause of the trouble must be looked for in some wrong cultural treatment.

SOIL FROM A VINE BORDER: W. B. The mycelium present in the soil is that of the vine-root fungus. Soak the soil thoroughly twice at an interval of a fortnight with a solution of sulphate of potash. Lift the soil with a fork to allow the solution to enter freely: the specific should be used at a strength of 1 lb. in 10 gallons of water.

THE MARKET FRUIT GARDEN.

LAST month was my fifteenth February in this place, and the rainfall of 4.02 inches has but once been equalled during the preceding fourteen years. That was in 1910, when the measurement was 4.28 inches. The only other very rainy Februaries were those of 1900, with 3.46 inches, and 1904, with 3.56 inches. In only two other years was the February measurement so much as 1 3/4 inch, namely, 1906, when it was 2.67 inches, and 1912, when it was 2.21. The lowest records were 0.21 inch in 1909 and 0.69 inch in 1905. The February average for the fourteen years ended with 1913 was 1.89 inch, so that the quantity last month was considerably more than double the average for the period named. All but a trifling proportion of the fall occurred in the second and third weeks of the month. The fall at my station may be compared with 3.62 inches for the South-East of England generally. For other districts into which the United Kingdom is divided by the meteorological authorities the figures are as follows, in inches:—Scotland N., 5.87; Scotland E., 2.67; Scotland W., 5.45; England N.E., 1.16; England E., 1.76; England N.W., 3.23; England S.W., 4.58; England extreme S., 3.89; Ireland N., 5.56; Ireland S., 6.32.

In an average of seasons February is one of the driest months in the year, in spite of its unfair nickname, "fill-dyke." Its average rainfall in thirty-five years at Brixton was the lowest for any month but March.

LABOUR LOST.

Unfortunately, my first trial of lime-spraying, so far as Plum trees are concerned, was to a very great extent annulled by the daily or nightly rainfall of February 11 to 21. The work was begun on February 7, and rain fell on the following day. Then we had two dry days; but afterwards rain fell a few hours after each instalment of the spraying, except at the last, although it was carried on only when there seemed to be some hope of fine weather up to the 21st. Consequently a large proportion of the lime was washed off the trees, although the wash was as thick as it could be used, 1 1/2 cwt. of lime to 100 gallons of water being the proportions. The trees from bases to tops were ghostly white when freshly done, but only a few are white now. The worst of lime is that it must be used soon after its arrival, and, as mine came from Buxton, it was necessary to have four tons at a time to avoid the extremely high rail rate per ton charged on less than a truckload. Moreover, it was sent a week sooner than it was directed to be despatched. Lime does not stick on the trees nearly as well as lime-sulphur, and if, as *E. M.* says on page 106, it has no effect in preventing aphid attack, I shall never use it again. Lime-sulphur is much less trouble to use, and, if fungicidal action is of any use in February or March, it has some action of that kind, whereas lime has practically none, while the former is superior to the latter for clearing moss off the trees. By the way, if lime is not a preventive of aphid attack, it is not easy to imagine why *E. M.*'s neighbour applies it when his Plums are bursting into bloom. If it does nothing but cleanse the trees of moss it might as well be applied in winter as in spring. I should be sorry to use it on trees in blossom, as it seems entirely improbable that it can fail to impair fertilisation. A thick coat of lime over the sexual parts of the flowers must interfere to some extent with the spreading and reception of the pollen, by the agency of insects or otherwise. Lime-spraying of young Apple trees will be deferred to a later date. The instruction of those who recommend lime-spraying is to apply the wash when hot. As a matter of fact, this is impossible without constant relays of boiling water for mixing, which would be almost impracticable in field work. Although the Buxton lime is the best that can be had, and generates great heat when slaked, dilution with cold water reduces the temperature below blood heat before a freshly-prepared tub of the wash is half

used. In my case the mixer kept only one tub ahead of the sprayers, and yet the wash, when it emerged from the machines, was quite cool to the hand.

ONE GREAT ADVANTAGE IN LIME-SPRAYING.

In the case of soil deficient in lime there is one great advantage in the use of lime-wash. It requires fully three gallons of the wash to thoroughly cover two mature trees of moderate size, or one very large tree, and each gallon contains 1.68lb. of lime. As my Plum trees number 300 to the acre, the application was over 7 3/4 cwt. per acre, allowing two trees to the three gallons, for, of course, sooner or later, all the lime applied is washed on to the ground. Such a dressing annually would be ample. But, as all my land has been very liberally chalked (about 15 tons per acre a few years ago), the advantage does not occur in my case. The quantity would be very much less in an orchard of young trees.

LIME-SPRAYING WITH KNAPSACKS.

A friend who has had experience in lime-spraying informed me that the work could not be done with knapsack machines. A trial made before ordering a large quantity of lime, however, proved that this is not the case. By wiring and soldering a small piece of brass plate on to a plain jet in such a way that it acts as a spreader my pneumatic knapsacks were found capable of spraying trees fifteen feet high, a seven feet lance being used with each. There is nothing in the jet to get blocked, and the spreader is turned up at just the right angle to catch what would be a solid stream, diverting it in proper spray form. Any ordinary nozzle would be frequently blocked by thick lime-wash, although, of course, the stuff is passed through a fine sieve into the tubs. The piece of brass plate can be bent by pliers to precisely the right angle for making the best spray. The size of the spreader above the part where it is first wired and then soldered on to the jet is 7/8 inch in length and 5/8 inch in breadth. It has its sides very slightly turned up.

HOME-MADE LIME-SULPHUR.

As factory-made lime-sulphur has increased greatly in price since the first sample used in this country was prepared for me, and since manufacturers will not take the barrels back or allow for them, I decided that I would make my own with some of the Buxton lime ordered for lime-wash. A 25-gallon portable boiler was obtained for the purpose, and some empty paraffin casks. The object was to make 20 gallons of the concentrated fluid in one boiling, two lots to fill, or nearly fill, a barrel. The plan of making is as follows:—Place 24lb. of fresh lump lime in the boiler, then beat 48lb. of flowers of sulphur into a paste,

breaking all lumps, dilute the paste and pour on to the lime to slake it, stirring thoroughly. The fire should be lighted as soon as the liquid is poured on to the lime. When the lime has slaked fill the boiler up to 4 inches from the top and boil for one hour, stirring frequently while the stuff is getting to the boiling point, and occasionally afterwards. An old spade is the best tool for stirring. As there is a good deal of loss from evaporation extra water has to be added after boiling has gone on a little while to keep the quantity up to 20 gallons. Great care is necessary to keep the stuff from boiling over. A 30-gallon boiler would be better, for then 25 gallons could be put into it immediately after the lime had been thoroughly slaked, thus avoiding the arrest of boiling caused by adding more water. This quantity would waste to about 20 gallons. There is hardly any sediment when the proportions of

to exclude air. If a draw-off tap is fixed in the boiler it should have a strainer over its opening into the boiler, for otherwise it will be blocked by the lime or sulphur.

A BACKWARD SEASON BECOMING FORWARD.

If the extraordinary mildness of February is not to be followed by a spell of severity, the comparative backwardness of vegetation will be transformed to at least moderate earliness. Last season was a very early one, and comparisons of a few developments of this season with those of 1913 show great differences. This year Snowdrops and yellow Crocuses were both in full blossom in my garden on February 15, as compared with January 28 last season. The double yellow Daffodil was only in bud at the end of February, whereas it was in full bloom on February 14 last year. The Almond, now dormant, was in full bloom at the end of January in 1913, showing phenomenal forwardness. For Elder

ORCHID NOTES AND CLEANINGS.

HYBRID CYPRIPEDIUMS.

MR. E. HILL, gardener to F. J. O. Montagu, Esq., Lyndford Hall, Mundford, sends blooms of four fine Cypripediums raised by him, as follows:—C. Master Andrew (chrysotoxum × insigne Harefield Hall), as large as, and lighter in colour than, C. insigne Harefield Hall. Petals yellowish veined with purple. Dorsal sepal white with rose-purple spots.

C. Rosemary (Hera × aureum Oedippe), with large dorsal sepal flushed and spotted with dark rose colour. The petals and lip are coloured yellow, tinged with chestnut-red.

C. Tracyanum aureum (aureum Surprise × Leeaenum Clinkaberryanum), a fine flower, following C. aureum Surprise in its clear, light yellow tint and clear, white upper part in the dorsal sepal.

C. nitens-Leeaenum, a pretty variety with white dorsal sepal.

All the plants show evidence of remarkably good culture.

ODONTIODAS AND ODONTOGLOSSUMS AT HAYWARDS HEATH.

THE great value of these beautiful Orchids for supplying bloom all the year round is well shown in the many houses devoted to them in Messrs. Charlesworth's Orchid Nursery at Haywards Heath, which is never without a good show of bloom. In the Odontioda house are thousands of spikes in all stages of development, making a bright show of varied tints of scarlet, red, and red and white. There is also a great show of bloom in the Odontoglossum house, the blotched, home-raised *O. crispum* being remarkable in two ways—in that the blotched forms outclass the imported varieties, and the perfect shape, fine substance, and clear white of the white forms are far better than importations can give. In all classes of hybrids here many interesting lessons in variability and heredity, as well as in seed-raising and cultivation, are to be learned.

HIPPEASTRUMS FROM SEED.

THE flowering period, when the plants are giving a wealth of colour, is the best time to mark Hippeastrums for seed production. The selection will depend on the strength of the plant, and what colours, and whether selfed or striped, are preferred. If the strongest plants are selected, the result will be large and well-filled pods of seeds, from which strong seedlings may be expected.

It is a good practice not to allow more than two pods to ripen on each plant. Should any particular flower be fertilised by its own or other pollen, it is advisable to enclose the whole inflorescence in a piece of muslin to prevent bees or other insects from carrying foreign pollen to the stigma. After fertilisation has taken place the pods will soon begin to swell until they burst and expose their black seeds. These are then ready for sowing, and the sooner this is done the better, their vitality is stronger and they germinate more quickly; the result is stronger plants.

The seeds should be sown in a well-drained pan filled with soil consisting of loam and leaf-mould in equal quantities, first passing these ingredients through a $\frac{1}{2}$ -inch sieve, and adding sufficient sand to ensure porosity. The soil should be made moderately firm, the seeds sown on the surface about $\frac{1}{2}$ -inch apart, and covered lightly with the same compost. Give a good watering with a fine-rose can, and, if possible, plunge the pan into bottom heat, placing a square piece of glass over it to prevent excessive evaporation. Shade the pans until the seedlings appear, which will be in about a month's time. After they

R.H.S. First-class Certificate, February 24, 1914 (see p. 154, ante).

lime and sulphur are as stated above, but there would be a great deal if a larger proportion of lime were used. The density of the fluid when cool should be not less than 31° as indicated by the Banmé hydrometer, or 1.2719 on the ordinary specific gravity instrument. The former is much easier to read. One gallon of the concentrated fluid of the density named or a little higher can be diluted with 12 gallons of water for a winter wash, and with 40 gallons for summer spraying. The cost of the concentrated fluid is under five-pence per gallon, including labour and the little coal used; but this does not allow for interest on the cost of the boiler and barrels or depreciation. At any rate, sixpence per gallon would be ample to allow to cover everything. In the long run there would be some economy in using a 50-gallon boiler in order to fill a paraffin barrel in one operation. But for anyone needing only ten to twelve barrels in a season, the expense of the larger size would hardly be warranted. The barrel should be filled quite up to the bung-hole

leaf the comparison is one-quarter expanded on February 15, against January 31. Lilac leaf-buds were bursting on February 28 this season, against February 14 last year. Forsythia was in full leaf at the end of February in 1913, but was not a quarter out at the end of last month, and the difference in *Deutzia scabra* is nearly as much. Gooseberries were beginning to burst their buds in sheltered spots on February 21, a fortnight later than they were last year, and the cases of Red Currants and early Pears are similar. Black Currants are exceptional in being a little forwarder than they were a year ago. Plum buds were no more swollen at the end of February last than they were at the end of January last year. The buds of early Apples are swelling suddenly at the time of writing, bidding fair to be as forward shortly as they were last season. Raspberry leafage was a quarter out last year on February 15, but only a few buds are hursting at present. *A Southern Grower.*

have made six months' growth they should be taken out carefully and transferred to boxes. I use champagne or claret boxes, which are about 10 inches deep. They are drained, and over the drainage material are placed turves, grass downwards, and then a layer of small bones, on which a compost of two parts of loam, manure from a spent mushroom bed and sand is placed and made firm. By planting the young plants out in these boxes much time and labour are saved, for the seedlings take about three years before they reach the flowering stage, and hence if this practice be adopted they require less handling. For the first twelve months these should be kept growing and not allowed to rest, keeping them well supplied with moisture both at the roots and overhead.

At the end of the two years they should be potted in 4 and 5 inch pots. Some of the strongest plants will then flower. Those in bloom should be removed to a well-ventilated

bed manure, charcoal, and a good dusting of bone-meal and silver sand. The size of pots must be governed by the size of the bulbs, which generally are 6 inches. The plants must be placed back again in the hot-bed to encourage root action, and a humid atmosphere must be maintained by damping down the house twice a day. Great care must be exercised with the watering can till the plants have recovered from their disturbance. Once the pots are filled with roots and growing freely, a little liquid manure will be beneficial. Whilst the plants are in bloom they should be gradually removed to a well-ventilated house having an intermediate temperature. After they have finished flowering they must be replaced in heat to complete their growth and to build up new spikes for another season. Manure water in a weak solution may be given two or three times a week, and a humid atmosphere must be maintained, for although the plant loves

NOTICES OF BOOKS.

THE HERBACEOUS GARDEN.*

It is probable that the old-fashioned hardy plantsmen who half a century ago composed the glowing borders in the Countess of Home's garden at Bothwell Castle, and those of Lady Eleanor Balfour at Newton Don, congratulated themselves on having attained almost to perfection. Yet those who can remember the glory of these and of a few other gardens and the stages through which hardy plant gardening has since been passing will experience much pleasure in dipping into the present volume to find the case for the herbaceous gardens of today presented in a novel and fascinating manner, and will easily forgive the clever authoress its production, notwithstanding that it adds another to the perplexingly large number of recent volumes on the subject. Mrs. Martineau's reason for writing is, moreover, a valid one.

FIG. 72.—CATTLEYA TRIANAE VAR. HYDRA WITH 96 FLOWERS: FROM THE COLLECTION OF LIEUT.-COL. SIR GEO. HOLFORD, K.C.V.O.
R.H.S. Cultural Commendation, February 24, 1914 (see p. 153, ante).

house having an intermediate temperature, and they must be afforded water carefully, avoiding a too wet condition of the soil. The bloom must also be shaded from bright sunshine.

In the case of old bulbs during the resting period, say, from November to January, no water is required. Indeed, one great advantage these plants possess is the economical method in which the bulbs may be stored during the winter in odd corners under stages, etc., so long as they are exposed to a fair amount of light and air. By bringing the plants in batches into heat the flowering period may be extended from February to the end of May. When starting the plants into growth it is an advantage to plunge the pots into bottom heat of 65°, but the overhead temperature must not exceed 55°. The plants must not be re-potted until the flower spikes are just showing, which will be about a fortnight if a proper amount of moisture is afforded by syringing. The bulbs should be shaken out of their old soil, and re-potted into a compost consisting two parts turfy loam, one part mushroom-

light, it cannot stand the direct rays of the sun at midsummer. Towards the end of August growth will have well-nigh ceased. The plants then should be removed to a cooler temperature, well exposed to the light to ripen the bulbs, which is of vital importance to the well-being of next season's flowering.

Properly treated Hippeastrums, or Amaryllis, as some people call them, will increase in size and strength of flower, often throwing up two spikes, each bulb giving off one or more offsets every year, which, when large enough, may be detached and grown on as advised for the seedlings. E. F. Hart, Hockley House Gardens, Twyford, Winchester.

PUBLICATIONS RECEIVED.—*My Garden In Spring*. By E. A. Bowles. With preface by Reginald Farrer. (Edinburgh: T. C. and E. C. Jack.) Price 5s. — *The Banana*. By W. Fawcett. With an introduction by Sir Daniel Morris, K.C.M.G. (London: Duckworth and Co.) Price 7s. 6d. net.

She has always been a gardener, has made, or rather built up, several gardens, and for a series of years has, with the help of a sufficient staff, successfully managed a moderate-sized garden. Hence she finds herself in a position to help those who, wishing to help themselves, need a volume such as this to point the way and guide their steps along the road to success. Admittedly it is not a book for gardeners, but primarily for amateurs—garden lovers—and much that a gardener writing for gardeners would include is not to be found in its pages. Still, the gardener who works for his living will gratefully pick out choice morsels to strengthen him in the pursuit of the aesthetic. The authoress has a predilection for gardening in miniature, dividing small spaces into spaces still smaller to make believe that an enclosure is larger than it is. Such devices will not appeal

* *The Herbaceous Garden*. By Alice Martineau, with an introduction by W. Robinson. (London: Williams and Norgate, 14, Henrietta Street, Covent Garden, W.C.) Price 7s. 6d. net.

to those to whom the trivialities of Pope's villa garden are as repugnant as the display of wealth apparent in some of our modern gardens.

Though the book has its chapters and headings, the narrative is somewhat inconsequential, and every now and again the reader finds digressions on current or obscure subjects. "Kew—a mixture of the highest scientific research and the tea garden," where "there is never anyone to explain things," is compared with Bagatelle in France, where "you will find someone willing—nay, anxious—to pour out rivers of knowledge." The French, too, are more to be admired in the use of trellis-work than we. Mrs. Martineau's views on gardeners and their emoluments—another digression—will be received with approbation by the men for whom she pleads. The subject is discussed even more sympathetically than it is in one of Miss Jekyll's early books, which is saying a good deal; and it is interesting to have the expressed opinion of the authoress that her best gardeners have been foremen from big places who have stayed a few years and then passed on to higher and better-paid positions. There is nothing new in this, though young men might lay it to heart and keep it in mind that many well-to-do gardeners have started, like the writer of this review, in a small but well-done garden, and thence to better things. Her one lady gardener, by the way, failed, not through lack of push nor through laziness, but from a deficiency of practical experience. Probably some of the wealthy people who are sinking fortunes in stone and concrete and hundreds of pounds in rockery stones and pavements may be induced by this lady's remonstrances to reconsider and revise the scale of remuneration of their gardeners.

The chapters on "Colour" and "The Mixed Border" are rich in material, and much of this material is new, or at least placed before the student in a new way. I should not care to assert that the chapter on colour is exhaustive, but so far as it goes it must be helpful to those whose training in the colour sense is deficient or has been hitherto neglected. Take these for examples:—"Always remember that the simpler the scheme of colour the more effective it is." "Clear blues should be kept together, and grey or purple blues must not be mixed with them" (an extremely important pronouncement). "Too much white in a border looks spotty, and looks best in a breadth by itself." Concerning "form," she remarks, "It is well to classify mentally the upright, literally spiral growth of some in contrast with the branching or massive forms of others." How important this is may be seen almost any day in gardens where the form of the individual has not been considered in the planting. On the whole, I should be inclined to pronounce the above-named chapter the most important in the volume. Other chapters deal briefly with "Annuals and Bulbs," "One-colour Gardens," "Massing of Distinct Species," "Spring and Autumn," and "My Herbaceous Garden," a short description of which is given, along with details of planting. What are called borders—60 and 52 by 12 feet—are really oblong beds, and the person who has to deal with borders five or six times the length will note how much easier it is to arrange those of Mrs. Martineau than his own. There is much suggestive matter relating to the appropriate furnishing of the border which will be most useful, not only to the tyro but also to those on the outlook for novel combinations. Here and elsewhere in the volume are diagrams showing how the plants are arranged, but, as usual, they are of but slight value. The second part is devoted to an alphabetically-arranged list of plants, with cultural and descriptive remarks, and subsidiary lists of the annuals, blue flowers, Phloxes and Delphiniums, which the authoress holds to be indispensable to the effective furnishing of a garden. The

volume is effectively illustrated by a number of excellently-produced reproductions of garden scenery, remarkable for their softness of expression, and by one or two coloured illustrations. Here and there throughout the text mistakes occur. One such refers to Asters thus:—"A very good variety was Harpur Crewe, but since Climax was introduced, with a flower twice its size and of better growth, there is now no reason to grow the former." The present writer threw out Harpur Crewe years ago for a better *white*, but how it could compete or compare with Climax, a light-blue variety, is not obvious. B.

ALPINE GARDEN.

CROCUS SIEBERI VERSICOLOR.

SOME flowers are like a choice work of art which only the connoisseur can appreciate, and this applies to the exquisite *Crocus Sieberi versicolor*. The variety *versicolor* is recognised by the high canonical authority for the *Crocus*-lover—Maw's *Monograph of the Genus Crocus*—a perfect source of delight to those who possess it. Still prettier than the presentations of *Crocus Sieberi versicolor* in that *magnum opus* is the flower itself. Words fail to describe its beauties, but I will fall back on Maw's description. He says: "The variety *versicolor* is an extremely beautiful plant, the segments being variously striped, like a *Picotée*, with purple and white, which blend into the bright orange of the throat." My plants flowered in February, and the blooms were a delight indeed to examine, either when closed or open. I grew the plant many years ago, but lost my original stock when I removed to my present garden. S. *Arnott, Dumfries.*

CANADA.

HORTICULTURAL OPPORTUNITIES.

A RECENT advertisement in the *Gardeners' Chronicle* from a Canadian firm offering steady garden work at an attractive figure suggests a few thoughts from one who has worked in horticultural circles recently in the Queen City of the Dominion, Toronto. Whether the practical gardener should emigrate depends upon the man himself. There is no chance whatever for anyone who does not bring to bear upon his work, as in England, common sense, downright earnestness, and a willingness to do his level best to push forward the interests of his employer. Horticulture generally is making great strides in the Dominion, especially in Toronto, and things move quickly. Great scope is offered to those with energy and some capital in the direction of market gardening. Toronto, though possessing a population rapidly approaching 500,000, is behindhand in matters relating to the growth of vegetables for market, the most familiar types, such as Lettuces and Spinach, being sold at prices that place them outside the means of those with moderate incomes. Hence well-directed enterprise in this direction should prove remunerative.

Market gardens are, however, already springing up in districts outside the city, and in the course of a few years it is to be hoped that a greater variety of good vegetables will be forthcoming at reasonable prices to help to reduce the present high cost of living. There seem to be an absence of skilled labour, and naturally much of the cultivation has to be accomplished under glass to keep anything like pace with the demand, especially during the long winter months. As in England, so in Canada: it is the produce that comes in before the same kind is ready in the open air that pays best, and in the direction of early vegetables, for example, Mushrooms, Seakale and Asparagus, the possibilities of realising excellent profits are very promising.

And it may be well asked, Why is this? In the first place, it has to be remembered that Canada is, so to say, a new country, and until comparatively recent times gardens were not seriously considered; but an awakening has come. The importance of vegetables in the dietary is now realised, and the use of gardening as a pastime for the sake of recreation and profit is gaining many advocates.

The cultivation of Mushrooms and Asparagus, to single out only two vegetables, is in its infancy, but a quick demand will exist when there is any supply at a reasonable figure. Horticulture under glass is reaching, as it has reached in England, something of a fine art. In St. Catherines, a beautiful city in the Niagara fruit belt, by the shores of Lake Ontario for the most part, an enterprising market gardener tills the soil under his huge glasshouses; it is, indeed, market gardening under cover and a source of great profit. Every effort is being made to make the cultivation of good vegetables a real industry, and for the furtherance of this skilled labour is requisite, with the possibility, when a man is determined to succeed, of his making a quick start for himself.

The experience of a year or so will suffice for the grower to accustom himself to the different conditions of temperature and ways of cultivation which obtain in Canada. Indeed, the differences are not great, though it need scarcely be said that the forcing of vegetables in such a winter as favours Canada demands constant watchfulness and patience. But a good price is willingly paid for good material, which, if it adds to the variety of things offered, means a greater reward for labour and skill expended. The emigrant, in whatever position in life he may be, must learn one thing, and that is to assimilate, remembering that in the land of his adoption he should make himself one with those born in the Dominion, and not stand apart and criticise as a foreigner the people and their ways.

The annual convention or meeting together in the Parliament Buildings, Toronto, of the Vegetable Growers' Association was an occasion of much enthusiasm over the progress of vegetable cultivation in this province, and there was a large attendance. The superb quality of English seed was referred to as one of the great factors in making this forward movement for finer produce in greater variety a reality. It is delightful to have English vegetables in the garden—the same luscious kinds that were enjoyed in the old country—and this is possible when the various kinds are grown in a way suitable to the altered conditions. A new vegetable garden on a farm about thirty miles from Toronto was filled with varieties from Carter and Co.'s splendid store in the city and the crops were remarkable. It is all a question of sowing at the right time, paying regard to succession, which is most important as growth matures with extraordinary rapidity, and preserving for winter use. Nothing save root crops—Parsnips, Beets and Carrots, and similar things—is available in winter. All else—unless forced, which makes them luxuries—must come from the preserved stock.

What has been written of vegetables is true also of flowers—solid progress everywhere, especially with Roses under glass, and an intense desire to acquire the most approved of novelties among the leading types, of which one may cite the Sweet Pea, a universal favourite, as an example. As I pointed out in a former note, the Rose is seen in many gardens in its latest development, the majority of the plants coming from the nursery gardens of Great Britain. The next few years will witness a great change, a gradual quickening of interest in everything that concerns the garden resulting in what is desired—beautiful surroundings to the home, spacious parks and recreation grounds (of which there are many already), and flower beauty everywhere, with an increasing trade with England. *Correspondent.*

THE GARDENS OF SERLBY HALL.

SERLBY HALL, the beautiful residence of Viscount and Viscountess Galway, is situated three miles distant from Bawtry Station on the

designated the East Garden, presumably so named because of its gentle slope eastwards. The plan adopted is gloriously unorthodox in design and execution. Conventional bedding-out, stereotyped floral mixtures, and the familiar row after row way of planting have no place

sections:—Scarlet and orange beds, with bronze foliage (2) (see fig. 75), blue and kindred shades (2), white (2) (see fig. 76), pink and rose shades (2), and 2 yellows. The first six mentioned are each 35 yards long by 10 feet wide; the pink borders are the same width, but not quite so long, and the yellow borders are 38 yards long and 4 feet wide. All the borders are in pairs, and excepting the yellows, which run *cat* horizontally right and left, are parallel with each other, with a grass pathway of 18 feet between. A low Yew-tree hedge about a yard high at the back makes a capital foil to the various plants. No colour arrangements are allowed to clash; too blatant colours are not tolerated, especially those in yellow shades, and the plants in the borders are not graded in height from back to front like galleries in a theatre, the aim being rather the preserving of a natural irregularity of effect.

At the bottom of this East Garden lie the rockery and semi-aquatic section, all together making four acres. The rockery, which is full of good things, is built facing an ornamental piece of water. To the right of the rockery, as one looks eastward, and linking it up with the aquatic part, is a great number of *Iris germanica* in three colours, the sight of which in flower, Mr. Turner said, "was truly gorgeous." Within the bog area two large batches of *Primula rosea* particularly attracted my attention. They looked healthy and vigorous, and had flowered profusely in their shady waterside quarters. Before leaving this delightful spot I should like to mention an extraordinary piece of work accomplished by Viscountess Galway and a friend. It is the hand-painting of trees and shrubs in two shades of green upon the high wooden partition which divides the water garden from another part beyond. The object of this painting was to give an effect of distance, an object which is in good measure unquestionably achieved.

We now pass to the kitchen garden section and glasshouses, but before entering my attention was directed to one of the outer walls covered

FIG. 73.—SERLBY HALL, YORKSHIRE, THE RESIDENCE OF VISCOUNT GALWAY.

Great Northern main line from London to York. The house, which is of a compact, solid appearance, is flanked on the west side by a finely-wooded expanse, which includes many noble Beech trees. The south and north fronts of the Hall give extensive views across the grandly-wooded park, while on the south lawn are two specimens of the Lebanon Cedar. Before the charms of the garden are described it may be mentioned that the Serlby estate and near surroundings are in the grip of a great coal-mining enterprise. I learned that some 60 acres of surface land had been acquired as a preliminary step for the sinking of a shaft and other preparatory work, one item of which is the building of 1,000 cottages.

The hugely terraced lawns of Serlby Hall are separated from the park on the north side by an ornamental lake, skirted on the lawn side by a mixed herbaceous border of some 150 yards length, while on the south side the dividing line is a most uncommon kind of balustrade work formed of semi-circular tiles, which have the appearance of large drain pipes cut in half, lengthways, and inverted row upon row, these in turn being capped with stone flagging. Adorning the top of this wall, spaced at certain distances between, stand a dozen or more examples of stone statuary, which together with the tiled parapet form an effective and imposing line of demarcation from the outer park grounds. I understand that Lady Galway was responsible for this novel and picturesque screen. On the opposite side of the same lawn, at the south front, we enter from near the mansion a massive brick wall and pillar pergola, with wooden crosspieces of a very substantial size (see fig. 74). It is 100 yards long, 8 feet wide, and 8 feet high at one end, but about 15 feet high at the other end, owing to a gradual fall of the ground over which it is erected. As may be expected, the masking of such a structure is no simple task, and many and varied climbers are requisitioned.

We now come to the most striking feature of Serlby Gardens, the hardy flower quarters,

here. Not even a plant of the Zonal Pelargonium, let alone a bed, is bedded out. The north side of this East Garden enclosure is bounded by a brick wall about 10 feet high and 150 yards long, clothed with wall shrubs and many climbers, including a number of

FIG. 74.—PERGOLA AT SERLBY HALL.

Roses; while running parallel with the wall, with a flagged walk between, is a splendid border of Lavender bushes about 140 yards long. Turning to study the chief borders of this garden more closely, we find they are 10 in number, divided into the following colour

with *Wistarias* for a distance of 100 yards; the sight of which in bloom may be better imagined than described. The extent of the kitchen garden is five acres, and this area is divided into two walled-in enclosures, making, by the way, with what has already been mentioned,

a vast amount of wall and training work. Big batches of vegetables, so necessary in large establishments, were in healthy evidence, most noteworthy among them were climbing French Beans, Scarlet Runners, and culinary Peas. Outside fruit is also strong at Serlby, especially Peaches and Morello Cherries. Concerning the

ADDITIONS AND ALTERATIONS AT KEW.

The following details of additions and alterations at the Royal Gardens, Kew, are supplied by the official *Bulletin* :—

RIVERSIDE AVENUE.—The work of providing a new screen of evergreen vegetation to hide the

NEW CHINESE RHODODENDRONS.—The large collection of Rhododendrons raised from seeds of Wilson's gathering, and obtained also from Messrs. Veitch, J. C. Williams, Miss Willmott and other donors, having become too large for nursery quarters, it has become necessary to provide space for them in the Ericaceae collection. This is situated on the western side of King William's Temple. One of the "spurs" of the mound on which the temple stands has been cleared of a nondescript mixture of trees and shrubs for their accommodation. There is still the large collection raised from seeds sent home by Forrest to be disposed of during the next few years. It seems probable that before the whole of the Chinese Rhododendrons and other new Ericaceae have been found permanent places most of the ground in this part of the gardens will have to be given up to them.

ROSE DELL.—The renewal of the Roses in this pretty feature of the grounds, which was begun last winter, has been completed. About 350 of the best free-growing or rambling Roses have been planted. The removal of a large sweet Chestnut that stood in the middle of the dell has given more room for planting and will admit more light and air.

"SEVEN SISTER" ELMs.—The remnants of two more of these famous Elms have had to be removed during the winter. The trees, once of very large size, had become reduced to mere fungus-eaten stumps a few feet high and dangerous to the public. There now remain three of the original seven, two of them lofty trees still vigorous, the other a stump with a propped-up limb on one side only. Judging by an engraving in the *Gardeners' Chronicle* of September 15, 1883, from a drawing by Fitch, six of these Elms were then in good condition. They appear as good-sized trees in an old eighteenth century engraving preserved in No. III. Museum, standing near the margin of George III.'s lake, which was filled up about 1814.

ADDITIONS TO ARBORETUM.—The most important contribution to the hardy ligneous collections during 1913 has been made by the pur-

FIG. 75.—BORDER AT SERLBY PLANTED WITH SCARLET AND ORANGE-COLOURED FLOWERS.

latter, Mr. Turner happened to mention that the young growths fruited just as well spurred in as they do when tied in. Apples, Pears, Plums, Figs, Raspberries, Gooseberries, Loganberries and Currants are also well represented. Apple Gravenstein was pointed out to me as being less frequently seen than others, though it is a most useful variety. Two other distinguishing crops in the kitchen garden were borders of single Asters (annuals) and Sweet Peas (see fig. 77). I have never seen a more glorious profusion of the latter anywhere. The rows totalled 150 yards in length, and were literally smothered in flowers at that late date—the third week in September, and disease had been practically unknown.

Looking around the glass-houses, the salient features proved to be Peaches among the fruits and Perpetual Carnations among plants. One other subject growing in the conservatory I must record, as it is seldom seen in such a splendid state; and that is *Luclia gratissima*.

Another most interesting feature in this twenty-acre garden is constituted by the two Mulberry trees. These trees were given to the Moncton family by Cardinal Wolsey. Hence they are of a ripe age, in witness thereof are the props and iron chains which support their declining years. The best example is eighteen to twenty feet high, supported by eleven posts. It covers an area of ten square yards, and is 8 feet 6 inches round the trunk at 18 inches from the ground.

In concluding this brief survey of Serlby Gardens it may not be inappropriate to add that, before taking charge here in June, 1912, Mr. Turner was general foreman at Lockinge Park, and had served previously in the gardens at Windsor, Penrhyn and Elvaston. C. T.

unsightly parts of Brentford from the view of visitors in the north-west part of the gardens, which was begun last winter (see *K.B.*, 1913, p. 51), is being completed. Owing to the number of large evergreens like Holm Oak, Holly and Yew that have been needed to make an imme-

FIG. 76.—"WHITE" BORDER AT SERLBY HALL.

PLANT INSPECTOR IN BRITISH EAST AFRICA.—Mr. HARRY BARRON SHEARPE, formerly a member of the gardening staff of the Royal Botanic Gardens, Kew, has been appointed Plant Import Inspector in the Agricultural Department, British East Africa.

diately effective screen of sufficient height, the work has been of an arduous nature—some of the masses of earth moved with the trees weighing four to six tons. Once planted, however, the belt will be not only increasingly effective but permanent.

chase from Messrs. Veitch of about 250 rare Chinese trees and shrubs collected by Wilson and Purdom. The impending dispersal of the collections at the Coombe Wood nursery made it imperative that Kew should acquire as many as possible of these before this lamentable but in-

evitable event happened. Many of the plants purchased were of species found by Wilson during his first journeys on behalf of Messrs. Veitch, which covered ground not since traversed by any collector. They have consequently not been again introduced, and some, not easy to propagate, are very rare in gardens. Many of the trees and shrubs are still under number, only the genus to which they belong being known. Among the more important ones obtained from Messrs. Veitch are:—*Cladrastis sinensis*, *Corylopsis sinensis*, *Actinidia Henryi*, *Eleutherococcus leucorrhizus*, *Diospyros armata*, *Meliosma Veitchiorum*, *M. Oldhamii*, *Pyrus Folgeri*, *Styrax Hemsleyanum*, *S. Veitchiorum*, and *Tsuga chinensis*. A tree of great interest is the true *Aesculus chinensis* of Bunge. Long known by name in European collections, this Horse Chestnut has not really been represented anywhere (except possibly by a single tree at Segrez, in France) until introduced by Purdom from North China. For many years the Japanese tree *A. turbinata* did duty for it on the Continent, and latterly it has been confused with the tree found farther south, in Hupeh, by

visit to Ireland in February. Among them were two seedlings of *Daphne retusa*, one of the rarest and most beautiful of *Daphnes*. Mr. T. Smith's remarkable nursery at Newry was visited at the same time and purchases made.

The most important contribution of seeds to the Arboretum were 449 packets, gathered by Mr. G. Forrest in South China. Some seeds of interesting species in North-West America were presented by Mr. F. R. S. Balfour of Dawyck.

Acknowledgments are due to Canon Ella-combe, Miss Willmott, the Hon. Vicary Gibbs and other amateurs for their willingness to contribute what they can towards making the national Arboretum as complete as possible.

The following trees and shrubs have flowered in the Arboretum Department for the first time:—*Berberis brevipaniculata* and *B. subcaulialata* (China), *Ceratostigma Willmottiana* (China), *Cotoneaster turbinata* (China), *Davidia involucrata* (China), *Deutzia compacta* (China), *Fatsia horrida* (North-West America), *Jasminum Beesianum* (China), *Meliosma cuneifolia* (China), *Prunus microlepis* var. *Smithii* (Japan), and *Rhododendron nigro-punctatum* (China).

Mrs. Charles Russell, last season's introduction of the Waban Rose Conservatories, Natick, Mass., has done well practically everywhere, and will be more planted than ever next season. As a single forcing Rose Irish Fire Flame has taken quite well. Mrs. Geo. Shawyer has also done well since being sent out by Mr. C. H. Totty, the *Chrysanthemum* expert.

Killarney Queen is enjoying a reign of wonderful popularity. Double White Killarney and Double Pink Killarney have in large measure taken the places of Killarney and the original white sport. Amongst yellows Mrs. Aaron Ward still leads in favour, followed by Sunburst and Lady Hillingdon. Other popular forcing Roses are:—Prince de Bulgarie, My Maryland and Radiance. The little baby polyantha, Mme. Cecile Brunner, also called Mignon and Sweetheart, long a favourite in California, has jumped into favour with the East and West, and is proving useful as a forcing as well as a bedding Rose.

NEW CARNATIONS.—About an average number of new Carnations are this season being offered in America. On the whole they are not equal to those offered in some previous years. None of the novelties secured 90 out of 100 points at the recent convention of the American Carnation Society in Cleveland. Matchless, a beautiful white of the largest size and splendid form, seems likely to take the place of White Wonder and White Enchantress, the two most popular whites grown at present. This variety is being introduced by the Cottage Gardens, Queens, New York, who have also sent out Mrs. C. W. Ward, our best deep pink, Alma Ward, and other sorts. Mr. Peter Fisher, Ellis, Mass., introducer of Mrs. Lawson, Enchantress, Beacon, Benora, and other good varieties, is giving us Gorgeous, reddish cerise in colour. This has been seen at the London and other shows. It is a big fancy flower, carried on very stout stems. Mr. Fisher will next season send out Alice, of a charming shrimp pink colour, freer flowering than Pink Delight, and of very good form. Ratten and Co., Tewksbury, Mass., are sending out Princess Dagmar, an immense deep crimson, the largest of this colour up to date. The Chicago Carnation Company is giving us Peerless Pink, a deep pink, in the way of Rosette, which latter has become quite popular. Philadelphia Pink, being sent out by S. S. Skidelsky and Co., Philadelphia, proved to be a great winner at the late Cleveland Convention; it is of a lovely warm pink colour, and is having an immense sale.

F. Dorner and Sons, Lafayette, Ind., have given us two very fine new yellows. As a rule Carnations of this colour have proved to be failures here, but Yellow Prince is as free as any other Carnation in commerce. Yellowstone is a larger variety, not quite so prolific. Their new Champion, scarlet, seems destined to be the future leader in its colour. At present Beacon is easily the leader, followed by St. Nicholas, Commodore and William Eccles. Messrs. Dorner have introduced some of the finest Carnations, including White Wonder, Pink Delight, Rosette, and Gloriosa. Miss Alice Coombs, from Mr. A. Roper, Tewksbury, Mass., secured a silver medal at Cleveland. It is intermediate between flesh and light pink in colour; a very large flower, beautifully formed. J. Leach and Sons, North Easton, Mass., are sending out Pink Supreme, a very pretty shrimp pink variety, a wonderfully free bloomer. Benora remains easily at the head of our white variegated Carnations. Enchantress has been largely dropped to make way for Pink Delight in the East, but in the West still holds its popularity. In spite of the great annual increase in the production of Carnations, they continue to sell well, and no decrease in their popularity is apparent. *William N. Craig, Brookline, Mass., U.S.A.*

FIG. 77.—SWEET PEAS IN THE KITCHEN GARDEN, SERLBY HALL.

Wilson. The latter has recently been distinguished as *A. Wilsonii* by Rehder. Bunge's *A. chinensis* from North China was included in the purchases from Messrs. Veitch.

A very valuable consignment of trees and shrubs was received from the Arnold Arboretum in December. Besides Chinese species of Wilson's and Purdom's collecting, many interesting North American ones were included. Amongst the more important items were *Larix Potaninii*, *L. Mastersiana*, new American Poplars, Plums and Cherries, Oaks, Hickories and Chinese Willows.

As the result of an official visit made in June by the Assistant Curator to the nursery of Messrs. Leon Chenault and Son at Orleans, this firm kindly presented to Kew over seventy new and rare trees and shrubs noted at that time. Amongst them were species that have been introduced to cultivation by French missionaries in China from districts not traversed by English collectors. Mr. Maurice L. de Vil-morin has also sent contributions from his fine collections at Les Barres.

From the Royal Botanic Gardens, Glasnevin, were sent about thirty kinds of trees and shrubs noted by the Assistant Curator during an official

AMERICAN NOTES.

NEW ROSES AND CARNATIONS.

SEVERAL fine new forcing Roses are this season being offered in this country. Of course, all are adaptable to outdoor culture where climatic conditions are sufficiently mild, but Rose culture under glass is a vastly more important industry here than outdoor Rose growing. In some sections, notably on the Pacific Slope, wonderfully fine outdoor Roses are grown, but in most of our States the hot summers and severe winters render their successful culture a somewhat difficult one.

Killarney Brilliant, one of Dickson's new varieties, is having a great run, and is an improvement on the very popular Killarney. Undoubtedly the latter variety has been the most popular pink forcing Rose ever introduced here. Hadley, a scarlet variety, raised by the Montgomery Co., Hadley, Mass., promises to give Richmond, our leading red Rose, a tussle for supremacy; it is proving very popular. Prince E. C. D'Arenberg is another red flower in considerable demand. Ophelia, one of Messrs. Paul and Sons' novelties, is being popularised by the E. G. Hill Co., Richmond, Indiana.

FLORISTS' FLOWERS.

DAHLIAS.

THE following PAPERS on Dahlias were read at the conference held under the auspices of the National Dahlia Society on February 23:—

THE DAHLIA TRIALS AT DUFFRYN, 1913.

Mr. Reginald Cory's paper was entitled "Observations on the Dahlia Trials at Duffryn, 1913." It was as follows:—

Seeing that the summers of 1912 and 1913 were respectively among the wettest and driest on record, it is instructive to note, from my own experience, that for growth and display of bloom there was little to choose between the two years, and I think there are very few other plants of which so much could be said. The weather of last year was exceptional, also, on account of the fact that we experienced no frost that did practically much damage until November 22, when the entire collection was destroyed, but it gave the Dahlia—rather at the right moment, as it happened—the opportunity of showing to the full its marvellous capabilities of producing bloom both in quantity and over a long period of time. To be able to cut blooms from the same plants in May and again on November 22 is an interesting fact, but to be able, from the same plants, to put up a big display at a local flower show, with summer climbing Roses as an adjunct, and another, yet finer exhibit, on November 5, with Pampas Grass and winter-flowering Kniphofias as accessories, proves pretty conclusively the value of the Dahlia as a bloom producer, and its especial value in those parts where the winters are mild and frosts not generally severe.

Several friends who visited the gardens frequently during the summer time remarked that they thought the seedling beds were, if anything, gayer and more attractive-looking than even the Dahlia garden proper, and as I had rather thought the same myself, I began to look around for enlightenment. The explanation which I arrived at, and which I think is the right one, demonstrates the value of the Singles, and especially of the gigantic Singles, for giving a *brilliant* decorative effect. The majority of my seedlings proved to be Singles, with a large percentage of giant Singles, and I have no doubt that the *transparency* of the great single petals, with the sun shining through, gave that appearance of lustrousness which is lacking where flowers of a double nature are viewed, especially with the sun behind them; for the latter, from their formation, are opaque, and their true colour value is only obtained when the light falls on them in the same line as that from which they are seen.

One of my favourites among the singles were the Mignonnes, which proved very attractive also to lovers of herbaceous flowers, on account of their extraordinary floriferousness and compactness. As a proof of the former good quality, one little plant some 18 inches high, and about the same through, produced, on an average, fifteen to twenty blooms a day. They also have the advantage of being extremely early. The Parisian Singles are another type, somewhat similar to Mignonnes in habit and growth, not quite so free, but exceptionally bright and decorative. I have a great liking for all the various kinds of Singles, on account of their freedom, lightness, brilliance (which I have pointed out, I consider a special attribute of theirs), and stiff stems, all combining to make them very valuable for garden display and as cut flowers.

With the exception of compactness, and in some cases freedom of blooming, these qualifications apply equally to the Colletteres, but the majority of those which have come under my observation I consider—speaking from an all-round point of view—to err on the side of coarseness of bloom and habit, whilst many of those that carry the finest flowers are rather shy and late. Henri Farman and Tuskar are gems of their class, brilliant in colouring, and very free; Diadem, though big, is a thing of beauty and a joy till the frost comes. There will be a great welcome for a plant in this most beautiful section, with small regular flowers, the dainty collar, which is characteristic of, say, Regularity and Diadem, with the freedom of these two, and

not more than some two feet and a half in height.

There is one other section which seems to fall into place here, and of which I had my second experience last year, and, unlike another section (of which I shall speak later), my further acquaintance fully justified the good opinion I had formed of it. I refer to the Stars. I consider they have the longest and stiffest stems of any, and this fact, combined with their prolificness and rather unusual form and colouring, make them very conspicuous, and remarkably useful for vases. These, mixed with the ordinary singles, made one of the prettiest table decorations I have seen.

I suppose there are few flowers that are more intrinsically beautiful than those of the Cactus section. From combination of colour, delicacy, and perfection of shape, they are, as flowers, marvellous, but, taken as a class, and in the mass, I consider that they proved the least decorative of any. I know there are exceptions, and I have no doubt that these will be greatly added to this coming year; but, speaking from my own observations of last season, the great majority of them—even when they threw their blooms well above the foliage—were inclined to look downwards. The blooms also, even before they were quite expanded, had a tendency to turn brown, which gives the whole plant a soiled and faded appearance. This defect is especially noticeable where the flowers are of a white or pale colour. This habit of "browning off," as I might term it, appears to be a fault of the Cactus section generally, as it is observable even in the dwarf bedding varieties, such as Gluchauf and Zwergsonne, both of which, upright in habit though they be, always required to be gone over for any special occasion. The first named of the two has a value quite inversely to its size, for it is very dwarf and bushy, but of brilliant colouring and generally good shape. The remaining members of this set did not come up to the opinion we formed of them the previous season. John Mortensen was very good to look *into*, but not so good to look *at*. The colour apparently is not of the right shade to be effective at a distance. Marianne was new this year to me, and I liked it, and it was most delightful as a cut flower, but for some reason or other it was not a favourite out-of-doors, which, I suppose, was the reason why it did not obtain three marks, which I think it was worth, especially in view of another of the same section which did.

With the exception of the Cactus Dahlia proper, all the other sections which I have mentioned, together with the dwarf bedders, such as Barlow's Bedder, Rising Sun, the Anemone-flowered variety, and Crawley Star (which is rather a variety unto itself, I think) go to form what I call a general utility crowd, suitable and fit for any garden, of any dimensions. I know that in making a general assertion such as this there are usually exceptions, and I have not lost sight of the fact that among the Colletteres Diomede has run up with us to some eight or nine feet high, and one or two of the Giant Singles have grown nearly as tall; but these monsters are the rarities of their classes. Nor have I forgotten that I have not mentioned the Ponpons, which, I suppose, must fall in this class; but I said "general utility," and I am not quite sure that this does altogether apply to them. Like some of the Cactus varieties, they were somewhat behindhand in making a display, and I noticed that the quarters assigned to them, the Shows and the Fancies, seemed to look dull for a very long time, but I must admit they formed a bright spot when they were at their best. The extreme formality of these three sections is, I think, rather against them for garden display, giving a somewhat heavy appearance when planted in big masses. The great multiplicity of the petals, too, results in the absorption of much light, so that it is only at certain times of the day that they show good colour values.

I gave a good trial to several of the "general utility" lot in tubs, but the result was not altogether up to my expectations, as it often happened that one of the group did not thrive so well as the rest, and the result was an unbalanced effect. However, I shall try a few again this year, as I rather fancy Marianne, and some of the Anemone-flowered varieties may prove more suitable.

The latter, together with some of the dwarf Colletteres, I found very valuable for the front and middle of the herbaceous borders, whilst selections from the best of the Paenies and Giant Decoratives gave colour notes in the scheme, which would have been impossible at attainment in any other flower. In fact, I found the Dahlia a very valuable asset in this part of the garden, as, owing to its late development, I was able to plant summer-flowering annuals and early perennials between and around, which, when they were over, were cut down, and the Dahlias took their place, and then, towards the end of autumn, when most of the hardy herbaceous plants were getting ready to hibernate, the former were at their best, and the borders, with the help of a few late perennials, looked almost as gay as during the summer months. But where I think the Paenies and Giant Decoratives seemed to me to be most at home was where they were backed by tall Bamboos, fringing a piece of woodland, or massed around groups of shrubs and trees.

Mr. J. Green, opening the discussion, said that after inspecting the trials at Duffryn he could only endorse what Mr. Cory had written. The trial was an excellent one in every respect, and, unlike nursery trials, the plants were arranged according to height and colour. Many were massed in beds, borders, on banks, and every conceivable place where a Dahlia would grow. It was an object-lesson to those who had charge of public parks and gardens where the Dahlia was not appreciated as it should be at the present time.

Mr. J. T. West was enthusiastic in his remarks on the trials, but was severe in his condemnation of the Cactus varieties sent to Duffryn, as many of them were incapable of producing an effect in the garden. He was of the opinion that the future of the Dahlia was bound up in all sections of the flower and not one class alone. Mr. J. B. Riding said that he was rather surprised Mr. Cory did not say more about the Paenony-flowered varieties in his paper, as at the time the Committee visited Duffryn they were extremely beautiful. He also failed to detect the coarseness alluded to in the Collettere section, with the single exception of Diomede, which was seven feet high the first week in September, and would doubtless grow another two feet before the end of the season. The trials had demonstrated the value of the Dahlia.

Mr. W. Cuthbertson said he took a keen interest in the Dahlia, and he was pleased to hear Mr. West's remarks on types. There had been a rebound from formalism in all types of flowers, perhaps too far; but it was a matter of fashion. He agreed with Mr. Cory's remarks on the Collettere that a smaller flower would be more effective, especially for vase decoration.

Mr. J. Cheal said he thoroughly endorsed Mr. Cuthbertson's remarks. As a raiser it had been his aim for some years past to send out varieties in the Cactus section which carried their flowers well above the foliage. He was delighted to hear that the single varieties had given such a good account of themselves.

Mr. C. G. Wyatt said there were plenty of Cactus varieties that would give satisfaction if the growers would only stake them out well so that the plants obtained plenty of sunlight and air.

THE DAHLIA OF TO-DAY.

Mr. H. Shoemith read his paper entitled "The Dahlia of To-day," from which we print the following extracts:—

"When about three years back Mr. J. B. Riding read a paper at one of these conference meetings, and told us the first and best thing to do would be to make a bonfire of all the appurtenances of showing, I did not think he was foretelling a change which would come about so soon. It really meant that the Dahlia of the future would be named in one word—this is 'stem.' And in this one word we have got the cue for the flower as we know it at its best at the present time. Personally, I am one of a school of gardeners which has been a stickler for beauty of form in a flower, whether it be a Dahlia or anything else; but as we grow older we have to learn to fall into line with changed

fashions and throw our cherished notions to the winds. Still, this fashion comes rather hard sometimes on those engaged in raising new varieties—Dahlias, for instance. All our energies may go to producing something taking to the eye, making the florets more narrow, or what-not, and before we have finished in such directions popular taste proclaims that there must be a change; everything must go before one great point, and that is usefulness in, maybe, kinds of a showy character only. This being so, I for one look back with a longing eye when recalling the many seedlings I have thrown away—how useful they would now be! In this connection I am reminded of an occasion when a market gardener—a man, by the way, who has made money out of the common field Poppy and other wild flowers—on looking through my plantation, pointed to a flower of one seedling and said: 'Were these Dahlias mine I would throw away all except this, then I would propagate it, exhibit it, and ask five pounds for each plant.' The variety in question was original in colour and shape, but it did not satisfy my own notions of beauty and was discarded; so that I lost what may have been a fresh type. Florists, as I have remarked, are usually slow to learn, and even now I think sorts like, say, John Riding, Prima Donna and Frederick Wenham, of the Cactus class, are the highest forms of beauty in the Dahlia, whether the blooms hang their heads or not; but the great difficulty is in making the general public think the same.

"The Dahlia of to-day, then, is one with a good habit of growth, and a stiff, upright stem. Persons may please themselves (within schedule rules, of course) in what way the plant shall be exhibited; but I take it that introducers of new varieties will not employ supports if the flowers can be shown in comely style without them.

CACTUS, SHOW, AND POMPON DAHLIAS.

"The Cactus Dahlia I regard as a fine type of the modern Dahlia, and it is well divided into two groups—the exhibition and the decorative or garden forms; and when the beautiful blossoms we now know in the former are produced on the stiff stems of the latter—this is not so in many instances to-day—then this class will please the greater number of people.

"The old, big, double show Dahlia, in the South at least, may be said to be on the down grade. Standing still practically, in the matter of new varieties we find exceedingly few fresh growers. It is not the same with the Pompons; these are popular as ever, and are likely to remain so on account of their usefulness for garden display and for cutting; and also because in this instance there is no doubt about that important attribute of stem. I should say, however, the acme of perfection in this class was reached some years back; anyhow, improvement upon the old sorts is somewhat slow.

THE COLLERETTE DAHLIA.

"It is justly claimed that the Collette type is showy, and therefore useful for garden decoration; it is valued for cutting because the flowers last a comparatively long time in water. But some think that this showiness is of a gaudy nature of colouring, and the sorts are not particularly distinct. In fact the present position of the class has been made by the blossoms possessing a collar which is a contrast in colour to the other shades of the flower. If, however, we get away from the shades of crimson and red, if we come to lighter shades—say yellow and white—such contrasts are not to be found, at least in varieties we have yet seen, and to my thinking these look very common indeed. Whether raisers will save us from this sameness I do not know; but certainly the novelties which came before the Floral Committee of this Society last year led me to think the process will not be rapid. Except for the distinct collar, what beauty has the Collette, which the ordinary single has not? Is it a better garden plant, more useful in a cut state? In general refinement and flower formation it appears to me to be decidedly inferior. In shades of colouring again, the type of single we have become accustomed to is much more varied. These

are only impressions, and from my point of view the present-day popularity of the Collette rests upon its novelty, aided by persistent exhibiting.

PAEONY DAHLIAS.

"If I were to say that the Paeonies are not of especial value for exhibition, only from a decorative standpoint, I should probably be right; but if I were to state that they are of no great use for the garden, those who saw the display at Cardiff last year could soon inform me that as a type they are the most gorgeously showy of all. There are those who would define the Paeony Dahlia, but it is questionable if this is advisable, for no two sorts are alike in shape. To my thinking the flowers may be composed of a single row of florets, a double or a treble. I would only ask that they be of effective colouring, that the stems shall be stiff, and that the habit of the plant is free-flowering and shapely. Further, it appears to me that all these might be classed with and known as Decorative or Garden Dahlias. For example, last year a variety named Aphrodite obtained the Certificate of this Society. Its value as an effective variety in the garden was apparent, yet it has but one row of petals, and on account of its great size will be found among those termed Paeony. To my mind this reducing of the number of special divisions would simplify matters."

RELATIONSHIP OF SOIL AND PLANT.

At a recent meeting of the Royal Dublin Society, Dr. RUSSELL, Director of the Rothamsted Experimental Station, delivered a lecture on "Mutual Relationship of Soil and the Plant."

Having expressed the thanks of the committee of the Rothamsted station to the Royal Dublin Society for the support given to the movement for erecting a laboratory to commemorate the centenary of the birth of Lawes and Gilbert, the lecturer said the fact had been long ago established by practical farmers that certain crops and plants showed marked preferences for certain types of soil, and would not do as well on other types of soil, no matter what care or skill was used. How was it, he asked, that the close connection between the soil and the plant arose? The answer was that each plant required certain conditions—water, air for the roots, food, etc., and where it found those conditions it grew well. Those were very largely soil conditions, but not entirely; climatic factors cut across the soil factors, and prevented too rigid a classification of flora according to soil types. But closer examination showed there certainly was a specific soil type effect, the study of which was of great practical importance. Investigation had shown that the plant had almost as marked an effect on the soil as the soil had on the plant. Right from the outset the soil had been affected by the vegetation growing on it. The mineral matter that formed the main part of the soil split off from rocks in consequence of various physical and other agencies, and after many wanderings came finally to form the surface of the present soil. But it did not remain bare. It soon covered itself with vegetation. Plants grew, took out from the soil moisture the mineral and nitrogenous food they wanted, built up carbo-hydrate material from the gases of the atmosphere and the rain water. There were two highly important effects produced—(1) organic matter was added entirely different in character from the matter already there, and impressing a new lot of properties on the soil; (2) the organic matter contained stores of energy derived from the sunlight; when it mingled with the soil and began to decay the energy was set free and enabled micro-organisms to live in the soil. The living plant also had an effect on the soil. It took out certain constituents which if not replaced would lead to exhaustion. Recent experiments suggested that that remarkable effect was only produced when soil bacteria were present. It appeared, therefore, that between them the plant roots, the soil, and the bacteria might set up something in the soil that was poisonous to plants. The possibility that a

plant might thus foul the soil and injure it for another plant had long been part of the tradition of the gardener and farmer. During the last year or so a new way had been discovered in which the plant affected the soil. It had been shown that the growing plant somehow interfered with the activity of bacteria that made plant food in the soil, so that less plant food was made on cropped land than on land lying fallow. Modern research showed that the soil was not a mere mass of inert minerals, but a wonderful structure honeycombed with recesses and inhabited by teeming populations, micro-organisms, which science was just beginning to explore. The plant sent its roots into this living mass, and in some way not yet comprehended those roots interfered with the normal life of the organisms, and so effects were produced that one did not get in soil bare of all vegetation. The difficulty of finding out what really was going on was increased by the fact that they could not see into the soil. No microscope existed that would peer into its recesses; they could only gain knowledge by indirect means. But it was imperative that the man of science should go on with exploration.

VEGETABLES.

BROCCOLI.—I never remember this important and useful vegetable having been more plentiful than during the whole of this winter. We have cut heads of splendid quality without a break since last autumn. This is partly due to the mild weather and partly because there is now such a splendid selection of successional varieties, which render the task of keeping up a constant supply much less difficult than it was a few years ago. After extensive trials the varieties we have found to be most satisfactory are as follows, maturing in the order in which they are placed:—Michaelmas White, a splendid autumn variety; Winter Mammoth, a distinct and good sort; Snow's Winter White, an old variety, but still one of the best sorts for winter; Superb Early, producing refined, excellent heads; Snow White, quite distinct from Snow's Winter White; Christmas White, an invaluable variety, one of the best of all Broccoli; Leamington, an old variety that should find a place in all gardens; Late Queen, very hardy and late in maturing; and Model, the best late Broccoli, producing heads of beautiful quality which may be had in good condition as late as June.

VEGETABLE MARROWS.—Early Marrows are much appreciated, particularly in the months of April, May and June. For early cropping the seeds should be sown singly in small pots at once and raised in gentle heat. As soon as the second leaf appears pot the seedlings into 6-inch pots and grow them in a position near to the roof-glass in a temperature of about 60°. When about a foot high they should be planted out into portable two or three light frames on a very mild hotbed composed chiefly of leaves. Afford the plants every care and attention to ensure them making sturdy growth. Very little soil is necessary at the start, and it should not be very rich; fresh compost may be added as often as is necessary, and when the Marrows are developing it should be richer in quality. Immediately it is safe to do so, the frames should be removed entirely. The same plants, if properly attended to, will continue to produce large crops until destroyed by frosts. Grown in this way Marrows will not only produce fruits early, but they will be in full bearing by the time the majority are contemplating planting them out. The situation should be an open and sunny one. We have adopted this practice at Aldenham for many years without once experiencing a failure. Suitable varieties for 'his system of culture include Moore's Cream, Perfection, Pen-y-byd and Custard, which crops abundantly under glass and always much better than when grown in the open. *E. Beckett, Aldenham House Gardens, Elstree.*

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

GENERAL REMARKS.—With the lengthening days and increasing power of the sun, a more liberal treatment in respect to moisture may be afforded to all classes of Orchids that are in a more or less active condition of growth. Let the damping of the floors, staging and spaces between the pots be done in the mornings as soon as the normal temperatures of the different houses are reached. In bright, drying weather the damping should be done again in the middle of the day, and a third time between three or four o'clock in the afternoon, at which time the ventilators are closed. In all departments excepting the cool houses the temperatures of the houses should be maintained about 5° higher at night, as compared with the winter conditions. A night temperature of 53° to 55° will be warm enough for *Odontoglossums*, but I advise every care to be taken to guard against fluctuations in the temperature. Rapid changes in the temperature give a check to the tender growths and developing flower-buds, and the injury resulting therefrom becomes permanent. Cold draughts of air from the ventilators or other sources are likewise harmful. The lower ventilators should be formed below the staging so that the cold air is warmed by passing immediately over the hot-water pipes.

WATERING.—In the north and north-eastern parts of England snow and hail-storms often occur in March and April, and the melted snow or hail dissolving on the roof finds its way to the tanks, lowering the temperature of the water considerably. Cold water is injurious to the plants, and it is advisable to test the temperature at all times after heavy rains or cold storms. At such times warm water should be added to raise the temperature of the water in the tank a degree or two higher than the normal temperature of the house. Overhead syringings will be advantageous, but this should be done sufficiently early in the day to ensure the foliage becoming dry before nightfall.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

EVERGREEN SHRUBS.—There being no great danger now from frosts, evergreen shrubs may be pruned and reduced in size and height, in accordance with requirements. The best system of pruning evergreens is to saw out every year a few of the old and exhausted branches. This will afford space for young growths to take their places. At the same time aim at preserving a proper balance in the individual specimens and prevent them from growing into each other. If the planting has been done too thickly do not hesitate to head down to the ground a plant here and there, as such will send up a crop of new vigorous shoots. A few plants may be treated in this way every year; thus the plantations will be kept in a healthy condition and the shrubs will furnish an abundance of fine flowers.

THE WILD GARDEN.—All planting in this part of the pleasure grounds must be purely informal in contrast with the trim neatness associated with summer bedding on closely-mown lawns. The plants may be arranged singly or in groups and allowed full freedom of growth, in order that they may show their grace of outline and floral beauty: Nature must be followed in all her simplicity and boldness. There are many who imagine that the wild garden means a wilderness or a vast tangle of crowded growths which, once planted, requires no further attention. But indiscriminate planting is the very opposite of the correct system. It must be remembered that there is considerably more difficulty in directing labour to the best advantage in the natural than in the formal garden.

Numbers of very beautiful plants may be grown in spaces which are usually occupied by coarse grass and even weeds, around shrubberies, on the margins of streams and ponds, and in woodland walks. It is not easy to prescribe for all cases, seeing that no two places offer the same facilities, but there are certain general principles to be followed.

PLANTS FOR THE WILD GARDEN.—To give a complete list of suitable plants would occupy too much space, therefore I will only enumerate a few that I have found especially attractive when grouped largely and irregularly in conjunction with clumps of dwarf evergreen shrubs, such as *Olearia Haastii*, *Azara microphylla*, *Veronica Traversii*, *V. Kirkus*, *V. angustifolium*, *Kerria japonica* fl. pl., *Choisya ternata*, *Berberis Darwinii* and *B. stenophylla*. Farthest away from the gravel paths plant bold groups of *Anchusa italica* Dropmore and Opal varieties, *Helianthus* Miss Mellish, *H. multiflorus*, *Galegas*, *Hemerocallis*, *Cimicifuga*, *Delphiniums*, *Clematis Davidiana*, *Epilobium*, *Chicory*, *Hollyhocks*, *Anemone japonica*, *Tree Lupins*, *Pyrethrum uliginosum*, *Valerian*, *Kniphofia*, and others. Plantations of *Hydrangea paniculata*, *Gladiolus Breuchleyensis*, *Papaver orientale* and *Galtonia candicans* will provide a succession of bright colour. Nearer the walks may be planted, both as single specimens and in groups, *Yuccas*, *Ruscus aculeatus*, *Phormiums*, *Hypericum*, *Megasea*, *Bamboos* in variety, beds of the common *Polyphy* and *Lychnis Viscaria*. *Lily-of-the-Valley*, *Polyanthus*, *Thrift*, and other dwarf evergreen plants, may be allowed to grow right up to the margin of the walks and thus obviate having artificial, clipped edges.

COLOUR SCHEME.—I am not in favour of indiscriminate mixing of the colours of flowers, but prefer to commence from a central group of one colour and as far as possible shade off in a subdued tone of the same colour, utilising the next strong colour in the same way, always provided such colours, when nearing each other, do not clash but are in soft, pleasing harmony. Now is the season for re-arranging and re-planting the strong growers, some of which are best shifted annually. Divide the roots and select the outer vigorous, healthy portions, discarding the old exhausted growth in the middle of the clump. The plants used for wild gardening are not over particular as to soil; still, they grow best in a deep root run and will always repay for good cultivation.

STEPPING-STONES.—Where stepping-stones are arranged through and alongside a stream some dwarf half-hardy, creeping annuals should be planted between the stones. A few of the most useful plants for the purpose are *Dianthus neglectus*, *Viola gracilis*, *Mesembryanthemums*, *Ionopsidium*, *Phacelia campanularia*, *Androsace*, *Arenaria*, *Aubrietias*, *Erodiums*, *Erineu alpina*, *Veronica repens*, dwarf *Campanulas*, and hybrid *Dianthus*, known as Mule Pinks, all of which may be raised easily from seed.

TREES AND SHRUBS IN FLOWER.—The following trees and shrubs are in flower in these gardens:—*Amygdalus Davidiana*, *Andromeda*, *Arbutus*, *Daphne Cneorum major* (a lovely plant), *Erica carnea*, *Viburnum Tinus*, *Mahonia*, *Spiraea Thunbergii*, and many others.

THE HARDY FRUIT GARDEN.

By J. C. WESTON, Gardener to Lady NORTHCOTE,
Eastwell Park, Kent.

PROTECTING FRUIT TREES.—The fruit-buds of the earlier-flowering fruit trees, such as the Apricot and Peach, are swelling rapidly, and the question of protecting the blossom from frosts must be considered. Local conditions govern the necessity for protection in a great measure. In cold districts and exposed situations, especially where the gardens are low-lying, spring frosts often ruin the crops unless measures are taken to protect the trees, and the coverings should be got ready at once. Notwithstanding what has been stated the protective material should not be placed in position until the earliest blooms are on the point of expanding, for up to that stage the trees are much better left fully ex-

posed. Heavy coverings of a permanent nature should not be used, as these often prove more injurious than the weather. By excluding the light and air they tend to make the young growths and embryo fruits tender, and therefore more susceptible to injury by inclement weather after they are removed. Fish-netting of double thickness, which has been used for protecting ripe fruit from birds, is often employed in the spring for protecting fruit-blossom from frost. The best coverings are those that can be removed when there is no danger from frosts; but if the nets must be left on during the day means should be taken to keep them well away from the trees or they will be of little use. This is best done by the use of poles or wires, or a combination of both. If the nets are simply hung up in front of the trees and a storm of rain or snow occurs from the quarter opposite to the wall, the wet nets may press directly on to the blossom and thus do more harm than good. One of the best systems is to fix blinds made of shading material or light canvas on to rollers that may be drawn up under the coping and let down whenever they are required. During inclement weather such blinds may be lowered at sunset and allowed to remain in position until the temperature rises next morning.

GLASS PROTECTORS.—In many establishments garden walls are provided with glass protectors on the coping, for the purpose of protecting the trees during bad weather. They are fixed on a strong iron framework and project 2 or 3 feet from the top of the wall. Such protectors are best glazed on a system that permits of the removal of the glass in the summer and autumn, to allow the rain and air to penetrate to all parts of the tree. During the blossoming period light canvas or tiffany can easily be suspended from the sloping front of these protectors, and if the canvas material is hung in position at the time when the sun is setting considerable warmth will be enclosed in them, thus keeping up the temperature to a safe degree during cold nights. Short of entirely covering the wall with glass and converting it into a fruit-case, the use of these glass copings with light blinds is probably the best method of protecting fruit trees from frost in spring. In older gardens slates are sometimes built in the top of the wall in the same manner, but their value is not to be compared with that of the modern glass protectors.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY,
Knowsley Hall, Lancashire.

SOUVENIR DE LA MALMAISON CARNATIONS.—Plants of the earliest batch of "Malmaison" Carnations are showing signs of growth, and they should be afforded plenty of air at this stage. A temperature of 45° to 50° is suitable. Regulate and tie the leading shoots neatly to stakes placed securely in the pots. Water should be only afforded when moisture is absolutely necessary; a more liberal watering and a dusting of concentrated manure will be beneficial when in full growth. Keep the leaves dry and the atmosphere moderately dry. The earliest and strongest of last year's layers that were potted into 6-inch pots last October are making top growth and healthy roots. Plants that have been grown in 60-sized pots through the winter should be shifted in 6 or 7-inch pots. The compost may consist of turfy loam three parts and leaf-mould one part, with sharp sand, wood ash and lime rubble added. The soil may be enriched with concentrated fertiliser at the rate of a 6-inch potful to every two bushels. Pot fairly firm, place a stake in the centre of the pot, and secure the growth thereto. Stand the plants in a close frame for a day or two, affording shade if required. Water the plants once after the first week, but afford moisture subsequently only when the soil is dry.

TREE CARNATIONS.—Plants that were rooted in the autumn are breaking freely into growth, and the points of the shoots should be pinched out when the latter are about 4 inches long. Side shoots will quickly form, and the plants will be ready for shifting into larger receptacles, the strongest specimens into 7-inch pots. Admit air on all favourable occasions, pot rooted cut-

tings as they become ready, and grow them in a close atmosphere and a temperature of 55° for a few days until they become re-established.

ERANTHEMUM PULCHELLUM.—A batch of well-grown plants is very attractive at this season, and the deep blue flowers always attract attention. The blooms are very fugitive, but others develop in quick succession. As soon as the flowering season is over the growths may be shortened; the new growths will form suitable cuttings, and may be inserted when they have attained a length of 3 inches. Root them singly in thumb pots in a brisk bottom heat. When the cuttings are well rooted pinch out the points, which will result in side-shoots developing, and the plants may then be re-potted.

ASPIDISTRA.—Plants that have become pot-bound may be re-potted now, and such as are too large for decorative purposes may be divided. A compost of gritty loam and leaf-mould will be suitable. See that the drainage is efficient. Specimens that require top-dressing should have a little of the old soil removed and replaced by fresh compost enriched with a slight dusting of bone meal. Sponge the leaves, and grow the plants in a warm house.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

VINES.—Mid-season vines should be started in a temperature of 50° by night and 55° to 60° during the day, rising to 65° by sun heat. Under these conditions the buds should break gradually and strongly. As the buds swell the temperature may be increased gradually both by day and by night. Started in this way mid-season vines require less artificial heat during the warmer months of the year—in some instances fire heat may be dispensed with altogether—and much better results will be obtained with less risk from insect pests than would be the case if the vines were started later, and hence needed considerable artificial heat to finish the crop. Late Grapes require, as a rule, a long period in which to ripen satisfactorily, so that the berries may keep well. Few, if any, of the vines should be started later than the beginning of March, therefore get the houses in readiness at once. Keep the inside borders moist and syringe the rods several times daily to favour the bursting of the buds. Should the spurs bleed, as they sometimes do on late vines, wipe the wounds dry and dress them with styptic. Stems that are partially exposed in vines growing in outside borders should be protected and the borders top-dressed with half-decayed manure and leaves, which will give all the protection needed at this time of the year.

MELONS.—Sow seeds for the general crop, and plant out successional plants so that no break may occur in the supply of ripe fruits. Plants that are approaching the flowering stage should be grown in a somewhat drier atmosphere until after the crop has set, but care should be taken that the plants do not lack moisture at the roots. The root-run should be limited, or the result may be plenty of foliage and but little fruit. At night the temperature should be 70°, and from 75° to 85° with sun heat during the day. Admit air regularly, but see that cold draughts do not reach the plants.

CUCUMBERS.—The beginning of March is a good time to make another sowing of Cucumber seed, and in all probability the plants will be sturdier than those sown last month. See that the linings of the bed are efficient where the plants are growing in brick frames, and bear in mind that the manure must be well fermented and turned before use. Make the linings about 18 inches or 2 feet in width and as high as the bed; examine the latter frequently to ascertain that its temperature is all right. Whether for spraying or watering the roots, always use water warmed to the air-temperature in the frame. Close the lights not later than 2 o'clock, thus conserving all the sun heat possible without risk of scalding the foliage. Rapidly-growing plants

should be fed with liquid manure at every alternate watering. Apply top-dressings of soil and manure about every three weeks to plants that are growing in houses, to keep them in a healthy, fruitful condition. Well thin the fruits on plants just coming into bearing, stopping the growths at one, or not more than two, joints beyond the fruit. Remove all superfluous growths and tendrils as they appear, and maintain a moist, brisk temperature of 75° to 80° by day, and 65° by night. The evaporating troughs should be kept well filled with liquid manure or water in which a small quantity of liquid ammonia has been placed.

CHERRIES.—The temperature of the house in the daytime should not exceed 55° by fire heat, but when air is admitted it may rise by sun heat to 65°. Whilst cold draughts are harmful, air may be admitted on every favourable occasion. Afford water in moderation until the fruit has set, when the roots may be soaked with weak manure water, or artificial manure may be applied and the soil watered afterwards. A stimulant may be applied at intervals of about fourteen days, according to the condition of the borders—less frequently if the borders are not well drained, for stagnant moisture at the roots will cause the young fruit to drop. Watch carefully for the first signs of black fly or kindred pests on the young leaves, and lightly fumigate the house with a nicotine preparation. After fumigating wash the trees thoroughly, syringing them with clear tepid water. Such leaves as are curled should be carefully examined for the presence of a small caterpillar, which causes much damage to the tender growths, making them unsightly for the remainder of the season.

FIGS.—Trees in successional houses should be kept steadily moving in a temperature of 55° for the first fortnight, gradually increasing the day temperature as the sun heat increases. See that the borders are neither sodden nor excessively dry. In houses where the trees have reached the fruiting stage watch carefully for red spider on the underside of the leaves. Sulphur made into a paste and brushed over the hot-water pipes will assist in destroying this pest, as well as syringing frequently with clear water. A dry atmosphere and high temperatures favour this pest, therefore maintain moist, genial conditions.

CAPSICUMS.—Seeds of Capsicums may be sown now. When the seedlings are sufficiently strong pot them singly in small receptacles, and keep them growing in a brisk heat, admitting plenty of air during sunny weather. Finally shift them into 7-inch pots, placing three plants of about the same size and strength in each pot. When the plants have recovered from the shift stand them where they will be fully exposed to the sun. If grown in heated pits the lights may be removed for two or three hours daily on warm, sunny days in summer.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tynninghame, East Lothian.

GLOBE ARTICHOKE.—The material used for protecting the plants in cold weather should be removed, which is most easily effected by digging it deep into the interspaces of the rows. For many years I have used leaves for protection, and they seem more suitable as a manure, being less forcing than farmyard litter. Fresh plantations may be made either from side shoots wintered elsewhere or from suckers carefully disjointed from the plants. I allow the sets spaces of three feet in the rows and five feet between the rows. First-year plants are valuable because they produce heads for autumn use, when, as a rule, the old plants are exhausted.

PEAS.—A sowing of the variety Pilot may be made now in one of the main quarters. It is an advantage for the ground to have been trenched deeply in October for this sowing, and for no other reason than that the soil will be warmer. For this and the succeeding sowings

shallow drills taken on the width of a spade are to be preferred to deep drills, also on account of warmth. I invariably have the trainers put in place as soon as the Peas are covered. This protects them from pheasants, etc., and is an assurance that they will not be neglected, as is not infrequently the case when the haulm is growing rapidly.

DRESSING CROPS.—It is safe now to dress Cabbages, Lettuces and Spinach that have been close picked with a stimulating manure, either nitrate of soda or sulphate of ammonia; I prefer the latter. About $\frac{1}{2}$ oz. applied to each Cabbage is a suitable quantity, but for the others it must be scattered evenly between the rows, at the rate of 1 lb. to each 40 square yards. This manure need not be covered, but it is, on the whole, beneficial to stir the surface by means of a hoe subsequent to the application.

EARLY ONIONS AND LEEKS.—Seedling Onions should either be potted singly or transferred to other boxes, using for them a rough compost that will enable the plants to be lifted each with a ball of soil. Leeks for use early in autumn should be treated similarly.

PARSLEY.—If a sowing of this herb was made in heat early in the year the seedlings should be pricked out singly into cutting boxes when they are large enough to handle.

LETTUCES.—The time is at hand when there may be a gap in the supply of this salad vegetable. I find that plants wintered in a cold pit—that is, young plants put into a border in autumn—grow to a useful size by about this time of the year, and continue furnishing a supply of heads for several weeks. During winter water is not needed at the roots, but with the increasing heat of the season applications of moisture are essential, as much to keep the plants growing as to preserve them sweet and free from a bitter taste. See that the leaves are not wetted, as this may set up rotting. For a time only a little ventilation need be afforded.

CARROTS.—A moderate breadth of a stump-rooted variety, which on the whole is the best garden type, may be sown in well-prepared ground. Where the Carrot fly is troublesome it is as well to make this the main crop. There are numerous specifics recommended to save the plants, but it is doubtful if any is a panacea. In light soils at least the drills should be drawn rather deeply, the seeds, first mixed with sand, drilled quite thin, and the drills only filled with sufficient soil to cover the seed sufficiently to enable them to germinate properly. When the seedlings are well established and thinned the drills should be filled with dry sand to cover the crowns of the plants 2 inches in depth. Slight dressings of soot periodically renewed are sometimes beneficial in combating the fly.

THE ONION CROP.—It is still the practice of many to raise this important crop from seeds sown in the open at this season, the object being to get the seed in as soon as the ground is fit after the middle of February, for, like the Leek, the longer the season of growth the larger the individual roots. Since manurial dressings throughout the growing season have been recognised as imperative, the soil need not be so highly manured preparatory to the crop as at one time was deemed essential. At the same time a dressing of superphosphate, 2 lb. to the rod, and a slight sprinkling of pigeon manure, will be advantageous. After applying the manures and just before sowing half dig the ground, preferably with a fork, by means of which the soil may be more easily broken up and the manure incorporated. Then compress the ground by foot-pressure, draw shallow drills, cover with the foot, and again compress the surface as evenly as possible, finishing by raking the surface smooth. Any bulbs of last year's crop which are beginning to grow in the store may be planted for scallions. They ask for no special cultivation. Pickling Onions may also be sown now. These are grown close in the rows, and, being of use only when small, the ground needs no such manurial preparation as for ordinary Onions.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plants to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

Special Notice to Correspondents. — The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MARCH 9—
United Hort. Ben. and Prov. Soc. Com. meet.

TUESDAY, MARCH 10—
Roy. Hort. Soc. Coms. meet., Special Bulb Show (2 days), (Lecture at 3 p.m. on "Adaptive Degradation of the Cause of Many Cases of Evolution Among Plants.")
Horticultural Club: House Dinner at 6.30 p.m.

THURSDAY, MARCH 12—
Manchester and N. of Eng. Orchid Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 40.8°.

ACTUAL TEMPERATURES:—

LONDON, *Wednesday, March 4* (6 p.m.); Max. 53°; Min. 44°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, *Thursday, March 5*, (10 a.m.); Bar. 29.6°. Temp. 53°. *Weather*—Fine.

PROVINCES.—*Wednesday, March 4*. Max. 52°, Rams-gate; Min. 42°, Aberdeen.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—

Roses, Rhododendrons, Perennials, Lilies, etc., at 12.30, at Stevens's Rooms, King Street, Covent Garden, London, W.C.

MONDAY AND FRIDAY—

Herbaceous Plants and Hardy Bulbs, Roses and Fruit Trees, at 12, at 67 and 68, Cheapside, E.C., by Protheroe and Morris.

WEDNESDAY—

Liliums and other Hardy Bulbs, Herbaceous Plants, etc., at 12, Palms and Plants at 5, at Protheroe and Morris's rooms.

THURSDAY—

Roses at Protheroe and Morris's rooms, at 1.

FRIDAY—

Freehold Property, Willard's Nurseries, Polegate, near Eastbourne, 4a, 2r, 19p., House, Greenhouses, etc., also Vines, etc., Fruit Trees, Crops, etc., at the Mart, London, E.C., by Protheroe and Morris, at 2.

Anyone with a taste for statistics and a leaning to the marvellous may read in the textbooks of botany wonderful estimates of the amount of water absorbed and transpired by trees. They may learn that a sunflower may give off several pints of water on a summer day; that in the case of a young tree the amount runs into gallons, and in that of a full-grown tree into tens or hundreds of gallons. The most recent estimate of this sort has been commented upon in the *American Press* (see *American Fruits*, February, 1914). According to these comments, Professor Pierce, of Harvard, has computed that a giant specimen of the Washington Elm, which he examined, gives off some 2,000 gallons of water per

day. The tree, according to the same computation, possesses 7 million leaves, the total surface of which is equal to an area of about 5 acres. The estimate is arrived at thus: An acre of grass gives off 6,000 quarts of water in 24 hours—presumably on a summer day—and on the basis of this estimate the tree's loss is computed.

We have not the text of Professor Pierce's original contribution, and hence can make no comment on these statements beyond saying that their author is well known for his conscientious, cautious, and valuable contributions to botanical science.

But on the general question of the amount of water given off by trees we may observe that, so far as we know, the estimates in the books have no proper experimental basis whatever.

That the amount of water given off by a tree is very large no one will dispute; but it is very doubtful whether that amount is anything like so large as is generally believed. To determine the amount of water given off by a branch, to estimate the total area of the leaf surface, and to work out a result by rule of three is to reach a valueless result. For no one can say that in the competition for water that takes place between the leaves all the leaves win first place. It may well be that failing in the daily competition the leaves of not a few branches are compelled to close their stomata, to shut down operations and to curtail their rate of transpiration. The poor development exhibited by many of the branches of an unpruned tree would indicate that this happens widely in Nature, and the conviction entertained by gardeners that light and air must be admitted to the centre of a tree, if proper ripening of wood is to be secured, may have its explanation in part in the fact that with a head of dense foliage transpiration of the inner leaves is reduced greatly.

In any case the figures so often given cannot be taken as the results of experiment, and it would be interesting if some botanist would take the trouble to carry out an actual experiment on the amount of transpiration of a large tree. We may confess that we ourselves planned such an experiment some years ago, purchased the necessary balance and potted up the trees. The trees still languish in their pots and the balance ornaments our laboratory, but owing to the pressure of other duties the experiment was never completed. Needless to say, the results of an experiment of this kind made with several different subjects would have a distinct practical value.

The recent researches of Willstätter and Everest appear to have settled finally a question which has vexed the minds of botanists and chemists—namely, the chemical composition of the anthocyan pigments of plants. These pigments, which occur in the flower and fruit and in other parts of the plant, are dissolved in the cell sap, and are generally, and perhaps always, of a blue, violet, or red colour.

By the use of large quantities of raw material—the corollas of the Cornflower (*Centaurea Cyanus*)—Willstätter and Everest have succeeded in isolating the anthocyan pigment in a pure state in sufficient quantity to admit of a chemical analysis. They find that there is, as was to be expected, a close and definite relation between the blue, violet, and red anthocyan pigments. All the pigments are glucosides—that is, substances which, when acted on by acids or other suitable re-agents, unite with water and split off sugar from their molecules. The anthocyan glucoside occurs in the flower in one of three forms. It may occur as a free acid, in which case the anthocyan is violet; or the free acid—known as cyanin—may combine with potassium to form a blue salt; or the cyanin may unite with a plant acid, and give rise to a red pigment.

Into the chemical details of these researches we cannot enter now, but the bare facts deserve to be put on record here, for a knowledge of the properties of these anthocyan pigments cannot fail to be of great service, not only to the student of plant-chemistry, but also to the plant-breeder. When he sets out to produce a new colour in a race of plants the plant-breeder is, in fact, undertaking to perform a chemical experiment. If he could but know in advance the nature of the pigments in his plant and their modes of reaction with other reagents he would have, if not a guide, at least a hint as to what he may expect as the result of crossing different colour-forms with one another.

We understand that Professor Willstätter is now engaged in further investigations on the subject of the anthocyan pigments, and we may, therefore, expect that before long one of the most obscure problems in plant physiology—the nature and relations of the anthocyan pigments—will be solved completely. If so, the plant-breeder will obtain a clue, for which he has long sought, to guide him through the maze of plant coloration.

It is of interest to observe that each of the three anthocyan pigments of the Cornflower, the blue, violet, and red, may be caused to undergo change into a colourless condition, and this without any chemical change other than that of a rearrangement of the parts of its molecule. Hence it might be supposed that the white forms of certain flowers are white because of the occurrence of the colourless (isomeric) form of anthocyan. So far, however, although Willstätter and Everest have examined many different flowers from this point of view, they have failed to obtain any evidence that whiteness is due to the presence in flowers of a colourless anthocyan.

Achillea argentea (see fig. 78).—The dwarf-growing plant known in gardens as *Achillea argentea* is one of the Yarrows which by reason of neatness and compactness of habit are well adapted for the rock garden. The flowers are large in proportion to the size of the plants, and the silvery-grey foliage is very attractive at all seasons. There is some uncertainty as to the origin of *A. argentea*, although it has been

[Photograph by C. P. Raffill.

FIG. 78.—ACHILLEA ARGENTEA GROWING IN THE ROCK-GARDEN, KEW.

cultivated in gardens for many years. The plant illustrated is evidently a hybrid, and has most probably been derived from *A. umbellata* and *A. rupestris*. The tufts of hoary, pinnatifid leaves are about 1½ inch long, and the heads of flowers develop on stems about 5 inches in length. The ray florets are pure white, whilst those of the disc are pale yellow. Like many other plants possessing silvery foliage *Achillea argentea* requires a dry, sunny position in well-drained, gritty soil. It is very liable to damp in winter, and should be planted on a rocky ledge or steep, rocky bank. The name is a synonym of *Tanacetum argenteum*, quite a different plant.

Coloured Supplement.—The subject of the coloured plate to be published with the issue for next week is the Collette Dahlia Skerryvore.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the Committees will take place on Tuesday, the 10th inst., in the Vincent Square Hall, Westminster. A competitive hulk show will be held and will continue for a second day. At the 3 o'clock meeting of the Fellows on the Tuesday an address on "Adaptive Degradations: the Cause of Many Cases of Evolution among Plants," will be delivered by Rev. Prof. G. HENSLOW.

DUTCH VISITORS AT THE HORTICULTURAL CLUB.—A House dinner will take place in the Club Room at the Hotel Windsor, Victoria Street, Westminster, on Tuesday, the 10th inst. Members of the Dutch Bulb Growers' Association, who will be present to assist in judging the flowers at the Royal Horticultural Society's exhibition of Dutch bulbs on the same day, and several other bulb experts from Holland, have accepted invitations to be present. After dinner there will be a talk about bulbs. The Rev. J. JACOB will introduce the subject.

THE NATIONAL DIPLOMA IN HORTICULTURE.—The number of gardeners who have registered their names as intending candidates for the forthcoming preliminary examination for the Diploma is 65. The Council of the Royal Horticultural Society has every reason to be gratified with the immediate success which—as judged by this number of candidates—has followed upon the decision to establish the Diploma. The candidates come from all parts of England and from Scotland, and hence it may be found necessary, in all probability, to hold the practical garden tests in some five or six centres in different regions.

THE ROYAL SOCIETY.—Among the men of science recommended by the Council for election to the Royal Society is Professor BIFFEN. As is well known to horticulturists, Professor BIFFEN has devoted himself for many years to the breeding of Wheat, and has been conspicuously successful in raising rust-resisting strains, and also strains which combine the characters of "strength" of flour and heaviness of yield. Professor BIFFEN is a keen gardener, and has a special predilection for Roses. Striking evidence of his wide horticultural knowledge and keen observation is to be found in the Masters Memorial lecture (see *R.H.S. Journal*, Vol. XXXIX., Part II., p. 313), which Professor BIFFEN delivered before the Royal Horticultural Society in July of last year.

ROYAL GARDENERS' ORPHAN FUND.—Mr. F. W. TOPHAM, of Northwick Hall Farm, Claines, Worcester, the local secretary for the R.G.O.F., is in the habit of promoting concerts and whist drives in Worcester in aid of the fund. The latest result of his efforts was a very successful whist drive, which took place a week or so ago, and realised a profit of £11 for the charity.

NATIONAL CHRYSANTHEMUM SOCIETY.—The National Chrysanthemum Society is holding three exhibitions this year; two will be held at the Crystal Palace, Sydenham, on October 7 and 8, and November 4, 5, 6 respectively,

whilst the other will take place at the Essex Hall, Essex Street, Strand, on Wednesday, December 9. Schedules may be obtained from the Secretary, Mr. R. A. WITTY, 72, Savernake Road, Gospel Oak.

THE SURVEYORS' INSTITUTION.—The next ordinary general meeting will be held in the Lecture Hall of the Institution on the 9th inst., when the discussion on Mr. CHRISTOPHER TURNOR's paper, entitled "Comments on the Land Enquiry Committee's (Rural) Conclusions," will be resumed. Mr. EDWIN SAVILL, member of Council, will re-open the discussion. The chair will be taken at 8 o'clock.

LEAMINGTON COUNTY SHOW.—The Committee responsible for promoting the Leamington and County Flower Shows may be congratulated on the financial success obtained in 1913, the result of this good fortune being evident in the balance in hand of £65 as against a deficit of £54 at the end of 1912. All the challenge cups which were won outright last year are replaced by the generosity of private donors. Mr. F. A. CHANDLER offers a 25-guinea Cup for hardy flowers, Mr. SHAW a similar Cup for a group of Roses, the MAYOR of LEAMINGTON a Cup for the Warwickshire Amateurs' group class, and the EARL OF CRAVEN a Challenge Cup for a group of hardy plants. In future it will be impossible to win the Challenge Cups outright, but these awards will be accompanied by money prizes as compensation. The forthcoming show will be held in the Victoria Park, Royal Leamington Spa, on July 22 and 23, and we are informed by Alderman HOLT, who takes a special interest in the event, that a good display is confidently expected. The secretary is Mr. LESLIE D. OVERELL.

RETIREMENT OF MONSIEUR TRUFFAUT.—On February 15 the farewell banquet promoted by the Société Nationale d'Horticulture de France in honour of Monsieur TRUFFAUT took place in the Banqueting Hall of the Palais d'Orsay, Paris. More than a hundred guests were present to celebrate the occasion and express their gratitude to the veteran horticulturist who had for so long filled the position of Honorary Vice-President. Monsieur VIGER presided, and Monsieur ABEL CHATENAY, as Secretary, Monsieur TRUFFAUT's oldest friend, was entrusted with the presentation of a beautiful work of art which had been subscribed for by the guests. Several congratulatory speeches were made, to which Monsieur TRUFFAUT responded. He thanked all those present for their kindness and for their good wishes, and observed that it gave him great pleasure to see in Monsieur CHATENAY his successor in office. He then briefly passed in review the chief events in the horticultural world since 1855.

THE FLOWERING OF THE ALMOND.—The first flowers of an Almond tree, situated in a favourable position in Wandsworth, five miles south-west of London, expanded fully on Monday last, the 2nd inst. Previous dates for the flowering of this tree are: January 25, 1913; February 24, 1912; March 11, 1911; March 12, 1910; April 1, 1909; March 23, 1908; March 20, 1907; February 28, 1906; March 7, 1905; and March 21, 1904.

MR. G. H. HOLLINGWORTH.—We are informed that Mr. G. H. HOLLINGWORTH, who has been horticultural instructor to the Gloucester Education Committee for nearly ten years, has been promoted to the position of Organiser of Agricultural Education for the county of Gloucester.

STORM IN ABERDEENSHIRE.—A severe thunderstorm occurred in Aberdeenshire last week, and produced a remarkable effect on a Silver Fir at Newton of Inch. The tree, which stood about 600 yards from the mansion house, was blown to pieces, and scattered far and wide by the lightning. During the night a vivid flash

of lightning lit up the scene, and a terrific report was heard, the windows of the house and outlying buildings being violently shaken. When morning dawned it was found that the tree, which contained about 45 cubic feet of timber, had been completely destroyed. One fragment, weighing about 2 cwt., was found over 250 yards away, and another, of about the same weight, over 150 yards away, and pieces had been carried into the neighbouring wood, where the trees showed the marks of the blows. A strong iron fence near the tree was smashed, and a similar fence over 100 yards away was considerably damaged, apparently by the fragments. From the way in which the fragments were spread in the neighbouring wood it was evident they had been blown to a considerable height. The destruction was complete, the tree had been torn right out of the ground and a big hole left.

ANIMALS AND PLANTS UNDER DOMESTICATION.—At the last lecture of this course, at the Royal Institution, Professor BATESON said that, as he had pointed out in the previous lecture, the development of most of our cultivated plants had followed similar lines, and the question now arises whether our animals have passed through an analogous course of development. Unfortunately, owing to the great antiquity of our domestic breeds, the evidence as to their origin is very incomplete. There are a few cases in which we know how a breed has originated. Such a case is that of the Suffolk breed of sheep, which was produced by crossing the Southdown breed with the old Norfolk breed. Again, a breed of silkworms is still used for the production of coarse silks which was raised by crossing *Attacus ricini* with *A. cynthia*. Nevertheless, the existence of a few such cases does not give any satisfactory explanation of the origin of our types, and when we turn to the critical examination of the part played by artificial selection, we fail to find any adequate basis on which to build a theory. Artificial selection picks out the types which are already in existence; it cannot produce a new type. As an example of the powers of artificial selection the history of the Sugar Beet was given. There was a great increase in the sugar percentage between the years 1850 and 1890. The first improvement was owing to mass selection, in which seed was saved from the best plants, and no precautions against cross fertilisation were taken. Then a further increase occurred when pure line selection began, in which the best plants were self-fertilised, and their offspring grown separately. When a plant which has been selected for a quantitative character, such as tallness, throws plants which are taller than itself, it is possible that segregation of factors has occurred. In this way selection may appear to produce new types, while in reality it is only weeding out the heterozygous plants.

HISTORY OF IRISH WOODS.—Prof. AUGUSTINE HENRY, in the course of a lecture at a recent meeting of the Belfast Naturalists' Field Club, said that the history of the woods of modern Ireland began after the Ice Age, as during this period all the vegetation and mould were destroyed, a barren sterile soil being everywhere left. He explained the occurrence of the submarine forests, found all round the coast, and of the great forests in the peat, which were formed in the Neolithic period, at the time when the climate was drier than now. There were Pine trees, however, in the great Leinster forest in 1010 A.D., which were carried to Kincora on the Shannon to make masts for the ships of King BRIAN. Firs grew, according to a note on an old map, on the mountains of Down in 1570. The association of the Pine with the capercaillie in Ireland was striking, as this beautiful bird gradually became extinct with the increasing rarity of the Pine woods. Ireland always had plains on which trees never grew, like the Curragh of Kildare, Lecale in Down,

and the great plain of Roscommon. During the Bronze Age man began to clear the forests for the cultivation of cereals and Flax, and the agricultural area increased in succeeding centuries. Half the island was probably covered with forest at the time of the Norman Conquest. The woods were remorselessly cut in the seventeenth century, as timber was the main source of profit to the adventurer, who exported oak staves abroad, established ironworks all over the country, and who consumed for charcoal all the smaller trees. Remnants of the old woods still existed in many parts, and are characterised by a peculiar flora and fauna, which is non-existent in plantations and unwooded ground. Professor HENRY gave a list of these plants, and alluded to the lingering of two species of *Pyrola* in a few spots as indications of former Pine woods. These little plants were dying out, and would become extinct like the capercailzie. He gave many instances of remarkable woods in Ireland, as the Oak and Holly woods of Castlewellan, out of which £500 of Holly timber was sold in one year. A remarkable Ash wood at Glaselough, in Monaghan, in 1801 was reported to be the finest in Europe at that day, being worth £1,000 an acre. Crab trees of great age were common a century ago along the shores of Lough Neagh, and the largest Oak that was ever known in Ireland was felled at Portmore about 1750. The most celebrated tree in Ireland is, however, fortunately still alive. This is the famous Yew now in the grounds of Crom Castle, in the townland of Crom, in Fermanagh. This tree is remarkable for the enormous spread of its branches, over 200 people being able to sit down to a banquet under its shade. The lecturer had discovered an early reference to this tree in O'CLERY'S *Contention of the Bards*, 1620, where the Yew of Crom is said to have been discovered, about 125 A.D., on the day when CONN of the Hundred Fights was born. This tree has probably an antiquity of over 1,500 years, and may have been associated with the worship of the pagan idol Crom Cruach.

COLD STORAGE OF FRUIT.—The Report of the Union of South Africa Department of Agriculture contains, in addition to much other valuable information, the result of investigations, made by the Fruit Inspector, Cape Town, on the temperature most suitable for the cold storage of fruit. Experiments were carried out on a large scale with various fruits—Apricots, Peaches, Plums, Grapes, etc.—and the conclusion was reached that 32° is the most suitable temperature. Fruit kept for from 18 to 30 days at 32° was found to last well for from 7 to 10 days when taken out of cold storage. Certain fruits, such as Burbank Plums and yellow-fleshed Peaches, are not amenable to cold storage treatment.

GARDENING IN AMERICA.—Mr. HARRY A. BUNYARD writes us from New York City as follows:—"A few years ago I wrote you relative to the scarcity of assistant gardeners and foremen for private estates in America, mentioning the fact that there were good openings for progressive young men willing to work and to adapt themselves to conditions here. At that time your editor took exception, stating that these young men should go to the British Colonies rather than come to the United States. However, a good many young men came over and found positions practically the day they landed. The immigration laws of the United States do not apply to gardeners, owing to the fact that they are classified as personal servants. This may be somewhat a reflection upon the profession, but it is nevertheless a fact. I am writing at this time to convey the same information, that there is a paucity here of young gardeners, more especially in the spring and fall. The wages run from \$60 to \$75 per month, without board, and \$40 to \$50 per month with board. The average cost for board and room here for gardeners is about \$20 per month. I may at this time state that while gardening is not quite

so far advanced as in the old country along some lines, there are immense private estates and florists' establishments that compare very favourably with those in Europe. I could cite many instances where assistant gardeners have grown up in this country and have now large commercial establishments themselves. It all depends upon the man. Should anyone wish to communicate with me on the subject I should be happy to answer any questions through the *Gardeners' Chronicle*. There are no openings for head gardeners, who are recruited here as in Europe from the foreman and assistant gardener."

GLADIOLUS.—An interesting account of the Gladiolus and of the Gladiolus trials made at Cornell was given recently by Mr. ALFRED C. HOTTES before the New York State Federation of Floral Clubs, Ithaca, N.Y. (see the *American Florist*, February 14). Some 700 varieties of Gladiolus have been grown and described in the course of the trials, and a careful inquiry has been made into the history of the cultivated varieties. Mr. HOTTES points out that up to 1841 the varieties cultivated were of the Gladiolus nanus type, e.g., *G. Colvillei* and its white variety, *The Bride*. Somewhere about this time BEDDINGHAUS, gardener to the Duc d'AREMBURG, crossed various African species of Gladiolus. As a result of certain of these crosses the hybrid known as *G. gandavensis* arose. The precise origin of this famous hybrid is unknown, but Mr. HOTTES gives his support to the view expressed by various experts that it originated in a cross between the brightly-coloured *G. psittacinus* and *G. oppositiflorus*, the flowers of which are opposite and more profuse than those of the *G. psittacinus*. The hybrid was brought out by VAN HOUTTE, and SOUCHER, gardener to NAPOLEON III., who admired the plant, set himself to improve it by crossing Gandavensis varieties, and also by hybridising these varieties with other species of Gladiolus. LEMOINE, of Nancy, also took up a like line and crossed Gandavensis with *G. purpureo-coloratus*, a species with hooded or bell-shaped flowers, greenish-yellow in colour with a conspicuous maroon blotch. The result was Lemoinei—a partially hardy form with deep coloured and velvety flowers, somewhat lacking in size, and often not open enough. Later LEMOINE crossed some of his namesakes with *G. Saundersii*, a species with wide-open scarlet flowers with spotted throat. Hence arose the forms known as *G. nancianus*, with the larger, wider-opened flowers of *Saundersii* and the wonderful colours of Lemoinei. LEICHTLIN, of Baden-Baden, at about the same time crossed Gandavensis with *Saundersii*, and obtained the *Leichtlinii*, a great flowering race. History now follows the plant to the United States. The stock of *Leichtlinii* was purchased by Mr. HALLOCK, of Long Island, and after some improvement passed into the hands of Mr. JOHN L. CHILDS, who rechristened it *Childsii*. The ruffled strain was originated by Mr. A. E. KUNDERD. Recently yet another species, *G. primulinus*, has entered the hybrid mosaic. The yellow of this species has proved useful in toning down the more garish colours of the hybrids, and this has facilitated the production of delicate orange and salmon pink shades. Mr. H. H. GROFF has also raised hybrids, which have been fertile in novelties.

BASIC SLAG.—A useful summary of the properties and modes of use of this important artificial manure is contained in Leaflet No. 267 of the Board of Agriculture. As is well known to many gardeners, basic slag is one of the most serviceable of fertilisers, and, although it exercises its beneficent effects most on a dry soil, it is doubtful whether any garden soil is not rendered more fertile by an application of basic slag. It is easily applied, and one of the most effective methods of application is to dust basic slag over the manure which is being dug into the

ground. The rate of application should be 2 to 4 ozs. per square yard. Good for flowers and for fruit, basic slag should be excluded from the lawn, and this for the very reason which makes it an excellent fertiliser for pastures—namely, that it encourages the growth of Clover. The leaflet draws attention to the importance of securing good basic slag. The goodness depends on several conditions: (1) the total amount of phosphate of lime which it contains, (2) the amount of readily soluble phosphate, (3) the fineness of the powder. The fact that basic slag contains a certain amount of free lime—from 2 to 5 per cent.—is also to be remembered, and makes this fertiliser of particular value for garden soils wherein lime is apt to be deficient. In many cases, for example on light soils, it is advisable to add kainit—at the rate of $\frac{1}{2}$ to 1 oz. to the square yard—as well as basic slag. Anyone who has not tried the effect of the latter should test for himself the value of basic slag when next making up a flower border, applying it in the way indicated to about half the length, and observing the growth of the herbaceous plants, not only in the following, but also in subsequent seasons.

OENANTHE CRUCATA.—A case of fatal poisoning of four heifers by the root of this plant has been reported recently from Wells, Somerset. At this time of the year, when ditches are cleaned out and the mud thrown up on the margins, the roots of this plant contained in it become washed clean by rain, and the white Dahlia-like tufts of fleshy roots then prove tempting to cattle grazing in the fields. The cases of poisoning recorded are almost invariably at this time of year, and, as the leaves do not appear until April, farm labourers do not recognise the root as belonging to a dangerous plant. The fleshy, spindle-shaped roots when broken across exude scattered drops of milky juice, which turn after a short time into saffron-coloured dots (hence the specific name "crocata" applied to the plant), and by this character and its white colour and spindle-shaped form the root may be recognised. Gardeners residing on farms where there are streams in pastures will do well to call the attention of farmers to the danger of this plant, which frequently causes death in cattle in less than three hours after consumption. The plant is illustrated in *Gardeners' Chronicle*, April 10, 1902, p. 265.

ANNUALS.—III.

ANNUALS growing from six to nine or ten inches in height are very numerous, and those to which I shall refer do not by any means exhaust the list; they must be considered only as examples, but that they are good examples, I can vouch.

ANAGALLIS (PIMPERNEL).

These, like all the others, I sowed in the open border on the 5th or 6th of May, and though they took a considerable time—twenty-four days—to get above ground, they did well, and continued in flower till quite late in the season. *A. Monelli Parksii* at the end of the season was nine inches in height. Its fine orange scarlet flowers were very freely produced at the axils right up the stem. *A. Monelli Phillipsii* had rich blue flowers on slender footstalks. The flowers were about one inch in diameter, and on close inspection revealed a deep rose-coloured ring round the centre, although the general effect of the flower was blue. Like the former variety it reaches a height of nine inches.

CAMPANULA ATTICA.

Two varieties of this were grown, both of the same height and habit, and both most floriferous. The flowers were about half an inch in diameter; those of the type being rich bluish purple with white centres, the other form having fine white flowers.

CLARKIAS.

Here I refer only to the dwarf race, which grew with me about nine inches in height. They are called Tom Thumbs, but all had a percentage of giants among them, which, however, are easily distinguished and may be removed. They were all double forms—white, purple, crimson, etc.—and each and all formed charming groups. Mr. Alfred Watkins has for a number of years been working hard at these dwarf Clarkias, and is getting the strains sent out by his firm very near perfection.

CANDYTUFT.

There is now a dwarf white Candytuft called Little Prince. It grows, according to the richness of the soil in which it is planted, from six to nine inches in height. It produces fine large heads, the individual flowers of which are broad and of excellent substance. Messrs. Sutton say, "Little Prince remains in perfection for a longer period than any other annual Candytuft," and this I found it to do.

EUCCHARIDIUM BREWERI.

This must not be judged by the common tall form *E. grandiflorum*, to which *Breweri* is very superior. It grew eight inches high and bloomed most profusely. The flowers were of a charming shade of pale rose marked occasionally with white.

DWARF JACOBEA.

There are many varieties of the dwarf double Jacobeas—white, purple, rose, red, etc. In the early stages of their growth they remain very dwarf. When in full bloom their height, to the top of the flowers, is eight inches. The strain seems quite true to dwarfness, as it gave no tall ones, but there is room for improvement in doubleness. It rather spoils the effect of a mass if several of the plants have large staring yellow eyes while all the others are perfectly double. I do not doubt the difficulty recognised by every seedsman of getting a strain quite true to doubleness. Very hardy and easily grown, the seed of this Jacobea germinates quickly, and plants should be thinned to at least four inches.

KAULFUSSIA.

This annual has other names, and is generally put down as growing six inches tall, but with me it grew to nine inches. *K. amelloides* produced brilliant blue flowers in abundance. *K. Kermesina* gave ruby purple flowers. The former was the more effective. Daisy-like, about one inch in diameter, on slender footstalks, describes the individual blooms.

LIMNANTHUS DOUGLASSII.

This free-blooming very hardy Californian annual grows eight or nine inches high to the top of its flowers. The latter are saucer-shaped, one inch in diameter, yellow in the centre and marked with white round the edges. It is very fragrant and much visited by bees. It germinated quickly, and was in full bloom in July. There is a slight difference between the several strains, some being larger flowered than others, doubtless due to the selection of stock seed from large flowered plants.

NEMOPHILA.

I grew four sorts of this trailing or spreading annual, the well-known *insignis* being the brightest and best of the four. Its flowers are one inch in diameter, bright sky-blue with white centres. *insignis alba* is a white counterpart of the former; the anthers are black and rather conspicuous. *N. atomaria* has white flowers, not quite so large as *insignis*, and covered with minute black spots. *N. discoidalis elegans* is most distinct. The flowers, which are rather over half an inch in diameter, are deep maroon in colour, and are edged or laced with pure white.

ZALUZIANSKIA SELAGINOIDES (see fig. 79).

A most charming little plant covered with myriads of star-shaped flowers— $\frac{1}{4}$ inch in dia-

meter. The colour was white, with only the faintest trace of pink. The pale coloration was no doubt due to the dry season, as it generally is much pinker.

PHACELIA CAMPANULARIA (see fig. 80).

One of the very best blue annuals, growing to a height of eight or nine inches. The flowers are bell-shaped and of the most brilliant ultramarine colour. The plant remains in bloom for a long time, the flowers opening in succession up the stem which carries six or more. The foliage is somewhat large for the size of the plant, it is

FIG. 79.—ZALUZIANSKIA (NYCTERINIA) SELAGINOIDES : FLOWERS WHITE WITH ORANGE-COLOURED CENTRES.

sage green in colour, shaded with purple at the edges and deeply veined.

The Saponarias are too well known to require an extended reference. They form fine clumps, and are literally covered with small star-shaped

FIG. 80.—PHACELIA CAMPANULARIA : FLOWERS BLUE.

flowers, either pink or white. They are most valuable for masses.

SILENE PENDULA COMPACTA (see fig. 81).

There are many forms of *Silene* which run from one to two feet in height, but the compacta varieties are the only ones proper to this division of annuals. They grow six inches or rather more in height. They may be sown in autumn as they winter well and are most useful for spring gardening. There are single and double forms, both of the white and rose varieties. The flowers are freely produced and are from a half to three-quarters of an inch in diameter.

The single rose-coloured variety has white centres to the flowers, and the edges are notched. They rather resemble some of the *Lychnis*, to which they are allied.

TAGETES.

Although invariably sown indoors and treated as half-hardy, or even tender annuals, I had remarkable success with *Tagetes* sown in the open border. Both *signata pumila* and *Legion of Honour* came up well, and bloomed persistently. The former produces small, single, bright yellow flowers in great abundance associated with fine feathery foliage, whereas *Legion of Honour* is a dwarf single French Marigold, also bright yellow but with much larger flowers than *Tagetes*, and blotched with rich brown. They both grow eight or nine inches in height. *Signata* is less formal, and therefore more graceful than *Legion of Honour*.

The remarks made above regarding *Saponarias* apply also to the well-known *Virginian* stock, but the latter is a much less prolonged bloomer. W. Cuthbertson.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

NON-INHERITABLE VARIABILITY.—I note that in the report of the general meeting of the Linnean Society of London, on the 19th ult., Dr. John P. Lott, of Haarlem, read a paper entitled "On the Origin of Species by Crossing," at the conclusion of which these expressions are quoted: "The author expressed his firm conviction . . . that no transmittable variation exists, and that all apparent variability is due to an original cross"; and that "inheritable variability does not exist, with the always possible exception of mutation through loss of factors." As, unfortunately, I was not present at that meeting I missed the opportunity of putting forward a few facts which, to my mind, entirely refute both contentions. With reference to the first, I would point to the easily-proved existence of innumerable variations in our native Lady Fern, *Athyrium filix foemina*, which have been found in a wild state. Since the species is here a solitary one, these variations cannot possibly be ascribed to crossing between it and another; that is absolutely an impossibility. Secondly, as there is no known species of Fern which is normally crested or tasselled at its terminals, how can the innumerable wild sports of many species which are so characterised have arisen by virtue of "original crosses"? Nor can they be imputed to "loss of factors," since they constitute additional ones to the normal plan. That inheritable variability does "not exist" is equally disproved by the fact—again easily demonstrable by living plants in my collection and others—that the spores of these varied individuals produce, as a rule, perfectly characteristic progeny generation after generation. If this be not by virtue of "inheritable variability," then my construction of the term must differ vitally from that of Dr. Lott. Chas. T. Druery, V.M.H.

TAX FOR TREES.—The *Daily Mail* reports that at a recent meeting of farmers in Hertfordshire a strong protest was made against hedges and hedge-row timber, on the grounds that these features of our country represent so much waste ground, and that nothing will grow where the roots of a tree ramify. One member estimated that each tree on his farm represents a potential loss of £1 per year. "The trees stood there 'eating their heads off,' benefiting neither landlord nor tenant." The hedges, which excite the admiration of nearly every visitor to our country, are, according to some of the speakers, simply wasters of the ground, nurseries of weeds and harbours of grain-eating sparrows and rats. Their value as wind-screens and for furnishing shade is apparently not worth considering. But, even though a suggestion for the taxation of every tree on a farm over a certain age was advanced, it is

difficult to believe that these farmers were serious in their remarks. *B.*

YELLOW VIOLAS.—The excellent coloured plate of *Viola* "Walter Welsh" in your issue of 28th ult. must have set many people wondering how such fine plants could be grown on the light sandy soil of Wisley. I was a visitor to the R.H.S. gardens on two occasions last summer, and admired the *Viola* beds very much. They had been well done. Mr. Wright, the superintendent, had delegated the duty of looking after the *Viola* trials to Mr. Blakey, and in conversation with him he frankly revealed his method of culture. The ground was prepared in August and early September. Old cow manure and leaf soil were put into the beds, in liberal quantity, 6 inches beneath the surface, to make certain that the roots would travel downwards, because, said Mr. Blakey, "when they get down among the manure and leaf-mould they can stand drought and other trying conditions and look happy." This they did, many of the individual plants bearing from forty to seventy flowers in the middle of June. Much

low in colour, with a perfect habit; Redbraes Yellow, deep golden-yellow of excellent habit; Royal Sovereign, also a grand rich yellow. Those who want the largest flowers of all produced on fine long stems must grow Moseley Perfection—66 per cent. of the plants of the two last-named stood over two winters at Wisley. No *Viola* has a deeper, richer yellow tone than Walter Welsh, the one you figured in colour. In spring and early summer its rays are apt to run together and assume a blotchy appearance, but that goes off. It is one of the strongest growers, growing if it gets the least encouragement to 15 or 16 inches. *W. C.*

GRAFTING ROSES (see pp. 52, 106, 135).—*Amateur* is correct in his remarks concerning temperature, etc. Having handled thousands of *Roses* in all stages of growth, I think the most important item is to prevent the damping off of the young growth. The temperature should be 70°, not more, and not lower than 65° at night. From the time when the stocks are brought into the pro-

amount of air may be increased gradually until finally the lights may be removed entirely for a short time daily. A temperature of 83° is dangerous for young grafted *Roses*, and I should think bad results would follow, for the high temperature promotes a quick growth, and when taken out of the frame the young growth would hang limp, to be put back into the propagating frame, and ultimately thrown away. *W. E. Kearn, Horsforth, Leeds.*

—In the further remarks by *Experience* it is observed that there can be no damage by damping providing dormant, well-ripened wood be used as scions. It will be remembered that he stated on p. 52 that only novelties were worth while grafting. Where will he get his well-ripened wood from, as the newer varieties are propagated to such an extent that one gets weak, pithy wood for at least the first two seasons? Sunburst was certainly an exception, but take *Rayon d'Or*, *Louise Catherine Breslau* and *Mdme. E. Herriot*, all *Roses* of *Lyons Rose* type, and where does his well-ripened wood come in? I was surprised to see that he has come down to five days as regards keeping the case closed. In a perfectly-kept case enough moisture arises to form big drops on the glass, which would drop in twenty-four hours, when the damage is done. He would also find the raffia round the grafts saturated with moisture. The lights should be taken off for half hour the second day to allow raffia to dry. If unestablished *Briars* were used, being potted only ten days, he would have, if grafting any number, a good number still in the case if left to the proper time of removing at the end of six weeks. If taken out in three weeks I would be interested to know how many per cent. die after coming out of the case. *Amateur.*

RUSCUS ACULEATUS.—The shade-loving *Butcher's Broom*, with its leaf-like branches, is fairly common, but, so far as I am aware, it is seldom seen in fruit. I had that pleasure last week when on a visit to Mr. Wilks' pretty garden at Shirley. As is well known, the species is usually dioecious, and it is only when the male and female plants are grown together that the bright red berries ($\frac{1}{2}$ inch in diameter) are abundantly produced. It might be suggested to those interested in the subject to examine the flowers and ascertain whether they possess male and female plants. This may easily be done as the protandrous male flowers are now appearing. They are star-shaped and about $\frac{1}{4}$ inch diameter. The bright yellow and sessile anthers are readily seen surmounting the short, stout and slightly purple column. In the female flowers, which appear later, the style is short and the stigma discoid. According to *Hooker's Flora* (1884), p. 403, the male flowers are on narrower cladodes; but while this may be borne in mind, a careful examination of the flowers would at once settle whether the plants in any particular locality are male or female, and a mutual exchange of plants might follow. *D. Morris, Boscombe, February 28.*

DER RUCKSACK.—Having grown up in the Austrian Alps, I have been familiar with the Austro-Bavarian dialects from childhood. Professor Farmer will, therefore, forgive me if I question the correctness of his derivation of the word "rucksack." To me there is no doubt that a "rucksack" is a sack carried on the "ruck'n" (i.e., back). An Austrian, Styrian, Tyrolese or Bavarian mountaineer, if asked why he called the thing a "rucksack" would reply, "Because I carry it 'auf'n ruck'n,'" that is, on the back. He would never say "auf'n rücken," unless he affects to speak "Hochdeutsch." The use of "u" in the place of "ü" is characteristic of the Austro-Bavarian dialects, as "buck'n" for "bücken" (to bow or stoop), "bruck'n" for "brücke" (bridge), "druck'n" for "drücken" (to press), "muck'n" for "mücke" (gnat), etc. Further, if the same man were asked what he does if the "rucksack" presses too heavily on his shoulders, he would say, I give it a "rucker" (a jerk) to shift it, but never a "ruck," which is "Hochdeutsch." The form "ruck" for "rücken" (back) also occurs occasionally in place names as "Hausruck" (Upper Austria), a range of hills

FIG. 81.—*SILENE PENDULA COMPACTA*: FLOWERS PINK.

(See page 173.)

the best results were obtained with the plants planted in October, which came through the winter without a single loss. October planting is not always convenient, and in some districts and in some soils not advisable. For spring planting the beds or stations for *Violas* should be prepared in a similar way to that adopted at Wisley. *Violas* need not be in beds. In clumps of six to a dozen plants of carefully selected colours, they are most valuable in the foreground of mixed borders. For such sites varieties should certainly be chosen which possess the power to stand over winter in the open. In the *Journal of the Royal Horticultural Society*, published in December, 1913, there is a valuable key to such varieties. There is a complete list of all varieties in the trial and the percentage of plants which stood successfully through two winters is given, the following yellows being specially commended on that score:—Bullion, Grievei, Kingcup, Molly Pope, Primrose and Walter Welsh. In addition to these, there are yellow *Violas* which most experts would term flowers of a better class. Such are *Sulphurea*, pale sulphur yel-

pagating house to the time when five-inch pots are needed the temperature should always be maintained evenly. The chief detail to observe after grafting is the drying of the lights each morning. I like to do this at one special time, namely, just before going to breakfast. The lights dry during the half-hour, and can then be closed. If the weather is fine no further alteration is needed until next day, but in dull, wet weather it is necessary to lift the light again for a short time in the afternoon, wiping all woodwork and glass to get rid of the condensed moisture. In a temperature of 70° a fair batch of the grafted plants should be ready to be taken out of the propagating frame in ten days or so, but some remain dormant for a long time. Grafts that were made from hard spur growths should be placed at the warmer end of the frame. These generally make nice bushy plants when started. As the plants are taken from the frame each should be labelled and stood in another frame on a layer of ashes, shutting and shading the frame if necessary for a few days. After a week or so a little air may be afforded by using a label as a wedge. The

with a wide, flat back. Finally, I would only add that the "u" in "rucksack" sounds as "u" in "put" or "push." *O. Stapf.*

THE MOON'S EFFECT ON PLANTS.—Your correspondent, Mr. C. Turner, might be interested to hear the opinions of many old men of the labouring class in my native county of Cheshire. Though personally I am at a loss to understand how such an extraordinary notion can be entertained by any educated man, yet the fact remains that I am well acquainted with many old Cheshiremen who profess to have firm faith in the effect of certain phases of the moon on their crops and cattle. They will tell one in all sincerity that one must always sow Peas and plant early Potatoes, to name but two garden crops, in what they are pleased to call "the decrease of the moon," so that these crops may show above the ground in "the increase of the next one." This idea also applies to the hatching of hen eggs, and they will keep a broody hen idle for a week or so rather than allow her a clutch of eggs at the wrong time. Tradition takes a lot of killing, and I well remember, when, in my schooldays, I ridiculed an old labourer for these ideas, he indignantly informed me that they were good enough for his grandfather, and therefore they were good enough for him. *Cestrian, Carnarvon.*

—Referring to the remarks of the effect of the moon on plants, p. 151, it is possible that many gardeners and farmers are guided in their operations by the phases of the moon more than they would care to admit. Some years ago I had the pleasure of the confidence of a very successful old gardener, who was very careful to perform certain operations during the first half of the moon. He carried the idea into the pruning of specimen stove and greenhouse plants. Of these he was then a very successful grower. In 1905 I made a test when sowing seed in the open air; the plants noted were Peas, Spinach, Radish. These plants, growing under exactly the same conditions, sown during the growth of the moon, showed a quicker and better germination and the subsequent growth was more satisfactory than with those sown when the moon was on the wane. Some twenty years ago a successful poultry rearer quietly informed me that if I wished to hatch the strongest chicks I should time them to appear during the second quarter of the moon. This is still practised by some poultry rearers. There is an opinion held by some farmers in mid-Wales that seed sown in the afternoon is more successful than that sown in the forenoon. There is, however, one practical reason why this should be so—that is, the soil is usually in a more workable and warm condition in the afternoon than it can be earlier in the day. Some seven or eight years back opinions were freely given in favour of the soaking in water of the seed of Peas, Beans, etc., before sowing them. I tried this for one season with Peas and could not find any difference in the time taken to get them ready for table. *John Edwards, Cefnarthryl, Berriew.*

SILVER-LEAF IN PEACHES.—In 1869, when I took charge of the gardens at Singleton, near Swansea. I found the Peaches and Nectarines (both inside and out-of-doors) suffering very badly from white or silver-leaf disease. I had no previous experience of white leaf, but it occurred to me that I must go to the roots to remedy the evil, which I did. As soon as we had gathered the fruit from the trees in the early house at the end of June we dug up the border, commencing outside the roots and gradually working inwards, taking care not to injure any of the fibrous roots, of which there were but few, and cutting away all cankered portions. We found a layer of concrete on top of the drainage, instead of the drainage on top of the concrete. After putting this right, we secured freshly-cut turves, and turned them grassy-side down on the drainage. We then filled in with compost, which was composed of fresh turf from the park chopped up roughly about the size of one's shoe, three loads of turf to one of old mortar rubbish. No manure whatever was employed, not even crushed bones, nothing but the mortar rubbish and turf. When the trench was filled to within a quarter of the required height, the roots were spread out on the surface, and covered

with some of the compost chopped a little finer. The roots were then about 2 inches under the surface, and the border would not be more than 1 foot deep. When all was finished the trees were shaded and the soil made just moist. The trees were syringed three or four times daily until the roots began to grow in the new material, when the shading was removed and the trees exposed fully to the sunshine. By the end of August the trees were well established, and the house was thrown open, but the roots were not allowed to lack water, or the fibrous ones would suffer. In the following November the house was again shut up and the trees gently forced. The shoots broke freely and flowered fairly well, but they were only allowed to carry a light crop. A few leaves showed silvering, but they soon grew out of it. Although no manure was used in the borders the roots were fed with weak manure water when the fruit was in the first stage of swelling, and again after stoning. The borders were mulched with half-rotted stable manure, sometimes cow manure, but less of the latter was employed. At the stage of the fruit's second swelling the roots were afforded a copious supply of chilled water (cold water should never be used). In the autumn the mulching, manure, etc., and fine soil were cleared away down to the roots and a good layer of fresh-cut loam and lime rubble substituted before shutting up the house. The border was renovated every fifth or sixth year, one half of the trees, those on one side at one time, to ensure a crop. I am pleased to say that for the 20 years over which I had these old trees under my charge they showed no more signs of silver leaf. I won my 1st prize with fruit from these trees, especially at the Royal Botanical Society's exhibitions in Regent's Park, at that time considered the best shows in London. *South Wales.*

CELERY DISEASE (see pp. 95 and 150).—*M. A.* is right in his assertion that weather and season have more to do with Celery disease than manure. In 1912 our crop of Celery—1,000 plants, grown in the usual way in trenches with well-rotted cow and horse dung to the depth of 6 inches in the bottom—was badly infested with the disease. Celery in several other gardens which I visited were also affected, and sprays failed to check the disease. In 1913 we cultivated our Celery in exactly similar conditions (excepting change of site) and no disease appeared. Nor did I see a trace of disease in any of the gardens visited by me during 1913, thus proving that the farmyard manure is not the cause of the disease. Celery last year was badly injured by the leaf-mining insect. *Wilmot H. Yates, Rotherfield Park Gardens, Hampshire.*

APPLE COX'S ORANGE PIPPIN.—There appears to be just now such a mania amongst gardeners to persuade planters of the value of this and that variety of late Apple for dessert from Christmas onwards, that one could scarcely find room for all the sorts recommended. For years I have wondered why gardeners hanker after so many varieties instead of planting extra trees of Cox's Orange Pippin, either as standards, bushes, or cordons in the open, when they know quite well that no Apple can equal it in quality. It is an admitted fact that when Cox's Orange Pippin is finished we have no English Apple in any way comparable with it; in fact, it is difficult to name one that is but an apology for a good dessert fruit. On p. 52, in your report of the admirably managed garden at Penrhyn Castle, you allude to the fact that fruits of Cox's Orange Pippin Apple are usually placed on the table in a fresh and plump condition in the second week in May. When we know how satisfactorily well-grown fruits of this Apple will keep it is a safe question to ask why do not more persons imitate Mr. Speed and grow more trees of this king of dessert Apples? *E. Molynaux.*

FAILURE WITH FORCED BULBS.—I should be glad to learn how other gardeners have succeeded with forced Narcissus this season. My first batch failed; the buds at the bottom did not develop, although the foliage was 18 inches long but rather weak. The varieties were Golden Spur and Princeps. The bulbs received

fair treatment and were not unduly forced. The varieties Horsfieldii, Empress and Mrs. Langtry that are just coming on are all weak and give little promise of much flower, being far from satisfactory generally. Never having had a failure of this sort before, it would be interesting to know the experience of others. The only variety that has done well with me is obvallaris, which has flowered very well indeed and has been my mainstay. Now the question: Why should this variety do well whilst all the others were failures, seeing that they were grown under the same conditions and obtained from the same source? The most profusely-flowered Narcissus I have seen this season came from Lincolnshire, and in future I intend to give home-grown bulbs a trial. *J. R. Wilson, Sulley Hall Gardens, Rugby.*

JOURNEYMAN GARDENERS' WAGES.—With reference to the subject of the low wages paid to journeymen, I should like to mention a case in which wages were stopped (I consider very unjustly) for time taken off. A friend of mine, having taken a situation not far from here, came to spend a week-end with me, being off duty for Saturday and Sunday. He was unable to get back until twelve o'clock on Monday, and on the Saturday following half a day's pay was stopped from his wages. At Christmas the head gardener asked if any of the men would like some time off, and my friend took Christmas Day and Boxing Day. On the Saturday following a whole day's pay was deducted for Boxing Day. Such treatment appears to me very mean, and I should like to know whether other readers have had the same experiences. *Salisbury.*

—In reply to *Another Journeyman* and *J. H.*, who challenge my remarks on page 96, I consider *A. J.*'s idea that we must demand more money is ridiculous. Perhaps he will explain how it is to be done, also if he has put it to the test himself. Then he blames the head gardener. If he will ask a few heads as to the journeyman's wage and their own, he may afterwards see the light. *J. H.* remarks: "How many situations are there at 18s. per week, with bothy, etc.?" If he will scan the advertisement pages of the horticultural papers he may find an answer to that question. If a journeyman is a good man at his work he will be able to jog along comfortably. As I said before, a higher wage all round will be thankfully received, but we must wait a wee bit longer. I should like to hear the opinions of head gardeners on my remarks on page 96. *Journeyman.*

—Having been a subscriber of your valuable *Chronicle* since 1879, I have read a great many articles on various subjects in Home Correspondence, and I doubt if some of our present-day journeymen are not far better off in every respect than they were thirty years ago. At the same time I am very pleased to see that there is an upward tendency in gardeners' wages. I have here a man aged twenty-eight as inside foreman, who is thoroughly practical in all branches of his profession, and who wishes to secure a post as head gardener and settle down. The following is a true copy of the terms relating to a situation recently offered him:—Wages 18s. per week, with excellent cottage and garden vegetables free. Duties: To have control over four other men and be generally responsible for the care and upkeep of the gardens, including hot-houses, fruit and flower culture, etc., etc. To be under the general supervision of the estate bailiff, who will certify all bills. I note some writers blame the head gardener for the present low wage. What would the journeyman's position be in a nobleman's place of this description? *A Well-wisher for Head and Under Gardeners.*

—In respect to the letters which have been written in these columns on the subject of the low rate at which journeymen are paid, I may say that I have worked with some men who think they ought to get more wages than the head and do nothing but talk about football, cricket, or boxing instead of doing their work. I think that if the head and the journeymen were to make an effort to work together in harmony, and the men were to leave the subject of sport until after working hours, there would be better feeling all round. *A. S., Kingston-on-Thames.*

SOCIETIES.

ROYAL HORTICULTURAL Scientific Committee.

FEBRUARY 24.—*Present:* Mr. E. A. Bowles, M.A. (in the chair), Sir J. T. D. Llewelyn, Dr. A. Voelcker, Messrs. W. C. Worsdell, W. Cuthbertson, A. W. Hill, Arkwright, Hales, and F. J. Chittenden (hon. sec.).

Azalea amoena.—Mr. W. C. WORSDELL showed double flowers of *Azalea amoena*, and drew attention to the fact that the sepals had become petaloid, giving rise to a "hose-in-hose" flower.

Odontoglossum angustatum.—Mr. R. A. ROLFE reported that the *Odontoglossum* shown at the last meeting by Mr. H. S. Goodson, of Fairlawn, Putney, was probably a form of *Odontoglossum angustatum*, Lindl. It had rather shorter segments and a less-toothed crest, but there are several imperfectly known species described by Reichenbach in this group (a group of only slight importance in the garden). The present plant may belong to one of these, but Mr. Rolfe could not quite make it fit any of them. More distinct things, he says, have been referred to *O. angustatum*, and he considers it should belong there for the present.

Tomatos dying.—Some small Tomato plants were shown from Guernsey, the grower complaining that they had drooped to some extent and looked otherwise unhealthy. The Secretary reported that he had found numerous though very small nodules on their roots inhabited by the "root-knot" eelworm, *Heterodera radicola*.

Hybrid scented-leaved Pelargoniums.—Mr. J. FRASER continued his remarks upon the scented-leaved *Pelargoniums* in the Wisley collection, and dealt especially with the hybrids of *P. cucullatum*, *P. angulosum*, and *P. acerifolium*.

Curious growth of Hyacinth.—Mr. R. C. NOTCUTT sent a curious *Hyacinth* with a flower-spike growing downwards into the glass, issuing from the base of the bulb. There was also a normal growth at its apex. A section through the bulb showed an adventitious bud to have developed on the edge of the ascale leaf, as often occurs when, as in the present case, the bulb has been injured. This bulb developed a flowering shoot, and this found its way out of the bulb by the easiest path—viz., through the damaged base of the bulb.

Small Narcissus fly.—Mr. P. D. WILLIAMS sent from Cornwall a bulb of *Narcissus* containing numerous larvae of the small *Narcissus* fly, *Eumerus lunulatus*. This fly is apparently very destructive to *Narcissus* bulbs in certain seasons, and has been reported to attack various bulbs, including onions. The Secretary said he had hatched out the flies from rhizomes of *Iris* attacked by the larvae. They are allied to *Meredon*, the better-known *Narcissus* fly, but are much smaller and more like a house fly in appearance. The larvae, with the three projections from the blunt tail end, the middle one of which is red, are also very distinct.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 12.—At a meeting held on this date the following awards were made:—

FIRST-CLASS CERTIFICATES.

Odontoglossum L'Empereur, parentage unknown, a magnificent flower of good shape and substance, bluish purple. A Silver Medal was also awarded; shown by W. R. LEE, Esq.

Odontoglossum crispum Palatine, a fine white flower, from WM. THOMPSON, Esq.

Odontoglossum × *Countess of Sefton*, parentage unknown, a large well-set flower, heavily blotched, shown by R. LE DOUX, Esq.

Cattleya Susanae Hye grandiflora, the largest of the variety seen, shown by Messrs. E. H. DAVIDSON and Co.

AWARDS OF MERIT.

Odontoglossums × *Desdemona*, *O. illustrissimum*, *O. Mrs. McVittie*, *O. eximium* "Walton Grange" var., *O. × Bonar Law*, and *O. crispum aureolum*, all from WM. THOMPSON, Esq.

Odontoglossum amabile var. "Daphne" (crispo-Harryanum × crispum), and *Odontioda Madeleine* (crispum × *Odontioda Charlesworthii*), shown by W. R. LEE, Esq.

Cattleya Trianae "Enimes," shown by Col. J. RUTHERFORD.

Cypripedium Griffin (Mrs. Mostyn × *Archimedes*), shown by Mr. J. EVANS.

LINNEAN.

FEBRUARY 5.—A general meeting of this society was held on the 5th ult., Prof. E. B. Poulton, F.R.S., President, in the chair.

The Secretary for Zoology read the following abstract of a paper on "The Mouth-parts and Mechanism of Suction in *Schizoneura lanigera*, Hausm.," by Mr. JAMES DAVIDSON, M.Sc., F.E.S., communicated by Dr. A. D. IMMS, F.L.S., the author being abroad.

The object of this paper is to give a detailed description of the anatomy and relations of the mouth-parts of aphids, with special reference to the working of these structures during the process of feeding.

As seen in this species, the head is divided by an articulation of flexible chitin into a distal, tapering portion, the "Vorderkopf," and a broader, proximal portion. The former is composed of several sclerites associated with the mouth-parts, and the latter portion bears the eyes and antennae.

The stylets play an important part during suction. They are four in number. The two maxillary stylets fuse together to form a median compound maxillary stylet. By this means two minute canals are formed along its length. The dorsal canal conducts the cell-sap from the plant host to the pharynx, and the ventral canal conveys the salivary secretion into the plant host.

The stylets are supported on the head by chitinous rods, and can be protracted or retracted by means of strong muscles, which are attached to various parts of the endoskeleton of the head. They extend distally from the head, and lie in a longitudinal groove on the anterior face of the proboscis.

During feeding they are forced into the tissues of the host plant, and the plant juices pass along the dorsal suction-canal formed by the compound maxillary stylet to the pharynx.

The salivary glands, situated in the head, secrete a salivary substance, which is conveyed by a median salivary duct to the salivary pump, thence it is forced down the ventral or salivary excretion canal, into the plant tissues.

The pharynx is a chitinous, distensible chamber, the upper wall of which is composed of thin flexible chitin. This wall is acted upon by large muscles, and thus the pharynx exerts a sucking action, the plant juices being drawn into it, and passed backwards into the oesophagus and stomach.

At the oral extremity of the pharynx the walls are continued to form a thick-walled canal, the "pharyngeal canal," which leads directly into the dorsal suction-canal. The anterior or dorsal wall of this region is perforated by eight minute pores, above which is situated a "taste organ." By means of this taste organ it seems clear that the aphid is able to appreciate the quality of the sap before it enters the pharynx.

The ascent of the sap along the suction-canal formed by the maxillae is probably largely due to capillarity.

One function of the salivary secretion is, I believe, to lower the surface tension of the cell-sap so that it may more readily ascend up this minute suction-canal.

LAW NOTES.

ARBITRATION CASE.

AT the Surveyors' Institution on the 5th ult. an important arbitration case was concluded before Mr. George Langridge, P.P.S.I., in the case of Smith v. Rayner. Mr. Bremmer and Mr. Aubrey Spencer appeared for the claimant (Mr. John Smith) and Mr. William Allen represented the respondent (Mr. Richard Rayner).

Mr. Smith claims £2,400 as compensation for tenant-right improvements carried out by him upon farms known as Great and Little Harlington, Middlesex. Evidence was given on behalf

of the claimant by Mr. R. J. Steel, auctioneer and valuer, of Boston Gardens, Brentford; Mr. Thos. Woods, auctioneer and surveyor, of Church Parade, Hounslow; Mr. James Benjamin Slade (of Messrs. Protheroe and Morris, 67, Cheapside, E.C.), auctioneers and valuers, and Mr. H. M. Cobb, of 61 and 62, Lincoln's Inn Fields, W.C. On behalf of the respondent Mr. H. Trustram Eye, F.S.I., Mr. Spencer Pickering, and Mr. William A. Neald gave evidence.

Mr. Trustram Eye, in reply to Mr. Bremmer, admitted he had no personal knowledge of the distance at which Morello Cherry trees should be planted. Taking an average farm in Middlesex, he could not say how many trees should be planted to the acre, as it all depended upon whether the lessee or the owner was planting and the sorts. Consequently planting varied all over the country. Mr. Robbins, the incoming tenant, was going to grub up all the trees. In re-examination, witness said the difference between gardens planted by the lessee and the owner was that a lessee always tried to get as much out of the land during his term as possible, whilst the owner had a long future in front of him and was not influenced by the fact that he had to give up the farm after a certain time.

Evidence was then given by Mr. W. G. Lobjoit, valuer and market gardener, of Heston Farm, Hounslow, Middlesex. He had over 100 acres of land under fruit, and he had been acquainted with the land under review for about twenty years, so was fully acquainted with its appearance and value. His valuation of the tenant right on behalf of the lessor was as follows:—

TWENTY-ONE ACRE FARM.

Planting 13ft. by 13ft.; 237 trees to the acre.	£	s.	d.
Grubbing half the trees: 126½ at 1s. per tree	6	6	6
Pruning and spraying at 6d. per tree	3	3	3
Trenching at 6d. per tree	4	3	0
	13	12	9
Estimated value of trees	20	0	0
Less cost of work as above	13	12	9
	6	7	3

21a. 3r. 18p. at £6 7s. 3d. per acre... 159 2 0

TEN ACRES (LITTLE HARLINGTON FARM).

Estimated value of trees and bushes per acre	£	s.	d.
Estimated value of trees and bushes per acre	40	0	0
Estimated cost of grubbing, pruning and spraying per acre	15	0	0
	25	0	0

10a. 1r. 20p. at £25 per acre

SUMMARY.

	£	s.	d.
Great Harlington Field	159	2	0
Little Harlington Field	259	7	6
Total	398	9	6

Continuing, witness said the trees in the larger field were too close, and consequently encouraging disease, and, in fact, he found a lot of the trees infested with blight. As to the smaller field, he found the trees healthy in parts, but rather interlined and interplanted. They were much too thick and there had been underplanting (bushes) as well. In cross-examination, witness admitted it was the custom in that part of Middlesex to plant closely together.

Morello Cherries could be started thickly, but when they began to grow into each other it was better to thin them out. The trees in this case had been put in in such a haphazard way that it would be a matter of difficulty to thin them out. All sorts were planted at varying distances. In re-examination, witness said that the new tenant of the farm was now grubbing up the trees.

Mr. Roland R. Robbins, J.P., market gardener, of Hollycroft, Sipson, Middlesex, stated he had been a market gardener for twenty-five years and was a member of several institutions connected with the land. He was also acting

partner in the market gardening firm of Wild and Robbins. When the claimant vacated his holding witness was approached by Mr. Rayner as to his taking of the fields, and eventually agreed to take a lease at a rental of £3 10s. per acre, commencing with Michaelmas, 1913. There was a clause in the lease empowering him to clear the land of all trees which were planted. He took possession on October 15 and found the trees were very crowded. Altogether he had cleared 17 acres of the larger field at a cost of £12 per acre, which included the cost of turning over. He would sell the wood whenever possible, but he was burning the brushwood.

Mr. William Allen, on behalf of the respondent, said they were asked to pay for 32 acres of land which had been turned from agricultural land to fruit land. What, however, was the state of the fruit land? Every witness agreed in his evidence, on both sides, that the plantations had been planted very thickly with trees. They also agreed that the time had come when they would have to be thinned to a very great extent. There was no agreement among the witnesses as to the effect of the thick planting, but all the witnesses that he had called (practical market gardeners who were engaged in the industry) were agreed that planting of that nature was conducive to disease. Moreover, the evidence of Mr. Steel, Mr. Cobb, and Mr. Slade, called by the other side, showed that the time had arrived when the plantations should be thinned. The evidence that the trees needed pruning, that there was mildew, and that the Apple and Plum trees were diseased was overwhelming, and even if it was not essential to grub up the whole of the two orchards, yet the trees must to a large extent be thinned. They would require a great deal of attention in the near future. Then with regard to the evidence of Mr. Robbins as to the state of the trees. That gentleman said he had grubbed the majority of the trees in the larger orchard, and 60 per cent. of the Plums were rotten in the middle. He could not see, therefore, how it could be said, as 60 per cent. of the trees were rotten, that the orchard was a valuable one. Indirectly, also, he thought there was evidence that the trees had not been properly pruned. The claimant's foreman had said that "if everybody had pruned as he had done there would have been nothing to grumble at." He (Mr. Allen) understood that statement to mean it was absolutely necessary to thoroughly prune in order to make up for lack of pruning in the past. Mr. Steel's valuation was based on the fact of the orchard being in a thoroughly good and efficient state. But, with the exception of one, all the witnesses agreed that they would not plant the same sort of trees again, as they were out of date. Mr. Miskin, a well-known local grower, told them (continued Mr. Allen) that he would not have these particular Apples in his orchard: the only thing he would be able to do with them would be to graft them with others. If these trees would have to be grafted and were out of date, how could it be described as an efficient and up-to-date orchard, for which an incoming tenant would be willing to pay for existing goodwill. It had been suggested that Mr. Robbins was in the position of partner to Mr. Rayner's son-in-law, but he did not see that there was any objection to this, as they formed quite a respectable firm. He suggested that in this case Mr. Smith had planted these trees so closely together because he wanted to get as much as possible out of the limited number of years he was tenant of the farm in question, and not caring at all whether the trees were of any value when he quitted the farm. A tenant, he contended, always tried to get as much as possible out of his land while he was in the position of tenant, and Mr. Smith was leasing a good deal of land in the neighbourhood as well as the orchard in question. Mr. Smith had kept no record of the fruit sent out from the orchard, although he thought it would have been advisable to do so, and he understood Mr. Smith had kept an account of his sheep stock, and could not understand his omission in this. When a claim of this kind had to be considered they not only wanted the evidence of professional valuers, but also the evidence of practical market gardeners. He said that his client had called three market gardeners on his behalf

and his opponent had called none, and he thought this pointed to the fact that he was afraid to do so. In conclusion, he said they had before them a claim for £2,400, and he submitted the question was whether this claim was reasonable or unreasonable.

Mr. Bremmer then stated the case for the claimant. He said this was not like an ordinary court of law where the jury tried the case. In this instance they had to leave the decision in the hands of one gentleman. When a jury tried a case they looked upon every witness as a wicked conspirator and treated them as such; that was what might be termed one of the "tricks of the trade." The whole question resolved itself into one of simple valuation, and nothing more; that was to say, the value of the estate to the incoming tenant. With regard to the question of costs, he thought when a man was afraid he would have to pay the costs of his own case he naturally made an application to the Arbitrator for an order for the other side to pay his costs.

Mr. Bremmer said he could see no legal answer to the claim; in his opinion, the legal point was absolutely a myth. He could not tell where it came in at all. There was no covenant in the lease about assignment, and he could not see what bearing the assignment by Mr. Smith had on the case. In the lease itself it said the tenant must carry out improvements to the estate, such as planting trees, etc., and trees had been planted; therefore, improvements had been made to the estate. With regard to Mr. Lobjoit, he thought that gentleman had come there not to assist the Arbitrator in arriving at a correct solution to the case, but to further the landlord's cause, and he thought he had done so in the best manner possible for an ordinary country gentleman. He thought he must say a few words regarding Mr. Robbins, but could soon dispose of that gentleman. Mr. Robbins' evidence should be very important, as that gentleman had declared he cared for nobody's opinion on gardening matters, not even specialists, and he himself knew all about gardening, and he did not see how Mr. Robbins' evidence could be excluded from the case.

Returning again to the question of costs, Mr. Bremmer said they had come into that room on several occasions for the Arbitration because they thought there was some legal answer to their claim, and he thought it had been amply proved there was none. They were forced into this arbitration; they did not enter into it of their own free will, and would gladly have settled the matter without these proceedings. He respectfully submitted that his client was entitled to costs. In conclusion, Mr. Bremmer said there was a great deal more he should like to have said, but thought they had been engaged on the case long enough now, and did not wish to waste any further time.

The Referee said he was very pleased with the clear and concise way in which each side had stated their case, and would let them know his decision in due course.

THE DECISION.

We are informed that the arbitrator's decision is as follows:—

"That the said John Smith is entitled to receive from the said Richard Rayner the sum of one thousand one hundred and thirty-nine pounds five shillings and sixpence (£1,139 5s. 6d.) as compensation in respect of the improvements comprised in the 1st schedule to this my Award." Each party pays his own costs and moiety costs of the Award.

DEBATING SOCIETIES.

EGHAM AND DISTRICT GARDENERS'.—The ninth annual dinner of this society took place on the 19th ult.; the president, Mr. W. G. Rigden, occupied the chair, and about 180 sat down to dinner. The chairman said that the principal object of these dinners was to bring together those interested in the work of the association and gardening generally. Mr. Swan alluded to the proposed new scheme of the Royal Horticultural Society, and the effect it may have on gardeners. In response to the toast of "The Chairman," Mr. Rigden said it gave him great pleasure to help gardeners. He was pleased to become their first president. Mr. G. Baskett, among other speakers, made some remarks on the responsibilities of gardeners having control of large gardens.

BATH GARDENERS'.—A meeting of the Bath Gardeners' Debating Society was held at the Forester's Hall on Monday, the 23rd ult. In the absence of the chairman (Mr. T. Parrott), Mr. G. Garraway presided. The chairman informed the meeting that Mr. C. Phillips had promised to give a silver medal to the exhibitor of the best bloom in the Chrysanthemum Show this year. The paper for the evening was delivered by Mr. C. J. Wait, on "Strawberries." The lecturer stated the Strawberry grows best in a deep, rich loam, but success might be obtained on almost any kind of soil by intelligent and liberal treatment. The Strawberry is a gross feeder and it is impossible to overdo it with manure. Any difficulty in the nature of soil can be easily overcome by treatment, but the beds must be given an open situation.

BANFFSHIRE HORTICULTURAL.—The annual meeting of the members of this association was held recently in the county town—Banff. There was a good attendance, and Mr. A. Mann, Broadcroft, presided. The secretary (Mr. Badenoch) submitted the annual balance-sheet, which showed that the income for the year amounted to £103 14s. 8d., and the expenditure to £104 8s. 2d. The ordinary income was £10 0s. 8d. more than in the previous year, and the expenditure was £1 4s. 8d. less, there being due to the treasurer the sum of £9 17s. 9d. A committee was appointed to arrange means of raising money.

BRISTOL AND DISTRICT GARDENERS'.—The usual fortnightly meeting of this association was held at St. John's Parish Rooms on Thursday, February 26, when Mr. Baston occupied the chair. The lecturer for the evening was Mr. Goodger, a member of the Reading Gardeners' Association, his subject being "Melons." The prizes offered by Messrs. Mansell and Hatcher for two Orchids in bloom were won by Mr. Scott (1st), Mr. Baston (2nd), and Mr. Jennings (3rd).

PLYMOUTH AND DISTRICT GARDENERS'.—This association met in the Mutley Grammar School on the 21st ult., Mr. T. R. E. Olver presiding. Mr. T. Willocks delivered a lecture on "The History of Some of Our Cultivated Vegetables." He stated that previous to the Roman invasion of Britain the inhabitants of this country fed on uncultivated roots and herbs. The Romans were famous for their knowledge of horticulture, and undoubtedly they taught us the art of cultivating vegetables. There were no books on plants in English before the sixteenth century, and as in 1552 orders were given for scientific books to be destroyed, it was almost impossible to know much about gardening before the time of Henry VIII., after whose reign rapid strides were made, due to Flemish settlers near London. Many gardens planted by them still flourish. Mr. Willocks traced the history and development of the Potato. The antiquity of the Garlic was spoken of, and the lecturer concluded with the history of the Cabbage.

DUMFRIES AND GALLOWAY GARDENERS'.—The president, Mr. S. Arnott, occupied the chair at the monthly meeting of this association held on the 26th ult., in the Wesley Hall, Dumfries. A paper on "Mannes and Manuring" was read by Mr. Alexander Frame, gardener to Sir J. E. Johnson-Ferguson, Bart., Springkell. Mr. Frame pointed out the value of the different manures, and considered them in regard to their uses to horticulture.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS'.—At the meeting of this association held on February 22, in the presence of a crowded audience, Mr. J. Smith, of King's Heath Park, Birmingham, read a paper on "The Perpetual Flowering Carnation." He stated that in 1893 he was in the employ of the late Baron F. Rothschild, and that he became acquainted with Carnation-growing when the cultivation of this flower was almost solely in the hands of a few. In those days old favourites like Mrs. Moore, Mrs. Llewellyn, Mrs. L. Rothschild, and Miss Jolliffe were the glory of Waddesdon Manor and Blenheim House. To-day these varieties had been displaced by such specimens as those he had displayed in two vases, comprising Britannia, Mrs. Burnett, Beacon, Enchantress, R. F. Felton, Windsor, and others. Directing attention to two sectional drawings of suitable Carnation houses, he demonstrated that well-ventilated, high-span roofing and good sidelights render it possible to obtain the proper atmospheric conditions which are imperative for cultivating this plant. He recounted all the details of potting, made recommendations regarding the making up of the compost, and advised that certain methodical treatment be observed in order to elude the dangerous insect pests. The paper gave rise to an interesting discussion, in which Messrs. Cryer, Sean, and Webb participated.

READING GARDENERS'.—The Rev. F. Page Roberts (ex-president of the National Rose Society) lectured on "Roses and Their Culture" to a crowded meeting of the members of this society on the 16th ult. Mr. G. G. Hamilton illustrated the lecture by autochrome lantern slides of Roses and of gardens at Bournemouth and neighbourhood. Mr. Roberts emphasised the necessity of proper drainage in Rose growing, pure air also being as necessary for plants as for people. The application of water with a can and a rose was worse than useless, because moistening the top of the ground resulted in the roots growing on the surface, and were then scorched by the sun. His practice was to loosen the ground with a hoe, and then gently pour in water so that it soaked right down to the roots. He confessed he failed to understand mildew. The only way to combat it was to begin spraying immediately after pruning in March. They needed an appliance that would distribute the finest spray into every cranny.

BRITISH GARDENERS' ASSOCIATION (Leamington Branch).—A meeting of the Leamington branch of the B.G.A. was held on the 28th ult., when a lecture on Rock Plants and Alpines was given by Mr. R. T. Law, Rhine Hill Gardens, Stratford-on-Avon. The subject was most exhaustively dealt with by the lecturer, and at the close of his remarks a discussion ensued, all members present taking part.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending February 28, is furnished from the Meteorological Office:—

GENERAL REMARKS.

March 3, 1914.

At the beginning of the week the centre of a large depression advanced over Ireland from the Atlantic. The system was unusually deep; at Dublin the barometer fell between 9 and 10 a.m. on Sunday as low as 950 millibars, while over the whole of the United Kingdom, except Shetland, the readings were below 982 millibars. The surrounding gradient was steep, and strong to high winds or gales occurred on all parts of the coast, from the eastward in Scotland, but from the southward, south-westward, and westward in most of the English and Irish districts. The disturbance moved rather slowly northward, and became less deeper, but did not disperse until the middle of the week. No other depressions of importance passed directly over these islands, but some large and deep systems arrived in the Icelandic region, and the general direction of the wind over this country was southerly or south-westerly, and its force occasionally strong along the western and north-western seaboard. Rain was experienced almost daily over a large area in the extreme west and north of the Kingdom, but in the east and south several days were dry, and some of them exceedingly fine and bright. A few stations in Scotland and the north of Ireland received more than 0.5 inch of rain on the 22nd, but the subsequent falls were, as a rule, moderate to very slight.

THE WEATHER IN WEST HERTS.

Week ending March 4, 1914.

The Fifth Unseasonably Warm Week in Succession.—Another warm week, and the fifth in succession. This was on the whole a much warmer week than the previous one, but on two nights the exposed thermometer registered respectively 9° and 12° of frost, the latter being the coldest night in February, but by no means unusually cold for the time of year. The ground is at the present time 1° warmer at 2 feet deep, and 3° warmer at 1 foot deep, than is seasonable. Some rain fell on two days, but to the total depth of less than a tenth of an inch. For the last few days there has been no measurable percolation of rain-water through either of the soil gauges. The sun shone on an average for four hours a day, which is rather more than an hour a day in excess of the average duration for the time of year. On each of the three sunniest days the sun was shining brightly for about eight hours a day. The first three days of the week were very calm, but since then the wind has been as a rule moderately high. The mean amount of moisture in the air at three o'clock in the afternoon fell short of a seasonable quantity for that hour by 7 per cent.

FEBRUARY.

Remarkably Warm, Very Wet, and Sunny.—In the last twenty-nine years there has been only one other February as warm, and that was in 1903. There did not occur a single unseasonably cold day, and there were only five cold nights. On the warmest day the highest reading in the thermometer screen was 57°, and on the coldest night the exposed thermometer registered 12° of frost. Both of these extreme readings are exceptionally high for the month. In fact, in the last twenty-nine years there have been only three other Februaries with as high a day temperature, and but two other Februaries when the lowest temperature on grass has been as high. Rain fell on sixteen days, and to the total depth of 3 inches, which is over an inch in excess of the February average for the previous fifty-eight years. There was little rain on the first five and last seven days of the month. Some snow fell on one day, preceded by rain and followed by a fall of soft hail, which for a short time nearly covered the ground. The sun shone on an average for 2½ hours a day, or for about ¼ hour a day longer than is usual in the last winter month. The wind was, as a rule, if anything, rather high for February, and in the windiest hour the mean velocity reached twenty-one miles—direction S.S.W. The average amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by 2 per cent.

THE WINTER OF 1913-14.

Very Warm and Remarkably Dry, with a Good Record of Sunshine.—This was the fifth unseasonably warm winter that we have had in succession, but was not so warm as either of the two previous winters. Taken as a whole, December was decidedly warm, January about average, and February remarkably warm. On the warmest day the temperature in the thermometer screen rose to 57°, which has been exceeded in only three of the preceding twenty-eight winters. On the coldest night the exposed thermometer registered 20° of frost, which is in no way remarkable. The total rainfall amounted to 4½ inches, or as much as 2½ inches in defect of the average for the season. In the last fifty-eight years there have been only nine other winters as dry as the past season. Both December and January proved remarkably dry, while February, on the other hand, was unusually wet. Snow fell on only seven days, and on no day was the ground completely covered by it. The sun shone on an average for one hour fifty-one minutes a day, which is nine minutes a day in excess of the average duration for the season.

OUR UNDERGROUND WATER SUPPLY.

Since the winter half of the present drainage year began in October the total rainfall has been 11½ inches, or 1½ inches in defect of the average for the same five months in the previous fifty-eight years, which is equivalent to a deficiency of rainfall on each acre in this district of 38,460 gallons. At the same time last year there was an excess of 7,010 gallons per acre. E. M., Berkhamsted, March 4, 1914.

Obituary.

HARRY COPAS.—The *American Florist* records the death of Mr. Harry Copas, member of the firm of Copas Bros., Elyria, U.S.A., at the age of 34 years, on February 2, after an illness of a year. Mr. Copas was a native of England and settled in America with his parents when a child.

APPLE SHOOTS DISEASED: R. Turner. The disease is Apple scab. Spray the trees with the Bordeaux mixture this spring, and next winter, when the trees are resting, drench them thoroughly with a solution of sulphate of copper—1 lb. in 25 gallons of water.

CORRECTION.—Messrs. W. Cutbush and Son's exhibit of forced shrubs, Carnations and Alpines at the R.H.S. meeting on the 24th ult. was awarded a Silver-gilt Flora Medal.

CYCLAMEN FAILING TO FLOWER: Stanwell. An excess of manure or growing the plant in too much warmth may partly account for the trouble. A minimum temperature of 55° is too high, except in the earlier stages of growth. The fault may be an inherited one, from lack of care at some time in seed selection. Non-flowering is more frequent in the giant-flowered forms, and it is usually accompanied by very vigorous leaf growth—a superabundance of leaves; the top of the corm, instead of developing the usual symmetrical crown of leaves, seems to break up and develop a crowded mass of foliage; this condition may arise from injury in the younger stages of the plant.

DEFORMED AZALEA LEAF: Novo-castro. The plant is attacked by a fungus—*Exobasidium rhododendri*—which causes the gall-like swellings on the leaves. If the galls are sought out and removed to the fire before they have developed any colour the same plants are free from attack in the following year, and this treatment is therefore the one that the cultivator should apply. The disease was described in the *Gardeners' Chronicle* so long ago as July 19, 1879, p. 119. See also the issue for August 9, 1879, p. 182.

FIG TREE DISEASED: G. Bates. The specimen submitted for examination was attacked by the Fig-tree canker, *Libertella ulcerata*. Cut out all diseased parts and cover the wounds with gas-tar. Entirely remove and burn the one diseased tree, as the complaint spreads rapidly.

KENTIA PALM ROOTS: C. C. G. The insects attacking the Palm roots are known as the Root-feeding Mealy-bug (*Ripersia terrestris*). Growing plants that are attacked with this insect should be removed from the pots and the exposed roots and soil sprayed with carbon bisulphide, using a glass spraying apparatus. It will be best to scald the pot and have it in readiness for replacing the plant immediately after spraying. It will be found that this treatment will not kill the eggs, so the process must be repeated. Shade the plants from sunshine for a week after treatment.

MUSHROOM BED: F. S. There is absolutely no cure when a Mushroom bed is invaded by another fungus. The only thing is to clear out all the old materials, disinfect the house, and start afresh.

NAMES OF PLANTS: H. J. Van Heyrt. *Senecio Petasitis*. — F. H. 1, *Dendrobium crystallinum*; 2, *Dendrobium Pierardi*; 3, *Eria acervata*; 4, *Pholidota imbricata*. — *Constant Reader*. *Selaginella Kraussiana*, commonly known in gardens as *Selaginella denticulata*. — Bourne. 1, *Epidendrum Stamfordianum*; 2, *Brassavola Perrinii*. (Insects next week.) — J. K. B. *Symphytum tuberosum*.

PEACH GROWTHS DISEASED: R. M. P. The trouble is due to silver-leaf. Silver-leaf disease is caused by the fungus *Stereum purpureum*, and there is reason for believing that infection may take place from the soil. Therefore, if you use the old compost it should be only after sterilisation. The infected soil may be spread in the vegetable quarters or on a herbaceous border, but not near trees.

PERPETUAL-FLOWERING CARNATION: T. J. R. The flower of the seedling Carnation which you consider to be finer than Rose pink Enchantress appears to be of good quality, so far as can be judged from a single specimen. Whether it is perfectly distinct from all varieties in cultivation we are not able to say; but it would certainly be desirable to cultivate it with a view to showing it next season before the Committee of the Perpetual-Flowering Carnation Society or the Floral Committee of the R.H.S.

TOMATO SEEDLINGS COLLAPSING: J. H. A. The Tomato seedlings are attacked by the Damping-Off fungus—*Pythium de Baryanum*. It is a common trouble with seedlings raised in heated houses, where the soil and atmosphere are usually charged with moisture. Thick sowings favour the disease. Care must be taken in ventilating the propagating frame. Pull out the worst of the seedlings and pour dry sand or sand and charcoal mixed amongst them. Stand the seedlings on a shelf near to the roof-glass, where the conditions are drier.

TROPICAL FRUITS CULTIVATED IN GREAT BRITAIN: M. Buysman, Java. The following is a list of tropical plants that may be included under the above term, and whilst it is in no sense a full and complete one, it will doubtless be of assistance to you. Many of these plants have fruited repeatedly in Great Britain, but few of them develop that full and rich flavour characteristic of the fruits grown under natural conditions:—*Mangifera indica* (the Mango), in variety; *Grias cauliflora* (Anchoy Pear); *Nephelium Lit-chi* (Litchi); *Cyphomandra betacea* (Tree Tomato); *Aberia caffra* (Kei Apple); *Sarcocephalus esculentus* (Negro Peach); *Eugenia malaccensis* (Malay Apple); *Eugenia gambos* (Rose Apple); *Eugenia jambolana* (Jambolana); *Psidium Guava* (Guava); *Psidium Cattleyanum* (Mountain or Purple Guava); *Anona squamosa* (Custard Apple); *Anona muricata* (Soursop); *Carica Papaya* (Papaw); *Carica candamarcensis* (Mountain Papaw); *Punica Granatum* (Pomegranate); several species of *Passiflora* with edible fruits, known as *Granadillas* or *Passion Fruits*, including *P. edulis*, *P. quadrangularis*, *P. macrocarpa*, and *P. laurifolia*; *Diospyros Kaki* (Kaki Plum or Persimmon) in several varieties; *Persea gratissima* (Avocado Pear); *Eriobotrya* (Photinia) japonica (Loquat); *Casimiroa edulis* (Mexican Apple); *Ficus carica* (Fig); *Vitis vinifera* (Grape); *Prunus persica* (Peach); numerous varieties of the Orange family, including the *Citrus nobilis* (Mandarin Orange); *C. Aurantium* (Sweet Orange); *C. Limonium* (the Lemon); *C. decumana* (Shaddock); Grape Fruit, a variety of *decumana*; *C. acida* (the Lime); *C. Medica* (the Citron); *C. Limetta* (Sweet Lime); *C. Tangerina* (Tangerine Orange), etc.; *Garcinia Xanthochymus*, (Mangosteen); *Theobroma Cacao* (Cocoa); *Coffea arabica* (Arabian Coffee); *Coffea liberica* (Liberian Coffee); and *Camellia theifera* and its var. *assamica*, which furnish the Tea of commerce.

**GARDENS FOR THE POOR
IN FRANCE, GERMANY, ENGLAND
AND AMERICA.**

MME. FÉLICIE HERVIEU, of Sedan, was in the habit of giving financial assistance to a family of ten, and yet they were always in want. The benefactress was struck by this fact, and at last said to the head of the family, "You must be saved from this plight. Instead of giving you continual temporary help I shall put 6 francs in the savings bank for you every month for one year, on the condition that you add 3 francs to it." It was difficult, but it was managed, and thus in a year's time 108 francs were saved. "Now you must employ the money advantageously," said the lady. "Rent a garden and work in it in your free time with your children." Averse from work and accustomed to help, the people seemed unable to find a garden, but Mme. Hervieu soon found one, and urged her protégés to work. At first unwilling, they soon took pleasure in it, and at the end of a few months found themselves able to obtain from their plot a large proportion of their food, as well as earn a fair sum of money by the sale of vegetables.

This was the beginning, about twenty years ago, of the present extensive charitable movement in France to institute gar-

dens for the poor. Mme. Hervieu's success induced a number of ladies in Sedan to lay by 60 francs each—instead of giving small alms in the streets—to enable them to supply garden plots for cultivation by the poor, and thus to fight against the professional begging so widely practised in the town. At first some 1,600 square yards were rented and divided between twenty-one families; seeds, manure and implements were placed at their disposal. This cost 531 francs during the first year—a sum which would have amounted to only 0.30 francs per head monthly if it had been given in coin, whereas in the form of garden plots it supplied 145 persons with a considerable part of their nourishment.

Mme. Hervieu then founded a society, "L'œuvre de la reconstitution de la famille," to facilitate the systematic diffusion of her ideas. By this society large families were allotted garden plots of from about 400-800 square yards each, according to the number of children, and also implements, manure and seeds. In 1895 a fresh venture was made by entrusting a similar plot of garden land to a set of lads from 15 to 16 years of age for their joint cultivation, on the condition that each lad should pay one franc from his profits monthly into the savings bank. In the first year the net proceeds amounted to 50 francs a head, and in 1899 a further step was taken in granting plots on similar conditions to school children of eleven to twelve years. Thus in 1903 there were in Sedan 260 organised gardens for the poor, occupying an area of some 55 acres, and cultivated by 1,500 workers. In the whole of France there were in 1906 11,547 such gardens in 224 towns, which were contributing to the support of no fewer than 40,000 persons.

Father Volpette, a Catholic priest in St. Etienne, who learnt of the successful efforts of the Sedan ladies, followed the example, rented a field of 3½ acres for 200 francs, and divided it into plots of 470 square yards, which he assigned to 30 needy families. Later he rented more land, and other plots were given him gratuitously. By the end of the year, with an outlay of 350 francs, he had about 12 acres at his disposal, which were divided among 98 families (608 persons in all). Fencing, draining, implements, manure and seeds cost 3,050 francs. In spite of drought, the proceeds of the outlay of 3,400 francs amounted to about 6,000 francs by the market sale of vegetables, including Potatos—that is to say, to over 60 francs per family. In the following years expenses came to about 1,500 francs per annum, while the profits, even in bad harvests, have amounted to from 6,000 to 7,500 francs, and of course much more in good years. Father Volpette made four conditions with his protégés:—Diligent, daily cultivation; Sundays and church holidays strictly excluded; no under-letting without an agreement; the avoidance of everything that could harm the good reputation of the allotment holders. I append an extract from Father Volpette's "Constitution":—

"Each combined group of gardens has its own board of directors. For this pur-

pose every five families choose a representative for three years. All the representatives of a group form its board of directors, who have to decide upon all matters of common interest to the garden owners. They also determine the extent of outlay to be made in favour of the separate families from the capital of the group, and can refuse seeds if the land is insufficiently prepared, and even decree the expulsion of families with the ratification of the General Council. The latter possesses the following powers:—Final decision as to admittance or expulsion; decision as to the amount to be spent on each group of gardens; alteration of the regulations and by-laws; deliberation over the common interests of the groups."

Father Volpette's enterprise is not only distinguished by its "Constitution," but also by facilities in the way of dwelling-houses. One day an old, disabled miner drawing a small pension began to erect a very primitive dwelling of only 24 cubic metres upon his allotment. It was a rather curious cottage, but it answered the purpose, and served to induce others more skilled in building to follow suit. In order to cheapen the building materials Father Volpette founded a brick-yard that was able to sell at 3 francs the thousand. The bricks are of the best quality, and are mostly made by allotment holders temporarily unemployed. There are at present about 800 Volpette gardens, from which nearly 4,500 persons draw profits. There exists also a Raiffeisen bank granting loans up to 500 francs, and defraying two-thirds of the cost of cottage-building for members able to furnish one-third from their own savings. In his *Arbeitergärten, Schülergärten*, Herr W. von Kalkstein mentions a remarkable experiment, without, however, naming the locality:—

"A French enterprise grants each garden contract for four years. The first year the allotment holder receives land, manure, seeds and plants free of charge, in the three following years the Association only bears the expense of the land rent, and from the fifth year onwards the garden-holder must pay a rent of 8 marks annually."

This excellent plan appears to have met with success all over France. Those disinclined for work learned to like regular activity, worked for themselves and finally became proud, in a good sense, of their independence. Their life in the gardens, where they can eat with their families, makes them lose their former predilection for the public house. In course of time they become thrifty, their manners improve, and in some instances they become prosperous. It is indeed not surprising that statesmen should have endeavoured to obtain for these small gardens the advantages of the excellent Small Dwellings Act of 1886, which makes provision (at 2 per cent.) for loans from public funds and interdicts distraint upon the holdings. An Act for this purpose came into force in April, 1908. *Leopold Klatscher.*

(To be continued.)

PRIMULA MALACOIDES.

As a plant for the amateur for greenhouse and window decoration during winter this beautiful *Primula*, which was introduced a few years ago from China by Mr. Forrest, stands unrivalled. The whole plant has a light and graceful habit, the inflorescences especially possessing a beautiful appearance, whilst the fragrant flowers vary from white-lilac to deep pink in shade. The plant is extremely easy of culture, and will grow out of doors on a rockery in a sheltered nook, flowering and ripening seeds freely, only needing protection from cold winds and extreme dampness.

flowered form was exhibited by Messrs. Bees, Limited, and the Floral Committee granted it an Award of Merit.

On January 13, 1914, Mr. James Box, Lindfield, Hayward's Heath, submitted to the Floral Committee of the R.H.S. the strong, vigorous growing form illustrated in fig. 82. The plant has stouter stems, a more robust habit, and flowers twice the size of those of the type, the colour being the deepest shade of pink yet seen in the species.

The origin of the giant form is unknown, but there is a possibility that it is an accidental cross with *Primula Forbesii*, as several plants of the latter species were growing in the same house, and in proximity with the seed-

[Photograph by R. A. Malby.]

FIG. 82.—GIANT-FLOWERED FORM OF PRIMULA MALACOIDES.

Seeds sown in pots or boxes during the spring germinate readily. The seedlings should be placed on a shelf until ready for pricking off. Watering must be done with extreme care, otherwise damping will occur. Afterwards prick off the seedlings into boxes until they are established and possess several leaves, when they may be potted, three in each 5 inch pot, or singly in $\frac{3}{4}$ inch pots. Grow them on a shelf in a greenhouse and gradually harden them for placing in a cold frame. Watering in summer must be done very carefully. The soil should consist of one part leaf-mould and two-thirds sandy loam; admit an abundance of air on all favourable occasions.

At the meeting of the Royal Horticultural Society on December 2, 1913, a beautiful double-

bearer. Furthermore, later batches have contained several more of this pronounced variety. At first sight it would appear to have *Primula Veitchii* blood in it, but this is impossible, as at the time the seed was saved no plants of *P. Veitchii*, or of any similar type, were in stock. The foliage greatly resembles *P. Veitchii*, but the colouring is that of *Primula Forbesii*; while it is quite distinct from the new hybrids raised by M. Lemoine, Ville de Nancy and La Lorraine. *E. S.* [The suggestion that the giant form of *Malacoides* is the result of a cross with *P. Forbesii* does not receive support from the results of numerous experiments which we have made. Although we have made the cross many times in both ways no fertile seed has been obtained.—Eds.]

POLLINATION EXPERIMENTS WITH FRUIT TREES.*

POLLINATION trials with fruit trees were commenced by Mr. W. O. Backhouse in 1911 at the John Innes Horticultural Institution, and are still in progress. The object of these experiments is to find the degree to which varieties are fertile with their own pollen, and, in the case of those which are self-sterile, to select good pollenisers for them.

PLUMS.—The varieties of Plums can be grouped into three classes according to their behaviour when self-pollinated:—(1) Self-fertile, (2) self-sterile, (3) partially self-sterile, setting about 1 per cent. of their flowers when self-pollinated.

From the point of view of the practical grower the last-named class should be treated as self-sterile, and planted beside other varieties.

The varieties which have been tested up to the present can be classed as follows:—

SELF-FERTILE.—Denniston's Superb, Early Mirabelle, Reine Claude Violette, Myrobalan, La Prune Géante, Monarch, Early Transparent, Reine Claude de Bavay, Prince Engelbert, Early Favourite, Gisborne's, Oullins Golden, Golden Transparent, Victoria, Czar, Pershore, Red and White Magnum Bonum, Kentish Bush, Warwickshire Drooper, Damson vars.

SELF-STERILE.—Histon Gage, Early Orleans, Late Orleans, Sultan, Kirke's Blue, Coe's Golden Drop, Coe's Violet, Wyedale, Grand Duke, Jefferson, Reine Claude d'Althann, Pond's Seedling, Washington, Early Green Gage, Old Green Gage, Curlew, Ickworth Impératrice, Late Transparent, Prune d'Agen.

PARTIALLY SELF-STERILE.—Rivers' Early Prolific, Stint, Mallard.

When the self-sterile varieties were cross-pollinated a few cases of inter-sterility were observed, although they appear to be rare amongst Plums. Thus it was found that Cox's Golden Drop would not set fruit with pollen from Coe's Violet.

If Coe's Violet is a bud sport from Coe's Golden Drop, as seems almost certainly to be the case, one would not expect them to be fertile with one another, seeing that they are parts of the same self-sterile individual.

Coe's Golden Drop and Jefferson are apparently quite inter-sterile, nor will the pollen of Jefferson set fruit on Coe's Violet.

The two Gages, Early Green Gage and Old Green Gage, only set about 5 per cent. of their blossoms when inter-pollinated, and Rivers' Early Prolific does not appear to set well with pollen from Early Favourite.

Apart from the above cases it was found that the self-sterile varieties which have so far been tested set freely when cross-pollinated.

Coe's Golden Drop set a full crop when crossed with any of the following varieties:—Rivers' Early Prolific, Reine Claude d'Althann, Wyedale, Early Mirabelle, Reine Claude Violette, Denniston's Superb, Monarch, Prune d'Agen.

Jefferson was quite fertile with Early Transparent, Monarch, Rivers' Early Prolific, and Reine Claude d'Althann.

Reine Claude d'Althann set freely with Coe's Violet, Coe's Golden Drop and Jefferson.

Washington set freely with Pond's Seedling and Late Transparent with Early Transparent.

It is not yet known which Plums will prove the best pollenisers for the Green Gages, but they will probably be found amongst such varieties as Monarch, Rivers' Early Prolific and Pond's Seedling.

CHERRIES.—As yet comparatively few varieties of Cherries have been tested at the John

* Summary of paper read by Mr. G. O. Sherrard at the annual meeting of the National Federation of Fruit Growers, February 25, 1914.

Innes Institution. Those that have been tried are as follows:—

SELF-FERTILE.—Morello, Late Duke.

SELF-STERILE.—Black Tartarian, Elton, Bigarrean Frogmore Early, Bigarrean Jaboulay, Bigarrean Napoleon, Black Heart, White Heart, Kentish, Guigne d'Annonay, Early Rivers, May Duke (set 8 fruit out of about 1,700 flowers self-pollinated).

In cross-pollinating the self-sterile varieties it was found that Elton and Bigarrean Frogmore Early set freely when inter-pollinated, but neither set a good crop with pollen from Late Duke. V. R. Gardner,† in America, observed that Bigarrean Napoleon and some American-raised Bigarrean varieties were almost sterile with May Duke pollen, so that possibly it is a general rule that the Bigarreans are not fertile with the Dukes. Further trials are being carried out to ascertain whether this is the case.

Black Heart is fertile with Morello pollen, and Guigne d'Annonay with pollen from Bigarrean Napoleon.

APPLES.—In Apples self-sterile and self-fertile varieties occur, and also a class which when self-pollinated yields seedless fruits. Nine varieties were studied.

SELF-FERTILE.—Baldwin, Washington, Stirling Castle.

SELF-STERILE.—Northern Greening, Lord Hindlip, Cox's Orange Pippin.

SETTING SEEDLESS FRUIT WHEN SELF-POLLINATED.—Lord Derby, Golden Spire, Duchess of Oldenburg.

The seedless Apples are usually smaller than the fruit of the same variety containing seed, but this is not always the case. In order to secure a uniform crop with these varieties it is advisable to treat them as if they were self-sterile and plant them with other sorts.

Cox's Orange Pippin does not appear to set equally well with different varieties; the best set was obtained with pollen from Duchess Favourite and Stirling Castle, while few fruit set with Lord Derby, and none with pollen from Bramley's Seedling. This variety (Cox's Orange Pippin) is undergoing further trial.

NURSERY NOTES.

PRIMULAS AT READING.

ALL Primroses are beautiful plants for the garden, where each has some special place and value, but, as in other families, one member is of greater importance than all its fellows, and in this genus it is *P. sinensis*, so that when gardeners speak of Primulas they refer to the cultivated forms of this species. The Chinese Primula is a remarkable flower in many respects. It is one of the best examples of a florist's flower, a term associated with those that have been so changed by cultivation and breeding as to bear little or no resemblance to their wild progenitors. The florist's Primula has been so far altered from the wild form that many doubt if its ancestral type is known, and will not accept Wilson's *P. sinensis* as its parent. How and when, then, was its career started, and by whom? By what means did we come to possess this invaluable plant, and what is the date of its introduction into Europe? All this remains a mystery beyond the fact that the flower has been cultivated in China for ages, and was introduced to Europe somewhere about the year 1821. But, clever as the Celestial may be, we have no evidence that he has raised anything approaching the beautiful forms that we possess, such as may be seen in Messrs. Sutton and Sons' nursery at Reading, where many glass-houses are filled with the manifold forms of the plant. The varieties enumerated in the seed catalogue of this famous firm number

no fewer than 50, and the Reading collection represents most of the finest sorts in cultivation. Those with compact, solid trusses and big blooms, of which Duchess may be cited as an example, were the chief fancy of the older florists; hence until recently progress was greatest in this direction. To distinguish them from those of the star type, they are known as *sinensis* varieties. But in recent times the star or Stellata Primulas have become as popular with growers as the older form, and they lend themselves even better to decorative uses. As cultivated in separate batches for seed purposes, row after row of the same variety gives a very formal effect, although collectively they make an impressive scene of floral beauty. These same Primulas, intermixed in the green-houses and conservatory at Hillside, Reading, the residence of Mr. Leonard Sutton, had quite a different effect, and some of the more attractive groups which we observed on a recent visit may be described.

The one that pleased us most was arranged on a central stage, which was filled with Silver Star and Ruby Star varieties, the former with eyeless flowers—that is, devoid of any trace of colour in the eye. Another very effective group was of Coral Pink and Crimson King, with spikes of the blue Salvia-like flowers of *Pycnostachys* arising at intervals. Stellata Coral Pink associated well with Giant White Star, and the latter also harmonised finely with Ruby Star. Pearl White and Coral Pink, both of the *sinensis* type, looked well together, the pale green foliage of the former enhancing the effect.

Primula malacoides, with its light and graceful trusses, makes a fine companion for any of the Chinese Primulas, and it was used most effectively at Hillside with White Queen and Pale Blue Stellata varieties. In another group were *P. malacoides*, white Hyacinths, and various large-flowered Primulas.

The plants grown for seed in the nursery number many thousands, and house after house is filled with them. Many of the sorts are old favourites, but Primulas are constantly changing, hence the visitor to Reading always finds something new. The old Giant White variety, sometimes known as Queen, has often a faint blush in the petals, but Messrs. Sutton's newer Giant Royal White is without this defect. The plants are distinct in foliage, for in the first the leaves are light green, whereas in the latter they are dark-coloured. It is noticed that white varieties with green stems generally develop a tinge of pink in the blossoms, so that the petals are never a dead white. There are other "Giants" in lavender, pink, crimson, salmon, and other shades. Giant Lavender is a most beautiful variety, but it is one of those unfixable sorts which cannot be relied upon to come perfectly true to seed. It is a hybrid raised from a white-flowered, dark-stemmed variety and the old Giant Red. Many of the "Giants," for example Giant Crimson, are poor seeders.

In Reading Scarlet we have the nearest approach to that colour, but there is none of a true scarlet shade in Primulas. The deepest of the blues is The Czar, whilst Reading Blue is a beautiful pale lavender colour. Lord Roberts is quite one of the best in the salmon shades, and occurs both in the "fern" and "palm" leaf forms of foliage. Plenty of heat enhances the colouring in this variety, although in many sorts it causes the blooms to become "washy." Giant Salmon Pink and Crimson King also throw brighter flowers in a very warm house, but in these cases the "pips" come smaller. The Fern-leaved form of Crimson King is not so robust as the type. Most of the staging in one house was filled with plants of the Duchess, which was raised from a dark-stemmed, white variety crossed with Crimson King. The Duchess is still the very finest in its class. It stands out

mainly by reason of its bright pink-coloured zone in the centre, contrary to what obtains usually, for in most others the more pronounced colouring is on the outside.

There are double forms of the Duchess, but in these the zone is partly hidden by the super imposed petals, which spoil the effect. Some of the other double sorts, however, are very pretty, especially Double Pink. There are also Duchess hybrids. One known as Lady Roberts is particularly beautiful, but it does not breed true, and is therefore not enumerated in the catalogue. It was raised from Duchess crossed with Crimson King. Brilliant Rose is one of the easiest of Primulas to cultivate, and for this reason is a favourite with amateurs, and the same may be said of Pearl, which is one of the best white varieties for general purposes.

One of the largest divisions, known as the "triple" house, because of the three-span roofs covering it, was filled entirely with Stellata varieties, the effect of which was superb. The pretty Dark Blue and Pale Blue Star varieties—counterparts of The Czar and Reading Blue—mark a great advance in this section. They associate finely with other shades. Pale Blue is especially pretty mixed with Coral Pink Star. Stellata Pink is a fine variety, but Messrs. Sutton have one better in Delicate Pink, the foliage of which is very pale—really bright green, palest among all the Star varieties. In contrast were some near by with stems almost a maroon colour—the variety Giant Carmine.

White Star has been improved, and a newer form with larger flowers and paler foliage is known as Giant White Star. White Queen is a very free bloomer; the foliage is neither very dark nor very pale, but intermediate. The original White Stellata form has dark-coloured leaves; it was noticed that many of the petals in this variety were marked, sometimes entirely, with lilac-pink. In the newer eyeless white variety even the yellow flush of the eye is absent. Parti-coloured varieties crop up now and then, and Messrs. Sutton have fixed one that has petals splashed with carmine. It is named Centenary, but there is no demand for it, the present taste being for those with self or clear colours. Stellata Lord Roberts is a very striking colour—rich carmine, but not so dark as Ruby, which has petals coloured crimson. There are some in this section with the characteristic "Duchess" eye, although not so pronounced as in the *sinensis* form, yet very beautiful. They are the offspring of a dark-stemmed White Star variety crossed with Ruby (Stellata). Ruby has yellow in the eye, but this has disappeared in the one known as Eyeless Ruby. Partial doubling has taken place in some of the star Primulas, and Messrs. Sutton have a race of these semi-double varieties.

The Cyclamens, which make such fine companions for the Primulas, were just past their best show, but sufficient remained to prove the excellent strain, which includes many choice named varieties.

PLANT NOTE.

NERTERA DEPRESSA.

This pretty berry-bearing plant was formerly grown largely for use in carpet-bedding. In more recent times it has been less frequently seen, though some excellent exhibits at the R.H.S. Hall last year clearly showed that the plant is still well cultivated. In former years I grew it largely, and found it expedient to increase the plant by division, usually in February, thereby enabling it to make growth and become established before flowering in April or May. The flowers are inconspicuous and sessile, and it is not a little remarkable that so fine a

† Bulletin 116, Oregon Experimental Station, U.S.A.

crop of brilliant scarlet berries should result. The plant grows freely in a mixture of sandy loam, peat and pounded brick rubble, and while not objecting to greenhouse treatment, is quite amenable to cultivation in a cold frame. Cultural items of importance include the withholding of overhead waterings and the giving of an abundance of air at flowering time. At other times an abundance of overhead moisture is beneficial. I grew the plant in cold frames, and it never received more than mat protection in the severest weather. *E. J., Hampton, Middlesex.*

TREES AND SHRUBS.

ARBUTUS MENZIESII AT BAYFORDBURY.

ALTHOUGH introduced by Douglas so long ago as 1827, this beautiful evergreen tree is still scarce in English gardens. The specimen illustrated stands in a sheltered position on the lawn at Bayfordbury, Hertford, the seat of H. Clinton-Baker, Esq., who kindly sent me the photograph, which was taken recently by Mr. Elsdén, of Hertford. The tree, which is now 29 feet high with a stem 2 feet 5 inches in circumference at 3 feet from the ground, was sent to the owner's grandfather about 30 years ago as a very small plant. In the autumn it produces masses of orange-red berries,* which form a striking contrast to the shining foliage and make the tree very ornamental. The reddish papery bark so characteristic of *Arbutus* is very noticeable in this species.

The Madrona, to give the tree its native name, attains its greatest size in California, where, under favourable conditions, it grows to a height of 100 feet. It is distributed through the Pacific coast region from Southern British Columbia through Washington and Oregon, to California. Its southernmost limit is in the Santa Lucia mountains. Here it becomes shrubby in habit. This species is quite hardy in England, except in a young state, when the shoots are sometimes frosted. Trees up to 50 feet high are known in England, the largest on record being one at Bassett Wood, near Southampton. I have not seen this tree, but according to Elwes and Henry,† it measured in 1907 50 feet in height with a stem clear for about 20 feet, and 3 feet 2 inches in girth. *Arbutus Unedo* also made a brilliant show at Bayfordbury last autumn, with its masses of "strawberries," but the birds made short work of them. *A. Bruce Jackson.*

FLORISTS' FLOWERS.

CHOICE COLLERETTE DAHLIAS FOR GARDEN DECORATION.

(See Coloured Plate.)

AFTER a few years, which may be termed a sort of probationary period, the Collerette Dahlia has asserted its right to a place in gardens, whether large or small. The fact of its suitability for small gardens should go a long way to popularise the type, for it is a common error to suppose that Dahlias are too large for gardens of moderate dimensions.

This, I feel sure, is entirely owing to a lack of acquaintance with many of the newer types and improved varieties of older sections. To those unfamiliar with the habit of the Collerette in the garden, and who intend giving it a trial, the selection of varieties is an important matter.

In 1912 the percentage of varieties possessing a really good garden habit was very high.

With an increasing demand for the type, it is probable that many were placed on the market in 1913 without having previously had a sufficient trial to justify their inclusion. It is

scarcely possible to judge the future habit of a plant from the first few blooms, or when it is crowded in the seedling beds.

As seedlings often commence flowering late in the season, one may be pardoned for over-estimating what appeared then a desirable variety. Now that numbers are increasing by leaps and bounds, it is necessary to sift the wheat from the chaff.

It is well known, too, how misleading a fine vase of cut blooms may be with respect to the garden value of the plant.

The blooms are very large and the foliage exceedingly robust; others of this type are *Ami Nonin*, *Ami Cachet*, *Crown Princess Charlotte*, *Diomède*, *Burgomaster Siefurth*, and *Souvenir de Chabanne*.

None of these large flowering varieties met with favour from the judges at last year's trial, but their much later time of blooming, even though given identical treatment with others, would always tell against them.

Souvenir de Chabanne, it may be mentioned, though it has the large, perfectly formed flowers

FIG. 83.—ARBUTUS MENZIESII AT BAYFORDBURY, HERTFORD.

An instance of this is seen in the variety *Albert Maumene*, which received an Award of Merit from the R.H.S. in 1912.

The individual blooms of this variety are beautiful, but as one rarely gets more than half a dozen expanded blooms at one time on very fine plants, it can readily be seen that, in comparison with many others, it would not receive a second glance when judged in the garden.

This particular variety belongs to a limited few, which may be considered distinct in that

and vigorous foliage, yet differs in habit somewhat from the others, having when at its best a handsome epergne-like appearance, and flower stalks quite 2 feet long.

It was greatly admired here last autumn, but was not at its best before the end of September. Owing to this drawback, these large bloomers cannot be recommended in a select list of varieties, handsome though their blooms are.

Especially is this the case now that one can have varieties which, under proper treatment,

* The fruiting specimen figured in *Bot. Mag.* t. 8,249 (1909) was obtained from the Bayfordbury tree.

† *Tree of Great Britain and Ireland*, III., 566 (1908).

NOTICES OF BOOKS.

THE CHEMISTRY OF THE GARDEN.*

This little book is to be recommended as an introduction to the practical study of the chemistry of the garden. It is designed for the use of teachers and students of gardening, and will prove useful to those who wish to find out for themselves how to identify the different chemical elements present in plant, soil and manure. In Chapter I. the various chemical tests by which the presence of carbon, nitrogen, phosphorus and sulphur in plant tissues is determined are described briefly but sufficiently, as also are the methods by which sugar, starch, cellulose, proteins and oils may be demonstrated. The second chapter, dealing with the soil, consists in the description of experiments which serve for the detection of phosphates, potash and lime. Chapter III. deals with manures, and in it are indicated the points to be observed in examining such artificial manures as nitrate of soda, sulphate of ammonia, superphosphate, basic slag, kainit and others. The final chapter is devoted to a brief account of the chemistry of sprays and washes.

AGRICULTURAL CHEMISTRY.†

THIS well-known students' text-book is a compendium of the whole subject of agricultural chemistry, comprising, as it does, a study of soils and manures, the plant and its products, animal feeding, milk and milk-production, etc. The previous edition no doubt suffered considerably from the author's inability, through residence abroad, to incorporate his alterations and additions with the main text, and also from the unfortunate circumstance that the revised edition was given to the public without mention of certain important advances in the study of animal nutrition, advances which have now been widely accepted as established. Nevertheless, Mr. Ingle's book has always been so thorough and clear that it has had, deservedly, a wide vogue amongst students of agriculture. It is pleasing, therefore, to find that the present edition, which has been fully revised and largely re-written, equals its predecessors in clearness, and is sufficiently comprehensive and up to date to make it unique amongst text-books of this kind.

The chapters on "The Chemical Constituents of Plants" and "The Plant" may be especially picked out for approbation; they are well written and provide a mass of correct information. It is impossible, however, to avoid deprecating the retention of loose expressions, such as "albuminoid" and "proteid" (except where they are used in a popular sense) in a book which is intended for those "who already possess a fair knowledge of general chemistry."

The sections particularly applicable to the requirements of the scientifically-trained horticulturist are full and to the point, those dealing with the processes operative in the soil being especially well worked out. Indeed most of the portion of the book dealing with soils and manures is admirably written, and the author's few faults are of omission rather than commission. It is a pity, for example, that in a book of this kind no mention is made of soil-surveys and soil-maps, for it is now realised that such surveys are of paramount importance to the agriculturist and horticulturist, both for the correlation of soil-types with agricultural practice and for the interpretation of soil-analyses. The latter, indeed, is treated in a manner more prevalent ten years ago than to-day, and might well be re-written.

The short sections on fungicides and insecticides are poor, and do not accord with the high standard of the remainder of the book, which can be given a cordial welcome in its new edition, and may be recommended. S. T. M. A.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to Mrs. COOKSON, Oakwood, Wylam-on-Tyne.

DENDROBIUM.—Most of the deciduous Dendrobiums have now their flowers in an advanced stage of development. Let the plants have the advantage of full exposure to the light until the flowers expand. They may then be placed in a somewhat drier and more shady place, such as will increase the durability of the flower. Any re-potting that may be necessary should be carried out as the plants pass out of flower, using a compost, etc., as previously recommended. Where large specimens of some of the evergreen Dendrobiums are grown, such species, for instance, as *D. thysiflorum*, *D. densiflorum*, *D. suavisimum* and *D. chrysetoxum*. They are exceedingly serviceable for house decoration when in flower. The plants here are often allowed to remain in the dwelling-room from the time they expand their flowers until they fade, which is a period of two or three weeks. Yet with proper care with regard to watering, by guarding against excessive root-waterings, no injury takes place. Plants of this section now producing their flower-scapes may be syringed overhead on all sunny days until the flowers commence to open. As with the deciduous species, so with these: re-potting should be carried out immediately after the flowering period, selecting for them a good lasting compost, so that frequent re-potting may not be necessary.

COELOGYNE CRISTATA.—The early-flowering plants of *Coelogyne cristata* have already bloomed. If the plants have grown into large specimens and the receptacles are full of roots it may be found that the pseudo-bulbs have become reduced in size and promise to give less satisfactory results than formerly. In cases of this description turn the plants out of their pots, remove the old potting compost, and cut away such portions of the back pseudo-bulbs as are not necessary, leaving two or three pseudo-bulbs behind each new growth, then pot up the leading portions into pots selected for their convenient size. The older pseudo-bulbs which have been cut off, if potted or laid on a bed of damp Sphagnum-moss in a shady position in a warm house, will produce new growths that may be potted up when they have formed roots. A suitable compost for *Coelogyne* is one consisting of fibrous loam two parts and peat one part, with a quantity of coarse sand and broken crocks added. The pot should be well drained, as only a shallow layer of potting compost is necessary. Following the re-potting operation, place the pots in a warm, moist house, shading them from too much light and spraying them overhead daily in sunny weather.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G., Madresfield Court, Worcestershire.

GARDEN ROSES.—Pruning may be put in hand now, beginning with the climbing section. A sharp "Saynor" knife, which will make short, clean cuts, should be used in preference to secateurs or shears. Cut out all spindly, weak growths, and reserve the stout shoots of last year. These should be shortened to about one-third of their lengths and the remainder trained to the wired walls or to the pergola frames, as the case may be. From the laterals of these last season's rods the finest flowers will spring. Each rod will require a space of about 1 foot between it and the next. The Roses to be recommended for pergolas are Mme. Abel Carrière, Reine Olga de Wurtemberg, Gloire de Dijon, and Félicité et Perpétue; but for low walls and the stumps of trees, semi-climbers such as Grass an Teplitz, J. B. Clark, Rêve d'Or, W. Allen Richardson and Climbing Liberty are excellent. Beds of Tea, Hybrid Tea, and Pernetiana varieties should be cut much harder and closer

commence blooming early in July, and continue until cut down by frost. The ideal type, of which I should name the variety Henri Farman as a perfect example, grows about 3 feet to 4 feet tall, with moderate growth.

The flowers are of medium size, poised on stiff stems, and produced in the greatest profusion throughout the summer and autumn. The range of colouring is now very wide and comprises varieties of self-colour, others self with the exception of contrasting collar, while many are prettily striped, blotched, suffused, or tipped. A good, clear pink, however, is still needed.

Dora Fisher is a very pretty pink, reminding one of the well-known "Pink Pearl" of the Cactus section, but the form of flower is not perfect, and the habit leaves much to be desired. Dainty, another so-called pink, has not much to recommend it.

Tastes differ; many prefer the selfs, while others favour the combination of colouring.

Selfs are particularly suitable for associating with herbaceous plants, while all are charming for groups, beds or borders.

In the following list varieties have been chosen which give a wide range of colour.

1. Diadem, flowers star shape, of a lovely bright rose pink, with white collar, grows taller than most, reaching from 4 feet to 4½ feet. In the opinion of many this is the gem of the section.

2. Princess Louise, flowers rich crimson, with white collar.

3. Prince John, crimson edged lake, white collar. These two are very similar in habit, making perfect bushes about 3 feet to 3½ feet high.

4. Holyrood, ruby, with yellow disc and collar. A striking and popular variety, 3½ feet.

5. Henri Farman, claret, edged primrose straw collar. A particularly fine variety, 3½ feet.

6. Queen Bess, orange-scarlet, tipped golden yellow, collar yellow, streaked red. A showy variety, 3½ feet.

7. Negro, maroon. A very fine dark, with white collar, 3½ feet.

8. Goldstern, flowers star shape, yellow self, the best of its colour, 4 feet.

9. Countess Dougon, white ground, striped and suffused rosy carmine, collar white. This variety is rather variable in colour. A good type, very attractive, 4 feet.

10. May, a pure white, habit not perfect, but the best so far as I know, 4 feet.

11. Queen Mary, deep rose with white disc and tips, blush-white collar, 3 feet.

12. Regularity, purplish crimson, with purple and white collar, 3 feet.

13. Prince of Orange. This variety is unique in colouring, being well named, a true self, 4 feet.

14. Tuskar, a charming variety with rich, rosy-crimson petals tipped with rose and white, collar straw-coloured, 3 feet.

15. Inchmarnock, bright red with yellow collar.

16. Eddystone, crimson scarlet, tipped golden yellow, collar pale yellow, spotted crimson, 4½ feet.

17. Skerryvore (see Coloured Supplement), bright scarlet, tipped with yellow. Yellow collar, 4 feet.

18. Sunburgh, purplish-mauve suffused and striped with white. Pure white collar, 3 feet. Arthur J. Cobb, Duffryn Gardens, Cardiff.

PUBLICATIONS RECEIVED.—*Journal of Genetics*. February. Edited by W. Bateson and R. C. Punnett. (London: Cambridge University Press.) Price 10s. net.—*Bulletin of Miscellaneous Information, 1914*. Royal Botanic Gardens, Kew. Price 3d.—*Colour Schemes for the Flower Garden*. By Gertrude Jekyll. Third edition. (London: Country Life, Ltd.) Price 12s. 6d. net.

to the ground than those mentioned above, so as to secure shoots right down from the base for the following year's growth, shortening the stronger shoots down to five or six dormant buds. These will supply a profusion of Roses of excellent quality this season, and will be cut out next year and succeeded by the shoots secured as above from the base. With regard to pruning, it may be stated that there is such a diversity of habit in Roses that no one system can safely be applied to all: the pruner must use his own discretion. Polyantha Roses are invaluable for bedding, flowering continuously all through the summer. They must be brought back by pruning, otherwise they will lose their compactness. Hedges of *Rosa rugosa* should be cut down to the ground.

SHRUBS.—Shrubs for flowering or foliage planted in beds (such as *Ceanothus Gloire de Versailles*, Golden Elder, *Hydrangea paniculata*, and *Paulownia imperialis*) should now be cut down close to the ground. Some are in flower now, notably *Elaeagnus longipes* (a scented shrub), Flowering Almonds, and *Berberis Darwinii*.

BULBS.—Owing to the very mild winter slugs are likely to be troublesome. Their haunts may

LAWNS.—Keep the lawns rolled once a week, or more often after rain, so as to disperse the worm-casts in readiness for the scythe. A dressing of fine soil or sand and sulphate of ammonia will kill the ground-moss and Daisies. Trim the edges of the lawns and line out correctly all the paths which may have been trodden out of shape. Motor or hand-power mowers should be put into thorough working order, ready for the season.

PLANTS UNDER GLASS.

By C. H. COOK, Gardener to the Earl of DERBY, Knowsley Hall, Lancashire.

SEEDLINGS.—Gloxinias, Begonias, *Streptocarpus*, *Primula obconica* and other seedlings will now be showing the first rough leaf, and should be pricked off into shallow pans without delay. Choose clean and well-drained pans, placing the siftings over the crocks used for draining, and fill the pans with light, sandy soil. The pans should then be placed in a warm house, and given a soaking with tepid water. In a day or two the soil will be quite sufficiently warm. The seedlings must be very carefully handled. Each should be lifted by means of a cleft stick held in the left hand and planted in the hole prepared for its reception with a dibber held in the

and *Pancretiums*, top-dressing those in which the drainage is good and general condition healthy. If re-potting is necessary, remove carefully as much of the old soil as possible. All small bulbs will do best in pots by themselves, with a porous compost of turfy loam, to which may be added a little rotten manure, sand, and broken charcoal. The pots must be well drained, and the coarser material placed over the crocks. Four or five bulbs to each 10-inch pot will be a suitable number. Press the soil firmly into the pots and insert the bulbs so that they will be just covered with soil; then plunge the pots in bottom heat at a temperature of 65° to 70°.

CODIAEUMS (*Dracaenas*) which have rooted should be potted up, keeping them close for a few days, until the roots have taken a firm hold of the new soil. *Selaginellas*, *Zebrinas*, *Pileas*, and *Oplismenus Burmannii variegata* (*Panicum*) can now be propagated. *Eranthemum pulchellum*, *Plumbago rosea*, *Begonia Gloire de Lorraine*, *Coleus thyrsoideus*, *Justicias* and *Reinwardtias* should be placed in a moist warm house to produce growth suitable for cuttings.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

VINES.—Early vines with berries on the point of stoning should be grown in a mild, steady temperature. Let the borders receive periodical waterings with liquid manure, or apply dressings of artificial fertilisers. Attend to successional houses as formerly directed. If Muscat vines are not already started forcing should be commenced at once, as the earlier the fruit ripens, the better will the berries keep during the autumn and early winter. Examine grapes that are stored in the fruit room, with a view to replenishing the water if it is low in the bottles.

PINES.—If the fruiting Pines are in good condition most of them will now be producing suckers, and if these are not required for increasing the ordinary stock all except one sucker to one plant should be removed by screwing them out; but do not remove them from the stem. Let the roots be carefully attended to, both in respect to the water supply and the degree of bottom heat. It is not infrequent for Pine roots to be burned owing to excessive bottom heat. A temperature of 70° to 80° is safe enough, but it should not be allowed to go higher. The atmospheric temperature at night should be from 65° to 70°, with proportionate increases of heat during the day, even up to 85° or 90°, with plenty of ventilation on sunny days. The house may be closed in the afternoon when the temperature is 80°. Successional plants may still have the temperature as previously advised for them. Closely examine the heat of the bed in which succession plants are plunged, and if it becomes too hot lift the pots and place a piece of inverted brick or small saucer beneath each pot, allowing them to remain so until the excessive heat subsides. Spray the plants lightly overhead at closing time on all sunny days and apply root waterings whenever the soil appears to be dry. Prepare soil for plants that require shifting into fruiting-pots, making the compost of fibrous loam, broken up into moderately sized lumps, and put plenty of drainage material into each pot.

PEACHES AND NECTARINES.—The bright sunny days of spring may prove very trying to trees which are being forced. To prevent injury occurring from this cause let the fires be checked directly it is seen that the weather is becoming sunny; admit air early and frequently, and sprinkle the paths and other surfaces of the house with water. Syringe the trees thoroughly at closing time with water slightly higher than the temperature of the house. Examine all inside borders and apply a thorough soaking of water to all that are found to be dry. In the earliest houses give prompt attention to thinning, disbudding, and tying-in of the young growths. Disbudding is an operation which requires daily attention, and the operator should have a knowledge of the condition of the roots. Young

FIG. 84.—BULBS IN THE GRASS AT MADRESFIELD COURT. (See "The Flower Garden.")

be disturbed with effect by breaking up the surface of beds of choice Tulips, Hyacinths, Anemones and Hepaticas with a small Dutch hoe. Apply a dusting of fresh soot and lime after each rainfall just before night. Bulbs in grass are now in active growth, and in some cases *Scilla sibirica* and *Chionodoxas* are in full bloom. Grown on a slope, combined with Primroses, these flowers have a charming effect. On slopes where Primroses abound note should now be made of their position, so that in the autumn some of the Primroses may be cleared away and *Scillas* and *Chionodoxas* planted for next year. Daffodils of the early section are opening their first flowers.

THE HEATH GARDEN.—This is now looking very bright. Space should be given for bold masses of *Ericas carnea*, *albans*, *hybrida*, *Serlei*, *Allportii*, *Hammondii*, and other dwarf species. These look well planted on a slope, interspersed with a few single specimens of tree heaths, such as *E. codonodes*, *Veitchii*, and *australis*. If a background of common or double Gorse can be utilised, the effect is much improved. If the soil is free from lime, it is astonishing how well the *Ericas* succeed if a little leaf-mould and charred vegetation can be added to the staple.

right hand. The soil must then be pressed close around each plant; being already moist it will not need root waterings for some time, a light spraying overhead being sufficient to keep the seedlings fresh. They will do best if kept close to the roof-glass, but shaded from sunshine.

GLORIOSA SUPERBA.—The tubers of this stove climber will now be showing signs of growth, and should be shaken clear of old soil. Two or three tubers should be placed in a 10-inch pot (previously well drained), and covered until the pot is three-parts full with peat and fibrous loam in equal proportions, with the addition of some sharp sand and broken charcoal. Bottom heat is an advantage, but not a necessity. The pots should be placed so that the plants can climb up the rafters near the roof-glass.

GENERAL WORK.—The sun is now becoming more powerful, and blinds for shading should be got out and fixed over the houses of the most tender plants. Growth is active, and an increase of temperature may be allowed. In the stove the atmospheric temperature may be increased to 70° at night and to 80° with sun-heat during the day. The necessary humidity can be maintained in the atmosphere by frequent damping of the floors and stages. Overhaul *Eucharis*

vigorous-growing trees should be divested of all fore-right growths. Strong-growing side-shoots should be pinched; they will then produce lateral growths of lesser strength, and therefore better suited for fruit-bearing. In applying stimulants of any sort to the roots, let the quantity always be governed by the condition of the tree. In the case of inside borders that are well made and provided with proper drainage there is very little danger of over-watering taking place, for the trees require, during the period of growth, a very large quantity of water, and drought is the worst evil that can overtake a tree. Close the ventilators early in the afternoon, thus conserving the sun heat.

ORCHARD HOUSE.—Peach, Apricot and Plum trees ought all to be in full blossom. On warm, sunny days let the house be given free ventilation; even at night, when the weather is mild, the ventilators may be left partly open as a means of assisting the fertilisation of the flowers. Take care that none of the trees suffer from want of water, specially those growing in pots. When the fruit is seen to be fairly set let the trees be given a light syringing with clear water, and keep up a close watch for green fly and other insect pests.

UNHEATED HOUSES AND WALL CASES.—These structures, which are often used for culture of late fruits, should be kept thrown open as much as possible, with a view to retarding the flowering season to the last degree possible, so that there will be less risk of injury from the spring frost. If sharp frosts occur without much warning, and the buds of the trees are sufficiently advanced to be liable to injury, lower the frost-proof blind on to the roof of the house and protect the sides with similar material or with stout tiffany. Do not nurse or push the trees in the least degree until the fruit is set; but in the meantime afford them plenty of water and an abundance of air.

STRAWBERRIES.—Plants bearing fruits that are nearing the ripening stage should be kept somewhat drier at the roots, and the atmosphere should be kept rather less moist by allowing a constant circulation of air through the structure both by day and night. Otherwise the fruit might prove to be deficient in flavour. Successional plants may be placed in heat at intervals of about a fortnight, or as often as necessary to satisfy the demand for early fruits.

THE KITCHEN GARDEN.

By R. P. BROTHERSTON, Gardener to the Earl of HADDINGTON, Tyninghame, East Lothian.

CAULIFLOWERS.—Plants of Cauliflower that have been wintered in frames, and others pricked out at the base of south walls, may be transplanted in gardens known to be moderately free from severe frosts in spring. But in the northern counties of England and the north-eastern counties of Scotland, and other cold districts, transplantation may be deferred for a few weeks.

LATE CABBAGES.—Both Brussel Sprouts and late Cabbages may be treated as recommended for Cauliflowers, in cases where seeds were sown in the autumn. In my own case, however, I prefer to sow seeds of late Cabbages and Savoys at the present time, making another sowing of Savoys at a later date; the produce is smaller, more tender, and of greater use than that from plants raised in the autumn.

LETTUCES.—Seedlings raised under glass a few week's ago are now strong enough for transplantation into the open ground. If slugs are numerous make the surface soil perfectly smooth with the back of a spade and sprinkle it occasionally with hot lime. Take other measures to destroy the pests, as they are most destructive to young Lettuces.

CELERY.—Prick out the earliest Celery plants, which, being of moderate numbers, may be put into ordinary cutting-boxes filled with a compost of loam and leaf-mould in equal quantities and made very firm; or two parts of loam to one of leaf-mould, according to the

quality of the loam. The leaf-mould is necessary in order to get the roots to lift with plenty of soil adhering to them at the next plantation.

TOMATOS.—The earliest fruits of the autumn-raised plants should now be approaching maturity, and in order to develop a good flavour in the fruits the heat of the house should be well maintained, and the roots should be kept rather on the dry side. Plants raised in January ought now to be large enough for placing in the fruiting-pots. Plant them rather deeply and leave a few inches of space to be filled with compost later on. A 9-inch scarement in one of the structures here holds 60 plants, placed at 1 foot apart. The compost is brought slightly above the level of the ball of roots, and surface dressings of soil and manure are added as necessity arises. The depth of soil at no time exceeds 6 inches, yet very fair crops are the result. Where pits or deep frames are otherwise employed during the summer they may be utilised for cultivating Tomatos. Sow the seeds and raise the seedlings in as cool a temperature as they will bear without damage and be very careful in applying water, as excessive moisture is most harmful.

VEGETABLE MARROWS.—The preparations for Vegetable Marrow culture may be commenced.

FIG. 85.—BULBS IN THE GRASS AT MADRESFIELD COURT.

The plants may be raised in 4-inch pots, allowing one seed to each pot, or the seeds may be germinated in 3-inch pots, in which case the seedling, directly the seed-leaves are expanded, must be transplanted to a 5-inch pot. The plants can be grown either in a manure-heated frame or an intermediate pit. A check to growth or to the extension of the roots is particularly harmful to Marrow plants.

THE "FRENCH" GARDEN.

By PAUL AQUINAS.

HOT-BEDS.—The Lettuces grown in the beds reserved for forcing Turnips are ready for marketing. When the frames are cleared of the crop rake the soil loose and press it down again. Sow seeds of Turnip Milan Round or Half Long in eleven rows per light; make ten holes in each row, placing two or three seeds in each hole. Turnips may be forced easily provided growth is not checked at any period. The chief causes of failure are: (1) Extreme bottom heat, which is obviated by growing a crop of Lettuces before the insertion of the Turnip seeds; (2) cold weather and sudden changes of temperature. Careful ventilation and covering with mats at night will overcome these difficulties. Admit air in moderation as soon as the cotyledons are developed. The Lettuces growing in the Carrot beds are hearting, and should be examined at

least once each week with a view to transplanting such as are ready for shifting, and thus favour the development of the Carrots.

COLD FRAMES.—Ventilation may be afforded the crops in unheated frames and cloches in favourable weather, especially where Lettuce Passion is grown. Covering the frames at night must be done more carefully than hitherto; in case of unexpected frost the mats may be spread over the glass till the plants have entirely recovered, and air may be admitted immediately after the mats are removed. Cauliflowers may be planted in cold frames in the same manner as in the hot-beds. Such varieties as All the Year Round and Driancourt may be planted at the rate of fifteen plants for every frame, or on the two outside rows in the cloche beds. The heads will be valuable as a successional crop to those grown in the hot-beds. After this operation the winter quarters of the September-grown Cauliflowers will be at liberty. Three barrowloads of black soil may be placed in each frame for sowing a crop of Turnip in a similar manner to the batch inserted in the hot-beds or for transplanting Cos and Cabbage Lettuces raised from seed sown in cold frames early in January.

MELONS.—Successive sowings of Melons should be made every week until the second week of April, in order to have plenty of young and vigorous plants. Where such sowings are made on hot-beds, it is advisable to make a fresh bed every week, and transfer all seeds and seedlings on the last bed as the manure is fermenting. The old bed will be again available after the materials have been turned over and two or three barrowloads of fresh manure added to it.

NURSERY BEDS.—Make up a small bed to accommodate one frame for sowing the first batch of Red Celery—Standard Bearer or Leicester Red—for a supply from November onwards. This sowing should be followed by a second one in a fortnight to ensure a supply of sturdy seedlings for pricking off late in May. Tomatos may also be raised in this frame for cropping out-of-doors. The seeds of the Tomatos germinate quickly, therefore preparation should be made for pricking the seedlings out as soon as they are large enough to handle. Fill the frames with good loam instead of black soil, which would favour a sappy growth. Seeds of Cauliflower may be sown very thinly in a cold frame, as the plants will not be pricked out before they are finally planted. A sowing of Endive La Parisienne or La Rouennaise may be made in boxes placed on the Melon bed. This crop when grown in small batches is a remunerative one. The rearing of the seedlings at this time of the year in a temperature of 60° is a rather tedious process, and should only be undertaken where time can be spared for the work.

THE APIARY.

By CHLORIS.

PURCHASING.—At this time of the year much secondhand bee material is offered for sale. It is not wise to purchase hives, etc., unless it is known for certain that no diseased colonies have previously inhabited them. In any case where secondhand hives are bought it will be prudent to scorch out the interior with a plumber's lamp, wash the whole of the woodwork with a strong solution of carbolic, and then place the hive in the fresh air for a few days before painting it. Beekeepers should order their requisites for the coming season early, so that sections may be fitted up and frames prepared in readiness for the honey-flow. In fitting up section crates do not omit dividers, and those of metal are more satisfactory than those of wood, because these latter twist. It is impossible to obtain shapely sections unless dividers are used. Those who are not able to plane and saw wood true will find it a decided advantage to purchase hives in the flat and put them together themselves in their spare time, and to give them at least three coats of paint before the end of March, so that the smell of the new paint may have passed off before it is necessary to utilise them for swarms.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Editors and Publisher. — Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the PUBLISHER; and that all communications intended for publication, or referring to the Literary department, and all plans to be named, should be directed to the EDITORS. The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.

APPOINTMENTS FOR THE ENSUING WEEK.

MONDAY, MARCH 16—

Surveyors' Inst. Exam.

TUESDAY, MARCH 17—

Broughty Ferry Hort. Assoc. meet.

WEDNESDAY, MARCH 18—

Stevenage and District Hort. Soc. Sh.

Roy. Met. Soc. meet. Lecture by Prof. A. C. Seward on "Climate as Tested by Fossil Plants."

THURSDAY, MARCH 19—

Linnean Soc. meet. Roy. Soc. of Arts meet. Paper by Mrs. Villiers-Stuart on "Indian Water Gardens."

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last Fifty Years at Greenwich, 41.9°.

ACTUAL TEMPERATURES:—

LONDON, Wednesday, March 11 (6 p.m.); Max. 47°; Min. 31°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London, Thursday, March 12, (10 a.m.); Bar. 29.3°. Temp. 52°. Weather—Dull.

PROVINCES.—Wednesday, March 11. Max. 48°, Cork; Min. 38°, Aberdeen.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—

Rose Trees, Rhododendrons, Perennials, Lilies, etc., at Stevens's Auction Rooms, King Street, Covent Garden, at 12.30.

MONDAY AND FRIDAY—

Hardy Bulbs and Herbaceous Plants, Roses, etc., at 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.

TUESDAY—

Nursery Stock, at the Royal Gardens, Hampton Court, by Protheroe and Morris, at 12.

WEDNESDAY—

Herbaceous Plants and Hardy Bulbs, at 12; Trade Sale miscellaneous Bulbs, etc., at 12; Japanese Lilliums, at 2.45; Palms and Plants, at 5, at 67 and 68, Cheapside, E.C., by Protheroe and Morris. Fifth Annual Sale of Nursery Stock at Ninebam's Nursery, Addison Road, Caterham, by Protheroe and Morris, at 12.

THURSDAY—

Roses, at 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 1.

FRIDAY—

Orchids, at 67 and 68, Cheapside, E.C., by Protheroe and Morris, at 12.45.

The Life of the Seed.

The seeds of the commonality of plants are docile things. Given but a modicum of attention and they practise straightway the magic of their growth. Yet, as we all know, there are recalcitrants among the commonwealth of plants—some refusing to germinate unless they receive special attention, others maintaining unimpaired their powers of development even though they be treated most neglectfully. But whether difficult or easy in their response to the cultivators' cozening, all the seeds of cultivated plants have this in common, that if not sown soon after they are ripe their vitality fades by slow degrees, until after a briefer or longer period of decline it is lost altogether. In sharp contrast with this brief temporal hold on life is the endurance of the seeds of various weeds. For the seeds of Charlock, of Foxglove, and certain other wild plants

time, as it were, stands still, and long years after chance has buried them in the ground these seeds may spring up again and minister to the wonder of the observant and the credulity of the casual looker on. The seedsman accepts the annual loss among his seed stores as incidental to his trade. After making the best provision he may for the storage of his seed he bows to the inevitable, discards his stocks of old seed of low germination capacity, and looks to each recurring harvest to make good the loss. He knows that deterioration goes on more rapidly if the seed be that of a bad harvest, and he is aware of the fact that this deterioration may be delayed—at the expense of rapidity of germination—if the seed be dried by artificial means. To the man of science it is evident that large problems lurk behind these phenomena, and numerous attempts have been made to discover the causes of deterioration and of longevity of seeds. Until the other day these attempts had met with but scant success; but now a new worker has appeared in the field, and his discoveries, announced at the meeting of the Royal Society on March 8, bid fair to clear up some of the mystery which attaches to the problem of the life of the seed.

Mr. Kidd, who has made this important contribution to our knowledge, has established the facts that if seeds be kept in an atmosphere containing from 20 to 30 per cent. of carbon dioxide their germination capacity may be held up indefinitely, and that they are none the worse for their enforced rest. When removed from the air charged with carbon dioxide and placed under ordinary conditions the seeds germinate at once. If this discovery be found to apply generally to the seeds of horticultural and agricultural plants it will prove of very considerable practical value. By Mr. Kidd's method, which would appear to be of very simple application on a commercial scale, the seedsman will be able to arrest the gradual deterioration of his seeds, and, if he chooses, hold over stocks from the harvests of good years to supplement those of leaner harvests. The planter will be able to obtain seeds of Para rubber (*Hevea brasiliensis*), which, unlike those which he is apt now to receive, may be guaranteed of high germination capacity. The traveller who includes in his kit a small cylinder of liquid carbon dioxide may succeed better than in the past in bringing home living seeds of the novelties which he has collected on his journeys. Indeed, should this simple method prove generally efficacious we may before long have seeds on the market as we have vintage wines guaranteed as the produce of a great year. To speculate thus is, however, to outrun the warrant given us by Mr. Kidd's brief abstract of his work. What is clear is that we possess in carbon dioxide, properly applied, a means of arresting the slow loss of vitality which seeds suffer when exposed to ordinary conditions. No less interesting is the further discovery that in one case at all events (*Brassica alba*) seeds which have been treated with car-

bon dioxide remain dormant even when put in conditions of air, moisture, and temperature which favour germination. Such seeds require special treatment before they may be awakened from the torpor in which they have been plunged. To induce them to germinate, the seed coat must be removed, or the intact seeds must be dried thoroughly and re-wetted.

This remarkable behaviour of the seeds of *Brassica alba* bears directly on the phenomenon of delayed germination manifested by the seeds of Charlock, Foxglove, and other wild plants; for it suggests that this delayed germination is due to a similar cause, namely, the "sealing" of the seed coat as a result of exposure to carbon dioxide. The effect of this treatment appears to be that the seed coat becomes less penetrable by oxygen, and so the seed, unquickenened by oxygen, remains dormant.

Mr. Kidd has shown by means of an ingenious experiment that seeds lying in the ground may be induced to remain dormant. Thus if a mass of green vegetable matter be buried deeply in the earth, and seeds be planted in soil over it, germination of the seeds is prevented by the carbon dioxide given off from the decaying plant remains.

We shall look forward with great interest to the publication of Mr. Kidd's researches, for we are confident that they supply a clue to the understanding of many obscure phenomena presented by the alternating states of rest and activity which occur among plants.

The Garden Strawberry.

Mr. C. W. Richardson, working at the John Innes Institute, has made an interesting and valuable contribution to our knowledge of the origin and genetical habits of the garden Strawberry.* As is almost invariably the case with origins, the origin of the modern garden Strawberry is obscure. There is no doubt, however, that the modern plant arose, as Mr. Richardson points out, from old forms of garden Strawberry, and that, in the production of the latter, *Fragaria vesca*, *F. vesca semperflorens* (the Alpine), and *Hautbois* (*F. elatior*) were involved.

The old form was crossed with other species—e.g., *F. virginiana*, introduced in 1629, and *F. chiloensis*, which was brought to England by Philip Miller in 1727. The hybrids from these crosses were crossed with *F. Ananassa* (*F. grandiflora*), introduced from an uncertain source into Holland, and thence to England in the eighteenth century.

It is incident to all attempts at the solution of origins that an element of mystery should attach to the plant suspected of playing a chief part in that origin.

This is the case with *F. Ananassa*, which is unknown in the wild state, is said to have come from Surinam, is said also to be a variety of *F. virginiana*, and may after all be a *chiloensis* cross. Whatever be its origin, *F. Ananassa* is undoubtedly, according to Mr. Richardson,

* *Journal of Genetics*, III., February 3, 1914.

COLLERETTE DAHLIA "SKERRYVORE"

(RAISED BY MESSRS. DOBBIE & CO.)

a progenitor of all our best garden varieties.

The author shows that of 1,000 plants obtained by self-fertilising eight garden varieties none resembles a vesca nor an Alpine, but many show traces of chiloensis and more of virginiana.

As was to be expected, Mr. Richardson finds conclusive evidence of segregation of characters. Thus runner and runnerless crossed with one another yield in the first generation runner-producing plants, and these self-fertilised give both types in the second generation; white crossed by red gives red in the first generation, and red and white in simple Mendelian proportions (3 : 1) in the second. Similarly the monophylla single-leaved form behaves as a simple recessive when crossed with the normal trifoliolate form.

The perpetual form—said to be derived from the Alpines—is dominant to the non-perpetual, but it is probable that the character is not a simple one.

Mr. Richardson has dealt also with the question of sex inheritance, a matter of great practical importance to the raiser of novelties, since the best fruit comes from plants which have the male and female organs well developed. The elucidation of the behaviour of the sex character in inheritance must of necessity be a somewhat laborious process. Mr. Richardson, so far as his experiments have gone, shows that crosses between pure female *F. virginiana* and pure male *chiloensis* give males, females and hermaphrodites in the first generation, whereas *F. virginiana* (female) by *F. grandiflora* (hermaphrodite) gave females and hermaphrodites only. We shall look forward with great interest to the next chapter in Mr. Richardson's experiments; for, as will be evident to anyone who reads this brief résumé, the working out of the details of the inheritance of the characters of such a plant as the Strawberry will result not only in an important gain to scientific knowledge, but in a smoothing of the plant-breeder's extraordinarily difficult path. As the result of that making smooth of the path the raiser of new varieties may not produce better varieties, but he will assuredly produce them more quickly and at the cost of fewer failures.

Coloured Plate.—The subject of the Coloured Plate is the new Collette Dahlia *Skerryvore* raised by Messrs. DOBBIE. In the Duffryn trials last season the plants grew about 4 feet high. (See p. 183.)

DEVELOPMENT OF THE R.H.S. GARDEN AT WISLEY.—In pursuance of the policy which they have for some time past had under consideration, and with the object of making the garden at Wisley of more general practical service to the Science and Art of Horticulture, the Council on Tuesday last appointed Professor KEEBLE, F.R.S., of University College, Reading, to the office of Director. The duties attaching to the position will include the general guidance and supervision of the trials, teaching, and research. In the further development of these several branches of horticulture the Director will have the continued assistance of Mr. F. CHITTENDEN, F.L.S., who will remain in charge of the Educational Section, and of Mr. S. T.

WRIGHT, the superintendent, who has for so many years carried out the important duties connected with the practical conduct of the garden. *W. Wilks, Secretary.*

NATIONAL CHRYSANTHEMUM SOCIETY.—On the nomination of Sir ALBERT ROLLIT, LL.D., President of the Society, His Excellency, M. INOUE, the Japanese Ambassador in London, has become a patron and Honorary Fellow of the National Chrysanthemum Society.

ROYAL METEOROLOGICAL SOCIETY.—A meeting of the Royal Meteorological Society will be held at the Institution of Civil Engineers, Great George-street, Westminster, on the 18th inst., at 7.30 p.m., when a lecture on "Climate as Tested by Fossil Plants" will be delivered by Professor A. C. SEWARD, F.R.S., Professor of Botany in the University of Cambridge. The paper will deal with vegetation in relation to climate: the plasticity of plants illustrated by their manner of response to different factors—e.g., temperature, light, moisture, etc. Cosmopolitan types and plants with restricted geographical range. The nature and value of the evidence afforded by fossil plants with regard to climatic conditions. The internal structure of fossil plants as an index of climate; the anatomical features of leaves and stems of extinct plants. Palaeozoic floras with

PROFESSOR KEEBLE, F.R.S., THE NEW DIRECTOR OF THE R.H.S. GARDEN, WISLEY.

special reference to the vegetation of the coal period. The distribution and composition of Jurassic floras in relation to climatic problems. Sources of error to be guarded against in attempting to use fossil plants as tests of climate.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The thirteenth annual social gathering and concert of the Liverpool Auxiliary of the Gardeners' Royal Benevolent Institution will take place on the 14th inst. at the Bear's Paw Hotel, Liverpool. The Hon. ARTHUR STANLEY, M.P., will occupy the chair.

SIR JOHN WOLFE-BARRY STUDENTSHIP IN ECONOMIC ENTOMOLOGY.—Mr. J. W. MUNRO, B.Sc., has been appointed to the Sir JOHN WOLFE-BARRY Studentship in Economic Entomology at the Imperial College of Science and Technology, London. Mr. MUNRO is the first Scotsman to hold a degree in Forestry. Although a graduate of Edinburgh University, Mr. MUNRO has been for long intimately connected with Aberdeen, where, after graduation, he was appointed assistant lecturer in Forestry at Aberdeen University. Among other distinctions obtained during his University career he was medallist in Forest Entomology. He has since studied under Professor ESCHERICH, of the Royal Forest Academy of Tharandt, Saxony.

PROFESSOR ENGLER.—A committee has been appointed in Berlin to make arrangements to celebrate the seventieth birthday of Professor A. ENGLER on March 25 next, by the presentation to him of his life-size marble bust and in other ways, as a sign of the appreciation by botanists of his varied and valued contributions by publication and otherwise to the advancement of systematic, geographical, and economic botany.

GALL-FORMING EELWORMS.—According to Mr. GEORGE MASSEE in the *Kew Bulletin* *Heterodera radicolica*, Mull., the gall-forming eelworm, is less known and does the greatest amount of damage in this country. The egg is large in size compared with the worm, colourless, elliptic-oblong, about $\frac{1}{256}$ th of an inch in length. The covering is very thin and translucent, so that at a certain stage the minute worm can be distinctly seen in its interior. Although so thin, the wall is very tough and resistant to extremes of heat and cold, chemical substances, etc., and the germ is with difficulty killed. The worm usually escapes from the egg in the gall, and is a tiny eel-like body, quite invisible to the naked eye. The young worms soon find their way into the soil, when they at once proceed to attack any rootlets that may be present. In this country Cucumbers and Tomatos suffer most severely from the ravages of eel-worms, but other plants are also attacked—Vines, Potatos, Roses, Phloxes, and Balsams, less frequently fruit trees. There is no known method by which the eggs of eelworms can be killed in the open ground, but the eelworms themselves can be killed by repeated dressings of sulphate of potash, 3 cwt. per acre, worked into the soil, though its efficacy soon passes away. Gas lime is better, but heating the soil with steam in Tomato and Cucumber houses is the most effective proceeding. It has been suggested that dressing the soil with rape meal destroys eelworms; the eggs, however, resist the treatment. Potassium permanganate solution, 1 in 200, kills eelworms if the soil is saturated at intervals of ten days, and does not injure growing plants; in this case, also, the eggs are unaffected. Carbon disulphide injected into the soil will kill any active eelworms present.

AMATEURISM IN THE PUBLIC PARKS.—We have pleasure in noting that the Bermondsey Borough Council has decided in future to make the superintendent of the public parks and open spaces directly responsible to the Council. The wisdom of conferring full responsibility on the men who possess the technical knowledge and training required in the management of the people's parks is becoming recognised; but there are still many boroughs where the chief responsibility is vested in surveyors or other amateur agents who would be glad to get rid of posts for which they have no special qualification. It is to be hoped that the example of Bermondsey will be followed in other towns.

NEW PLANT HOUSE FOR EDINBURGH BOTANIC GARDENS.—In the estimates which have been presented to Parliament for the ensuing financial year, the sum of £3,000 is allocated to be expended on a new plant house for the Royal Botanic Gardens, Edinburgh.

CONGRESS ON FUNGUS DISEASES OF PLANTS.—The International Phytopathological Conference summoned by the French Government in conjunction with the Italian Government to meet at the International Institute of Agriculture, was inaugurated by his Majesty the KING OF ITALY on February 24 last, and was brought to a conclusion on the 5th inst., in the presence of the fifty delegates who represented the 35 States who took part in the Conference. The final draft of the text of the proposed International Convention was discussed at the morning session, and was read for the last time in the afternoon. Adhering States pledge themselves in the first place to take whatever legislative and administrative measures are necessary

to prevent the distribution of all diseases of plants in their own countries, but specially to organise an effective service of supervision over nurseries, gardens, glasshouses, and other establishments which carry on a trade in living plants. The proposed Convention, however, excludes vines, grain, seeds, tubers, edible bulbs, rhizomes and roots, as well as fruit, fresh vegetables, field roots, and general agricultural produce. The measures which adhering States would pledge themselves to take include (a) the erection of one or more institutes for scientific studies and research; (b) the organisation of an effective service of supervision over nurseries, including the packing and despatch of plants; (c) the issue of phytopathological certificates. They would bind themselves only to admit plants accompanied by phytopathological certificates issued by or from a competent official authority, except in the case of plants which are imported for scientific research at an institute authorised by the Government. These certificates must be in conformity with a model given in the Appendix to the proposed Convention. They include a declaration by the consignor that the plants come from a nursery subject to phytopathological inspection, a certificate in accordance with the Phylloxera Convention of Berne, and a certificate from the official phytopathological service that the plants are in a satisfactory state of health, and are free from any of the diseases, or enemies of plants, scheduled by the Government of the country to which they are being sent. The compilation of this list is left to each importing country, but it was decided that this list must be as short as possible, and confined to those diseases which are epidemic in character, and destructive or at least injurious in their action, as well as being easy of propagation. Common diseases which are widely distributed are excluded. Adhering States would recognise the International Agricultural Institute of Berne as the official headquarters for all questions dealt with by the Convention. The Institute would collect all information of an administrative, scientific, and practical character concerning the diseases of plants submitted to the adhering States, and would issue a monthly bulletin giving the results. The Conference was particularly concerned to interfere as little as possible with trade, and to harmonise the interests of plant hygiene with those of commerce. A special article prohibits adhering States from giving better terms to those outside the Convention than is accorded to those inside it.

HOME CORRESPONDENCE.

(The Editors do not hold themselves responsible for the opinions expressed by correspondents.)

ROSES AT CHRISTMAS (see p. 141).—As the R.M.S. Phenological Committee is receiving notes on this subject from all parts, there is an additional interest in the article from such an authority as *White Rose* (see p. 141). If you are willing to receive lists and someone would then tabulate results it might be of some value. Of the forty-seven varieties flowering in this exposed garden in December thirty-three were still "out" in Christmas week, some being fit to pick. More surprising was the number that survived the January frosts, a very few, again, being presentable enough to pick in February, and two or three were worn as "buttonholes" (Hugh Dickson and A. K. Williams). Even now, March 1, a few are lingering; last year one (Petit Constant) did so for the first time. Those out at Christmas were as follows (J., F. and M. stand for such as lingered into January, February and March):—A seedling *Polyantha*, *Homer* (J., F., M.), *China pink* (J., F.), *China dark red* (J., F.), *China Mme. J. Perrian* (J., F.), *President Roosevelt*, *Dupuy Jamain* (J., F., M.), *Aschenbroedel* (J.), *Comtesse du Cayla* (J., F.), *Long-*

worth Rambler (J.), *Bennett's Seedling*, *Marie Pavie* (J., F.), *Gloire de Dijon* (J., F.), *Minnehaha* (J., F., M.), *American Pillar* (J., F., M.), *Jessie* (J., F., M.), *Comtesse de Rambaud*, *A. K. Williams* (J., F.), *Viscountess Folkestone* (J., F.), *Ma Capucine*, *Aimée Vibert*, *La France* (J., F., M.), *Mme. A. Chatenay* (J.), *Mrs. Sherman Crawford*, *Irish Glory* (J.), *Petit Constant* (J., F.), *Gustave Régis* (J.), *Kaiserin Augusta Victoria* (J., F.), *Gruss an Teplitz* (J.), *Général Jacqueminot* (J., F.), *Bouquet d'Or* (J.), *Lady Ashdown* (J.), *Caroline Testout*, *Mme. Ravary* (J.), *Isabella Sprunt* (J.), *François Foucard* (J.) and *Hugh Dickson* (J., F., M.). Totals.—Christmas week, 36; January, 29; February, 18; March 7. *J. Edmund Clark, Purley, Surrey.*

TAX FOR TREES (see p. 173).—Hedgerow trees are a great hindrance to successful farming and gardening in this country. No one will assert that crops in general, particularly Corn and Potatos, give anything approaching an average yield when grown under trees. It is easy to see how far the roots extend into a field by observing the short straw of Corn and dwarf haulm of Potatos. The value of the trees as wind breaks cannot be very much on account of their great distance apart; but it must be admitted that the trees form one of the great features in the landscape of our islands. *C. Robinson, St. Hilary Gardens, Cowbridge.*

A NEW SOURCE OF OAK TIMBER.—A story not easy of credence has recently appeared in the Press of a wonderful discovery of old Oak trunks "in the bed of the River Moksha, a tributary of the Oka, which in turn joins its waters to those of the mighty Volga at Nishnei-Novgorod." This discovery is said to have been made by a Russian military officer who "noticed that the bed of the stream for long distances was paved with immense logs of Oak. Further investigations proved that this condition obtained for a distance of 500 miles, and upon one of the logs being brought to land and cut into planks the wood was found to be very sound, and naturally of a very dark colour, approaching that of Bog Oak." The sensational character of the discovery of the trunks and how they are brought to land will be best given in the words of the newspaper account referred to, which states before the Russian officer "made his great discovery he was aware that the peasants living on the course of the Moksha had for generations been using beautiful Black Oak timber for all sorts of domestic purposes, such as building their dwellings, making furniture, and even constructing outhouses and pig-styes. Inquiries as to the origin of this material elicited the surprising answer from the peasants that they 'got it out of the river.' The method of obtaining it was very simple—namely, a loop of chain or rope was dragged along the bottom, and invariably it immediately caught a log and brought it to the surface." Some of the logs are said to be of enormous size, measuring 60 feet in length to the first branches and 5 feet in diameter. Another peculiar point is that the logs are said not to lie in a single layer. "At points where those on the top have been removed the stream has washed away the sand, disclosing yet other layers below. This circumstance led to further investigation, and it has been ascertained that in places the logs lie at least ten deep in long stretches of the river." The article then proceeds to explain the "origin of this remarkable accumulation of valuable timber" as follows:—The River Moksha meanders through a level open plain from five to seven miles in width. This plain is composed of sandy alluvial soil, and the river banks are consequently very friable and easily worn away by the heavy floods, especially when the ice is breaking up in the spring. In consequence the river is constantly changing its bed as the loose soil of its banks wears away. At some remote period the whole plain was covered with a dense growth of magnificent Oaks, and as the river cut away the soil these fell into the stream and, becoming water-logged, sank to the bottom and remained there. The remains of the ancient beds of the river are found everywhere over the plain, some dry, the more recent filled with water in the form of long, narrow lakes. The bottom of these lakes, like that of the river

itself, is also filled with Oak logs. It is impossible to estimate the total quantity of timber, but careful calculations go to show that it must run into many millions. In the present bed of the Moksha, without taking into account what lies in the lakes and the old dry water-courses, there is sufficient to yield at least 20,000 logs annually for fifty years or more, and the stream is constantly exposing fresh deposits. The object of bringing all this to light is to establish a trade in timber of a character similar to Bog Oak, chiefly for cabinet work. *John R. Jackson.*

RUCKSACK.—I have read Dr. Stapf's valuable contribution to the philology of the word "rucksack" with much interest, and I quite admit the force of his arguments in favour of one of the possible solutions of the problem which I had rejected. It is, of course, not easy to attain to finality in the face of conflicting evidence, especially when, as in this instance, the evidence is so largely a matter of authority. Indeed Dr. Stapf, had he been so minded, might have quoted *Murray's Dictionary* against the weight of *Muret-Sanders' views* as cited by me. Furthermore the word "Rüchenbeutel," which I have heard used in Northern Germany, might be also adduced as supporting the derivation of rucksack from the dialect word "ruck" (back). Nevertheless, apart from the conflicting evidence of the lexicons, as well as of persons who are intimately acquainted with patois and the dialects of Alpine villages, it still seems to me that there are good reasons for adhering to the view that it is the other ruck (jerk, pull) which has contributed the first syllable to the word under discussion. It expresses in so accurate and picturesque a fashion the peculiar little ways of the load carried on a rough mountainside, whilst ruck (back) appears so unnecessary, and if I may say it, so dull a description that I find it hard to believe that the latter word represents the original significance, whatever meaning be read into it at the present day. It may be remembered that our own word knapsack refers to the victuals carried, and not to the position in which they are borne. Is it possible that to the notion that a rucksack is a "back-sack," a habit (which to me seems to be growing more common in the Alps) of dropping out the ruck altogether may be due? But however these things may be, it appears that neither meaning is unapplicable, though perhaps we may never discover evidence of a kind to settle once and for all which is really the primitive one. *J. B. Farmer.*

UNSTAMPED LETTERS.—You would be doing nurserymen and seedsmen a great favour if you would draw your readers' attention to the fact that when writing for a catalogue they should either use a postcard or stamp their letters with a penny stamp. Every post I receive applications for catalogues on which I have to pay 1d. extra through the applicant writing in the form of a letter and placing in an open envelope bearing only a 3d. stamp. In my own little way this is probably costing me 3s. to 4s. per day, and no doubt similar expense is borne by the trade generally. *H. N. Ellison.*

CURE FOR MILDEW ON ROSES.—For many years past Rose mildew has caused much trouble and disappointment in these gardens, more especially during the early autumn, when one expects a wealth of fragrant flowers. We have tried almost every specific which has been advertised, but not until the past year have we been successful. I was induced to try a preparation called serum, and this gave splendid results. Certain varieties which are very liable to attacks of mildew were, when very badly affected in early autumn, given two applications of this specific, and not a particle of mildew could be found afterwards. The foliage became healthy and the plant produced an abundance of flowers until quite late in the year. One very important point in its favour is that no deposit is seen afterwards on the flowers or foliage. I have used the specific on other plants with the same good results. *Edwin Beckett, Aldenham House Gardens, Elstree.*

SOIL FOR CARNATIONS.—That the soil is not suitable for perpetual-flowering Carnations is the common excuse of the gardener who fails. Yet

I do not believe that there is any soil which could not be made suitable for this flower. Some years ago I was associated with a nursery in Holland, and we found that by burning the soil and using a good proportion of mud from the canals we could grow Carnations to perfection, yet previously it was considered almost impossible to cultivate the plant successfully in that country. But there is practically no definite rule to guide the gardener; he can simply get ideas from others, and must discover the details for himself. However, the following are a few points upon which most Carnation growers agree. Lime is essential. With very heavy soil it is best added as unslaked lime, with medium soil as old mortar rubble and with light soil in the form of pulverised chalk. It is safe to say that wood ashes or ashes from burnt garden refuse are beneficial to all soils. If the soil has a natural free drainage sand should not be added for the final potting, because the lighter the soil the quicker and weaker the growth—that is why firm potting is almost universally practised. The quantity of manure used should be influenced by the richness and texture of the loam, but, as is generally known, cow manure is best for light soil and horse manure for heavy soils. This should not be so old that it almost powders, but sufficiently old so that it can be chopped up with a spade. The same rule would apply to the loam. We believe that when this has been stacked over nine months it is of little value for Carnations, and the bulk of ours is only stacked six months. Peat is a thing Carnations abhor; the very nature of the plant proves this. The same applies to leaf-mould, and beyond mixing a little with the soil for the first and second pottings in the case of heavy loams it should not be used. The only artificial manure which should be added to the soil should be given in organic form, for chemical manures are too available, simply enriching the soil when sufficient food is to be had. We favour surface feeding when the plant is well established. This particularly applies to the use of bone meal, except instead of being too available when buried and the air is excluded the reverse takes place, and in a good organic food the phosphates are given in the form of finely-ground bone. Ground oyster shells are a luxury which do not enter into commercial horticulture, but they are very useful. We always use sea sand for mixing with our soil. *M. C. Allwood.*

BUTCHER'S BROOM.—The fruiting of this native plant is not so infrequent as Sir Daniel Morris supposes. In the neighbourhood of the New Forest and in the hedges near Hayling Island its bright berries are very conspicuous. Last month I gathered a number of them near the Guards' cemetery at Bayonne. It surprises some people to be told that this queer shrub belongs to the Lily order. *Herbert Maxwell, Monreith.*

CYANIDING TO DESTROY MEALY BUG.—My recent experience in cyaniding to destroy mealy bug in glasshouses may prove interesting to your readers. Early in January I used potassium cyanide, $\frac{1}{2}$ oz. per 1,000 cubic feet, in a large conservatory, but the effect on the bug was very slight. I wrapped the cyanide in tissue paper and dropped it into the jar of dilute acid, but found next morning that only part of the cyanide had dissolved. On February 3 I used sodium cyanide, 2 ozs. per 1,000 cubic feet, dropping the cyanide into trays of acid without any tissue paper, and left the house closed all night. After this dose I could not find any bugs alive. On this occasion I left in the conservatory as an experiment one each of the following plants, some of which were infested with mealy bug:—Asparagus Sprengeri, A. plumosus, Coelogyne cristata, Cyripedium insigne, Cyclamen, Cineraria, Primula obconica, Dracaena, Richardia (Arum Lily), Azalea, Aspidistra, Show Pelargonium, Dendrobium nobile, seven Palms, six Adiantums, and six other Ferns. None of the plants appeared to be damaged, except the Coelogyne, Show Pelargonium and Asparagus Sprengeri, which were slightly scorched. In order to destroy any bugs which might have hatched subsequently I fumigated again on February 13, using the same dose of sodium cyanide. On this occasion I fumigated in the morning, and only left the house closed for an

hour. Seeing that so little damage had been done by the second fumigation, I decided this time to leave the conservatory practically full of plants; but the results were disastrous. All the Coelogyne, Cyripediums, Dendrobiums, Primulas, Cyclamen, Palms and Asparagus were badly injured, and some of the plants of Adiantum and Nephrolepis scorched slightly. A strange feature is that in nearly every case the old foliage is damaged, and the young growths are unharmed. This applies particularly to Adiantums, Asparagus, Cyripediums and Cyclamen. Several of the Orchids were in bloom, also the Cyclamen and Primulas, but, with the exception of the last-named, the flowers were not damaged in any way. The plants had been left unwatered for two days before fumigating, and the conservatory was as dry as the presence of a large rainwater tank under the stage would allow. Notwithstanding all this damage to plants the bug was not entirely destroyed. I found a live insect on a Streptosolen five days after the fumigating. Is it possible to use too strong a dose so far as the effect on bug, etc., is concerned? I know that when poisoning a dog with prussic acid an excessive dose will cause sickness and the dog will recover. Perhaps some of your correspondents can throw light on this point, and also explain why old foliage should be damaged and young growths escape. One small Adiantum with young fronds has been fumigated twice and is still quite healthy, whereas similar Ferns only once fumigated are scorched. Since writing the above I have noticed to-day that some brown scale is still alive. *Ben Walmsley, Baddesley Grange, Northam, N. Devon.*

CELERY DISEASE.—Referring to Mr. W. H. Yates's observation on p. 175 as to Celery being badly injured by the leaf-mining insect last season, it will be interesting to know if this was general, and the cause of it. My experience was, that up to the beginning of September the larvae of *Acidia heraclei* was scarcely observable, but afterwards they became more troublesome than I have ever known them, and on the last day of that month we hand-picked about a bushel of infected leaves from 300 plants. According to Leaflet No. 35, issued by the Board of Agriculture and Fisheries, the fly attacks Thistles, *Cnicus arvensis*. This weed here last season, owing to pressure of work, became very abundant, it was late before it was cut, and it is possible that the late attack of the larvae of the Celery fly came from insects which had pupated on the Thistles. An interesting remark is made by Mr. Massee on p. 308 of *Diseases of Cultivated Plants*. There he states that *Cnicus arvensis* is commonly attacked by *Puccinia obtogens* (Tub.), and that as infection is readily effected by lashing healthy plants with infected ones it should be possible in this way to eradicate one of our worst weeds. *Cnicus arvensis* is very common in this country, and there are also a few plants of *C. lanceolatus* and *C. pratensis*. *John Edwards, Cefngarthmyl, Birriew.*

PAEONY-FLOWERED DAHLIAS.—In the discussion which followed the reading of my paper at the National Dahlia Society's Conference (see p. 164), I notice that Mr. J. B. Riding said he was rather surprised I did not say more about the Paeony-flowered varieties. I feel that in justice to one of the finest of all the sections of Dahlias, I ought to give some explanation of the omission which he points out, and which might be construed on my part as a lack of appreciation of that very type which was responsible for my conversion from indifference to enthusiasm for the whole tribe! When putting my observations on paper, I rather endeavoured to keep them off the lines of the usual critique on a collection of Dahlias, as so much has been written by able pens on all the well-known varieties, and hence it was that I passed them over with rather a cursory reference, to deal more fully with those that are at present new, or little known to the general public. As a matter of fact, the Paeonies and Decoratives (with the exception of a few beds of Singles) were assigned to a garden to themselves, and gave the most splendid and impressive display of any, and even those who found their favourites among other sections were none the less astonished at

the first sight of this garden full of huge blooms. *Reginald Cory.*

FORESTRY STATISTICS.—I am desired by the Council of the Royal English Arboricultural Society to ask for the assistance of your readers in the collection of forestry statistics. The Council feels that properly prepared statistics should prove of the utmost value, and they propose to collect data under three heads:—(1) The volume of timber that can be produced by various kinds of trees under different conditions of soil and treatment. This inquiry will involve the establishment and periodical measurement, on a set plan, of sample plots. (2) Volume tables which will show the average volume of trees of given heights and diameters. This inquiry will involve the measurement of felled trees on a set plan. (3) The financial return from woodlands, i.e., figures showing the expenditure on, and income from, the woods on estates. This will involve the analysis of estate accounts on a set plan. The Council recognises that it will be possible for very few persons to supply information on all three heads, but they desire me to express the hope that some of your readers will, if possible, help with one or more. *Edward Davidson, Secretary, Royal English Arboricultural Society.*

JOURNEYMAN GARDENERS' WAGES.—The writer of the review on Mrs. Martineau's book, *The Herbaceous Garden* (see p. 160, March 7), calls attention to the authoress' views upon gardeners and their wages. Mrs. Martineau is a practical horticulturist herself, and is naturally sympathetic; it is always to those who have made a personal study of gardening that the gardener must look for encouragement and help. The casual observer is in the habit of remarking, "What delightful work gardening must be!" Certainly, it is delightful when carried on under pleasant conditions, but it is only fair that those engaged in it should receive adequate remuneration for their services. Many owners spend large sums on the equipment of their gardens, and then seek to keep them up by employing men at a low wage. I know of an instance in which the journeymen in a garden struck because the labourers employed in some landscape work, though their hours were shorter than those of the gardeners, were receiving higher wages. Surely a skilled gardener, who is supposed to use his brains as well as his hands, should receive at least as much as an unskilled labourer. *Roamer.*

—*Contented Journeyman* tells us that we must not forget that gardens are hobbies, and not profit-making concerns; but several years ago I was employed in a garden—the owner of which was certainly not dependent upon it for his living—where three-quarters of the produce was grown for sale. The utmost pains were taken to grow such produce as would command the best prices, and quantities of fruit, vegetables, and flowers were sold in local shops and in Covent Garden market. I fail to see how such gardens can be described as "hobbies." *Discontented.*

—*C. H.* states on page 62 that it is not only journeymen who are paid low wages, and that they are sometimes paid more than responsible gardeners. I admit that some ignorant gardeners get higher wages than experienced men. I have myself met some ignorant men in the position of head gardeners, and I should think it is quite time that *C. H.* tried to get something better. With the experience which he has got he ought to be earning 35s. per week, with cottage; he could then allow some of the ignorant to apply for his situation. *H. H.*

—I cannot agree with the statement of some of your correspondents that there is an upward tendency in gardeners' wages, but any increase there may have been is certainly more than balanced by the rise in the cost of living. Some weeks ago I noticed an advertisement for a head gardener for the Royal Botanic Gardens, Regent's Park, "salary £120 and house." An applicant for such a situation must possess the highest qualifications, and keep up a certain amount of appearance; yet the wage offered is probably not much more than that of an omnibus conductor! *J. Harrison.*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 10.—The meeting held on Tuesday last in the Vincent Square Hall was remarkably successful. The building was filled to its utmost capacity with exhibits, and both the annexes were requisitioned to accommodate groups. The great demand for space was largely due to the special bulb competitions, on which a deputation of the Dutch Bulb Growers' Association adjudicated. The Narcissus Committee met for the first time this season, and this also had its effect on the show, for several growers staged large collections. Two new varieties of Narcissus received Awards of Merit from this Committee.

The Floral Committee recommended an Award of Merit to a hybrid Rhododendron, and awarded twenty-seven medals to collections, including the Gold Medal for an exhibit of Alpines.

The Orchid Committee granted one First-class Certificate and two Awards of Merit to novelties.

The only exhibit before the Fruit and Vegetable Committee was a collection of vegetables staged by Messrs. SUTTON AND SONS. At the three o'clock meeting of Fellows an address on "Adaptive Degradations: The Cause of Many Cases of Evolution Among Plants," was delivered by Rev. Prof. Geo. Henslow.

Floral Committee.

Present: H. B. May, Esq. (in the chair), Messrs. C. T. Drury, G. Reuthe, W. J. Bean, W. Cuthbertson, John Green, C. E. Shea, F. Page Roberts, Chas. E. Pearson, E. J. Jenkins, W. P. Thomson, Arthur Turner, H. J. Jones, C. Dixon, John Dickson, W. H. Page, C. Blick, Wm. Howe, J. F. McLeod, Thos. Stevenson, A. A. Dorrien Smith, W. A. Bilney, C. R. Fielder, J. W. Barr, F. W. Harvey, Jas. Hudson, R. C. Reginald Nevill, and R. Hooper Pearson.

Messrs. J. CARTER AND CO., Raynes Park, made one of their delightful spring gardens which have become an established feature of the spring shows. The simple, yet dignified, conception of cool, green lawn with borders of flowering plants and low buttressed wall with wrought-iron gates of exquisite design and workmanship, was a charming effort. The centre stand supporting the cinerary urn described last week attracted the interest of numerous visitors. On adjoining tables Messrs. Carter exhibited an immense collection of superb Hyacinths in pans, the chief varieties being Schotel, Moreno, Lord Derby, King Menelik, Lord Balfour, and Queen of the Pinks. (Silver-gilt Flora Medal.)

Col. the Hon. MARK LOCKWOOD, M.P., C.V.O., Bishop's Hall, Romford (gr. Mr. G. Craddock), staged some 200 Hyacinths in 6-inch flower-pots, instancing first-class cultivation. Adjoining this meritorious exhibit was a collection of "miniature" Hyacinths in 3-inch pots. (Silver Flora Medal.)

Messrs. SUTTON AND SONS, Reading, arranged charming colour schemes of pot Hyacinths. Such combinations as cream and pale blue, pink and white, yellow and dark blue, pale blue and pink, rich red and apricot, and shades of mauve. (Silver-gilt Flora Medal.)

Messrs. DOBBIE AND CO., Edinburgh, exhibited in colour blocks wonderfully fine Crocuses of good size. Of the many excellent varieties, Caroline Chisholm (white), Pollux (purple), Mammoth Blue and Mammoth Yellow are merely a few of the great number shown. (Silver Flora Medal.)

Messrs. J. PIPER AND SON, Bishop's Road, Bayswater, grew upwards of 900 Hyacinths in anticipation of the bulb show, and as sufficient floor space could not be allotted to them, displayed great ingenuity in planting the bulbs on a framework against the wall under the gallery, where the large collection attracted much attention, but it may be hoped that it will not again be necessary to adopt the method of exhibiting. (Silver Flora Medal.)

Mr. A. DAWKINS, King's Road, Chelsea, contributed a collection of forced Darwin Tulips.

Messrs. H. J. JONES, LTD., Hither Green, Lewisham, showed bunches of zonal-leaved Pelargoniums, the varieties including two novelties—

John Beckford, a large, purplish-coloured flower blotched with scarlet, and Mrs. F. W. Parsons, of the shade known as cherry-red.

Messrs. H. CANNELL AND SONS, Swanley, were awarded a Bronze Banksian Medal for bunches of zonal-leaved Pelargoniums.

Messrs. JAMES VEITCH AND SONS, LTD., King's Road, Chelsea, staged miscellaneous greenhouse flowering plants. (Silver Flora Medal.)

Messrs. W. CUTHBUSH AND SON, Highgate, were awarded a Silver Flora Medal for Carnations, Alpines, and greenhouse flowering plants.

Messrs. H. B. MAY AND SONS, The Nurseries, Edmonton, showed Pansies, Polyanthus, varieties of Clematis, and a seedling *Richardia* named *alocasaefolia*, with broader dwarf leaves and more expanded spathes than the type. (Silver Flora Medal.)

Mr. L. R. RUSSELL, Richmond, Surrey, had many beautiful plants of Clematis, of the large-

Fox, Esq., Penjerrick, Falmouth, were awarded a Bronze Banksian Medal.

Mr. A. H. COLE, Swanley, put up a small group of Primulas and Cyclamens.

Mr. GEO. PRINCE, Oxford, again showed Roses, having similar varieties to those displayed by him at the last meeting.

Carnations were shown by Mr. H. BURNETT, Guernsey (Silver Flora Medal); Mr. C. ENGELMANN (Silver Flora Medal); the Misses S. C. PRICE and A. B. FYFE; Mr. J. C. JENNER, Lynwood Nurseries, Rayleigh; Messrs. ALLWOOD BROS., Wivelsfield, Haywards Heath; W. WELLS AND CO., LTD., Merstham, Surrey; and Messrs. YOUNG AND CO., Hatherley (Silver Banksian Medal).

HARDY FLOWERS.

Sir EVERARD HAMBRO, K.C.V.O., Hayes Place, Hayes, Kent (gr. Mr. J. Grandfield), was

FIG. 86.—SAXIFRAGA FALDONSIDE; COLOUR OF FLOWER GOLDEN-YELLOW. SHOWN BY SIR EVERARD HAMBRO AT THE R.H.S. MEETING ON THE 10TH INST.

flowered type, and the scarlet *Clianthus puniceus*, for which a Silver Flora Medal was awarded.

Messrs. J. PEED AND SON, West Norwood, staged a large group of forced shrubs, of such kinds as Azaleas, Weigela "Conquête," double flowered Cherries, Rhododendron Pink Pearl and *Prunus triloba* with Maples for relief and a background of Palms. (Silver Flora Medal.)

Messrs. WILLS AND SEGAR, florists, South Kensington, contributed a collection of greenhouse flowering plants for which a Silver Banksian Medal was awarded.

Messrs. STUART LOW AND CO., Bush Hill, Enfield, were awarded a Silver Banksian Medal for Carnations and a pretty group of *Acacia armata* arranged with *Daphne Mezereum* and White Ericas.

Messrs. R. GILL AND SONS, Falmouth, were awarded a Silver Banksian Medal for Rhododendrons and Violets.

Trusses of Rhododendrons shown by ROBERT

awarded a Gold Medal for Alpines. This magnificent exhibit was arranged on a wide table next to the wall, the background being of Azaleas, Dentzias, *Andromeda floribunda*, and dwarf Conifers, with Tulips and the tall-growing *Primula cashmeriana* as foils at intervals. Most of the Alpines were growing in large pans, and were principally fine forms of encrusted Saxifragas and species of Primulas. The gem of the collection was a fine clump of the beautiful golden *Saxifraga faldonside* (see fig. 86), the finest variety in its section. There were very large pans of *S. Burseriana*, *S. B. Gloria*, *S. scardica obtusa*, *S. apiculata*, *S. Paulinae*, a fine yellow Saxifrage but not so imposing as *faldonside*; *S. marginata*, and, in smaller receptacles, *S. Boydii*, *S. Burseriana crenata*, with crimped or wavy margin to the white petals; and many others. Of the Primulas we noticed the beautiful *J. H. Wilson* variety with lavender-violet coloured flowers; *P. frondosa*, *P. spectabilis*, the rosy-coloured petals being very deeply cut; *P.*

Winteri (magnificent specimens), *P. viscosa*, *P. megaseaefolia*, bearing large umbels of soft lilac-coloured flowers, and *P. rosea*. There were also beautiful specimens of *Soldanella alpina*, *Sedum dasyphyllum*, the pretty glaucous stems and leaves being tinged with rose, and a host of other interesting subjects, every plant being an object-lesson in good culture.

Messrs. T. S. WARE, LTD., Feltham, arranged a large rockery exhibit in the corner by the east annexe, for which a Silver Flora Medal was awarded. At the back was a row of Conifers, and against these the yellow *Dendromicum rigidum* showed up well, the plants being finely flowered. A border of Christmas Roses and Primroses next to these led on to the stone work, in which were growing large patches of *Viola gracilis*, *Pulmonaria rubra*, *P. azurea*, *Anemone blanda*, and other dwarf-growing flowers.

Messrs. JOHN WATERER, SONS AND CRISP, Twyford, Berkshire, arranged a rockery with stones of old weathered limestone planted with rare and choice Alpines. A new *Viola*, *V. Thuringia*, with purplish flowers shaded with mauve and yellow eye; *Hepatica angulosa*, *Ophrys aranifera*, the Spider Orchid; *Primula marginata*, with petals a delicate shade of lavender; *Iris persica*, *Viola gracilis*, *Mazus reptans*, *Omphalodes cappadocica* and *Tulipa Clusiana* were all finely flowered. (Silver Banksian Medal.)

Mr. G. REUTHE, Keston, Kent, showed *Rhododendrons*, *Camellias*, and *Alpines*. A large truss of *Rhododendron argenteum* was a conspicuous feature, and prominence was afforded the new yellow-flowered *R. Keiskii*. (Silver Flora Medal.)

Mr. CLARENCE ELLIOTT, Six Hills Nursery, Stevenage, planted a rockery with broad sweeps of *Saxifraga apiculata*, *S. oppositifolia alba*, *S. o. splendens*, the finest patch of colouring of all; *S. Boydii alba*, *S. Elizabethae*, *Anemone blanda Ingramii*, *Muscari azureum* and other *Alpines*. (Silver Banksian Medal.)

Messrs. BLACKMORE AND LANGDON, Twerton, Hill, Bath, showed a good strain of coloured Primroses, and varieties of Violets. (Silver Banksian Medal.)

A pretty exhibit of hardy flowers was shown by Messrs. GEO. JACKMAN AND SON, Woking, for which a Bronze Flora Medal was awarded. The plants were grouped against a background of flowering trees, such as *Prunus Pissardii*, *Spiraea arguta* and *Almonds*. *Amygdalus Davidiana alba* has rose-tinted buds, but the flower when expanded is pure white.

Messrs. BAKERS, Wolverhampton, made a feature of *Primula denticulata*, and its white variety in an exhibit of *Alpines* arranged in boxes.

Messrs. REAMSBOTTOM AND Co., Geashill, Ireland, showed *St. Brigid Anemones* in a variety of colours.

Hardy flowers were also shown by Mr. G. W. MILLER, Wisbech; Mr. MAURICE PRICHARD, Christchurch, Hampshire; Mr. H. HEMSLEY, Crawley; Messrs. R. TUCKER AND SONS, Oxford; Messrs. WHITELEGG AND PAGE, Chislehurst (Silver Banksian Medal); the Misses HOPKINS, Shepperton; Messrs. R. WALLACE AND Co., Colchester (Silver Banksian Medal); T. H. GAUNT, Farsley, near Leeds; BURTON HARDY PLANT NURSERY; GUILDFORD HARDY PLANT NURSERY; THOMSON AND CHARMAN, Bushey, Hertfordshire; and Messrs. G. and A. CLARK, LTD., Dover.

AWARD OF MERIT.

To *Rhododendron* × *Liliani*.—This was the finest of a beautiful strain of arboreum × *Shilsoniani* hybrids. The colour is a brilliant blood-red shaded with carmine. The carmine in it is distinct, and brightens and increases as the flowers age to such an extent that the old trusses shown appeared at first sight to belong to a different variety. The handsome trusses consist of about 18 compactly-arranged flowers, each of which at its best is 3½ inches in diameter. The foliage is also bold and handsome, whilst in habit and freedom of flowering this variety is described as the best of the batch of seedlings from which only cut trusses were shown. Shown by R. Fox, Esq., Falmouth.

CULTURAL COMMENDATION.

This award was made to F. D. GODMAN, Esq., for three fine pans of the beautiful Chilean

Crocus, *Tecophilaea cyanocrocus*, which was figured in *Gardeners' Chronicle* so long ago as February 17, 1872, p. 219.

OTHER NOVELTIES.

Rhododendron × *Barclayi*. — The most interesting of the beautiful *Rhododendrons* shown by R. Fox, Esq., was not found in the arboreum hybrids but in this Sikkim hybrid, derived from *Scarlet Aucklandii* crossed with *Thomsonii*. The foliage is very distinct and handsome, and the plants now flowering for the first time have been watched for many years with the greatest interest by *Rhododendron* enthusiasts. The flowers are larger than those of *Liliani* above, deep blood-red, very telling, both in form and colour, but

very beautiful *Laelio-Cattleya Glaucus* Westonbirt variety (*L.-C. Rubens* × *L. purpurata*) from the same cross, for which Sir George Holford received a First-class Certificate on August 13, 1912.

Messrs. JAS. VEITCH AND SONS, Royal Exotic Nursery, King's Road, Chelsea, were awarded a Silver Flora Medal for a fine group of *Dendrobium Wardianum*, *Lycaste Skinneri*, and *Odontoglossums*, all finely flowered, the *D. Wardianum* having the tall pseudo-bulbs well furnished with blooms. The plants were grown and flowered at Chelsea from imported pieces. A grand dark form of *L.-C. Gottiana* was also shown.

Messrs. CHARLESWORTH AND Co., Haywards

[Photograph by R. A. Malby.]

FIG. 87.—NARCISSUS NORTHERN QUEEN.
(See page 192.)

not held so closely in the truss as in the arboreum hybrids.

Orchid Committee.

Present: Sir Harry J. Veitch (in the chair), and Messrs. Jas. O'Brien (Hon. Sec.), Gurney Wilson, F. M. Ogilvie, R. A. Rolfe, R. G. Thwaites, F. J. Hanbury, T. Armstrong, A. McBean, W. Cobb, J. Charlesworth, J. Cypher, W. H. Hatcher, H. G. Alexander, G. Hunter, A. Dye, E. H. Davidson, S. W. Flory, C. Cookson, W. Bolton, and De B. Crawshaw.

Lieut.-Col. Sir GEO. L. HOLFORD, K.C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), sent the finest Orchid of the show, and the finest *Sophranitis* cross in the brilliantly-coloured *Sophranitis* × *Cattleya Wellesleyae*, which gained a First-Class Certificate (see Awards); also the

Heath, were awarded a Silver Flora Medal for an excellent group of hybrid *Odontoglossums*, with several very fine white forms of *O. crispum*, *Odontiodas*, *Laelio-Cattleyas* and *Brasso-Cattleyas*. The front of the group had compact plants of the graceful white *Angraecum citratum* with scarlet *Sophranitis grandiflora*, *Coelogyne sparsa* and yellow *Oncidium concolor*. Specially noteworthy were a fine plant of the singular *Lycaste gigantea* with twelve flowers; a good *Cypripedium Rothschildianum*, *Miltonia Bleuana* varieties, and *Dendrobium atroviolaceum*.

Messrs. SANDER AND SONS, St. Albans, were given a Silver Flora Medal for a varied and interesting group, the novelties in which were *Cymbidium amabile* (*Lowii-Mastersii* × *insigne Sanderi*), a pretty hybrid with the usual

characteristics which follow most of the *C. insigne* crosses, *Brasso-Cattleya Sylvia* (*B.-C. Digbyano-Trianae* (*Sedenii*) × *C. Trianae*), a pretty white flower, merged into *C. Trianae*, but with a fringed lip, and *Laelio-Cattleya Dulce* (*C. Mendelii* × *L. anceps Sanderiana*) (see Awards). Some pretty *Odontoglossums*, good *Cymbidium* *Gottianum*, *Cattleya Olaf* var. *venusta*, *Masdevallia Schröderiana*, *Cirrhopetalum picturatum* well-flowered *Odontoglossums* set up with *Renanthera* *Imshoottiana* were also noted.

Messrs. STUART LOW AND CO., Bush Hill Park, and Jarvisbrook, Sussex, were awarded a Silver Banksian Medal for an effective group of *Dendrobiums*, *Cypripediums*, *Odontoglossums*, etc., with scarlet *Sophranitis grandiflora* in front. At one corner stood a fine specimen of the noble dwarf form of *Dendrobium Jamesianum* known as *D. Donnesiae*, with thirteen large, white flowers with yellow centres. A very fine *Laelio-Cattleya Myra*, a rich red *Odontioda Charlesworthii*, some well-flowered *Brasso-Cattleyas*, and *Odontoglossum Jasper* of specially good quality were included.

Messrs. ARMSTRONG AND BROWN, Tunbridge Wells, were awarded a Silver Banksian Medal for a good group specially rich in hybrid *Odontoglossums*, some between *O. eximium* and *O. illustrissimum*, and some home-raised blotched *O. crispum* being excellent. Among hybrid *Dendrobiums* *D. Chessingtonense* was the best deep yellow. *D. nobile Virginale* was well shown; *Laelio-Cattleya Myra*, varying in tints of yellow and rose, and *L.-C. Myrosa* (*Myra* × *luminosa*), a fine improvement on *L.-C. Myra*, with yellowish sepals and petals tinged and veined with purple, the violet-purple lip having a yellow patch on each side. Forms of *Miltonia Hyeana*, *Odontiodas* and *Cypripediums*, with a plant of the beautiful little *Maxillaria sanguinea* were also noted.

Messrs. J. CYPHER AND SONS, Cheltenham, secured a Silver Banksian Medal for a well-arranged group of good *Cypripedium* *Calanthe* *Bryan*, and *William Murray*, *Lycaste Skinneri* and the best white form; *Brasso-Cattleyas*, *Laelio-Cattleyas*, *Dendrobium Wardianum* album, the pretty *Laelio-Cattleya Lady Miller* in several forms, varying in tints of copper-red; a finely-flowered *Sarcochilus Fitzgeraldii*, *Angraecum citratum* and *Ada aurantiaca* were included.

Messrs. FLORY AND BLACK, Orchid Nursery, Slough, were awarded a Bronze Banksian Medal for a small group of remarkably good hybrids, including the new *Laelio-Cattleya Verona* (*L. anceps* × *C. Hardyana*) with soft rose-coloured flowers with orange disc to the lip; some good blotched *Odontoglossum crispum*; the very distinct *Cattleya Trianae Exquisite*, a finely-shaped flower with broad, purple feather on the petals—an improvement on the variety *Backhouseana*—some new hybrid *Cypripediums*, and two plants of the pretty white *Disa sagittalis*.

Messrs. W. B. HARTLAND AND CO., Cork, were awarded a Bronze Banksian Medal for a group of *Cypripediums*, *Cymbidium* and *Odontoglossums*, *Cypripedium aureum Surprise*, and other forms of *C. aureum* and *C. Euryades* were effectively displayed with *Cymbidium Lady Colman*, *C. insigne*, and a hybrid between *C. Tracyanum* and *C. giganteum*.

The Earl of CRAVEN, Combe Abbey, Coventry (gr. Mr. H. Chandler) sent *Laelio-Cattleya Corneliensis* (*L.-C. Haroldiana* × *C. Schröderae*), a softly-tinted cream-white flower tinged with yellow, the front of the lip rose-purple.

R. G. THWAITES, Esq., Chessington, Streatham (gr. Mr. Harrington) showed a very fine *Cattleya Octave Doin*; several of his rich yellow and maroon *Dendrobium Chessingtonense*, *D. Austini*, a distinct *Cattleya Empress Frederick*, and two new hybrid *Odontoglossums*.

PANTIA RALLI, Esq., Ashted Park, Surrey, showed *Odontioda Hemptinneana* (*Od. eximium* × *C. Noezliana*), *O. Keighleyensis* Ashted Park variety, and another deep-red *Odontioda* named *Illustris*, of unknown parentage. Also *Miltonia St. Andre* Ashted Park variety; *Odontoglossum crispum Mrs. T. Zarif* and *O. c. Ashted Park* variety.

E. R. ASHTON, Esq., Broadlands, Tunbridge Wells, showed *Laelio-Cattleya Marion* (*L. C. Clive* × *L. tenebrosa*), a very richly-coloured

flower of medium size, and *Cattleya Trianae* Broadlands variety, large and of good shape.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day) sent *Brasso-Laelio-Cattleya Joan* (*B. L. Mrs. Gratrix* × *C. Octave Doin*) of a pleasing yellow colour, and *Sophr-Laelio-Cattleya Marathon Goodson's* variety.

W. C. CLARK, Esq., Boscombe, Bournemouth, showed *Laelio-Cattleya luminosa Clark's* variety, with buff sepals and petals tinged with rose, lip rose-purple in front.

F. M. OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth) showed in fine form *Lycaste Skinneri alba magnifica*, *Cattleya Empress Frederick alba* and others.

Messrs. E. H. DAVIDSON AND CO., Orchid Dene, Twyford, showed a selection of handsome *Orchids*, including their very fine form of *Cattleya Trianae*, *C. Empress Frederick*, the richly-coloured *Sophr-Laelio-Cattleya Elissa*, *Brasso-Laelia Helen* with unusually large flowers, two *Brasso-Cattleya Digbyano-Mendelii*, one being a grand white form with a small rose-coloured line on the lip; the new scarlet *Habenaria Roebeleinii*, *Laelio-Cattleya Feronia superba*, some brightly-coloured *Odontiodas* and *Sophranitis*.

Messrs. J. AND A. McBEAN, Cooksbridge, staged a small group in which the bright-red *Odontiodas* were conspicuous, the best being *O. Lambeauana Ceres*, *O. Diana* varieties *Doris* and *Pluto*. At the back were hybrid *Cymbidium* and *Odontoglossums*, and among others noted were the new *Laelio-Cattleya Euripides* (*Myra* × *Goldcrest*), a pretty flower of a uniformly clear yellow colour, and the handsome *Cattleya Trianae F. McBean*.

Messrs. HASSALL AND CO., Southgate, staged an effective group, at the back of which were *Odontoglossum Thompsonianum*, *Renanthera Imshoottiana*, and a good example of *Angraecum sesquipedale*, with *Odontoglossums*. The white *Brasso-Cattleya Menda* raised at Southgate, and other hybrids, were also noted.

Monsieur MERTENS, Ghent, showed some hybrid *Odontoglossums* and *Cattleya Trianae* alba.

AWARDS.

FIRST-CLASS CERTIFICATE.

Sophr-Cattleya Wellesleyae Westonbirt var. (S. grandiflora × *C. labiata*) from Lieut.-Col. Sir GEO. L. HOLFORD. One of the finest of *Sophranitis grandiflora* crosses yet shown, and unique in the brilliant tint of its richly-coloured flowers. The inflorescence bore three flowers of fine shape, deep scarlet, with a bright cerise-red glow varying in tint in different aspects. The base of the lip is yellow, with red lines. The cross was first shown by Francis Wellesley, Esq., and is sometimes called *S.-C. Mrs. Francis Wellesley*. It is a charming hybrid, and extremely rare.

AWARD OF MERIT.

Laelio-Cattleya Dulce (C. Mendelii × *L. anceps Sanderiana*) from Messrs. SANDER AND SONS. Flowers of good size, nearest to *C. Mendelii* in size and shape. Inflorescence 1ft. high, three flowered. Sepals and petals silvery-white, tinted with lavender colour; front of lip violet-purple.

Dendrobium Bassattii (Rolfeae × *Melanodiscus Salteri*), from Mrs. T. B. HAYWOOD, Woodhatch, Reigate. A pretty rose-coloured flower nearest to *D. Rolfeae*, but larger; lip white, with rose-tinted tip and some purple lines at the base.

Narcissus and Tulip Committee.

Present: E. A. Bowles, Esq., in the chair, the Rev. Joseph Jacob, Messrs. W. F. N. Copeland, Arthur R. Goodwin, A. M. Wilson, Herbert Smith, Christopher Bourne, Charles T. Digby, R. W. Wallace, J. T. Bennett-Poë, F. Herbert Chapman, W. A. Watts, W. W. Fowler, W. Poupert, Walter T. Ware, G. W. Leak, C. L. Adams, and Chas. H. Curtis (hon. sec.).

Messrs. CARTWRIGHT AND GOODWIN, Kidderminster, staged a comprehensive collection of the various types, amongst which such brightly-cupped *Barrii* varieties as *Firebrand*, *Fire Spaniel*, and *Southern Star* arrested attention. But the gem of the exhibit was *Northern Queen* (see fig. 87, p. 191), a *Leedsii* variety with a perianth of *Cassandra* type and a small, pale yellow crown—a very chaste and fascinating flower. *Swashbuckler*, a bicolor

Incomparabilis, has a nearly white perianth and a very large, open cup; *Aquarius*, a *Leedsii* with a very large perianth and a crimpet crown, which is delicately tipped with orange; and *Onslaught*, a bicolor *Trumpet*, in which the yellow of the trumpet merges into the white of the perianth, are desirable novelties. Amongst the smaller flowered section, a cross between *Golden Spur* and *cyclamineus* was interesting in that it showed but little of the *Trumpet* parentage; the flowers are almost purely of *cyclamineus* form, but twice as large, and with a slightly wider mouth. (*Silver-gilt Banksian Medal*.)

Messrs. BARR AND SONS, Covent Garden, London, showed many seedling *Trumpet* varieties under numbers, several of them of such merit that they are deserving of names. Of these, 1,983, rich yellow in colour and widely expanded cup; 2,646, a similar, but rather larger flower; 1,068, a very long trumpet of pale primrose colour and a lighter perianth; and 407, rich yellow and of good substance, are the very best. Of the named sorts, *Sunrise*, a distinct *Barrii*, perianth white with a broad primrose-coloured bar along the centre of each segment and a fluted fiery-orange crown; *Sparkler*, a *Leedsii* which has a rich yellow perianth and a fiery orange rim to the crown; and *Fire-dome*, a similar flower differing in the paler colouring and wider crown, were pleasing. Amongst the small section *N. cyclamineus*, *minimus* and *Bulbocodium conspicuus* were also shown in good condition. (*Silver-gilt Banksian Medal*.)

Messrs. JAMES CARTER AND CO., Raynes Park, arranged a large collection of *Narcissi* and *Tulips* growing in bowls of fibre. Of the former *Barbara*, *Sir Francis Drake* and *Vanilla* were uncommonly successful, and the bowls of *Tulip Prince of Austria* were very gorgeous. (*Silver Flora Medal*.)

Messrs. J. R. PEARSON AND SONS, Lowdham, Notts, specialised with the *Giant Leedsii* varieties, and of these *Lowdham Beauty* and *Louise L. Linton*, both of perfect form and widely expanded crowns; *Capella*, with so large a cup as to give a first impression of being a *Trumpet* variety, were uncommonly fine. *Florence Pearson*, a *Trumpet* variety, which may be described as a greatly-improved *Madame de Graaff*, will have a great future. (*Silver Flora Medal*.)

Messrs. W. T. WARE, LTD., Inglescombe Nurseries, Bath, arranged a large number of the richly-coloured *Queen of the West* (*Trumpet*) on each side of a few very choice novelties. *White City*, a *Leedsii*, in which the perianth is large and stout and the crown small, curled and slightly incurved; *Lolah*, a slightly pendulous *Trumpet* variety with a nearly white perianth and sulphur-yellow trumpet; and *Macebearer*, an orange-tipped *Incomparabilis*, were of great merit. (*Silver Flora Medal*.)

Mr. C. BOURNE, Simpson, Bletchley, had a predominance of the chalice-cupped *Narcissi* in his display, and of these *Bernardine*, a very round *Leedsii* bloom; *Lady Moore* and *Cossack*, two bright-rimmed *Barrii* varieties, were of much more than average merit. (*Silver Flora Medal*.)

Messrs. R. H. BATH, LTD., Wisbech, made an attractive display of *Tulips*, *Crocuses*, and a few *Narcissi* growing in pans of fibre. In the centre was a vase of *Hercules*, a new *Trumpet* *Daffodil* of great size and rich yellow colour. (*Silver Banksian Medal*.)

Messrs. HERBERT CHAPMAN, LTD., Rotherside Gardens, Rye, showed novelties and standard varieties in the annexe. T. G. Sharpe, a slightly pendulous *Trumpet* of good substance and pale yellow colouring; *Scabbard*, a bright-eyed *Barrii*, which has the attributes of a naturalising variety; *Albatross*, a chaste *Leedsii* of good form; *Bracken*, a twin-flowered *Incomparabilis*, and *Shrove*, an appropriately-named *Barrii* which has an unusually flat crown, are all very good. *N. triandrus* hybrids, *N. minicycla* were shown in quantity.

Miss C. MICHELL, Oakfield, Cricklewood; Messrs. W. B. HARTLAND AND SONS, Ardcairn, Ballintemple, Co. Cork; Messrs. CARTER PAGE AND CO., London Wall, London; Messrs. BARRIE AND BROWN, King William Street, London Bridge, London; and Messrs. ROBT. SYDENHAM, LTD., Birmingham, showed *Narcissi* and *Tulips* in pans of fibre.

AWARDS OF MERIT.

Olympia.—An Award of Merit was given to this well-known large yellow Trumpet Daffodil, in recognition of its great value for cultivation in pots.

W. P. Milner.—A very old Trumpet Daffodil with pendulous flowers of sulphur-yellow colouring. The flowers are of small size, and are freely produced; this variety is of value for planting in rock gardens, which attribute influenced the award.

Fruit and Vegetable Committee.

Present: J. Cheal, Esq. (in the chair), Messrs. John Harrison, W. Bates, F. Perkins, A. R. Allan, J. G. Weston, Horace J. Wright, P. C. M. Veitch, A. Grubb, A. Bullock, W. E. Humphreys, G. W. Wythes, F. G. Treseder, C. G. A. Nix, H. H. Williams, and George Reynolds.

Messrs. SUTTON AND SONS, Reading, were awarded a Silver Knightian Medal for vegetables. This attractive exhibit contained choice heads of Early White and Snow White Cauliflowers; Early Purple and Early Purple Sprouting Broccoli; Harbinger and April Cabbages, Golden Ball Lettuce, Seakale, Mushrooms, Cucumbers, and Climbing French Beans.

Competitive Bulb Classes.

Although the entries for this annual show were not so numerous as usual, this falling off was atoned for by the superlative excellence of many of the exhibits, some of which were as near to perfection as we ever expect to see. The object of the show is "to discover the varieties best suited for gentle forcing," and as the varieties shown were almost identically the same as at recent exhibitions, there does not appear to be any new sorts of greater value for forcing purposes than what may be termed the standard varieties.

The Gold Medal of the General Bulb Growers' Association was awarded to the Duke of PORTLAND.

AMATEURS' CLASSES.

Eighteen Hyacinths, distinct.—The competition in this large class must have been very gratifying to the Council, for it is no light undertaking to present such a collection in show condition. 1st, the Duke of PORTLAND, Welbeck Abbey, Worksop (gr. Mr. J. Gibson), who had a magnificent collection which was characterised by splendid stout spikes of large, closely-disposed flowers rising from broad, short, healthy foliage. In this exhibit the varieties Koh-i-noor, Hofgarten Kurnet and La Victorie, were superb; 2nd, Lord HILLINGDON, Wildernesse, Sevenoaks (gr. Mr. J. Skelton), who also had an admirable exhibit, in which the varieties King Menelik, Electra and Jacques were especially fine; 3rd, Colonel the Hon. MARK LOCKWOOD, Bishop Hall, Romford (gr. Mr. W. Craddock).

Twelve Hyacinths, distinct.—The competition in this class was very good indeed, and there could not have been many points separating the leading exhibitors. 1st, the Marquis of SALISBURY, Hatfield (gr. Mr. H. Prime), who staged splendid spikes of Correggio, Electra Schotel, and City of Haarlem; 2nd, R. G. MORRISON, Esq., The Hollies, Victoria Park, Liverpool; 3rd, Miss NATHAN, Little Heath House, Potters Bar (gr. Mr. W. Newton).

Six Hyacinths, distinct.—The exhibits here were not of equal merit to those in the larger classes, but an occasional spike was magnificent. 1st, Miss A. LEVITA, Norton Priory, Chichester (gr. Mr. H. Edwards); 2nd, Mr. L. THOMSON, Ailsa Craig, Formby, Liverpool; 3rd, Lady TATE, Park Hill, Streatham Common (gr. Mr. H. Howe).

Four pans of Hyacinths, 10 roots of one variety in each.—This was the outstanding feature of the show, and it is safe to say that never before have such examples of cultural skill with these bulbs been seen. The competition was so keen that the judges felt constrained to award equal 1st prizes to the Duke of PORTLAND and the Marquis of SALISBURY, who both showed pans of City of Haarlem, La Victoire and Correggio. The blue variety in the first-named collection was King of the Blues, whilst the Marquis of SALISBURY presented the paler, Schotel; 2nd, Colonel LOCKWOOD, who staged splendid plants, but little inferior.

BULBS IN MOSS FIBRE.

The following classes were for bulbs grown in vases of moss fibre, and the varieties had to be selected from published lists.

Six Single Hyacinths.—There was good competition in this class, where many of the spikes were of splendid size and form. 1st, Lady TATE; 2nd, Miss C. MICHELL, Oakfield, Cricklewood.

Six Vases of Tulips.—1st, LADY TATE, who sent floriferous vases of such varieties as Kaiser-skroon, Le Réve and Van der Neer.

Six Vases of Narcissi.—All the exhibits were very graceful and attractive, well illustrating the value of this method of culture. 1st, Lady TATE; 2nd, Mrs. GUY BARING.

FOR TRADE GROWERS.

Messrs. R. and G. CUTHBERT, Southgate, were the only exhibitors in the class for the Gold Medal of the General Bulb Growers' Association of Haarlem, and they were awarded the trophy for a monster display of Hyacinths, which filled the end of the hall. There were over 60 pans, each containing 9 plants, as well as a large number of single pots, and all the flower spikes were of first-rate quality. Where all were so good it was a difficult matter to select any for especial mention; but the pans of Jacques, City of Haarlem, Lord Derby, Queen of the Blues, and Lord Balfour, were of exceptional merit.

SILVER CHALLENGE CUP FOR ROCK GARDENS.

A Silver Challenge Cup has been presented to the Society by the proprietors of the *Daily Graphic* and offered by the Council in open competition at the Chelsea Show on May 19, 20, 21, 1914, for the best rock garden judged not from the point of view of size, but for (1) the natural artistic grouping of the stones; (2) evidence of design in construction; and (3) suitability to the growth of Alpine plants. The rarity or otherwise of the plants themselves to carry but little weight in this competition. Special judges will be appointed representing as far as possible an artist, an owner of a rock garden, and a gentleman accustomed to the planting of rockwork. The winner will hold the cup for one year subject to a sufficient insurance against loss, and a written guarantee to return it in good condition; or failing this, to refund to the R.H.S. the sum of £55. On return of the Cup in good condition the holder will be presented with a small commemorative Cup. The same exhibitor may only win the Cup once in three years, but should the winner of the previous year be again considered first, the Council will bestow a special award.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 26.—*Committee present*: Rev. J. Crombleholme (in the chair), Messrs. J. Bamber, J. Cypher, A. G. Ellwood, J. Evans, A. Hammer, J. Howes, J. Lupton, D. McLeod, C. Parker, W. Shackleton, A. Warburton, Z. A. Ward, A. A. McBean, and H. Arthur (secretary).

AWARDS.

FIRST-CLASS CERTIFICATES.

Odontoglossum eximium var. "Iduna," shown by W. B. LEE, Esq.

Cattleya Trionae "Orchid Dene" var., from Messrs. E. H. DAVIDSON AND CO.

AWARDS OF MERIT.

Odontoglossum × *Rufus*, *O. Distinction*, *O. crispum* var. *Meteor*, *Odontioda Brewii* var. "niger rubra," all from R. ASHWORTH, Esq.

Odontoglossum Fuscans, *Laelio-Cattleya Lucasiana* and *Cypripedium Lord Trevor* var. "Pyramus," shown by WM. THOMPSON, Esq.

Cypripedium Thisbe (Mrs. Mostyn × *leeanum* *Clinkaberryanum*), from W. R. LEE, Esq.

Odontoglossum Edith d'Abrew, shown by R. LE DOUS, Esq.

Odontioda Diana "Leeman's" var., shown by J. LEEMAN, Esq.

Odontoglossum Twyford Gem (*Rossii rubescens* × *formosum*), shown by Messrs. E. H. DAVIDSON AND CO.

Dendrobium cybele album (*nobile virginale* × *Findleyanum album*), shown by Messrs. A. J. KEELING AND SONS.

SCOTTISH HORTICULTURAL.

MARCH 3.—The monthly meeting of this Association was held in the Goold Hall, 5, St. Andrew Square, Edinburgh, on the 3rd inst. Mr. Fife, one of the vice-presidents, was in the chair, and there was an attendance of 90 members.

A paper, entitled "A Talk About Potatoes," was read by Mr. GEO. M. TAYLOR, Edinburgh. He said that a disease-proof Potato was something very desirable in the interests of every grower of this important crop, and he discussed the possibilities of such a Potato being evolved by the practical plant breeder. He traced the evolution of the Potato from the year 1846 to the present time, and endeavoured to show that careless cultivation in the way of seed selection was primarily responsible for the frequent attacks of *Phytophthora infestans*. Careful selection of tubers for seed, said Mr. TAYLOR, was a vital necessity if disease was to be successfully combated, and rubbish left over after the ware had been sold for food was useless for planting, and was a sure method of weakening the constitution of the plant, rendering it unfit to ward off the attacks of blight. The problem of fighting diseases in the Potato was one that required the attention of the plant pathologist, and the manuring methods as applied to this crop required considerable investigation. The scientist alone could not hope to arrive at a satisfactory solution without the aid of the practical seed grower and breeder. Our seed was obtained from many countries, and the need for new methods was pressing if the crop was to remain a paying one in these islands. The Scottish Board of Agriculture had lately approached a distinguished scientist to make some experiments in the breeding of Potatoes immune from disease. He asked the Board to declare to practical men what it required. He, for one, was willing to submit a race of hybrids to the Board for severe trial, and he believed they would resist disease. The application of Mendelian laws to Potato breeding was now an accomplished fact, and much progress had been made on these lines. If immunity from disease was proved to be a recessive character (and everything seemed to indicate that it was), a disease-proof Potato was a matter of certainty. The fact remained, however, that careful seed selection was a necessity if resistance to disease was to remain a permanent character of the Potato.

The exhibits were:—*Clematis indivisa*, exhibited by Mr. WM. SMALE, Blackford Park, Edinburgh; *Galanthus Elwesii*, *Helleborus orientalis* vars. *purpurascens major*, "No Plus Ultra" and "Dr. Moore," exhibited by Mr. C. COMFORT, Davidson's Mains.

At the meeting to be held on April 7, Mr. CHARLES W. B. WRIGHT, Edinburgh and East of Scotland College of Agriculture, will give a lecture on "Methods of Controlling Disease by Spraying" (with lantern illustrations).

GARDENING APPOINTMENTS.

[Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.]

Mr. G. Marcham, for the past 2 years and 4 months Gardener to J. F. SYMONS JEUNE, Esq., Runnymede House, Old Windsor, Berkshire, as Gardener to Madame FREEMAN PRINCESS DE BOURBON, Ashleigh, Virginia Water, Surrey.

Mr. W. H. Jones, formerly for 3½ years Gardener to J. T. Hereford, Esq., and for the past 6 months with Messrs. THE KING'S ACRE NURSERIES, LTD., as gardener to Captain HEYGATE, Esq., The Wells, Bromyard, Herefordshire.

Mr. W. W. Penniford, for the past 7 years Foreman at Franklyn's, Haywards Heath, Sussex, as Gardener to A. J. NORRIS, Esq., Court House, Bantstead, Surrey.

MARKETS.

COVENT GARDEN, March 11.

We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Eds.1

Cut Flowers, &c.: Average Wholesale Prices.

Table listing various cut flowers and their prices, including Arums, Azalea, Carnations, Daffodils, Gardenias, Lilies, and Tulips.

Cut Foliage, &c.: Average Wholesale Prices.

Table listing various cut foliage and ferns, including Adiantum, Agrostis, Asparagus, and Carnation foliage.

French Flowers.

Table listing French flowers such as Anemones, Lilacs, and Mimosa.

Guernsey and Scilly Flowers.

Table listing flowers from Guernsey and Scilly, including Anemone fulgens and Daffodils.

REMARKS.—There is very little that is fresh to record, and prices show but little alteration from those of last week. There is an abundant supply of good Daffodils; the best blooms are Victoria and Emperor. Both double and single Tulips are also good and plentiful. Darwin's Tulips are already on sale. Roses are more numerous than last week, and include fine blooms of Richmond,

Countess of Derby, Lady Hillingdon, Rose Queen, Sunburst and Yellow Souvenir. General Jacqueminot, Sunrise, and other novelties are seen on Messrs. Beckwith's stands. There is a good supply of Princess of Wales Violets, and the bunches are arriving in a good condition. There is a better demand for home-grown Violets, as those from the Continent reach the market in an unsaleable condition. This week the salesmen have offered a few bunches of blue Spanish Irises. Flowers from Guernsey and Scilly continue to arrive in large quantities, and are very difficult to clear even at low prices.

Plants in Pots, &c.: Average Wholesale Prices.

Table listing various potted plants and their prices, including Aralia, Asparagus, Azalea, Cacti, and various ferns.

REMARKS.—Flowering plants are beginning to make a bright show. There is still a good supply of Azaleas, Cyclamens and Ericas persoluta and Willmorel. The salesmen are gradually filling up their stands with Genistas, Cinerarias, Marguerites, White Spiraeas, Hyacinths and Mignonette. Ferns are not at their best condition; indeed, the quality is very poor. Flowering plants are required most, and trade is better for these subjects. There are also a few good plants of pink, white and blue Hydrangeas, each carrying from three to six small trusses. These plants should find a ready sale.

Fruit: Average Wholesale Prices.

Table listing various fruits and their prices, including Apples, Lemons, Nuts, Oranges, Peaches, and Pears.

REMARKS.—The best Nova Scotian Apples are Wine Sap, Albemarle Pippin, and Oregon Newtown. About 24,000 packages of fruit have arrived from the Cape this week, consisting principally of Plums, Pears, and Grapes. Gros Colmar Grapes from English and Continental growers continue a good supply. The quantities of forced Strawberries are increasing daily. The first consignment of the new crop of Brazil nuts has arrived. Some fine samples of Asparagus are obtainable. Cucumbers are very plentiful, and there is a large supply of Broccoli from home and abroad. Forced Beans are an increasing quantity, but forced Peas are scarce. Madeira Beans are a good supply. Seakale is scarcer. Mushrooms are marketed in fair quantities. Forced Mint is more plentiful. Good samples of Tomatoes are arriving from the Canary Islands. Broad Beans from France are packed in pad baskets, each containing about

12 lbs. The market is well supplied with outdoor vegetables of all kinds. E. H. R., Covent Garden, March 11, 1914.

Vegetables: Average Wholesale Prices.

Table listing various vegetables and their prices, including Artichokes, Asparagus, Beans, Cabbages, Carrots, Cauliflowers, Celery, Cucumbers, Endive, Garlic, Horseradish, Lettuce, Leeks, and Potatoes.

Table listing various potato varieties and their prices, including Bedford, Blacklands, British Queen, Dunbar, and Evergood.

REMARKS.—Trade is no better than last week and prices are about the same. Stocks in London are not quite so large, but consignments are quite equal to the demand. E. J. Newborn, Covent Garden and St. Pancras, March 11, 1914.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending March 7, is furnished from the Meteorological Office:—

GENERAL REMARKS.

Pressure, Wind and Weather.—With the barometer highest in an anticyclonic system between Spain and the Azores, and depression centres travelling in a general easterly direction on a track to the northward of Scotland, the type of distribution was westerly. The disturbances of the early days of the week were deep enough to cause frequent strong winds over the United Kingdom, but gale force was not reached, except very locally, until late on the 5th. The depression that lay off the North of Scotland at 6 p.m. on that date was deep, and during the night it developed further intensify. By the morning of the 6th the barometer at its centre had fallen to about 965 millibars, and as it subsequently moved east-south-eastward the wind over these islands increased to a gale from between west and north-west very generally. The force of a strong to whole gale was experienced over a large area, the greatest violence occurring in the North and North-east of England. At the close of the week, when the depression had reached the Baltic, a small secondary system was passing eastward over England. Rain fell daily in Ireland, the South-west of England, and the greater part of Scotland, and the total fall for the week in those regions was considerably in excess of the average. Many places over the northern half of the Kingdom experienced a little sleet or snow from time to time. Thunder occurred at Foyens on the 1st, and at some other stations in the north there was lightning singly.

THE WEATHER IN WEST HERTS.

Week ending March 11, 1914. The Wettest Day for Eighteen Months, and the highest Wind for Over Four Years.—This was the sixth unseasonably warm week that we have had in succession, notwithstanding the last two days and nights having been rather cold for the time of year. On the warmest day the highest temperature in the thermometer screen was 56°, and on the coldest night the exposed thermometer registered 12° of frost. The ground is at the present time 2° warmer than is seasonable, both at 1 foot and 2 feet deep. Rain fell on four days, and to the total depth of nearly 2 inches—making this the wettest week since September, 1912. Rain or snow fell almost continuously from 11.30 p.m. on the 7th to 9 p.m. on the 9th, or for 4½ hours—the total measurement being 1½ inches, or nearly as

much as the average quantity for the whole month. On the one very wet day (8th inst.) the fall of rain amounted to rather more than one inch—making this the wettest day since Michaelmas Day, 1912, or for nearly eighteen months. During the past week nearly eight gallons of rainwater has come through both the percolation gauges—which are each a yard square and nearly a yard deep. The sun shone on an average for nearly two hours a day, which is 1½ hours a day short of the average daily duration for the same period in March. On five days no sunshine at all was recorded. The winds were, as a rule, high during the early part of the week, but light airs have alone prevailed for the past five days. In the windiest hour on the 6th inst. the mean velocity amounted to twenty-six miles—direction W.N.W. We have to go back to December, 1909, or for over four years, in order to find any wind as high. The average amount of moisture in the air at 4 p.m. exceeded a seasonable quantity for that hour by 6 per cent. *E. M., Berkhamsted, March 11, 1914.*

LAW NOTE.

QUESTION OF AGREEMENT.

IN the King's Bench Division, Court IV., on the 23rd ult., an action was opened in which the plaintiff was Mr. Archibald Forshaw Dutton, proprietor of the Nurseries, Iver, Buckinghamshire, and the defendant Colonel Frederick Charles Wood Rideout, proprietor of the Clury Nurseries, Langley. Mr. Dutton alleged wrongful termination of an agreement, under which he had been practical adviser to the defendant at the Clury Nurseries, and claimed an account and payment of all sums found to be due to him under such agreement, damages for wrongful dismissal, or, in the alternative, that the agreement be declared to be still subsisting, and himself (the plaintiff) entitled to perform his obligations thereunder, and that an account, as before mentioned, be taken, and all sums found to be due to him under the agreement be paid. Colonel Rideout denied the wrongful termination of the agreement, and counterclaimed, alleging that he had suffered damages by reason of loss in the working of his nurseries, caused in whole or in part by the plaintiff's misconduct and breach of agreement.

The evidence of the plaintiff was that in August, 1911, an agreement was made between himself and defendant under which the plaintiff was to be employed as practical adviser in connection with the management of the Clury Nurseries at Langley for a period of seven years and fifty-two days, subject to the defendant's right to terminate the agreement should the defendant sell the nurseries from such date as should be mutually agreed upon, the plaintiff being entitled to a proportion of the net profits up to such determination. The remuneration of the plaintiff was to be computed as follows:—At the end of the first year and fifty-two days he was to have a sum equal to the net profits (if any) in excess of £300. At the end of the second and every subsequent year a sum equal to the net profits (if any) for the year in question in excess of £350 up to a total of £450, after which sum any excess would be equally divided between the defendant and the plaintiff; and should the defendant, at the consent and on the advice of the plaintiff, incur further capital expenditure on account of the nurseries, then the net profit due to the defendant should be increased by 10 per cent. on this capital expenditure, certain deductions, particularly referred to, having been made. The accounts of the business were to be made out annually, as on September 30, and audited by a competent firm of auditors. The plaintiff entered on his duties at Clury Nurseries on or about August 10, 1911, and continued to perform them until June 20, 1913, when the defendant, by a letter of his solicitors, Messrs. R. H. Barrett and Son, terminated the agreement as from the following day, although the nurseries had not been sold.

Several salesmen and growers gave evidence relating to the stocks of blooms at the Clury Nurseries. Mr. Curry, a Covent Garden salesman, said he had purchased blooms from these nurseries both before and after August 10, 1911. Before this date the blooms were very poor, but had afterwards improved. Later still, after June 20, 1913, the quality had gone back again.

On the question of some beds of Carnations in which numbers of the blooms had died, Mr. Carl Engelmann, of Saffron Walden, stated that

if they had died in patches it was most likely due to "stem rot," and not, as had been suggested, to the use of improper or too great quantities of manure. The manure used was the proper kind, and was used by 75 per cent. of growers.

Mr. Frederick Burnett, who had been employed at Clury Nurseries from February 20, 1911, to April 25, 1913, stated that Mr. Dutton's visits had been very regular—he had been to the nursery twice a week and very often on Sundays. Between February, 1911, and August, 1911, the condition of the nursery was wretched. After Mr. Dutton came there was a great improvement; the methods of planting out were placed on a new basis, and the production of the nurseries in the way of bloom was much increased. In the opinion of the witness the cause of the dying of the Carnations was stem rot, as the roots were found by him to be alive.

The defence offered was that the plaintiff did not visit the nurseries regularly once each week; that from April 29 to June 30, 1913, the plaintiff did not once visit the nurseries on a working day; that he had endeavoured to induce the defendant's foreman and stoker to leave and enter his (the plaintiff's) service. It was also stated that in a competition for Carnation blooms at the Perpetual-Flowering Carnation Society's Show, held in the Royal Botanic Gardens, Regent's Park, on December 5, 1911, the plaintiff showed in his own name 28 Mikado blooms which were grown at defendant's nurseries and obtained a first prize for them, and that he had also obtained various other awards for defendant's blooms. It was further contended that the accounts taken for the year ending September 30, 1912, and properly audited, showed a loss of £400 on the nurseries, and that the next year a profit of only £8 was made.

The reply of the plaintiff was that during the period between April 29 and June 13, 1913, he visited the nurseries on several Sundays, and on weekdays communicated with the foreman by telephone and ascertained that a personal visit was unnecessary. From April 25 to 28 plaintiff was at Ghent, and from May 24 to June 8 he was on his holidays, with defendant's full knowledge, and without any objection being raised. A denial was given to the statement that he had tried to induce the defendant's foreman and stoker to leave and enter his own service. All he had said was that if they should be obliged to leave he would endeavour to find situations for them. The blooms referred to as having been shown by plaintiff were sold to him by defendant in December, 1911. The plaintiff had honestly advised defendant not to exhibit at shows, as it had been arranged that the wholesale cut-bloom trade should be specially catered for. As to the three beds of Carnations, he considered that the plants had been killed by stem rot, and through no fault of his own. With reference to the profit, he said that if the stock had been properly and fairly valued the results of the trading would have appeared in a much more favourable light.

Colonel Rideout gave evidence, and said that he was a retired colonel of the Indian Army, and not himself an expert in horticulture. The Clury Nurseries were started in 1909, and Mr. Dutton came in 1911. After Mr. Dutton's arrival the foreman, Wharton, was put under him; but defendant was not at all satisfied with the number of times Dutton came, and told Wharton to keep a record of his visits. The record was kept, and showed that Dutton came very seldom.

The accountant, Mr. Ernest Hohler, C.A., stated that he had perused the agreement in question, and had examined the books of the Clury Nursery. He had not checked the stock. He found that in the year ending September, 1912, there was a loss of £403, and in the next year a loss of £14 18s. 10d. The difference between the Colonel's balance-sheet, showing £8 profit, and his own finding of a loss of £14 18s. 10d., was due to his having allowed depreciation on additions made to the green-houses the previous year.

The Lord Justice put the following questions to the jury:—(1) Did the plaintiff duly perform the duties of the agreement into which he had entered? (2) If not, did he so neglect his duties or so misconduct himself as to entitle the defendant to terminate the agreement?

The jury conferred for nearly an hour, after which they returned the answer: To No. 1, "Yes, except in the attendance." To No. 2, "No." Replying to a further question based on this, they put the plaintiff's damages at £100. Judgment was therefore entered for the plaintiff, £100 damages on the claim.

TRADE NOTE.

JOHN WATERER, SONS AND CRISP, LTD.

IN connection with the amalgamation of the Wargrave Plant Farm, Ltd., with the firm of John Waterer and Sons, we are informed that Mr. Bernard Crisp, son of Sir Frank Crisp, Bart., promoter of the Wargrave Plant Farm, will be a director in the new company, together with Mr. Gomer Waterer and Mr. John Waterer.

The Twyford Nurseries will be chiefly devoted to the culture of rock plants, herbaceous plants, Roses and bulbs.

At the Bagshot Nurseries choice shrubs, Chinese plants, American plants and Rhododendrons are largely cultivated, 60 acres alone being devoted to Rhododendrons. The two nurseries extend to 200 acres. The Bagshot Nurseries have been established over 100 years.

ANTS AND WOODLICE: Destroyer. Nests of Ants are sometimes made in places where boiling water can be poured over them, which is sufficient to destroy these pests. If this is not effective inject a little bisulphide of carbon or vaporize into their burrows, and the fumes will kill the ants. The "Ballinrain Ant Destroyer," which is prepared by Messrs. Alex. Cross and Son, Glasgow, is another effective and poisonous preparation. Traps may be made to catch woodlice by hollowing out pieces of Potato, Turnip, etc., and placing them hollow-side down. If the baits are examined every morning it will be found that they contain woodlice, which must be killed, and the baits replaced. Another method of killing woodlice is by placing baits which may be poisoned with Paris green or white arsenic. There are also other effective poisons on the market: Steiner's "Vermin Paste" is recommended by Mr. H. W. Ward, who has used it in his nursery at Rayleigh. The paste should be mixed with Barley-meal or middlings, and set on pieces of glass, wood, or tin, and then placed in the haunts of the woodlice. This means has been found sufficient to eradicate the pest in a week or ten days.

APPLE SHOOTS: A. T. H. The malformations are due to the attacks of the woolly aphid or American blight. As it is too late now to spray with the ordinary alkali wash we would recommend treating the affected parts with this specific by means of a brush, keeping the fluid clear of the buds.

BOWLING GREENS: Conscious of Ignorance. A green surrounded by wooden troughs must also have a grass bank. It is recommended that raised borders or banks be formed as a margin to bowling greens, and to prevent disputes these banks should be 18 inches above the green level, with an angle from the green of not more than 120 degrees. With regard to your query as to whether championship matches may take place on a green in perfect order, correct in size, surrounded by wood troughs, but without grass banks round same, there is, so far as we are aware, no written law to the effect, yet it is implied that if there is no bank there must be a board fixed equivalent to the bank in match games,

the meaning being to prevent reckless driving. Bowls are out of play when they go into the ditch unless they are "touchers," also if they go over the lines and lie in adjacent rinks. In laying the turves place them tightly together, as a green laid thus will be sooner fit for play than one laid with spaces left between the sods.

CANKER IN APPLE TREES: *W. B.* Canker (*Nectria ditissima*) is a wound parasite, entering into the living tissue by means of ruptures in the bark of the tree caused by the woolly aphis, by "gummosis," etc. It generally attacks trees that are in bad health, neglected, or that have been planted in badly-drained or unsuitable soil. All badly-diseased branches should be cut off and burnt. When the attack is only slight, cut out the affected parts and coat the wound with tar. It is not wise to allow badly cankered trees to remain as a source of infection for others; they should be rooted out and burned.

CARNATION DISEASED: *P. I.* A fungus is present in the specimens. Spray both diseased and healthy plants with a rose-red solution of permanganate of potash.—*Hale.* Carnation rust is present. Remove diseased leaves, and spray or sponge the plants with a rose-red solution of permanganate of potash.

CORRECTION.—In Mr. Correvon's notes on spring-flowering Cyclamen (p. 142), the word *winter* in line 13 was erroneously printed *white*.

CUCUMBERS DISEASED: *Gravesend Gardener.* Spraying with the Bordeaux mixture has not been very effective against Cucumber Spot Mould or Blotch (*Cercospora melonis*), but if commenced at an early stage it may do some good. Carbolic acid has been used by some with success. Mix a pint bottle of No. 5 Calvert's carbolic acid with five quarts of water, and water the path with this fluid just before shutting up the house in the evening. Mr. H. W. Ward relates that a similar mixture of carbolic acid and water was placed about in saucers in Cucumber and Tomato houses, and in all cases the plants remained healthy. Carbolic acid is a virulent caustic poison, and great care should be exercised in handling it or making use of it for this purpose.

DAFFODILS: *J. T.* The bulbs are badly attacked by eelworm. Sterilise the soil in which they grew by heating it.

FIG: *Brown Turkey.* The small Figs received have black spots upon them, which may be due to too much moisture being present in the air when the temperature of the house was rather lower than it ought to be. At this season of the year forced Figs require vigilant care. They like plenty of atmospheric moisture; indeed if they do not get this the leaves very soon become attacked by red spider, but whilst they like moisture, they like heat equally as well, and at the same time a circulating atmosphere. The difficulty is in adjusting the amount of moisture and heat in the hot-water pipes with a mild circulation of air admitted from the back of the house. Of course it may be that the Figs are attacked by the well-known fungous disease, *Cercospora Bolleana*, but your specimens are not sufficiently developed to show this pest. If you have further trouble with them we would recommend you to send some more specimens with the spots in a further state of decay.

GOOSEBERRY SHOOTS: *A. W.* American Gooseberry mildew is not present on the shoots, which have been injured by aphides.

GRUBS OF KITCHEN GARDEN: *C. H.* The specimen sent is a fully-grown larva of the common cockchafer, *Melolontha vulgaris*.

GRUBS: *C. A. B.* The grubs submitted for identification are commonly known as "leather jackets." They are the larvae of a species of Tipula, and feed upon the roots of various plants.

HYACINTH: *T.* The bulb has produced many side-growths because the central growth received a check of so severe a nature that the bulb has been unable to produce a flower-spike. Whether this check happened last season before the bulb was taken from the nursery plantation we cannot say, but the probabilities are that such was the case. There does not appear to be any specific disease present in the tissues.

INSECTS: *Bourne.* You are correct in your surmise with regard to the large tunnel in the Holly branch. It is undoubtedly the work of the larva of a moth—possibly *Cossus ligniperda*, though in the absence of the insect it is impossible to be definite on this point. The eggs are those of the vapourer moth, *Orgyia antiqua*. The egg masses, which are invariably attached to the cocoon, should be collected systematically and destroyed. If the caterpillars are found to be troublesome you should spray with arsenate of lead.

MORELLO CHERRIES: *N. L.* Cherries have always given more trouble than most other fruits by reason of their proneness to fall prematurely from the tree, but the habit is more characteristic of Sweet Cherries than Morellos. In both cases the bloom is produced with extraordinary profusion, and the drain upon the tree at a particular time during the setting of the flowers, swelling of the fruit, or formation of seed may be such that the tree suddenly casts the crop owing to temporary exhaustion. To prevent this misfortune gardeners sometimes thin out the flower-buds before they expand, which may be done very liberally whilst still leaving many more upon the tree than are required for the crop. In your case the fruits appear to get through the trying process of stoning without difficulty, but fall from the tree after they have commenced to develop colour. We think that the cause will be found in lack of sufficient moisture at the roots. Let steps be taken to keep the roots abundantly supplied with water and manure water whilst the fruit is swelling and colouring next season, and note the result.

NAMES OF PLANTS: *A. M. L.* 1, *Cedrus atlantica* var. *glauca*; 2, *Retinospora squarrosa*; 3, *Cryptomeria elegans*; 4, *Ruscus aculeatus* (Butcher's Broom).—*F. C. Steele.* 1, The green-leaved female variety of *Aucuba japonica*; 2, *Juniperus chinensis*; 3, *Taxus baccata*; 4, *Viburnum Tinus*; 5, *Pyrus sp.*, send when in flower; 6, *Berberis Darwinii*.—*R. NARCISSUS DISEASED: *J. S.* The injury has been caused by *Fusarium bulbigenum*, and the soil in which the bulbs grew will in all probability be infected with the fungus.

PLANTS FOR A ROCKERY FACING NORTH-EAST: *Alpine.* The following plants would be suitable for your purpose:—*Adonis amurensis*, *Anemone alpina*, *A. apennina*, *A. blanda*, *A. sylvestris*, *A. Hepatica*, *Aquilegia glandulosa*, *A. coerulea*, *Arenaria balearica*, *Aubrietia* in variety, *Campanula carpatica*, *C.*

Portenschlagiana, *C. pusilla*, *C. pulla*, and others, *Cerastium Bilbersteinii*, *Chrysogonum virginianum*, *Bulbinella Hookeri*, *Cornus canadensis*, *Cortusa Matthioli*, *Cyclamen neapolitanum*, *C. coum*, *C. ibericum*, *Dodecatheon Meadia*, *Epigaea repens*, *Epimedium pinnatum*, *E. rubrum*, *Euphorbia epithymoides*, *Funkia ovata* vars., *Galax aphylla*, *Gentiana asclepiadea*, *G. septemfida*, *Geum montanum*, *Haberlea rhodopensis*, *Hacquetia* (*Dondia*) *Epipactis*, *Helleborus orientalis*, *H. niger*, *Lindelofia spectabilis*, *Lithospermum purpureo-coeruleum*, *L. prostratum*, *Maianthemum convallaria*, *Meconopsis aculeata*, *M. sinuata latifolia*, *M. cambria* and its double var., *M. Wallichii*, *Mertensia primuloides*, *M. echioides*, *Myosotis* in variety, *Omphalodes verna* and var. *alba*, *Primula Bulleyana*, *P. Beesiana*, *P. rosea*, *P. japonica* and many others, *Pulmonaria rubra*, *P. saccharata*, *Ranondia pyrenaica*, *R. serbica Nathaliae*, *Ranunculus amplexicaulis*, *R. platanifolius*, *Rodgersia pinnata*, *Romanzoffia sitchensis*, *Saxifraga hypnoides*, *S. caespitosa*, and all others of the mossy section, *Thalictrum aquilegifolium*, *Tiarella cordifolia*, *Trillium grandiflorum*, *T. erectum* and others, *Erythronium Dens-canis*, *E. giganteum*, *E. Hendersonii* and others, *Vancouveria hexandra*, *Veronica Teucrium prostrata*, *Vinca minor* in variety, *Viola gracilis*, and *Waldsteinia trifolia*.

PRIMULA MALACOIDES: *A Dorset Gardener.* The note on p. 180 will furnish the information you ask.

TODEA SUPERBA: *O. D. K.* This plant is seldom propagated in this country; strong stems are usually imported from New Zealand for supplying offsets. It is seldom that the old stems produce any offshoots, and the only other method of increase is to raise the plants from spores, which are, as a rule, produced in abundance on strong, healthy specimens. The spores should be sown as soon as they ripen or become brown, and should be afforded the same conditions with regard to shade and atmospheric moisture as the parent plant. The spores are best sown on a piece of soft sandstone or in a small pot of carefully sterilised compost consisting for the most part of peat and sand. In either case the pot or sandstone should be stood in a saucer of water, in order to keep the compost moist, thus obviating overhead watering. On no account should the soil be watered from above, as the minute spores would be washed into the soil, and they would then fail to germinate. After sowing the spores fill the saucers with water, and add water whenever necessary. The spores germinate and produce dark green, kidney-shaped prothalli, and when this stage is reached they may be watered overhead. Later on the young plants may be pricked off into small pots and afforded exactly the same treatment as the parents. At no period should this plant be exposed to the sun; it should be carefully shaded at all times.

TOMATOS: *C. A. B.* Send specimens of the affected seedlings for examination.

TREE SURGERY: *A. C. M.* Remove all, or as much as possible, of the decayed wood, then wash the surface with a strong solution of carbolic acid, and after this has become quite dry smear the surface with coal tar. This antiseptic treatment is intended to destroy parasitic fungi and arrest the decaying process. The hole should then be filled up and made watertight. If it be small the best "stopping" is formed of a piece of Oak made to fit, but large holes should be filled with cement. In either case a final coating of tar should be given. Except when the hole is very large, a new layer of bark will grow over the cavity when treated in the way described.

THE DATE PALM.*

MR. POPENOE has written a fascinating book on the Date Palm—"The Dadel, a Tree Unknown to Us" of John Ogilby, the seventeenth century traveller.

The book is fascinating because it brings the superstitions of remote antiquity into friendly communion with the latest word of the strenuous scientific commercialism which is to Europeans such an impressive feature of modern American life. Mr. Popenoe demonstrates that the hard-bitten man of affairs, bent on making the Date one of the chief fruit crops of the United States, may in proper time and place take a kindly cognisance of the curious legends and bizarre practices which have grown up in the countless centuries during which the Date Palm has been in cultivation. It is so easy to treat in diffuse, sentimental and patronising digressions of the historical aspect of such a subject as the "Dadel": it is extraordinarily difficult to write a clear, businesslike, practical and continuous narrative which contains, without detriment to its directness, as much of the past as of the present phase of Date cultivation. This difficulty Mr. Popenoe has overcome, and it is evident that he has overcome it because he is at once a practical man and an artist. Mr. Popenoe is a firm believer in the commercial promise of Date cultivation in the United States. He holds that in California and Arizona the cultivation of the Date has already proved a success, and is of opinion that the near future will see an extension of commercial Date-growing into California and Texas, as well as in Mexico.

With that American thoroughness which is the envy and admiration of the easier-going Englishman, Mr. Popenoe has pursued his investigations not only at home but in the chief Date-growing countries of the world. His journeys have extended from the North African littoral and deserts through Turkey and Persia into India. He observed in the last-named country that "there has been during the last half-century a small but continuous effort to establish the Date Palm on a large scale"; and he holds out some hope that in some localities these efforts may meet ultimately with success. Mr. Popenoe's enthusiasm for Phoenix dactylifera is almost equal to that of Mohammed, who proclaimed that "there is among the trees one tree which is blessed as is the Muslim among men; it is the Palm. Honour your uncle, the Palm: I call him your uncle because he was created from the earth left over after the

the Date Palm. Apart from this need for water the tree is not exacting. It grows and is fruitful in light and heavy soils, responds well to manuring with dung and humus, and in the adult stage withstands winter frosts; though it must be protected from wind. It is found advisable, however, to protect the ripening fruit (see Fig. 89).

Propagation may be effected by seed or by offsets (see Fig. 88); but, as the author insists, the latter mode of propagation is by far the better, and this for two reasons. First, the offset from a female Palm is of course female, whereas, of seedlings, about half are male and half are female, and hence large numbers of useless male plants must be grown until they declare their sex at flowering time, when those not required as pollen-bearers must be discarded. Second, as is the case with all long cultivated plants, Date Palms are extremely variable, and hence the offspring

FIG. 88.—CULTIVATION OF DATE PALMS: SETTING OUT OFFSHOOTS.

(Quarantine regulations in the United States require that they be planted in nursery rows, and kept there for one year.)

creation of Adam. . . . The Palm resembles man by its erect position and its height, by its separation into two sexes and by its necessity for the pollination of the female. If its head is cut off it dies. . . . Is it not the same with man! If its leaves are cut off it cannot grow others in the same place; no more can man if he lose his members. It is covered with a fibre analogous to the hair of man." To those only familiar with the Date Palm in pictures or pots the most striking point of Mr. Popenoe's account of its "cultural requirements" is the need of the Date Palm for large and continuous supplies of water. It grows and fruits best (see figs. 90 and 91) when well and even constantly irrigated. Thus in Persia the immense plantations around Busreh are irrigated naturally and copiously every twelve hours throughout the year. Indeed, the author maintains that irrigation is the principal item in the cultivation of

of a choice kind are anything but true to the characters of the parents. The work of breeding pedigree races, which has been undertaken in America, will without doubt meet ultimately with success; but in the meantime offsets from fine forms should be used, because, as is the case generally with asexually produced plants, they are true to character.

That the Date Palm fails to set seed unless the female is pollinated was known centuries before the present era, and bas-reliefs on Assyrian monuments illustrate the operation of pollination. Mohammed never showed his astute genius better than in retrieving the great error into which he fell when he forbade the artificial pollination of the Date Palm on the ground that it is an unnatural practice. The obedient followers of the prophet abstained and the harvest was barren. As Mr. Popenoe puts it, "an indignation meeting was held," and as a result the Prophet announced, "You

* *Date Growing in the Old World and the New.* By Paul P. Popenoe. Published by the West India Gardens, Altadena, California. 2 dollars 16 cents.

are weak in spiritual knowledge, but are worldly-wise; therefore in future I will confine myself to the government of your spiritual welfare, and let you manage the affairs of this world to suit yourselves"—a pronunciamento bound to be acceptable to a race of people with commercial instincts.

To secure crops, artificial pollination must be, and is, practised both in the Orient and in Occidental countries—wind pollination is too uncertain and insufficient. The male inflorescence with its spathe is detached as soon as it is mature, the spathe is slit open and the sprigs of male flowers are removed and placed in a basket for twenty-four hours. The cultivator climbs a tree on which the female flowers have burst their spathe and inserts several clusters of males among the females, and ties them in their place. If kept dry the pollen lasts a long time, and it is interesting to observe that it is cus-

into the methods devised for ripening the fruit artificially, although these are matters which to our readers in sub-tropical countries are of considerable interest; but we may conclude our review by recommending horticulturists generally to read this entertaining and beautifully illustrated work, for we are assured that whether they grow Dates or not it will bring them both pleasure and profit.

GARDENS FOR THE POOR IN FRANCE, GERMANY, ENGLAND AND AMERICA.

(Concluded from page 179.)

SMALL gardening for the poor is on a different basis in Germany. In consequence, doubtless, of the brilliant success attending the French private movement, it has come to pass in a number of German towns during the last three or

imitated in Königsberg, where the Poor Relief Board prepared an acre or so of municipal land for agriculture and kitchen-gardening, and in May, 1910, divided it into allotments, each of from 80 to 600 square yards. The first experiment was made with 25 married or unmarried recipients of poor relief, a preference being given to widows with children and those who though infirm were not incapable of garden work. The under-letting of allotments is prohibited. Larger tracts of land are to be prepared for the same purpose. Frankfort and Strassburg have also recently come to follow the good example of Posen. Not long ago the town council of Dresden decided to devote provisionally 4,800 square yards, together with the necessary seeds, to the same purpose. A rapid advance in this new small gardening movement will doubtless soon be made in consequence of the following decision of the Third International Congress for Workmen's Gardens (Brussels, autumn, 1910)*:—

"Taking into consideration the fact that the poor relief burdens weighing upon municipalities and charitable institutions are not infrequently to be traced to drink, consumption and the consequent corporeal and moral distress, and that family gardens form one of the most efficient weapons against this distress, the congress expresses the request that municipalities and poor relief boards shall promote such gardens and assign them to large families, instead of giving cash assistance. The State and municipalities should be bound to lease to garden societies at moderate rates a part of their land suitable for cultivation."

The same congress also requested the speedy enactment of laws that, like those in France, should render family gardens not subject to mortgage or distraint.

A novel kind of experiment in plot-gardening for unemployed workmen is being successfully carried on in a wretchedly poor part of the East End of London. In 1906 the West Ham Unemployed Aid Society obtained permission to use gratuitously three acres of the Gas Light and Coke Company's vacant land in Canning Town for the purpose of granting garden plots to temporarily unemployed workmen. In 1907 two acres were added. Two years later the Mansfield House Settlement took the concern over, and were given the free use of the whole of the Company's vacant land—30 acres. This area is at present divided into 340 plots. The holders have to buy their own seeds, or else they have to repay the price out of the sale of produce. Only vegetables are grown, the vicinity of the gasworks having proved detrimental to flowers. The average annual yield amounts to about £5 per plot. In 1912 the management of the Settlement asked for a voluntary yearly contribution of 2s., and most of the holders cheerfully responded. Up to then nothing had ever been paid in the way of rent. This kind of gardening gives some work to the unemployed, and enables them to earn at least part of their living.

* The first two were held in 1903 and 1906.

FIG. 89.—PROTECTING THE RIPENING DATES.

tomary in some districts to keep pollen from year to year. Trials made at the Mecca Experiment Station have shown that pollen may be kept for seven years and retain its power of fertilisation. Equally interesting is the statement that fertilisation may be effected by the pollen of other species of Phoenix, e.g., *P. canariensis*, and with other genera of Palms such as *Washingtonia filifera* and the Mediterranean dwarf Palm, *Chamerops humilis*. Growers are advised to establish three or four males for each hundred females. An old statement by Schweinfurth (in 1901) that the qualities of the fruit are influenced by the pollen used for fertilisation is said to be borne out by recent experiments made by Bruce Drummond in California. This statement is by no means in disaccord with modern views on fertilisation, and might well be tested in fruits other than the Date. We need not follow the author in his estimates of the profit of Date-growing, nor

four years that the municipal authorities themselves have assigned land for market gardening, instead of cash, to those entitled to relief. This was first done in April, 1909, at Posen. In the suburb Gurtsein there were first rented about 1,800 square yards, which were assigned to seven large families for cultivation. A few loads of manure were given them free, and the seeds they bought themselves. The crops not only supplied the said families with all their vegetables during the summer and autumn, but also yielded a small store for the winter. They drew much more money from the garden than would have been given them in cash, and the town fared equally well, for with a total expenditure of 17 marks (rent) from 70 to 100 marks had been saved in cash assistance. The new arrangement is of even greater value as regards health and education. Naturally in Posen there has been a considerable extension of the successful experiment. It was

This principle of putting waste land to philanthropic use might be called a "Columbus egg" in its simplicity, inexpensiveness and usefulness. No wonder it is beginning to be acted upon on a larger scale in England and America. Recently I received the fifteenth annual report of the Philadelphia Vacant Lots Association. From it I gather that "the land is prepared, and fertilisers with seeds are supplied annually, at a cost of \$5 to the Association for each plot." No rent is charged, but every holder is required to contribute, for what is supplied to him, \$1 the first season, \$2 the second, and so on, so that a family which

funds, it has to be content at present. It obtains the loan of this land from the owners, letting it in 500 plots to needy men or women of the working classes. It is noteworthy that every sovereign spent by the V.L.C.S. means five times this amount in vegetables for the plot holders. "Recognising the value of the aid they receive, and aware of the fact that the society is not adequately supported by the public," most of the holders lately volunteered to contribute to the management and seed fund. Some offered to pay as much as 15s. a year, stating that they "would much prefer doing so to receiving continuous gra-

THE BULB GARDEN.

JAPANESE LILIES.

THE rapid rise in popularity of Japanese bulbs of *Lilium longiflorum grandiflorum* is one of the most noteworthy features of present-day gardening. It is the more remarkable in that until about thirty years ago but little attention was paid in Japan itself to the cultivation of *L. longiflorum*. The flower was left to waste its sweetness on the desert air—or rather to grow wild among the bushes of Oshima, the island which lies about 200 miles south of the town of Kagoshima.

It was only about twenty-five years ago that bulbs of *Lilium longiflorum* were brought from Oshima to Yokohama, where they were grown,

FIG. 90.—DATE PALM IN FRUIT.
(A recent frost had destroyed some of the leaves.)

FIG. 91.—HARVESTING DATES :
Taking the crop of an unusually tall Palm at Elche, Spain.

continues to cultivate a garden pays in the fifth season the full five dollars.

Encouraged by the good results obtained in the States, the late Mr. Joseph Fels, the well-known land reformer, called into life a Vacant Land Cultivation Society for London, in 1908, which, according to its fourth annual report, is doing splendid work—materially as well as educationally. An official return of the L.C.C. puts the metropolitan acreage of unused vacant land at 14,000. Part of it would be too expensive to prepare for plot gardening, but there is ample that would need comparatively small outlay. The society could, if it had the money, very well manage ten times as much as the 60 acres with which, owing to lack of

tuitous aid." Recently a branch society was founded in Birmingham. The report rightly expresses a desire for "substantial recognition" of its work from public bodies to enable it to effect a large extension of its acreage. I hope that not only public bodies but some public-spirited persons of means among my readers will do something substantial for the meritorious work of the V.L.C.S., or for establishing similar agencies in other large towns. There are few ways in which money may be spent to better and more lasting good purpose; for to this discriminating form of help the Pauline aphorism certainly applies: "Faith, Hope and Charity, these three; but the greatest of these is Charity." *Leopold Katscher.*

and obtained high prices. In those early days the bulbs fetched about ten times their present price. The imported bulbs flourished in Japan and, after the manner of introduced plants generally, began to show a certain amount of variation. It was discovered, however, that the Lily is a capricious plant and soon tires of any one soil, and if not given the change for which it craves degenerates year by year. In spite of this discovery not a few growers in Japan continue to grow the bulbs in the same ground, and hence arise the complaints so often heard in England as to the quality of the bulbs imported into this country. In consequence of the deterioration of the bulbs the reduction of prices pressed heavily on the local growers and on the exporters. In these difficult times not a few Japanese growers endeavour to speed up or cheapen production of bulbs of *L. longiflorum* by planting in shallow soil, with the result that

though the size of the bulbs may have been increased the quality was undoubtedly reduced.

The custom of some dealers of collecting indiscriminately bulbs grown by large numbers of small men contributed also to a lowering of quality, especially in the winter-flowering variety of longiflorum. The form known as *L. l. formosanum* is held by some to be a separate variety obtained from Formosa; but, in point of fact, this form, put on the market about nine years ago, is obtained from Oshima, the home of *L. longiflorum*.

The reason for the greater vigour of the formosanums is that they are grown in their native habitat, and, when proper care is taken in selection, their growth and time of flowering are perfectly uniform.

The giganteum variety which is amenable to pot cultivation is distinct from that known as formosum giganteum. Now that I have grown the latter for many years in its native home thoroughly satisfactory bulbs are obtainable. It has the further great advantage that it can be shipped two months earlier than the ordinary giganteum, and so is ready earlier for winter forcing. *Sei Miyake*.

CYCLAMEN PSEUD-IBERICUM.

Cyclamen pseud-ibericum (see fig. 92) is the finest of all the hardy members of the genus. The species was described in 1901 by Hildebrand from plants growing in the nursery of Messrs. Van Tubergen, of Haarlem, but its origin was not given. The leaves, like those of *C. ibericum*, are marbled with a zone of white; but instead of being entire, the cartilaginous margin is crenulate, while the under sides are a ruddy-purple colour. The rich rose-coloured flowers with the faintest tinge of purple are borne well above the foliage on stems 4 inches to 5 inches long. The segments are 1 inch long and more than half-an-inch wide; each has a dark-purple blotch at the base, whilst the edge of the ring is white. The first flowers are produced early in February, and the plant continues in bloom through the month of March. *Cyclamen pseud-ibericum* is quite as hardy and as easy to grow as *C. coum* and *C. ibericum*, but is a great advance on either in the size of its flowers, which suggests that it is a hybrid rather than a true species. *W. I.*

THE ROSARY.

PLANTING, PRUNING AND MANURING.

PLANTING may still be carried on with every prospect of a successful display. It is well to plant some Roses rather late each spring, as they will thus provide blossom a little later than the general crop. Retarded plants should be procured if possible.

Upon heavy land it is best not to dig or trench too much in advance of planting. If, however, the land does not require trenching, it is a good plan to throw it up in ridges. In a very short time it will become level and be in good condition for planting. Very short manure mixed with the soil as it is levelled will assist in keeping it in condition, and will be beneficial to the plants. Roses should be pruned back hard immediately after planting. It is essential to water them at this time of year, not only as soon as they are planted, but once or twice afterwards at intervals of a few days.

Mulching in spring is a mistake, as it tends to keep the roots cold. Leave the surface soil rather rough, and see that it does not become too consolidated.

Old pot Roses which have been discarded from the forcing house, if healthy at the root, may be planted out early next month, and will then make useful plants for cut-flower purposes. Instead of pruning such plants bend them over, so as to induce basal growths. Such plants will develop well if carefully planted and given a little bone flour at the beginning.

Hedges of Rambler Roses should be planted

wherever opportunity offers, or in line down the kitchen garden. They furnish most useful sprays for table decoration, and the plants quickly establish themselves. The Multiflora tribe may be kept pruned quite low if necessary, and will blossom to the ground: the long growths should be tied out in a fan shape. The Wichuraianas not only provide handsome trails of blossom, but are worth growing for the decorative value of their foliage. It is becoming the fashion now to use Rose foliage only when decorating a table with Roses. This is right, and it is a good thing that the National Rose Society stipulates that only Rose foliage shall be used by competitors in their decorative classes.

The mildness of the winter has shown the wonderful beauty of the Wichuraiana foliage. Edmund Proust has been perfectly evergreen, and so also has American Pillar. We shall soon be using this latter Rose instead of Ivy for many of our outdoor effects.

As to pruning, much doubt still exists in the minds of amateurs as to methods.

Unquestionably the correct practice is to prune plants hard the first season, whether bush,

prune hard in the spring. If this cannot be done, then prune severely, and peg down the young growths when they are firm enough. Some of the more pliant shoots produced early last summer may be retained full length and tied over in April.

Wild Roses and all the briars are left practically unpruned; so are also the little Scotch Roses.

In all pruning one should endeavour to picture what the plant will be like in June and July. If growths are too numerous, reduce their number rather than their length, so that all foliage may have an opportunity to obtain air and sunshine.

If manure was dug in last autumn established Roses may be dressed with some bone flour now. Good, well-rotted manure may still be applied, but let it be lightly forked under the soil at once. If the beds or borders allow of it, first lightly fork up the surface, and then lay on the manure, covering this with some fibrous soil. Roses produce roots very near the surface, so that careless forking may do a great deal of harm. They are sometimes benefited by scooping away the soil around each plant and filling

FIG. 92.—CYCLAMEN PSEUD-IBERICUM.

[Photograph by W. Irving.]

standard, or climbing plants—i.e., within 4 or 5 inches of the base in the majority of cases. Vigorous growers, such as Juliet and Hugh Dickson, and also climbers, should be pruned to within about 12 inches of the ground. The Wichuraiana group forms an exception. These plants possess such a natural tendency to throw up basal growths that one may safely retain nearly the full length of two or three growths per plant. Weeping Roses of this group should not be pruned the first year until after the flowering time; then cut away some of the growths quite to their base.

Prune established Roses according to their vigour. Those making very strong shoots may be cut back less than the varieties of less vigour. Old wood should be freely discarded after the second year. This is best done in autumn in the case of the hybrid perpetuals. Free-growing Roses of the type of Margaret Dickson, Clio, Ulrich Brunner, and Hugh Dickson may have their ripened one-year-old wood retained for some 2 feet in length; they are thus more likely to blossom freely than if severely pruned. Frau Karl Druschki is sometimes a difficult Rose to manage. A good plan is to lift the plants in autumn and replant at once; then

up the cavity with cow manure, which may be covered with some of the soil.

If there are any old bush Roses which are not required, they may be cut down to the ground and the new growths that will spring from the base may be budded with good, popular kinds.

Several of our modern Roses make such strong, upright growths that they could be readily converted into standards by retaining one such growth some 5 or 6 feet long and cutting away all other shoots. Juliet is such an one. Coronation, the beautiful new H.P. of Messrs. Hugh Dickson, is another. In Belfast several standards of this Rose have been produced in the manner indicated. Some of the lovely Penzance briars treated like this would make interesting objects.

All exhibitors should plant out a few dwarf briar stocks annually, so as to be able to bud some of the varieties that yield their best upon "maiden" or yearling plants. Roses such as A. K. Williams, Alfred Colomb, Horace Vernet, and Marquise Litta, are never so good from a cut-back plant as from a maiden. Most of our eminent amateur exhibitors have several hundred stocks every year.

The present is a good time to plant out such stocks. Plant them upon good, rich, deeply-dug land, in rows 2½ to 3 feet apart, and the stocks about 8 inches apart in the rows. Many of the Teas and Hybrid Teas yield superior blooms from half-standard or standard briars the first year after budding, so that if any briars have been planted they should be reserved for such Roses. *Experience.*

appeared there had been described. There is certainly a rich reward in store in the shape of a harvest of bloom when flowers are scarce for those who follow in Mr. Bowles' footsteps and start a cold frame or two for the early-flowering Crocuses.

Early Irises, Daffodils, Primulas, Anemones and Tulips have each a chapter to themselves, but the subject is so broadly handled that frequent digressions occur. These deal with other flowers in bloom at the same time, with the structure of moraines, with collecting in the Alps, and even with the pigments that the artist must choose and combine if he is to depict the true colours of the flowers that are described.

The style in which the book is written is decidedly conversational; but if this occasionally has its drawbacks, it allows of a free introduction of amusing incidents and horticultural anecdotes. The tale of the wiles of the old man who for years provided a firm of druggists with an abnormally cheap supply of Hemlock is certainly worth recording, and it is interesting to find that there is no truth in the story of the theft of *Caltha polypetala* from the Vatican Gardens. It was always alleged that one member of a party engaged the attention of the gardener by inquiring as to the whereabouts of the stables in which the famous Papal bulls were kept, while another hooked fragments of the giant Kingcup out of the pond with the handle of an umbrella and secreted them in its folds.

Of misprints there appear to be very few, but the difficulty of the last sentence on page 119 is increased by the fact that "derivatives" occurs instead of "derivations."

The illustrations are numerous and of two kinds. There is a set of twenty-four excellent reproductions of photographs of views in Mr. Bowles' garden, and in addition there are sixteen coloured plates of various flowers, mostly reproduced from the volumes of the "Present Day Gardening Series." The latter seem to vary greatly in faithfulness to the originals. Some are successful, but *Iris susiana* has become

quite red, and *Iris longipetala* has taken on a shade of pink which it does not wear in nature. The plates of Tulips seem to show that it is still difficult by this mechanical photographic process to get both the reds and pinks of the flowers and the varying shades of green in the stems and leaves. It is a pity that the plates seem to have been scattered at random throughout the book instead of being inserted, as far as possible, where they would face the text that they illustrate.

In this description of his garden in spring Mr. Bowles has given us a book which is at once entertaining and instructive; and, if only our gardens contained half the treasures to which we are here introduced, they would gain greatly in interest and beauty. *W. R. D.*

NOTICES OF BOOKS.

MY GARDEN IN SPRING.*

ANYONE who knows Mr. Bowles and the catholicity of his taste in gardening will find that this account of his garden in spring is exactly the kind of book that he would have expected it to be, for it deals with nearly every class of spring-flowering plant that can be grown in English gardens.

The author is one of those lucky gardeners who are also men of leisure, and who are consequently able to rush off to Mr. Farrer's garden at Ingleborough when a *Galanthus Elwesii* has "poculiformed itself," and to Bitton when a note from Canon Ellacombe announces the arrival in his garden of a double-flowered form of *Anemone blanda*. Few gardeners, and least of all Canon Ellacombe, could refrain from being generous to a fellow enthusiast who had made a special journey to see his latest new treasure, and so it comes about that many interesting and rare plants find their way to Mr. Bowles' garden while they are yet unknown to the majority of gardeners.

Another result of Mr. Bowles' happy position is that he has the time to be his own gardener, and has thereby gained that first-hand knowledge of plants without which any writer on horticultural subjects is only too apt to be neither interesting nor informing.

The outstanding feature that will strike the reader is Mr. Bowles' passion for, and extraordinary knowledge of, the rare and freakish forms of well-known garden plants. He confesses that it gives him "more pleasure to have got together the three distinct forms—grey-leaved, golden and major—of *Sedum spathulatum*, and to make them share a flat-topped rock with at least six other species of *Sedum*, than to have the same space monopolised by *Sedum pilosum*, new, rare and lovely though it be." This pursuit of unusual forms has even led him to establish what he calls a lunatic asylum, to which he relegates the more eccentric. Here, for instance, we are introduced to a pigmy form of *Elder* which started life as a *Witch's Broom*, and to "the first crazy occupant," a *Hazel* so twisted that "it never produces a bit of straight wood."

Another instance of the results of the long-continued search for various forms is that, in spite of his complaint that his garden is not very well suited to *Snowdrops*, Mr. Bowles has got together so many different species and forms of this flower that the descriptions of them—with sundry excursions—occupy some twenty pages.

A whole chapter is devoted to a description of a separate garden of plants with silvery leaves or with the variegated foliage for which Mr. Bowles frankly confesses his admiration. A few purple-leaved trees and shrubs, such as the purple-leaved *Peach*, are introduced to heighten the effect of the pale foliage of the majority.

The chapter on spring-flowering *Crocuses* occupies some thirty pages, but the impression left by a recent visit to the frames and seedling beds makes it seem probable that several chapters of this length could easily have been written if all the beautiful seedlings that have

ORCHID NOTES AND CLEANINGS.

DISA SAGITTALIS.

A SMALL batch of this pretty little *Disa* is flowering with Messrs. Flory and Black, Orchid Nursery, Slough, where it proves to be very free-growing and produces its flowers in profusion, although the other small-flowered *Disas* have a reputation for being difficult to cultivate. It is hoped to obtain a new race by crossing it with some of the showier hybrids, which are also about to flower. The stems rise from a tuft of leaves, are clad with close-fitting whitish bracts, and bear on the upper part six or eight white flowers slightly marked with rose-purple, and of very singular structure. The plants, which bear five to eight spikes each, are grown in the *Odontoglossum* house with the other *Disas*, which seem to like the position, home-raised seedling *Disa grandiflora* having flowered there in fair quantity.

HYBRID ORCHIDS.

(Continued from page 87.)

The names and parentage are those given by the owners of the plants.

Hybrid.	Parentage.	Exhibitor.
Brasso-Cattleya Sylvia	B.-C. Digbyano-Trianae x C. Trianae	Sander and Sons.
Cattleya Cappel	Trianae x Schröderae	Armstrong and Brown.
Cattleya Domitian	Harrisoniana x Schröderae	Armstrong and Brown.
Cymbidium amabile	Lowio-Mastersii x insigne	Sander and Sons.
Cymbidium Cooperi	insigne x Schröderi	Sander and Sons.
Cymbidium Dryad	insigne x Parishii Sanderæ	Sir Geo. L. Holford.
Cymbidium Iona	insigne x giganteum	Armstrong and Brown.
Cypripedium Florida*	Fowlerianum x glaucophyllum	Armstrong and Brown.
Cypripedium Marcus	Dicksonianum x Leeaunum	Flory and Black.
Cypripedium Marina	areum x Lord Wolmer	Flory and Black.
Cypripedium Master Andrew	chrysoxum x insigne Harefield Hall	F. J. O. Montagu, Esq.
Cypripedium Mogul	Mrs. Wm. Mostyn x chrysoxum	Sir Geo. L. Holford.

The Week's Work.

THE ORCHID HOUSES.

By H. J. CHAPMAN, Gardener to MRS. COOKSON,
Oakwood, Wylam-on-Tyne.

SUMMER-FLOWERING ONCIDIUMS.—The warm-growing *Oncidium*s are producing their flower spikes, and need a liberal treatment to assist them to develop their flowers. One of the most serviceable species both for exhibition and decorative purposes is *O. Marshallianum*. This plant often produces several dozen large flowers which are coloured yellow and brown, and this free-flowering characteristic is probably the cause of the plants deteriorating early. After two or three years in cultivation the plants become weaker, and the pseudo-bulbs smaller year by year. I draw attention to this fact so that everything may be done that will contribute to the plants' well-being, such as removing the flower spikes within a reasonable time after the flowers have expanded. The production of these huge spikes of bloom entails a great drain on the plants' energies, and if they remain for long after the flowers are open the pseudo-bulbs will shrivel, and plants affected in this way rarely regain their former vigour. Large specimens of the tufted-growing species such as *O. obryzatum*, *O. haematochilum*, and *O. flexuosum*, are all useful when well flowered. The best time to undertake re-potting is immediately after the plants have finished flowering, for then the roots are in an active condition. I find that the plants derive considerable advantage from leaves mixed with the potting compost. Many *Oncidium*s that I found were difficult to cultivate grew satisfactorily when the compost contained at least one-third its bulk of broken Oak and Beech leaves. The other materials should be peat and moss, with plenty of sand and broken crocks added to render the compost porous. The greatest care is necessary at this season of the year to keep the growths and flower-scapes free from thrips, green fly, and other insect pests. It is a good plan to spray the plants in the different houses with an insecticide on frequent occasions, whether insects are observed or not, for then there will be little danger from this trouble during the spring, summer and autumn months. Vapourings are best in winter, for if spraying was resorted to then the foliage would remain wet for too long. Even at other times spray only when the weather is fine and dry. Where yellow thrips have infested such close-growing plants as *Miltonias* and *Cypripedium*s, it is a difficult matter to eradicate the pests. A red, rusty appearance of the leaves and on the inside at the base of a new growth is a sure indication of the presence of thrips. In cases of very bad infestations the plants should be dipped into the insecticide, but do not wet the potting compost. Let the plants afterwards be placed on their sides to drain. This treatment should be practised weekly for a time, and, when satisfied that the pests are destroyed, spray with the insecticide as recommended above. It is much better to use any specific at a slightly weaker strength than advised by the manufacturer, for an overdose may prove very harmful to the plants.

THE FLOWER GARDEN.

By W. CRUMP, Gardener to Earl BEAUCHAMP, K.C.M.G.,
Madresfield Court, Worcestershire.

PREPARATIONS FOR PLANTING ANNUALS.—All borders of beds which were manured and dug roughly in the autumn should be well dressed with soot in fine, dry weather, and the soil broken with a fork to prepare a fine tilth in readiness for planting. This early preparation of the soil will allow for the ground to become settled again before planting time arrives, and no amount of trouble taken in this matter can be considered too much. The soot will make the soil untenable by slugs and other insect pests: no small boon when the young, tender plants are put out. Meanwhile push

forward with the work of pricking out into boxes or cold frames a suitable number of each kind of plant for furnishing the beds. Use good friable soil and transplant the seedlings before they become crowded in the seed-bed. The importance of thin sowing, transplanting early and growing the plants stocky cannot be too strongly emphasised, as once seedling annuals become crowded and drawn they are practically useless, for they can never be restored to a good condition. It is far better to sow one variety thinly in two boxes than to crowd the same number of seeds in one box. Moreover, the young plants when well apart in the seed-bed do not require such early transplanting. A select list of the best half-hardy annuals was given in the issue for January 24, p. 54.

DAHLIAS.—Continue to insert strong, healthy cuttings, taking them, whenever possible, with a portion of the old tuber at the base, or strong roots may be cut into portions with one or more eyes like Potatoes. For the first time we intend to include some of the Paeony-flowered varieties, and they will be planted in bold groups in the wild garden. A few plants with their bright, showy flowers on long stalks, should, if the colours are well-chosen, make a fine effect in autumn amidst the greenery of grass and trees. In such parts of the pleasure-grounds with such surroundings there cannot be too many gay colours.

BORDER CARNATIONS.—Where wild rabbits can gain access to these plants in the beds, it is necessary to take up the rooted layers in the late autumn and winter them in pots in cold frames. In view of re-planting them the ground should be prepared in a similar manner as recommended for annuals. If planted out as soon as the ground is ready the plants will grow away at once and bloom satisfactorily.

TREE CARNATIONS.—Cuttings that were rooted last autumn, if treated in the same manner as the border varieties, may be relied upon to bloom freely all through the summer, and to continue in flower until frosts occur. Old plants left out all the winter have furnished a few good flowers as late as the time of writing, but this is unusual.

PINKS AND PICOTEES.—These flowers require much the same treatment as the Carnations. Pink Mrs. Sinkins makes a pretty edging to paths other than with grass verges, and the blooms are sweetly perfumed. Mule and other Pinks, such as Napoleon III., *Dianthus neglectus*, and many of the single varieties, should be planted amongst the stones in the paved garden, between stepping-stones, etc.

CALCEOLARIA AND MARGUERITE.—These plants should be removed from the frames in which they were rooted, and planted out in cold frames in friable soil, thence direct to their permanent quarters. It is a mistake to pot bedding *Calceolarias*.

THE HARDY FRUIT GARDEN.

By J. G. WESTON, Gardener to Lady NORTHCOTE,
Eastwell Park, Kent.

THE LOGANBERRY.—This bramble is of very vigorous habit. Therefore, when planting allow plenty of room for the canes to develop without overcrowding. The plant is not very particular as to the kind of soil or the position in which it is planted, for it will succeed almost anywhere, but it thrives best in a good, strong loam that has been well enriched with manure. If only a few plants are grown the shoots may be trained on a fence or a wire-trellis in the kitchen-garden, where the plants will occupy but little room, succeed well, and be easy to get at. If trained on poles the canes should be retained their full lengths, for the Loganberry is a prolific cropper and well-ripened shoots fruit to their ends. The berries are a little later in ripening than the main crop of Raspberries, and provide a welcome addition to culinary fruits. They are also excellent for bottling if gathered before they are over-ripe. The plants should be afforded similar treatment to the Raspberry, that is, the old fruiting canes should be cut to the ground as soon as the crop is picked. Thin the young canes early, loop those

that are left out of harm's way in the early part of the season, and after the old wood is cut out train them in their permanent places. If this work has been overlooked it should be done now, and weak or immature shoots cut back to ripe wood. Established plantations should be afforded a heavy dressing of manure annually. Young canes may be planted now with every prospect of success, but a light mulch should be spread over the roots to protect them from drying winds.

BLACKBERRIES.—The common Blackberry, when well cultivated, has the best flavoured berries of these fruits, which are exceedingly prolific, and the berries are valuable for cooking and preserves. They succeed well when trained on a fence or trellis as a screen, for which purpose they are well adapted. A few bushes may be allowed to grow almost wild on the outskirts of orchards or in corners of the outside garden, and they will fruit freely if there is an old tree stump or heap of stones over which they can ramble. The Parsley-leaved variety, *laciniatus*, is a very ornamental plant as well as valuable for its fruit, and is suitable for planting in the wild or woodland garden.

THE LOWBERRY.—The Lowberry, raised from the Loganberry and Blackberry, succeeds under the same treatment as the common Blackberry. The fruits are long, jet black, and of Blackberry flavour.

FILBERTS AND COBNUITS.—The pruning of Nuts is usually left until fairly late in the season, but the work should be finished now. In market plantations the bushes are trained in the form of a cup or basin, the centre being entirely open. Grown in this manner the bush is restricted to a small size, making it an easy matter to prune the shoots and pick the crop. There is still time to plant young trees, but on no account select rich or recently-manured ground, or growth will be gross and unfruitful. All nuts grow well in poor, stony soils, and may be planted on sloping banks or boundaries which are not always suitable for other fruits. Being accommodating in the matter of soil Filberts and Cobnuts are often planted in out-of-the-way corners and allowed to suffer from neglect, but, like most crops, they repay for a reasonable amount of attention. After the work of pruning is completed fork the ground over, burying all annual weeds and leaves. Choose plants with clean stems, and rigorously keep down suckers. Good varieties to plant are Kentish Cob, Early Prolific Filbert, and Merveille de Bollwyller. The purple-leaved variety, apart from the value of its nuts, is well worth planting in the shrubbery or wild garden for its ornamental foliage.

FRUITS UNDER GLASS.

By W. HEDLEY WARREN, Gardener to the Aston-Clinton Park Estate (the Rt. Hon. LORD ROTHSCHILD), Buckinghamshire.

FIGS.—A temperature of 60° to 65° at night, and 75° to 80° in the daytime, will not be too high for the early house, with a rise of a few degrees by sun heat. The Fig delights in an abundance of heat and moisture, but plenty of light and fresh air are also essential, therefore admit air early in the day during warm, sunny weather. Continue to give the necessary attention to the work of thinning, pinching and tying the young growths where the trees are trained on wires or trellis-work, also thin the young fruits where they are growing too thickly. Follow the instructions already given on the management of pot-trees, by feeding and syringing the plants daily, or as required. The swelling of the young fruits may be hastened by affording top-dressings of rich soil and artificial manures, a little at one time, just sufficient to keep the trees in a healthy condition. Applying a little and often is far preferable to affording heavy dressings at long intervals.
