PATRICK BARRY,

VICE-PRESIDENT OF THE AMERICAN POMOLOGICAL SOCIETY.

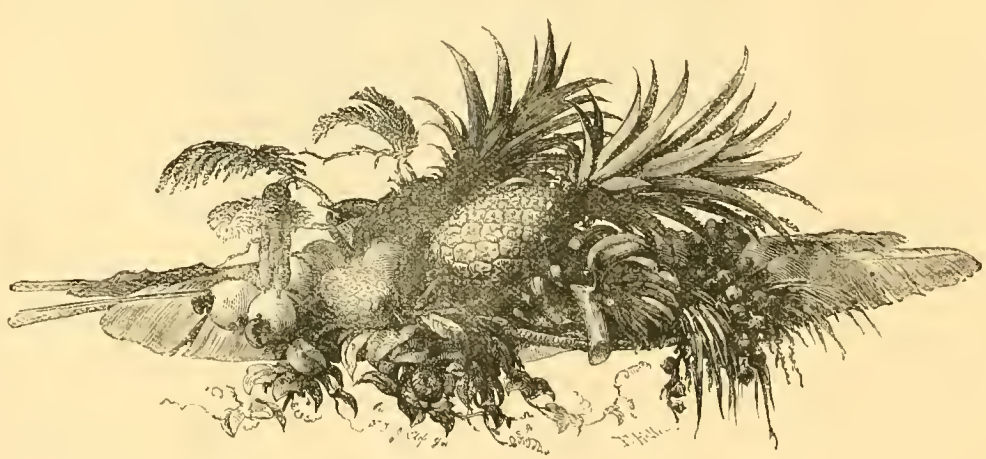
In accordance with our plan of prefacing each volume of The Garden with a portrait of some one distinguished as a horticulturist, we now offer one of Mr. P. Barry, of Rochester, New York, whose work has had a widespread influence on American horticulture during the past quarter of a century. He had long been known as an effective writer through papers in different periodicals, when in 1852 his first work, "The Fruit Garden," appeared. In 1852, Mr. A. J. Downing was drowned during the burning of the *Henry Clay* on the Hudson River, and the *Horticulturist*, which with Mr. Luther Tucker, of Albany, he had established, was purchased by the late Mr. James Vick, and edited by Mr. Barry, in whose hands it remained two years, until 1854, when it was sold. Mr. Barry's best work, however, is probably the "Catalogue of the American Pomological Society," the preparation of which as chairman of the committee chiefly fell to his share. Until recently the association had a vice-president from every State, but no one specially designated as vice-president of the whole body. That office was created a few years ago, and Mr. Barry was unanimously chosen as first vice-president, an office to which he has been constantly re-elected. For more than twenty years he has been president of the Western New York Horticultural Society, one of the most useful and flourishing of its kind in the United States. He has also been president of the New York State Agricultural Society, and is at present a member of its Board of Control over its experimental station. His father was a farmer near Belfast, where Mr. Patrick Barry was born in 1816. He was given a good education, and at eighteen was appointed schoolmaster of one of the national schools. Two years later he resigned in order to try his fortune in the New World. In his twentieth year we find him acting as clerk in the then celebrated Linnean nurseries of the Princes at Flushing, in which capacity he served four years, having gained in that time a thorough knowledge of the nursery business. Fixing on the fair city of Rochester, in Western New York, he, in partnership with Mr. Ellwanger, started business on seven acres of land. This was in July, 1840, and was the foundation of the celebrated Mount Hope Nurseries, which are now of vast extent and among the best in the world, as we can testify, from having visited them. These nurseries are chiefly remarkable for a very fine collection of hardy fruit trees, and for general collections of great extent, the whole admirably arranged.

American horticulture will in future be of increasing interest to us. The fact that it is our own kindred who are at work there will no doubt make their doings more useful to us than those of other races; but we have a real interest in horticulture and fruit growing in the United States, because they possess a northern climate somewhat like our own, and, moreover, many plants, fruits, and vegetables are common both to Britain and to N. America. Our gardens and farms already owe to America not a few fine vegetables and fruits, and our markets are notably affected by the fruit supply. These influences are likely to increase as time goes on, and it will be to our interest in the future to pay a greater amount of attention to the fruits and plants raised by American orchardists and gardeners, and to their methods of management. Among the institutions of which American horticulture may be proud is the Pomological Society, of which Mr. P. Barry is the vice-president. We have in past volumes shown the valuable work done by this society in the progress of fruit culture in the United States, and often regretted that like societies at home are not so efficient for good.



THE GARDEN.

VOL. XXX.

Fruit Garden.

GOOD STRAWBERRIES.

We beg to call the attention of our readers again to the important subject opened up in The Garden as to the Strawberry and its varieties, and to say that we should like to hear from them at an early date as to any further views they may have to urge in connection therewith. It will be noted in the valuable articles that we published in the last two numbers of The Garden how much our correspondents d well on well-known kinds, and these very few in number. We particularly desire to call our readers' attention to the importance of considering as far as possible other sorts than those commonly in cultivation. Many sorts have been raised and more variety would be desirable. We invite our readers' notes on the following points in addition to any other observations that they may think worth setting down :—

Best kinds for flavour, bearing, and district.
Early or late kinds, especially for open-air culture.
New, foreign, or little known sorts.
Best plan to secure good and regular crops.

Strawberries for Early Forcing.

Early varieties.—Much diversity of opinion exists as to the merits of the various sorts of Strawberries, both as regards their adaptability for pot culture and their quality when forced. All things considered, there is no more profitable early variety than Vicomtesse Hérieart de Thury. It is not so early as either Black Prince or Princess Frederic William; but as to the former, few succeed in growing it to a presentable size; while the latter, though earlier by a week or ten days and a vigorous grower, blooming very strongly and freely and also setting well, is rather inferior in point of quality. We commenced gathering this sort about March 16, at which time we had good dishes of fairly large fruits, but being ripened in strong heat they were sour; whereas the Vicomtesse, under similar conditions, was nearly as large and very much superior in point of flavour. Any other sorts but the latter ripened in a strong heat and a moist atmosphere require to be stood for a short time in a cooler, drier position, otherwise they are certain to be sour; therefore the Vicomtesse, as being especially amenable to all sorts of good or bad treatment, ought to be most extensively cultivated in pots, pits, or frames. It is also the best for late autumn fruiting, as the forced plants, being either planted out or plunged deeply in a rich border, bloom strongly a second time, some on the earliest forced plants ripening in the open, while the remainder can be lifted and the fruit ripened on shelves in Peach and other houses. At Longleat, where some 5000 or 6000 plants are fruited in pots, about one-half consists of Vicomtesse and the remainder President. The good old Keen's Seedling is still forced in some gardens, but I should say it is gradually being superseded by the Vicomtesse. La Grosse Sucrée is a very handsome early sort, but not often met with, only one grower of my acquaintance forcing it extensively. With us it has failed both in pots and in the open ground.

Later varieties are fairly numerous, though were I left to choose for myself President would be the only one grown in pots, this kind being of good habit, fruitful, and really of easy culture. Its fruits are usually of good size, very handsome, and, when given a fair amount of air, excellent in quality. Both this and the Vicomtesse are also good travellers, which cannot be said of several that I have named or may hereafter allude to. Sir Joseph Paxton forces fairly well, and the fruit is large, firm, and fairly well flavoured, but it is too gross in habit and does not suit all situations. Seven-inch pots are the size most suited to this variety. James Veitch is sometimes cultivated in pots, but size is its only recommendation, and the same may be said of Oscar, a variety very well grown for exhibition in the neighbourhood of Bath. At Orchardleigh, near Frome, Somerset, the favourite variety is Sir Charles Napier, and when well grown, as at that place, it certainly has much to recommend it. Under rough and ready treatment it is, however, far from satisfactory, the flavour frequently being decidedly acid, beyond even the moderating influence of sugar and cream. Besides, in many gardens, strong early runners are unprocurable, and weakly plants of this or any other variety are to be avoided if possible. In a well-known Suffolk garden the selected variety is British Queen, several thousands of plants of this sort being fruited in pots with marked success. Quite recently I tasted some Queens that were ripened in a light, airy house at Rood Ashton, Wilts, and these were highly coloured and most delicious, surpassing anything of the sort I had tasted this year. As a rule, the colour is not good, and it is only under most favourable treatment that the flavour is quite satisfactory. At the same time, it is the variety that I would add, if possible, to the Vicomtesse and President, keeping it entirely for the late supplies.

The effect of treatment upon the quality, as I have just hinted, is most marked, much depending, in fact, upon the culture given to each sort, as in one garden we may find a certain Strawberry exceptionally good and in another scarcely fit to eat. Of all reprehensible practices, that of fruiting Strawberries with the pots standing in saucers of water is one of the worst. Doubtless it saves much labour in the shape of watering, and red spider is also more or less prevented, but that is all that can be said in its favour, as it quite spoils the flavour of the fruits, rendering them not unfrequently quite sour. The same remarks are applicable to the plan of providing water-troughs instead of plain shelves for the plants. On the other hand, if too little water is given various evils follow, and it must be well known that fruits gathered from plants actually suffering from want of water are quite acid. Where available, squares of turf, placed grass-side downward, if cut fresh, are best for standing the pots on. Into these the roots soon find their way, and besides, to a certain extent, checking a rapid loss of moisture from the pots, these turves also serve as a rich feeding ground, the loam absorbing much of the liquid manure running from the pots into it.

Procuring fresh plants.—By the time the principal portion of plants in pots has been fruited attention will have been directed to the establishing of a fresh lot of plants for forcing next season. A few, a very few, growers, I should say, fruit some of their plants the following year in the same pots; but not having tried the plan, I can say nothing about it. Our plan is to lay the runners direct into the fruiting pots as soon as this can be done, or before they have formed many roots, and, may be, lost them again. One operation only is needed, and it can be easily and properly performed; whereas by the old system of layering into small pots, and subsequently shifting the perhaps much root-bound plants into the fruiting pots, more labour is expended, and there is less likelihood of the work being properly done. We use 6-inch pots principally, this size suiting both Vicomtesse and

President, and the compost usually consists of two parts of good turfy loam, or the best loam procurable, to one of old Mushroom bed manure, with a sprinkling of half-inch bones added. This, after a little drainage in the shape of a few crocks, some strawy manure, and a little soot over that to keep out the worms is placed in the bottom of each, is firmly rammed down, and the pots are then stood in position round the old plants; a single runner is placed on each, and fastened down with a stone. If given water as required they soon become well rooted, when they are at once detached and the plants stood in a sunny position on beds of ashes. This is by no means a novel practice, nor is it popular with various growers, but we are perfectly satisfied with it, believing it to be the most labour-saving, and it gives us stronger plants than are usually obtained by any other system. Runners that last season were either allowed to root naturally around the old plants, or are taken off early and dibbled out on good ground, may be potted up or later on be lifted and planted in frames where they are to fruit with every prospect of ultimate success; and we have also had fairly strong plants from runners taken off the old plants and placed at once in the fruiting pots instead of layering. This plan commends itself when the runners are procured from a neighbour or from a distance, but they succeed all the better for having a few strong roots to support them. Whatever plan is adopted it should not be long delayed after the runners are once procurable, as the season is a late one. — W. I. M.

British Queen Strawberry.

I must take exception to what Mr. Douglas (p. 579) says respecting the possibility of this Strawberry being grown well in ninety gardens out of a hundred. If a census was made of all the best gardens in England, I will undertake to say that it will not be found in fifty gardens out of a hundred, much less cultivated with any degree of success. Mr. Douglas must be congratulated on his success with it, but I can assure him that I have known many of our best gardeners fail to get it to thrive. When I had charge of a garden attached to one of the residences that skirt Wimbledon Common, a place famous for its peat and loam, I could grow British Queen as well as anybody; but here I fail, and so do nine gardeners out of every ten in this neighbourhood.—Taunton.

Notes on Strawberry Culture.

Strawberries, like other plants, do best when grown on from first to last unchecked, and, thus managed, there is no reason why they should not bear a full crop when only twelve months old. It will, of course, be understood that a runner taken, say, about the end of June will not as a rule produce more than one crown; therefore, plants two years old, with several crowns, will produce a greater number of fruit than single-crowned plants will. Still, a single crown, well developed by steady continuous unchecked growth, may be made to yield a very heavy crop of fine fruit. Strawberry forcers know how important it is to have runners taken early. The moment the long pliable stems are thrust out far enough to show a pair of leaves, pots should be made ready, and the buds or germs beneath each little tuft of leaves should be immediately placed in contact with rich soil, and secured there either by means of a small peg or by a stone laid on it. The latter plan is quite as good as the former, as it conserves moisture and encourages early root formation. For planting in beds, the runners may be pegged on to mellow pieces of sod, or pressed down into the soil, with a stone laid on them to keep them steady until they have formed roots. The sods should have been cut two or three months previously and laid in a heap, with alternate layers of horse droppings. Another plan is to form mounds of rich soil, and peg several runners into each mound, forming little colonies of plants, whence they can be removed with balls when the beds are ready to receive them. They must be moved to their permanent quarters before they have become crowded. When small pots are used for Strawberry runners, the soil within them should be kept moist till the young plants can be separated from the old ones, as few plants suffer more than Strawberries if at any time starved for want of moisture. For this reason, if pots are used, 5-inch ones are not at all too large in which to lay the runners. Small hard, dry, rusty-looking fruits, that will not swell nor ripen properly, are the natural outcome of starvation from drought.

Making ready the ground.—In a well-managed kitchen garden there are never any plots of land long vacant, and the growing crop should not only be profitable in itself, but it should make preparation for the next. Land planted with early Potatoes now fit to lift, or nearly so, should have been prepared last winter for Strawberries by trenching and manuring, and the Potatoes will still further prepare it for that crop. As soon as they are lifted, a dressing of soot, lime, and artificial manure should be given, and the surface hoed over deeply. Thus treated and manured, it will be ready to receive the plants. The earlier planting is done, the stronger will the plants get before winter. The end of July or the first week in August is a good time for planting Strawberries. The space allowed for each plant will, to some extent, be influenced by the kinds grown. One of the great evils in Strawberry culture is overcrowding; unless the sun's rays can have free play round the plants, the fruit will neither be so good in flavour nor so well coloured as it should be. On good Strawberry land a well-grown plant of British Queen, President, or Sir J. Paxton should profitably occupy a square yard. Keen's Seedling, Sir C. Napier, and Vicomtesse Héricart de Thury, being less robust, may each have 6 inches less space. Sometimes double the number of plants required are planted, and half of them cut away at the end of the first year; but where pains have been taken to get the plants as strong as possible, and they are set out in good time, the full distance apart should be given at once. The soil should be made firm round the plants as they are planted. I generally press them down with the foot on both sides. When firmly embedded in the soil, the roots begin to work at once and no check is experienced; but I only plant when the surface is dry, as I should not tread the land about the roots when wet. A good soaking of water is given to settle them in their places. A little of the dry surrounding soil is drawn around them, and very little attention beyond stirring the surface with a hoe is required till the autumn mulching of manure is given. If the same pains were taken to obtain strong plants for beds in the open air as most growers take with their plants for forcing, good crops of fine fruit might be had the first year.

A succession of fruit.—With the early-forced fruit under glass, and the Elton Pine and alpines at the other end of the season, there can be no difficulty in obtaining a succession from March till September, or say for six months—a period long enough for most people. The early border could be utilised for the first crop in the open air. The main crop could occupy an open situation, and a few Elton Pines on a north border, though too acid for most people, might close the season so far as large fruit is concerned; but the alpines will continue bearing later if the early blossoms are cut off.

As regards flavour, tastes differ much, and of late years flavour has been greatly sacrificed to mere size. Good-sized varieties are, however, not always flavourless, for the British Queen is both large and good; indeed, I doubt if anything among newer sorts can beat it if it has a good position on deep warm land. It is generally considered to be more delicate than it really is. President is a good cropping, handsome kind, and Sir Joseph Paxton has many admirers. Keen's Seedling, when carefully selected, maintains its position in many gardens where good old fruits are valued. The White Pine in a sunny situation, planted thinly, so that the fruit can be exposed to the warm sun, is a very agreeably-flavoured kind. During the hot weather last summer fruits of this variety were very fine and high-flavoured, but the bright sunshine gave them a pinkish tinge. In fine sunny seasons I have had the alpines very good—superior to most of the large kinds in some people's estimation.—E. Hobday.

Best Six Strawberries.

Considering the ease with which Strawberries can be raised from seed, it seems strange that good new kinds are not more plentiful than they are. True, we have had numerous additions since the days when the Hautbois and Grove End Scarlet stood in the front rank, but still slow progress has been made in Strawberry raising compared with that of other fruits. With old Strawberry fanciers the flavour of the Hautbois was held to excel that of all other kinds. Now, our highest standard of excellence is British Queen, a finely flavoured sort, no doubt, but, as long experience has proved, a very unprofitable kind, cropping indifferently and often going blind. Though we have numerous varieties that crop freely and regularly and produce very fine fruit, yet none seem to possess what may be termed high class flavour. To put the matter fairly, it would seem as if abundant cropping and fine flavour were, in Strawberries, incompatible. Private growers have often their own fancy Strawberries, and, considering the small patches which they cultivate, a moderate crop is of no great consequence; but with those who grow for the million not only by the acre, but sometimes by hundreds of acres, it is a matter of the first importance that the kinds grown shall be reliable and free croppers. Now, if we turn to the most popular kinds of the day, it is difficult to withhold an expression of surprise on finding how few of them are really new; indeed there is not one that has not been under cultivation for probably fifteen years—a long period in the life of many garden products. But were the question put to the growers of Strawberries of every class throughout the kingdom, "Give a list of the best six kinds in your estimation," we should certainly find three at least, and probably four, included in every list. These are President, Sir Charles Napier, and Sir Joseph Paxton, and the fourth Vicomtesse Héricart de Thury. Some may substitute President for Keen's Seedling, a good old early sort, and add for a late kind even an older one, viz., Elton Pine. Others still may prefer Frogmore Late Pine. For mid-season croppers there would no doubt be some votes in favour of La Grosse Sucrée and Jas. Veitch, both fine, but rather coarse kinds. Neither of these, however, seems to have found much favour for market culture. The preponderance of opinion would probably favour, as the best six sorts, Vicomtesse Héricart de Thury, President, Sir Joseph Paxton, Sir Charles Napier, La Grosse Sucrée, and Frogmore Late Pine. If British Queen is omitted, it is simply because its cropping qualities can rarely be trusted. Raisers of Strawberries, I fear, have been working too much for mere size and too little for flavour. Cannot someone raise for us a kind having all the rich flavour of the British Queen with the many other admirable qualities of President or Sir Joseph Paxton?—A. D.

The Pear crop.—Although this is not likely to be heavy, it is several years since it has been such an even one; out of about thirty different varieties on walls with east, south, and west aspects there is no difference as regards the condition of the crop, let the trees be old or young. The proportion of fruit according to the size of the tree is almost equal in each case. Even an old tree of Napoleon, that has only hitherto borne poor fruit, is this year quite equal to the others. Small trees of General Todleben, Pitmaston Duchess, and Doyenné du Comice are bearing freely. The fruits on large trees are already swelling fast, and where too thick we have already commenced to thin them; if possible, we shall go over them a second time about a month hence, and remove such fruits as appear to be crowding each other. This will be more necessary in the case of such sorts as

Marie Louise, Brockworth Park, and Williams' Bon Chrétien than in that of others. These all grow to a large size if the tree is not over-cropped, and a small crop of fine, handsome fruit is always more valued than a greater quantity of fruit inferior in point of size. Comte de Paris, which I believe is scarce in the country, is also bearing well; this is a small, but delicious November Pear. Thompson's, Glou Morceau and Beurré Diel invariably bear well with us, but in our soil they are only suitable for culinary purposes.—J. C. C.

NOTES ON HARDY FRUITS.

STRAWBERRIES.—I cannot quite agree with "W. I. M." (p. 576) as to its being useless to attempt the cultivation of Strawberries on shallow soils as a profitable speculation, for this reason, viz., in South Hants Strawberries have of late years become quite a large local industry. Several large tracts of land that only a few years ago were well-nigh barren have been now converted into fertile Strawberry fields, yet the soil is exactly the reverse of what is generally supposed to be the right sort for Strawberries, some being loose and stony and others light peat, while perhaps the next field may be a fairly good loam, so variable is the staple. In fact, nearly every kind of soil can be found under Strawberries. The system of culture as to firmness of soil and other details are exactly such as are described by "W. I. M.," and the enormous quantities of Strawberries sent from this neighbourhood testify to the suitableness of the South Hants fields for their growth. Let no one, therefore, be deterred from growing Strawberries by reason of their soil not coming up to the standard of a good sound loam. Some of the growers here on light, shallow, warm soils having the earliest crops make more money of their first gathering than those with double the crop do later in the season on much better soil. A scarcity generally occurs between late crops under glass and main crops out of doors—an opportunity embraced by light-soil cultivators to make the most of their crop of early fruit.

BRAMBLES.—South Hants is a Blackberry as well as a Strawberry-growing district, and we have tried some of the best of the American varieties of the first-named fruit, but I must confess that up to the present their produce has not come up to the descriptions given of it. Our native Blackberries, however, come to great perfection in hedgerows and on common and crown lands, and realise as good, and frequently better, prices than the cultivated Strawberry. As ornamental climbers American Blackberries are certainly good; their blooms are large and abundant, and I hope I may have formed an erroneous impression regarding their esculent properties. This could, however, be easily settled by offering prizes for dishes of any or all the varieties of them at our fruit shows.

DAMSONS.—How is it that in many parts of the kingdom these are but little grown? Here, scarcely a Damson tree or bush can be found, and young trees fit for planting are unobtainable; the general idea is that they would not grow in this part of Hampshire. To test this, I sent to Maidstone for a good supply of the genuine Crittenden or Cluster Damson, and planted them in the stony, light soils of this district. They certainly did not appear fit for choicer fruits, but the result has been that they have grown luxuriantly, and the largest are just commencing to bear fruit. Hardy fruits are scarce merely because they are not planted. My advice to each fruit grower is, try what can be done. Soil for any kind of fruit tree is doubtless of the first importance, but if we cannot get just what suits them we must make the best of what we can get.

Gosport. J. GROOM.

Early Grapes and their prices.—Early Grapes at Keele Hall, consisting of Black Hamburgh and Buckland Sweetwater, during the time of the late Mr. Hill realised 25s. per lb. in March and April, 1863, and 21s. per lb. during the same months of the year 1864.—GEO. BOLAS, *Hopton, Wirksworth.*

SYRINGE-SET GRAPES.

IN gardening matters, as in most things, old lines of practice with which people have long been familiar are often considered the best and only course that can be followed, so that even when something else turns up to answer the purpose better it is long before it meets with anything more than very limited acceptance. Nor is a conservative feeling of this character without its advantages, as if people were always ready to discard that which has been proved to answer fairly in favour of every new fangled notion that is set afloat, disappointments would be much more the rule than the exception. It is not, therefore, to be wondered at that the use of the syringe in the case of shy-setting Grapes has hitherto made comparatively little way. But there seems to be a chance that the advantages of its use will be better understood and appreciated now when good cultivators, like Mr. Coleman, have taken to using it, and advise others to do the same. Anyone who will give the method a trial, with even the most inveterate of bad setters, if they carry out the operation as it requires to be, will soon be convinced of the simplicity, the expedition, and the success attending the practice.

When or how the practice was first hit upon is a matter of no consequence. Not unlikely it may have been known to Grape growers of the past, but who, through some cause or other, kept to the old methods. For myself, I became acquainted with it accidentally a few years after I began gardening. On a wet day one of the outside hands was directed to clean an Orange tree that stood in a mixed vinery, and which was affected with brown scale; he was told to clear the insects off the wood and the leaves, to sponge the latter, and then to syringe them well with clean water. This he did, evidently not stinting the water. Immediately over, and not more than a foot or 15 inches above, the top of the Orange was a Black Morocco Vine that happened to be in bloom; in syringing the top of the Orange the bunches on some half-dozen of the shoots got regularly drenched. The gardener came in just at the time, and said he believed that the crop would be spoiled for the season; all the bunches that had been wetted he looked on as lost. The day after he directed the foreman to go over the Vine to set the berries with the brush in the ordinary way, but told him to disregard those on the shoots that had been wet. This was done, but, much to the surprise of those who knew the circumstance, the syringed bunches set much fuller than those operated on with the brush. There was much speculation as to how this could have happened, and it might have been thought that the incident was sufficient to have warranted a trial of the syringe afterwards on this, which is proverbially one of the worst setting varieties in cultivation, and other bad setting kinds in the house, but prejudice was too strong. To set Grapes by the direct application of water where a dry condition had been looked on as the first essential was too much of a departure from the old line of practice to be accepted. However, I did not lose sight of the circumstance, and as soon as I had Vines to deal with on my own account I tried the syringe on a few bunches of indifferent setting kinds, including Muscats, and after the first season I was so satisfied with the result, that I never afterwards used any other means. I have advised many to adopt the practice, but it is a rare occurrence to get an experienced Grape grower even to try it on ever so limited a scale; not so, however, young hands, a good many of whom have followed the advice I have given them. Last year a gardener in a large place, whom I had induced to try the method, sent me a bunch of Muscats as a sample to show how it had acted. I took the trouble to ascertain what condition the berries were in as to the stones which they contained, and there was not one that contained less than two, and by far the greater number had three and four. This is a fair example of the effects of syringing. Last week I had a letter from the same gardener, saying that this season when his Muscats were in bloom the weather was the worst which he had ever experienced in spring, adding that in his principal house of Muscats containing 250 bunches there was not one in which the set was not perfect; and in another house filled with young Vines of the same variety coming into bearing, he had 150 bunches set equally well. This season in several places in which I have seen houses of Muscats syringed they have looked as if it would be a difficult matter to find a bunch with a stoneless berry in it. The certainty and the expedition with which the setting can be effected in this way are its great merits. But, as already said, in order to insure the set being as it should be, the work must be properly done; several whom I have recommended to try the method have only partially succeeded in the first instance, through syringing too lightly. To be thoroughly effectual, the water requires to be sent into the bunches with a moderate amount of force, and it should be applied to each side of the bunches when fully in bloom. My practice has been to carry out the operation in the middle of the day; no harm will occur through wetting the leaves then, however bright the weather may be, if there is a little air on at the top of the house.

If syringe-setting was generally followed, there would be little heard of the provoking failures that often take place in the case of bad-setting Grapes, as even the worst to deal with in this respect, such as the Black Morocco already named, Muscat Hamburgh, and Alnwick Seedling, could be set so that they are as regular in the bunches as a Black Hamburgh. T. B.

GOOSEBERRIES.

AMONGST small fruits few are more missed when there is a failure than Gooseberries. I have known them to be in use from the beginning of June until the beginning of October. In the instance to which I allude ripe Gooseberries were preferred to Grapes. Therefore, prolonging their season as much as possible was important. A row of trees was planted across one of the quarters of the kitchen garden specially to provide a supply of fruit for dessert. The sort grown was the Warrington, which as a late Gooseberry was considered superior to all others in flavour, and its berries hang long on the trees without cracking. I remember picking for two seasons in succession firm and good flavoured fruit from these trees in the first week in October, and I have not forgotten the way in which the trees were treated; not a fork nor spade was allowed to go within 4 feet of their stems. Every year as soon as cleared of their fruit a layer of half-rotten manure was laid on the surface for some distance outwards from the stem, and sufficiently thick to last all the year round. This mulch served, moreover, to keep the fruit free from grit. Before each fresh mulching was put on the refuse from the old one was cleared away. These trees were also pruned in a particular way, *i.e.*, they were pruned rather severely for the purpose of getting fine fruit. As much of the old wood was cut out as could be spared, the object being to let in as much light and air as possible to the middle of the trees, which were at least 5 feet through and nearly as much in height. Fortunately, birds did not interfere

with the buds, but we had to net the trees very carefully to keep them off the ripe fruit. When the fruit began to change colour a temporary framework of wood 6 feet high was erected over the trees, and on this framework was placed a strong net reaching on both sides to the ground, and made secure by being pegged down. This arrangement was most convenient, as we had only to lift up the net at one end and walk in and pick the fruit, again leaving it secure as before.

The trees which supplied ripe fruit during August and the first part of September were trained to wires placed in the form of espaliers. Choice Gooseberries grown in this way get more light and air than those on ordinary bushes; therefore they are of better flavour, and the fruit is kept perfectly clean. Gooseberry trees trained in this way bear regularly and freely, and their fruit being exposed to view, can, if necessary, be thinned out with very little trouble. The varieties dealt with in this way were Early Rough Yellow, Whitesmith, and Red Champagne. I can in no way account for the circumstance, but it is a fact that I never knew birds to eat either the buds or fruit of these trained trees. I ought to mention that although the wires were horizontal, the branches took nearly a vertical direction; the trees were planted 4 feet apart, and the branches spread out and trained across the wires 6 inches apart. In pruning care was taken to let a certain number of shoots grow their own way during the summer at various points between the middle and the bottom of the tree. At the winter pruning some old shoots were cut out and young ones tied in to take their places, and in this way sufficient young bearing wood was secured.

In many gardens the soil is not deep enough to grow Gooseberry trees successfully. I am aware that most of us have to take the soil as we find it, but that is beside the question. The fact that in some gardens the Gooseberry crop is always heavier than in others proves that soil has a good deal to do with the matter. The question to decide by those about to plant Gooseberry trees is, is the soil deep enough for them? My contention is that where the soil is deep and of a good holding character, not only will better crops and finer fruit be produced, but the trees will last much longer in vigorous condition with considerably less labour in the matter of manuring than they would do where the roots are insufficiently nourished in a poor medium. Where, therefore, the soil is unfavourable more than ordinary care must be devoted to its preparation. In every case there ought to be a depth of at least 2 feet. In the matter of planting, it will be clear to anyone who investigates the subject that Gooseberry trees are, as a rule, planted too closely together. In very few instances have they room in which to properly develop themselves, and the result is that a severe system of pruning has to be adopted in order to keep them within bounds. If the trees are required to grow into large bushes, 6 feet apart each way will suffice for sorts having an erect habit of growth, but 8 feet apart is not too much for sorts like the Warrington, the branches of which take a spreading or somewhat drooping direction.

As to pruning, two distinct systems should be adopted. If large fruit is wanted, rather severe pruning becomes a necessity, but if a full crop of ordinary fruit only is desired, then very moderate pruning will answer. As a rule, Gooseberry trees are pruned too severely; by far too much of the young wood is cut out every year—a circumstance which reduces the number of fruits much below that which the tree is capable of maturing. The proper way to prune in order to get heavy crops is to cut out one or two old branches right back to the stem every year. This makes room for young growth, which will quickly take the place of that removed, and produce larger fruit than the old wood. Gooseberry trees growing against north walls produce plenty of fruits, which hang long on the trees quite sound and fresh, but the flavour, compared with that of fruit from trees growing in the full sun, is indifferent.

Fruit for exhibition.—At fruit shows surprise is often expressed at the large size of some of the Gooseberries. The secret lies in judiciously thinning the berries when young and only allowing the tree to carry a light crop. As the biggest fruit invariably takes the prizes, provided the skin is clear and the fruit fresh gathered, no one can expect to become a successful exhibitor who does not aim at securing large fruit, and they can only do so by beginning to thin out the young berries as soon as they are large enough to handle, taking care to see that the fruit is evenly distributed over the tree, and so placed that it can get plenty of light and air.

Indoor Garden.

CULTURE OF PASSIFLORAS.

Amongst the numerous climbing plants suitable for growing under glass Passion-flowers hold a foremost position. They are easily managed, grow vigorously when in the enjoyment of suitable conditions, and are extremely effective when blooming freely. They must, however, get plenty of light and air, as, if grown in houses which do not get the sun during the greater portion of the day through the summer, they do not acquire the maturity which only a free circulation of air and abundant sunshine endow them with. This remark applies equally to the cool house kinds and to those which demand the more elevated temperature of a stove or intermediate house. There are two ways of growing Passifloras; they may be kept in pots or boxes, or may be planted out in a specially prepared border. It is needless to say that by the latter method a more vigorous growth and a correspondingly larger amount of bloom will be obtained; indeed, it is only in the case of houses of small dimensions that the roots of this family of climbers should be confined to such a small amount of soil as even the largest-sized pot contains. At the same time good and timely feeding will at all times ensure a fair amount of floriferousness. By means of top-dressings of concentrated manure and watering with liquid manure the necessity for change of soil can be in a great measure obviated. It is only food that a plant wants, and if you give it that through the spout of the watering-pot it will be as thankful as if the means of building up strength and flower production were supplied in any other way. It is well to bear this in mind, because it is not always practicable to form borders where this form of culture cannot be carried out. A box will be found better than a large pot to grow the plant in. A box about 3 feet square will hold enough soil to grow a Passiflora to quite large dimensions; but, as in the case of climbers generally, shifting is hardly practicable; good drainage should therefore be given, or the comparatively large body of soil will become sour before the roots can fill it.

Loam should form the basis of the compost, the only other necessary ingredients being a little leaf soil and some coarse white sand; and if some charcoal in pieces about the size of a nut are added to it, the soil will be better insured against the effects of an overdose of water. It is during the first two years that over-watering is to be feared, and great care must be taken not to bring the compost into a close, sour condition during that period. Passifloras are strong-rooting plants, and although they more quickly fill a comparatively large body of soil with fibres than the generality of greenhouse climbers, they nevertheless soon show the effects of over-watering. Up to the time that the box becomes filled with roots, the rule must be to allow the soil to become almost dry before watering, but when the plants are well established with a good head of foliage the roots should be constantly maintained in a moist condition. This equable state of moisture, in combination with frequent doses of liquid manure, or occasional top dressings of some concentrated stimulant, will maintain a sufficiently vigorous development to allow of the production of good flowers. When boxes or large pots are used for Passifloras and the floor of the house is not paved, they should be stood on bricks or something similar to prevent the entry of worms. Pruning to a certain extent in the case of old-established plants is necessary, as when the wood becomes too crowded it cannot mature as it should do, and plants allowed to ramble unrestricted soon become a flowerless mass of foliage. The aim should be to secure a sufficient number of strong shoots which can be trained quite 6 inches apart over the allotted space. Having selected the requisite number, the remaining growths should be cut clean away, and those which remain allowed perfect freedom; and if the culture is right in other respects, they will, in due course, form plenty of flower-buds. The best time to prune is in March, cutting the shoots of the preceding year back to within two eyes of the base.

Insect pests.—The principal enemy of Passifloras is scale, although plants in a healthy condition do not usually become attacked. When this pest makes its appearance it should be grappled with immediately, before it has time to get firm hold. Like all insect pests, scale multiplies exceedingly, and as it infests leaves and young and old wood indiscriminately, it soon arrests the flow of sap and brings the plant into a crippled condition. Fortunately, the nature of scale allows of its destruction at the time when the plants are at rest; and if proper measures are taken, one season will suffice to bring the infested specimen into a tolerably fine growing condition, and in two years the insects may be annihilated. Directly after pruning should be the moment selected for cleansing, and as there is more leisure in winter than in spring, a badly infested specimen may be taken in hand at that time, for, although when the sap is rising is the best time to prune, no actual harm will result from doing so in winter if the plant is kept rather dry until it breaks again into growth. Any of the insecticides recommended for the destruction of scale may be used and are efficacious, although I have found nothing better than a solution of soft soap at the rate of 4 oz. to the gallon of water. I have never known scale able to resist for any time repeated applications of soft soap at this strength. When the scale has obtained a firm hold of the old wood it is well to thoroughly wet every portion of the plant, and a day or two after scrub it with a toothbrush. The majority of the scale will come off easily, their hold having been loosened by the soap, but some will remain, and these should be looked after during the growing time. In a general way, a second season will be required to completely clean a plant which has become smothered with this insect.

Plants in a growing condition may also be syringed with soft soap if so desired, but the succulent wood will not bear the solution so

strong as the hard wood of a plant at rest. A solution at the rate of 2 oz. of soap to the gallon is a good deterrent, is quite safe, and if the soap has been well dissolved it will not stain the foliage; on the contrary, I always think that it has a more glossy look after being washed with a weak solution of soft soap. By syringing once a week, getting the mixture well on the wood and under-surface of the leaves, scale will not increase during the growing time to any appreciable extent, and may be dealt with at the resting period as above recommended. It may be as well to state that, in making a soft-soap solution, the water should be boiling when poured on the soap, and it should be well stirred two or three times before the water gets cool. If this detail is not attended to, the soap does not become thoroughly incorporated with the water; small particles are left floating in it, which discolour and sometimes injure the foliage.

Varieties.—One of the best varieties for a cool house of moderate dimensions is P. Campbelli, bearing bright-coloured flowers and blooming freely. It does not grow quite so strongly as some other kinds, and is therefore suitable for houses of moderate dimensions. P. racemosa is an excellent kind, one of the very best of the Passion-flowers, and Impératrice Eugénie is a fine variety, and one which is said to bear better than any other the vitiated atmosphere of towns. Of the Tacsonias, exoniensis and Van Volxemi are the two best for a cool house, their congener, Buchani, being more suitable for an intermediate structure. The hardiest of all the Passifloras is cærulea, which does very well in the open air in the warmer districts of England, and it thrives very well on the chalk; indeed, the best plants I ever saw were thus situated. This Passion flower grows well within the influence of the sea breeze. It should have the warmest position on a wall and the shoots should be thinly trained, so that they may ripen well, otherwise undue succulency puts them at the mercy of a frost that better matured tissues would enable them to bear. In a suitable position and in a warm summer this Passiflora perfects fruits, which are of a decidedly ornamental character. For a cool house this is well suited, and is sure to flower and fruit well. Trained up the rafters or to iron rods in a roomy glass house, and allowed to hang down in festoons, it has a very ornamental appearance. In large conservatories I should certainly prefer this way of training, as being better adapted to show the true character of the genus, and the pendent shoots get a more free circulation of air round them than when trained near the glass. One species, *i.e*, edulis, I have omitted to mention. It is an old inhabitant of our gardens, and when climbing plants were not so numerous as now was much used. When the orangery was more common in English gardens than now, it was often to be seen rambling under the roof and fruiting freely in the summer-time. J. C. B.

Lilium candidum under glass.—We all know that this lovely white Lily makes a glorious display at midsummer in beds or borders, but I do not think its merits as a cool-house plant are fully recognised. It may not stand forcing for very early bloom, but for cool houses I have ample evidence of its suitability in the shape of magnificent spikes, that have lately proved most welcome in a cut state, being of that ivory whiteness which is so much prized for wreaths and other floral decorations. The way in which we treat our plants is to lift large clumps of them in autumn and set them in boxes about 6 inches deep, filled with light soil (for I may remark that this Lily grows here without any special mixture of soils); we leave them out of doors until frosty weather sets in; they are then transferred to a light airy part of a cold orchard house, or set in frames, and they grow on gently through the winter. No artificial heat is employed in their culture at any time, and under the protection of glass alone ours were in full bloom on the 1st of June, a time at which they are more valuable than a month earlier when so many white flowers are available. To anyone who has to supply a constant succession of white flowers throughout the year this white Lily will be found to be most useful, and for the conservatory a few potfuls of it will form striking objects at any time. If planted out after flowering no harm will result to the bulbs, as the best time for transplanting them is just after they have done flowering.—J. Groom.

Mignonette.—I lately saw some fine plants of this at Cuerdon Hall, Lancashire. They were in pots varying in size from 4½ inches to 9 inches. Those in the smaller sizes were brought into flower about the middle of March. The seeds had been sown in the smaller size and the plants shifted into the larger size. The best of those in 9-inch pots were compact bushes a yard through, and 2 feet 6 inches high measuring from the rim of the pot, and furnished with plenty of deep green leaves. Others were, if anything, taller, but not so broad; one of the spikes measured 16 inches, seed vessels and flowers together.—V.

Bougainvilleas.—We have here, beautifully in flower, a Bougainvillea glabra, trained up a column and forming a cylindrical mass 8 feet high and 6 feet in diameter. I have been familiar with this variety more than twenty years when it flowered in a 4-inch pot in the garden where I then was; I have frequently flowered it in pots of various sizes, and, as "T. B." stated in The Garden (p. 348), two or three times in the year. Will B. spectabilis do this? It should do so if there is no more difference between the two than "S." represents (p. 369), viz., "one being a stronger grower than the other." "S.'s" knowledge concerning the two varieties must have been gained from seeing B. glabra growing strongly in one place and weakly in another.—W. P. R.

Tuberoses.—Some of the best Tuberoses I have ever seen in small pots are in one of the plant houses at Dunedin, Streatham Hill, the residence of Mr. Sherwood. The method of treatment appears to be both simple and effectual. When the Tuberoses are set to work, they are placed singly in small pots and plunged in bottom heat, a little white sand being placed at the base of each bulb, and it is believed that the sand encourages them to root more freely. They are then potted in 4½-inch pots and again placed on, but not plunged in bottom heat; here they remain until they have made a good start, when they are taken to an intermediate house and brought on into flower. The plants are just flowering, and have spikes of seven to nine fine blossoms, though growing in such comparatively small pots, and they retain their foliage green to the very base of the plant. They are well looked after in the matter of watering, and treated to occasional doses of Clay's Fertiliser. A little is placed on the surface while the soil is quite moist from recent watering and watered in. This manure appears to suit the Tuberoses well, as their fine condition testifies.—R. D.

SHORT NOTES—INDOOR.

Repotting Camellias.—The best time for repotting Camellias is the months of June and July, after the plants have made their growth. Strong growing plants may be repotted before their wood is ripe or their buds set; weak ones, after setting their buds. Plants without buds may be repotted any time before October.—E. N.

Aralia Sieboldi.—The best way in which to get dwarf well-furnished plants of this Aralia—say about 18 inches high and 2 feet wide—is to sow its seeds in April. They soon germinate, and the young plants may be pricked off into pans or boxes as soon as they can be handled. By the beginning of July they may be placed in 2½-inch pots, and after a few days put out-of-doors in a shaded place where they may remain till late in November. In winter they must be kept as cool as possible to avoid starting them into growth. In the beginning of May they may be planted out-of-doors in well prepared beds, and after being planted, mulched. When growing they like once a week to be watered with liquid manure. They may be out till September, when they should be potted and put into a cool house.—E. N.

Epiphyllum Gibsoni.—This is described in the *Revue Horticole* as being a charming addition to Epiphyllums. It is nearly allied to E. truncatum, requires the same culture, and may be propagated in the same manner. The flowers, which are produced in bunches at the end of the shoots, are of a fine orange-red, a colour certainly quite distinct from that of any other member of the genus. M. Carrière suggests that by crossing it with the varieties of truncatum, some distinct varieties would be obtained.—Byfleet.

Hybrid Begonias.—In no London nursery have I met with hybrid varieties of incarnata so beautiful as at Lyons. The flowers of these hybrids are much larger than those of the ordinary B. incarnata and of various colours. The kinds called M. Chomer, M. Crosse, M. Ed. Pynaert, M. Eug. Vallerand, and M. Jean Sisley are all pretty, as are also Caroline Schmitt, Mme. Fanny Giron, Mme. Thibaut, M. Louis Van Houtte, and Victor Lemoine. They force well in winter, and in summer succeed outdoors in beds; they are also useful plants for windows, as they do not need large pots and they flower very abundantly. Their culture is easy. They may be propagated at any time of the year in moderate heat; for this purpose they must be cut down in order to get young shoots, because when they once begin to flower it is difficult to get shoots for cuttings.—Polander.

Kitchen Garden.

SPRING CABBAGES.

Small early hearting sorts of Cabbages are the best to select when wanted as early as they can be had. There is no lack of reputed sorts that answer this description, but if their history was traced back, we should find that all of them are selections from an old well-known variety called Atkins' Matchless. Of sorts offered by the trade, Early Heartwell Marrow, Stuart and Mein's No. 1, and Daniels' Defiance are all good. Cabbage seed, to produce plants for an early spring supply, should be sown from the middle of July to the end of the first week in August. For the northern counties the middle of July may not be too early, but in the west of England I find a fortnight later quite early enough. In this matter we must remember that the character of the weather during autumn and winter has a good deal to do with the behaviour of the plants in spring. After a mild winter it is more than probable that many of the earliest sown plants will "bolt" in March. For that reason it is safest to make two sowings at intervals of a fortnight, and to use half of each to fill up the space, or what I consider to be a better plan is to put out the plants of the first sowing 2 feet apart, and as soon as the next lot is ready put another lot between them, so that if any, or all, of the first lot "bolts," there will be enough left to form a crop. Should neither lot "bolt," it is an easy matter to thin them out if too thick. It is a common practice to sow Cabbage seeds too thickly, and the result is that the plants stand so close together in the seed-bed that they get drawn up weakly. Much stronger plants are obtained when plenty of space is allowed for the seed bed and when the seed is scattered thinly over the surface. All seeds of the size of those of Cabbage or Broccoli should be sown in shallow drills, or if sown broadcast be covered with finely sifted soil, but drills 9 inches apart are best. If the weather should be dry, the bed must be kept regularly moist, or the seed will not vegetate so soon as it ought to do.

Respecting ground for Cabbages, I need hardly say it must be deep and fairly rich. Nothing is gained, however, by making the soil too rich for any member of the Brassica family that has to stand through the winter; strong manure forces on growth, and growth obtained under such circumstances is not so hard as that made in poorer ground. On the other hand, in the case of the early crop, we all know that Cabbages are gross feeders, and that to insure tender-hearted

plants their growth must be made quickly, which cannot be effected if the soil is not fairly rich. A fairly good dressing of manure is therefore necessary. Cabbages should not be planted on land that has been recently occupied with any of the same family or the result will not be satisfactory. They should follow Potatoes, Peas, or Onions. Many of us might get earlier Cabbages if we were to devote a small space on a south border to them. The number of plants put out need not be many, oven a couple of score of plants would extend the season.

The main crop must, of course, occupy open quarters, as each plant takes up a good deal of space. The first planting should be made early in October and another a fortnight later. Should dry open weather occur during January tread the ground firmly about the roots, draw up some earth all round the stems and in sufficient quantity to prevent wind-waving. J. C. C.

POTATO FERTILISATION.

Were we dependent upon the seed of Potatoes for the production from year to year of our Potato crops we should have to vary our cultivated sorts materially, for many of the best Potatoes produce no seed whatever. On the other hand, kinds that do not rank as first-rate are often great seeders. But little inquiry is needed to show that whilst such remarkably free seeders as Woodstock Kidney, Grampian, Bedford Prolific, and Radstock Beauty are far from being disease-resisters, such kinds as Magnum Bonum, Chancellor, Reading Hero, &c., all very robust growers and comparatively disease-resisters, are yet absolutely non-seed bearers, indeed, producing seed only when blooms are artificially fertilised, and not otherwise. Why some kinds of Potatoes should have in their blooms such a liberal supply of pollen whilst others have none is one of those things hard to understand. What is probable is, that modern kinds develop such tuber-producing properties that material which otherwise might go to the production of pollen and seed is now diverted to the formation of tubers. We find lack of pollen specially marked in the American kinds, but very few indeed producing enough naturally to set blooms; indeed, all our best new kinds, products of Anglo-American crosses, have resulted from the application of pollen from home-raised kinds to the flowers of American sorts.

To all anxious to try their 'prentice hands at Potato cross-fertilisation, it is not possible to recommend better seed parents than some good Americans, and better pollen parents than some good English sorts. Last year there seemed to have been an unusual lack of pollen in many kinds which, as a rule, give some, resulting most likely from the heat and drought. For that reason cross-fertilisation was difficult, and in some cases where blooms were set the seed-balls fell ere mature, owing to the drought. This year Potatoes look already so well, and early kinds are showing bloom so freely, that ample opportunities should offer to any wishing to take a turn at Potato raising. It is perhaps rather a drawback that they find the field already pretty well occupied with sorts all fairly, if not superlatively, good. Perhaps the superlatively good ones may yet be produced by some enterprising fertiliser who can devote time and attention to the subject. If but some half-dozen kinds be so fertilised, and but one seed-ball obtained from each, there will be found during the winter, when the decaying flesh of the seed-ball allows the seed to be cleared out, enough of the latter to produce quite one hundred seedling plants. These are readily raised by sowing the seed in pots or pans in fine soil about the middle of April, as with ordinary care the seedling plants may then be strong enough to plant out in rows in good free-working soil early in the month of June. If of so many some few are not deliberately set aside as undesirable the first year, these seedlings may the second year prove a serious trouble; hence it is advisable to sacrifice the first year all but the most promising, and those should not exceed twenty diverse ones. That quantity of sorts, each perhaps being represented by from eight to twelve tubers, will need considerable space in a small garden the second year, and at the lifting time some more must be relegated to the kitchen, not more than one-half, perhaps but half-a-dozen sorts, must be saved for further trial. All this work is exceedingly interesting, and to those who have faith in their labour as well as intelligent appreciation of its usefulness, much enjoyment is found in it. Having regard to the fact that no seedling Potatoes need be wasted, and that no labour expended in raising them is wasted either, there is perhaps even more to attract amateurs in Potato-raising from seed than is found in that of many other garden products. A. D.

KITCHEN GARDEN NOTES.

Early Peas.—We had two varieties of Peas ready for gathering on a south border on June 1; one was American Wonder, the other a new sort which we had on trial. We have sowings of other early Peas, including Ringleader, William the First, and some other American and Canadian varieties with great pretensions as to earliness, but the two just named have beaten them. The American Wonder only grows about 1 foot in height, and although very prolific for its size, there is not much of the "gather-and come-again" character about it. It is good for one early gathering, and that is all. The new one is better in this respect, as it grows 3 feet in height, is equally early, exceedingly prolific, and a most valuable first-crop Pea. Telegraph, now in pod, is earlier by several days than Telephone, and Duke of Albany is later than either. Ringleader and William the First are as nearly equal as possible. We have lately heard of many Peas being bought in the market which were quite void of flavour, and I am inclined to think that this must be the result of the fermenting process which they undergo in their transit to market, as when large quantities of them are placed in boxes or baskets together they heat like newly-mown Grass, and then the flavour must deteriorate. Anyone gathering Peas from their garden who has the least regard for flavour must avoid this.

Seakale.—This being a favourite vegetable in winter and spring, many are anxious to grow it well. About this time of year all plants of it above one year old show a great disposition to run to flower; they throw up strong stems and then produce masses of white flowers. These are excellent as bee flowers, but that is the only good purpose which they serve; they are indeed injurious to the plants, and the whole of them should be removed as soon as formed. What may be termed fruiting crowns will then be produced, and should more flowers make their appearance, they must all be cut off as before, as large leaves and flowerless crowns give the best returns next spring.

Early Turnips.—Of all the sorts we have ever grown Early Milan is the earliest. We had nice bulbs of it on May 18 from a patch sown in the open in March. It bulbs wonderfully quick, and is not over-burdened with top growth. It is a white with a purple top, and exceedingly good in quality. Early Turnips are always most acceptable, and the aim should be to grow only the earliest as a first crop, and that is undoubtedly the one in question.

Rhubarb flowering.—All sorts throw up long stems and flower at this season, but flowers are no advantage to the plants—indeed, they are injurious, and all who wish Rhubarb to do well must keep it constantly free from flower-stems.

Hoeing.—This must be followed up vigorously now. Hand-weeding any vacant space where a hoe can be used is slow work. Apart from the ready way in which weeds may be destroyed by hoeing on a fine sunny day, the operation opens up the surface, and this is very beneficial to the crops. Even where there are no weeds the hoe should still be run amongst crops now and then. Young vegetables are especially benefited by hoeing. Onions, Turnips, Carrots, &c., should be hoed once a fortnight until the leaves obstruct the work. Corners containing odd crops are very apt to be neglected at this season when other work presses, but on no account should weeds be allowed to run to seed in such situations. If they cannot be raked off they should be hoed over at least, and if timely attention is given to this, weeds will almost cease to be troublesome.

Mulching Peas.—The advantage of mulching is that it retains the moisture about the roots, keeps the top growths fresh and growing, and the Peas tender, sweet, and juicy. Peas mulched also bear longer than Peas unmulched, and if a long succession is desired from a row, mulching must be resorted to. It is during the warm, dry summer months when the practice is most beneficial; some use good manure for mulching, others only light material of any kind. If the Peas are to be watered artificially, rich manure is of much service, as the richness is washed down to the roots; but when rich manure is put on and never watered all its best qualities are lost, and therefore, any kind of material, such as lawn mowings, half-decayed leaves, &c., may be used for mulching, as they will retain the moisture in the soil as well as anything; mulching saves watering and averts mildew.

Early Lettuces.—The Paris Market was our first Lettuce this season. It is a Cabbage variety, grows very dwarf, produces fine heads, is very tender, exceedingly crisp, and altogether a grand sort. Midseason Lettuces are very plentiful, and new ones are annually being introduced, but I do not know of any new early one to equal the Paris Market. Veitch's Perfect Gem follows it. It is of much the same type, but larger and darker green in colour. It well deserves its name.

Late Cabbages.—When grown to come in new and fresh about October, Cabbages are really very acceptable, being as tender and nicely flavoured as in early spring. When old plants are kept on to produce sprouts in autumn they furnish a large quantity of green material, but the produce of old roots and stems is not half so tender or well flavoured as the heads which form for the first time in autumn. To secure these seed should be sown in June, and the plants transplanted and grown on in the ordinary way when ready.

Cutting Asparagus.—There is always a danger of cutting too late. As soon as Peas are ready many cease to expect Asparagus, but where Peas are late and other choice vegetables scarce the temptation is great to cut Asparagus later than is good for the roots or the permanent success of the beds; those who are inclined to cut on will find out that ultimately there is no profit in this. Cutting should never be carried on after there is danger of depriving the roots of all the best growths, as some of these should always be allowed to remain to strengthen the plants for the succeeding year. The middle of June is late enough in all cases to cut, and in some parts where the crop was early cutting ought to have been given up before that time.

Autumn Onions flowering.—In some seasons the majority of autumn-sown Onions run to flower before they begin to bulb; if allowed to go on and seed no bulbs will form and the crop will be spoiled, but if the flower-stems are broken off as soon as they begin to appear fresh ones will not take their place, and the bulbs, although they will not be so large as the non-flowered ones, will nevertheless reach a useful size. J. Muir.

Margam, South Wales.

SHORT NOTES.—KITCHEN.

Early Peas.—Soil, season, and situation have much to do with getting Peas early. My earliest this season has been Early Champion. I sowed it, American Wonder, Sunrise, and William the First on February 5. Early Champion was ready on the 19th of June, and American Wonder three days later. I think the Champion superior to the American Wonder, as it is a better cropper.—W. A. C.

Red Cabbage.—Though full late to plant Red Cabbage, yet it may still be done If planted among rows of Potatoes, the latter should be at least 3 feet apart. Fork in a little artificial manure, and plant at once; but the Cabbages will not be large. To grow early Potatoes to come in soon after Christmas, the pit must be heated with hot-water pipes; both top and bottom-heat should be supplied.—H.

ORCHIDS.

CŒLOGYNE CRISTATA MAXIMA.

THERE is not a more popular, and there could scarcely be a more lovely, Orchid than the old Cœlogyne cristata, which for nearly half a century has been an occupant of English hothouses. It is one of the few Orchids that have found their way into general cultivation. Like the ever popular favourite Dendrobium nobile, it is to be met with in almost every good garden, and, like the rest of what may be termed everybody's Orchids, its culture is of the simplest kind. There are now about half a dozen varieties of it in cultivation, more or less distinct, one of the most recent additions being maxima, of which we herewith give an illustration. This variety is undoubtedly the largest flowered of all, its blossoms being much larger than those even of the Chatsworth or Trentham varieties, which until recently have been looked upon as the largest. The flowers of maxima are quite a third larger than those of the ordinary form, and as many as eight or nine are produced on a spike. One can, therefore, readily imagine what a lovely object a large specimen of this Cœlogyne must be. The engraving was prepared from a photograph of a plant which flowered in the St. Albans Nursery in February, and is said to be the largest specimen of the variety known. When out of flower it may be recognised by its bulbs, which are large and truncate, and by its foliage, which is very deep green in colour, while the Chatsworth variety (major) has more pointed bulbs. The other named forms of this Orchid are hololeuca or alba, a kind with snow-white flowers, and which it is the desire of every orchidist to possess, and Lemoniana, which is equally beautiful on account of its primrose-yellow lip, not orange-yellow, as in the ordinary form. This is also a scarce variety, and always commands a high price. It was named after the late Sir Charles Lemon, of Carclew, with whom the variety originated, and not on account of its lemon-coloured lip, as is generally supposed. The culture of Cœlogyne cristata is so well understood, that little need be said respecting it. It requires a greenhouse temperature, and is best when grown in pans on account of the spreading tendency of the bulbs. These are apt to become very crowded; it is therefore a good plan to cut the old bulbs away, otherwise the flowering bulbs become weakened. The plant likes plenty of water during active growth, which commences just after flowering; at no time, indeed, must it be allowed to get dry, otherwise the bulbs shrivel. It flowers in winter and early spring, and no Orchid is more valuable at Christmas-time than is this fine variety of Cœlogyne.

Cœlogyne cristata maxima. Engraved for THE GARDEN from a photograph.

SUMMER NOTES ON ORCHIDS.

CATTLEYA HOUSE.—May, June, and July are busy months in Orchid houses. We begin at one end of each house, and closely examine and attend to the wants of every plant till the other end is reached. This season our plants of Cattleya Trianæ flowered very late; the last of them were in blossom when the first flowers of C. Mossiæ opened. Such plants of C. Trianæ as required repotting were all attended to; others were surface-dressed with the best fibrous peat and a little live Sphagnum, working in amongst the compost lumps of charcoal and clean potsherds. Under careful attention to watering and keeping up the right temperature and atmospheric conditions, the young healthy roots soon set to work amongst the compost, pushing along freely on the surface and immediately under it. We are even now repotting Cattleyas and Lælias that have just gone out of flower, and, not to delay the work, some have been repotted that are yet in full bloom. Lælia majalis has flowered well with us this year, and one plant of small size has had on it two beautiful blooms. It was equally fine last year, and one of the flowers of last year ripened a fine pod of seeds. Orchid growers asserted that the pod of seeds would cost the plant its life; but no apparent harm is the result; indeed, I have ripened many pods of seeds on Orchids, and never could observe any harm that seed-bearing did them. I never, however, allowed an unhealthy Orchid to ripen a seed-pod, nor interfered with plants on which seed-pods were developing. Plants of Dendrobium Wardianum, D. nobile, D. thyrsiflorum, D. Farmeri, D. Dalhousianum, and others which flowered late have now been potted. The young growths of most of them had started about an inch or so, and new roots had begun to push out freely from their bases. They root freely in the new potting material, which causes them to push rapidly and make good growths. Some may not need repotting; in that case they ought to be surface-dressed, as is done in the case of Cattleyas. If the plants cannot be placed in a warmer house, they ought to have the warmest corner of the Cattleya house. During the operation of repotting, basketting, &c., great care must be taken not to injure any of the young roots. It is undesirable to saturate these plants with water, but the surface ought to be kept sufficiently moist to keep the Sphagnum Moss in growing condition; if this becomes dried up, the plants never succeed so well. Aerides odoratum and Fieldingi grown in this house, and some of the Vandas, such as V. tricolor and V. suavis, not potted in the spring, have now all been repotted. I have frequently potted such plants in June, and none of them have been any the worse for it, though it would have been better to have done so earlier. Odontoglossum vexillarium should now be repotted, *i.e.*, as soon as it is out of bloom. It then begins to grow and should be repotted, though I have repotted it in July, August, and even as late as September without any bad results. Cypripediums we generally repot as they go out of bloom, and altogether we have had plenty of work amongst Orchids during these last few weeks.

IN THE COOL HOUSE all repotting was done early in spring, and the plants are now rooting freely. The whole of these cool Orchids seem to thrive best when the surface of the potting material is covered with healthy, growing Sphagnum. One of the most successful growers of cool Orchids with whom I am acquainted told me that he clips the Moss from the surface of the compost in which established plants are growing with a pair of scissors whenever he wants any with which to surface-dress other plants. All that is required in this house at present is to keep the plants free from insect pests, and to attend to ventilation, which ought to be ample night and day; in calm nights the ventilators may be quite open, as

out-of-doors the night temperature is now quite warm enough for the plants, and the moist night air resuscitates them after they have passed through a hot day. Oncidium macranthum is now in flower, and its long spikes, the flowers on which take at least six months to fully develop, greatly exhaust the plants. The best way is to treat them liberally, and occasionally to give them a season's rest before flowering them again.

IN THE WARMEST HOUSE there is not much repotting to be done at present, except in the case of plants of Odontoglossum Roezli; these may be repotted either now or during the two following months. I have also repotted them in September and they have afterwards made exceedingly good growths. This is a plant which requires a good season of growth; water must be freely given it, and it also requires to be kept drier at the roots in winter than when growing. The Cypripediums which thrive best in the warm house, such as C. Lowi, C. Stonei, C. lævigatum, C. superbiens (Veitchi), C. Dayi, &c., may also be repotted. Some of them were potted a month ago, but a few still remain to be done. They do not seem to suffer even if potted during any month of the year. J. DOUGLAS.

The Vanilla Orchid (*Old Sub.*).—Information is asked in THE GARDEN as to how this plant should be treated in order to induce it to fruit. It flowers freely, he says, but the flowers do not set. In order to induce them to do so, he must resort to artificial fertilisation. My plan is as follows: Remove the anthers carefully with the finger and thumb, and with a small camel's-hair brush transfer the pollen to the stigmatic surface. In order to do so, it is necessary to raise the rostellum, which protects the latter. Thus treated, our plants set fruit quite freely. Some recommend that the rostellum be entirely removed, but I consider such a practice unadvisable.—G. C.

Cattleya gigas Sanderiana.—Two magnificent flowers of this Orchid have been sent to us by Mr. Fowler, of Ashgrove, Pontypool. They represent the finest form of it—that with the largest flowers most richly coloured. The flowers sent measure over 8 inches across; the sepals are 2½ inches broad, deep lilac veined with deeper colours; while the lip is 2½ inches broad, and of the richest crimson magenta imaginable, intensified by a dash of pale yellow in the throat. This variety of C. gigas is certainly the most satisfactory of all, as it grows and flowers freely, and the colour is so much finer than that of the other forms.

Cattleya Gaskelliana.—Some flowers of this superb new Cattleya, the first we have seen this season, have been sent to us by Dr. Duke, of Lewisham, who thinks highly of it. This Cattleya is doubtless one of the most valuable introductions among Orchids of late years; its flowers are not only most lovely, but they come in at a time when other Cattleyas of similar character, such as Mossiæ and Mendeli, are going out of bloom. Dr. Duke's flowers represent two distinct forms, one a very large flower with pale mauve sepals and petals and a crimson-purple lip stained with yellow; the other a much smaller flower, with mauve sepals of oval outline and a lip of the richest crimson-magenta, broadly margined with pale lilac and with a dash of primrose yellow upon it. There will, no doubt, be many varieties of this Cattleya, as there are among other varieties of the variable C. labiata; already there is a white and several distinct pale forms.

Masdevallias.—"B." (p. 593) justly remarks on the similarity of the flowers of the pretty triaristella group of Masdevallias. Like as they may appear to be, however, to the casual observer, there are many unmistakable differences by which they may be determined. If he refers to the figure of M. triaristella in the *Botanical Magazine* (t. 6268, I think), he will see that its slender flower-stalk is so densely studded with pinnate wart-like ridges as to appear hairy, while that of M. tridactylites, of which you gave an illustration from the plant when it first flowered with me, is smooth. Of M. trichæte, which has similar flowers, but flat, recurved leaves, I am not so sure, as I cannot find any feature to distinguish it from M. gemmata, of which I sent the first flowers to Prof. Reichenbach.—JAMES O'BRIEN.

Books.

THE MARIANNE NORTH PAINTINGS.*

IT is only four years since Kew became possessed of the rich collection of pictures painted by Miss M. North, the accomplished artist and traveller who has visited countries all over the world for the purpose of painting plant-life at home, and yet in that short space of time no less than four editions of the catalogue have been issued, a fact which in itself is sufficient to show the high appreciation in which these pictures are held by the Kew-visiting public. The last edition of this catalogue, recently issued, deserves to take rank as a valuable contribution to geographical botany, as well as a most useful little book of reference, both for horticulturists and botanists. In the introduction we are informed that the whole of the pictures, numbering 848, were executed by Miss North between the years 1872 and 1885, and nearly all of them in the countries inhabited by the plants. An excellent map is given, in which the places visited are shown, and a list of the species of plants named in the collection is added, arranged in their Natural Orders, so that an idea is obtained of the representative character of the collection. Out of about 200 Natural Orders of flowering plants recognised by English botanists, no fewer than 146 are represented in this collection of paintings, and in these are included 727 different genera. The value of these pictures, as revealed by these figures, must be apparent to anyone who has seen the pictures themselves, Miss North's accuracy in points of detail being conspicuous in every picture, so that there is no difficulty in recognising the plant intended. Indeed, we believe that almost every one of the plants has been named by Mr. Hemsley by means of the pictures alone. Short chapters on the general features of the vegetation of the countries visited contain much interesting and instructive information for gardeners as well as for botanists. In this new catalogue we find that 220 pictures have been added to the collection since the issue of the edition of 1883, and these represent some of the most beautiful plants of Chili, the Cape, Natal, the Seychelles, and several other islands.

Taking the principal garden plants shown in the pictures, we find figures of thirteen species of Rhododendron, ten of Ipomæa, thirteen of Hibiscus, twelve of Eucalyptus, six of Protea, six of Disa, and nine of Lilium. Among plants of special interest we may mention the life-like pictures of the beautiful Amherstia, Poinciana regia, Aristolochia Goldieana, Beaumontia grandiflora, Nymphæa gigantea, Ranunculus Lyalli, Richea dracophylla, and Drosera cistiflora. The pictures of the splendid Puyas from Chili are as attractive in themselves as they are when considered as works of art. We select the following as an example of the sort of information given by Mr. Hemsley in reference to the plants represented:—

THE SACRED LOTUS OR PUDMA.—Nelumbium speciosum is the most beautiful and graceful of all the Water Lilies, its leaves and flowers rising considerably above the surface of the water; and at the same time it is the most interesting on account of its remote historical associations. Four thousand years ago it was the emblem of sanctity in Egypt amongst the priests of a religion long ago extinct; and the plant itself has long been extinct in that country, though very widely spread in the warmer parts of Asia, extending through the Malay Islands to Australia. In India and China the flowers are held especially sacred, and the plant is commonly cultivated. For this purpose the seeds are first enclosed in balls of clay and then thrown into the water. The same method was employed by the early Egyptians.

A panelled wainscot below the paintings is formed of 250 distinct slabs of wood, mostly beautiful in the grain and all polished, to show their value to cabinet-makers, &c. The names of these, both vernacular and botanical, are given in the catalogue, and the native country as well as a word or two about their uses is added in most cases. An excellent index concludes the book, which contains 160 pages, and is well printed on good paper. Copies can be obtained only at the Royal Gardens, Kew, the price being 4d. each. For horticulturists this is by far the most interesting of the series of guides and catalogues now in course of publication at Kew.

* Descriptive catalogue by W. B. Hemsley, A.L.S.

Alpine Flowers.—This book is now out of print and will not be re-issued—at least, in its present form. If the art of drawing flowers with some of their native grace of form and beauty of colour existed, we should probably continue the book under the same title with a series of life-sized plates of all the beautiful alpine flowers. Alas! such art is so rare, that we despair of doing justice to the flowers. We should not like to add to the collections of wiry outlines which have hitherto passed as representations of the prettiest gems in Flora's garland.

GARDEN FLORA.

PLATE 551.

THE SWAMP LILY.

(LILIUM SUPERBUM.*)

THE accompanying plate illustrates this Lily when in flower so faithfully, that little further description of it is needed. Its brightly coloured reflexed blooms, with their curiously irregular markings, are very pretty, and an additional recommendation is the fact that this species is amongst the latest to bloom of all the North

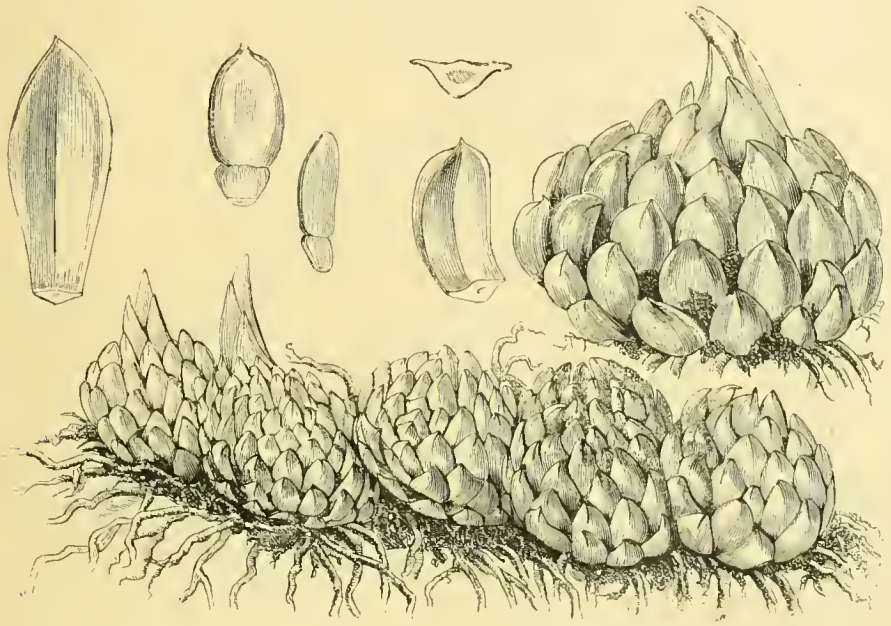
Lilium superbum, showing habit of growth.

American Lilies. In a general way it flowers about the end of July or early in August, though position and other circumstances of course influence to some extent the blooming period. This Lily has the curious creeping roots common to a few kinds; that is to say, the flowering bulb pushes out a rhizome sometimes 6 inches in length, on the point of which a new bulb forms, so that when in a thriving condition this Lily is always seeking fresh quarters. The bulbs greatly resemble those of L. canadense, being only distinguished from those of that species by being generally flushed with red. The flower-stem of L. superbum when grown under favourable conditions reaches a height of 6 feet or 7 feet, and is more or less tinged with purple, especially in its earlier stages. The leaves are narrow, acutely pointed, and arranged in regular whorls round the stem, a considerable distance being usually between each whorl. This Lily may be found in North America, from Canada to Georgia and Carolina, where it grows principally on the out-

* Drawn in Mr. G. F. Wilson's garden, Oakwood, Wisley by Mrs. Duffield, in September, 1885.

skirts of damp woods and in the neighbourhood of streams, where the soil is always moist. There is a variety of it figured in the "Flore des Serres" under the name of superbum pyramidale. This is described as bearing a pyramid of flowers consisting often of from forty to fifty in number, but as usually seen it certainly does not seem sufficiently distinct from the type to be recognised as a variety; different individuals of this Lily vary to a certain extent in many particulars, yet even amongst the most dissimilar connecting links may readily be found.

Culture.—The conditions under which this Lily is found wild afford a trustworthy clue to the treatment which it requires under cultivation; it thrives best in a cool, moist spot, where the soil is largely composed of vegetable matter. Though called the Swamp Lily, I am, however, convinced that it dislikes waterlogged ground, especially when dormant. Led astray by its name, I planted several in what I considered to be a fair specimen of a swamp, and they gradually dwindled away; whereas in a moist, but well-drained, spot they have succeeded admirably.



Bulbs and portions of bulbs of Lilium superbum.

Even in a dry situation it has done fairly well, though its dimensions are less than those of plants liberally treated. T.

WORK DONE IN WEEK ENDING JUNE 29.

June 23, 24, and 25.

The real summer weather which began on the first-named date has made one so busy—in fact, completely tired one out—that the daily record of work done has not been touched for the last three days. The work, however, has been of a general, rather than of a specific, character, and there will, therefore, be little difficulty in bringing up arrears. The flower garden—herbaceous department—has been overhauled, plants tied to stakes, bad flowers and foliage picked off, and the borders weeded and hoed where not mulched with Cocoa fibre. Aquilegias, Delphiniums, Pentstemons, Sweet Williams, Pinks, Pyrethrums, Potentillas, and Pæonies now make a magnificent show, the latter being particularly showy, and most of the varieties are as sweetly scented as Mignonette. It is a pity that their flowering season is so short, but there is some consolation in the fact that their foliage is massive and handsome, and helps to heighten the effect of other flowers near them. In the bedded-out flower garden we can always find plenty of work. The whole has been mulched with Cocoa fibre, which saves hoeing, weeding, and watering. Pegged down Violas, Petunias, variegated Mesembryanthemums, Leucophytums, and Heliotropes, and pinched into form Gold Feather Pyrethrum, Gnaphalium lanatum, and Iresine; also picked flowers off Calceolarias, Pelargoniums, Marguerites, Fuchsias, to induce more rapid growth in the plants. Clipped Box edgings; the small shrubs—Retinosporas principally—that we use in some of the flower-beds have had part of their new growth cut away to keep the plants rotund and shapely, but not too stiff or formal. Kitchen gardening has for the most part consisted of hoeing and staking succession lots of Peas. We are now digging Potatoes in quantity; they are not large, but clean and yield well. The ground thus liberated we again immediately crop either with Cauliflower, French Beans, or Lettuce, and presently with early Peas for the latest crop. Our first crop of Peas being over, the ground has been cleaned—not dug—and planted with Savoys in deep drills 18 inches apart, and 15 inches from plant to plant in the rows. The rest of outdoor work has been the maintenance of neatness generally and watering, which work we always endeavour to do at night in preference to the morning. Indoors, or rather work connected with indoors, has been pinching out side shoots of Chrysanthemums and tying the main shoots to their supports. In this hot weather they require water twice, and sometimes thrice, a day, and they are syringed at 6 a.m. and at 7 p.m. Bush plants are now being staked. Pots and soil are ready for Strawberry layering, and the shelves on which they have been forced in the Pine stoves and vineries are now cleared out, washed, and put away till December next. The Strawberry house is being prepared by a thorough cleaning out for the reception of tuberous Begonias, Coleus, Primulas, and such like easily grown plants that are required for vases in rooms in the autumn. Several Pines that are just coloured, and which are not likely to be required for use for some time to come, have been taken from the fruiting pit to the coolest vinery to retard their ripening, or rather to preserve them in good form for the longest time; they are already usable, else such a sudden check would arrest further growth. The fruiting pit has been filled up with successions—principally Smooth Cayennes—that are required to ripen from October onwards, and to take the place of these others are being potted, and the bottom heat in pits renewed as time can be spared for such work. In a house of mixed sorts of Vines that have just done stoning, this sudden burst of sunshine has caused a few berries to scald. White Tokay and Madresfield Court are the varieties affected, and to prevent further harm, air will now be kept on all night, increased very early in the morning, and slight warmth be turned on each night: the latter is necessary to the maintenance of an atmosphere—airy, yet warm—that is best suited to the swelling up and perfect colouring of fruit.

June 26.

This has been a scorchingly hot day, and we thought it advisable to shade early Vines by lightly syringing the glass with whiting and water. If a little skim milk be added the mixture will resist all but the heaviest rains, after which, if deemed necessary, it can quickly be renewed. The shading in our case is the more needed, because in spite of all our efforts at prevention red spider has gained a lodgment, and the colour of the fruit, from a deep black, is degenerating to a dirty red, but which the shading now given will probably stay. We dislike shading for Vines, and, indeed, all other fruits—Smooth Cayenne Pines excepted; but when once the foliage has become weakened with insects, and consequently unable to bear the full rays of the sun, then it is that shading is beneficial. Figs now in full bearing we keep constantly aired and in a somewhat dry atmosphere, but as soon as the present crop of fruit is over syringing and closing up early will again be had recourse to, as under such conditions only does the fruit attain the largest size. Watering of Pines and Vine and Peach borders and a general clean up complete the round of indoor work. The work outside has been of a varied description, such as clipping the Grass edgings of flower-beds, picking bad flowers off Roses, thinning out seedlings of Mignonette, and filling in after watering the drills in which Asters, Stocks, and Zinnias were planted. Gathered first outdoor Strawberries. We are several days later than usual, and the general gathering for preserving will be fully ten days later than in the average of seasons. Watered Peaches, Apricots, and cordon Pears on walls; our crops of the latter fruit are thin this season, which is attributable more to the heavy crops of last year than to inclement weather in the spring. They have all had their first summer pruning and their principal shoots tacked in to the wall. The hose has been plied on Morello Cherries with force to dislodge black fly from the tips of the young shoots before laying them in to the walls. Plums on walls are loaded with fruit, and in the absence of rain watering of these will soon be necessary, or the fruit will be small. Small fruits—Strawberries, Raspberries, and Currants—are abundant, and netting over is imperative, or the birds would have at least one half.

June 28.

Still very hot, and growth of all crops is now rapid and satisfactory. Peas are abundant and good, so that we can now afford to discontinue cutting Asparagus. Hoed over the plots to destroy self-sown plants and small weeds, and hoed more deeply between the lines of young plantations that were made in the spring. There is space between the rows sufficient for Lettuce, and the Black-seeded Bath Cos variety will be sown there as soon as we get a shower. This is the best of all Lettuces for late autumn and winter supplies. Well watered Celery and the later sowings of dwarf French Beans and Peas. We have no stable litter to spare, or they would be mulched, and thus reduce the need for artificial watering very much. Clipping Box edgings and knifed into shape standard Portugal Laurels. Trimming up flower-beds by clipping flowers off Sedums, and clipping the edgings and groundwork lines of Herniaria glabra, variegated Thyme, Gnaphalium lanatum, and Veronica incana. Planted another batch of Melons; a house of them, swelling up their fruit preparatory to ripening, has been given a thorough watering with liquid manure made from sheep droppings; syringings and waterings we continue till the fruit is nearly quite ripe, and by this means we rarely

lose any of the foliage, on the due preservation of which quality of fruit so much depends. To small decorative plants in the stove we have given more space by moving the hardier Ferns into pits. There being a quantity of hungry surface roots on Calanthes, Sphagnum and small pieces of peat have been mixed up, wherewith the plants are being top-dressed. The pots being well drained, we find watering necessary about twice a week.

June 29.

Grand weather, but drying; and watering is now the order of the day both indoors and out. There is an incentive to do such work when one can see a perceptible progress and well-doing of crops consequent on this desirable change in the weather. Watered wall trees, Peaches, Apricots, Pears, and Cherries, and, of course, all the flower beds. The longer established perennial and herbaceous plants do not yet show signs of requiring rain, but, having got all of them tied up, the hose can—should occasion require—be brought into play without injury to any. Continued clipping edgings and cutting Laurel hedges, and began to earth up latest crop of Potatoes. Indoors, too, the amount of watering and syringing now needed is very great, and takes up a great part of the time each day. Pinched back lateral shoots in late vineries, and cut out small berries from some of the bunches of Lady Downes and Muscat of Alexandria. The bunches of the latter require a fair amount of sunlight to colour them well; hence the lateral growths on these are more severely stopped back than is the case with black Grapes generally. Began layering Strawberries for forcing; our soil is rather a poor light loam, and to make amends for the former, a small proportion of bone-dust and animal manure is mixed with it, and in lieu of adhesiveness the soil is extra well pounded in the pots. Hants.

HARDY FRUITS.

The season is now sufficiently advanced to enable us to form an opinion of the crops of the various kinds of hardy fruit which we may hope to harvest should the weather prove favourable to swelling and ripening. So far the elements, though not dead against us, are not so decidedly with us as we could wish, and the time lost in the spring is still in arrear. Ordinary fruits will, of course, ripen, but unless the weather becomes much warmer and the sun gains the mastery of the cold winds and floating vapour which intercepts its rays the fruit must be vapid and deficient in flavour. This is the more to be regretted, as crops generally are plentiful, and, as far as my observation extends, we have not been so free from aphides and other insect pests for many years. Our first crop to ripen is the Strawberry, and, judging from the prolific bloom and the way in which the fruit has set, the yield will be satisfactory, but decidedly late. Of early sorts we grow Héricart de Thury, La Grosse Sucrée, and Princess of Wales. Last year the Vicomtesse was the first to ripen in the open air, and La Grosse came in second. This year the tables are turned, and although first in flower the order of ripening is reversed. A correspondent thinks the Vicomtesse is only fit for forcing, and that early. With us, the crops it produces in the open air are enormous, and its bright colour places it fairly well on the list for preserving, but for quality, colour, and flavour the old Elton beats it out of the field altogether. La Grosse produces finer fruit, both in the forcing house and in the open air, and although a lighter cropper, size, earliness, and brilliant colour will always insure it a prominent place in every garden. Our next Strawberry to ripen is President, a most prolific and delicious variety when not overfed into the production of a profusion of foliage, and the plants are placed at least 2 feet apart. When crowded and the fruit cannot have full exposure to sun and air we find it subject to mildew, a parasite which is speedily conveyed to other varieties by the pickers. Sir Joseph Paxton stands well amongst hardy, handsome varieties; it is a good cropper, and stands packing and carriage well. British Queen and Doctor Hogg by some are considered miffy in closely walled gardens, but a Strawberry garden is no more complete without them than a set of vineries is complete without Muscats. The best site for Queens is a broad open quarter in the centre of the garden where the plants can have full exposure to sun and air and the soil is deep, well drained, and heavy. Then to secure fine fruit and avoid unsightly gaps from sudden deaths, three-year-old plantations should be destroyed, and an equal breadth of young plants put out on fresh ground every year. If the soil is not naturally heavy, a spadeful of suitable loam placed round the ball of each runner at planting time and good mulching will be found a profitable investment. Under the impression that Queens require coddling, many people put them out on warm south borders, and allow them to remain too long on the ground. In course of time the soil becomes dry and exhausted; spider and mildew attack them; and the queen, truly, of Strawberries is voted a failure, because she dies or becomes unfruitful under unskilful treatment. Where the Queen is well grown it cannot come in at the wrong season; a host of good all-round sorts may be in use at the same time, but both for dessert and exhibition, a dish of Cockscomb-shaped Queens, whose points have been turned up to the sun, always heads the list. For late use, Elton Pine and Oxonian on north and east borders are invaluable. The first, a sub-acid Strawberry, deeply coloured to the core, is grateful in hot weather and makes the best of all preserves, as it is neither mawkish to the taste nor liable to smash during the process of boiling. For this purpose the plants should be grown and treated as Queens on open quarters where they can be well mulched and have full exposure to the sun. Oxonian on a north border is the most profitable variety I have met with. I grow it extensively in front of Cherries and wall Currants; truss or tie up all the plants to keep the fruit off the ground, and kill two birds with one stone by netting from the top of the wall to the top of a breadth of wire-netting, 1-inch mesh, secured to stakes along the front in a perpendicular position. A few slating laths keep the nets clear of one's head; they merely hang over the top of the wire netting, but quite clear and safe from decay, as they do not touch the ground. Pickers can move freely beneath them—no unimportant matter where all hands are fully occupied.

Two Strawberries I have omitted which ought to be included in every selection where high quality is allowed to make up for a somewhat wayward tendency to sudden death in hot, dry seasons. These are Frogmore Late Pine and Loxford Hall Seedling. Like the Queen and Dr. Hogg, they rejoice in deeply trenched ground out in the open quarters, where they can be clear of shade from trees and buildings. A few rows should be planted annually early in August, and a corresponding number destroyed when the third crop has been picked. Half a foot cube of fresh loam at planting time, good mulching, and plenty of water are essentials which should not be overlooked.

Bush Fruits.

Currants and Gooseberries, an abundant crop and free from blight, thanks to repeated winter washings with soapsuds, now require attention. Bush trees of the first from which we pick our earliest fruit have been divested of a portion of the young wood to let in sun and air, and the long rows will be netted before the berries change colour, a condition for which the birds are patiently waiting. We sometimes see the whole of the bushes closely cropped before the wood is half ripe and this mode of treatment hastens the ripening process, not only of the fruit, but the soft immature leaves, so suddenly and ruthlessly exposed to the scorching influence of a July sun, receive a shock from which they never recover. Early Currants are, of course, needed for use with Raspberries, but we do not require all at one time; and good fruit that will keep until November and do good service through the autumn months should be but sparingly exposed before it is fully developed and the ripening process has set in. Then by all means thin freely to insure the perfect maturation of the young growths and spurs, and let in light and air so essential to the preservation of the fruit. Gooseberries we do not find it necessary to prune in summer, as the choice dessert varieties on rather tall clean stems always keep best under a good covering of foliage. Birds with us, whose name is legion, we can keep in abeyance by timely double netting, strained clear of the head, over the quarters and supported by wires secured to stakes driven into the ground a few yards apart. All our feathered friends we do not profess to exclude, as we have red-billed cunning blackbirds capable of defying the skill of our most expert netters. I always protect these charming creatures until they are able to top the highest walls, when they become legitimate game for the netter and the fox-terrier, who understand and enjoy the early morning's sport. Our worst enemy is the relentless wasp, not unlikely this year to be terribly troublesome. Much, however, depends upon the weather, as I have known a plentiful wasp spring like the past to be followed by a waspless autumn, and *vice versâ*. Hexagon netting is the best protecting material, but many owners of gardens think it too expensive for use on an extensive scale, presumably overlooking the fact that a dish of well-grown Warrington or Ironmonger is often enjoyed by the wealthy when Grapes are left untasted.

Raspberries

are too often left to take care of themselves from the time they are mulched until the fruit is ripe; but this is not good treatment, as some varieties throw up a profusion of suckers, which rob each other and overcrowd the fruiting canes. These we find it necessary to thin out to five or six to each stool, and run a piece of matting rather loosely round them to prevent injury from wind and rain when growth is very rapid. Raspberries, like Strawberries, require close netting in wooded districts, otherwise the colour of the fruit would not be seen. When grown in squares, the cheapest protection is a permanent enclosure of galvanised netting 6 feet in height, well secured to Larch posts or stakes with a wire door for entrance. Stout wires strained from post to post form a skeleton support for square-meshed twine netting large enough to cover the whole of the plantation. If well tanned when new and put away in a dry store room as soon as the crop is over, such nets last a number of years, and pay over and over again for the original outlay. Raspberries, it is well understood, resent the introduction of the spade or fork, and revel in heavy mulchings and copious supplies of water during a continuance of dry weather; moreover, they pay for being kept free from weeds, but nothing more penetrating than the Dutch hoe should ever be introduced amongst them.

Apples,

as forward leafing and backward flowering led me to anticipate, are not a regular all-round crop. A great number of trees, it is true, are heavily cropped, but others, especially those which were in full flower when the heavy deluge of rain fell in May, are thin, and in some orchards fruitless. The air temperature since that time has been low, and heavy land being still cold and wet, the fruit swells slowly and will ripen late, if it does not thin freely by dropping. Pyramids and bushes in gardens are also partial; the latter, where the spreading branches shaded the roots during the long-continued drought last year, with us are carrying good, in some instances immense, crops, while pyramids which did not receive a corresponding degree of shelter are thin by reason of their having been sparsely set with perfect flower-buds. Cordons are good, and we have commenced pinching to keep the spurs close at home and get them forward. These with us, and with growers generally, produce the finest fruit; but in this there is nothing remarkable, as we always find this class of trees well mulched and in other ways receiving special attention. Pyramids

in course of formation may now be pinched to keep them in shape and force the sap into channels where it is most wanted. The manipulation of larger or full-sized trees comes next, but it must be borne in mind that this work should be performed gradually, as a complete sweep of soft and tender growth in cold or wet seasons especially results in a forest of spray instead of flower-buds. In ordinary seasons it is a good plan to thin the fruit early and freely, but this operation this year may well be deferred until all that are to drop have fallen; then, with a liberal hand, thin well and follow up pinching to let in sun and air throughout the remainder of the season.

Pears

on walls, especially those facing full south, it is to be feared, will be a light crop, and unless we have a decided change, and that soon, it is doubtful if the choice and tender varieties will ripen properly. Much may be accomplished by timely stopping to force the fruit forward and let the sun into the spurs and walls, which, if composed of brick, will absorb a great deal of heat on bright days, and remain through the night several degrees warmer than others which are shaded by spray and foliage. Pyramids and standard trees, as far as quantity goes, promise to be most profitable—that is, on the assumption that the weather will improve, and varieties usually grown in this way will have time to ripen. At the present time the fruit is quite a month behind, but this will not justify carelessness or neglect, as there is yet a long growing period before us, and, aided by good management, the trees may make up for valuable time apparently lost. Continue, then, to remove or pinch back the vigorous shoots, not only on Pears, but on fruit trees generally. Always commence at the top and work downwards, as the shoots near the apex are the most forward and rob weaker growths near the base. Pinching, it is hardly necessary to repeat, should be performed piecemeal, little and often, and the nailing or tying in of young shoots should never be attempted until they are free from insects.

Cherries

in orchards and on walls at one time promised a most abundant harvest, and may yet yield a quantity of fruit, but on our cold, heavy land the rainfall at a most critical time was too much for them. We generally succeed in ripening and keeping until a late period a quantity of the better kinds of dessert Cherries on north walls. May Duke, Late Duke, Bigarreau Napoleon, Governor Wood, Black Eagle, and Elton do well on a north aspect; but then the borders are thoroughly drained and the roots are confined to the 4-foot pathway. This spring they set the heaviest crop I have yet seen, but some of the trees now look starved and yellow in the foliage, and I fear we shall not have the pleasure of much hand-thinning. When Cherries on cold, heavy soils become gross they are apt to gum, but by planting in rather thin beds of good loam resting on deep drainage, and laying in young shoots on the extension principle instead of spurring back, this troublesome disease does not make much headway. Many shoots must, of course, be removed, but these we pinch when we commence searching for grub and black aphis early in the spring. Black fly with us has not yet put in an appearance; indeed, fruit trees of all kinds are cleaner than I remember having seen them. This happy relief is the more remarkable, as we generally find myriads of insects following checks and chills, of which the trees have had many this season; but my freedom I attribute to the persistent washing of the trees and walls with soapsuds throughout the winter. Cherries on walls must now be netted, and if any of them are wanted for a late succession, broad coping boards, from which the nets may hang, will be found invaluable in wet weather. If Morellos have not been well washed, the hose should now be laid on to free them from stoneless fruit and filth, as the time will soon arrive for netting. Many gardeners nail in their trees in July, but it is a question if this is not a superfluous operation, as I find the fruit keeps best where due regard is paid to the removal of a portion of the young growths, and those intended for nailing in are allowed their freedom until the autumn or winter training. Nailing is not an essential to the ripening of the wood, as we find pyramids and bushes producing heavy crops of fine fruit annually.

Peaches and Nectarines

are now making excellent growth, and the trees are quite free from insects. My own trees have been nailed in rather loosely; I never tie, as the shoots lose the benefit of so much warmth from the bricks. Although the dividing space on wired walls may not exceed half an inch, still it is sufficient to prevent the bricks and shoots from touching, and the backs of the leaves and wood are more or less exposed to cold currents of air. The fruit has been repeatedly thinned, but not finally, twenty per cent. or thereabouts having been left over my usual number. These will be taken off shortly, and when finished each tree will carry as many Peaches as it covers square feet of wall with foliage. A light crop, some may say, but many years have elapsed since I first made Peaches a specialty, and I find my trees cannot carry more year after year in succession. When once nailed or tied in, summer training must receive constant attention, and each shoot must have plenty of room for extension and the full development of its foliage. All leaders and side growths cannot be kept too close to the wall, otherwise the main object, perfect maturation without having recourse to stopping, will not be attained. A few, perhaps, above the breast line may become too gross, but this inclination to take the lead can be seen at a glance, when the points can be pinched to throw the sap into weaker growths below the line. Shoots so pinched generally throw out laterals, all of which, with the exception of one at the extremity, must be pinched and re-pinched, whilst the leader may be secured to the wall to increase the size of the tree and draw the sap forward instead of forcing it into breast growths, which sometimes start near the working. By adopting this plan the largest trees will require very little autumn pruning beyond the removal of shoots from which the fruit has been gathered, and the centres will be abundantly furnished with healthy bearing wood. Two points the extension trainer should never lose sight of; the first is liberal disbudding to make room for summer growths; the second is close training to secure well ripened wood. If not already done, all wall paths should now be well mulched with good stable litter to keep in moisture and draw the working roots to the surface. Up to the present time the borders have been wet enough and cold, but a hot July sun, combined with the rapid action of thousands of perspiring leaves and a full crop of fruit, may soon exhaust the supply. This year the outdoor Peach grower has a good start, for his trees are clean, his borders have been thoroughly moistened. All that is now needed is bright sun and copious supplies of water.

Eastnor Castle, Ledbury. W. Coleman.

The Potato crop in North-east Suffolk.—Potatoes have not looked so promising at this season for years past as they do at present, both in gardens and fields. Their tops have not been cut off or injured, as in former years, by late spring frosts; consequently they are looking strong and healthy. The last frost which we had likely to do any injury to vegetation was on May 1, when but few Potatoes had shown themselves above ground. The principal sorts grown in the cottage gardens along the Waveney valley are Early Rose and Magnum Bonum. A few others are sometimes grown, but none find so much favour as Roses and Magnums.—H. F.

The winter of 1885-6.—Upon looking at my meteorological register, I find that here at Fulham Palace I registered 106° of frost from October 6 (the first night of frost here) to December 31, 1885; and that from January 1 to May 6 (the last night of frost here), 394°—making a total of 500° of frost for the winter of 1885-6; the sharpest frost was on the night of January 7, 1886, when we registered 18°.—A. J. Ballhatchet.

Garden Destroyers.

INSECTICIDES:

their use and abuse.

When bunglers take up edge tools it not unfrequently happens that they cut their fingers. This is an old adage—nevertheless, a true one—which may also be applied to the careless or inexperienced use of insecticides. Remedies for the destruction of every known insect and parasite are now as plentiful as Blackberries, and, judging from testimonials, all must be good when carefully and properly applied. How, then, does it happen that we so often hear of many a well-known remedy proving more destructive than the disease? The question is easily answered. A chemist's nicety may not have been observed in the preparation of the wash or mixture; the plants or trees may have been carelessly prepared, or most likely neglect after the application may have led to serious injury or destruction. Fumigating with Tobacco or Tobacco paper, as all know, is one of our oldest remedies for the destruction of aphides, and hundreds of pounds are consumed daily by men who know what they are about with the best possible results; but this does not do away with the fact that the tender and valuable occupants of many a house are ruined by its injudicious use. Tobacco paper is, nevertheless, a valuable article, and experienced cultivators will not discontinue to use it because a score of bunglers have introduced carbonic or sulphuric acid with their igniting coals, or have allowed the sun to shine on the plants and run up the temperature before they were syringed and shaded. In the same way a wash or solution applied over-night after the sun has gone down and well syringed off before it rises may be found effectual, while neglect the following morning may prove fatal to the foliage of plants and fruits under glass. My object in offering these remarks is plain and straightforward, and if I succeed in drawing the attention of the inexperienced to the fact that all life-destroying remedies should be applied with great caution and under well-proved rules and conditions, the end I have in view will be attained. Some two years ago a gentleman residing in the midland counties introduced

Sulphide of potassium as a well-proved, sure, and safe remedy for the destruction of mildew, green fly, and spider. A small quantity of the sulphide was sent to me for impartial trial, and the result proving highly satisfactory, I have repeatedly recommended its use through the pages of The Garden and privately. My first experiment was made upon some old winter Cucumbers badly infested with mildew. Two dressings cleared them; they started into new growth and bore good fruit for months afterwards. I did not, it is hardly necessary to say, allow the sun to catch them in their sulphur bath, but syringed well the next morning and shaded until the foliage was dry. I next tried it upon an old Vine touched with mildew and just coming into flower; bunches, foliage, and every part of the structure received a thorough drenching, for I had made up my mind to the loss of the crop of Grapes. Early next morning the Vine was syringed with pure water and shaded; mildew disappeared for the time, and the Grapes set and finished well. My next application was to a very tender Melon plant, about 3 feet high, and badly infested with green fly. The fly disappeared, and the plant grew away freely without a blemish. Early in the autumn I again observed a tendency to Oidium on the laterals of my Vine, and, knowing what a subtle enemy I had to deal with, every house then clear of Grapes was thoroughly syringed more as a pre-

ventive than an antidote. The result was satisfactory, and I felt quite justified in giving the sulphide my warmest commendation. Early this spring a leading gardener wrote me to the effect that the Vines in his metallic houses always became badly infested with spider, and expressed a wish to try the sulphide. I sent him the necessary information, and soon by parcel post received a few leaves which he stated were badly affected with mildew. I examined them carefully, and arrived at the conclusion that they were free from spider and mildew, but badly scalded. Leaves afterwards found their way to the office of a contemporary, and the answer was a full corroboration of mine. Anxious to ascertain the cause of the scalding, I applied for full information respecting morning syringing, shading, and ventilating, but the reply has not yet reached me.

In a late issue of The Garden (page 588) "R. M." states that he has used sulphide of potassium for the destruction of mildew on his Peach trees, and complains of the loss of the leaves. Now, a bad attack of mildew, brought on by imperfect ventilation or want of water, would be sufficient to destroy the leaves; but sulphide having been used, "R. M." will greatly oblige me, and, I have no doubt, the thoroughly practical and scientific gentleman who introduced it, by kindly stating how and when the chemical was applied, and what steps were taken for the protection and safety of the trees the following morning. If sulphide of potassium was really dangerous when carefully and properly applied, I should be the first to make the *amende honourable* by publicly withdrawing every word I have written in its favour; but having proved to my entire satisfaction that it can be used with safety, and when properly understood will prove a great boon, not only in gardens, but in Hop yards, I shall esteem it a favour if others will give it a fair trial on a small scale and publish the result. Not so many years ago gas tar, forsooth, was introduced as a remedy for mealy bug on Vines. People who had been scraping, and painting, and slaving half a lifetime were horrified, and resolved on giving it a wide berth. A band of tar pure and simple drawn round the stem of a growing tree means certain death, but, applied as gas tar is now applied to the rods in winter, it is found one of the most efficacious remedies ever introduced, and although it may have proved a sharp-edged tool in the hands of those who will not pause to weigh and consider, scores of intelligent men have exterminated bug by it in their vineries when all other insecticides have failed.

Paraffin in the same way is an excellent servant, but a bad master. When properly used amongst plants and the syringe is well plied as soon as it has done its instantaneous work, there is a speedy disappearance of bug and filth, for the first melts on being touched by mineral or vegetable oils, and the excrement is loosened and washed away by pure water. The judicious use of insecticides is not, as a rule, studied as it ought to be, the majority, I suppose, consoling themselves with the thought that their plants or their Vines will never suffer as their neighbours' suffer, and so they live in a fool's paradise until the Philistines are down upon them, when, overtaken by terror, they fly to dangerous expedients, or act upon advice, sound enough in itself, but death-dealing when the usual common-sense precautions are neglected. W. Coleman.

Eastnor Castle, Ledbury.

The slug pest.—I should dislike killing slugs after 10 o'clock at night by means of a lantern and scissors, as suggested by "T. P. N." I would rather resort to "D. T. F.'s" plan of dosing them with soot and quicklime. In a rainy season our garden is overrun with slugs, and when planting out winter greens, such as Brussels Sprouts, Cabbages, or in fact anything on which slugs prey, I put a good ring of fresh sawdust round each plant, and this plan I find to be very effectual as far as keeping them off the plants thus surrounded is concerned. Slugs do not venture to crawl over the sawdust, of which enough must always be used to prevent the first shower of rain washing it away. A good plan is, after rain, to go round and destroy all slugs that can be seen; a few hands at this work for an hour or so will destroy thousands. Going round at night with a lantern and scissors would doubtless answer admirably in the case of a small garden, but going over acres is quite another matter.—W. A. Cook, *Hunts.*

Flower Garden.

GENTIANA ACAULIS.

It has been asserted that this is easy to grow, but it is nevertheless a fact that in many places it will not even live in the natural soil. I tried it for years in our soil and I could never get it to grow; indeed, it wasted gradually away until I adopted the following plan: I took out the natural soil several inches deep, and filled in with good loam, with which I mixed a little leaf-soil, some mortar rubbish, and pounded brick in pieces the size of a nut. I pressed the soil in very firmly round the roots, and towards the surface I embedded some small stones. When I did this my plants were on their last legs, but the change of soil operated magically; they regained almost at once their healthy hue, and after taking a season for convalescence they are, I see, hard at work renewing the growths of which chronic invalidism had to a great extent deprived them. So many have complained to me of a want of success with this lovely little flower, that I am induced to chronicle my experience in the hope of helping those who have hitherto failed with it. In good loam and mortar rubbish the Gentianella is sure to thrive, and a good spadeful of this mixture will suffice to cure debility in a fair sized specimen. I know an enthusiastic amateur grower of hardy flowers who, for the special accommodation of this Gentian and its little congener, verna, pulled down an old cottage for the purpose of getting a good supply of suitable material. I know, too, that this grower has made verna tractable, and that acaulis flourishes weed-like with him. Truly, these two little alpine gems are lovely enough to warrant such a sacrifice of time and material; their beauty is unique, their vigour perennial when they find a home to their liking. It is in rich, firmly retentive loams that G. acaulis succeeds best, but it is in very light soils that it does worst.

The mechanical as well as the chemical nature of the soil no doubt much influences its well-being, and I have therefore thought that the sinking four or more bricks level with or projecting slightly from the soil would be helpful. If the bricks stand out only a little, this would allow of a can of water going directly to the roots in hot weather, and the Gentian's special food would thus be better kept away from greedy neighbours. The unsightliness of the bricks would be overlooked for the sake of the exuberant Gentian growth. Moreover, old bricks could be used, and in time the exposed surface would become either mossy or overlapped with Gentian shoots. In very porous soils I believe this to be the only safe way of growing the Gentianella. The roots are fibrous near the surface, and in a soil which quickly parches they are burnt up in the hot summertime. Four bricks and a spadeful of loam and mortar rubbish will make a happy home for the Gentianella. J. C. B.

Hepatica angulosa.—I have been more than once during the past few years surprised to see how admirably this Hepatica thrives in the Messrs. Hooper's nursery garden at Twickenham. The soil is deep, but very light and porous, and this Hepatica seems to revel in it, producing big clumps and fine heads of foliage. No other kind thrives so well. The position is a warm one. There is quite a big bed of it, and in early spring it is very beautiful.—A. D.

SOWING STOCK SEED.

June is the proper month in which to sow the seed of perennial Stocks, and in dry, well drained soils in which the plants stand through the winter unhurt, few hardy flowers are more attractive than a good strain of Brompton Stocks. It is useless attempting to disguise the fact that cottagers excel even skilled gardeners in the cultivation of this class of Stocks. Why that should be so I cannot explain, except that in gardens the soil may be too rich for them, thus rendering them more susceptible of frost and damp. In my own case damp and a rich soil are fatal to them. Even in ordinary winters I lose two-thirds of my plants. The different varieties of the Brompton Stock are general favourites with cottagers hereabouts. They sow the seed about the middle of June, and transplant as soon as the seedlings are large enough to handle, and the most successful grower with whom I am acquainted lifts all his plants again in October. He simply places a trowel under the roots, lifts the plant out of the ground, and puts it back again in the same place. His motive for doing so is to check the growth and to harden that already made, which is consequently in better condition to resist any unfavourable influences than that of plants which are allowed to keep growing until frost overtakes them. Be that as it may, he has a fine show of Stocks every year, while I, who have to deal with a rich heavy soil, have to lament the loss of most of our plants. A place in an open spot should be prepared for the seed. The ground should be made rather fine, the seeds being small. Drills half an inch deep should be drawn to receive the seed, and should be filled in with some fine sandy soil. In order to prevent the surface from becoming too dry, a few green branches should be laid on the bed to shade it, but they must be removed as soon as the plants appear above ground. I ought to say that the seed cannot well be sown too thinly; if the plants stand thickly in the rows they get so weak that it is long after they are put out before they get sufficient strength to make good growth. On the contrary, if allowed sufficient room in the seed bed they get strong and sturdy before more space is required, and then they feel the moving less, and consequently make much the stronger plants. The scarlet and white are the most vigorous of the Bromptons, but the purple variety is also very useful. J. C. C.

NOTES ON HARDY PLANTS.

Anemone Robinsoniana.—No more convincing proof, I think, could well be had that this form is distinct from nemorosa and its so-called blue varieties than the fact that all its foliage shrivels up almost as soon as the flowers fade, while in the others it remains more or less green for two or three weeks after they have flowered. Such are the differences which occur in the case of plants that have grown side by side for two years, and which are otherwise placed on an equal footing as regards soil and other conditions, so far as I can judge.

Geranium eriostemon.—What a grand flower—large and richly coloured—this plant produces! Each flower is 2 inches across, and practically a violet-blue or purple, though the lower parts of the petals are paler or inclined to reddish purple. Why is not this showy Crane's-bill more largely grown? I have known it to last nearly three months in good form, all the while affording valuable material for cutting purposes. It grows about 18 inches high, and is erect and robust.

Plant-edgings of a permanent character are more or less grown in every garden; everybody must have an edging plant, be it only Thrift or London Pride; of the latter there are at least a dozen sorts, and the kind known as Saxifraga Ægilops is truly a gem for the purpose. In the case of Thrifts, too, why not plant the brilliant and exceedingly neat Armeria Laucheana instead of the worst variety? There are plants well adapted for edgings near Grass, and others for ordinary walks; the Saxifrages and Stonecrops asso-

ciate admirably with stones, and tall broad-leaved Thrifts and dwarf Grasses for bold borders. Milkworts and creeping Phloxes do well for fringing shrubberies. Sun Roses, preceded by the pleasing purple of Aubrietias, have both the useful property of wreathing sunny walk sides with masses of flowers, and the two together maintain a large amount of gaiety from April to August. For subtropical borders might be used the finer-foliaged Heucheras, choicer Megaseas and Asarum europæum, all being evergreen. It is unnecessary to do more than thus hint at the endless variations which might be adopted in the case of edging plants.

Camassia esculenta.—This, to be fully enjoyed, should be seen like Bluebells in quantity. The comparison, however, reminds one that the spikes of rich blue of the Quamash would be more appreciated if they came a little earlier, or a little later, so as not to be "in" with the Bluebells, which, in effect, they so much resemble. May I suggest that those who intend planting the Camassia should use only the variety which goes by the name of C. esculenta atro-cærulea? Its flowers are larger than those of the type and darker in colour. They are produced a little earlier, too, and in greater profusion.

Margyricarpus setosus.—This is worth planting in a front position on rockwork. Its pearly fruits are most persistent, and, owing to their great quantity and the small size of the foliage, they form an attractive feature. When these drop on clean moist soil, they germinate freely, and by the following spring become thrifty little plants. If on flat cold soil they are apt to damp off; they should, therefore, be set in sunny places, with their roots in deep black mould.

Dianthus petræus.—I often wonder why this is not equally as much valued as alpinus, neglectus and the glacier Pink. It is as easily grown as any of these, and certainly not inferior to them in beauty or neatness, though a little taller in the flower-stems, which, however, do not exceed 5 in. or 6 in. when grown fully exposed to sunshine. Moreover, it is a reliable Pink—one which when once got into growing condition is not apt to "go off" in such a manner as to make one suspect that it is but of biennial duration; on the contrary, it widens its rigid glaucous tufts year after year, without leaving dead patches in the middle, and year by year the bright rosy red flowers become more numerous. It will thrive well in such soil as suits the commonest Pink.

Two alpine plant pests give a deal of annoyance in the early summer months. These are green fly and what is known all over the country by the name of cuckoo-spit. Seldom do Androsaces, Drabas, Arenarias, or Pinks escape the fly. The yellow hue assumed by alpines in summer is often caused by aphides when allowed to get the upper hand. Fortunately, a handy remedy is to be found in tobacco dust, puffed upon both the spit and fly with a puff-pot. When thus operated on they disappear in a day or two. This remedy will not, however, be of much use if the pests are allowed to exhaust the plants before it is applied.

Tropæolum speciosum.—The wet, cool season which we have had has suited this plant well. It doubtless likes moist weather as well as a moist position, for its tender stem-skin is soon scorched by hot sunshine. Nor is it a difficult plant to establish, provided a cool spot is selected for it; but slugs infest such quarters, and attention must be paid to keep them from eating off the young shoots. So fond are slugs of this plant and its roots, that they will eat it down as far as possible. This Tropæolum likes to overrun living twigs rather than wires or dry material, the latter being unsuited to its tender skin. J. W.

Chrysanthemum segetum.—This yellow field flower shows under cultivation a considerable tendency to grow large in size. The ordinary dimensions of the flowers are about 1¾ inches in diameter, but I have occasionally had blooms 2¼ inches across, and as the petals are longer and less formally placed, large blooms are more pleasing than small ones. I have no doubt whatever that in a few years we shall find this Chrysanthemum rivalling other members of the family in the dimensions of its flowers.—D.

Societies.

ROYAL HORTICULTURAL, LIVERPOOL.

June 29 to July 5.

This great exhibition may be termed the first of a new series of provincial horticultural shows which the Royal Horticultural Society intend to hold—a movement which cannot fail to be productive of much good. The success that has attended the present show will serve as an encouragement to hold such gatherings, for a success it undoubtedly is. No exhibition of such importance has been held since 1866. It is in every sense of the word a representative show; in it one sees something of everything connected with gardening, although, of course, some departments have been better represented elsewhere. It is held in the Wavertree Park—a wretched recreation ground about two miles out of Liverpool—and adjoining the Botanic Garden, which for the occasion has been turned into a promenade—altogether a capital arrangement. The park is wholly occupied by the tents, plant houses, garden appliances, boiler trials, and the display made by the Bee-keepers' Association. The principal department of the show is, of course, the plant tent, a capacious structure 260 feet long by 120 feet wide. In this the plants have been effectively arranged by Mr. Barron on ground laid out in a natural style with irregular mounds and undulations, so disposed as to break the monotony inseparable from a flat surface. The effect would, perhaps, have been enhanced had the tent been higher, but there was a difficulty in the way of sinking the paths. Brilliant colours are gathered into distinct groups—those, for instance, of Pelargoniums and Orchids which contrast strikingly with groups of great Palms and Ferns. There are also large groups of beautiful-leaved plants, such as Crotons, other mounds being occupied by miscellaneous gatherings of plants chiefly from the great London nurseries at Chelsea and Upper Holloway. Altogether, one scarcely expected to see so bright a show at the end of June as this is. Its chief features are the Orchids, especially those from Mr. Hardy, of Pickering Lodge, Timperley, who is second to none in every class in which he exhibits; the Crotons from Messrs. Ker; the Pelargoniums, both show and zonal, the hardy Ferns, and the hardy flowers, particularly those in pots and alpines, from Messrs. Backhouse, of York, and Messrs. Paul, of Cheshunt, and the cut flowers.

The fruit show, too, is good, better even than was expected considering the season. Vegetables are excellent; in fact, the fruit and vegetable tent, though large, is filled with as fine examples of good gardening as could possibly be seen at the end of June. There is a great gathering of cut flowers, but among them nothing particularly new, and there is almost an entire absence of new plants that have not already been exhibited in London. The schedule contains no fewer than 133 classes, exclusive of the implements and art sections; we can therefore do little more on this occasion than advert to such salient features as we consider noteworthy, especially as we publish in another column a full list of the awards.

Orchids.

A great show of Orchids was expected, and the display of them is certainly very good. Those who admire *bonâ-fide* specimens may see some of the best examples that could be grown, while for variety we imagine that almost every popular Orchid in bloom at the present season is represented. The finest group in the show is that which Mr. Hardy, of Timperley, furnishes, and wins with it the silver cup and £10, given by the Liverpool Horticultural Company. There are twelve plants in the group, every one being a marvellous example of good culture. The largest specimen is a mass of Cattleya Mossiæ in a shallow basket; it is over 4 feet across, and carries nearly 100 flowers. The next remarkable plant is one of Dendrobium Devonianum, a pot specimen, with about thirty hanging growths, each wreathed with blooms. Other plants are Cattleya Warneri, with fifteen flowers: C. Mendeli, with fifteen flowers; another variety, with twenty-five flowers; C. Sanderiana, with thirteen flowers; Odontoglossum vexillarium, two plants each, nearly a yard across and covered with bloom; Cypripedium superbiens, with nineteen flowers; Dendrobium Jamesianum, a mass of white bloom, a yard through; and Cypripedium Stonei and Brassia Lawrenciana, both good.

The class for a dozen Orchids from amateurs is best represented by Mr. Hardy, who has one of the finest groups we have ever seen. The most remarkable specimens are Dendrobium Wardianum, 4 feet high and a yard across, full of bloom; Cattleya Mossiæ, two plants each 4 feet over; C. Sanderiana, three spikes, four flowers in each; Odontoglossum vexillarium, two plants, a yard across; Cypripedium Parishi, eleven spikes, four flowers on each. Mr. Harvey shows the second best dozen, which includes some noteworthy specimens—for instance, Cattleya Leopoldi, with three spikes, one carrying fifteen flowers; Masdevallia Harryana, two and a half feet across; a highly coloured Odontoglossum vexillarium; Cattleya Mendeli, with a score of blooms; Phalænopsis speciosa, with six spikes; and Aerides crispum, a deliciously scented species, the only plant in the show. In the third group, from Mr. Thompson, of St. Helens, is a plant of the rarely seen Cattleya labiata, with five spikes, carrying twenty-one flowers. This collection also contains the most remarkable Orchid in the show, a species of Schomburghia, presumably undulata. It has growths like those of S. tibicinis, and a long spike bearing about a score of large flowers, with wavy petals and sepals of pale yellow and a claret-tinged lip.

The class for twenty-five Orchids, arranged for effect with Palms, Ferns, and other fine-foliaged plants, is a good feature, being quite a change from the usual style of showing Orchids. There were three exhibits, and it is not difficult to single out the finest, which is that from Mr. Hardy's garden. He shows not only fine plants, but numerous varieties, including among them huge plants of Cattleyas and Odontoglossums intermixed in a tasteful way with greenery. Among the less common kinds are Vanda Denisoni, Aerides Veitchi, with branching spikes, and Saccolabium præmorsum. The choice Orchids shown in the other groups are Odontoglossum cordatum aureum and Kienastianum, from Mr. James; and Oncidium Lanceanum. A remarkable specimen among the Orchids is a specimen of Lælia purpurata in a bushel basket, from Mr. Boscawen's garden in Cornwall. The variety is a magnificent one, the lip of the flower being 2½ inches across, and of the deepest velvety crimson. There are two spikes on the plant, one with six, the other with four, flowers, and the large bulbs show exceptionally fine vigour.

The best twelve Orchids from nurserymen are from Mr. Cypher—a fine group containing several remarkable specimens, the most noteworthy being Dendrobium Dearei, 3 feet through, Epidendrum vitellinum majus, Anguloa Clowesi, Dendrobium suavissimum, and Odontoglossum vexillarium. In Mr. James' second group are the rare Lælia Schilleriana, a near relative of L. elegans; Dendrochilum filiforme, with several scores of elegant spikes; and Aerides Fieldingi, with a spike 2 feet long—a superb object.

Mr. Hardy shows the finest six plants from amateurs, and, like his silver cup collection they are magnificent. There are Cattleya Mossiæ, 3 feet through; C. Mendeli, 3 feet; Odontoglossum vexillarium, 3 feet, covered with bloom; Cattleya Sanderiana, with eighteen flowers (a splendid specimen); Dendrobium crassinode Barberianum, and Cypripedium barbatum. In the second group

from Mr. Harvey are the rare Epidendrum Wallisi, with a spike of a dozen flowers, and Oncidium crispum grandiflorum, a very fine variety.

The great Orchid emporium at St. Albans contributes a small group of its choicest things among Odontoglossums, Cattleyas, and the like. There are great round-flowered forms of O. crispum, superbly-coloured forms of Cattleya Mendeli, Mossiæ, and Warneri, besides a specimen of the rather uncommon C. Aclandiæ, which, by its distinct colours, stands out conspicuous from all the rest. Among the hybrid Odontoglossums are some exquisite forms, but one can scarcely attempt to describe them. Among other choice kinds are the true Oncidium Rogersi, which is at once recognised by the large lips of the flowers over 2 inches across, and of a clear yellow. Mormodes eburneum, with large curiously-shaped ivory-white flowers, is also a noteworthy plant in the group.

The Liverpool Horticultural Company shows a group of Orchids containing numerous uncommon kinds, among them being Vanda Roxburghi, with mauve-coloured lips and beautiful tessellated sepals; Aerides crassifolium, one of the finest species in the genus; Chysis aurea; the true Miltonia Weltoni; an extremely fine form of Odontoglossum nebulosum, one of the finest we have seen, in fact; some great plants of various Cattleyas, including an exceptionally fine form of C. Eldorado with a labellum almost wholly yellow.

Fine-foliaged Plants.

Crotons are unquestionably one of the features of the show, for a finer group than Messrs. Ker, of Liverpool, show has perhaps never been seen in Europe. The group occupies a prominent position at the entrance of the big tent, and therefore gives visitors a good impression of the plant exhibition. Each of these Crotons is from 4 feet to 5 feet through, glorious masses of subtle colouring, from the strongest yellows to the richest crimsons, arranged in a hundred styles of variegation. The finest plant is Mortfontainense, one of the trilobed group, crimson and gold with green veins; Evansianum, Newmanni (both bright carmine-crimson), Countess, Aigburthense, and Interruptum aureum, all being narrow-leaved kinds of high colour; mosaicum, Weismanni, Sinitzianum, with elegant long foliage; Bergmani, a huge mass, with leaves like those of Magnolia grandiflora, yellow mottled with green; and Hawkeri, yellow broadly margined with green, are other remarkable plants in this splendid group. One of the chief points about these plants is the entire absence of sticks, all being vigorous young specimens, the oldest not more than three years. Mr. Cypher shows the second best dozen Crotons, all fine plants, but not nearly so large nor so rich in colour as those from Messrs. Ker. The best among them are those named Frank Selliere, Thompsoni, and Baron James de Rothschild.

CALADIUMS are shown grandly from London, Messrs. Laing, of Forest Hill, having a group of six which, for size and high quality, could scarcely be equalled. The sorts, too, are of the best—perhaps the best half-dozen one could grow. They are, Ornatum, Ferdinand de Lesseps, Mad. Fritz Koechlin, Luddemanni, Leopold, and candidum, the latter a huge mass of silvered foliage.

COLEUSES are admirably shown by Mr. Colton, of Birkdale, who has six specimens, Mushroom-shaped, and each 5 feet across. The sorts are Gloire de Rougemont, bright crimson; Marquis de Nadaillac, Magnificus, Mrs. G. Simpson, Matterhorn, and Mrs. Baxter. A finer group of Coleuses we have rarely seen, and if these plants could be always shown in such fine condition, they would be an important feature of an exhibition.

PITCHER PLANTS are not remarkable, except those from Mr. Schloss, of Bowdon, who shows some half a dozen specimens of Sarracenia purpurea which could scarcely be better, also S. flava and S. Drummondi; but the judges thought these fine specimens inferior to the nine small Nepenthes which they placed first. They are good, healthy plants, but small and poorly pitchered. The classes for Sarracenias and Nepenthes should have been distinct. Groups of fine-foliaged plants from nurseries are shown best by Mr. Cypher, who has some monster Crotons, well coloured, also Palms and Cycads, and a capital plant of the true Cordyline indivisa. There are two classes for Palms, but neither represents any remarkable examples. Among the kinds shown may be seen the new Licuala grandis, the noble Pritchardia grandis, Phœnix rupicola—the latter a most graceful Palm that is likely to supplant others in a similar way. Bromeliads are shown by Messrs. Ker, the only collection in the show, and a very creditable dozen they are.

Ferns.

These are plentiful, there being several classes set apart for them, and their cool-looking foliage helps greatly to produce a fine effect in the great tent, as they tone down the gay colours of such things as Pelargoniums. The best nine plants in the open class come from Mrs. Horsfall's garden at Aigburth, the finest examples being Dictygramma variegata, the best plant we have seen of this extremely elegant Fern which looks like a magnified Pteris cretica. There is also a plant of Davallia bullata a yard across; Adiantum formosum, 5 feet; Davallia Mooreana, 7 feet; Microlepia hirta cristata, and a magnificent plant of Alsophila Moorei, one of the finest of all Tree Ferns. The second nine are remarkable for a large specimen of that most graceful of all Ferns, Goniophlebium subauriculatum, with fronds hanging like a curtain on all sides of the pot, some being quite 6 feet long. The amateurs show some grand specimen Ferns, especially Mr. Schloss, of Bowdon, who has the best half-dozen. These include Gleichenia rupestris, 7 feet through; G. rupestris glaucescens, 6 feet through; G. Mendeli, not much smaller; Cibotium regale, with immense drooping fronds; Brainea insignis, with a central tuft of copper-tinged new fronds. Mr. Barlein, of Didsbury, has in his second group of six some noble Tree Ferns, including the South African Cyathea Burkei, one of the best cool house Tree Ferns one can grow, and a plant of Davallia divaricata, two yards across, a beautiful object, as the stalks of the deep green fronds are of a vinous purple. In other groups the most noteworthy are Adiantum Veitchi, whose young fronds wear such a lovely coppery red tinge when young; Gymnogramma argyophylla, the best silver Fern; Adiantum farleyense, A. Williamsi, the golden Maiden-hair Fern.

HARDY FERNS, so seldom seen at London shows, or, in fact, anywhere in the south, in anything like a creditable condition are here among the most noteworthy plants in the show. There is one large group spread over one of the rising mounds in the large tent which, for the number of kinds represented and their excellent growth, has seldom been equalled—certainly not excelled. The group comes from the noted Fern growers, Messrs. Birkenhead, of Sale. Here one sees plants of all the choicest kinds. The best group of fifteen kinds comes from Mr. Bolton, of Carnforth, who has a wondrously fine collection, consisting of Athyrium Filix-femina plumosum and Stansfieldi, a plant 4 feet high and like a huge mass of ostrich feathers; Trichomanes radicans, 2 feet across; Osmunda regalis cristata, Scolopendrium vulgare crispum, Lastrea Filix-mas grandiceps and ramosissima, Lastrea dilatata grandiceps, Polystichum angulare venustum, and Pateyi. These are the finest specimens of this group, and they could scarcely have been finer. Among the four other collections of hardy Ferns shown there are some exceptionally fine specimens, and one wonders in looking at them that so much variety can exist among hardy Ferns. The Filmy and other Ferns from the York Nurseries are a centre of attraction, which, like the alpines from the same place, are admirably grown and arranged. Among the most noteworthy are Trichomanes exsectum, T. meifolium, T. reniforme, T. Luschnathianum pulchrum, Hymenophyllum pycnocarpum, tamariscifforme, H. cruentum, H. pectinatum, H. dichotomum. One of the most remarkable plants in Messrs. Backhouse's group is a miniature Fern (Rhipidopteris peltata gracillima), an exquisite little plant different from any other Fern. Intermixed with these dew-bedropped Filmy and other Ferns are brilliant flowers of Cattleya gigas and other Orchids, which produce a charming effect.

Stove and Greenhouse Plants.

On account of the late date for the early summer flowering kinds, there are not many collections shown. In the class for twelve, six in flower and six foliage, there are three collections, and the judges had no difficulty in selecting the best, as Mr. Cypher's group is a long way ahead of the rest. All the flowering plants are huge specimens finely flowered, the best being Erica affinis, Allamanda Hendersoni, Dipladenia amabilis, Ixora regina, Erica tricolor Wilsoni, Anthurium Scherzerianum. Among the six fine-foliaged plants are great specimens of Latania borbonica and other Palms, and two grand Crotons, Prince of Wales and Queen Victoria.

The second prize group in this class, from Mr. Mould, contains a well-flowered Bougainvillea glabra; and in the third, from Mr. James, is the beautiful Allamanda grandiflora. In the class for nine, Mr. Cypher is first. He has brilliant Ixora Pilgrimi and Williamsi, Allamanda Hendersoni, Azalea Brilliant, a huge untrained bush 6 feet through, and Anthurium Scherzerianum Cypheri. The class for six plants is best represented, the specimens being fresher and more uniform in quality. The first group, from Mr. Watts, of Wavertree, contains three large Ixoras; and the second lot, from Mr. Schloss, includes a plant of Stephanotis, about 5 feet high, and the pretty Boronia elatior. Mr. Cypher shows the best six Heaths: his group includes the lovely E. Parmentieri, a plant 4 feet through, E. depressa, E. ampullacea, E. ventricosa grandiflora, E. tricolor Wilsoni. Taken altogether, it will be seen that there is absolutely nothing novel about the stove and greenhouse plants—no extraordinary examples of culture.

Hardy Flowers.

Hardy flowers, both alpine and border kinds, are uncommonly well shown, especially compared with what is usually seen at London shows. One sees here great masses of such noble things as Lilies, Pæonies, Irises, Spiræas, Pyrethrums just as vigorous as one sees them in the open border. The two groups of fifty kinds make a fine display and occupy a prominent position—not an out-of-the-way corner, as is usually the case. The first prize group is that from Messrs. James Dickson, of Chester, whose chief plants are Lilium speciosum and candidum, huge specimens covered with bloom; Spiræa Aruncus, Mimulus cardinalis and varieties, Campanulas, Phloxes, Spiræa palmata, Delphinium nudicaule, Irises, bulbous and bearded, large-leaved Funkias, and a host of other things, including Sprekelia formosissima, which we hardly recognise as a hardy flower. An Ixia is also shown; but what of its hardiness at Chester? A brighter, and in our opinion a much finer, group is shown by Mr. Harvey, of Aigburth, who is placed second. He has grand plants of herbaceous Pæonies, reminding one of bushes of Roses, one in particular being like La France. There are also numerous fine plants of Pyrethrums—perhaps too many; Iris sibirica, Mimuluses, Erigeron aurantiacus, Campanula glomerata, azurea, nobilis, Phlox ovata, Ajuga genevensis, Achillea tomentosa, and double Rocket.

Alpine or rock plants are shown best by Messrs. Paul, of Cheshunt, who have a group of fifty, all well-grown plants, representing such beautiful things as Lithospermum petræum, Androsace lanuginosa, Campanula muralis, Erigeron glaucus, Dryas octopetala, Campanula turbinata and pulla, Gypsophila cerastioides, Ramondia pyrenaica.

Messrs. Backhouse show a marvellously fine group of hardy flowers, border and alpine, and contains a selection of the finest kinds, among the most conspicuous being the following: Saxifraga lantoscana superba, a panful 18 inches across; Chrysanthemum Puy de Dome, a large mass;

Lilium tennifolium, about twenty flowers; Gaultheria nummularifolium, 3 feet across; Polypodium vulgare var. trichomanoides; Dianthus cruentus; Gazania longiscapa, G. l. aurea, G. Pavonia major; Cypripedium acaule, three flowers; Linum provinciale, fine; Potentilla nitida var. atrorubens, 12 inches across; Linnæa borealis, large pan in flower; Asplenium marinum var. plumosum, new; Philesia buxifolia, grown as a hardy plant; Silene acaulis, 24 inches across; Saxifraga sancta, Cistus formosus, Pernettya speciosa, covered with white Lily-of-the-Valley-like flowers; Cypripedium spectabile, Rhododendron azalcoides, Aster alpinus albus, Pentstemon ovatus, Darlingtonia californica, Campanula speciosa, fine pan; C. palla, large mass; C. G. F. Wilson; Rosa pyrenaica, a large mass; Achillæa argentea; Athyrium F.-f. Kalothrix; Centaurea nervosa, flower large; Silene petræa, new; Lithospermum graminifolium, deep blue; L. tinctorum; Ourisia coccinea; Azalea Maximowiczi; Saxifraga lingulata, large mass; Hieracium pilosum; Campanula turbinata, pan; C. neglecta, C. alpina; Menziesia bicolor, two-coloured; Anthericum Liliastrum majus.

Tree Carnations from Slough make a pretty group, the plants being quite up to Mr. Turner's high standard of excellent culture. The group consists of about half a hundred of Souvenir de la Malmaison and its lovely pink variety, all big flowers, quite a foot in circumference. Intermixed with these are a few choice sorts of the taller Tree Carnations, the chief of which are the old Prince of Orange, a beautiful large flower, yellow ground edged with carmine. A new white, Lady Rose Molyneux, named after Lord Sefton's daughter, is the finest white yet raised among tree sorts. The flowers are 3 inches across, snow-white, and plentifully produced. A large and very beautiful group of Souvenir de la Malmaison Carnation from Mr. Leopold de Rothschild's garden at Ascott is a great feature in the great tent. About a hundred plants of it are shown, all with flowers about 4 inches across and in rude health. The group as a whole does great credit to Mr. Jennings, the gardener.

Annuals are admirably shown by Messrs. Carter, of High Holborn, who not only take the first prize for twenty-five plants, but also have a large group of brilliantly coloured kinds, such as Tropæolums, Chrysanthemums, Clarkias, Cornflowers, Sweet Peas, Rhodanthes, and Convolvuli. The prize group is a beautifully grown collection, the most remarkable kinds being Phlox Drummondi, Clintonia pulchella, Kaulfussia amelloides, Rhodanthe Manglesi, Candytuft, Silene pendula compacta, Sphenogyne speciosa, Leptosiphons, Schizanthus, and Tagetes—a capital selection for flowering in pots.

New Plants.

We certainly expected to see a fine display of these; but, as it is, there are very few plants shown that are new to us, the majority having been exhibited in London. The chief exhibitors of new plants are Messrs. Veitch, of Chelsea, Mr. B. S. Williams, and Messrs. Ker, of Liverpool Some members of the floral committee met on Wednesday, when the following plants were awarded first-class certificates: From Messrs. Veitch.—Gymnogramma schizophylla gloriosa, Philodendron grandidens, Nephrolepis rufescens, N. tripinnatifida, Pteris tremula foliosa, Rhododendron Aurora. From Messrs. W. and J. Birkenhead.—Nephrodium Sangwelli, Lastrea montana coronans. From Messrs. Kelway and Sons—Pyrethrum (double), Sambouburgh, Gaillardia Ormonde. From Messrs. Ker and Son.—Croton Newmanni, C. Aigburthiense. From Mr. B. S. Williams.—Araucaria Vervaetiana. From Messrs. Backhouse, York—Polypodium vulgare trichomanoides, Asplenium marinum var. plumosum, Chrysanthemum Leucanthemum Puy de Dome, Hymenophyllum pectinatum, Trichomanes meifolium. From Messrs. Cannell, Swanley.—Lobelia King of the Blues. From Mr. E. Claxton.—Tea Rose, Madame Cusin, was commended.

The competition in the class for new and rare plants sent out during the past three years is very limited, and only two local exhibitors represent the class. These are Messrs. R. and P. Ker, who take the first prize for a group including Adiantum cuneatum deflexum, Ficus elastica albo-variegata, Davallia fenienlacea, Anthurium Veitchi, Adiantum rhodophyllum, Croton Aigburthiense, Gymnogramma schizophylla gloriosa, Anthurium carneum, Medinilla Curtisi, Croton ruberrimum, Selaginella viridangula, and Vriesia hieroglyphica. Messrs. W. and J. Birkenhead, Sale, show Adiantum Mariesi, Davallia tenuifolia Veitchi, Nothochlæna Aschenborniana, Pellæa pulchella, Anemia Dregeana, Nephrodium Sangwelli, Nephrolepis Bausei, Cheilanthes leucopoda, Adiantum Neo-Caledoniæ, a species of Pellæa, Adiantum Collisi, and A. digitatum.

Miscellaneous Groups.

These contribute largely to the importance of the plant show; indeed, one of the chief features in the great tent is the extensive mixed groups from Messrs. Ker, Messrs. Veitch, Mr. B. S. Williams, and Messrs. Birkenhead, of Sale, whose group of Ferns is one of the finest we have seen, so well grown and so rich in variety. Messrs. Veitch's group is very handsome, and occupies one of the central positions. It is made up of some of the finest plants in their Chelsea Nurseries, exclusive of Orchids, the most prominent plants being the following: Among Aroids are Anthurium Veitchi, Warocqueanum, Rothschildianum, and ferrierense, Dieffenbachia Jenmanni, Philodendron grandidens, and a pretty new Caladium named minus erubescens. Among the Ferns is the lovely new Nephrolepis rufescens tripinnatifida, one of the best Ferns ever introduced; also Davallia tenuifolia Veitchiana, Gymnogramma schizophylla gloriosa, Osmunda japonica corymbifera, Pteris tremula foliosa, Adiantum Weigandi, and Selaginella Emiliana. A number of the finest kinds of Pitcher plants (Nepenthes) are a conspicuous feature of the group. These include N. Mastersiana, with great pitchers, N. Veitchi, Wrigleyana, intermedia, Sarracenia Swaniana, and melanorrhoda. Among other fine-foliaged plants are Dracæna Lindeni, norwoodensis, Goldieana, Aralia Chabrieri, Tillandsia zebrina, and Phœnix hybrida. A small group of insectivorous plants is interesting to the visitors; it includes Drosera binata, capensis and spathulata, Darlingtonia californica, Cephalotus follicularis. All these are interspersed with flowering plants, such as Gloxinias, of which there are numerous new sorts; Hydrangea paniculata grandiflora in great masses; Hæmanthus hirsutus, Exacum macranthum, and Caraguata angustifolia.

Mr. Williams' group, which also occupies one of the central mounds, is bright with flowering Orchids and other plants interspersed among a large collection of fine-leaved plants, altogether forming a beautiful display. Among the less common Orchids may be seen the rare Cypripedium Druryi, Houlletia odoratissima, a splendid Cattleya Mossiæ named grandis, Oncidium Krameri, O. Jonesianum, Masdevallia Schlimi; while among other flowering plants are the beautiful hybrid Amaryllises of the reticulata section, like Mrs. Lee.

Messrs. Ker's miscellaneous group, which won the first prize for effective arrangement, is made up chiefly of Crotons, which they grow so wonderfully well. These were made to rise from a groundwork of Ferns, and intermixed with groups of flowers like Lilium longiflorum. The group is exceedingly effective, as is also the whole of Messrs. Ker's exhibits, which almost entirely occupy the largest mound in the tent. Messrs. Birkenhead's Fern group, though it lacked brightness, is, nevertheless, very tasteful, and certainly quite novel. There are some very pretty arrangements of groups in the cut-flower tent, which are quite above the ordinary style of plant arrangement by amateur gardeners. Messrs. Dickson also show a mixed group in a prominent position in the large tent.

Trees and shrubs are poorly represented as regards numbers, but finer groups of specimen Conifers and Hollies than those which are shown by Messrs. Barron, of Elvaston, could not be seen. The Conifers, the only group shown, include fine examples of such beautiful kinds as Abies ajanensis, Parryana glauca (8 feet high), concolor, magnifica, lasiocarpa, polita, Douglasi glauca, Tsuga, Pinus parviflora, Golden Yew, Cupressus Lawsoniana intertexta, Cedrus Deodara alba spica, and others. The Hollies include the finest sorts, and one named latifolia nova is particularly noteworthy. The show of ornamental deciduous trees and shrubs is poor, and what there is is put under the large tent, which is perhaps the best place for Japanese Maples, which form the bulk of the two groups shown, and which do not certainly represent the wealth of beauty to be found among trees and shrubs now-a-days.

Bright-coloured flowers, such as Pelargoniums, Begonias, Petunias, and Gloxinias, are plentifully shown, and in most cases in admirable style. We have seldom, if ever, seen finer Gloxinias than those shown by Mr. Agnew, while the tuberous Begonias from Messrs. Laing, of Forest Hill, are equally remarkable, and it need scarcely be said they won the first prize in both classes set apart for these flowers. The show Pelargoniums from Mr. Turner, of Slough, though not so fine as we have seen them earlier in the season, are nevertheless very fine and by far the best in the show, while the zonals are as fine as could be seen. Mr. Turner's small pot Roses are much admired, and likewise the group of miniature kinds like Mignonette and Paquerette, which form a group by themselves, from the Liverpool Horticultural Company's Nursery.

Cut flowers are plentiful, a large number of classes being provided for them. There are cut Orchids, stove and greenhouse plants, hardy florists' flowers and Roses, which are the chief features in this tent, being shown splendidly by the Cranston Nursery and Seed Company, Hereford, who are first in the principal class. Mr. Prince's Tea varieties are unsurpassable, and the amateurs' class is best represented by Mr. Claxton, of Allerton, who is, we think, one of the best Rose growers in Lancashire. His blooms were very fine, particularly a boxful of that lovely newish Tea Rose Madame Cusin, which is finer than we have ever seen it. Hardy flowers are shown admirably, the Pansies from Mr. Forbes, of Hawick, the Violas from Messrs. Laird, of Edinburgh, the Pyrethrums from Messrs. Cocker, of Aberdeen, the Pæonies from Messrs. James Dickson and Sons, of Chester, and the grand display from Messrs. Kelway, all the way from Somerset, being the most remarkable. The bouquets, wreaths, and other floral devices are numerous, but we saw no new feature among any of them. A large collection of flower paintings is to be seen, and among them some are good.

Gold medals were awarded to Messrs. J. Veitch for a miscellaneous group of plants; to Messrs. J. Backhouse for Filmy Ferns and herbaceous plants; to Mr. B. S. Williams for group of plants; silver medals to Mr. Alexander; to Messrs. J. Carter for annuals; to Mr. C. Turner for a group of tree Carnations; silver gilt medals to Mr. Jennings; to Liverpool Horticultural Co.; to Messrs. W. Cutbush and Son for a group of plants; to Messrs. F. and A. Dickson and Sons for group of stove and greenhouse plants; to Mr. F. Sander for a group of Orchids; bronze medals to Mr. E. Bridge for show and fancy Pelargoniums; to Messrs. J. Dickson and Sons for a group of succulents.

A gold medal was also awarded to Messrs. Sutton, of Reading, for their extensive display of garden produce, which included seeds, models of roots, beautifully executed, miniature lawns, illustrating the growth of their lawn Grasses. Besides these there were fine examples of fruits and vegetables, such as Cucumbers, Melons, &c. Messrs. Sutton's exhibition formed quite a feature in the open ground.

Fruit and Vegetables.

A special tent is set apart for these, and a very creditable show they make, considering the sea-

son. The fruit is excellent, and the vegetables could scarcely have been finer. There are a good many classes set apart for them, but the competition is not numerous, and, of course, it cannot bear comparison with the great fruit shows we have seen of late years in September, such as at Edinburgh, Manchester, Dundee, but it may be called a thoroughly representative display. The finest classes are those for Pines, Peaches, Nectarines, and Strawberries. The collections of fruit are few, the best eight kinds being these from Impney Hall, which include, of good Grapes, Black Hamburgh and Foster's, some very fine British Queen Strawberries, Pitmaston Nectarines, and a capital dish of Noblesse Peaches. Lord Normanton's gardener (Mr. Richards) shows the second collection, which contains some first-rate dishes. The smaller collections of six kinds are more numerous, and Lord Cork's gardener (Mr. Iggulden) heads the list with a very creditable display. He has Peaches and Nectarines, Melons and Strawberries, President being noteworthy. The second collection is from Rood Ashton, and the third from Elvaston Castle. The Grape classes are moderate only in quality. Among the eight sets of Black Hamburghs, Lord Harlech's gardener shews the finest bunches, not large, but admirably finished for a midsummer crop. There are some other excellent bunches shown of Black Hamburghs even amongst those net in the prize list. The best Madresfield Court bunches come from The Quinta, Chirk, from which garden Mr. Louden also shows excellent Black Hamburghs. There are no really good Muscats ; none shown are ripe, though fairly good in bunch and berry, and the other white Grapes are not remarkable, except Golden Champion, from Mr. Louden, and some fine bunches of that much-criticised, but handsome Grape, Duke of Buccleuch.

Peaches are first-rate throughout, the most prominent sorts being Stirling Castle and Early Albert, which are the best varieties (from Mr. Divers), Royal George, Grosse Mignonne (second), while Bellegarde, Violette Hâtive, Hale's Early are among other prominent sorts in the class for two dishes. The best among nine single dishes is a fine dish of Crimson Galande, from Mr. Wallis, of Keele Hall, one of the finest dishes in the show. Nectarines, too, are good, the leading sorts being Lord Napier, Elruge, and Violette Hâtive, Pine-apple, and Balgowan, which latter heads the class for single dishes. Among Strawberries there are very fine examples of President, which sort (from Lord Eversley's garden at Heckfield) heads the list in the single dish class. Other prominent sorts are Marguerite, Sir J. Paxton, British Queen, and Sir Charles Napier.

The best Melon among about three dozen is Longleat Perfection, which has a high reputation for fine quality. Other favourite sorts are shown, including some that are new. The Melon competition for Messrs. Sutton's prizes brings out fine examples of their Scarlet Invincible and Imperial Green Flesh, and Hero of Lockinge varieties, all first-rate sorts. Cherries are not numerous, and only standard sorts, such as Black Circassian and Elton, are shown. Some excellent late-keeping Apples are shown from Messrs. Cheal, of Crawley, who also display their excellent styles of cordon fruit trees. One of the most remarkable exhibits in the fruit show is a group of pot fruit trees from Messrs. Rivers, of Sawbridgeworth. The trees are perfect examples of what orchard house trees should be, being loaded with fruit in different stages of ripening. They include Peaches, Nectarines, Cherries, Pears, Apples, and Plums, representing some of the finest sorts and several that are new. Vegetables are shown by some of the best gardeners in the country. The finest collection of eight kinds is that from Mr. Miles, Lord Carington's gardener at Wycombe, so well known as a successful exhibitor. Mr. Richard's second collection from Somerley is a credit to him, and among other collections shown are some uncommonly fine examples, and all are remarkable for the admirable selections of sorts. The classes for Pears are good, and the finest exhibi on varieties are shown grandly. Potatoes, Onions, Cauliflowers, and Tomatoes are good. Another is a good competition for Messrs. Sutton's prizes for collections of vegetables, the most successful exhibitor being Mr. Miles. Further comments upon the fruit and vegetables we must leave for a future number.

Implement Show.

MEDALS AWARDED.

There is a great exhibition of garden structures, appliances, and implements—one of the largest displays that have been brought together by the society. The exhibits occupy nearly the whole of the park, and we imagine that there is scarcely an article that has the remotest connection with horticulture that could not be found. As the exhibits are so numerous, we are only able to give a list of those exhibitors in the various classes who have received awards up to the time of going to press. The gold medal for the largest and best display is taken by Messrs. Foster & Pearson, of Beeston, who occupy a large area with a multitude of structures and appliances. In the class for the best modes of heating a small conservatory, Messrs. Halliday have won the silver medal with their "Perryshire" boiler, while Messrs. Messenger take the bronze medal in the same class. Mr. Watson, of St. Albans, is awarded a certificate for his new gas stove and apparatus. The awards of the larger boilers will not be made until after the boiler trials, which are still taking place. In the class for hot-water piping, modes of fixing it, Messrs. Foster & Pearson win the silver medal, and Messrs. Messenger take the bronze medal. The silver medal for a plant house, vinery, or orchard house is taken by Messrs. Foster & Pearson, the bronze medal in the same class by Messrs. Peel & Sons, Wood Green, London. Another bronze medal is taken by Messrs. Stewart & Jack for their cheap portable plant house, while Messrs. Halliday are commended. The judges selected for a silver medal the ornamental conservatory shown by Messrs. Richardson & Co., Darlington, and a silver medal is also awarded to Messrs. Halliday for their ornamental conservatory. A bronze medal is taken in the same class by Messrs. Wrinch, of Ipswich. In the class for movable plant pits or frames, Messrs. Halliday & Co., of Middleton, are awarded a silver medal for some excellent structures, to which we shall allude in a future number. Messrs. Foster & Pearson and Mr. J. Webster, of Wavertree, also take silver medals ; while bronze medals are taken by Messrs. Crispin, of Bristol, Messrs. Wrinch, and Messrs. Richardson. The silver medal for improvements in glazing is awarded to Mr. S. Deards, of Harlow, for his Victoria Dry Glazing, and Messrs. Crespin take a bronze medal. Lawn mowers are very plentifully shown, but no awards were made in those constructed for horses. Hand mowers are shown by about a dozen exhibitors, a silver medal for lightness of working being awarded to the Chadborn & Coldwell Manufacturing Company for their "Excelsior"; Messrs. Barford and Perkins, Peterborough, take a silver medal also for their new "Godiva" machine ; The Standard Manufacturing Company, Derby, take a bronze medal for cutlery, which includes a great variety of tools. In the class for garden pottery, Mr. Matthews, of Weston-super-Mare, has a large display, and wins a silver medal, and Mr. Crute is also awarded a silver medal for his new "Chrysanthemum pot" and other patterns of pottery. For garden tools, Messrs. Glassey, Liverpool, take a bronze medal, as do also Messrs. Leedham and Heaton, of Leeds ; while Mr. Swete, of Worcester, and Mr. Drummond, of Bridgnorth, are commended, the latter for his patent turf-cutting machine. Messrs. Bramham, of Liverpool, take the silver medal in the class for wirework, and Messrs. Brooks, Manchester, and Messrs. Peake, of Liverpool, win bronze medals in the same class. The silver medal for garden seats is taken by Mr. Cæsar, of Knutsford, and the bronze by Messrs. Wrinch. The only exhibitors of meteorological instruments are Messrs. Joseph Davis and Co., Kennington Park Road, who win a silver medal. A bronze medal for garden engines, &c., is taken by Messrs. Barford and Perkins for their "water ballast" barrows, and Messrs. Crispin are commended for their patent syringe. A bronze medal is awarded to Messrs. Halliday for decorations for conservatories, which consist of ornamental tiles for flooring. Messrs. White, of Edgware Road, take a silver medal for garden tenting, shading material, &c., and Messrs. Richardson are commended for their Parisian greenhouse blinds. Mr. Pinches, of Oxenden Street, London, takes a silver medal for his now well known stamped zinc labels. In the miscellaneous class, bronze medals are awarded to Messrs. Bennett, Liverpool, for wirework, to Mr. Freeman, Stockport, for ornamental rockery stone; while commendations are accorded to Mr. Harkin for teak Orchid baskets, &c.; to Mr. Sydney, Liverpool, for "parcel post" flower boxes; to the Horticultural and Agricultural Chemical Company, Tonbridge, for a new insecticide and syringing stand; to Messrs. Richardson for various exhibits; to Mr. Bloxham, Bletchley, for a new fumigator; to Messrs. Blake & Mackenzie, Liverpool, for postal flower and plant boxes.

A prize list is given in our advertising columns.

ROYAL BOTANIC SOCIETY'S FETE.

The annual fête of the Royal Botanic Society took place on Wednesday evening last, under most favourable auspices. The weather was delightfully fine, and the grounds, conservatory, and marquee were crowded with visitors. The illuminations were never more brilliant, no fewer than 30,000 lamps being brought into use. The exhibits were of the usual character; prizes were offered for the floral decoration of the dinner table (several classes), arrangements of flowers for sideboard and for recesses, hanging baskets, bouquets, &c. In the awarding of the prizes for the arrangement of the dinner table the judges seemed disposed to favour quiet colours; most of the arrangements were neat, though in some cases somewhat crowded. Mr. Peacock, of Sudbury House, Hammersmith, brought together a very fine collection of Orchids (consisting chiefly of Odontoglossums, Masdevallias, and Cattleyas), which received much attention. A similar exhibition was also made by Messrs. Sander, St. Albans, and Mr. William Rumsey, Waltham Cross, showed a nice group of Roses. There was the usual extensive exhibition of vases for the purposes of floral decoration, and some table aquariums attracted a large share of attention.

NOTES OF THE WEEK.

Calanthe natalensis.—This new introduction is now in flower at Kew, where it flowered last year for the first time in Europe, and was figured in the *Botanical Magazine*. It belongs to the same group of the genus as C. masuca, C. veratrifolia, and C. furcata, but is distinguished by its pale violet flowers, which are borne on erect tall spikes springing up with the new foliage. It is a pretty plant, and quite equal in beauty to the above named sorts.

Olearia macrodonta and Veronica Haasti. I send you herewith flowering specimens of these two shrubs. The first was sent to me two years ago by Messrs. Veitch, under the name of Olearia dentata, but I at once saw that it could not be that species, as its foliage in nowise resembled that of the plant figured under that name in vol. xcviii. of the *Botanical Magazine*, t. 5973, and the correct name has been since determined at Kew. My plant produced a single truss of bloom last year, but failed to open properly ; this year, however, it is covered with bloom, and is an exceedingly ornamental shrub, and seems to be perfectly hardy. The little Veronica is from New Zealand, and came to me under the name of V. Colensoi, but I believe Haasti to be its correct name.—W. E. G.

Acineta densa.—This is one of the handsomest of the eight species of Acineta now known, and it is also one of the easiest to keep in health if planted in peat and Sphagnum in a roomy teak basket, and suspended near the glass in a tropical

house. A plant of it at Kew is now bearing two fine drooping spikes of flowers, which are as large as the flowers of the Dove Orchid, but from eighteen to twenty-four flowers are borne on each raceme. The colour is bright yellow, with numerous peppery dots of crimson on the inside, and blood-red blotches on the lobes of the lip. The flowers usually remain fresh on the plant about a month. A remarkable feature in this species is the length of time the flower-spikes take to mature after first appearing, the plant at Kew having pushed the spikes just now expanding as early as last December. The Acinetas, Stanhopeas, Batemannias, and several Peristerias develop their flower-scapes at the extreme base of the pseudobulbs, and they grow downwards; it is, therefore, necessary to grow such plants in open baskets, so that the spikes may grow on unimpeded. When pots or pans are used for these plants it often happens that their flower-scapes are ruined before the discovery is made that they have grown down into the pot.

Oncidium Lanceanum.—There are very good and also very bad varieties of this noble Oncid, but fortunately the former are oftenest seen in gardens. If some one could tell us what it is exactly that this Orchid requires to keep it thriving in this country, what a popular plant it might become, as no one could resist the rich beauty and delicious odour of its flowers. The leaves also are not unattractive, being very large, thick, and leathery, and thickly mottled with purple-brown on a green ground. The flowers have the excellent quality of keeping perfectly fresh on the plant for over a month after they open. A specimen of this species may now be seen in flower at Kew, along with various other handsome-flowered Oncidiums.

Scuticaria Steeli and S. Hadweni are both of that class of Orchids which are peculiar in having long terete foliage growing downwards, and of which these and Oncidium Jonesianum are the most attractive as flowering plants. S. Steeli has a zigzag rhizome, from which spring numerous long flagelliform leaves, their length on strong plants being from 3 feet to 4 feet. The flowers are developed from the base of the ripened growth and are on short scapes, two or three flowers being the usual number on each; they are as large as the flowers of Cattleya intermedia, their colour being cream-yellow with numerous large blotches of reddish brown, except on the labellum, which is striped with deep crimson. S. Hadweni has shorter leaves (about 1½ feet) and one-flowered scapes, the flowers being smaller, darker in colour, whilst the lip is blotched instead of striped. Both species may now be seen in flower at Kew. They are natives of South America, and require an intermediate temperature with a damp atmosphere during early summer when they are in active growth. The plant of S. Steeli at Kew is an exceptionally fine variety.

Griffinia Blumenavia.—There are seven or eight species of this genus of Brazilian bulbous plants, and most of them are in cultivation with us, though one seldom sees them in flower. The best of the lot is the species here named, which has been known for about twenty years, and which flowers freely in midsummer if grown in a stove and kept moist all through the spring, withholding water from September till February, when the plants should be placed on a dry shelf in a temperature of 55° or 60°. It has oblong lanceolate foliage 6 inches long, dark green, the nerves prominent and suggesting the Lattice plant. The flower-scape is erect, shining, brown-red, and bears an umbel of six or eight flowers, which are 2 inches long and wide, Amaryllis-like, except that the lowest petal is smaller than the others; the colour is white, with streaks and veins of purplish rose. The anthers vary in length and are curved upwards at the points. A plant of this species is now in flower in the Begonia house at Kew. G. hyacinthina has blue and white flowers 3 inches across.

Dasylirion acrotrichum.—A specimen of this saw-leaved Mexican Lily is now in flower in the succulent house at Kew. It has a stem 5 feet high, hidden by the persistent dead leaves which hang about it, and bearing a large head of dark green serrated foliage, which is straight as Yucca leaves, and bears upon its tips tufts of brown fibre; hence the name acrotrichum, which signifies bearded tips. The flower-spike is at present 12 feet high and the upper half of it stands above the roof of the house. The flowers are all female and are not unlike the fruit of Rhubarb, being arranged on numerous erect branchlets, and having winged angular ovaries. A plant of the other sex flowered in the same house last year. The growth of the flower-scape is very rapid, careful measurements showing that this specimen now at Kew grew from 5 inches to 6 inches every twenty-four hours.

Thysanotus multiflorus is a pretty flowered plant belonging to the same section of the great Lily family as Arthropodium and Cyanella. There are some score of species of Thysanotus, all of them Australian, and several have been introduced into this country at various times, but have proved unsatisfactory, owing to the fugaciousness of their flowers, which do not expand, except under the influence of bright sunlight, and then last only a few hours. T. multiflorus forms a tuft of linear grassy foliage with a thick keel and about a foot long, and they are clustered in the same way as an ordinary Rush. The flower-scapes are nearly erect, as long as the leaves, and bear crowded tufts of flowers 1 inch across; the petals are broad and spreading like a Marica, and their margins have a deep fringe of soft silky hairs so prettily arranged that the flower seems more like the extravagant work of some milliner than Nature's handiwork. When in flower this plant is a very beautiful object. We saw a fine potful of it at Kew the other day in the Cape house.

Ardisia mamillata.—The only species of Ardisia that may be termed a garden plant at present is A. crenata (generally written crenulata), although a great many other kinds have been introduced at various times, and a few of these, such as A. japonica, a hardy little shrub, with numerous stems and bright red berries, A. polycephala and A. humilis, both tropical Indian plants, which bear black, shining Currant-like fruits, may be met with in a few collections. At Kew, these and other kinds are cultivated, and to the numerous species there represented the above named new species from Hong Kong has lately been added. It grows to a height of about 4 inches, and has an erect stem, clothed with ovate, thick woolly leaves, the surface of which is covered with thousands of raised dots, each crowned with a silky hair. The flowering branches are axillary, as in A. crenata, 3 inches long, with a few small leaves near the end, where the flowers are arranged in umbels; they are bell-shaped, half an inch across, ivory white, with small rose coloured dots, the little pyramid of anthers in the middle being yellow. There is much beauty in the foliage of this plant, and in the flowers, too, which though not large, are prettily formed and coloured. It requires stove treatment.

Clianthus Dampieri (Sturt's Glory Pea).—It is only rarely that this plant flowers in places generally accessible to gardeners, and we therefore note with pleasure a fine flowering specimen of it in the conservatory at Kew. No plant, perhaps, has tantalised cultivators so much as this, for it is apparently easily grown till nearly ready to flower, but there it usually stops and suddenly dies, turning black at the base and perishing at the root in a few hours. No one has yet accounted for this sudden fatality in this plant, but whatever its cause it is obvious that now and then it is avoided, and a beautiful flowering plant is the result. Someone wrote that by grafting this species when in a seedling stage on to a young plant of C. puniceus success in flowering it would be almost certain. The suggestion seems good and worth a trial. C. Dampieri is a native of the desert regions of Australia. It forms an erect herbaceous shrub with pinnate silky leaves and axillary pedunculed of large bright scarlet flowers, with a large shining black boss at the base of the standard. Such a plant is incapable of being seen by means of a description, and to those who have heard of Sturt's Glory Pea, but have not seen it alive, the specimen at Kew would be worth a long journey to see.

Quisqualis indica is a scandent stove shrub with long main branches, from which are developed short branchlets with the leaves arranged opposite in pairs, so that at first sight one would call the plant pinnate-leaved, and not unlike Wistaria. The flowers are in a terminal bunch on these branchlets, and they have long thin tubes with a spreading limb 1 inch across, and formed like Ixoras, but having five instead of four petals. On first opening, the flowers are creamy white, and about half the size of mature ones, which are coloured a beautiful Indian red, margined with orange. A delicious fragrance is given off by the flowers, particularly after they have been cut and placed in water, so that on this account alone they are worth growing. Unfortunately, however, the plant is a shy bloomer in this country, although in India, where it is a common garden plant, it flowers most freely. A large plant in the Palm house at Kew is now blooming, but it is in an exceptionally sunny position, and is never shaded; whereas plants in a less favoured aspect have never borne flowers. The genus is closely allied to the Combretums. Its peculiar habit of changing the colour of its flowers from white to red is remarkable. In India it is known as the Rangoon Creeper.

QUESTIONS.

5505.—**Grey Moss on Rhododendrons.**—Can any of your readers tell me the cause of grey Moss appearing sometimes on the wood of Rhododendrons and hardy Azaleas? What is the best cure for it?—Scotia.

5506.—**Stocks in Hyde Park.**—A lady tells me that when in London last month she saw the gardeners in Hyde Park bedding out in one bed some very strong dwarf purple Stocks, then in flower, mixed with Mignonette plants. I shall thank some of your readers very much if they will tell me what Stocks they were and how they are managed so as to have them in flower at bedding-out time.—R.

5507.—**Runners from "blind" Strawberries.**—I shall be glad if some of your readers could give me an answer to the following query: I made a good plantation of British Queen Strawberries last year, but they were late, as the season was so dry. They have grown well, however, but are throwing up no flower buds. If I take early runners from these blind plants, are such plants likely to become blind themselves?—E. M.

LATE NOTES.

Yellow Scotch Roses (*Mrs. Witham*).—Very beautiful flowers; finer than we have hitherto seen.

Seedling Single Rose (*B. Lodhams*).—Flowers were so withered on arrival, that we could not form an opinion of the variety.

Books (*Mrs. H.*).—We do not know of a work of the description you mention. Johnson's "Gardener's Dictionary" may suit you, but it is much above the price you name.

Seedling Pansy (*A., Clapham*).—Your T. M. Barnes Pansy is bright in colour and large in size, but defective in form—at least, from a florist's standard.

Odontoglossum crispum (*D. B. Crawshay*).—An extremely pretty variety, which may be best described as an edged petaled roseum, the broad white margin being so conspicuous in contrast with the violet-purple body colour. The Odontoglossum seems to be O. Ehrenbergi.

Papaver orientale.—Can some one learned in Poppies set us right as to the nomenclature of the two grand flowered, but undoubtedly distinctive, Poppies grown under the designations of bracteatum and orientale? I call the large orange-scarlet kind bracteatum, and the deep crimson-scarlet orientale, and yet I have doubts as to the correctness of these appellations.—A.

Names of plants.—*W. B. H.*—1, Reseda luteola; 2, Fumaria officinalis; 3, Stellaria Holostea.——*C. H.*—1, Tradescantia virginica; 2, Campanula glomerata; 3, Buddleia globosa; 4, variety of Iris variegata.——*C. C.*—Calycanthus occidentalis.——*W. S.*—Lycaste Deppei.——*M. S.* (*Tenby*).—1, Dicentra eximia; 2, Dimorphotheca pluvialis; 3, Asplenium Adiantum-nigrum; 4, apparently Aira cæspitosa.——*J. W. K.*—Luzula nivea.——*M. Nicholson.*—Eutoca viscida.——*R. V. & S.*—Habenaria chlorantha.——*E. Poole.*—Scilla peruviana.——*St. Patrick.*—Oxalis acetosella.——1, Campanula pusilla; 2, Veronica longifolia var.; 3, species of Achillea; 4, Lysimachia ciliata.——*J. D.* Peony had shed its petals, so could not name.

Died at Stanstead Park, Forest Hill, James Laing, late of Tarbut, Ross-shire, and brother of John Laing, aged 65 years.

Woods & Forests.

PINES FOR PROFITABLE PLANTING.

For between twenty and thirty years now the Corsican Fir has been more or less planted up and down the country, and the testimony of those who have grown it or seen it grown has been almost uniformly in its favour. Both in The Garden and in its contemporaries, too, has this tree been highly praised of late as being the best Fir to plant for timber, and everywhere nurserymen are multiplying their stock of it as fast as they can, and in not a few cases not fast enough, to meet the demand. When, therefore, one reads statements like those of "J. F." (p. 589), to the effect that this Fir "will not compare in quality with the Scotch Pine, except one, and that ornamental only," one is driven to the conclusion that the writer is totally unfamiliar with the qualities of the tree he condemns. So far as I have seen or heard, the Corsican Fir is not more ornamental than the Scotch, for there your correspondent is in error also; but in England, and especially in the midlands, where I am best acquainted with it, it beats the Scotch Fir as a rapid grower in bulk of timber for the same time, and it will grow either in the shelter or exposure as well or better than the Scotch, and this I can prove to anyone who is open to believe the testimony of their own eyes. As to the quality of the timber, it is admittedly superior to the Scotch where used, and its much more resinous habit in a young state in this country indicates that much also. I would like your correspondent, "J. F.," to find, if he can, a Scotch Fir of the same age as the Corsican at Kew (and lately shown in The Garden) and grown under similar conditions that will match it for size and symmetry. I offer also to procure him opportunities of seeing the Corsican Fir on some of the most bleak moorland spots in Yorkshire, not hundreds, but a thousand or more feet above the sea level, where it beats the Scotch Fir, except in one thing, and that is, that it grows so much faster in such situations, that it is sooner blown to one side by the wind, unless planted thickly. I was over our high moorland plantation the other day, and could not help admiring the fine free growth and lustrous foliage of the Corsican Fir, planted alternately with the Scotch, and everyone who has seen our plantations has done the same. I took one of the best known of our nurserymen tree growers over these plantations last year, and he said to me that he, too, had had doubts about the Corsican Fir, but the sight of our plantation had dispelled them for ever, and he writes me that he is doing everything to multiply his stock. I am not so sure that "J. F.'s" fine sounding phrases about "acclimatisation" and "legitimate naturalisation" are worth so much as he would have us believe. I believe I am correct in stating that the oldest and best Larch forests in this country are those that have been acclimatised—that is, raised from foreign seed—while those younger plantations from home-raised seed are the most diseased. It is not the earlier, but the later plantations that are most affected as far as I can learn, and I do not suppose there is any data to show that Firs from home-raised seeds, *i.e.*, legitimately naturalised, are any better, if as good, as those raised from foreign, but more perfectly matured, seed. The testimony of nurserymen goes to prove that good foreign seed of most kinds of trees produces the finest plants for the first few years at least, and there is no evidence to show that they become worse than the others later on. This was told me once when I was remarking on the height and vigour of a quarter of young Oaks from French seed compared to another quarter from English seed, the difference being remarkable; when I afterwards saw a heap of French Acorns lying in a shed in the same nursery and compared them with our own, the explanation was clear, for the French Acorns were very much larger and finer in every way. It does not stand to reason that a starved or debilitated race of trees or animals can produce a healthy offspring, however much they may be naturalised. It is observed by authorities on such subjects that the first generation of transplanted members of the human family are, as a rule, the most vigorous, and that the offspring degenerate afterwards, as witness the European in India and other countries and *vice-versâ*, and in all probability the rule applies also to trees and plants. Yorkshireman.

The time to fell Oak.—"W. B. H." last week, in speaking of Oak bark, indirectly raises a rather important point, viz., the time at which Oak timber should be felled. It is, I presume, pretty generally conceded that the only ground upon which felling Oak late in the spring is carried on is for the sake of the profit to be derived from harvesting the bark. The prices given last week will, I believe, very fairly represent the range of the bark market this season. If so, where is the profit after all expenses have been defrayed? There is something in what "W. B. H." says about giving all the employment possible to the hands on the estate, but if bark-peeling leaves no profit, it would be as well to divert the labour into some other channel. The question is certainly one for consideration. When bark was realising £5 or £6 per ton, it would have been, without doubt, a bad policy to have cut the trees so as to lose it; but now the circumstances are entirely different. The objections to felling in the spring and peeling are, I take to be, that the work is going on when the hands could be employed about other things, and the damage done to the Grass and crops in the field and the young growth in plantations. On the other hand, it will not, I suppose, be disputed that the wood of the winter-felled tree is at least equal in quality to that of the spring-felled one. That the sap-wood of the former is more durable is pretty generally accepted. In addition to these points, horse labour is generally more available in the winter season. When the price of bark rises enough to leave a fair margin, the stripping could be resumed, but at present I fail to see the advantage of continuing the system of spring felling.—D. J. Yeo.

Variety in the Firs.—I see someone is writing elsewhere to further multiply the "varieties" of the Scotch Firs. It has long been believed that there are a red and a white-wooded variety in the north of Scotland, and the red-wooded kind is believed to be the better of the two, but it is doubtful if they are constant. Both sorts are said to come from the seed of either variety. Nurserymen do not select their stock, and in every plantation of Scotch Firs several varieties, as indicated by the foliage and general appearance, may easily be picked out, and if anyone chooses to give them a name, plenty of "varieties" could be found. Mostly all kinds of trees vary considerably, but it is more apparent in some of the Firs than in others, and noted botanical authorities have even discovered as many as three distinct species—*species*, mark you—from examples from one and the same tree, the specimens having been gathered from the top, bottom, and under branches. This happened in the case of the Japanese Fir (Abies firma), dried specimens of which were respectively labelled as distinct species before the explanation was given. Experts might easily be puzzled also by examples of the growth of the Austrian Fir, and even by examples of the trees. We could show half a dozen different varieties of this Pine within sight from almost any one spot in our young plantations, the trees being over 20 feet in height. Some are very dense in habit, short-jointed in the trunk, with a rounded top and distinct foliage, while others more resemble the Corsican Fir, with all shades of difference between. As timber trees, it would certainly pay to select the varieties of this Fir, because while some are comparatively worthless in that respect, being slow growing and knotty, others are tall and clean. The Larch, too, is prolific of varieties in the young state, but such differences to a great extent disappear as the trees grow old, and probably there is not much difference in their timber.—Yorkshireman.

OVER-THINNING IN PLANTATIONS.

I have before dwelt on this subject and pointed out that the main object of foresters should be to plant and establish forests of useful timber, and leave cultural matters like thinning to after consideration, not being of nearly so much importance as some seem to think. There can be no doubt of the fact that plantations of trees of similar habit can be grown to maturity without any thinning at all, and we will even go so far as to assert that in numbers of instances our plantations would have been far better left alone in that respect to thin themselves. I have lately had an opportunity of discussing this subject with Mr. Maries, who has studied to some purpose both the natural and other forests in Japan, produced in a climate like our own, and who has also had even longer experience in India in both the highlands and lowlands there. His opinion is, that we thin our woods far too severely. I said to him, "That is exactly the subject under discussion at present among foresters and of the utmost consequence in the future management of our woods, and I shall be glad if you will, as near as you can, give us an idea how thick the trees stand in a natural forest of mature age." We went into the woods, and coming to a young plantation in which the trees are about 10 feet high and *crowded*, as some good English and Scotch foresters would think, Mr. Maries observed, "That is about as thick as the trees stand. In the natural Fir woods the trunks are perfectly straight, and for 70 feet or 100 feet without a branch or a knot, the tops of foliage bearing but a small proportion to the length of trunk, and so crowded as to form a tangled interlacing mass that makes it almost dark underneath near the ground." Pointing, in another place, to two Oaks with a quarter girth in the middle of 12 inches or more, and about 6 feet asunder, he said, "Firs of these dimensions are never farther apart than that, if as much; in some places trunks are so close you could not squeeze your body through between them, and the ground is a tangled mass of roots." He also informs me that the Japanese foresters imitate Nature, being great tree planters, inasmuch as they plant thickly and do not thin. From all I could gather, there is no reason why our timber trees in this country should not be allowed to stand as thickly on the ground as they do in Japan, the species, climate, and all the conditions being very much alike in both countries. Looking at some tall young Corsican Firs twenty-two years planted, and 3 feet or 4 feet in cubic bulk, I reckoned that at the above rate 1200 could have been accommodated on one acre of ground at least, and at the present low price of Larch their value would have been about £120—not a bad investment on land which, previous to being planted, fetched less than £40 in rental in the same time.

But, whatever these calculations may be worth, the facts related show that some, if not the most, of our plantations are over-thinned in their youth, because the trees are left much further apart than the distances stated above, and hence the need for pruning, that should be obviated altogether. Yorkshireman.

Wood of the Ailanthus.—Of trees introduced into the United States, says an American paper, the Ailanthus is said to be a much more valuable one than is generally admitted. For posts no timber is better suited. The testimony of many farmers shows that it is nearly as good as locust, and for fuel is equal to Oak. It is hardy, grows rapidly, and is said to be well adapted to growth on the prairies in the western United States. In its native county (China) it often attains a height of 175 feet.

No. 764. SATURDAY, July 10, 1886. Vol. XXX.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SUMMER FOLIAGE TINTS.

AT the end of every summer we generally hear a good deal about autumn tints, but it is not often that the same subject meets with much attention in summer, although tree tints then are quite as interesting as in autumn. I have been watching for the past few weeks the effects of changes of colour on a richly-wooded landscape, and it has been a source of much gratification to witness from day to day the varying hues of the different trees. In Somerset the Larch is the first to herald the approach of spring with its refreshing green. It seems to start into life and beauty with much less effort than many other trees, and it lights up the distant landscape in a way that is quite delightful. The Sycamore and Beech come next, and add depth of colour and importance to their surroundings. The Oak quickly follows, and then day by day the scene changes. The variation in the conditions of the first stage of development in the Oak is somewhat remarkable in different trees. Many of them unfold their leaves with a strong tone of greenish yellow. In others a bronzy aspect is maintained for a time. Taken altogether, no trees differ so much in the early stages of their leafing as Oaks, and this, I may remark, extends thoughout the summer, although in a lesser degree than during spring, according to the character and the nature of the soil in which they are growing. As a matter of fact, I do not know any forest tree whose foliage is so much influenced by soil and season as the English Oak. In the deep sandy ground resting on the red sandstone in this county it is not unusual to see it clothed with light golden foliage, and this occurs more frequently in dry summers than in wet ones. I do not for a moment imply that soil alone makes this difference in the colour of the leaves, but soil and climate together develop it. Trees which partake of this golden character are also perhaps slight variations from the normal type. However that may be, I can point to examples upon the estate from which I write, whose characters are conspicuously different from those of the common variety; and I look upon them as valuable on account of the variety which they afford in the summer landscape. On the Chestnuts there is a wonderful wealth of foliage, that adds considerably to the general effect, especially when viewed against a background of Scotch Fir.

If we turn from plantations to park scenery, or the more immediate surroundings of the pleasure grounds, the materials for observation are not only more numerous, but, owing to the greater care bestowed upon their disposition, their effects are more varied and striking. Intending planters may, therefore, do worse than take a survey of a place noted for its collection of trees, in order to watch their aspects both in spring and summer. A mind capable of receiving impressions will be able to store up much useful information therefrom that should prove valuable for future use. As an example of the kind of impressions I mean, I may instance a beautiful group of trees which I once saw, the effect of which remains indelibly fixed upon my mind. It had in the foregoing a copper Beech, a variegated Sycamore, and a Huntingdon Elm, planted probably about fifty years; therefore they were stately trees, and in perfect health. In the background were a fine green-leaved Beech and a grove of Spanish Chestnut, with an undergrowth of evergreen shrubs of various kinds. The strong contrast which the copper Beech made with the variegated Sycamore against the light green foliage of the other trees in the background is more easily imagined than described. For my own part, I have never seen another instance of ornamental planting that made on me such a lasting impression. So far as I have seen, no place in England contains better examples of park scenery than Knole Park, near Sevenoaks. In that park there are many judicious blendings of trees of fine growth and handsome foliage, well distributed in regard to space; and so much has been made of the various surface undulations, that trees of all forms and hues combine to make it a scene of quiet grandeur. At Beauport, again, may be seen what may be done with such a simple subject as the Silver Birch. There it is planted on the brinks of charming dells, into which its graceful branches dip in a most pleasing manner; and I might go on multiplying instances where pleasing effects and good combinations have been secured by a judicious disposition of suitable subjects; but sufficient has been said to show that good effects invariably follow wise selection and treatment. A tree in itself may be beautiful, but its beauty is further enhanced when its surroundings are such as to render it still more conspicuous. A variegated Sycamore standing alone is only a second-rate object; but, associated with other trees different from it in colour, it becomes strikingly beautiful.

In order to secure a full measure of success in planting for the purpose of creating distinct features in the landscape, it is necessary to know something of the characters of the trees it is desirable to use. I may therefore mention a few groups of trees which, in point of habit of growth and colour of foliage, are capable of creating diverse features. The first I shall mention consists of Ilex, Cedar of Lebanon, Weeping Birch, and English Elm. Whether this group is seen close at hand or in the distance, the subjects of which it consist are of such a diverse character, that they cannot fail to please even the most critical. The Deodar, Turkey Oak, and green Sycamore also make a distinct group. Ilex, Fern-leaved Beech, Picea Nordmanniana, and the English Oak likewise make an imposing group. The Balsam Poplar, Silver Poplar, Horse Chestnut, and scarlet Maple are also interesting trees for this style of planting, the last-named being particularly conspicuous both in spring and autumn. The evergreen Oak, Horse Chestnut, and Huntingdon Elm make a picturesque group, both as regards habit of growth and colour of foliage. The peculiar grey-green which overspreads the Oak is as distinct from other trees as the tree is remarkable in outline. The deviations amongst the forms of trees when judiciously disposed are very striking, and when to that is added diversity of foliage, strong contrasts are the result; and there is no time in the whole year when these are so conspicuous as in the leafy month of June.

The same principles in regard to grouping also apply to low-growing trees and shrubs, and especially to Conifers, which are as diverse in the colour of their foliage as any genus of plants which we possess. One group I may mention is particularly effective, viz., Picea Nordmanniana, with its strong tone of dark olive-green; Pinus excelsa, which has silvery grey leaves; and the handsome Picea nobilis, with its distinct glaucous colour. These and the Weeping Hemlock (which has not inaptly been called the queen of evergreens) have a beauty of their own rarely seen in other trees. These four subjects, if judiciously placed, are capable of making an interesting group. Many more might be mentioned, but I must be content to merely briefly direct attention to a few subjects with golden foliage that cannot be passed over being capable of creating fine effects. Amongst deciduous subjects the most striking are the golden Acacia, golden Elder, Catalpa syringæfolia aurea, and the golden Poplar. In the evergreen class there is a wonderful variety suitable for almost any soil or position. Amongst these may be named the golden form of the Lawson Cypress, Thuja aurea, Retinosporas, Biotas, Hollies, Osmanthus, and Elæagnus. With such a variety of subjects, most of which are of a thoroughly reliable and hardy character, it is clear that our ornamental grounds need not be destitute of summer tints as well as autumnal ones. No one would wish to say a word against deciduous trees, which do so much to beautify the landscape; but the superabundance of them should not preclude the use of others not so well known, but equally valuable for landscape effect. J. C. C.

ROSE GARDEN.

OWN-ROOT ROSES.

"D. T. F." must have misunderstood my statement in reference to this subject. I may now say that last year I destroyed a bed of worked Paul Neyron under glass, and replanted it with plants raised from cuttings. I have also a few plants of Gen. Jacqueminot on Briers in my early Jacqueminot house, but they are never so good as the plants in other parts of the house; the flowers are about the same, but I do not get nearly so many from the same space. I have imported quantities of worked Roses, and also Roses on their own roots, and after making allowance for over-fed plants from a nursery, the plants from cuttings were the most satisfactory. The Manetti stock I detest; it fills the ground with suckers, which one may cut and dig out everlastingly and never be free from them. The Brier stock gets burnt up in hot weather, and will not stand the winter here. I have no doubt that many of the best flowers in England are cut from Roses on the Brier or Dog Rose, a natural circumstance seeing it is a native; but I may also mention that in unusually cold winters without protection the Rose itself gets killed if the stock happens to escape, which it seldom does here. As regards the strong shoots of La France with a number of buds and single flowers on them, I may mention that we tie our shoots of that Rose down; thus treated they break from every eye, and as a rule produce one large flower on each shoot. The large upright shoots I mentioned start from the base and never yield very fine flowers individually, although more in number than on shoots tied down; but as these large Roses here are all required with long stems many buds must be sacrificed.

Roses from cuttings will root as freely as Verbenas, and every eye will make a plant. The young plants can be either grown on in pots or planted out during summer and potted if required, or they can remain in the ground the same as worked plants. As regards the query about Gloire de Dijon, to which I alluded in a previous communication, I may say that some plants of it were standards, probably 5 feet in height, trained on a west wall; others were in a bed with a west exposure, on stocks about a foot high. I believe they were all on Brier stocks, but I only speak from memory.

We have hundreds of acres of Roses here planted under glass, and unless Roses are required in pots for a special purpose, I consider that way of growing them to be waste of time and labour. It also appears strange to us to read the list of varieties recommended in England for forcing. I am aware that some of our large growers for the New York cut flower market have grown some of such kinds as Gloire de Dijon, Reine Marie Henriette, and Madame Falcot, but the trade can get on without

them. Alba rosea is not often seen; Catherine Mermet and The Bride are, of course, indispensable; but of what use in the trade are such varieties as David Pradel, Devoniensis, Etoile de Lyon, Mdme. Lambard, Marie Van Houtte, Perle de Lyon, and Céline Forestier? Niphetos is, of course, indispensable. T. Taplin.

Maywood, New Jersey.

CLIMBING ROSES.

It is unfortunate that so many of our best climbing Roses are of such exuberant growth that they need so much pruning to keep them in order. Even Maréchal Niel, which might be said almost to bloom itself to death, so profusely does it flower, produces wood in such abundance, that probably more plants, especially where they have ample room, suffer more from want of pruning or thinning than from too much of it. But the other day I cut a barrow-load of wood from some strong-growing plants in a cool house, and yet they are now full of new and almost luxuriant growth, showing that not only do the plants like the knife and ample room, but also that more thinning will have to be done later on. Madame Berard, Lamarque, and similar good climbers literally cram a house with wood, so that space cannot be found for it, whilst the quantity of bloom is far from being proportional. I found Reine Marie Henriette, though producing rich, deep-coloured buds early under glass, producing them sparingly proportioned to the wood, and I have cut it out, and indeed all other strong growers, leaving only the Maréchal, which seems to find in these coarse growers admirable stocks. On the other hand, whilst the Maréchal does not thrive well out-doors, even on a south wall, Reine Marie Henriette does admirably, and so well that I shall plant a good quantity of it next autumn. It blooms earlier than most others, has with its flowers nice long stems, fairly free of thorns, plenty of petals in the flowers, and opens well. I wish I could write as highly of the over-praised Niphetos, as some others can. Here, on a warm south wall, it is rather bushy than free, and is exceedingly spiny, so much so, in fact, that it is quite unpleasant to handle. I should say that, planted a foot apart in good soil, plants of this Rose would rival Blackthorn in the formation of fences. Then I find fault with the colour of the outer petals of the flowers, which are so much tinted with colour, that they detract materially from the purity looked for in Niphetos. Would that Rose raisers stopped producing creamy and buff-coloured Roses, of which we have so many, and give us in lieu thereof a pure white Tea, that is of good, robust, yet not absolutely excessive growth, blooms profusely, and has flowers as long enduring and as solid as those of Maréchal Niel. Homère is a capital house Rose, though really not a climber, because it never ceases growth, and no sooner has produced one lot of blooms than it pushes other shoots and a fresh lot of flowers, and so on all through the season. That, with a couple of plants of Catherine Mermet, one of the loveliest of Teas, are all that I tolerate in the Rose house now besides the Maréchal; for where the market has to be regarded, quantity and value must be fully regarded. Safrano, usually so ready to burst to pieces, has in the recent dull weather, on a south wall, been exceedingly well behaved. A. D.

ROSES AT MALVERN.

The first Rose show of the season in the west midlands was held in the new Assembly Rooms, at Great Malvern, on Thursday, the 1st inst., and was well attended. Had the managers of this recently erected building, with its tastefully laid-out grounds, depended upon local growers, their first gathering in honour of the queen of flowers would have been a brilliant success; but when it is borne in mind that the Rose nurseries at Worcester and the famous Rose grounds at King's Acre are within an hour's run by rail, and the redoubtable exhibitor, Mr. Grant, is located on the deep loam of the old red sandstone on the Herefordshire side of the hills, no one will be surprised to hear that flowers of the finest quality were exhibited, and that the famous Vale of Severn once more became the scene of another, but let us hope not the last, battle of the Roses. Rose growers on all hands tell us that the past has been one of the most trying winters for Roses on record; Hybrid Perpetuals as well as tender Teas have suffered terribly. This may be true, but, judging from the size, build, and magnificence of the Hopend and Cranston blooms, one might imagine that it has been peculiarly favourable, or otherwise the plants have been wintered under glass. Such, however, as far as Mr. Grant is concerned, is not the case, for he has no glass, nor does he require it, as he assures us that all his finest Teas are cut from plants clear of walls or hedges in the open ground.

A handsome prize was offered for one hundred blooms in not less than ten varieties, and the class being open to all comers there was a strong contest. Mr. Grant was, however, well to the front with a magnificent exhibit consisting of twenty-five varieties well staged and tastefully arranged. The second prize fell to the King's Acre exhibitors, who had also a grand lot of blooms which must have given the judges some trouble; but when we state that the Rev. Mr. Cam was at the head of the trio, there exists but little doubt as to the righteousness of the decision. In the same open class Mr. Grant was again placed first, with a splendid box of choice Teas, also for a bouquet composed entirely of Rose-buds. In the nurserymen's class all the prizes fell to the King's Acre exhibits, Mr. Grant occupying a similar position at the head of the amateur classes. Messrs. Smith & Co. made a fine display with Roses, Irises, and herbaceous flowers, for which their nursery is now celebrated. Messrs. Rowe had extremely fine blooms of A. K. Williams. Mr. White sent from the Haywood's Nurseries Roses, herbaceous plants, and florists' flowers. Messrs. Lewis and Sons also proved how well the pure Malvern air, combined with skill, suits Roses, Clematises, herbaceous plants and florists' flowers. Equally good was the display of their now well-known Pelargonium, Duchess of Albany, a profuse bloomer, and admirably adapted for forcing and furnishing. Smaller exhibitors came out well with Roses, and the brilliant uniforms worn by their Generals and Marshals proved at a glance how they feed and flourish on the *détritus* of the grand old hills. The new Assembly Rooms and grounds are a great boon to visitors and a credit to those who at great expense have created them. W. C.

Rose Earl of Pembroke.—We have recently cut several fine blooms of this variety, and I am of opinion that it is by far the best I have yet grown of Mr. Bennett's hybrids. It opened its blooms much more quickly than any of the Hybrid Perpetuals placed at the same time in an early Fig house, and we hope to work up a good number of plants for forcing. The blooms, which are freely produced, are large and full, of a rich crimson colour, and sweetly perfumed. It is a vigorous grower. Half-ripened flowering shoots, if taken off with a heel and placed singly in small pots filled with loamy sandy soil, and plunged in a moderately strong bottom heat, will strike root in about a month.—W. I. M.

SHORT NOTES—ROSES.

Diseased Roses (*P. D. D. and A. D.*).—Your Roses are infested with red rust or Orange fungus of gardeners (Coleosporium pingue), an ailment which has been extremely prevalent this year. Infected leaves should be looked after and hand-picked and burnt in the early stage of the fungus growth.—W. G. S.

Standard Roses.—We have a standard Rosa rugosa (Japanese Rose) now in bloom here. It is about 5 feet across the head, and, judging by the remarks made by visitors and the admiration it has excited, this Rose must be less grown as a standard than it deserves to be. It is good in many ways; though the foliage is early, it stands frost well. When in bloom the glossy green leaves contrast well with the bright colour of the flowers, and in autumn the fruit is beautiful. The tree is pruned rather close in spring.—George F. Wilson, *Heatherbank, Weybridge Heath.*

Scotch Roses.—These grow like weeds in this part of Wales. Some planted three years ago are now large bushes, and from the middle of May until the end of June they were covered with their quaint little flowers and miniature buds. Hitherto they have been growing in rows in a border amongst Hybrid Perpetuals, but they do not associate well with these; their right place appears to be by themselves in beds or borders in the pleasure grounds, to which they will be lifted and transferred in October next.—J. Muir, *Margam Park, Glamorganshire.*

NOTES OF THE WEEK.

Olearia dentata.—I take the opportunity to send you a sprig of this beautiful flowering shrub. I got it from the Coombe Wood Nurseries three years ago. It is quite hardy and very sweet.—T. M. Bulkeley-Owen, *Tedsmore Hall, Westfelton.*

*** A beautiful New Zealand shrub, with bold foliage and clusters of Daisy-like flowers.—Ed.

Babiana rubro-cyanea.—This has one of the strangest coloured flowers to be found among Cape bulbs. The blossoms are about the size of a florin, bright purple with a large crimson centre. Three or four flowers are borne on a stem, which is about 6 inches high. It is a beautiful plant, and as easily grown as any of the Cape bulbs. It requires a warm sunny frame, protected during winter. Mr. Kingsmill sends us a flower-spike of it from bulbs he received from the Cape, but it may be bought at bulb shops.

Veronica anomala.—A branch of this shrubby Veronica, sent to us by Mr. Gumbleton from his garden at Belgrove, Queenstown, shows it to be a pretty and very free-flowering shrub, every twig being covered with tiny white flowers. The leaves are small and abundant, somewhat in the way of those of Girdwoodiana. We presume it is hardy with Mr. Gumbleton, though he does not say whether it is under glass or in the open.

Cape bulbs.—Mr. Bartholomew, Park House, Reading, sends us flowers of some pretty bulbous plants, including Sparaxis grandiflora purpurea, with flowers of a deep claret colour; Babiana disticha, with crowded clusters of purple flowers; and Ferraria undulata, a most peculiar flower, more like a Sea Anemone, in fact, than a real flower. The blossoms are star-shaped, about 1½ in. across. The petals are white, heavily blotched with black, and margined with singular wart-like excrescences. The scent, too, is very peculiar.

A pink Ceanothus.—Among a gathering of flowering shrubs, Messrs. Veitch send us from Coombe Wood a pink-flowered Ceanothus named Marie Simon. It has the appearance of the well-known C. Gloire de Versailles, the clusters of flowers being long and feathery, and of a delicate pink. In the gathering there is also Escallonia Philippiana, with multitudes of small white flowers and tiny evergreen leaves. It is a neat growing shrub, and is valuable on account of its flowering now.

Carpenteria californica.—A flower spray of this beautiful new Californian shrub has been sent to us by Messrs. Rodger, McClelland, of Newry, who are under the impression that it has not previously flowered in this country; but we saw it in bloom three years ago, and at the present time it is in bloom at Munstead, Godalming. Messrs. Rodger, McClelland state that they have had plants of this shrub out of doors the whole of last winter; when they showed flowering buds they were lifted and placed in a cool house to flower. We shall shortly give a coloured plate of this shrub in The Garden.

Notes from Knockmullen.—I send you a few flowers of Poppies, but I fear there is no chance of these Poppies reaching you sufficiently fresh to give any idea of their effect. The single white smooth-edged and the single rose-coloured one, Danebrog, are beautiful either when growing or when freely cut, but their beauty seems to last but for a day as cut flowers, all seem to be self-sown seedlings of the double white Flag of Truce and the scarlet and white single Danebrog, both kinds having varied, and I think improved, by their variations. I also send a Delphinium, named Minerva, which is beautiful in colour and desirable on account of the

size of each blossom. Codonopsis ovata as a bog plant (here it is doing well in partial shade) seems worth a place in even a small bog bed, from its curious flowers, for though it may not be a showy plant, the markings inside the bell flowers are pretty and quaint. I also send Erigeron multiradiatus, which I do not think is yet common. It flowers freely on rockwork. Though we have as yet given Convolvulus sericeus the protection of a cold frame in winter, it seems to be a good plant for a sunny wall or rockwork in summer.—C. M. Owen.

*** The Poppies, unfortunately, arrived in a shattered condition, yet sufficient remained to show how beautiful they had been. The Erigeron is one of the best of the genus, and deserves all the praise which Miss Owen has bestowed on it. The Delphinium is beautiful, and so is the Codonopsis—a plant that possesses a peculiar beauty different from that of any other Campanulaceous plant.—Ed.

A new Poppy.—Another brilliant annual Poppy has been added to those already available for garden decoration. Papaver pavoninum (Schrenk), a native of Turkestan, has brilliant flowers of a deep orange-scarlet inclining to blood colour, of a powerfully lustrous quality; the blooms are 2 inches to 2½ inches across, of a rather deep goblet shape. Near the base of the petal is a black ring that shows equally outside and in. The buds are curiously shaped like a crab's claw, each sepal ending in a kind of hook. The plant is about 15 inches high, compact and upright in habit.—G. J.

Genista elata.—This is a tall-growing variety of the common native Genista tinctoria, but is very different in habit of growth, the latter being a low-trailing shrub. G. elata is a useful shrub, as it blooms profusely at this season when few other shrubs are in flower. Every slender twig is covered with a multitude of tiny yellow flowers Some specimens of it have been sent to us by Messrs. Veitch from their Coombe Wood Nurseries, where it is now in bloom.

Clematis coccinea.—It may not be generally known that there are good and bad varieties of this distinct-looking North American Clematis. Those who have seen only the inferior variety have but a poor opinion of it as a garden plant, but the best variety should be seen, such as that which Messrs. Veitch send us from Coombe Wood. The flowers of this variety are over an inch long, of conical shape with spreading sepals, and wholly of a bright blood-red colour. It is a beautiful and most interesting climber and quite hardy. Strictly, it is regarded as a variety of C. Viorna, but in the garden C. coccinea is the best name.

Souvenir de la Malmaison Carnation.—At Alderbrook, Cranleigh, there is just now a grand display made by means of this Carnation. It consists of about 100 specimens, all two-year-old plants, in 9-inch pots, and each plant is producing from five to six blooms perfect in shape and quality. The average size of each bloom is from 4 inches to 5 inches in diameter. There are also about 200 one-year-old plants in 3-inch and 4-inch pots. The young plants in the 4-inch pots produce much larger blooms than older plants, some of them measuring as much as 18 inches in circumference.—P. W. H.

Philadelphus grandiflorus. — Some flower-sprays of this beautiful Mock Orange, the largest flowered of all the species, have been sent to us by Mr. Kingsmill, of Eastcott, Pinner. They are wonderfully fine; indeed, we have never before seen such vigorous shoots or such large flowers—presumably the result of the close system of pruning which Mr. Kingsmill practises. The leaves are over 4 inches broad and the flowers are 2½ inches across, snow white and deliciously scented. It would be difficult to name a lovelier flowering shrub than this, and the hint with regard to pruning may be useful.

Boiler trials at Liverpool.—The following competitors have been successful in obtaining awards at the Royal Horticultural Society's recent show at Liverpool: For a boiler capable of heating 2000 feet: 1, Messrs. F. & J. Mee, Liverpool, silver medal. Heating 1000 feet: 1, Mr. S. Deards, Harlow, silver medal; 2, J. Witherspoon, Durham, bronze medal. Heating 500 feet: 1, Mr. S. Deards, Harlow, silver medal; 2, Mr. J. G. Wagstaff, Manchester, bronze medal; equal 2, Mr. T. Wood, Bristol, bronze medal.

Odontoglossum Alexandræ.—I send you a flower of this Orchid to show you what a fine variety it is. There were two flowers on the spike, the measurement of both being 4⅛ inches across, upper sepal 1¼ inches wide, petal 1½ inches wide, lip 1 inch. The flower was grown at my garden at New-Hall-Hey, Rawtenstall, so it had to travel over 200 miles.—G. W. Law-Schofield.

*** An exceedingly fine variety, as large as we have seen, and perfect in form.—Ed.

FRUITS AT THE LIVERPOOL SHOW.

These were scarcely so good as one would have expected, a circumstance attributable, perhaps, to the early date of the show, but there was also an absence of well-known exhibitors. Only three competed in collections of eight kinds of fruit, and there was not a really conspicuously good dish amongst them. The majority were presentable, but nothing more. In the six varieties there were more competitors, and here the Melons, Strawberries, and Cherries were better than in the preceding class. In Grapes there was not a bunch that would exceed 3½ lb., and the majority were much less. Bunches below medium size and berries of very ordinary type predominated. Black Hamburghs were the most plentiful, eight lots of three bunches were staged. The first prize lot were large in berry, slightly rubbed, and one of them, the middle bunch, very red. The second three were badly formed bunches with berries of various sizes, but black. The third prize three had small berries, too much crowded. Three bunches from The Quinta, Chirk, were of uniform shape, jet black, spotless, green in footstalk, slightly loose, but as near perfection as possible, and yet they were unrewarded, a circumstance freely commented on in the fruit tent. Madresfield Court had a class to itself, and was represented by three bunches. These were well coloured and shown in fine condition. Muscats were poor in quality and deficient in numbers. The first prize lot was quite green and the berries so round as hardly to indicate the Muscat type; none but the judges seemed to know in what their merits consisted. The second prize lot showed more of the Muscat type, but hardly more of a matured character. The third, although somewhat loose, were true Muscats, good in berry and golden in colour—so much so, indeed, that look at them as one would the impression remained that they were undoubtedly the best Muscats in the show. Foster's Seedling was favoured with a class, and was represented by eighteen bunches in six lots. The clusters were not large and the berries were below the average in size, but the winners, especially the first, were beautifully ripened. In the class of any other variety Golden Champion secured the first prize, the bunches of it shown being very good; the berries were unusually large, but they were hardly ripe, and little black spots were visible on some of them. The second prize went to Duke of Buccleuch, the bunches of which were rather small, but the berries large and spotless. The Trebbiano which gained the third prize was small in bunch and unripe; indeed, it was a mistake to show this variety at this time of the year.

Pine-apples were good throughout. The specimens competing in pairs were all Queens. The first prize brace weighed together 9 lb.; the second prize pair would weigh about 3 lb. each; and the third prize lot 10 lb. the two together. These were tall, fine, conical fruit, perfectly fresh and well coloured. How they came to be placed third, and the preceding pair second, was a mystery. We heard one of the judges observe that their crowns did not match, one crown being 3 inches in length and the other 3½ inches. Now a 5 lb. Queen with a crown of either of those dimensions surely merits attention. The first prize fruit in the single Queen class was decayed at the bottom, while the second and third specimens were equally large and without blemish. One fairly good Black Jamaica was the only specimen shown in the "any variety" class.

Peaches numbered twenty dishes, and were very good. In the two dishes Early Albert and Stirling Castle were first, Royal George and Gros Mignonne second, and Royal George and Bellegarde third. All of these were finely ripened and beautifully coloured. In the single dish class very large specimens of Galande were first, and equally fine Violette Hâtive second. Sea Eagle was shown in one instance in the shape of fruits weighing from 13 ounces to 15 ounces each, and very handsome; we do not remember to have before seen this late variety shown at this season of the year. Nectarines were, if anything, better than Peaches. They were very uniform in size and highly coloured. Pine-apple and Lord Napier were first in the two dishes, and Lord Napier and Downton second. Balgowan was first in the single dish class, Violette Hâtive second, and very fine Lord Napier third. This is a very good show variety at this season, but we question if it would figure so highly if judged by flavour.

Strawberries were just in their prime. The finest by a long way in the show was the new variety named Noble. A large dish of single fruits of this kind was shown, and a large trayful of clusters to show its manner of cropping, and in both instances the specimens were very fine. Those shown singly would average about 2 oz. each, quite firm, and very highly coloured. Its flavour is equal to that of President, and in earliness it comes in with Black Prince. As seen here it may be briefly described as one of the earliest, largest, most showy and fertile varieties extant, and it well merited the first-class certificate that was awarded it by the fruit committee. President, Sir J. Paxton, and Marguerite were the winners in the leading class, and a magnificent dish of President, from Heckfield, was first amongst a multitude of single dishes.

Cherries were few, not more than half-a-dozen dishes being shown in two classes. Black Circassian was the most attractive variety, and also one of the best. Figs were more numerous, and chiefly consisted of Brown Turkey, Lee's Prolific, and Negro Largo. Melons were in strong force, and one of the judges stated that he had never tasted so many inferior fruits at a show before, a remark, however, that does not apply to those that gained prizes; on the contrary, the Longleat Perfection, which gained first prize, and Hero of Lockinge, which was second, were exquisite; of the two, the latter is perhaps the best, having a really pleasing flavour, without too much sweetness. The first prize fruits were large and handsome. A collection of last year's Apples shown from Sussex was wonderfully well preserved, the French Crab, Gloria Mundi, and Alfriston being amongst the best.

Notes on this department of the show would not be complete without reference to the magnificent collection of orchard-house trees, in pots, from Sawbridgeworth. They numbered five or six dozen, and consisted of Peaches, Nectarines, Plums, Pears, Oranges, Cherries, Figs, &c. They were all compact trees, the majority not more than 4 feet in height, with strong young wood, clean, healthy leaves, and bearing astonishing crops of ripe fruit. "Oh! how I would like to have an orchard house," exclaimed many, and certainly this unique collection will do more to popularise orchard houses than anything else that could have been shown.

Vegetables.

These were sufficiently numerous in some classes but deficient and poor in others. Potatoes were very much so, hardly one of the tubers being fully grown, and anything but well formed. The Onion class only contained three dishes, and the bulbs were but of medium size. Collections were the strongest in point of quality. Large bundles of Asparagus, more than one could take conveniently between their two hands, figured conspicuously in several of the collections. Carrots were backward,

Cauliflower small, and Kidney Beans well developed; Cucumbers were more varied in form than usual, and all somewhat deficient in form. Telephone, Telegraph, and Stratagem were the leading kinds of prize Peas, all being remarkably well filled. They were so numerous, too, that the judges got confused amongst them, as in the first instance, and until some outsider corrected the mistake, the society's first prize for three dishes of Peas was awarded rightly, then the second was awarded to a special prize group, and the third came back to the proper quarter. This might easily have been avoided by the judges counting the number of dishes in each class before beginning to judge them, and also looking to see if the numbers on the cards corresponded with the class which they were judging before awarding the prize. Tomatoes made a capital show, but although exhibited under a dozen or more names, there were not really more than two or three distinct varieties there, and the only one perfectly distinct was Dedham Favourite. Cambrian.

NOTES ON PLANTAIN LILIES.

During the past few years the different species of Plantain Lilies (Funkias) have gained great popularity with gardeners, owing, in a great measure, to the extensive use made of some of them in the London parks and other places where what is known as subtropical gardening is carried out. This anyone acquainted with the genus will not be surprised at, for to the value of its species as fine-foliaged plants is also added the good quality of being free and handsome-flowering herbaceous plants, all of which produce spikes of bell-shaped flowers. Another point in favour of plants of this kind is that they thrive in almost any soil, although, like many others, they are seen to the greatest advantage when grown in well-drained sandy loam. All the species are easily multiplied by means of division, an operation that may be performed either in spring or in the autumn. One of the most useful and ornamental species of this genus is F. Sieboldi, a plant which is known in gardens under various names, the most common of which are sub-cordata and glauca. It grows from 1 foot to 2 feet in height, and has large, somewhat heart-shaped, glaucous leaves, and bluish or pale lilac flowers. Good sized tufts of this are very imposing in borders or on turf, and beds of it are likewise attractive—a fact proved by some that have been planted in Battersea Park within the past few years. It may also be used advantageously in mixed beds of foliage plants, such as Melianthus major, Acanthus latifolius, the dwarfer Cannas, &c. F. japonica, commonly known in gardens as F. grandiflora, is a species which grows from 12 inches to 18 inches in height, and which produces numerous large, handsome, pure white, sweet-scented flowers in August and September. Its leaves are of a clear pale green, and are much smaller than those of the preceding kind. In some places this species is used as a flowering plant for edgings; but it is seen to the greatest advantage when planted in tufts, in beds or borders, in a well-drained sandy loam. Another desirable kind is that known as F. ovata, which forms a neat tuft from 15 inches to 20 inches high. Its leaves are large, broadly oval in outline, pointed at the tip, and of a dark shining green colour. This makes a useful edging plant for sub-tropical beds or borders. Besides the above, which are all quite distinct, there are numerous variegated kinds that form desirable edging plants. Of these I would recommend the varieties of F. ovata, lancifolia variegata, and albo-marginata. S.

Double-flowered Myrtle indoors.—Everybody acquainted with flowers knows the lovely double-flowered Myrtle, which is a very desirable plant both for bouquet work and for decorative purposes generally. A neat bushy plant of it looks well when in bloom, but its beauty is much enhanced if trained as a standard with a stem about 2 feet high. However, as the double-flowered Myrtle grows rather slowly, it is a good plan to graft it on the common broad-leaved kind (Myrtus communis), of which rooted cuttings, when planted out in suitable soil, make in one season plants fit to be grafted on at the above mentioned height. The best time to perform this operation is in the end of August or beginning of September, when the branches of the Myrtles are sufficiently ripened, and the plants must be kept close until the scion has taken, after which period they may be treated as is commonly the rule to deal with plants in such circumstances, that is to gradually harden them off, to untie the ligatures, and to cut away the branches of the stock. It must be understood that all the branches must not be cut clean off at once, as that would very likely cause the death of the plant, while, on the other hand, these branches assist to strengthen the trunk until the scion has grown sufficiently to consume all the nourishment the roots furnish. Care must be taken to get a well-shaped crown; therefore stopping of the branches must be made in time, and they must be pruned annually in spring. Plants grown in this manner may often be seen in Continental nurseries.—G.

Heather edgings.—Few have any conception of what an effective edging for large beds or borders can be formed of the common Heather, or Ling, as it is often called. The more choice kinds are much used in clumps in shrubberies, but, until the other day, I had no idea that the wild Ling could be effectively employed as an edging plant. A friend of mine has a short drive up to the house, and on the right hand side is a wide border filled with standard Roses and backed by a hedge of the same trained against wires; under the standards are bedding plants, the whole being finished off with a wide border of Heather next the narrow band of Grass which separates the drive from the border. On the left side is the lawn, along the edge of which is a narrow ribbon border about 3 feet wide, along the centre of which is a row of standards. Each side of the band is edged with Heather, next the Heather are Calceolarias, and in the centre a row of single purple Petunias. The effect of this arrangement as a whole is very good. The Heather used in this case was got from a common near at hand, care having been taken to see that it was all of one variety, and that it was cleared of all weeds and Grass.—A. H.

Sedum carneum variegatum.—This pretty Sedum makes a very desirable little drooping plant with which to face the edges of flower-stands in drawing-rooms, ball-rooms, or corridors, and it retains its freshness a long time without requiring to be changed, unless a change should otherwise be desirable. It is also very useful for giving a dressy appearance to, and for hiding the wirework of, hanging baskets filled with plants, whose growth may not have so decided a drooping tendency. Its long elegant growths have a light and pretty effect when used sparingly round the upper tiers of tall glasses either for dinner-table or drawing-room decoration. I have always found the more frequent the changes of materials and style in this class of decoration the more satisfactory it is. Too much repetition of anything, even when tastefully done, palls and satiates. This Sedum, like many others of the same family, also makes a very desirable hardy bedding plant, either for edging on the flat for covering the edges of raised beds, or for furnishing undergrowth for tall succulents or Palms, Dracænas, &c.; and it is also a useful plant in the rock garden. It is easily propagated in heat in spring, when every little bit will strike root freely.—E. H.

Mimuluses in pans best.—The variety of striking colours to be found in the flowers of Mimuluses should be sufficient to recommend them; but if we may judge from the few gardens in which they are found in satisfactory condition, it is evident that they are not so popular as one would imagine plants of such easy culture should be. It is a simple matter to raise a stock of plants from seed in three or four months' time; if a commencement is made in spring, thrifty little specimens may be had that will produce a good number of flowers. They are, properly speaking, spring and early summer flowering plants—seasons at which the flowers not only last longer, but are larger than those produced during the usually hot months of July and August. If an old plant or two have been carefully brought through the winter, plenty of young shoots will be produced by them in February. Many of these may be taken up with roots attached to them, ready for potting. Those who require large specimens should grow them in pans from 6 inches to 8 inches deep, and from 10 inches to 20 inches in diameter, according to convenience. Mimuluses are moisture-loving plants, and therefore a good substantial loam is the best soil for them, and only moderate drainage is required. They are equally well suited for growing in pots, but pans are best for large specimens. People who have young pieces that will form plants should dibble them in 3 inches apart, and then the pans may be placed in an ordinary greenhouse. When they begin to grow they will want plenty of air; if much confined, the growth will be weak and the flowers small. Unless there should be any plants making more growth than ordinary, they require no stopping; but they will be the better for having some neat sticks placed to the strongest stems, as the flowers are often so large and heavy that the stems are unable to support them. They require a rather liberal supply of water when making growth, and they should also be shaded from very bright sunshine. Those who have to raise a stock of plants from seed should be careful to save it from a good strain of flowers, and there are plenty of such in the country. It is best to sow it thinly in a rather large pan of fine sandy soil, so that the plants may have room enough to grow to a good size, as in that case they can be transferred from the seed pans to those in which they are to flower. Seedlings require a little more nursing while young than plants from cuttings; but as soon as they have grown 2 inches high, they may have the same treatment as rooted plants in pans. Three seedlings put into a 5-inch pot make pretty little plants for greenhouse or conservatory decoration.—J. C. C.

Winter-blooming Carnations.—In some places enormous quantities of these flowers are required, and must be supplied. Plants and cut flowers must be had for rooms, the dinner-table must be provided for, and bouquets for button-holes must be abundant. For the latter purpose nothing surpasses these Carnations, of which there are now several fine winter-flowering varieties that everyone ought to grow. Among these I consider the following the best for the winter months, viz.: Monsieur Baldwin, Lady Frances, Garibaldi, Vulcan, Van Houtte, The Bride, Napoleon III., Empress Eugénie, and Miss Joliffe; the last is the best of all. Since I first began growing this variety I have kept yearly increasing my stock of it until now I grow it by the hundred. It is such a profuse flowerer that one may cut an immense quantity of blooms from it daily, flowering, as it does, as freely in pots as the old dark Clove does in the open border. The raiser of this useful variety was Mr. Keen, gardener at Campsey Ash, Wickham Market. To be successful in having a plentiful supply of flowers through the winter, I find it best to get the cuttings rooted in good time; therefore I generally put in a good batch of them early in March, in a gentle bottom-heat; the plan I adopt is to place a couple of hand-lights on a bed filled with leaves in our Rose house where the Roses are plunged, and then put in the hand-lights about 4 inches of sandy soil, which is made quite firm, and the Carnation cuttings inserted. A good watering is then given and no further trouble is required until they begin to root, when air must be admitted by degrees. I have never found this plan fail; the night temperature of the house is about 50°. I use 6-inch and 8½-inch pots for flowering them; if larger pots are employed the plants do not flower so freely.—W. A.

QUESTIONS.

5508.—**White Cucumbers.**—Can any reader of The Garden tell me the cause of Cucumbers coming almost white and very soft? They are watered every day. The temperature is kept at about 90° in the daytime with sun-heat, and at about 70° at night, the bottom-heat being about 80°.—A. N.

5509.—**Premature ripening in Vines.**—I have six Gros Colmar Vines that were struck in January, 1885, and planted in May of that year. During the last few weeks many of the bottom leaves are discolouring—indeed, have become autumn tinted; in fact, some of them have dropped off. The rods were cut back last December to a foot from the ground. They started again in March, and have made canes about 10 feet long, and about the thickness of one's finger. What, I want to know, can have caused the premature ripening? The temperature of the house is kept up to about 80° with sun-heat, and 70° at night. The Vines are syringed every day at 4 o'clock—at least in time to allow the heat to rise up to 90°, when the house is closed.—C. R.

Garden in the House.

BOWL OF MEXICAN ORANGE-FLOWER.

This noble shrub, with its wealth of clusters of Orange-like bloom, yields a bountiful supply of flowers for cutting. The glossy foliage, of great substance, forms a rich setting to the solid white petals and pale gold-coloured anthers. The engraving of a handful of flowering sprays loosely arranged in a glass bowl shows its value as a cut flower, and also the good effect of one distinct flower arranged simply by itself with its own foliage.

Dahlias in a cut state.—Finding Dahlias, especially whites, such as Constance and Little Gem, and scarlets or crimsons, such as Jaurezi, so useful for cutting both earlier and later than they are ordinarily to be had, we last season grew a quantity of young spring-struck plants in pots for late flowering, and as the outdoor supply was cut off very early by frost, they proved to be most useful, keeping well in a cool orchard house until Chrysanthemums came in. They were dried off and cut down just before Christmas, and laid on their sides in a cool place just free from frost until March, when they were again brought out and started into growth. After taking off what cuttings we required the tops were allowed to grow unchecked, and, by gradually hardening them off like ordinary bedding plants, we had fine bushes full of flower-buds by the time it was safe to plant them out. The result has been that, instead of having to wait until August for flowers, we have cut a good many in June, and an abundance is coming on. If planted in good soil and the blooms cut, as soon as they are fit for use there need be little fear of Dahlias ceasing to bloom from exhaustion. During the hottest weather when fragile flowers fade quickly, it is no small boon to have a good supply of Dahlias to fall back upon, and amongst them may be found nearly all shades of colour required.—J. Groom, *Gosport*.

The Mexican Orange-flower (Choisya ternata). From a photograph. Engraved for The Garden

Skeletonised Nepenthes.—In the charming collections of skeletonised leaves and flowers shown at the recent Liverpool exhibition, the Nepenthes were very conspicuous, several very fine pitchers having been successfully subjected to this process. This is the first time in which I have known these pitchers to be skeletonised, and as they show a very close network of fibre and retain their natural shapes, they certainly rank amongst the most desirable of all forms of vegetation for skeletonising. They are remarkably curious and very effective, and all who take a delight in skeletonising should introduce them into their work.—Cambrian.

GARDENING IN THE SOUTH OF FRANCE.

The Blue Gum tree appears likely to prove a good friend to owners of gardens in districts which border the Mediterranean. The great bar to the successful culture of many tender exotics in that sunburnt region has been want of shade and shelter, and this the stronger growing kinds of Eucalyptus can supply. They thrive apace in positions where much difficulty has been found in inducing the production of vegetation having the requisite protective power. In a climate where the thermometer never falls to freezing point and where the summer heat is high it is natural to infer that a large number of exotics which in a more northern latitude require constant protection from cold would be happy. Orchids, amongst other things, are mentioned as having been tried with good results, and as it has been found that a considerable number of species actually enjoy being in the open air in this country during the warmest months of the year, we are justified in assuming that they would do even better where the average summer heat is higher than with us. The experiments that have been made in this direction are sufficiently satisfactory to warrant the hope that the south of France will one day be a happy home for a large number of plants which we are compelled to keep most of the year under cover.

French salads.—Every Frenchman seems to know how to make an appetising salad, probably owing to salads being considered in France to possess considerable nutritive value. I do not exaggerate when I say that a French workman will make a dinner on a salad and a piece of bread and be quite satisfied therewith. This will not appear strange when the amount of oil consumed is taken into account. The quantity of oil that a French workman will eat at a meal would surprise those who are accustomed to a very moderate use thereof. It little matters to a Frenchman whether the basis of his salad is formed of Lettuce, Corn Salad, or Dandelion; only give him plenty of good oil and a variety of herbs, and he will make a differently flavoured, tasty, satisfying salad for each day in the week. The great fault commonly committed in this country is the too free use of vinegar and the absence of herbs, also want of careful preparation of the esculents employed as a basis. It is a curious fact, and one that illustrates the importance attached to salads in France, that they are not eaten with flesh, but always with bread alone. If we were to eat salads for their own sake we should make them better, and in hot summer weather they are certainly more wholesome and palatable than meat. I never cared for salads until I eat them abroad, and I have rarely found them to my liking in this country, principally, I think, because the delicate flavour which a judicious admission of herbs gives is wanting. Cream and Cucumbers have been mentioned as forming ingredients in French salads, but I never saw either used in that way. The utmost care should be taken to secure the purest oil; some kinds of oil sold by grocers in this country are coarse and often rancid, the sufficiently free use of which produces nausea.

Flower shows.—The flower show held in connection with the Agricultural Society of France in February last was remarkable for the variety and high quality of the produce exhibited. The Messrs. Vilmorin obtained the grand prize (*prix d'honneur*), their collection of Cinerarias, Hyacinths, Cyclamens, Violets, and Primulas being extremely fine. M. Truffaut showed cool Orchids. M. Millet, the largest grower of Violets in France, exhibited a collection of this fragrant flower, conspicuous in which were two varieties of his own raising—Madame Millet and Armandine Millet, the latter having variegated foliage. M. Dugourd, of Fontainebleau, had a varied collection of hybrid Hellebores raised by him; and M. Salomon, of Thomèry, who is *facile princeps* among French Grape growers, had a whole glasshouse devoted to his exhibition, consisting of Grapes of the preceding year and Vines in pots bearing ripe fruit. M. Salomon appears to have brought the art of keeping Grapes to perfection, for on more than one occasion he has exhibited Chasselas de Fontainebleau in May as fresh as when first ripened in autumn.

At the exhibition of the French National Horticultural Society M. Bleu's new hybrid Bertolonias were much admired, the best of them being

Mademoiselle de Freycinet, a kind with greenish brown foliage distinctly reticulated and spotted with brilliant metallic carmine; Marguerite Wilson, much veined and spotted with silver on a dark ground; and Alice Van Geert having very large leaves greenish white, with rose-coloured veins. The same exhibitor had also some new hybrid Caladiums of exceptional beauty, as well as a hybrid Begonia of great promise, but cumbrously named villosa argentea purpurata—the result of crossing B. stigmosa with the variety Otto Forster. Messrs. Chantrier's Crotons and Dracænas were of the usual excellence, amongst the former being some good seedlings. A superb specimen of the typical Anthurium Andreanum and a group of its varieties were also exhibited by this firm. M. Paillet had a fine collection of tree Pæonies, of which he makes a speciality; prominent amongst them were Louise Mouchelet, Reine Elizabeth, Zenobia and Athlète. M. Lemoine showed some of his new double Lilacs, such as President Grévy, Horace de Choiseul, and Michel Buchner. M. Salomon staged two lots of Chasselas Grapes, one composed of forced bunches, the other from the crop of the preceding year. As regards freshness and colour, there was little, if anything, to choose between them. The Compagnie Continentale exhibited some fine novelties at the 106th annual exhibition of the Royal Floral Society at Brussels in May last. Noteworthy among them were Alocasia Lindeni, the lively green hue of the foliage of which contrasts agreeably with the white foot-stalks and veins; A. Augustiana, with large green leaves and red foot-stalks striped with red; A. nigrescens, marked with blackish grey on a green ground; and A. regina, exhibited last year for the first time. Amongst new Orchids there were Cattleya Malouiana, having very large flowers, with magenta-rose sepals and petals, and an extremely large and showy lip; and Spathoglottis angustorum, a species with tall stems, which keep blooming continuously for three months at a time. Other plants of special merit exhibited on this occasion were a new Aphelandra from Brazil, one of the most singular of coloured-leaved plants; Cycas tonkinensis and Bellefonti; Sagenia mammillosa, a distinct and curious Fern; Pandanus Kerchovei, and Heliconia albo-striata. M. de Smet, of Ghent, exhibited a variegated form of Areca Baueri, and M. Vervaet had a fine variety of Odontoglossum Pescatorei named Vervaetianum, the flowers of which are strongly marked with large violet-red spots. J. CORNHILL.

NOTES.

IN SUMMER TIME we have green trees and soft fresh turf, Poppies and Roses, Pæonies, Irises, and white Pinks in masses in every garden, and, best of all, hot sunshine and warm showers, giving new life to all things. A bit of good soil works miracles. From the time of Christmas Roses until June it may bear myriads of beautiful blossoms. So rich and effective, indeed, are the flowers of summer, that one forgets the earlier offerings of the garden. Snowdrops and netted Irises and Crocuses of golden beam, the Narcissi, many and varied, and the hundred and one of our earliest blossoms of the year are gone, even if not forgotten. The point in good gardening is never to forget one's bulbs—any plant, indeed—but more especially the bulbs, which, being out of sight for a part of the year, are apt to be also out of mind. Scillas, Chionodoxas, and many kinds of Narcissi may now be taken up and replanted at once with perfect safety, better now, indeed, than at any other time—that is, if their leaves have faded away. There is a whole world of little secrets to be learned in the management of bulbs, but the main point we have to grasp is this: if the bulbs are moved at the rootless and leafless period of their existence, most of them are absolutely the better for replanting every year.

HARDY FLOWERS.—The display of these made at Liverpool last week was remarkable in several ways. Quantity and quality alike were noticeable, and perhaps for the first time were they seen at a flower show in a fairly representative way. No one could look on the great masses of Pæonies and Irises without being brought face to face with the fact that there are hardy blossoms quite as lovely and effective in their own way as are the choicest of hothouse productions. Let all who can grow Orchids and hardy flowers also, but the main point in open-air flower culture is this: the finest of hardy flowers, of Narcissi, Irises, Pæonies, or even Roses, may be grown beside nearly every cottage door in England, and only when so grown and admired will they have become appreciated at their true value. Hardy flowers represent democracy in the garden, and by their aid we can, if we will it so, bring freshness and beauty to the homes of the people. Public parks and people's gardens may do much and are great blessings in towns, but the sense of real ownership is necessary to the full appreciation and best culture of a garden, and for every ten people who own hothouses there are five hundred who can grow hardy flowers.

HOT WEATHER.—What a blaze of colour there is on the borders during these hot, dry days! On the grey walls Clematises and Roses strive for pride of place, and dark-spotted Gum Cistus opens anew its satin petals every morning. English and Spanish Irises, Pæonies, Delphiniums, Stocks, sweet smelling at eventide, and masses of Canterbury Bells, white, pink, lilac, and purple, make a flower show of the garden. How swiftly the flowers throw off their green top-coats; how eagerly they open their petals to the sun. The great Verbascum olympicum, 8 feet high, is like an uprising flame of yellow flowers, and Flax blossoms flutter in the hot breezes like little blue butterflies amongst meadow flowers. Here and there, amid all the colour and flower happiness, there comes an appeal for showers. Primulas especially resent these hot, dry days and sigh for rain; so also the Spiræas and shallow-rooting things generally; but in the garden everything happens for the best, and the hot sun is a boon we appreciate at its true value. It means the full ripeness of buds and of bulbs of all kinds—flowers now and flowers hereafter.

PLANT NAMES.—At the Orchid Conference at Liverpool last week the outcome of the opinions there offered may be summed up as follows: 1. Latin or Greek names are to be confined to wild species or types only, and the same to be applied and explained by a properly authorised botanist. 2. All wild variations or forms, all garden hybrids, seedlings, sports, &c., to be known under English names only, subject to the approval, alteration, or rejection by the Royal Horticultural Society's committees if placed before them for certificates or awards. 3. That it is desirable that a register be kept, that coloured drawings be made, and that actual specimens be dried or otherwise preserved for future reference. Dr. Michael Foster suggested that some idea of the plant or its history should be embodied in its name, and that there should be some distinction made in the construction or termination of the generic and specific names, so as to give some distinguishing mark between wild species and garden hybrids. The proceedings at Liverpool were so amicable and progressive and the tone so healthy, that this important subject should not be allowed to fall into abeyance. Perhaps the best thing now to do would be to appoint a nomenclature committee at South Kensington, the object of which shall be the organisation of a dual system of naming: viz., (*a*) botanical, (*b*) horticultural.

THE TIME OF LILIES.—One of the very finest of all our Lilies now in flower is the ivory-white Martagon, its spire of fifty flowers and buds being borne on a stem nearly 5 feet in height. Several good well-established clumps of L. Szovitzianum have also borne a rich harvest of their canary-yellow bells. L. croceum is now brilliant as red-hot iron, and some large forms of L. Thunbergianum have also been very effective in the sun. L. alutaceum is a quaint little Lily of this group, its solitary, erect, saucer-like flowers being borne on stems only 2 inches or 3 inches above ground level. I see L. Washingtonianum also in bloom in a pot; but, after all, the time of Lilies is yet to come, for is not the heyday of Lilytide when the silvery chalices of the Madonna Lily (L. candidum) expand, followed by L. auratum, L. longiflorum, and L. speciosum of Japan? After all the competition and introduction of new Lilies of late years, what have we finer, for garden uses, than the old white Lily, which was a common flower in the days of Chaucer?

POSIES.—It is pleasant to hear that the Mushroom bouquet is at last to be superseded, and that the old-fashioned poesy or posy—*i.e.*, a poem in garden blossoms instead of in words—is to be welcomed back with all the honours reserved for dear old friends. Time was when no visit was complete, no good-bye at the door perfect without that last sweet gift from old country house gardens, the posy, rich in colour and rich in fragrance also. There is no limit to the fashioning of the posy as a work of art. Unlike the modern bouquet, it need not be circular, nor are paper collars or sham lace collarettes *de rigueur;* all one requires are good flowers and fresh green leaves. A handful of white Pinks, or of Cabbage Roses with their own leaves if well arranged, may make a gift worthy of a queen. The same is true of Irises, Stocks, or Carnations, Cornflowers, Ixias, or Bride Gladiolus with Iris leaves. Hothouse flowers are most acceptable in the dark days of winter time, but the very name of a hothouse is almost unbearable beneath the sunshine of rosy June. Now is the heyday of garden flowers, and it is but meet that the old-fashioned sweet posies should gladden our own hearts, as they did those of our grandfathers' in bygone days.

ENGLISH IRISES.—It cannot be too generally known that these beautiful Irises may be raised from seeds by the hundred, if the seeds be sown as soon as they ripen on the plants after flowering. We commenced growing the ordinary Dutch mixture a few years ago, and have now some very good seedling varieties, their colours ranging from pure white to the darkest of purple and blue shades. On light rich soils these Irises flower the second or third year from seed. The pure white form is a great beauty, figured years ago in the "Jardin du Roy" and other illustrated folios of A.D. 1612 to 1647. As cut in the bud stage and brought indoors to open, no Orchid could well be finer in form or texture. Grouped on the borders along with Gladiolus Colvillei albus these English Irises are very lovely, even although the hot sun is just now making short their time of loveliness. Scarcely any hardy flowers just now in blossom are more useful for big pots or vases indoors if we except the Spanish kinds, which yield us the rich tints of yellow and bronze which these English kinds deny us. Dutch grown roots of both races are cheap enough to buy in quantity, but where seedlings can be raised one has the added chance of novelty as well as of infinite variety.

THE BIG POPPIES.—P. orientale and P. bracteatum are doubtless only geographical varieties of the same plant, although the first is said to have

been introduced from Armenia in 1714, and the second from Siberia as recently as 1817. P. orientale is a spreading plant, both stems and leaves being densely covered with silvery hairs, which give to it a somewhat hoary aspect. The flowers vary in size, and in colour they range from apricot-buff to a vivid scarlet. P. bracteatum is a dark green plant of erect habit, the stems and leaves being less hairy and the flowers of a rich blood-crimson colour. The last is to my mind by far the best garden plant, some of its forms bearing flowers nearly 12 inches across. Like P. orientale, it varies from seed, but I never yet succeeded in raising plants of P. orientale from P. bracteatum or *vice versâ*, as some cultivators are said to have done. The old idea was, that the presence of a bract or two immediately below the flower-bud distinguished P. bracteatum from P. orientale, but if ever this held good, it is useless now-a-days, since one often finds bracts below the buds of P. orientale. The hoary aspect and the decumbent flower-stems at once distinguish the last-named from P. bracteatum, apart altogether from the orange-scarlet (not blood-crimson) blossoms. VERONICA.

FLOWER GARDEN.

ORNAMENTAL RHUBARBS.

In gardens of large dimensions, especially those in which distinct effects are sought, Rheum officinale, planted in bold groups, has a striking appearance. When this plant bursts into leaf in spring, the fresh tender tint of the foliage is very pleasing, and the ornamental effect of the plant is heightened later on by its noble inflorescence, which, in the case of strong well-established specimens rises to a height of 12 feet or more. The only defect which this Rhubarb has is that it quickly feels the summer heat, the foliage by mid-July becoming somewhat yellow and brown at the edge. This tendency to premature decay may be counteracted by planting in moist positions, or, at any rate, where the roots can obtain an unlimited supply of moisture through the summer. This Rhubarb and its congeners would doubtless thrive better close to water than elsewhere, and, therefore, I would recommend those who have water margins thus to embellish them. When thus used, good-sized roots should be set out, as small specimens are likely to be somewhat crippled at first by encroaching neighbours. The species above mentioned and R. Emodi are the two best for forming bold groups or for naturalisation, but if a more moderate growing kind is desired for purposes of isolation on Grass, the best is R. palmatum tanguticum, a kind having deep green foliage, much divided, and which resists dry weather well. For the centre of a large bed this is a good plant. It grows compactly, and in colour it differs from that of other fine-leaved plants. Even the common Rhubarb has claims beyond that of mere utility. When allowed to develop freely, and to produce its flowers at will, it has quite a stately appearance. It is only in this way that Rhubarb is used on the Continent, where it is by no means uncommon to see it occupying a prominent position on the lawn. We shall never probably thus employ it in this country, although I see no reason why it should not be introduced into the wild garden, where it would look quite in place associated with giant Parsnips, Reeds, tall-growing Michaelmas Daisies, Golden Rods, and similar coarse-habited plants. J. CORNHILL.

Spiræa palmata.—This is a plant that loves coolness, moisture, and shade, for although it will grow almost anywhere, it will not flower properly unless the weather be coolish, cloudy, and the ground moist. This season we had the heaviest rainfall in May on record—nearly 7 inches—which was the cause of disastrous floods in the midlands and elsewhere. June was also cool, not to say cold, and we never saw this Spiræa in such fine growth. Then came a dry spell with warmer weather, and the flower-scapes on every plant, and we have many, were speedily ruined. This Spiræa is one of the very finest of herbaceous plants, but it wants coolness, moisture, and partial shade in dry localities.—J. S.

GOOD HARDY CLIMBERS.

Climbing plants should have a little more attention bestowed upon them than they generally get. The uses to which they might be put are many, though, as a rule, they are only employed for covering walls and for forming screens, their fitness for festooning trees and shrubs or rugged places being overlooked. When trained on walls the first consideration is the border in which they are planted. The roots must have good soil. A border 4 feet wide should, if possible, be allowed them, and it should be at least a yard in depth. A border of the size just mentioned well trenched will give newly-planted climbers a good start. After they are planted a good plan is to nail them securely to the wall till the allotted space is covered, and then allow them to grow as they like. In this way stiff artificial formality will be avoided. I have now under observation a stretch of wall covered with Forsythia suspensa that was at first treated in the manner just described, and now, after a lapse of three years without any labour being spent on it, the whole wall is quite a mass of long flexible shoots, many of which droop gracefully down to the ground. So thoroughly is it covered, that even when stripped of its foliage little of it is to be seen, while during the time the leaves are retained it has quite the appearance of a green bank. In the case of these Forsythias, which flower charmingly in spring, many of the shoots have rooted at the tips where they came in contact with the soil, and have quickly grown into good sized plants. This is a mode of increase worth noting by anyone wishing to propagate this Forsythia; all that is needed is to just cover the tips of the shoots with soil and make them firm in their place by means of pegs. In this way most of the Brambles will readily strike root. In planting climbers for covering a neighbouring tree or shrub the roots should, if possible, be outside the radius of the branches of the tree or shrub over which the plants are to climb. By the aid of a neighbouring branch the climbing shoots can soon be led to the head of some tree.

Amongst hardy climbers of a ligneous character few surpass the well-known Virginian Creeper for fast growth and for the rich tints of its decaying leaves in autumn. Ampelopsis Veitchi is more delicate than the common Virginian Creeper during its earlier stages of growth, but afterwards it seems to thrive even in towns equally well as the ordinary kind. It is altogether a weaker-growing plant, but still it possesses one great advantage over the first-named, and that is it clings to walls securely by itself while the other needs attaching to them. The more vigorous kind is, indeed, best fitted for festooning, and Veitch's for covering walls with close, dense foliage. Though its leaves are for the most part small, yet it occasionally produces very large foliage, such as may be seen in the temperate house at Kew, where there is a large plant of this creeper under the name of Vitis tricuspidata. It is a native of Japan, as is also Akebia quinata, a pretty and distinct climber, but one that is rather tender except in the south and west of England. It is a slender twining plant with light green compound leaves and curious claret-coloured blossoms, borne during the early part of the summer. It succeeds best in a warm sunny spot. Aristolochia Sipho (Dutchman's Pipe) belongs to a large genus in which this is by far the most ornamental. When growing vigorously its huge heart-shaped leaves make it a conspicuous and distinct climber, and its brownish blossoms add to its singularity. Celastrus scandens is a comparatively unknown climber in this country, but in the United States it is one of the most popular. The habit of the plant is that of a confirmed twiner, and it is one of free vigorous growth. The reddish fruits which it bears in autumn are very pretty.

The varieties of Clematis are now so numerous, that many shades of colour are represented amongst them; the blossoms vary, too, in other ways. C. Jackmanni, which at one time created such a furore, is still the best of its class, taking into consideration flowers, freedom of blooming, and good constitution. Other species of Clematis, too, are beautiful climbers, and especial mention should be made of C. Flammula and the common Traveller's Joy, a white-flowered kind frequently met with in hedgerows during the summer. The Himalayan C. montana is likewise a beautiful plant, the flowers of which are large, pure white, and are at their best in May before other kinds of Clematis come into bloom. Equally notable as C. montana, owing to its flowering at a season different from the rest, is the yellow C. graveolens, which flowers till its beauty becomes tarnished by autumnal frosts. Nor must C. Viticella, florida, and Viorna be omitted. The last resembles in the shape of its blossom the much-talked-of C. coccinea, which, when represented by a good variety, is a useful small or rather medium sized climber. Ivies are well known to be valuable evergreen climbers that will thrive even in the heart of towns where little else will keep alive. Large numbers of Ivies are catalogued by various nurserymen; therefore, a selection in many cases is necessary. The best and most distinct are Hedera algeriensis and amurensis, H. Rægneriana, a kind with deep green heart-shaped leaves, the Irish Ivy (H. canariensis), and the following varieties of the common kind, viz., digitata, palmata, sagittæfolia, and lucida, the distinctive characters of which are indicated by their respective names. In atropurpurea the leaves are smallish, and acquire a bronzy tint with prominent veins of a lighter hue. This is the variety that supplies the leaves now so much used for button-hole bouquets. H. caenwoodiana is a miniature kind with deeply divided leaves, and forms a pretty climber where only small ones are needed. Among variegated varieties must be mentioned madeiriensis variegata, canariensis, latifolia, maculata, japonica variegata, Helix variegata, and H. argentea.

Of Jasmines I will mention first of all the common white Jasminum officinale, a favourite with everybody, and a kind that will thrive in almost any situation. J. nudiflorum, whose flowers are borne soon after Christmas, is a most valuable early-blooming wall plant; and the somewhat tender J. revolutum, with large golden blossoms, is, where sufficiently hardy, a very ornamental species. The Honeysuckles (Lonicera) are general favourites, the common species of our hedgerows (L. periclymenum) being one of the most fragrant. L. Caprifolium, with its peculiar perfoliate leaves, deserves mention, as do also the scarlet L. sempervirens, a kind particular as to soil and situation; and the Japanese L. brachypoda aurea with bright golden veins. L. japonica, or Halleana, is a free-growing, very fragrant kind. Menispermum canadense (the Canadian Moonseed) forms a stout rootstock whence spring numerous slender twining stems clothed with heart-shaped foliage. It is a climber that, when once planted, takes good care of itself afterwards. Passiflora cærulea is hardy in some parts of England, and where it is so it is a handsome and distinct climber. Periploca græca, a plant with ample deep green foliage and peculiar brownish flowers borne during the summer months, might well be oftener seen than it is. To induce it to flower freely it needs a sunny spot. Roses of various kinds make beautiful climbers, or, more strictly speaking, ramblers, and of these there are a great number of garden varieties to choose from, as well as some species. One of the best for overrunning a good-sized tree is R. Brunoniana, a kind which, when

once established, will grow most vigorously and produce large clusters of single white blossoms in the greatest profusion. Several kinds of Smilax are neat climbers, all having firm glossy foliage; a strong family likeness runs through the whole. S. aspera is for general purposes one of the best. Stauntonia hexaphylla and latifolia are good climbers for the southern parts of the kingdom, but northwards they are liable to be injured during severe winters. Of Vines there several well worth growing, especially the Cut-leaved or Parsley Vine, the purple-leaved Vine, and some of the huge-leaved North American kinds, of which Labrusca and cordifolia may be quoted as examples. No mention of climbers would be complete without noting the Wistarias, of which many kinds are now included in nurserymen's catalogues. W. sinensis is that commonly seen, and besides it we have the North American W. frutescens, altogether a smaller-growing plant than sinensis. Of the latter there are a couple of varieties, viz., alba, in which the blossoms are pure white, but, as far as my experience goes, it does not bloom so freely as the common kind. The second is the double-flowered sort, which I can never induce to open its blossoms properly. W. multijuga is said to bear enormous bunches of flowers, but as far as I am aware it has not yet bloomed in this country. W. multijuga alba is to be found in some catalogues.

Alpha.

BREEDER TULIPS.

I think that were the gardening public more intimately acquainted with the beautiful varieties of the florist's breeder Tulips than they appear to be, many would be inclined to grow them. The best of our self-coloured early flowering Dutch Tulips cannot compare in beauty and refinement with those that can be seen at the Tulip shows in Lancashire, Cheshire, and elsewhere. The superior cultivation given them causes them to throw up strong, tall, straight stems surmounted with self-coloured blooms of varying shades, great numbers of which are of exquisite form, as well as large in size. The Tulip almost always (and the exceptions are very rare) takes the breeder or self-coloured form when it first opens. But from the time of sowing the seed until such time as the plants flower, five or six years pass. Patience, therefore, is a quality needed by Tulip raisers, but anyone who has been at the work for years, and raises seedlings annually, has something coming into flower every season, provided he has been at the work long enough to have seedlings sufficiently matured to bloom. A good many that bloom are thrown away as useless, being deficient in the two requisites in a good breeder Tulip—a fine clear bottom and a cup of good form. The colour of the breeder is of little importance compared with the two requisites just mentioned. Many bad or ugly breeders, as they are termed, break into very fine varieties, provided the base is pure and the form good: on the other hand, good coloured varieties often break into characters that are worthless from the florist's point of view. Breeders are sometimes ten or fifteen years breaking into colours, but these are exceptional cases: the general time may be set down as five or six years. Occasionally, but rarely, a flower takes on the broken form the first time it blooms, and never passes through the breeder state. Really, the Tulip is a curious flower. Why do some varieties of it exist so very long in the breeder state, while others take on the broken form much more quickly? What influences tend to promote the breaking of flowers? and what phenomena operate in or on the petals to disturb the previous arrangement of colours? Why, in the case of broken flowers, are the colours so apt to run in some varieties and be so steady in others? How is the colouring transmitted or developed, and what constitutes the colouring matter? Why are some habitually stained at the base, and some habitually pure? Steady and unsteady? These are questions asked thirty years ago, and they propounded riddles that remain unsolved to this day.

Tulips are divided into three classes—bizarre, byblœmen, and rose. There is a fourth class of selfs, but it is a scarce one, and does not possess the importance attached to the other three. A bizarre breeder always has a yellow base, and it is present also in the broken flowers. The rose and byblœmen breeders have a white base. Bizarre breeders are suffused with brown or brown-red, red, bronze, black-brown, and this deepening to almost black. Rose breeders are suffused with rose, rosy pink, deep rose, cherry colour, deepening almost to scarlet and crimson. Some of these are very lovely. Byblœmen breeders are tinged with grey, greyish lavender, deepening into violet, purple, or black of various shades. The base must be pure if to be regarded as perfect; there must be no stain of black upon it; the anther stems must be pure also. A young flower may sometimes be shaded on the base, but it will bleach out while the flower is maturing. If it does not, then this is a radical defect. The pollen on the anthers may liquify and run down the base of the stamens and stain them, but that is an accident; not an inherent impurity.

At a Tulip show there are classes for breeders as well as for broken flowers. They do not take the same rank as broken flowers, still they have a value of their own. As the raiser of seedling Tulips sows seed only of those that are of fine form, flowers of similar character may be raised from them; but, as before stated, many of the varieties prove worthless. Some beautiful breeder Tulips were shown at the recent exhibition of the National Tulip Society at Manchester. There was a class for six breeder Tulips, and the Rev. F. D. Horner brought from his home in North Yorkshire some beautiful flowers, and he was fortunate in obtaining the first prize in the class for six blooms. The varieties were—bizarres, Dr. Hardy and Sir Joseph Paxton; roses, Thomas Parker and Miss Burdett Coutts; byblœmens, Glory of Stakehill and Alice Grey. The second half-dozen ought, I think, to have given place to the one that was placed fifth, for it contained some charming flowers. A few other good breeder Tulips shown in this class were—bizarres, Excelsior and Horatio; roses, Industry, Mabel, and Mrs. Barlow; byblœmens, Talisman and Glory of Stakehill. Now, a breeder may be ever so good, but be worthless when it breaks into character. Take that most beautiful variety, Mrs. Barlow. This is a seedling raised by the late John Hepworth, of Huddersfield; it is of the best form, pure, and of a lovely rose colour, perfect as a breeder, but it is worthless when it breaks, retaining its colour, but destitute of character. But what a grand border flower this would make so long as it remained in the self character! Alice Grey (byblœmen) is another lovely breeder. This was raised by John Walker, of Winton, as distinguished from another raiser of that name; it is of a very light lavender colour and highly attractive; it breaks into fair character, both feathered and flamed, but cannot be relied upon; and when a premier breeder Tulip is selected at a show, this often bears away the palm. Glory of Stakehill is another byblœmen breeder—perhaps, taking it altogether, the best breeder grown; but it breaks into a weak rosy byblœmen without character, and so it is worthless when it becomes rectified. It is a very tall grower; but I may mention that, as a general rule, when a breeder breaks into character the height at which the plant grows is reduced and the bloom is smaller. This beautiful flower was raised by the late Luke Ashmole. Horatio was raised by the late Mr. Richard Headly, of Cambridge; it also is very fine as a breeder, bright yellow at the base, and of a light orange-red colour. It may be described as a red bizarre, but it is worthless when it becomes rectified. Thomas Parker is a pleasing rose breeder, raised in the Wakefield district, and at present grown by a few only. Mr. James Thurstan, Wolverhampton, exhibited two seedling rose breeders of his own raising of excellent character; one, named Tryphera, is of fine form, the base pure waxy white, the colour bright soft rose; the other, named Tryphosa, another of the same class and of high character. R. D.

VARIEGATED TREE MALLOW.

Those who have not seen this plant grown in a fairly satisfactory manner, and pass through a winter unharmed, cannot be in a position to judge of its merits. Plants of it raised from seed last year and planted out in good soil in a sheltered corner are already very attractive. They are nearly 4 feet in height, and all the young leaves are so irregularly marked with green, grey, and white, that they have a remarkable appearance. The beauty of our plants is doubtless enhanced by the fact that they stand close to a green Box hedge—an admirable background for them. The great merit of this Mallow is the fact that the variegation is constant all over the plant, and instead of reverting to the normal colour, as many variegated plants do when raised from seed, the variegation in this case increases. As the plants get older many of the young leaves are quite white when they first unfold, and what is equally noteworthy is the fact that the variegation does not burn under a hot sun. As it has not been thoroughly tested as to its ability to endure hard frost, it would be premature to recommend it for extensive planting, because it may eventually prove incapable of standing in the open through a severe winter. But as it is clear that the variegation is better the second year than the first, some means of keeping the plant through the winter without running the risk of losing it altogether might be adopted. It has been recommended that it should be lifted in autumn and kept under glass all winter. But seeing that when the seed is sown early in spring, and the plants put out in good soil early in the summer, it gets too large for many of us to find room for it, it seems to me that the better plan will be either to grow a few plants of it in pots, which would be the means of curtailing their over-luxuriance, and thus enable us to afford them space under glass the first year, or else not to sow the seed until midsummer, and thereby make a greater certainty of securing plants of a suitable size to keep under glass. Of course, the larger the plants kept over the winter the more effective they would be; but, from what I have seen of the behaviour of this Mallow, I should say that plants of it raised from seed sown at midsummer, and grown in pots under glass until the following spring, would prove eminently satisfactory for placing in the centres of large beds of fine-foliaged plants. For wide borders in positions exposed to the full sun this Mallow is admirably suited, and as to its merits as a flowering plant opinions no doubt will differ; for my part, I like it better without flowers than with them. J. C. C.

SHORT NOTES.—FLOWER.

Perennial Lupines.—What fine plants these are for mixed borders, and how well they thrive in almost any kind of soil. They are great favourites with cottagers in some parts of Somerset, and in their gardens one may frequently meet with specimens bearing a dozen or more noble spikes of flowers. The way in which these and other fine hardy flowers have been elbowed out of our gardens is matter for surprise. —J. C.

Doronicum austriacum.—This hardy border plant was well in flower with us in the middle of April, and its deep yellow flowers have been particularly bright and valuable, as, except Daffodils, there were at the time but few hardy plants in bloom to cut from. This Doronicum is not only valuable on account of the early time at which it blossoms, but the individual blooms are so perfect that they strike one as possessing a certain amount of refinement. Its erect flower-stems render it a useful plant from which to get cut blooms.—J. C. C.

Cyclamen Coum.—In mild winters I have had this Cyclamen in flower quite early, but I did not think it could open its lovely blossoms in such a long and continuous low temperature as we experienced last winter. Our stock of it is growing close to a south wall in a sheltered corner, where it never fails to flower when other outdoor blossoms are scarce. The plants I find do not increase in size to any appreciable extent. Is that owing to a south aspect being too hot and dry for them in summer?—Somerset.

Romneya Coulteri, sown in March, 1885, came up in the seed pans about six weeks ago. Many who sowed it last year may have turned out the contents of their seed pans as hopeless. Mr. Thompson, of Ipswich, advised me to have patience, and not to expect seedlings for six or eight months. None came within that time, but a fortunate extension of the patience for a few months longer has been rewarded by a fair crop.—G. J.

NOTES ON LILIES.

A week ago, after a month's absence in Scotland, I looked over our Lilies. My friend, Mr. McIntosh, many years ago established the fact that whatever the season may be, L. auratum, and a good many other species, will bloom well year after year if planted among healthy Rhododendrons, the reason, I believe, being that the Rhododendron leaves shelter the young shoots from April and May frosts, and from what is still more dangerous, bright sunshine after them. When gardeners speak to me about difficulties with Lilies, I recommend them to keep to this safe ground, that is when not many dozen plants are required; but as our experiments have for years past been in the direction of growing Lilies more in masses, and as this has been an unusually trying season, I think that you may like to have some of the results at which we have arrived.

Having acquired a strip of wood at our cottage garden near here, we, three years ago, dug out the soil for some large beds about 5 feet deep, made a sheltering bank of the natural soil, filled up the holes with good Lily soil, and planted a number of L. auratum bulbs. These were successful; therefore, the following year we made more similar beds, and planted them with L. auratum, L. speciosum, L. tigrinum, L. elegans, L. Krameri, L. Batemanniæ, and L. longiflorum. These prospering, we, last year, made another large bed, and planted it with L. auratum. In all these beds the Lilies looked as healthy, with the exception of L. longiflorum, as if they had had the advantage of Rhododendron shelter. There is no protection overhead, but the surrounding wood was thick enough to protect the plants from the bright sunshine in May which followed the night frosts.

At Oakwood, Wisley, in two beds in which L. auratum had come up constantly stronger, in one since 1881, the other since 1882, a good many Lilies are damaged; some L. cordifolium, which had fine strong shoots at the beginning of May, were killed to the ground, while L. giganteum, just opposite them, had the leaves, which were then developed, frosted, and looked bad. They have, however, thrown up flower-spikes, and hardly show where they were damaged. I think it may be taken as a fact, from our experience of now a good many years, that L. cordifolium, unless planted where Evergreens will protect it from sun after spring frosts, requires the protection of Fir boughs or similar shading. I had an instance of the efficacy of light protection in the case of two lots of Vallota purpurea planted near the water's edge; over them we placed common wicker coops, with Bracken interlaced; most of the bulbs are all right. Even some of the North American Lilies, pardalinum, &c., have some shoots frosted, though in some beds these Lilies are untouched.

In the narrow field of L. auratum, where the protecting cut-Furze fences are not high, so giving but little protection from weather, most of the Lilies seem to have done better than where they had more, though insufficient shelter. For some years past the weather has not been severe enough to try Lilies fairly, but I think last winter may be taken as above an average one as a test, and I hope to send a few further notes when more of the Lilies have flowered. We planted L. tenuifolium in all sorts of soils and situations; it has bloomed in all, though with different strength; it will require another year on the ground before the best treatment can be ascertained. A few days back I saw a stem of L. Krameri, in one of Mr. McIntosh's Rhododendron beds, with nine flower-buds. It may be remembered that when this Lily was introduced, it was considered one-flowered. I ventured to predict that when it strengthened it would have more flowers, but no one ever dreamed of nine. George F. Wilson.

Heatherbank, Weybridge Heath.

WILLOW GENTIAN OR SWALLOW-WORT.

(Gentiana asclepiadea.)

The species represented in the annexed illustration is, as far as we are aware, the only one in this large genus that can be naturalised in woods and similar places with any degree of success. It is not uncommon to see in gardens now-a-days large patches of this beautiful plant both in beds and flower borders, but it may not be generally known that it also flourishes equally well in uncultivated places, apparently unmindful of the rank Grasses and other weeds with which it may be associated. It is truly herbaceous, dying down out of harm's way in winter and reappearing late in spring when all chance of injury from frost is past, and flowering at a time when bold masses in such situations are most desirable. It is not difficult to raise from seed even in the open; space cleared round the parent plants at seeding time will produce thousands of young plants the following spring, and these will be ready to flower the second year. There is a white-flowered variety of this Gentian, also a very desirable plant, either for growing separately or in company with the blue one. When well intermixed the effect of the two together is most charming, both being about equal in size and habit. Choice of situation is not, however, the least important item as regards its cultivation. It loves shade, in which, if not so dense as to draw and weaken it, it does much better than in places exposed to full sunshine. Attention to watering in dry weather is also essential; it is apparently very susceptible of drought, losing all its lower leaves and becoming unsightly. With us it grows generally from 2 feet to 3 feet in height, but it not unfrequently reaches 4 feet under favourable conditions. It is a useful plant for cutting purposes, its flower-sprays lasting a considerable time in water. It is a native of Southern Europe, and flowers in July and August. K.

Flower-spray of Gentiana asclepiadea.

Hardiness of Eucomis punctata.—Although generally grown as a greenhouse plant, there can be no question as to the hardiness of this Eucomis. We left a quantity of it out in the open ground last winter when the soil was frozen so hard that ordinary kitchen garden tools could not penetrate it for weeks together, and I thought this spring to find the Eucomis dead. All the plants of it left, however, shot up with extraordinary vigour. The long rest seemed to have done them good; their large tufts of foliage now have a fine appearance, and I may add that the fragrance of the tall flower-spike when in bloom in autumn makes this plant a welcome addition to the flower garden.—J. G., *Hants.*

Plants for dry banks.—I am frequently reminded of the suitability of Marigolds for dry banks where the soil is poor, and where little else will grow, by seeing large masses of them at railway stations and similar places. Where these homely plants once get a footing they soon spread and reproduce themselves year after year from seed with but a tithe of the attention which other plants require. Nasturtiums are also especially well suited for similar spots, and some of the most brilliant masses of colour I have ever seen have been produced by Antirrhinums. The latter will even grow on old walls where scarcely any other vegetation besides Wallflowers can exist. In fact, there is abundant material to make any desert spot of this kind blossom as a Rose. The only secret in the matter is getting the plants well established during the moist, rainy months of autumn, and not to attempt any transplantation between May and October.—J. G. H.

Delphinium Cantab.—I have a fine plant of this 7 feet high, more than 3 feet in diameter and carrying about 35 flower-stalks; these, however, have this defect, the blooms are not continuous; some appear at the top, others low down on the stalk with a hiatus between them like that in Osmunda interrupta. Is this defect a peculiarity belonging to this variety? all my other Delphiniums are right as regards this point. I should add that my Cantab is in rich deep soil and in full sun, and what blooms there are are of large size. Last season I attributed this hiatus to the work of slugs or snails, but careful examination satisfies me that the flowers were never formed in the bare parts of the stalks; moreover, the plant made strong growth in March and April while slugs and snails were dormant. I find the best protection for Delphiniums and other hardy plants against these pests to be collars of zinc, either perforated or plain; these apparently slugs and snails will not climb. Much as has been written in The Garden in praise of Delphiniums, not one word more than they deserve has been said. I place them No. 1 amongst herbaceous plants, and of many varieties I have seen, I think that the sterile Belladonna is queen of the race. J. H. Thomas, *Belmont, Carlow.* *** Many think that Cantab is as fine as Belladonna, but it lacks its fine habit.—Ed.

NOTES ON HARDY PLANTS.

Pentstemon nitidus.—This produces large racemes of pale, but effective, blue flowers, a colour which would probably be better liked by many if it had not been inclined to purple; however, from their abundance and brightness this Pentstemon is not likely to want admirers; the stems, which are 1 foot high, are full of blossom from bottom to top. The plant is very dwarf, indeed almost flat, and when not in flower suited for association with the smallest and neatest of alpines. It is more especially a satisfactory species because it is perfectly hardy. It hates stagnant moisture, however, and thrives best on a raised bed of rich soil, or on rockwork.

P. humilis is even dwarfer than the preceding, but the individual flowers are larger and of a lovely shade of sky-blue; they are also more laxly produced on the stems, which are about 6 inches or 9 inches high. I potted a small quantity of this Pentstemon in the same manner and in the same compost as that used for Auriculas, and one could hardly wish for better results. The little pots stood out of doors, but plunged in sand all last winter, a test surely severe enough to indicate its hardiness. There is a disposition now-a-days to overlook Pentstemons owing to their tenderness, but the two kinds just referred to should surely form exceptions.

Wireworms in pots.—It is good practice to closely examine and hand-pick all composts that are to be used in pots; but, careful though we may be, some will escape notice. In about a week after they have got into the pots they work their way to the sides, and there they remain until the ball of soil begins to get consolidated. It is, therefore, only necessary to carefully turn out the ball and examine it well all round, picking off such wireworms as may be seen. Then put on the pot cap-fashion again, and let this examination take place as often as wireworms are suspected to be in the pots. In the case of the Dianthus family, and, I should say, wherever a deal of rather fresh turfy loam is used, every means should be tried to free the plants from this deadly pest. I have invariably found the most marked instances of wireworms at the pot sides in cases where new pots have been employed.

Hippocrepis helvetica.—This is even a more free bloomer than the better-known H. comosa, and, if possible, the flower-stems lie closer to the ground, and being longish a small plant affords a broad gay patch of bright yellow. Its flower-heads are fuller than those of comosa, and altogether this little plant is worth noting by those in search of neat and free-flowering rock plants.

Veronica Lyalli.—This is a newly imported dwarf shrubby Speedwell of doubtful hardiness. I left a number of well-established young plants of it out all last winter; they were plunged in sand early in the previous summer, and their roots had gone down into that material. In spring the plants had the appearance of being dead, but early in May they began to push new shoots through the soil, and in one or two instances from higher up on last year's wood; these growths are now all tipped with lovely lax sprays of flowers. The latter are large, somewhat bell-shaped, and of a pale mauve, prettily veined. We have therefore in this miniature shrub a distinct and beautiful Speedwell, quite as hardy as parviflora, pinguifolia, buxifolia, Traversi, and chathamica, and more hardy, according to my experience, than Hulkeana, epacridea, and anomala.

V. glauco-cærulea.—The leaves of this resemble new lead in colour. I have not tried this Speedwell in the open, but the roots have been frozen hard in a cold frame; there, however, the extra dryness would prevent the frost being so harmful as when they were exposed to all weathers. It must never be forgotten that wet kills many plants when dormant which dry cold would not kill. I assume that all these new New Zealand Speedwells are not hardy in this country until we have thoroughly tested them.

Saxifraga Cotyledon and its varieties.—The form pyramidalis is perhaps more grown and better known than the type, its more symmetrical panicle and larger flowers entitling it to that distinction, and of late years it has come into use pretty generally for conservatory decoration, as well as for borders. Now, however, there begins to be many inquiries for the pure white form, and of course the original plant is coming into favour, as it is without the reddish colour on the petals and a better white; but, as already stated, the panicle is less in size and the flowers fewer in number than those of pyramidalis, and, moreover, the petals are much narrower, all of which detract from the otherwise bold flower-spike. For the improvement in colour, therefore, something will have to be sacrificed. Another charming form of this species, raised and grown by the late Mr. Niven, of Hull, is called S. Cotyledon gracilis. Its rosettes are smaller, the leaves more leathery, of a deep green hue, and without the silvery exudation, except in the regular small round cavities on the edges of the very blunt foliage, and thus situated on dark green they have a distinct effect in the way of an even setting of minute pearls. Its blossoms are pure white, and thickly borne on a stem of from 8 inches to 12 inches, feathered down to the rosette. It is by far the most useful form for rockwork, being dwarf and stout in the flower-stem, and not liable to topple over like pyramidalis. Whether in or out of flower, it is a distinct and desirable Saxifrage. The only drawback which it possesses is the fact that it is rather wanting in hardiness in some soils, and of all the Saxifrages I grow, or ever did grow, it is the most difficult to perpetuate. The best place is under a dry west wall on a thin layer of sandy loam over plenty of dry rubble. So situated, it may be called hardy, but even then it increases very slowly indeed. I have nearly lost it several times within the eight years I have had it. I now give it no other than outdoor treatment.

Grubs and alpine plants.—As I have before pointed out, the smaller alpine Pinks may be lost in a wholesale manner from grubs, which may never be seen, unless sought for. The other night a most noticeable proof of grub ravages was witnessed on a favourite alpine of the same Natural Order, viz., Lychnis Lagascæ. This, I believe, fails to give satisfaction in many gardens, owing to the way in which it is attacked by grubs. I find that grubs also attack alpine Wallflowers and the finer Arabises, such as the variegated lucida. What I saw in the case of the Lychnis was this: looking over a batch of healthy seedlings in the stillness of a warm summer evening, I saw five or six little plants agitated in a box of, say, 100; they moved in jerks and half circles; the cause was at once suspected, from having seen similar movements in the centres of Pinks. There was found in each little plant a brown headed grub one-eighth of an inch long, and very leathery and strong, but there were others not so large and greenish white. Each plant that moved was injured; the leaves and stems had been eaten on one side, then the grubs reached the heart, and the whole plant toppled over. We have sometimes called this damping off. The signs by which the presence of this grub may be known are the disappearance of one side of the plant, the grey skins of the leaves being drawn together towards the crown, and so serving as a sort of covering for the grub. The early action of this grub may be known by brown patches or streaks on the leaves and in the stems of the younger parts as they come into existence. The only remedy I know of is that of hand-picking, removing the leaves entirely where the grubs are seen to be boring between the skins, and poking with a toothpick among the dead material in the heart of the plant for the strong grub which saws off the top parts from the roots. There can be little doubt that these grubs are a chief hindrance to the successful culture of some plants which we have deemed hard to grow.

Silene quadrifida.—This is a little less in all its parts than the favourite S. alpestris, but it has a much more compact habit. This glistening pure white and starry-flowered alpine is worth attention; seen in a pan as kindly sent to me by Dr. Appleton, it strikes one as eminently suited for the exhibition table, and the pale or apple-green herbage further enhances its effectiveness. Among hundreds of other alpine plants this Catchfly stands out as one of the best; it delights in hot sunshine and may be made a good deal of, for it flowers for many weeks.

Genista radiata is not an unknown plant, but considering its pleasing habit, distinct form, and free blooming properties, it is odd that it is not more used on sunny rockeries where it loves to grow than it is. Even where the rockwork is on a small scale it may be used with good effect; it is only needful to strike a few cuttings of it annually; the first year they make neat and graceful plants 9 inches or a foot high and as much in diameter, and the second season they are bright with blossom. They may then be pulled out if getting too large for their places, but so satisfactory will they most likely have proved, that to pull them out in their prime will take a little courage.

J. W.

TREES AND SHRUBS.

TREATMENT OF SHRUBBERIES.

This is a hackneyed subject, but all has not been said, by any means, that can be said about it. As to soil and situation, any ordinary good soil will suit a great variety of shrubs well enough—viz., Rhododendrons, Azaleas, Laurels, Hollies, dwarf Conifers, Yews, Roses, Weigelas, Brooms, Furze, Daphnes, Kalmias, Junipers, Pyracanthas, Pyruses of several sorts, Box, Euonymus, Barberries, Bays, Aucubas, Spiræas, Lilacs, Ribes, tree Pæonies, Syringas, Jasminums, Guelder Roses, Forsythias, Elders, Deutzias, flowering Cherries and Plums, Laburnums, Acers, Laurustinuses, Lavender, Clematis, Honeysuckle, Ivies, Wistarias, Ampelopsis, and Brambles, &c.—nearly fifty species or distinct varieties, without including the numerous fine kinds of Rhododendron and Azalea, both of which should enter largely into any collection of shrubs. All the above, I am certain, grow in ordinary loam, a soil in which mostly all kinds of garden crops succeed. It is not the fault of the soil in many cases that shrubs do not thrive, but the treatment they receive otherwise; and it is a good plan to plant a good variety, as some species are sure to find a suitable home on the spot, and develop accordingly. Presuming that the soil is moderately deep and well drained, it will answer well enough. I do not approve of a deep soil for shrubs that are expected to live long and flower, nor is such a soil needed. It is not depth of soil that is wanted so much as head room and light. All the above will grow strongly in 9 inches of soil, provided it is occasionally mulched on the surface with refuse manure, and that dead leaves are not annually cleared out from under the bushes. But the main point is to give room and light. It is hopeless trying to grow anything successfully under tall shady trees. In such positions they are starved at the root, and killed by drip and darkness at the top. When it is necessary to plant such spots with shrubs, Hollies, common Rhododendrons, Yews, Privets, and common Barberry are sufficient; but it is perfect waste to put select shrubs in such places. All named above will thrive on east, west, and south aspects, or in the open, and make fine specimens individually, but they must have full exposure. They will then ripen their growth, better endure severe winters in consequence, flower more freely, and always look better, because a bush that has plenty of light and air always makes the most even growth and finest foliage.

Planting shrubberies.—A needful preparation for planting is digging the soil; trenching 18 in. deep is preferable, but if the soil is well turned over by a good full-sized spade in the hands of a good digger, that will be enough. A proper digging spade is about 8½ inches wide and 12 inches long, and the nearly straight-handled and bladed Scotch spade is the best. Ground that has never been dug before, although perhaps ploughed, should always be at least dug deeply to make the surface soil of an uniform depth, and a single digging deep and straight will make a nice tilth for planting. Should the soil be heavy, plenty of light leaf mould, manure, or peat should be dug into the surface at the same time. The best time to plant is in October or in November, and the earlier the better. Some shrubs will not be ripe enough to lift at the end of September, but many will, and deciduous shrubs especially may be got and planted then, if the young wood is ripe and firm, no matter if the leaves be green. These will fall off a little earlier from the check, but the bush will make a much more vigorous start in spring than if moved later. All planting should be finished by the middle of November, and if preparations are made in time, it is just as easy to finish then as not. Moderate sized young shrubs are best, and so long as they have good roots, and are not taken up in frosty weather or left long out of the soil exposed to the air, it does not matter about their having balls of soil attached. After planting, it is an excellent plan to mulch the surface with half-decayed leaves, or loose, light, half-rotten manure. It keeps the roots safe from frost—a consideration of some importance the first winter after planting, and it insures good growth the summer following.

Habits of shrubs.—It is necessary to know something of this in order to manage the bushes rightly. Of Rhododendrons and Azaleas little need be said. Both make tall and broad bushes of even outline, filling up densely down to the ground all round when not too thickly planted, and they need no pruning. Rhododendrons, when they encroach on walks and have to be cut back periodically, never flower at that part; hence the best plan is to plant them far enough back at first, so that they will not encroach beyond the desired point. The lower limbs root into the soil, and among the leaves that fall annually and rot on the ground; and such bushes in the course of years attain a large size. The Weigela is another subject that makes a fine specimen by itself under favourable conditions. It throws up strong shoots annually from the root, and the older ones branch out freely, creating a compact bush 6 feet or 7 feet high and as much through, and under ordinary circumstances covered with flower. The plant grows freely north and south, but it flowers best where it has a warm soil and exposure, as it then ripens its wood properly. In June and July Weigelas of different sorts ought to be amongst the most showy and ornamental shrubs in the garden. They should on no account be pruned. Another fine shrub is Berberis Darwini. In a few years a plant from a layer makes a bush about 6 feet high and 8 feet or 10 feet through—a dense, dark green mass in winter or when not in flower, and always covered with a profusion of rich golden flowers in spring. A fine July and August shrub is the comparatively little known Deutzia crenata fl.-pl., which, if planted in any common soil, grows as high as a Currant bush or higher, and produces thousands of fine white double blossoms, which last much longer, either on the bush or in a cut state, than those of the single variety. Plants taken up and potted in autumn force freely, and look even better in pots than outdoors, the foliage and flowers being of a purer colour. It should be freely planted and never pruned, unless it be to remove weak or old branches to make room for the strong shoots that push up annually. All Deutzias, Ribes, Lilacs, Syringas—in fact, we may say most of the species named—should be treated in the same way, as the whole of them only manifest a disposition to flower profusely, or at all, when the strong branches have run out their natural length and become twiggy. Care must be taken to prevent crowding. It is right enough to plant thickly at first, because the thinnings will transplant readily in another two or three years, and be better than newly bought plants for extending shrubberies, but thinning out must be attended to in time. J. H.

SPIRÆAS IN FLOWER.

The most select of these beautiful shrubs in bloom now are the following: Spiræa ariæfolia is a free, bold-growing shrub—indeed, one of the stoutest of the Spiræas. The flowers are, when first expanded, of a creamy white colour, and though they become of a purer tint afterwards, are never thoroughly white. The large feathery terminal panicles in which they are arranged render a specimen of this kind, when in full bloom, a most beautiful and graceful object, and one very different from all other shrubs in flower at the same time. This species has in some places been in blossom for weeks past, while in others it is just now at its best. S. Douglasi forms a mass of closely-packed shoots, each terminated by a dense spike of pretty rose-pink coloured blossoms. It is a most beautiful shrub, and will flower for months together. Of this the different individuals vary a good deal in the colour of the blossoms as well as in the quantity of pubescence on the foliage. S. salicifolia, in general terms, may be said to resemble the last in many particulars, but the foliage is glabrous, and the colour of the flowers varies from whitish to pale pink, never being of so deep a hue as S. Douglasi. What is commonly regarded as a variety of this, under the name of S. salicifolia paniculata, has the blooms arranged in large branching panicles, and their colour is pure white. It is certainly very distinct from the type, and is well worthy of a place among the best. S. trilobata is a neat, compact little shrub, at most reaching a yard in height, and is now covered with small flattened corymbs of pure white blossoms. The habit of S. callosa is that of a somewhat open bush, with pointed foliage and branching corymbs of bright rosy red coloured blossoms. It is very effective from the rich hue of its flowers, which are almost rivalled in colour by the young leaves and shoots. S. sorbifolia is a stout-branched shrub, very prolific in the production of suckers and clothed with pinnate foliage, thus suggesting the name of sorbifolia. The flowers are borne in loose terminal panicles, and are of a whitish hue. There is a variety known as alpina, Pallasi, or grandiflora, which is dwarfer in habit than the species, but with larger flowers, which are pure white in colour. This pinnate-leaved Spiræa and its variety especially need a cool, moist spot, for they are natives of Siberia, and therefore, unless so situated, the hot dry weather generally experienced during summer is apt to try them very much. An extremely pretty Spiræa, and one just now at its best, is S. splendens, which is, I believe, of garden origin. It is of dense bushy growth, reaching a height of about a yard, with terminal clusters of rich reddish pink coloured blossoms. These blooms are borne in dense flattened heads, and in such profusion that a specimen of it presents the appearance of one mass of flowers. H. P.

The Azalea season.—Hardy Azaleas, in my opinion, surpass even the Rhododendron in several ways. Their flowers are more enduring; they are delightfully fragrant, and of rich and varied colour. At this season they are the most conspicuous dwarf flowering shrubs in our long hardy plant borders, and we only wish we had more of them. With the comparatively new Azalea mollis—which, however, is quite scentless we have now crimson, rose, white, purple, light yellow, deep rich yellow, orange, red and white, besides intermediate shades; and when a mass of varieties is in flower together, with the young and tender foliage just bursting the buds at the same time, I question if we have any shrub, or mixture of shrubs, that could produce an equally fine effect. Rhododendron planting has monopolised the gardener's attention hitherto, almost to the exclusion of the Azalea, which I strongly recommend for garden borders and shrubberies. This shrub possesses a value which the Rhododendron does not; it is one of our most ornamental foliaged plants in autumn, its leaves almost rivalling the colours of its flowers in spring; it presents the richest shades of crimson to be found among autumn tints, some varieties assuming the true hue of the Japanese Virginian Creeper, while others are of the richest crimson. To produce an effect, however, either in summer or autumn, a good mass of the different varieties should be planted together, either in beds or clumps. In the trade these Azaleas are known under the name of Ghent and English Azaleas; and the Japanese variety mollis resembles them in every way, except that it has better formed and more varied coloured flowers. All are deciduous, and flower before the leaves push, or contemporaneously with the breaking of the leaf buds. Some of the white varieties produce flowers with the leaves, and all late; they are also amongst the best.—J. S.

Genista elatior.—Every season numbers of large bushes of this Genista, especially in the vicinity of the Pagoda at Kew, are the admiration of everyone, and deservedly so, for they flower so profusely as to be quite a mass of bright yellow blossoms, which seem to light up the Laurels, Rhododendrons, and other subjects with which they are associated. As a flowering shrub, this Genista, indeed, should occupy a prominent place, yet, strange to say, though the specimens under notice have been in their present position for years and are so much admired, it is quite a scarce shrub, and is seldom or never planted for ornamental purposes. Its propagation is of the simplest, as seeds are freely produced, and grow readily enough.—T.

Philadelphus speciosus.—With the long list of Mock Oranges to be found in various catalogues the selection of one or two is rather puzzling, but to anyone needing a thoroughly good form perhaps the best is P. speciosus—at all events it will not prove a source of disappointment, for it forms a handsome bush, is most prolific in bloom, while the individual flowers are large and of the purest white. A specimen of this kind when in bloom points particularly to its value as a lawn shrub, for it is of pleasing outline (in no way stiff or formal) and will thrive in drier spots than many other shrubs. A specimen here of the pretty little P. microphyllus, with small Myrtle-like leaves and flowers about as big as a shilling, is growing with greater freedom than it hitherto promised to do, for shoots nearly a yard in length are pushed up from the base, and the plant is still in full growth. Altogether it is a neat little shrub, and its conspicuous blossoms are just commencing to expand.—H. P.

Calycanthus floridus, or Carolina Allspice, as this is called in North America, is a very ornamental hardy shrub, and one very dissimilar from most of those in cultivation. It forms a rather compact-growing bush, with deep green leathery foliage, and peculiar fleshy flowers borne in the axils of the leaves. The blooms are about 1½ inches in diameter and agreeably scented; indeed, the wood, bark, and leaves all emit a pleasant odour when bruised. The foliage is deciduous, so that it possesses no special attractions during winter; but in summer, from the fragrance of its blossoms and ornamental foliage, it is well worth the attention of planters as a desirable shrub where strong-growing subjects would occupy too much space. A fairly cool, moist spot seems to suit it best, but it is not very particular as to soil or situation. There are several varieties of it, but a strong

family likeness runs through the whole of them therefore, unless for the purpose of forming a collection of them, one or two kinds will suffice. The Carolina Allspice is nearly allied to the sweetly-scented Japanese Chimonanthus fragrans.—T.

LATE-FLOWERING THORNS.

Though the majority of Thorns are now out of flower, some of the latest are still in bloom. The Tansy-leaved Thorn (Cratægus tanacetifolia), of which a coloured plate was given in The Garden last year, is a desirable late-flowering species, which, from the hoary character of its deeply cut leaves, can be readily distinguished from all others. It forms a stiffer-growing tree than the common Hawthorn, and the individual blooms are larger, though borne in rather smaller clusters. They are, however, produced so freely that a tree of this species in bloom is as white as a sheet. The Cockspur Thorn (C. Crus-galli) and its numerous varieties, though rather past their best, are still in flower; the different forms of this Thorn have glossy foliage, which contrasts strikingly with that of the preceding. The varieties of the Cockspur Thorn differ widely from the large bold-growing C. arbutifolia and from the tabuliform-shaped C. linearis. This latter often pushes out its branches in quite a horizontal direction. The Fire Thorn (C. Pyracantha) is now blooming most profusely; indeed, a specimen here raised from a cutting of the variety called Lælandi is quite a mass of white. The North American Heart-shaped Thorn (C. cordata) is a free-growing kind, and forms a handsome small tree with deep shining green foliage, while in autumn the fruits, though small, are very bright. Another American kind now in flower is C. pyrifolia, whose large clusters of white blossoms are now at their best. This forms a medium sized tree, with, especially in the case of young vigorous specimens, unusually large leaves. Of quite a different character from any of the above is C. parvifolia, a much branched bush about a yard high, with dark green ovate leaves and solitary flowers, with which it is thickly studded. In some specimens the flowers are nearly an inch in diameter; their large size and the dwarf habit of the plant render this Cratægus very distinct from any of the others; indeed, it resembles more a dwarf form of Mespilus grandiflora than a Hawthorn. The last I will mention is one that has been in flower a long time, and of which a woodcut illustration recently appeared in The Garden—viz., a variety of the common Hawthorn known as C. Oxyacantha semperflorens. This forms a much-branched dwarf shrub, and flowers more or less continuously throughout the summer months. In miniature gardens it should find a home. H. P.

Magnolia fuscata.—This Chinese Magnolia needs the protection of a greenhouse, or in specially favoured spots the protection of a wall, to enable it to pass through our winters without injury, and, generally speaking, it blooms better under glass than in the open air. The best treatment for it is that which suits Camellias. Its flowers are in no way showy, and being hid, as they are, under the foliage, renders them still more inconspicuous, but their fragrance is such that even a single bloom will fill a whole house with an agreeable odour. The flowers are purplish brown in colour. Another point in favour of this Magnolia is the fact that it will often bloom for months together throughout the summer, and even small bushes of it will flower, especially those propagated by means of cuttings or grafts. Unlike some other Magnolias, this one is not difficult to increase by cuttings, formed of the half-ripened shoots, dibbled firmly into pots in open sandy soil, and kept in a close case till rooted.—H. P.

The Mexican Mock Orange.—This somewhat rare shrub (Philadelphus mexicanus) is well grown by Mr. Walker, of Thame, who lately sent us some flowering sprays of it. It is a good deal like the common P. coronarius, but the flowers are smaller, more numerous, and arranged in less crowded clusters. They are, moreover, devoid of the strong perfume which some think objectionable in the Mock Orange. P. mexicanus is, unfortunately, not hardy, but it makes a pretty greenhouse shrub for flowering in early June. Mr. Walker tells us that he places the pots out of doors during the summer, standing them on bricks or tiles to prevent the roots from protruding to the soil below. About November he takes the plants to the greenhouse, where they never fail to make a beautiful display.

MARKET GARDEN NOTES.

After a vegetable famine of more than ordinary duration, it is cheering to find once more a full supply. Potatoes have, however, been fortunately both good and cheap all through the year. Old kinds are now nearly over, but new ones are already plentiful. The greatest demand at first is for kidneys, especially the Ashleaf, Walnut-leaf, and Myatt's Prolific; these are firmer and have a better flavour than the early American kinds, but the latter fill the baskets quickest; and in towns American Rose, Beauty of Hebron, and similar kinds, if cheap, supersede the kidneys, and are cleared off in time to allow a crop of autumn Cauliflowers or Broccoli to be taken off the ground. Cabbages are now good and realise fair prices, the difficulty of getting plants in spring having prevented planting to such an extent as to cause a glut in the market. Cold frosty winds in March made plants scarce in this locality; they got partially uprooted and withered up.

Lettuces, both Cos and Cabbage, are plentiful and good. The custom of sowing thinly and avoiding transplanting is now very generally followed, the small extra outlay in the way of seed being more than counterbalanced by the saving of labour effected and the quicker turning in of the crops. Paris White Cos and All the Year Round Cabbage Lettuces are good old sorts. Vegetable Marrows are now making rapid progress; they like plenty of heat. I find the Bush Marrow to be hardier than any of the others; where both kinds were put out at the same time plants of the Bush variety are now coming freely into bearing, while the others have made but little progress. Winter Broccoli, Kales, Savoys, &c., are now being planted as fast as ground can be got ready for them; the prospects of another dry season like that of last year make growers anxious to get their plants out before the soil loses its moisture. Sowing of main crops of Cabbages is now claiming attention; Early York, Wheeler's Imperial, Early Rainbow, and Early Fulham are the sorts in most request. James Groom.

Gosport.

Hæmanthus insignis and H. cinnabarinus are beautiful flowering plants which should be grown in every garden where there is a warm greenhouse, both species requiring a little extra heat when making their growth, though during summer an ordinary greenhouse or frame would suit them. H. insignis has about a dozen leaves with folding bases forming a kind of stem or neck. The flower-spike is pushed up near the side of this neck from between the bulb-scales, and it attains a height of about 8 inches, its large spherical head of cinnabar-red flowers measuring 6 inches across. The flowers are packed very closely together and are composed of narrow segments and long stamens, the latter being the attractive part; the anthers are pale yellow. H. cinnabarinus belongs to the same section, but its leaves are broader and longer, and its flowers are not so numerous nor so closely packed on the scape. In these the petals are 1 inch long and a quarter of an inch wide, and the stamens are very thick and curved; their colour is pale scarlet. Both these plants are now in flower at Kew, as also is H. Kalbreyeri, a crimson-flowered tropical species, and H. albiflos, which, as the name signifies, has white flowers.

Phaius bicolor.—This handsome plant is now in fine flowering condition in the Orchid house at Kew, where it has been in cultivation for a long time, but has never attracted the attention of Orchid growers as much as it should. Of the section of the genus represented by the stately P. grandifolius and P. Wallichi it is by far the most desirable kind, its flowers being large in size, numerous on the stout tall scapes, and lasting much longer than those of any other species of Phaius. The spikes are 4 feet long, and bear each a dozen or more flowers; these have the sepals and petals arranged regularly like a fan, and 2 inches in length; their colour is pale green at the back, pale chocolate in front. The lip is cucullate, spreading at the top, and crisp edged, whilst the base is narrowed and formed into a hooked spur. The tubular portion is pale yellow, whilst the spreading part is wholly pale magenta. For its cultivation this species requires the same treatment as its near relatives named above. It is a native of Ceylon. The chief points of interest in this kind are its flowering season—June to October—its lasting character, and the beauty of its colours. Of course, it is not so gorgeous a plant as P. tuberculosus, but it is superior to it in its free and vigorous habit.

Garden Flora.

PLATE 552.

CISTUS LADANIFERUS MACULATUS.*

Of all the species of the genus Cistus—Bentham and Hooker estimate the number of those which are specifically distinct at about a score—C. ladaniferus is one of the most beautiful and bears the largest flowers. The type, which seems by no means common in gardens, has white flowers, each petal being tinged with yellow at its base; in size, too, they are larger than those of the variety here figured. The accompanying plate represents the variety maculatus, which differs principally from the type in each petal being marked at its base with a rich dark brownish crimson or blood-coloured blotch. C. ladaniferus is a native of South-western Europe, and the name was given it by Linnæus under the mistaken impression that the plant yielded the labdanum of commerce, a medicine largely used during the prevalence of plague. Labdanum is in reality obtained from C. creticus and other species from Crete, Cyprus, and the Levant. Most of the Cistuses, or Rock Roses, thrive best in dry sandy soil, and under such conditions withstand much better the severity of English winters than when grown in rich damp soils. Seeds are ripened freely enough in most seasons, but the readiest method of propagation is by cuttings. A somewhat full account of all the species of Cistus in cultivation is given in The Garden, Vol. XXVII., p. 570.

Geo. Nicholson.

Thunia Marshalli.—This easily grown and very free-flowering plant deserves to stand as much in favour as a garden plant as the Calanthes, for it is as beautiful as any of these, though perhaps not quite as lasting. A few roots planted in good turfy loam and manure and placed in a moist stove to start will make stems 2 feet high in about three months, when each stem will bear a large pendent bunch of snow-white flowers with a richly marked yellow lip. After flowering the bulbs should be ripened by exposing them to bright sunshine and fresh air, a frame out of doors being the best place for them; they should then be removed to a dry place in a temperature of about 45° for the winter. They usually show signs of new growth about February, when they should be shaken out of the old soil and repotted. There is another very beautiful Thunia with coloured flowers. This is T. Bensoniæ, which has a habit of growth like that of Marshalli, but its flowers are smaller and of a soft lilac-rose colour.

* Drawn in Dr. Lowe's garden, Woodcote, Wimbledon Park, in July, 1885.

CISTUS LADANIFERUS VAR. MACULATUS

WORK DONE IN WEEK ENDING JULY 6.

June 30 to July 6.

A complication of circumstances having prevented the daily posting up of the diary, our notes of work done must be made from memory. On each and every day of the week the heat has been intense, and watering has been the one great item of labour, for, having a good supply, it has been put on without stint. Peaches, Apricots, Plums, and Pears on walls have had a fair share of it; so have flower-beds and Roses and indoor fruits a full supply. We mulch all borders with long litter or manure, and this aids in the keeping of the soil moist should anything intervene to prevent the application of water at the proper time. The restricted amount of labour has not admitted of our watering vegetable crops, except recently planted winter greens and Broccoli, which work has been compulsory to keep them alive. All these we plant in deep drills, a plan that enables us to water quickly with large-spouted pots, and as soon as well established the soil is filled in to the ground line, and thus forms a mulching that keeps the soil about the roots moist, and which, except in long-continued drought, renders further watering unnecessary. The fierce sunshine scorched a few Vine leaves and berries of Grapes in the latest houses; we therefore deemed it advisable to apply a slight shade of whiting and water, and no further injury in this direction has taken place. Free ventilation in the early morning, increasing it as the day goes on, will, as a rule, prevent scalding, but the conditions—sudden heat after a long sunless time—are this year so exceptional, that shading is no doubt the safest plan, and we have applied it to all houses in which the occupants were deemed likely to suffer from the sudden advent of such tropical weather. On the 3rd inst. we gathered Strawberries in quantity for preserving; a week previous to that date they were so late, that we did not anticipate their being fully ripe for another fortnight: this will indicate how suddenly summer has come upon us, and how necessary it is to take precautionary measures in respect to shading to prevent injury, either from scorching or lack of root moisture. Red and Black Currants, also Raspberries, will a few days hence be quite ready for gathering, and meanwhile we have been compelled to net them over to preserve them from birds. Previous to netting the new growths were partially thinned out to admit of all fruit ripening alike, and to let in daylight to all parts of the bushes, which will aid the ripening of the wood, and at the same time contribute to longer preservation of the Currants should rainy weather set in. As regards Raspberries, we gather all fruit as soon as ripe, and rely for successional supplies on an autumn fruiting variety. Pulled up suckers of these, and only left sufficient new growths to furnish the espalier fence to which the new canes are to be tied next winter. Layering Strawberries; about half our quantity, all Vicomtesse Héricart de Thury, is now finished. They require watering twice a day, for, though the pots are plunged in the soil beside the mother plants, the bulk of soil in pots is so little that it rapidly dries up, and if once it gets very dry, root formation is a very slow process. Cauliflowers have shared alike with fruit in rapidly attaining maturity, and to keep up regular supplies we have lifted some and put them in a cool shed, with their roots in water. Cleared off Lettuces, and exhausted stocks of Peas and Spinach, and the ground, having been hoed and raked, is now ready for sundry kinds of winter greens as soon as rain comes to admit of our planting them out. Staked Dahlias, and pegged down a few of the most branching and dwarfer of the single varieties that we use in the summer bedding arrangements, in which garden, too, we have completed most of the pegging down of the plants that form the framework of designs, and have again clipped all edgings of Herniaria, variegated Thyme, variegated Alyssum, and picked the flowers off Stonecrops and Saxifrages. Sowed under handlights on a south border Brompton and East Lothian Stocks, Pentstemons, Antirrhinums, Canterbury Bells, Delphiniums, and Wallflowers. Made the last sowing of Sweet Peas for this year, and off our earliest batch all the flowers and seed vessels have been picked, also the points out of the haulm, which, combined with the mulching of manure and soaking of water that we hope to apply soon, will give them a new lease of life. Tying out bush Chrysanthemums, potting on winter-flowering Carnations, Bouvardias, and tuberous Begonias have also to be included in the work of the past week.

Hants.

FRUITS UNDER GLASS.

The Orchard House.

When the late Mr. Rivers commenced growing Peaches and Nectarines in pots under the shelter of his hedge orchard houses, he little thought the early varieties he was about the same time raising from kernels would be the first instead of the last to ripen their crops of fruit. Such, it appears, is now the fact, as there are not a few gardens in which the hedge orchard house has been superseded by a light, elegant, efficiently heated structure, from which the earliest fruit of the year is gathered, and the original Peach houses are allowed to come on later and keep up a running supply until the end of October. Where size, colour, and quality must be unsurpassable, the old lean-to or span roof with trellises 16 inches to 18 inches from the glass will always stand first, and few gardeners who know the cost in time and money of erecting and establishing bearing trees in a good lean-to would willingly convert such structures into orchard houses. Modern houses in modern gardens are, however, constantly springing up in different parts of the country, and many good cultivators for two reasons now approve of having at least one house fitted for the culture of Peaches and Nectarines in pots. In the first place, handsome pyramids and bushes of all the leading early kinds can be purchased at a cheap rate ready for starting on the day the house intended for their reception is finished, and ripe fruit in plenty can be gathered from them long before the anniversary of laying the foundation brick comes round. This, when time is of more importance than money, is a great gain and a good reason for embracing pot culture. In the second place, the system enables the fruit grower to keep pace with the times by making himself acquainted with the new varieties whose names are distressingly numerous, and to thoroughly test a great number under pot culture before he condemns or honours them with the chance of a twenty years' lease on the orthodox trellis. Forty years ago our best early Peach was Early Anne; then came Acton Scott, Early Rivers, Early Alfred, Early Albert, Early Beatrice, Early Louise, and others, whose chief recommendation was their extreme earliness. All of these I have grown, but for reasons which it is unnecessary to explain they have been given up, the last to go being Early Louise, and better varieties have been allowed to extend, or in other ways take their places. The next batch included Alexandra Noblesse, Crimson Galande, Doctor Hogg, Magdala, Rivers' Early York, A Bee, Early Grosse Mignonne, Hale's Early, Stirling Castle, and many more, but these I have thoroughly tested, still grow, and should duplicate to any extent if refurnishing. Of recent introductions, we have Amsden June, Alexander, and Waterloo, extra early varieties. The first two I have tried on walls and under glass, but their tendency to become adhesive and their thin watery juice render them useless to me. The third, I am told, is really first-rate, but I have not tested or even purchased it. With me, on a good heavy loam, which grows Roses and Strawberries well, the following new and old varieties are special favourites, and, like the Scotchman's ox, bad to beat: A Bee, Grosse Mignonne, Early Grosse Mignonne, Large Early Mignonne, Belle Beauce, Belle de Doué, Bellegarde, Barrington, Crimson Galande, Doctor Hogg, Dymond, old Noblesse, Alexandra Noblesse, Magdala, Royal George, Sea Eagle, Stirling Castle, the Nectarine Peach, Walburton Late Admirable, Violette Hâtive, Hale's Early makes up an even score, but I have not yet been able to join in the high praise which it has received, as it is greatly inferior to A Bee and the Mignonnes. Nectarines, fortunately, are not so numerous as Peaches, but Sawbridgeworth has swelled the list, and some of the new varieties are very fine and great acquisitions. Taken alphabetically, I can recommend the following: Advance, Albert Victor, Darwin, Elruge, Hardwicke Seedling, Humboldt, Murrey, Pitmaston Orange and its offspring Pine-apple, Lord Napier, known and grown by everybody, Stanwick Elruge, Violette Hâtive, Victoria, under glass. Growers who appreciate the delicious Stanwick flavour should grow the first and last, also Darwin, Improved Downton, Milton, Newton and Spenser. Some, I may say all, of the new race of Nectarines having been raised by crossing older varieties with the Stanwick or Syrian blood, grow to an immense size; some taken from pot trees have weighed 8 ozs. to 10 ozs. each. They are free growers, hardy, rich in the peculiar almond flavour, never crack like the parent, and look like delicate models in wax when grown under glass. Few, very few, private growers cultivate half the varieties enumerated in the preceding list, but having drifted into the giving of names, I have made a selection from which the amateur may again select, or he may grow the whole of them, Peaches and Nectarines, without running the risk of getting a second-rate variety.

Cultural remarks.—Assuming that the amateur has forced a few of the earliest of these Peaches and Nectarines, and the fruit has been gathered, the question is, what is the best treatment to insure a crop from the same trees, not only another, but for the next score of years? Well, the main points for the present are thinning out old fruit-bearing wood to let in light and air, good syringing to keep the foliage healthy and free from insects, and liberal watering with weak liquid to fill up the flower-buds before the leaves fall. If in small pots and a shift is thought desirable it matters little how soon preparations are made for carrying out this operation, as the trees can then be kept under glass, well syringed, and shaded if need be, until the roots have taken to the new compost. When trees are merely shifted out of small pots into others a size or two larger the balls should be well soaked and divested of crocks and straggling roots before the compost, in a somewhat dry state, is firmly rammed about them. This ramming, be it borne in mind, is very important, as loose potting round a firm ball is the deathblow to many a good tree, and why? simply because the loose soil allows water to pass by the solid ball; the latter becomes dry and the tree dies. When firmly potted, a good watering carries the soil home to the roots and a rather close moist atmosphere, produced by light syringing and early closing with solar heat, speedily restores them to a growing condition. All the parts of a healthy tree being active, ten days or a fortnight in a moist, growing atmosphere will set them right, when, lest the prominent buds should start, more air and perhaps more water will be needed until they are fit for placing in the open air. When larger and older trees require reducing as a preliminary to repotting in the pots they have previously occupied, a little more care becomes necessary, as the operation is more severe; but the same rules apply, and, provided they are not over-watered and the house is kept moist, trees whose roots are completely washed free of old compost will speedily start into new root action.

Pots, crocks, compost.—The first and second should be quite clean and perfectly dry when they are taken into use, and a 12-inch pot will not be overcrocked with 2 inches of broken pots, bones, or rough charcoal placed over the drainage apertures. When firmly rammed with the potting stick and a little soot has been introduced to keep back worms, the pots may be set aside until the compost is ready. This may consist of heavy loam—if naturally rich and calcareous, so much the better; old lime rubble one part to five, and bone dust one to ten of the loam. If light and

very poor, marl and well rotted manure may be added, but soils which make good wood without the latter always answer best, as they contain nothing that can become sour or get out of order. It should be used in a dry, rough state, and very firmly rammed into the pots to prevent the possibility of water passing through without entering the old balls.

Fruiting orchard houses.—A most remarkable change having set in within the last few days, 80° in the shade with a cloudless sky, doors and ventilators may be set open to their full extent, and water in abundance through the hose must be spread over the floors and amongst the pots to keep the roots cool and the atmosphere moist. Let all root watering be performed every evening before the trees are syringed, and be guided by the period at which ripe fruit is wanted in shutting up and giving night air. Under any circumstances it is always well to err on the side of safety, as Peaches will now swell and colour to perfection in the open air, while those which are over-forced will be pale and flavourless if they do not ripen up when they ought to be commencing the last swelling. Now is the time to lay on the top-dressing or mulching, as trees in pots will take any amount of liquid food, and constant watering soon carries away not only the essence, but the substance also. As often as this disappears replace it with more from the store shed, and resort to pure water only when the fruit begins to show signs of transparency and a slight aroma is perceived in the house. If the trees in mixed houses are becoming crowded, I would suggest the removal of Cherries, early Plums and Pears to a suitable situation where they can be plunged in the full blaze of the sun in the open air. In a position of this kind they will take more water than would be good for them in a glass structure, as the atmosphere will be constantly drawing on the foliage, but heavy mulchings, which must be moistened with the hose every evening, will keep them clean, cool, and healthy, and the fruit will be perfect in colour and flavour.

Strawberries.

Where a regular system of putting out runners every year is not practised, and old beds are depended upon for stock, the supply for forcing will most likely run short; certainly they will be late, as this dry, hot weather is against old stools, which cannot be expected to perform double duty. A plentiful supply of water is, of course, a great help, but a dripping time is always most favourable to the production of vigorous runners, which root quickly and soon become fit for removal from the parents. Where the old system of layering into 3-inch pots is still in favour, the incessant watering which they will require will dictate the importance of getting them taken off as soon as they are fairly rooted, but why use small pots when much time can be saved and a better stock secured by pegging on the fruiting pots evenly and firmly filled with suitable compost? The transfer of young plants from small to large pots requires a certain amount of skill, as nothing can be more detrimental than loose or strangling potting; but once prepared, handy men or boys can fill the fruiting pots with compost, peg down the runners, and keep them supplied with water. Another advantage which should not be lost sight of is the elevated position, clear of shade, which the 7-inch pot gives over the small one, independently of the fact that a runner which sits on the top of the compost is always furnished with short petioled leaves and firm plump crowns whose colour and appearance give promise of early maturation and successful forcing. Plants in small pots we must have for making new plantations in August, and these can always be secured where Strawberry culture is conducted on the three or, at most, four-year system. The ground for my August planting was broken up two spits deep and manured in June. It is now well pulverised, and will give a successional supply of the finest Cos Lettuce throughout the season. The rows of Lettuce are sown thinly 2 feet 6 inches apart, and thinned to the proper distance when large enough. Deep tilth and manure enable them to set dry seasons at defiance, and they produce a certain amount of moist shade when the Strawberries are turned out between them. These remarks may be considered slightly digressive, but, knowing how difficult it is to keep up a good supply of large, crisp Lettuces in hot, dry seasons, this hint to some may be quite as valuable as a cut-and-dry Strawberry calendar.

Melons.

The weather of late has been all that the most fastidious Melon growers could possibly desire, and the plants in all stages and positions where they can enjoy the full blaze of the sun are making rapid growth and finishing very fine fruit. Where very late fruit is in demand, seeds of suitable varieties may still be sown and the plants grown with every chance of success, always provided they can have plenty of top and bottom heat turned on when the fruit is finishing. Late Melons should always be grown in pots or confined troughs placed immediately above the hot-water pipes for aiding the fermenting material when sharp dry heat becomes necessary. At all other times, especially through the early stages, well-worked Oak leaves, occasionally renovated, will keep the roots progressing, and the moist genial heat which they impart to the atmosphere, aided by early closing, will enable the grower to dispense with fires until the end of August. Melons of late having become so numerous, the choice of varieties adapted to early and late culture is sometimes a difficult matter, the more so as growers who save their own seeds know they cannot keep them true where a number of sorts are tested in the same house or even in the same garden. For many years I depended upon Improved Victory of Bath, a quick grower and a good setter, for my first and last crops, but this is now beaten out of the field in point of earliness, not in quality, by others which I have this season tested by its side. Last season I obtained true stock from Messrs. Veitch of an old friend, Golden Perfection, which I grew more than thirty years ago, and, being much pleased with it, I have again given it a prominent place in all my mixed batches. In my earliest house it was first to ripen, some of the fruits, the colour of virgin gold and beautifully netted, weighing 6 lbs. each, from 12-inch pots plunged in Oak leaves. Highcross Hybrid, a good Melon, but a bad colour, came in a few days later, closely followed by Reading Hero, a very handsome round, slightly flattened Melon in the way of Golden Gem. The netting is, however, broader and heavier, and the plant being a more compact grower and a free setter, its handsome appearance and medium size should secure it a prominent place with market growers. Several plants of these three varieties in my second house having already yielded ripe fruit, whilst Victory of Bath is still green and now netting, I can strongly recommend them for early and late use. For home consumption where quality is the true test of merit, Veitch's Golden Perfection with me carries the palm.

Pits and Frames.

The weather until quite recently has been the reverse of favourable to this mode of culture: indeed, for several years past good crops from frames have been anything but satisfactory. This falling off we now generally attribute to the elements, but it is questionable if a portion of the blame does not rest with the hot-water engineer, who has given us such facilities for the quick growth of Melons from May to December, and Cucumbers all the year round. This advance is a great boon to the majority of fruit growers, who have almost forgotten, if ever they had learned, the art of making up sustaining manure beds, but a few there are who must still plod along in the old groove or give up Melon growing altogether. To these I would say, put in your annual plea for cheap hot water, and if you do not obtain the grant follow up instructions contained in previous papers, and the brilliant weather we are now enjoying will yet lead to success. Do not allow a few fine days to interfere with the slightest detail, but keep up the heat in the linings by renovating the back and front alternately, and mat the lights as soon as the sun leaves them at night. Keep the frames clear of useless spray to give the main leaves and Vines the full benefit of sun-heat and air, fertilise all female flowers until a good set is secured, then pinch at the first leaf beyond the fruit, and be satisfied with fair crops which the plants can carry to maturity. If this fine weather continues, give a little air very early to let out impure gases and superfluous moisture; gradually increase it until a rising thermometer touches 85°. Manipulate and regulate before 4 p.m., and shut up with moisture and sun heat that will run up to 90°. When the fruit has attained the size of hens' eggs, elevate them on inverted pots until they can be seen peeping through the foliage, and feed liberally with diluted liquid by flooding without wetting the collars of the plants or foliage. On non-feeding days syringe freely with water at 80° to 90°, and shut up with full sun heat immediately.

Eastnor Castle, Ledbury. W. Coleman.

Fruit Garden.

GOOD STRAWBERRIES.

Could not someone with plenty of land and time at their disposal get together all the known sorts of Strawberries, whether of English, Continental, or of American origin, and test them thoroughly, especially with regard to the following points:—

1. Vigour or robustness of constitution.
2. Time of flowering, and also time of ripening. This would include also notes as to how the fruit coloured, and whether all the crop ripened equally well, there being a difference in this respect, some kinds ripening all the fruit off of a good size, others leaving a residuum of no particular value.
3. Size, texture, and flavour, these being the most important of all. At present, in many places too much praise is given to mere size. Very often large fruits are soft and flabby and travel badly, the last named point being an important one.

The owner or manager of such a Strawberry garden as this would be would soon become possessed of information that would benefit us all. New varieties might be raised in which the merits of the good old sorts might be blended with the greater size and robustness of constitution that modern kinds possess. Something might also be done to improve our alpine and Hautbois Strawberries.—E. Hobday.

The British Queen.

This would appear to be the most fickle of all known Strawberries, yet so superior is it in point of flavour that all who cultivate Strawberries ought to attempt to bring it to perfection. I have worked in gardens where it proved as profitable as any variety grown, and that, too, without any special treatment; while in the very next situation I held it could not be induced to grow or bear freely, and further experience inclines me to take the same view as "Taunton" does in The Garden (p. 2). In a fertile, deep, loamy soil it ought to thrive, but it does not always do so, and to succeed there would appear to be something special required in almost every garden. For instance, in a Sussex garden in which I was employed only the old plantations of British Queen were at all prolific, and the plants that yielded us most and best fruits were said to be twelve years old. They were kept well thinned out, and received annual rich surfacings of loam and manure, especial care being taken to mould well up to the plants, so as to effectually bury the old stems, which otherwise would soon be-

come exposed to all weathers—a frequent cause of failure with old Strawberry plants of Dr. Hogg and other somewhat weakly growing sorts. Much the same treatment has long been given to Strawberry plantations generally by a friend in Essex, but in this case sewage water is freely distributed among the plants through the winter and spring months, and this would appear to maintain sufficient vigour and to induce the plants to produce some of the finest fruits and heaviest crops in a noted Strawberry-growing district. Liberal treatment of young plants has frequently the effect of causing a heavy growth of foliage, but not much fruit, and those who cannot succeed to their own satisfaction with young plants should try what can be done with them after they have become older and weaker. What at first would appear to be almost incredible is the fact that not only British Queen, but also all other sorts will in some gardens fail completely after the first year, no matter how liberally they may be treated. This proved to be the case in a Middlesex garden of which I had charge for a time. Every season a fresh plantation had to be formed, or no fruit fit to eat would be had. The ground was double dug, care being taken to bring up little or no London clay, which thereabouts was much too near the surface, and after the ground had been well trodden the plants were put out as early in August as possible. Strong layers in pots were planted, and these, being subsequently well attended to, grew to a great size, oftentimes as large as many have them at double the age. Heavy crops of fine fruit were invariably obtained, and are, I believe, to this day under similar conditions, but each time the plants were left to bear a second time nothing but small flavourless fruit was the result. It is the young plantations of British Queen that are also most profitable in the garden now under my charge, and this season the two-year-olds are also particularly well cropped.—W. I., *Somerset.*

Two-year-old Strawberries best.

Strawberries can be grown on nearly any kind of soil, but some kinds need more attention than others. In shallow light soils they require more watering than in deep rich loams, but in any case in order to have very fine fruit thinning must be resorted to, and a good soaking of manure water given two or three times a week. New beds should also be made every two years, two-year-old plants being the best. After that time they begin to deteriorate; the fruits become inferior in quality, and the plants die out here and there. Good fruit may be obtained in one year provided the plants are put out sufficiently early, and the necessary attention is given them in the way of mulching and watering, and keeping them free from weeds. Our earliest Strawberry this season was Dr. Necaisse, which is bearing a good crop and good in flavour. The next was Keen's Seedling, which seems less suited for our ground; it makes too much foliage. Vicomtesse Héricart de Thury does very well, but is rather later than usual. President does well, and is producing a grand crop. Sir Charles Napier does fairly well, but not so well as President. Countess is a Strawberry which I very much admire; it acquires a good useful size, colours well, and is rich in flavour. For forcing, none are better than Keen's Seedling, Vicomtesse Héricart de Thury, and President. Our soil is very harsh and hungry, resting on a clayey subsoil, and in dry weather it cracks badly. The few warm days which we have already had has caused it to crack deeply in places, and so widely that one might nearly get one's foot in the cracks.—W. A. Cook, *Holme Wood.*

Early and Main-crop Strawberries.

Here we only grow four sorts of Strawberries as main-crop varieties, others only being grown in small quantity or on trial. Our first is Black Prince, then come Keen's Seedling, President, and James Veitch. Black Prince is not so much grown as it deserves to be. It is invariably ripe a fortnight before any other variety, and though small compared with President and some others it is an enormous cropper, and in good soils the fruit will average two to the ounce. The colour is deep and rich, and as the flesh is very firm the berries bear transit well. Last year we gathered quantities of it in the open air on June 1, but this season it was not ripe until June 10. As a first crop under glass I know of none to equal it; I prefer it, indeed, to any variety I have tried for forcing. It is the fault of the cultivator, and not that of the sort, if it does not attain a good size and prove in every way satisfactory. Keen's Seedling is a charming Strawberry for home use, but it is too soft when quite ripe to bear transit by rail. It is a second early kind, produces an abundant crop, and invariably attains a good size; its colour, too, and flavour are both good. It forces readily as the days begin to lengthen, and becomes richly flavoured under glass. President is so well known as to require no description, but I consider it inferior in point of flavour to either of the preceding. It bears heavily, and its fruits have always a good appearance. James Veitch is handsomer still, slightly less prolific, and not so high in flavour. It is a robust grower and very hardy. Vicomtesse Héricart de Thury we have discarded, as its fruit never swelled up uniformly, and in flavour only fourth-rate. Dr. Hogg surpasses them all in flavour, but it bears so thinly as to be quite unprofitable. Sir C. Napier, owing to its inferior flavour, we discarded. British Queen has also been discarded, as, although good in flavour, as a rule it is such an uncertain bearer that few would care to grow it extensively. Fortunately, we have just secured our main crop of Strawberries for this year, as the plants are now suffering from drought. In later gardens in Wales than ours three parts of the crop are failing to swell or ripen owing to the drought.—James Muir, *Margam, Glamorganshire.*

PACKING STRAWBERRIES FOR MARKET.

Mr. Coleman's statement that Strawberries for market are gathered before they are quite ripe does not apply to forced fruit. The beauty of a Strawberry lies in that perfect finish and rich colour which distinguish the fruit of the best growers for Covent Garden. This fine appearance is only acquired after the berries are red, so that gathering them then would rob them of much of their market value. Moreover, it too frequently happens that the market grower has no inducement to pick his fruit before it is fully ripe. Holding fruit back a few days will sometimes, especially during May and up to the middle of June, add considerably to its value, as prices about that season are constantly fluctuating. Take this year, for instance; the trade was so bad during the few days preceding and following Whit Monday, that we kept back all the Strawberries we could until the latter end of the week, when better prices were realised. If growers of forced Strawberries did not study to hit the market, but always gathered their fruit as soon as ripe, they would often fail to make the most of it. Packing in layers and wrapping each berry in a leaf is the best mode of packing when small packages of Strawberries have to be sent long distances.

The Strawberry is such a soft fruit that, if loosely packed and subjected to rough treatment, the berries are sure to lose much of their beauty. Market growers, however, in the neighbourhood of London make special arrangements whereby such risks are avoided. At one time we packed according to a system of our own invention. Crates were made of common plasterer's laths and half-inch boards. The latter formed the ends, the laths being nailed to them in the shape of sides and bottoms. Punnets sufficiently deep to allow of the berries to come just below the rim were used; a row of punnets was placed in the bottom and covered with leaves, then two laths were laid along on the top of them; on these another row of punnets was placed, and so on till the crate was filled. Each basket of fruit was enveloped in paper and the crates were made to hold ten pounds. Three laths nailed on the top fixed them in firmly, and stout string made all secure, and formed a handle for carriage. These crates looked rather fragile when filled, but although we have sent nearly half a ton of fruit packed in this way in a season to Covent Garden, only once had we any injured, and that was under exceptional circumstances. We do not pack in this way now, because salesmen said good fruit should not be hidden, as in a measure it was, in the deep baskets which we were obliged to use. We now employ baskets sufficiently shallow to allow the topmost layer of berries to come rather above the rim than below it, and thus the beauty of the fruit is much better seen. The punnets, which are packed in boxes, are not lined with leaves, but two or three are put at the bottom. The boxes are made to contain 12 lb. in half-pound baskets. These are arranged in three layers, the two shelves on which the two top layers are placed resting on pieces of wood nailed on to the inside of the box. Towards the end of each shelf or false bottom there is a hole large enough to put the finger through, and this facilitates removal. On each basket a whole Strawberry leaf with a portion of the stalk attached to it is carelessly laid, and the shelves are so arranged that they gently press on the leaves without crushing or bruising the berries. When the boxes come into the salesman's hands all that he has to do is to take off the lid and remove the leaves, an operation easily and quickly performed, and the fruit is at once exposed to the inspection of the purchaser.

Fruit grown under glass is nearly always put up in half-pound punnets, a size which meets the requirements of the London and suburban fruiterers better than those of large dimensions. The lid is fitted with a narrow piece of wood all round the edge and fits on the box, and a strong cord keeps all firmly in position. The cord is an important item in the arrangement, as it provides an easy means by which the boxes can be lifted carefully. If the lids are nailed or fastened down in some similar way and no cord is used, the box has to be grasped on each side, and is thus often tilted in carrying it to the guard's van at railway stations. At the terminus a porter from the market awaits the arrival of the train, undoes the cord, and examines the top layer of fruit; if any are injured he directs the attention of the authorities thereto, and a claim is made for damages. If the fruit should be spoilt it is left at the terminus, and notice given immediately to the company to that effect. It is, however, rarely that any damage is done; the attendants soon get used to such packages, and where a grower sends a quantity of fruit from a railway station every year his goods are looked for at the proper time, and are carefully used. It is chance packages of fruit to which damage is most likely to occur.

By this system of packing we can gather fifty pounds of Strawberries in a morning, and get them into market as fresh as when gathered by 9 a.m. We begin at break of day, two picking the fruit and one punneting it; we never gather anything but the small fruit over night, and we do not grow much of that. The celerity with which the picking and packing are accomplished depends much upon the quality of the fruit. We endeavour to get ours as large as possible, as the smaller the berries the longer it takes to fill the baskets. A good deal of our

fruit has run this year at the rate of about ten to the half pound, and when one gets berries of this size the work of picking and punneting goes on briskly and pleasantly. Every package should have a label on it, not written, but printed in bold type, and the train by which it has to go should be specified thereon; the date should be added, and the words "to be called for" in a conspicuous position. With little variation the generality of the London Strawberry growers send their fruit to market in the manner here recorded. Byfleet.

PACKING MATERIAL.

It takes a long time to perfect a crop of any kind of fruit, and therefore when sent to a distance it ought always to be carefully packed. Moss as a packing material for Peaches, Nectarines, and Grapes is in great favour with many fruit packers, and where it can be procured, no cheaper material can be had, but I am not so much pleased with it as some of my friends are. Unless it is both soft and springy it is liable to bruise Peaches, especially when these are fully ripe. A well ripened fruit suitable for eating directly it is received is most tender; even its weight alone, if merely wrapped in tissue paper resting on Moss, is almost certain to injure its base. If Moss must be principally used it should not be in a stinted way; instead of placing the fruit on a shallow bed of it the box should be filled with it, and holes formed in it with the hand for the fruit. In this way the surrounding Moss partially supports the weight of the fruit, and bruising it at the base is thereby prevented. As neither market salesmen nor fruiterers care to receive very ripe fruits, these both travelling and keeping badly, consigners should gather such fruits before they are soft, and these may safely be wrapped in tissue paper and packed firmly in Moss. But for immediate use the fruit must be nearly or quite ripe when packed, and for safe carriage we prefer for packing cotton wool to Moss. This we pull into strips, which when folded skin side outwards are rather wider than the fruits are in depth. Each fruit is first wrapped in tissue paper and then the strips of wool are bound somewhat firmly round them. They are then closely packed together, the wool keeping their bases just clear of the bottom of the box, and unless extra deep the lid shuts down tightly on the material without touching the fruits. In this manner the latter are kept quite clear of any hard substance, and, unless very roughly treated indeed, will travel without a bruise. All cannot have boxes made specially for any kind of fruit, and if those employed are too deep, a bed of Moss, or other springy material, may be placed in the bottom and a strip of cotton wool laid on the top, the lid closing down tightly on to this. Nectarines are usually packed similarly to Peaches, but in shallower boxes. Nothing in the shape of divisions for each fruit is advisable, either for these or any other kind of fruits. We have a large number of tin boxes of various sizes and for all kinds of fruit. They are divided according to the size of the respective fruits to be packed, but we find that they are of little use. They are cumbersome and awkward to pack in, and we found that the fruit travelled indifferently in them. Clean deal boxes are best, these being light, yet sufficiently strong, notably the lid, to bear rather rough usage. Plenty of such boxes, suitable for holding a single layer of fruits, whether these be Peaches, Nectarines, Apricots, Figs, Strawberries, or Cherries, can usually be bought from grocers and confectioners. Care, however, should be taken not to use soap boxes, as the scent from these might affect the flavour of the fruit, especially that of Strawberries. We prefer good home-made boxes for sending fruit to the town house, but these are too good for market use, or for sending fruit in as presents to people, who rarely return the boxes. Figs travel badly in spite of careful packing. They should not be over-ripe, or they will be found to be partially rotten on arriving at their destination. We wrap each Fig in a square of soft tissue paper, afterwards in a strip of cotton wool, and they are then laid in thickly in a shallow box.

Strawberries travel better than might be expected, but they pay for being carefully packed. We always send them in single layer, each fruit being enclosed in either a limp Strawberry leaf or a Kidney Bean leaf and packed closely together. They rest on a thin layer of either cotton wool or soft dry grass; over them are placed a few Grape leaves picked from an open wall, finishing off with a strip of cotton wool. The fruits ought to be gathered when quite cool or early in the morning in order to insure freshness, without which their value is diminished. Those gathered in open fields for market are placed direct in the punnets, a few of the best fruits being reserved for the top. The punnets in their turn are packed in airy boxes, either in one or two layers according to the value of the fruit, and in this state are sent hundreds of miles in fairly good condition. I recently saw large quantities thus packed travelling from Saltash to Glasgow, a great distance to send Strawberries; later on the Scotch growers will supply the southern markets. From another south-western district Strawberries are now being sent northward, packed in small cross-handled baskets in which the fruit is well papered over, the baskets being slung in sixes on strong stakes. Another way is packing the fruit in large deep punnets, which are firmly fixed in a large flat lidless basket furnished with a cross handle for convenience of lifting. Railway officials know what these packages contain, and on the whole handle them with as much care as time will permit. For packing Pine-apples, Melons, Tomatoes, Pears, and Apples, paper shavings are most suitable and much cheaper than cotton wool, and the best substitute for either shavings or Moss is short well-dried lawn Grass. That from the mowing machine is usually too dirty; we get ours from banks which are mowed with scythes and not so often as the lawns. If this is well dried it can be stored away in quantity and will be found both soft and springy, surpassing all but the very best Moss. It has the merit of being within the reach of all, whereas Moss cannot be procured in many places. The choicest fruits are first wrapped in squares of tissue paper and then firmly bedded among the Grass in one or more layers, the box being then well filled with smaller fruits, as it is imperative that the lid should close down tightly.

Cut flowers travel badly during hot weather, especially if cut in the daytime and packed in masses. In a few hours they will have heated badly, and when unpacked are quite useless. They ought either to be cut over-night and placed in water, or early while yet cool and laden with dew, and then, if packed closely in a single layer, or at the most in two layers and divided with paper, no room being left between the flowers and the lid, they will usually reach their destination in good condition. Roses, if cut when only about half expanded, can be packed very closely together, and will travel well either by post or rail. Not much packing material is required for these or other fairly robust flowers, and on no account should cotton wool come into contact with them. Last spring I had sent to me a large box of button-hole bouquets to be sold at a bazaar, but instead of these being taken out of the box when received over-night, it was thought they would keep better undisturbed, the consequence being the ruin of the flowers, causing a loss of about £5. Cotton wool was the packing material used, and this robbed the flowers of what little moisture they contained. If it must be used, and it is a difficult matter to pack Eucharises, Stephanotises, and other choice white flowers without it, the stems should rest on damped portions, and in most instances a sheet of tissue paper should be placed between it and the flowers. For Roses and similar flowers we prefer Spinach leaves placed above and below each layer of Roses. If Spinach is scarce, Lettuce leaves with crushed stalks are substituted, either kind serving to preserve the freshness of the flowers. Cardboard boxes are frequently sent by post, but they are not the cheapest or best, simply because they are oftener crushed than light wooden or tin boxes. Moistened flowers or soft fruit, such as Strawberries, are apt to saturate the sides or bottoms of these boxes, and this soon ends in a collapse. I have frequently sent fruit, flowers, and plants by post, and they usually arrive at their destination safely, but then the boxes are always strong enough to stand a fair amount of pressure, will not be softened by moisture from the inside or outside, sufficient packing material is used to keep the contents firm and steady, and the address is always plain, and to a certain extent indestructible. Many seem to think that boxes to be sent either by rail or post will always be kept upright, and pack accordingly; whereas they are often wrong way upwards, or on their ends or sides. A box properly packed may be carried in any position without injuring its contents. W. I.

CROPPING VINES.

Allow me to say a word or two on this subject. Rules have often been laid down on this point, but they are not often applicable to particular cases, for the Vine varies much in its behaviour under different circumstances as regards culture, soil, and situation. I should say no general rule can be laid down for the weight of fruit allowable to the rod, and experience shows that the quantity of crops that may be carried to a good finish can only be ascertained after the capabilities of Vines have been proved. Both strong and weak Vines will ripen Grapes of equal quality as regards colour and flavour if cropped proportionately. Some of the finest coloured Grapes which I have ever seen were all borne by two Vines which filled a small house, all the bunches being perfectly black, well finished, and well flavoured, and the crop good for the Vines, which were weak, the leaves small, but healthy, and retained quite green till the fruit was ripe. The late Mr. Robert Thompson said that some cultivators could grow good Grapes occasionally, but all of them could not grow good leaves—and there is more in this than appears at first sight. I would be disposed to give the following general advice on this point, viz.: grow good leaves on your Vines, and keep them on year after year till they fall naturally, and the crop of fruit, if estimated by the general vigour of the plant, will be sure to be good for many years in succession. I have noticed this in instances well worthy of record. How to take care of the foliage of Vines grown under glass is, however, the rub. Some Vines endure forcing and indoor culture much better than others, but there can be no doubt of the fact, I think, that cultivation under glass is exhaustive to all. All the conditions tend to weaken the vitality of the plant—hot-water pipes, exhaustive evaporation from the leaves at night when they ought to be at rest and covered by dew, and, above all, sudden transitions from dull weather to sunshine, through glass, in a still atmosphere, which exerts a destructive effect upon the tissues. I do not think gardeners ever accurately estimate the effects of these matters. Of course, they understand the necessity of shading, syringing, and damping, &c., but I am speaking of the actual effects produced by the above-mentioned conditions while they last, and which no after-treatment can altogether counteract. The thermometer gives one but a faint idea of the actual conditions in a hothouse. The plants themselves tell us, but it is by the signs of suffering they exhibit, as a rule, after the mischief is done. I was looking, the other day, at some Vine foliage that had been actually burnt up during a blink of fierce sunshine, but did not show it till the following day, when a broad, brown margin round each leaf, as dry and crumpled as a piece of tinder, showed how excessive evaporation had been. My idea is that, although shadings are very apt to be abused, they should be used far oftener than they are. Some cultivators would ridicule the idea of shading Vines, Peaches, or Melons, &c., but such ridicule shows ignorance. The foliage and flowers of none of these are in a condition to stand fierce sunshine, even for half an hour, through glass in

an artificially heated house during May and June, after a spell of dull cold weather during which the leaves have been expanding their thin tissues under a forcing temperature. Hence it is that one so often sees burnt or brown foliage, red spider, and poor or ill-finished crops. The cause is the partial paralysation of the growing functions of the plant. The difficulty with shadings is that they are not graduated sufficiently in texture to suit plants, and are so expensive and troublesome to use, otherwise it would be a good plan to have them on all houses and pits, if only the gardener would learn to use them judiciously. S. W.

SETTING GRAPES WITH THE SYRINGE.

This is doubtless a good way of distributing the pollen of shy-setting Grapes, but is "T. B." (p. 3) not slightly in error with regard to its efficacy in the case of Alnwick Seedling? According to my experience, this variety sets very indifferently when operated on with the syringe alone; in fact, the plan may be said to be a complete failure. Unless the tiny globules of viscid matter are removed from the points of the embryo berries, no amount of pollen will effect a good set, and if we syringe with sufficient force to dislodge them we also wash away every particle of pollen. True, we might substitute foreign pollen, but then the very simplicity of syringe-setting is at once done away with. It is the hand-set bunches that are the most perfect, and we now set them in no other way. We find the blooms to open very irregularly, and therefore have no fixed time for setting, but simply pass the hand lightly over the bunches two or three times a day, or when we notice a considerable number of glistening drops developed. The hand both removes these and distributes the pollen, and this, it should be added, is as potent as that produced by any other Grape. Will "T. B.," or any other reader of The Garden, mention where a good crop of syringe-set Alnwick Seedling is to be seen? There is no disputing the fact that other varieties, notably the Muscat of Alexandria, may be most evenly set by means of the syringe, and even the Black Hamburgh, Alicante, and Madresfield Court will have, other conditions being favourable, more perfectly stoned, and therefore larger, berries than they would have if not syringed when in bloom. At the same time we must not overlook the fact that the syringe is only one important factor in the production of a crop of perfect Grapes, as what may apparently be a good set may yet prove most disappointing. Much depends upon the vigour of the Vines and the composition of the border. Even the very quality of the loam has much to do with the formation first of plenty of good bunches, and subsequently properly stoned berries. We may try all sorts of methods of effecting a good set and yet fail, simply because the Vines are in a weakly state or are too crowded. Strong, well-formed blooms from which clouds of pollen escape are most essential to a good set, and where this is secured a sharp tap on the laterals is frequently all that is necessary. The bunches of Muscats in a crowded house are certain to be much drawn and thinly set, and consequently the rods ought at least to be 4 feet apart, and the laterals not less than 12 inches apart on each side. About half these distances are allowed in many vineries—why I fail to see, as it is possible to grow a much more valuable crop when each rod is given its proper space. In our vineries we have numbers of well set bunches and numbers that are thinly set all under precisely the same treatment. In the former case the Vines are in good order at the roots, while the others are not, and will not be cropped again. "T. B." doubtless knows that various agencies are at work in the production of good examples of shy-setting Grapes, but at present he evidently prefers giving much of the credit to the use of the syringe.—W. I. M.

—— I have proved over and over again that Grapes may be well set by means of the syringe—better, indeed, I think than by the old camel's-hair brush or rabbit's tail which some use. I have set Hamburghs, Muscats, Madresfield Court, Alicante, Muscat Champion, Barbarossa, Lady Downes, and Gros Colmar with the syringe, and with good results in each case. Let those who are afraid to use the syringe just try it upon half-a-dozen bunches and mark the result.—W. A. Cook.

RENOVATING OLD TREES.

In very old trees restorative measures often fail to produce any lasting improvement. But in the case of trees that are still comparatively young, and which may be suffering from neglect of some kind, and are not deficient in vitality, renovating measures are often attended with most satisfactory results. It takes time, however, and patience must be exercised. What has been going wrong, maybe for years, will require a proportionately long period to be put right again, but the progress of improvement will be more rapid every year. This is owing to the peculiarities of tree growth. Improvement always, of course, takes the shape of better growth, healthy foliage, and stronger wood. These in turn deposit fresh layers of tissue, which promote a more active circulation of the juices every season, the effects of which are observable in the more rapid distension of the trunk and limbs, and a proportionate increase in the roots, till, in time, the tree grows out of its debility and recovers. Old fruit trees are oftener operated upon in this way than other subjects, and there are few gardeners who are not familiar with examples of old or feeble Vines or Peaches, &c., that have, so to speak, been made to renew their youth in the course of a few years. Feeble-growing and unhealthy trees are, as a rule, the result of starvation, bad soil, or unfavourable conditions of the atmosphere, climatic or otherwise. When a tree dies from old age the signs are plain enough, and very little can be done to help it, except taking great care of the scant foliage it puts forth each year, and encouraging young growth by every means to sustain the flickering vitality; but in other cases the same signs are observable in young trees, the causes of which may be found and removed. One of the surest signs of debility is the pushing of adventitious growths from the trunk and main branches, and the dying off year by year of the twiggy terminal shoots. The sap does not circulate freely to the extremities, but chiefly about the trunk, putting out a feeble growth on those parts, which grow stronger the nearer they approach the root. Old Laurels often afford very good examples of this. When the tree is healthy the top is luxuriant: when it is weak or old the top dies, or makes little or no growth, and small shoots sprout out all over the trunk. Very often, when such bushes are cut over, they push from the base and do well, and if aided by a good soil put to the roots the result will be all the more satisfactory. In fact, renovating measures may be said to consist in the judicious removal of the feeble decaying tops and branches, and encouraging fresh root action. The trees should be pruned rather late in the spring, when growth is about commencing, and only the really diseased or dead portions should be cut away. This having been done, the roots should be examined, and, if there be reason to suppose that water stagnates about them, the site should be drained thoroughly. In such a case, that of itself will effect a cure. We remember once a case of several young trees that were mysteriously dying off year after year at the extremities of their shoots, a wet soil not being suspected as the cause, because the whole ground had been drained years before. The accidental digging of a pit near where they grew, however, revealed the water standing within 15 inches of the surface, owing to the main drain having been choked up. We need not say the obstruction was removed, and the soil and trees both presented a better appearance afterwards. But it is not so often that want of drainage is the cause of trees dying. In thin indifferent soils the cause is simply want of sufficient nourishment and drought—both bad in themselves; and the cure is a good layer of fresh soil, common manure, leaf mould, and the like laid over the roots, and thorough watering during the summer whenever the ground is the least dry. Only those acquainted with such matters know how dry the soil becomes where the roots of trees abound, and it takes much water to soak it afterwards. The fresh soil and the water will work wonders. The effects will not be very apparent the first season, unless it be in the production of numerous buds and small growths from the older wood; but the next year and years following the progress will be very marked, till the tree quite fills up with young healthy growth again. This is observable in the case of all Evergreens, but especially in Yews, Hollies, and Rhododendrons, &c. Conifers, too, reciprocate such generous treatment, but they must not be allowed to go too far, as it would then be almost as well to plant fresh trees.

At the present time, or perhaps next summer, we need not be surprised to see many trees showing signs of debility, because the soil got too dry last year, and in many places has not yet had sufficient rain to soak it thoroughly. Consequently, unless the rainfall of the coming months is sufficient, deep rooting trees will suffer, not only from drought, but from want of food, because without water the roots cannot avail themselves of the food that is in the soil. We have frequently noticed trees that have shown the first signs of decay the season after a long drought, as in 1868, which was succeeded by dry seasons. For want of sufficient moisture, a tree may starve with its roots in the midst of plenty. No plant affords a more striking example of the effects of renovating measures than the Vine. Old plants that have become bark-bound will, after being lifted at the root and allowed more development at the top, rend their old bark in all directions, and swell up to twice the thickness they were before, and that in two or three years—the leaves and crops augmenting proportionately. We have seen feeble old Vines eighty years old quite restored in this way, and produce fine young wood of greater girth than the old stems, and bear remarkably fine fruit that took prizes at exhibitions. J. S.

Diseased Strawberries.—I shall be much obliged if you can enlighten me as to the constant failure of Strawberries in my garden. My neighbours can grow them, but for years and under every treatment our crop always fails. The ground is clay, and grows other fruits and vegetables to perfection. The plants flower well, and generally fruit well, when, just before the fruits get ripe, they die off like the three samples sent herewith.—E. V. D., *Romsey*.

*** The Strawberry fruits sent are attacked by a fungus named Gloeosporium lœticolor, common on Melons and various succulent fruits and vegetables. The ordinary mildew of Strawberries is Oidium Balsami, common on Sainfoin, Turnip foliage, &c. It is remarkable that whilst your neighbours grow Strawberries successfully yours always fail. Possibly in your garden the fungus is well established on other plants besides Strawberries. Gloeosporium, which is probably an imperfect state of some other fungus, is extremely common this year. It should be burnt wherever seen. Why do correspondents pack succulent objects like Strawberries in wool? It is very easy to wrap them in wool, but extremely difficult to get them out. The wool fibres add greatly to the difficulty of a microscopical examination, without which no answer can be given.—W. G. S.

Vines (*G. C.*).—It is impossible for us to say why some of your canes die at the ends and then push out a lateral, "which grows away well," especially as you say the Vines are "perfectly healthy," and carry a "fair crop." There must be something amiss in the mode of culture, but not being on the spot to see, we cannot say what.—W. G. S.

Cold Peach house.—I am building a cold Peach house, and should much like the opinion of some of your readers as to planting it. It will be 18 feet wide, the back wall will be 11 feet high, and the house will be 38 feet long, with a high glass front. I should grow Tea Roses on the back wall (at least at first), so I should not let the Peaches go to the top of the glass. I intend to have a border all round and a bed in the centre. Could I not plant two rows of trees—low dwarfs against the glass front and the second high standards?—H. W.

Garden Destroyers.

CROP-DESTROYING INSECTS.

Another annual report on injurious insects has recently been published by Miss Ormerod containing the reports of various observations made last year. This is the ninth annual report, and it is quite as interesting and full of information as any of its predecessors. It is not quite so large as that published last year; but that dealt very fully with two noted pests, the Hop aphis and the warble fly; to the latter, however, is devoted several pages of the present report; twenty-five different insects are reported on, no less than nineteen were not reported on last year, and nine have not hitherto been noticed in these reports. In the preface Miss Ormerod says: "The chief features of the insect attacks of the past season have been the great amount of aphides or plant lice which swarmed on most crops in consequence of the long drought being favourable to their increase.' Surface caterpillars also were unusually destructive throughout the autumn, and but for the snow, which in melting brings wet alternately with frost to bear on them (a state of things especially destructive to them), a further visitation was to be expected this spring. Some kinds of injurious crop insects not previously mentioned in these reports have been brought forward, and amongst various notes of habits, means of prevention, &c., which have been reported, I wish particularly to draw attention to the observations at p. 21 on absence of injury from daddy-longleg grubs where the land was thoroughly trampled by animals. The observations of each year show more and more the importance of autumn—measures to destroy in embryo the pests that, if left alone, raise (as a regularly recurring loss and trouble) the various attacks which devastate crops sown after broken up pasture." She also alludes to the rearrangement of the cases of injurious insects at the South Kensington Museum, "which is now in progress, and promises to be of practical service. The insects exhibited are for the most part those which are serious in their ravages, and as far as possible they are shown in their various stages, either by specimens, models, or drawings associated with samples of the injury done by them. The plan now followed of placing the various kinds of insects which attack any individual crop (or kind of fruit, &c.), together with the name of the crop or fruit in plain letters at the top of each case, removes all difficulties as to reference. An inquirer has only to look for the word Apple, Cabbage, Oak, or whatever it may be, at the top of the case, and then may see, or rather will be able to see, when the cases are duly placed, the common kinds of attack, and if he has brought a specimen with him, to name it by comparison." This method of arranging an economic entomological collection I cannot consider a good one. Many insects attack several kinds of plants, and if the specimens, drawings, &c., are given over and over again under each plant which the insect attacks, much expense and a much larger amount of space would be required. There are other disadvantages, too, which cannot now be discussed.

The Bean aphis appears to have been very abundant last year. The Beans seem to have fared best on land which had been previously dressed with gaslime. The difficulty of knowing when and how much gaslime to apply is mentioned, and the following extract from a pamphlet by Dr. Voelcker, which is of considerable interest, is quoted: "With regard to the quantity of gaslime that ought to be put on the land no general rule can be laid down, for the quantity should be regulated by the relative deficiency in calcareous constitutents which different soils exhibit. Speaking generally, however, two tons may be used with safety, and in many instances a heavier dressing will not be amiss. The proper time for application is autumn, or during the winter months when vegetation is at a standstill. On arable land gaslime should be applied to the stubble spread out evenly, and left exposed before ploughing up for three or four weeks; on grass land it should be spread during the months of December or January, or, at any rate, before vegetation is making a fresh start." The next insect which calls for comment is the small or garden swift moth, or, as it is perhaps better known, the common swift moth (Hepialus lupulinus), the grubs of which are no doubt very injurious to the roots of many kinds of plants. Parsnips, Lettuces, Potatoes, Celery, Beans, and Strawberry plants are mentioned. The corn aphis (Siphonophora granaria) seems to have been particularly severe in its attacks; no means at present are known for preserving our corn crops from this insect. The leather-jackets (the grubs of the daddy-longlegs), as usual, were very troublesome. Turning cattle into fields in the autumn as much as possible seems a practicable way of dealing with this pest. A correspondent gives his experience, which is very favourable to this plan. Eating the Grass down short and the trampling of the cattle are apparently most useful in destroying the eggs of this insect, and the shelter which long Grass gives to them, it is also mentioned as a corroborative fact "that the hindland never suffers to the same extent from the fact that it is closer grazed and more trodden in shelter of the fences." Some experiments are quoted which Miss Ormerod instituted to ascertain what effect rape cake had on wireworms. Many persons assert that they will feed on it until they burst, and this fable is again and again brought forward every now and then. These experiments show that the wireworms which had access to the cake were remarkably healthy, and were even longer than usual before they underwent their change to chrysalides (a very far from desirable result). The rape cake undoubtedly draws the wireworms from Oats, for in these experiments two boxes of Oat plants treated exactly in the same way, except that one only had pieces of rape cake in it, fared very differently; in the one in which there was no cake the oats suffered considerably; in the other they were hardly touched. The black Currant gall mite is reported on for the first time. This ery minute creature is the cause of much injury to the bushes which it attacks; it infests the buds and sucks the juices of the young leaves; the buds swell and sometimes open to a certain extent, but the leaves never come to perfection. This pest is usually well established on the bushes before its presence is noticed, for if only a few buds fail to open in the usual manner no suspicion is aroused, and it is not until so many prove abortive that attention is called to the state of the bushes that persons are aware of the attack. In the spring, when the buds are opening, if any fail to do so and become rounded and swollen, they should be at once picked off and burnt, as it is pretty certain that they contain this mite. Close pruning is a good remedy, and certain insecticides are useful, full particulars for the uses of which are given. Another kind of mite is also reported on, but, in this instance, it is a member of a family which is decidedly beneficial; it has been found feeding on the Hop aphides. These mites are small red creatures belonging to the harvest mites, or Trombidiidæ, and should be encouraged in every way. One disadvantage in washing Hops is that the washes which kill the aphides also kill these and other beneficial insects at the same time. It does not appear quite certain to what species the Mangold aphis belong, whether it is the same as the Cabbage aphis, or Bean aphis, or some other species; however, this is of no great moment, except that if all the plants on which a certain species feeds was known, it would be easier to devise means for its destruction.

Miss Ormerod here gives the recipe for an excellent wash for destroying aphides. She would have done better if she had given this and the remarks about gaslime under a heading of "Recipes" or "Remedies," for as placed at present they are not easy to find unless the index is consulted. Millipedes appear to be a pest which is increasing in numbers; little can be done to destroy them after the attack has begun. In gardens they may be trapped by burying slices of vegetables near the plants infested; but in fields this is impossible, and watering with brine seems the best remedy, but much must depend on the nature of the crop, soil, &c. A curious circumstance is reported concerning these creatures: they were noticed in large numbers on a turnpike road, apparently travelling across from a field of Oats towards a piece of pasture land. The night feeding ground beetle (Steropus madidus) is a very common insect, which has hitherto had an untarnished reputation. Curtis, in his well known work on "Farm Insects," speaks of it as decidedly beneficial, and shows most conclusively that it eats wireworms; in fact the whole formation of the insect, its powerful jaws, and rapid movements point to its being a carnivorous insect. Miss Ormerod's correspondent, however, seems to have caught them in the act of attacking Mangold roots in the early morning; in one instance three beetles were found at one root. The injuries to these Mangolds were somewhat peculiar, and had obviously been caused by some insect with powerful jaws; this insect, however, may have only taken to a vegetarian diet from lack of other food. Whatever benefits may arise to the human race by the adoption of vegetarianism, its most ardent apostle would hardly urge its adoption by carnivorous insects. The well known beetle, the black Vine weevil, which is often such a pest in vineries and greenhouses, now stands convicted of attacking Mangolds, and it is suggested that this insect and millipedes are often carried on to the ground in manure heaps.

The common sparrows come in for general abuse from all quarters; not only are they shown to seriously injure certain crops, but to drive away useful birds such as swallows, martens, &c. The American Ornithologists Union has come to the same conclusion as the majority of English agriculturists, that sparrows do more harm than good. Nine of the North American States have laws for the preservation of small birds, but in two the sparrow has lately been exempted; and in another (New Jersey) it is proposed to offer a "bounty per head for sparrows destroyed." If these reports teach one general principle more than another, it is that now-a-days every care should be taken to examine crops frequently, and at once take steps to combat the enemy if any insects are found injuring them. G. S. S.

SHORT NOTE—GARDEN DESTROYERS.

Potato insects (*J. Harris*).—The creatures attacking your Potatoes are the London snake millipedes (Julus londinensis). They are difficult to get rid of. Few insecticides will reach them in sufficient strength to injure them. Watering with a brine of salt and water has been recommended; and a heavy dressing of salt applied to land which is infested in the winter would be very useful, particularly if it was put in after the ground had been slightly broken up. Manures should be examined before it is spread on the land, and if it contains any of these pests it should be treated with gaslime, or salt.—G. S. S.

Slugs.—"T. P. N." recommends trapping slugs with bran, and then sallying out at about 10 p.m., scissors in hand, and executing the captives. A much simpler plan is to use grains from the brewers', scattered lightly in small heaps, and covered over with bits of slate or board. Next morning the slugs will be found quietly reposing under the coverings, and by means of a bit of stick and a pan of salt and water they may be consigned to instant death. A few years ago, when I held my garden as joint tenant with innumerable slugs, as many as fifty or sixty were often found under one bit of slate. One year the gardener kept a reckoning of the numbers captured as far as 40,000, when he ceased counting. The following year there was a perceptible falling off in the supply, and by persevering the pest has been reduced to a mere trifling nuisance. Snails are more easily dealt with than slugs, and can be caught readily on damp evenings or after a slight shower; and the thrushes and blackbirds, whose presence I encourage by giving them a pan of water for drinking and bathing throughout the year, and more substantial refreshment in winter, spend a good deal of their spare time in hunting snails. I have not much faith in quicklime. It is doubtless destructive if it hits the right place in sufficient quantity. One evening, when I found slugs swarming on the lawn, I dusted a certain space with lime and sprinkled another plot with fine salt. Next morning the salted ground was dotted over with the slimy remains of the victims, but there was no vestige of slug where the lime had been sprinkled. I have no doubt they are able to purge themselves of moderate doses of lime, but salt is instantaneously destructive, only it may destroy plants also, and must be used carefully.—G. H. W.

Cabbage grub (*B. W. H.*).—Your Cabbages are attacked by the grubs of a small fly, doubtless Anthomyia radicum, but without seeing the perfect insect it is impossible to be quite sure of the species. This insect has a most unfortunate English name by which it is known by some authors, the root-eating fly; now, the fly itself does not eat roots. However, it should be known as the Cabbage fly, as it is nearly the same as the Cabbage fly (Anthomyia brassicæ). Lime water has been recommended as a remedy. Soak hot lime in water for twenty-four hours, and water with the clear fluid. Remove and burn all plants which are very badly attacked, taking care not to leave any grubs in the ground. A proper rotation of crops would greatly tend to lessen the numbers of this and many other insects.—G. S. S.

Indoor Garden.

PARIS DAISIES IN SMALL POTS.

It is a mistake to shift Paris Daisies on too quickly into large pots, as they will bloom, I find, very freely in 4½-inch and 6-inch pots if well watered and fed during the time they are in flower. For early spring decoration the large-flowered white and the yellow Etoile d'Or are invaluable, but in order to have them in good condition at that time preparation should begin at once. If cuttings are put in now and the young plants are grown along freely they will become fair-sized specimens by the end of the autumn, for Paris Daisies continue to grow until the days get very short. The best results are, however, obtained from cuttings struck in May, and it is just at that time that the wood is most succulent; a month or two later there is some difficulty in obtaining cuttings in proper condition, the tendency of Paris Daisies being then to make short, wiry, bloom-producing shoots. All flower-buds should be picked off until the middle or latter end of September. If the white kinds are required to bloom through the winter they should get a little warmth, but the yellow one will flower quite freely in a cool house. During winter only water should be given, but as soon as the power of the sun stimulates flower production, frequent doses of weak liquid manure should be given, and in hot weather, such as frequently occurs in April and May, the plants should be looked to twice or three times a day according to the position which they occupy. This is essential when Paris Daisies are grown in small pots, as if the soil remains dry only for an hour or two each day the continuous growth of the plant is in a measure stopped, and the blooms come small and often deformed. The fine examples of Paris Daisies seen in Covent Garden are grown in this way. In hot weather they are gone over and watered with weak guano water every hour in the day from the time the sun comes on them till it goes off them in the afternoon. On such plants the blooms are often quite 4 inches across. I have grown Paris Daisies in 4½-inch pots much to my satisfaction, however, by an easier method. I stood the pots when they became root-bound in pans, and by filling the latter up with water in the morning the plants were carried through the heat of the day without further attention. J. C. B.

Lilium davuricum.—The numerous varieties of this Lily frequently cultivated under the name of L. umbellatum are now in bloom, and a goodly show they make; some of the so-called varieties are, however, too much alike, and, moreover, the Dutch growers through whom they are imported into this country every season in considerable numbers do not agree among themselves as to nomenclature. For instance, the short-leaved, upright-flowered variety usually grown as erectum at times does duty for incomparabile. The latter when true is a fine dark velvety-flowered variety, but it seems to be getting scarce. Under whatever name, however, these Lilies may be grown they are most useful, not only when planted in the open ground, but also when grown in pots, and employed for the embellishment of the greenhouse or conservatory. The treatment which we give them is as follows: In autumn we lift some of the clumps of established bulbs and select the best for potting; the others we plant again to furnish a supply at some future time. The bulbs retained are then potted in fairly good soil, enriched with cow manure; they are placed in a well-drained situation, and covered with coal ashes, under which they pass the winter. In spring before growth re-commences the ashes are removed, and the pots being by this time full of roots, young shoots soon begin to come up; they are then plunged in a bed of Cocoa-nut refuse, in which they remain till they flower. The only attention needed during that time is to water them when necessary; they are not troubled with aphides in the way in which some Lilies (auratum and longiflorum, for example) are. A little manure water given as the pots get full of roots will benefit them. A large bulb or three small ones in a 5-inch pot form serviceable little plants, while if desired large clumps or masses can be made by putting several together in a good-sized pot or pan. A selection embracing the most distinct varieties should consist of grandiflorum, bright orange; erectum, a sturdy variety with short leaves and erect brightly coloured cup-shaped flowers; Sappho, a rich brightly tinted variety of dwarf habit; and incomparabile, already alluded to. These constitute the most select of those that I have tried, but, as above stated, their nomenclature is in a very confused state.—Alpha.

SHORT NOTES—INDOOR.

Boiler trials at Liverpool.—I am not inclined to place much faith in these. The piping was erected in the open air; the majority of the pipes were varnished and glistened in the sun, which at mid-day, and indeed during the greater part of the day, was very hot. This in itself would interfere with the genuine work done by any boiler. The open air does not appear to be the proper place in which to test boilers, especially at midsummer.—Cambrian.

Asparagus procumbens (*M. S.*).—This usually loses its stems annually. Cut off all the dying stems from your plant, top-dress with some good soil, water well, and strong healthy new shoots ought to soon show themselves. The species requires a cool greenhouse and plenty of root-room; planted out it always does well.—B.

CONSTRUCTION OF CHEAP GLASSHOUSES.

Economy in the construction of these houses is the order of the day, and probably at no time have prices been so low, and, it may be added, in numerous instances, the wood and workmanship so inferior. Timber is cheap, however, and has been for some time, so that there is less excuse for either the builder or the owner putting up houses with wood of inferior quality. If the wood used is not sound to begin with, much trouble and disappointment will result in a few years. It is a serious matter when a glass structure begins to give way at its knees at all points, and it becomes a question of rebuilding or repairing on an extensive scale. I lately saw a range of fruit houses, fifteen years built, that were all in this condition, and in order to keep them upon their feet the proprietor is now tying the joists together with iron cramps. It is not a question of paint, as some builders insist, but sound timber. Regular painting is of much importance, no doubt, but the quality of the wood is the first consideration. We have old houses standing sound in the rafters, and even in the slender astragals that hold the glass, that will see our new houses ended, although the former have been up eighty years and the latter less than twenty. The difference between the two is due solely to the quality of the wood, which in both cases is red deal, but of very different quality. For the rafters of glasshouses not an inch of "sap" wood or outside wood of the tree should be used, and it is easily detected by its colour and texture, which are white and soft, incipient decay being quite often visible at the edges of the planks in the black streaky fibre. None of this should be used. It is specially important that all the main bearers be sound, and also other portions where any morticing has to be done. Above all, pass no timber that has received the "first coat of paint," which hides most deficiencies, and is usually put on before the timber leaves the works. We have on occasion taken up bar after bar of shelvings in this state, and broken them over the knee, to find the wood of the worst description, and actually so black that the colour shone through the paint.

So much for the quality of the materials, and now for cheapness in the planning. Now-a-days, in houses for the culture of plants and flowers, masonry is dispensed with as far as practicable. The great point is to admit as much light as possible, and this means glass instead of brickwork. Except where there is a back wall, there is really hardly any need for masonry, unless it be in the pillars that support the house, and these are, or should be, out of sight. Dispense with stone paths, curbs, and pillars wherever possible, which only take space that can be better employed. Have few angles, gutters, and gables, and contrive to have the houses all joined to each other for the sake of appearance, convenience, and economy in heating them. A glasshouse with a cold outer end or gable will consume more coal than one which has its ends abutting on other houses, just as inner rooms in dwelling houses are warmer than those having outer walls. As to heating itself, that should be schemed to save needless junctions, valves, and pipes, which increase the cost immensely. The simpler the plan the better. The use of pipes is to heat the air of the house uniformly, to do which they must be distributed in rows over the floor in such a manner as not to interfere with the paths, doorways, or borders. Have the boiler near its work, and as few pipes under ground and in inaccessible positions as possible, and so save a hundred per cent. when repairs become necessary. In glazing the roof, use good broad and long panes, but no outside putty. The warmest roofs are still those in which the glass is bedded in putty, because they keep the cold winds out; but there is no need for putty outside, only one copper sprig on each side at the top and bottom of each pane. Lastly, it is not necessary to use heavy rafters for any sort of glasshouse. He who does such work by contract will not recommend them; but he who does the work by the day, and by measure and value, may. The bearers must be strong enough for their

place, but staying by means of iron rods has now superseded iron posts, pillars, and heavy rafters, thus leaving more space inside, and rendering the house lighter as well as more elegant in appearance. J. S. W.

ALPINE FLOWERS.

WE have just received a letter from a friend travelling in Switzerland, wherein he describes the exquisite beauty of the alpine plants he has met with in flower on the Swiss Alps. At this season the Gentians, he says, dye square yards of rocky cliff with blue, and of the same hue is that little gem, Eritrichium nanum, which we spend so much thought upon in trying to grow freely. Saxifrages are going out of bloom, but some of the Campanulas are in the height of beauty, and so is the curious Phyteuma comosum and the little trailing Toadflax (Linaria alpina), which is the one most commonly met with. The Edelweiss has been in bloom for some time, and another Composite, Leucanthemum alpinum, a near ally of our Ox-eye Daisy, together with the mountain Avens (Geums), are long lasting flowerers. Primulas—those jewels of the Alps—have been profusely in bloom, and the dead flower-stalks of other early flowers show how beautiful the slopes must have been in May. The majority of English tourists miss much of the beauty of alpine flowers by deferring their visits to August and September, when flowers are past and fruits are ripening. Every alpine plant grower should see the Alps in early summer, when they will learn an impressive lesson, which will often assist them in the management of their gardens at home.

A tuft of Saxifrages, Pyrolas, and Veronicas.

KITCHEN GARDEN.

COUNTERACTING DROUGHT.

PEOPLE are now complaining of the heat; but bright warm summers are more enjoyable and more fruitful than those of a dull damp character. We cannot have too much sunshine if we prepare for it aright, but the first and great preparation cannot be improvised: I mean, of course, deep working of the soil, which should be systematically done. If this be neglected, no amount of surface stirring will compensate for depth of soil. Stirring is a valuable expedient when the roots have plenty of room below; but if cramped in their action we have no right to expect a favourable result. Where the soil lacks depth, then mulching is better than earth stirring, as it not only keeps it cool and imparts nourishment, but on deeply worked, well-manured land, the hoe, worked deeply all over the surface, breaking it up to a fine ash-like consistency 2 inches or so deep, will answer the same purpose without robbing the land of solar warmth in the same way as mulching does. Of course the mulch saves labour, and that is an object sometimes; but I have found, with a deep, well-manured soil and a loose surface, the warmth of even our summer days is beneficial rather than otherwise. Mulching on shallow, imperfectly worked land is invaluable—in fact, indispensable to many things. Watering permanent crops is not an unmixed good; it tends to carry off the fertilising matters from the soil if given in sufficient quantity to be of any use, and if the surface only be moistened the roots are kept near the top, where they are alternately parboiled and roasted, instead of striking downwards, which they would have done if left to cater for themselves. The earth is the storehouse of plants, and if a good supply of food be there ready for their use, the result will be more satisfactory than if they are living from hand to mouth on the limited supplies which can be given to them in dry, hot weather in the shape of surface moistening. I have been speaking more especially of vegetables, such as Peas, Cauliflowers, &c., which cannot be had in good condition in a dry, hot summer unless the land be well attended to. A light mulch to fruit trees, especially to those carrying heavy crops, is a great help in keeping the roots near the surface; but we do not want to keep out all solar heat; we have not had too much of it lately; it is the only thing lacking to make our climate perfect for fruit growing, as without it the wood will not ripen, and the whole question of fruit growing hinges on this. No one ought to require to be told that, if we water at all, enough must be given to reach the bulk of the roots. Yet there is generally a want of thoroughness in work of this character that detracts from its value, and, in fact, often renders it worse than useless. E. H.

Sowing Parsley.—If I had to depend upon one sowing in the year for our supply of Parsley, I should sow about the 10th of July in an open situation, thinning the plants to 5 inches or 6 inches apart when large enough to handle, and planting the thinnings on a warm border at the foot of a south wall or a warm thick hedge. One of the advantages of sowing now is the fact that a large proportion of the plants will not run to seed next year. The few that do seed may be drawn out, and still a good Parsley bed will be the result.—E. HOBDAY.

Beet Spinach.—This Beet should be sown some time in the month of June, or at the latest in the first week in July. Those only who have a large demand for green vegetables in early spring will appreciate the merits of this so-called Spinach, as if sown in a sheltered corner it will be available for use when ordinary Spinach is withered up by cold winds and frost. I find it best to sow it rather thickly, and let it remain so all winter, as then the plants shelter each other. In our strong soil we find, if it is sown in drills 1 foot apart and the plants left 3 inches asunder in the rows, that they pass through the winter better than where they have more room. It is very desirable that the bed should be in a position sheltered from east and north winds. If sown in the open, probably it would not prove more hardy than ordinary Spinach. I do not say that this Beet is equal to ordinary Spinach for table purposes, but it is useful when other garden produce is scarce.—J. C. C.

Cropping without digging.—Wishing to sow quickly early in the year, under press of time and a lack of labour just then, a piece of ground some 30 rods in extent with Peas of various kinds, I had some portion prepared by merely forking it up ready for the rows a spit wide at intervals of 3 feet, leaving the intervening space to be dug at some future time. The soil is a stiff clay, and whilst left by the winter's frost after Potatoes were got up last autumn with a fairly friable surface, I found that the bottom came up very stiff and lumpy, rendering the drawing of drills difficult and the proper covering of the seed more so. I therefore allowed the forking to be dispensed with and simply drew the drills on the surface, getting

them a fairly loose soil some 3 inches in depth; the result has been better than if all had been dug. The seed germinated well and the rows throughout proved true and even. All the kinds have made capital growth, quite exceeding my best anticipations, and are even better where the soil was not forked at all than where dug; certainly, some two years ago the ground was half trenched, but still it had since borne crops of runner Beans and Potatoes. Experiments of this kind, when successful, are worth detailing, as it may happen that others similarly plagued with a stiff clay may hesitate to do what sometimes is obviously best, because contrary to common practice. Still, the plan might hardly have been safe had there been no previous trenching.—A. D.

Horn Carrots.—A sowing made now of the Nantes Horn will produce Carrots that will prove useful in winter, sweet young roots being always in demand. The border from which early Potatoes have been lifted will do admirably for Carrots with no other preparation than a sprinkling of soot hoed in and the surface well pulverised before the drills are drawn. Thin the plants from 1 inch to 2 inches apart when large enough to handle.—E. Hobday.

Farly Cabbages.—The best early Cabbage I know of is Early Gem; seeds of it were sown on March 9, their produce was planted out on April 20, and was ready to cut on June 18. It bears small compact heads, and is beautifully green in colour.—W. A. Cook, *Holme Wood*.

Warted Cucumber roots (*E. M. G.*).—Your Cucumber roots seem attacked with a disease very similar to club-root in Cabbages, &c., and is, no doubt, caused by a fungus. Remove all the earth the Cucumbers have grown in, and burn it or bury it deeply.—G. S. S.

Societies and Exhibitions.

THE CRYSTAL PALACE ROSE SHOW.

July 3.

This annual exhibition was not only considerable in extent, but the Roses were in most instances very fine, though the intense heat soon began to tell upon them. The main part of the show was under the central transept, the flowers being arranged on lines of tables in the usual manner. Along the nave Mr. Head had arranged tables of cut Roses, with Palms, &c., in the centre. This broke up the monotonous arrangement usually seen on these occasions, and also distributed the crowd of visitors.

In the nurserymen's class for 72 varieties, Mr. B. R. Cant, nurseryman, Colchester, was first, and Messrs. Paul and Son, Cheshunt, second, and the same exhibitors took similar positions in the class for 48 varieties, 3 trusses of each. In that for 24 varieties, 3 trusses of each, Mr. C. Turner, Slough, was first, and Messrs. G. Cooling and Son, Bath, second. In that for the same number of varieties, single blooms, Mr. G. Prince, Oxford, was first, and Mr. C. Turner second. Of the Hybrid Perpetual Roses, the following were finely shown in these classes: Abel Carrière, Alfred Colomb, A. K. Williams, Baroness Rothschild, Beauty of Waltham, Camille Bernardin, Charles Darwin, Charles Lefebvre, Countess of Rosebery, Dr. Andry, Dr. Sewell, Duc de Rohan, Duchesse de Vallombrosa, Duchess of Connaught, Duke of Teck, Dupuy Jamain, Emily Laxton, Etienne Levet, Ferdinand de Lesseps, Fisher Holmes, François Michelon, Gen. Jacqueminot, Hippolyte Jamain, Horace Vernet, Jean Soupert, J. S. Mill, La France, La Rosière, Le Havre, Louis Van Houtte, Madame Gabriel Luizet, Madame Hippolyte Jamain, Madame Lacharme, Marie Finger, Madame Montet, Madame Victor Verdier, Marie Baumann, Marie Rady, Marquise de Castellane, Maurice Bernardin, Merveille de Lyon, Mons. E. Y. Teas, Mons. Noman, Mrs. Jowitt, Pride of Waltham, Prince Arthur, Prince Camille de Rohan, Reine du Midi, Reynolds Hole, Star of Waltham, Ulrich Brunner, Violette Bouyer, and Xavier Olibo.

Of Tea-scented varieties, Anna Olivier, Belle Lyonnaise, Catherine Mermet, Comtesse de Nadaillac, Devoniensis, Etoile de Lyon, Hon. Edith Giffard, Innocente Pirola, Jean Ducher, La Boule d'Or, Lady Mary Fitzwilliam, Madame Bravy, Madame Hippolyte Jamain, Madame Lambard, Madame de Watteville, Marie Van Houtte, Niphetos, Perle des Jardins, Souvenir d'Elise, Souvenir d'un Ami, and Maréchal Niel.

The class for 18 Tea and Noisette Roses brought some lovely flowers, Mr. George Prince being first, and Mr. G. W. Piper, nurseryman, Uckfield, being second with such fine varieties as Alba rosea, Francisca Kruger, Princess of Wales, La Boule d'Or, Niphetos, Catherine Mermet, Jean Ducher, Marie Van Houtte, Souvenir d'Elise Vardon, Anna Ollivier, Innocente Pirola, and Madame H. Jamain. The class for a collection of yellow Roses was a very attractive one, and all shown were Tea-scented and Noisette varieties. Mr. George Prince was to the fore with beautiful blooms of Jean Ducher, Princess of Wales, Francisca Kruger, Etoile de Lyon, Comtesse de Nadaillac, Perle des Jardins, Madame C. Kuster, Marie Van Houtte, and Amazone. Other good yellow Roses were Anna Ollivier, Boule d'Or, Belle Lyonnaise, and Princess of Wales. In the class for white Roses, Mr. B. R. Cant led the way with Edith Giffard, Niphetos, Devoniensis, Jean Pernet, Madame Lacharme, very fine, and Madame Bravy. Anna Ollivier, Alba rosea, and Innocente Pirola were also shown in this class. Messrs. Paul and Son had the best crimson Roses, setting up fine blooms of Madame G. Luizet, Marguerite de St. Amand, Madame Montet, Madame Hippolyte Jamain, Mensieur Noman, Pride of Waltham, Baroness Rothschild, Catherine Soupert, Princess Beatrice, Julie Touvais, Lady Mary Fitzwilliam, Marie Finger, Duchesse de Vallombrosa, Madame Cusin, &c. Messrs. Paul and Son were first with crimson Roses, chief among them being A. K. Williams, Duke of Edinburgh, Dr. Andry, E. Y. Teas, Gen. Jacqueminot, Duke of Teck, Ulrich Brunner, Comte Raimbaud, Marie Rady, Marie Baumann, Madame Victor Verdier, and Camille Bernardin. Mr. B. R. Cant had the best velvety crimson Roses, showing Duke of Edinburgh, Fisher Holmes, Prince Arthur, Duke of Marlborough, Dr. Sewell, and Maurice Bernardin. Louis Van Houtte, Reynolds Hole, Charles Darwin, and Prince Camille de Rohan were also shown in this class.

And in the classes for varieties, Maréchal Niel was grandly shown by Mr. B. R. Cant and Mr. G. Mount. In the class for any Tea or Noisette Mr. Cant had 18 beautiful blooms of Souvenir d'Elise, Mr. Grant coming next with Marie Van Houtte. The best of the Marie Baumann type was Ferdinand de Lesseps, from Messrs. Keynes and Co.; of the Prince C. de Rohan type, Abel Carrière, from Messrs. Paul and Son; of the François Michelon type, Marquise de Castellane, from Mr. W. J. Grant. Mr. H. Bennett had the best 12 blooms of Lady Mary Fitzwilliam; Mr. Geo. Prince, of A. K. Williams; the Rev. J. H. Pemberton, of W. A. Richardson, finely coloured; and Mr. B. R. Cant, of Niphetos.

Messrs. Paul and Son had the best collection of Rosa Polyantha, having Ma Paquerette, Perle d'Or, Simplex, Mignonette, and Anne Marie de Montravel. Cecile Brunner was also shown in this class. Messrs. Geo. Cooling and Son, of Bath, had the best trusses of Rosa rugosa and its white variety. In the amateurs' classes the leading exhibitors were Mr. T. B. Haywood, Reigate; Mr. A. T. Waterton, Reigate; Mr. J. W. Grant, Ledbury; and the Rev. Dr. King. Messrs. Laing exhibited a group of tuberous-rooted Begonias in flower. Cut flowers of Carnations, Picotees, and Pinks were also limited. The leading prizes were taken by Mr. C. Turner, Mr. J. Douglas, and Mr. H. Hooper. First-class certificates of merit were awarded to Picotees Agnes Chambers and Annie Douglas, two yellow ground varieties shown by Mr. J. Douglas.

A fine collection of Roses, &c., was sent by Messrs. W. Paul and Son, Waltham Cross, who had two seedling varieties, Great Mogul and Silver Queen.

NATIONAL ROSE SOCIETY, SOUTH KENSINGTON.

July 6.

The show of this society held in London is now looked upon as the representative Rose show of the season. It took place in the Royal Horticultural Gardens, the conservatory in which was filled from one end to the other with cut Roses. It was a great gathering, but, as like former shows, as two Potato shows are like each other, the same long lines of boxes, the same exhibitors, the same familiar sorts of Roses. Nobody looks for novelty in a Rose show, and yet no flower shows are so popular. Novel features, however, might be introduced into a Rose show, and particularly into such large shows as the National one is. The only attempt at arrangement occurs in the class for "a basket of Teas or Noisettes," but even in this class the arrangements have long since settled down into such a stereotyped affair that they have become insipid. Who is responsible for this other than those who frame the schedule, wherein it is stated that "all exhibits are to be shown in one uniform wicker flower-stand on legs." How can exhibits be other than monotonous under such conditions. Three or four classes for arrangements of cut Roses could well be substituted for others included in the bewildering number of classes, extra, closed, and open. These open classes, however, represented what seemed to interest the visitors as much or more than the classes for the ordinary Hybrid Perpetuals. Among the classes were some for garden Roses, for Moss and Provence Roses, for Roses suitable for "button-holes," for new Roses, and for Roses of particular colours.

As regards the quality of the blooms throughout the show, it was, according to the general opinion, decidedly below the average. Some very fine blooms were to be seen in the best stands, but the uniformly high quality usually seen at this great London show did not prevail, for even the great trade exhibitors, like the Cants and the Pauls, with their acres to cut from, could not muster large collections of uniform quality. A good many of the blooms in even the prize winning stands were second rate, and the weather being so hot did not tend to improve them.

In the nurserymen's classes, Mr. B. Cant was, as usual, unapproachable. He showed the best six dozen single trusses and the finest stand of four dozen treble trusses among seven, while in the class for two dozen Teas or Noisettes, Mr. Prince, of Oxford, stood out conspicuous from the rest, his blooms being superb. In the smaller classes for nurserymen, the most successful were Messrs. Curtis and Sandford, of Torquay, whose blooms from that mild quarter were of remarkable excellence. Mr. Mount, of Canterbury, also showed well, and the best Teas in this division also came from Oxford, from Mr. Mattock's nursery. There were seven classes set apart exclusively for nurserymen, while the amateurs enjoyed the privilege of competing in thirteen classes in either of the two divisions. On the whole, the amateurs' exhibits we considered superior to the nurserymen's; and though Mr. Pemberton's challenge trophy collection of forty-eight trusses did not represent the high quality which we have seen in former years, when such rosarians as Mr. Baker and Mr. Jowitt competed so spiritedly for the trophy, yet this year's collection was highly creditable. The flowers were large, full, of high colour, and of uniform quality throughout the stand, whilst the selection of sorts was excellent; the light and dark colours, as well as the proportion of Hybrid Perpetuals and Tea varieties, being well balanced.

Among other prominent amateur exhibitors were the Earl of Stanhope's gardener (Mr. Gray), Mr. Grant, the Rev. Dr. King (who showed the finest bloom of a Tea variety in the exhibition, a marvellous Souvenir d'Elise Vardon), Mr. Waterlow, Reigate, and Mr. Claxton, who showed so finely at Liverpool last week. The exhibitors came from widely-separated points, as far north as Liverpool, but the finest blooms came from the gardens in the

home counties, particularly Essex, Kent, Surrey, and Sussex. There must have been thousands of blooms shown, and these were chiefly of popular sorts, there being comparatively few new or uncommon kinds in the collections. Running through the nurserymen's classes, we singled out the following as the most conspicuous: The lovely new Lady Mary Fitzwilliam was shown numerously; every large collection included it; and on the whole it was shown admirably. Its large and finely-formed flowers and their exquisite colour—a delicate blush-pink—captivated everyone. Violette Bouyer, in the way of the old Madame Lacharme, was also finely shown; but a better white Rose, and apparently a greater favourite, is Merveille de Lyon, which was perhaps more plentiful than any other light Rose. Ulrich Brunner is another sort that has rapidly become popular. It has a fine bold flower of a bright crimson-red. Mr. B. Cant had it fine in one of his large collections. Madame Gabriel Luizet, M. Isaac Perrière, and Queen of Queens are now established favourites, and there were some grand blooms of the latter Rose which Mr. W. Paul considers one of the best he has sent out from Waltham Cross. Mons. Fillon was one of the brightest-coloured Roses, the centre of the flower being almost a scarlet. Throughout the show A. K. Williams reigned supreme as a dark Rose. It was a matchless Hybrid Perpetual in the amateurs' classes, and a faultless bloom of it shown by Mr. Pemberton was selected by the judges for a medal. Many consider this the finest Hybrid Perpetual of its colour yet raised. That excellent dark Rose, Reynolds Hole, was in superb form; indeed, we have never before seen so many fine blooms of this Rose at a show before. The present season seems to just suit it, for none of the other dark Roses, such as Abel Carrière, Prince de Rohan, could come up to it. That curious, yet beautiful new sort, Pride of Reigate, recognisable at a glance by its flaked petals, was shown beautifully by several, but finest from the garden at Reigate, where it originated. William Warden and Penelope Mayo, of about the same age, are proving to be fairly good Roses, and so is another named Heinrich Schultheis. Among Tea varieties in the collections, the most noteworthy among the less common sorts were Etoile de Lyon, which is fast rising in popularity, for although there are so many Tea varieties of a similar stamp, it possesses a beauty peculiar to itself, the faint golden glow in the flowers being so beautiful. Peerless among coloured Teas was Madame Cusin, which, though a comparatively new Rose, was plentifully shown. It is undeniably one of the loveliest of all Roses. Its flowers are made up of broad crimply petals of a soft rose-pink, and their fragrance is delicious. The new Madame de Watteville was shown well by several. It is a good addition to Tea Roses, being different from any other, having excellent flowers, both as regards size and colour, while each ivory-white petal blushes with pink. Another similar variety, Princess of Wales—one of Mr. Bennett's seedlings, we think—was shown by one exhibitor in beautiful condition, but we have never seen it so fine since Mr. Bennett showed it first. Other Teas we thought specially noteworthy in the collections were Souvenir de Paul Neyron, Souvenir d'Elise Vardon, Sunset, the new American Rose; Marie Van Houtte, exquisitely coloured; David Pradel, and Madame Hippolyte Jamain. We do not intend now to inflict upon our readers a list of the sorts in each winning stand, so we will pass on to the open classes, which were more interesting.

New Roses were not plentiful, only three collections of twelve being shown. The first prize lot was that from Messrs. Paul, of Cheshunt, who had fairly good blooms of the following, viz., Longfellow, a good dark colour; Pride of Reigate, Ella Gordon, Baroness Nathaniel de Rothschild, Marshall Wilder, in the way of Alfred Colomb; Victor Hugo, a very dark velvety crimson, which will probably come to the front; Madame Julie Gautier, Madame de Watteville, Etendard de Jeanne d'Arc, Madame Norman Neruda, and Grace Darling, the latter, a Tea variety, and one of promising appearance. Messrs. Curtis & Sandford's second prize collection contained President Senelar, in the way of Abel Carrière; Madame Massicault, of a similar stamp to the old La Reine; Madame Norman Neruda, Souvenir de la Reine, Levêque, Alphonse Soupert, bright carmine-crimson; Gloire Lyonnaise, like Niphetos; Caroline Swailes, General Appert, a good dark sort; Madame de Watteville and Baron Nathaniel de Rothschild. Mr. B. Cant's third collection was made up chiefly of the foregoing sorts, besides Prince Bearni and Directeur Alphand. Mr. Girdlestone showed the best six new Roses sent out since 1884. He had for sorts Madame de Watteville, Joseph Matral, Gloire Lyonnaise, Grace Darling, Souvenir de Gabrielle, Drevat, and Lady of the Lake. There was no award made in the class for seedling Roses, but Mr. Turner showed his new dark sort The Colonel. Messrs. Paul & Son had the Grand Mogul, a rich crimson-scarlet, and another called Silver Queen, pale pink.

Garden Roses, as distinct from exhibition Roses, formed a class of themselves. There were several collections, composed of a great diversity of kinds; some had flowers of sorts rejected by exhibitors, and not included in the society's catalogue; others had Rosa rugosa and Polyantha, which presumably come under the term garden Roses. Mr. Pemberton's first prize collection comprised the following: Rosa rugosa, the old China; Paquerette, W. A. Richardson, Maiden's Blush, Rosa Mundi, Aimée Vibert, Félicité Perpetué, Homère, Juno, Jules Margottin, Charles Lawson, Céline Forestier, Captain Ingram, and Gloire de Dijon. It would be well to have a clear definition as to what constitutes a "garden Rose." Are they worthless Roses for the exhibition table, or do they belong to classes other than Hybrid Perpetuals, Teas, or Noisettes?

Moss and Provence Roses were a good feature, and a very fine lot was set up by Messrs Paul, of Cheshunt, who showed a beautiful collection for the first prize. It comprised the following: Baronne de Wassenaer, a beautiful deep rose sort, very mossy, raised about thirty years ago; Blanche Moreau, a rather new white variety; Comtesse de Murinais, white tinged with flesh, a very old sort; James Veitch, deep violet-crimson; Lanei, red; Bath, white tinged with flesh; and White Provence. Messrs. Bunyard showed the next best lot, having Lanei, Reine Blanche, Crested Moss, Blanche Moreau, common Provence, Little Gem, and Selina.

Button-hole Roses were shown by two only—Mr. Mattock and Messrs. Bunyard—both good collections, and many considered that from the latter the best. The sorts included in the stands were W. A. Richardson, Homère, Mad. de Watteville, Perle des Jardins, Mad. Falcot, Comtesse de Nadaillac, Souvenir de Paul Neyron, Caroline Kuster, Marie Van Houtte, Jean Pernet, Niphetos, and Amazone. These were selected as being beautiful in the bud state, and therefore most suitable for button-hole bouquets, but there are scores of other sorts equally suitable.

The classes for Roses of particular colours were interesting. The twelve best blooms of a yellow Rose were shown by Mr. Grant, who had some superb flowers of Marie Van Houtte, while Maréchal Niel won the three next prizes, and was shown by six competitors. The best white Rose was Niphetos, from Mr. B. Cant, while Merveille de Lyon (shown by five) was second, and Niphetos third. Other white or pink Roses shown in this class were Alba rosea, Captain Christy, Duchesse de Vallombrosa and Souvenir de la Malmaison. The crimson Rose which won the first prize was A. K. Williams, from Mr. B. Cant, which was shown by five, and took the second and third prizes also, while Alfred Colomb was fourth. Le Havre was also shown in this class. The best dark crimson was Reynolds Hole, shown splendidly by Messrs. Keynes. Xavier Olibo was second and third, Prince Arthur fourth. Charles Lefebvre, Abel Carrière were also shown in this class. The best twelve trusses of any Rose were shown by Mr. H. Bennett, of Shepperton, who had superb blooms of his new Lady Mary Fitzwilliam, which was shown by six others. Among the sixteen competitors, Ulrich Brunner, from Messrs. Curtis, was second, Souvenir d'Elise Vardon third, and Xavier Olibo fourth. Baroness Rothschild, Xavier Olibo, and Comtesse de Nadaillac were also shown.

The medals for the best blooms in the exhibition were awarded as follows: Among nurserymen, Mr. B. Cant had the best Hybrid Perpetual, a splendid bloom of Boieldieu; and the same exhibitor also showed the finest bloom of a Tea—Souvenir d'Elise Vardon. Among amateurs, Mr. Pemberton showed the best Hybrid Perpetual, a perfect flower of A. K. Williams; while Dr. King had the best Tea—Souvenir d'Elise Vardon.

Full lists of awards of both of the above shows are given in our advertising columns.

Gardeners' Royal Benevolent Institution.—The annual dinner of this institution took place at the Albion Hotel, Aldersgate Street, on Friday evening last. Mr. N. N. Sherwood presided, and there was a large company present. The chairman, in proposing the toast of the evening, gave a brief summary of the history of the institution, the origin of which dates from 1838. It did not prosper at first, but matters began to improve in 1842. The proceeds of the first anniversary dinner in 1843 amounted to £40; since that time they had never retrograded, and at the present moment their income is over £2000 a year, and they have funded the sum of £21,000. There are now 118 pensioners, the men receiving £20 per annum and the women £16. Since its foundation the society has helped 553 persons, at a cost of over £43,000. He commended the institution to the sympathy and support of all interested in horticulture. Gardeners had to do their work in all weathers, in all seasons, in hothouses and out of doors, and therefore were liable to contract ailments that incapacitated them for employment. There were in England more than 21,000 gardeners, and therefore it was easy to imagine how useful such a society could be. He spoke with commendation of the way in which the funds of the society had been looked after. The toast, which was warmly received, was coupled with the name of Mr. John Lee, who was described as the father of the institution. Mr. Lee responded. Several other toasts followed. The subscriptions of the evening amounted to over £1400. Towards this sum the chairman subscribed £105; his three children, each £25; the mayor of Chester (Mr. G. A. Dickson), £105; Mr. R. Tait, Manchester, £74; Messrs. Fisher, Son, and Sibray, Sheffield, £68; and Mr. Williams, of Holloway, £50; Major Lambert, £31 10s.; Baron Schroeder and Sir Trevor Lawrence, £26 5s. each. Mr. Veitch's list amounted to £320.

The Egyptian Lotus.—I am surprised to see in the extract (p. 8) from Mr. W. B. Hemsley's descriptive catalogue of Miss North's drawings at Kew that the pink Nelumbium which we call Lotus, and which has been considered sacred in Japan and China, is the same as the sacred Lotus of the Egyptians! This has been so often contradicted and the error exposed by archæologists of the greatest authority, that it is inconceivable how such a statement should be allowed to pass at Kew. The sacred Lotus of the Egyptians is the blue Nymphæa Lotus, so deliciously sweet that in all the drawings in tombs the gods or their guests are depicted as smelling it; and in no instance can I recollect having seen a pink Nelumbium represented. The discovery of blooms of the blue Nymphæa in the coffin of Amenhotep the First in 1881 shows most conclusively that it was in his early period the "sacred Lotus of the Egyptians."—Edward H. Woodall.

Names of plants.—*W. R.*—1, Chrysanthemum Leucanthemum; 2, species of Ornithogalum; 3, Asphodelus luteus; 4, Campanula latifolia.—*G. Thompson.*—Pittosporum Tobira.—*A. S.*—Habenaria chlorantha; Gymnadenia Conopsea.—*J. B.*—Odontoglossum Lindleyanum.—*A. K.*—Philadelphus microphyllus; Boykinia aconitifolia (ordinary variety); Serapias Lingua (Orchid); Spiræa prunifolia fl.-pl.—*M. F.*—Crassula jasminea. Others next week.

WOODS & FORESTS.

THE USES OF HOME-GROWN TIMBER.

There are certain trees that grow to the greatest perfection in these islands. These are either naturally British, or have become quite acclimatised. Among trees of the highest value in the timber culture of this country, native or naturalised, are the Firs. These include the Larch, Scotch Pine, Silver Fir, and the Spruce. Every county in the kingdom will furnish a soil suitable to the growth of one or other of these Firs; and there are no other trees whose wood comes into such daily demand for all purposes in connection with building. The object of the following remarks is to draw the attention of landowners and timber proprietors to the great value of the timber they possess within their own estates for all useful purposes in building construction, whether this must needs be carried out in the most ornamental, massive, and stable manner, or in the simplest, most rude, and rustic fashion. It irritates one somewhat to read how some writers abuse the produce and use of British timber, and how well they belaud the foreign timber, as if we were more interested in its use and produce than in our own native product. Let us protest against this use of foreign timber to the exclusion and disparagement of our own most excellent timber. Wherefore, indeed, should we be more interested in finding a market to the foreigner, in getting and giving him a big price for his timber rather than try to make the most of and do the best possible with our own production? All obstacles are thrown in the way to prevent the use of home-grown timber in building, in mining, and, in fact, in every other thing connected with the consumption of native timber. In short, British timber in the eyes of some people possesses endless faults, and is of no value compared with the foreign article.

It is difficult now-a-days to understand how so many hindrances arise with regard to the working of home-grown wood into all sizes of scantlings and prepared boardings adapted for every purpose in building construction. Has not machinery reduced the expense of preparing wood? Is not time and labour saved by its use? Is not the work accomplished by it more satisfactory and rapid than when done by hand labour? So we believe. Still, no matter what advantages machinery offers over manual labour in the simplicity of preparing timber for use, there are many persons with antiquated ideas who look upon all machinery with contempt, and regard it as being something which interferes with their living. It is not worth while to discuss this question with these, because they have already made up their minds that the use of machinery is a bad substitute for handwork, and that the use of home wood is likewise a bad substitute for foreign.

However well fitted home-grown wood may be in building, and so forth, yet it ought not to be used indiscriminately. For instance, no young or immature timber, nor should any unseasoned or green timber be used in any structure of permanent importance, for the injudicious use and abuse of such timber has in a way brought the use of home wood into disrepute. House building timber should always be matured and seasoned; and that it should be so is absolutely necessary.

If proprietors would refuse to use foreign wood in buildings they would help to bring about a much needed change in the value and economy of home-grown wood. We are not restricted in the choice of wood; there are a great number of excellent timber trees to choose from, and there is no excuse for using foreign wood in preference to home wood. From the dense wood and beautifully grained Oak to the plain, but handsome, wood of the Scotch Fir, there are ample varieties of wood of British production to select from, which might please even the most fastidious of estate carpenters. J. F.

WASTE PRODUCE OF WOODLANDS*

Many thousand loads of waste forest produce throughout Scotland, in the shape of limbs and branches of trees, worth many thousand pounds, are annually allowed to rot in the woods, and in some cases are gathered into heaps and burned, thereby destroying a large amount of firewood, which might be utilised and contribute not only to the revenue of proprietors of woodlands, but also be a great contribution to the public good, while in the southern counties of England everything is carefully utilised for fuel and made into cordwood and faggots; everything in the woods is turned to account, even the roots and smallest twigs are disposed of, which forms a large amount of revenue to proprietors of woodlands in this part of England.

In treating this subject I shall divide it into three branches: 1, that of the large limbs and branches and roots of all trees into what is termed cordwood for fuel and making charcoal; 2, the smaller branches into what is termed faggots, which is a bundle of wood just as much as a man can pitch on a wagon, these being used for lighting fires and heating bakers' ovens, &c.; 3, the smaller spray is tied into bundles about the size of a sheaf of corn and are termed brush or kiln faggots, and are used for brick-burning in place of coal.

After the trees are felled the branches are all pruned off the trees and cut into lengths of 3 feet each, and piled up 3 feet high and 14 feet long, which is called a cord of wood. This is pruned off the trees and cut and piled up, at the rate of 3s. per cord for soft wood, and 4s. for hard wood; at this rate the men can earn from 3s. 6d. to 4s. per day.

The cordwood is used in its simple form for fuel, which has realised from 20s. to 22s. per cord in the woods, but if delivered to any large town 30s. to 32s. is realised. These have been the current prices for the last four years, when coal has been exceptionally high, but of late, owing to the fall in the price of coal, about 2s. per cord less has been the current prices for last summer.

Charcoal.

Large quantities of this cordwood are made into charcoal for drying Hops by men who make it a trade for the greater part of the year, and go through the country from place to place and burn charcoal at from 5s. 6d. to 6s. per cord, according to the size of the wood, as to whether it requires much splitting or not. Large quantities of charcoal are sent to London, where it realises 1s. per bushel, and is used not only as a common article of fuel and for heating hall stoves, but is extensively used in cooking and boiling preserves; it is also extensively used in the forges of large ironworks. It is also largely used in the arts and manufactories, where it occupies an important place in the making of ivory black, lamp black, and black paint, and in the manufacture of ink. It is also used in combination with other substances for cleaning silver, brass, and copper, and last, though not least, in the manufacture of gun and blasting powder, &c. As Kent is the great Hop growing county of England, every farmer who is a Hop grower requires a certain quantity of charcoal for drying his Hops, which is regulated according to the number of acres he grows, ranging from 5 acres to 200 acres. This explains the great demand for charcoal in this part of England, as nothing but charcoal and the best Welsh coal is fit for drying Hops. For this purpose charcoal has sold for the last four years at 1s. per bushel, but this year 10d. has been the current price, owing to the reduction in the price of coal.

The mode of making charcoal is as follows: A circle is formed from 20 feet to 30 feet in diameter, and made as level, firm, and smooth as possible. In the centre of the circle a round piece of wood tapering at one end is placed with the small end downwards, and the large pieces of wood having been previously all split asunder to the thickness of about 3 inches diameter are placed around this eye-pole. The wood is built in an upright position, slightly slanting towards the centre. In this manner pile after pile and tier after tier is laid till the whole of the wood to be charred is built and finished in the shape of a dome. After which a layer of straw, or litter, or turf is laid over it, and a slight covering of earth or ashes (when turf is not used) laid over all, and firmly and smoothly beaten with the back of a spade. The eye-pole is then withdrawn and the hole filled with burning charcoal; it is then covered up on top, admitting sufficient air to make it burn. Great attention is afterwards necessary both night and day to regulate and secure an equal fire in every part. This is done by inserting the end of a fork handle at equal distances all round, beginning at the top and finishing at the bottom. The object of these holes is to admit air and attract the fire to the apertures thus made, and when the surface falls too much, the holes at that part are closed up and more made at the next highest part. This operation is continued for about three days and nights, till smoke ceases to issue from the holes, when the wood will be found to be sufficiently charred and ready for cooling.

The cooling is the next operation, which is no less important than the burning. After being provided with about nine bucketsful of water, the whole of the covering is carefully and cleanly raked off with long-handled wooden scrapers made on purpose, care being taken to prevent the earth falling among the charcoal. The charcoal is then covered with cool earth about 3 inches thick, to which eight buckets of water is applied, which will make the earth a sort of puddle; this is beat with the back of a spade and then covered with the hot earth just raked off, and allowed to remain for twelve hours, after which insert a few holes and pour in one bucket of water, and let it remain about ten hours, when the whole of the fire will be extinguished or smothered. It is always safest to turn the charcoal carefully over, and allow it to cool before being put into bags; the want of this precaution is the cause of frequent fires resulting from its being too hurriedly put into the bags.

A cord of Oak and Beech cordwood well cut and closely set up and properly burned yields from forty to forty-five bushels of charcoal, which sold for the last four years at 1s. per bushel. Thus a cord of wood made into charcoal would realise 40s., from which, if we deduct the price of cutting at 4s. per cord, and the burning at 6s., would leave 30s. clear profit per cord for the wood.

Since coal has fallen in price from its maximum in 1873-4, during the coal famine, when best house coal realised 42s. per ton in this quarter, a great reaction has taken place in the price of charcoal. While the price in

* Communicated to the "Highland Society's Transactions," by James Duff, forester, Bayham Abbey, Kent, who was awarded the gold medal.

London remains unaltered, only 10d. per bushel is the top price realised for Hop drying, which would leave 23s. 4d. for the charcoal per cord.

Large wood is not so profitable for charcoal as medium sized and small wood, not only because it is dearer in the first instance, but on account of its requiring more labour to cleave it, and also because it does not yield so much charcoal, weight for weight. Nevertheless, a cord of large wood will yield more charcoal than a cord of small wood, because both cords are of equal dimensions, while the weight of the large wood is much greater than the small. Hardwood is more valuable for charcoal than either Pine or Fir, and the hard and close-grained kinds more valuable than the soft and porous. Roots of trees are burned into charcoal in the same manner as that of cordwood. Grubbing is done in winter when labour is more abundant. In many districts the rural population cannot always find employment during winter, and when a piece of woodland is to be grubbed to be replanted with Larch for Hop poles, or for arable or Hop land, labourers frequently solicit permission to grub the coppice and tree roots to sell for fuel. At this job they can earn from 2s 6d. to 3s. per day, and frequently, to my knowledge, woodland has been grubbed spade deep by such labourers having the roots for their labour, and carting the roots for them any reasonable distance. The roots are all split asunder into pieces in the course of grubbing, and piled up 4 feet high and 4 feet wide, and 8 feet long for a cord of roots.

Roots made into charcoal produce about 30 bushels of charcoal per cord of roots, which, if sent to London and sold at 1s. per bushel, would realise 30s., from which deduct the price of burning at 6s., and the grubbing at 9s. per cord, leaves a balance of 15s. per cord of clear profit. The system of grubbing and giving the labourers the roots for their labour does very well when only a small shaw or belt is to be grubbed ; but when a large quantity is to be grubbed, the general system is to pay them from 9s. to 10s. per cord of roots grubbed. By this system the grubbing is soon finished, and the roots sold or charred, and the whole job completed. It will be seen from the foregoing that, owing to the price of fuel here, woodland can be grubbed free of cost for small patches, and when large quantities are grubbed the cost is very trifling, the roots nearly covering the expense of grubbing. This is only effected in winter when work is scarce.

House Faggots.

These are made of the smaller branches, or what is too small for cordwood, and also the crooked and waste wood of the coppices not fit to be cut into Hop poles, hooping Pea boughs, and flower sticks, &c.; they are made 5 feet long and 5 feet round, and bound with a withe in the middle, just about the size of a truss of wheat straw. They are made from the branches of trees at 4s. per hundred, and from the refuse of the coppices at 5s. per hundred, and sold from 20s. to 22s. in the woods. They are chiefly used for fuel, lighting fires, and heating bakers' ovens, &c. Delivered in any large town they realise from 30s. to 32s. per hundred ; the price is regulated by their being of easy access or otherwise, or being near a large town or distant therefrom. All the Hop poles in the Hop gardens that are broken by the wind and otherwise worn out are made into faggots at 5s. 6d. per hundred, and sold in Tunbridge Wells and other towns at 56s. per hundred.

The small spray of the underwoods and of all kinds of trees is tied into bundles about the size of a sheaf of corn, with a withe in the middle. Before the underwood is cut, a man or boy with a handbill brushes or prunes off all the side branches and other rubbish off the coppice as high as he can reach and ties them into these bundles, which are termed brush or kiln faggots for brick-burning. This is done at the rate of 2s. 6d. per hundred ; a smart boy or lad, about 15 years of age, will make a hundred faggots per day. They are put up into lots of 25 or 50 as soon as they are made, where they remain till the month of March or April, when they are quite dry and seasoned (the coppices being all cut in winter—beginning in November just after the fall of the leaf). These faggots are then built into large stacks by the side of the nearest clearing road at 6d. per hundred for stacking, where they remain till required throughout the summer. Delivered at any brickwork, which are very plentiful in this part of England, they realise 5s. 6d. per hundred, as bricks are the principal or nearly sole building material in this quarter. These faggots are in good demand, enabling proprietors of woodlands to utilise even the smallest twig of forest produce, which not only greatly contributes to their income, but the woods are thereby cleared of all branches, spray, and rubbish ; consequently they are kept neat and tidy.

The brick-kiln in which these faggots are burned are in every respect built the same as for coal, only the furnace is on the ground, and the opening to admit the faggots being put in with ease is 2 feet 3 inches wide by 4 feet high. They are thrown into the furnace by a long-handled fork, the lower part of the handle being made of iron to prevent its being burned by the fire.

Being far from the coal-mines here, it will be seen that waste produce of forests and woodlands is of more value in the southern counties (especially Kent) than any part of England where they are near the coal-fields, and more so on account of its being a thickly populated county and in close proximity to London.

Kent, Sussex, Surrey, and Hampshire are the most wooded counties in England, with the exception of Yorkshire. And much more so is waste forest produce more valuable here than in Scotland, not only on account of being far from the coal-fields, but also on account of the acreage of woodland being so much less than in Scotland in proportion to the population.

Seeing that waste forest produce is so valuable and so much utilised in this part of England, could it not be made use of to some extent in Scotland, where so much firewood is allowed to lie and rot in the woods ? In some places it would cost more than it is worth for carriage from the place where it is grown to where it is wanted for fuel ; but in such places where the road is long and bad, the best way would be to have the best of the branches cut and trimmed of all the smaller spray and foliage, which would reduce it to about half the weight (especially Scotch Fir), or have it cut into lengths of 3 feet each and made into charcoal on the spot, which would be the better way and the most profitable.

In cases where a forest of Scotch Fir is cut down, the branches could be cut into lengths of 3 feet long and piled 3 feet high and 14 feet long at the rate of 3s. per cord (such is the price for Scotch Fir in Kent, which sells at 15s. per cord in the woods, or 12s. clear profit for the cordwood), and as charcoal is a very light substance, the carriage would be very small, and if sent to any large town where there is a demand for charcoal, the revenue from waste forest produce would be found very remunerative.

DIFFERENCE OF BULK IN OLD TREES.

In an ancient avenue of Elms I know where all the trees have had an equal chance, so far as can be ascertained from their history, a great difference is observable in the bulk of timber in the different trees, both as regards the thickness of trunk and the quantity and size of the branches. Some of the trees appear to have put forth stronger branches than their neighbours at an early age and usurped the most space, but their is not so much difference in their height. It is the same in an avenue of Spanish Chestnuts of the same age. A more reliable example of difference originating in constitutional vigour and habit is observable in our plantations of Scotch and Austrian Firs, now about seventeen years planted. The difference in the rate of trunk growth is very marked, hardly any two trees showing the same length of node or annual growth, but each tree indicating a uniform rate of growth in itself. Of course, those trees which have made the longest leaders are the giants in this case, but only as regards stature, for the dwarfs having as a rule most branches, have as thick, if not in some cases thicker, trunks. The only two deciduous trees of good age which afford a fair comparison are two rather old Sycamores, o the same age, growing side by side under equal conditions in every way, and one of them contains nearly twice as much timber as the other. The common Sycamore is subject to great variation of habit—some trees assuming a compact pyramidal shape, while others are umbrageous and wide-spreading. In this case the small tree is of the former, and the large one of the latter habit, and the last is much the larger in head and trunk. These trees were planted many years ago to hide buildings, and, so far as anyone can see, the difference between them is due to habit of growth alone. G.

Extraordinary "evidence" on forestry.—The *Timber Trades Journal* in a late number relates what it calls "interesting and valuable evidence" given before Sir John Lubbock's committee—among other items, that "Colonel Pearson, who has had experience in the forest schools of India and at Nancy," stated that "Beech timber could not find a market in England, but was a valuable cultural tree to plant with Larch or Scotch Fir," &c. If this is the kind of evidence tendered and accepted, one hardly knows which are most to be pitied, the committee or the witnesses. If Colonel Pearson really did say that there was no market for Beech in England, it is clear he does not read timber trade papers nor papers on forestry in England, or he would see from both that its uses are legion, and that it is one of the most saleable timbers in the market, hardly a fall of timber ever being set out without it. What the witness meant by saying a tree that has no market in England "was a valuable cultural tree to plant with Larch or Scotch Fir," is more than we can guess, because it is more than useless as a nurse to either, is never employed for such a purpose, and in situations where it does grow it spreads out and smothers the Larch, so that it does not appear very clear where the "cultural value" comes in. We think if the committee was to publish its evidence in an accessible form, it would be to the advantage to all whom it might concern if only for the sake of having the evidence sifted. —Y.

Barking standing Oaks.—In passing through a southerly district in Yorkshire during the past week I saw a wood, composed chiefly of Oaks, in which there were hundreds of trees stripped of their bark, though unfelled. What are the advantages of thus barking standing trees ? Can "Yorkshireman" or any other of your northern correspondents tell us ? If there is an advantage as regards the quality of the timber, by all means we should know of it in the south.—G.

No. 765. SATURDAY, July 17, 1886. Vol. XXX.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSE GARDEN.

TEA-SCENTED ROSES.

ANYONE who visits Rose exhibitions will have noted how very popular the beautiful Tea-scented varieties are. People crowd about the stands of them and admire their delicate colouring, sweet scent, and exquisite build. Since Rosa odorata was introduced from China in 1810, and the old yellow Tea-scented Rose in 1824, what a marvellous progeny has sprung from the union of these two. That Tea Roses are tender is well known, but some are hardier than others, and probably we may be getting near the day when we shall have a group of sweetly perfumed Roses that retain their delicate colours and are as hardy as Hybrid Perpetuals. Sweet-scented as many of the latter are, Tea-scented varieties beat them in point of fragrance, a circumstance which makes them such favourites. Moreover, they can be grown in pots, planted in conservatories or against walls; in the last named position, if established in suitable soil, they flower profusely, and among Teas are to be found some of the finest autumn-blooming varieties we possess. They also do well planted in beds, but the tender character referred to makes it needful to give some protection, such as Fern or hay, during winter when the weather is unusually severe. As to soil, they do well in any good loam, but in whatever position they are placed, it should be a warm one, and the soil well drained. The following is a selection of the best varieties made at the Rose shows. They are, Anna Ollivier, rosy flesh; Belle Lyonnaise, a charming yellow of the Gloire de Dijon type; Catherine Mermet, light flesh coloured, one of the most charming of Tea Roses; Comtesse de Nadaillac, a variety that colours in some districts more deeply than in others. At the Longworth Nurseries this variety comes remarkably fine. Devoniensis still maintains its position, but it does not always come large enough to be included in a stand of twelve blooms at a Rose show. Etoile de Lyon, sulphur yellow, deeper in the centre, should be noted as a very fine pot Rose. Hon. Miss Edith Giffard comes almost pure white at times, though in its usual character it is slightly tinted in the centre with salmon-red. Innocente Pirola is at times pure white, at others slightly tinted with pink; a lovely Rose, and one that should certainly be grown for exhibition purposes. Jean Ducher is another most useful and beautiful variety, yellow in colour, shaded with salmon, the centre being sometimes rosy peach; a large full Rose, and good in form. Jules Finger is one of the red class of Tea Roses, distinct and good. La Boule d'Or I regard as the best yellow Tea Rose grown; its flowers are large, double, and in form most exquisite, but to have them in their best condition the plant should have a warm and rather dry situation. Madame Bravy bears grand flowers, large and full; Mr. B. R. Cant invariably shows this beautiful variety in its best character; it is cream coloured, but at Colchester it comes almost pure white. Madame Cusin is a deep pink or pale rose-coloured Tea, the petals of which are suffused with colour, but more deeply towards the edges than elsewhere; the centre is always perfect, but the outer petals curl somewhat; nevertheless it is a beautiful flower and one which is effective on the exhibition table. In Madame Hippolyte Jamain, a charming variety, the circumference of the flower is white, the centre coppery yellow, and the edges of the petals tinged with rose. Madame Lambard is sometimes bright rose and sometimes pale pink; it is changeable in colour, but at all times pleasing. Madame de Watteville is white tinted with salmon, and each petal is bordered with bright rose; a charming flower, but the outer petals curl somewhat. Marie Van Houtte is one of the most lovely of Tea Roses; its colour is pale yellow, rather deeper in the centre than elsewhere, and the outer petals are bordered with bright rose; a dozen blooms of this at the Crystal Palace Rose Show, shown by Mr. Cant, appeared to be as near perfection as they well could be. Moire, rosy fawn, with a deeper shade, is occasionally remarkably good. With Niphetos all of us are well acquainted; in the bud state it is one of the most useful of Tea Roses. Souvenir d'Elise, also one of the most perfectly-formed Tea Roses grown, is creamy white in colour, tinted with delicate rose. Souvenir de Paul Neyron, creamy white shaded with salmon and bordered with rose, is, like the last, large and full; and Souvenir d'un Ami, pale salmon, shaded with rose, is always reliable for show purposes. In the small group of Hybrid Tea and Hybrid Noisette Roses, Lady Mary Fitzwilliam stands at the top. Its flowers are large and globular, and of a bright, yet delicate, flesh colour, and it is a variety that yields a number of finely formed flowers. I have scarcely seen a good bloom of Cheshunt Hybrid or Reine Marie Henriette on a stand this season. Of Noisette Roses properly so-called (for I think the Hybrids will in course of time be absorbed into the Hybrid Perpetuals), there are few that have made a name as exhibition varieties. Is not that most glorious of all the Noisettes—Maréchal Niel—to be found on every stand? Bouquet d'Or is sometimes to be seen in fine condition, with its deep yellow circumference and coppery centre. Next to Maréchal Niel comes Madame Caroline Kuster, a beautiful pale yellow Noisette, large and full, generally finding a place in every dozen Teas and Noisettes. Lamarque is a lovely Rose to grow against a south or south-west wall, where early in the season it will come almost or quite pure white. At Shimdda Hir, Mr. Samuel Barlow's place in North Wales, it does remarkably well, and in the bud state is an almost perfect white Rose.

The seedling Brier is undoubtedly the best stock for Tea-scented Roses; it is the most lasting and reliable. I suppose we shall go on planting standard Roses in forecourt gardens for years to come, but there is no reason why we should not grow Tea Roses more than we do on the walls of our dwellings, or pegged down in beds. Many appear to like a glare of showy red Roses in their gardens, as if this was the only colour Roses afforded. Let them root out some of the standards and plant Teas on the seedling Brier as bush specimens in their places. They may need a little protection in winter, and the exercise of a little more care than is necessary in the case of the more robust Hybrid Perpetuals; but if they succeed, as they are pretty certain to do, no one will regret planting them: and it will be admitted that for making a display in their proper season, for yielding flowers in the autumn, and for use for bouquets and general decorative purposes they are unequalled. R. D.

ROSES FROM CUTTINGS IN SUMMER.

CUTTINGS of Roses are often planted in sandy soil, but that is a mistake. A porous soil requires much water, while all that the cuttings need to insure a good strike is an equable condition as regards moisture. A partially spent hot-bed having a temperature of 76° covered with a frame and lights (it being essential for the cuttings to be kept close) will make a good summer striking bed. On this bed place 6 inches in depth of partially decayed Cocoa-nut fibre and press it down firmly. Where Cocoa-nut fibre cannot be obtained I have used sawdust from hard wood that had lain in a heap for some time exposed to the weather. These substances are easily kept in an even, regular condition without the use of the watering pot. In summer propagation, to which my remarks now refer, the cuttings should be taken when the buds on the young wood are plump and well developed, but not started. They will then be acquiring a certain degree of firmness, and the danger of damping off will thus be diminished. The cuttings may consist of single buds or eyes, with 2 inches or so of wood at the base. If cuttings are plentiful greater length may be allowed, and if convenient they may be taken with a heel of older wood. They may be inserted as thickly in the bed as the foliage will permit. When inserted, the sawdust and fibre should be pressed firmly round them. They must be kept close till signs of growth are visible and shaded from bright sunshine. All the water that will be needed will be a light dewing over with a fine-rosed pot to keep the foliage fresh, and this attention will only be required in very bright weather. A great deal depends upon keeping the leaves left on the cuttings from wilting. If allowed to flag they will prove a source of weakness; but if kept fresh they will be a source of strength, as they encourage the formation of roots. As soon as they have made roots a quarter of an inch long they should be potted into small pots, and be plunged in fibre in another frame till established; then they should be hardened off and planted out. Most of the plants will produce a flower or two in the autumn if the sorts are Perpetuals or Teas. Of late years a great impetus has been given to the culture of Tea Roses. They are delightful for cutting, and with a dozen varieties planted on a warm border well mulched with manure, no one need be without blossoms from early in June till at least November; and, with a warm greenhouse in addition, they may be had, more or less, all the year round. E. H.

Proposed Rose congress.—We learn from M. Sisley, of Lyons, that it is proposed to form a congress of rosarians under the auspices of the Central Horticultural Society of France, its object being to judge all new seedling Roses before they are put into commerce. The project, we hear, is not altogether approved of by the French horticultural press, though, if properly carried out, it would appear to be a step in the right direction.

Licuala Veitchi.—It will be remembered that the beautiful Palm which was first introduced under the name of Pritchardia grandis flowered a year or two back at Kew, where it was re-named and figured in the *Botanical Magazine* as Licuala grandis. About the same time Messrs. Veitch introduced a somewhat similar Palm which they called the true Pritchardia grandis, but this, like the preceding one, was not a Pritchardia at all. A plant of it is now in flower at Kew, and it proves to be an undescribed species of Licuala. No doubt the name under which this most beautiful Palm has already been made known in gardens will be adopted by the authorities at Kew. The flowering specimen referred to is only small, the leaves being about 18 inches in diameter and regularly plaited, the texture being stiffer than in L. grandis.

Stove flowering shrubs.—In the porch of the Water Lily house at Kew are three handsome flowering stove shrubs, all of them old acquaintances, but, perhaps, in most gardens nearly, if not quite, forgotten; they are the large semi-double-flowered scarlet Hibiscus (H. rosa-sinensis fl.-pl.), Lasiandra macrantha, now called Pleroma, and the Indian Lilac, Lagerstræmia indica. The first is so easy to manage and so free flowering, that it requires more skill to keep it in bounds than to make it thrive, whilst its flowers are graceful as well as large and brilliant. True, they are of no value for cutting, but surely we may admire plants and find a use for them, even though their flowers will not live long in water. There is not much difference in taste between a lady who judges flowers by their fitness for adorning her bonnet and a man who values them only when they are useful for cut-flower purposes. Nor can the flowers of Lasiandra be employed in this way, and yet they are among the very choicest of handsome stove flowers. Indian Lilac may be cut and placed in water, where it lasts a good deal longer than our own Lilac; but for our

part we would prefer to see the flowers left on the plant. In an intermediate house, or even a warm greenhouse, these three plants are thoroughly at home and able to take care of themselves, particularly if planted out.

NOTES OF THE WEEK.

A large white Bellflower from Messrs. Backhouse, of York, under the name of Campanula persicifolia alba grandiflora, is an extremely handsome plant, having flowers a good deal larger than usual, snow white and produced on tall stems. It is an excellent border flower.

Strawberry Bothwell Bank.—We have received from a garden in Kent some fruits of this little-known Strawberry which the gardener tells us is the best sort grown there. It is a fine looking dark red fruit of good flavour, though more acid than most others. Perhaps some of our readers can tell us more about it.

Orchis maculata superba.—This is so much finer in every way than the common form of this native Orchis, that it quite merits the name superba. A spike received from the York Nurseries is dense, cylindrical, nearly 6 inches long, and of a very deep and rich purple.

Crimson-flowered Thyme.—A variety of the common Thymus Serpyllum has been sent to us from the York Nurseries. It is a pretty little plant, differing from the type in having flowers of a rich reddish crimson, and must have a beautiful effect in large tufts on a sunny ledge in the rock garden.

Passiflora Constanee Elliott.—We hear a good account of this new variety of the common hardy Passion-flower (P. cærulea) from Mr. Ware, of Tottenham. He says he has a plant of it which has been planted but eight months carrying no fewer than 235 flowers and buds. This speaks much for its floriferous habit. The flowers are said to be white, but there is too much green in the petals to entitle it to be called a white flower.

Roupellia grata, the Cream Fruit of Africa, is now finely in flower in the Palm house at Kew. It is a scandent shrub with succulent dark green leaves, and bears terminal bunches of creamy-white bell-shaped flowers as large as Canterbury Bells, with a ring or corona composed of ten teeth just inside the bell. The flowering of this plant is of rare occurrence, although in tropical countries where it has become naturalised it is a most prolific bloomer.

Iris juncea.—There is such a brilliancy about the yellow of the flowers of this Iris, that it can never be mistaken, even if there are no visible means of identifying it by its elegant and very distinct growth. It is one of the bulbous group (Xiphion) and has flowers as large as our common waterside Flag of deep clear yellow. It is considered not an easy plant to manage, but the New Plant and Bulb Company send us numerous finely developed flowers, but no note accompanies them respecting the conditions under which they have been grown.

Varieties of Cattleya Eldorado.—The different forms of this Cattleya are well known to be numerous; but we have not seen so many of them brought together as have been sent to us by Mr. Thompson from his garden at Ghyllbank, St. Helens. These vary from white to deep purple, and all are remarkable for the large size and deep colour of the yellow blotch on the lip. The finest in the batch is number twelve—a large flower with dark sepals, and an extraordinarily fine lip. The nearest approach to white is number one, while the rest vary between these extremes.

Vallota purpurea magnifiea. Of this grand new variety the New Plant and Bulb Company, Colchester, send us a four-flowered spike, which is quite as fine as those shown last year at South Kensington, when the plant attracted so much attention. It is immeasurably superior in every way to the common Vallota, the flowers being much larger, the colour brighter, and it may be at once recognised by the conspicuous white centre to the flower. A finer greenhouse plant than this bulb does not exist, and we hope to present our readers with a coloured plate of it shortly.

Mesembryanthemums are all aglow with bloom at Kew just now, the bright warm weather affording them just what they require to make them grow and flower freely. The Kew collection is a large one, and, except a few small species, all are placed out-of-doors during the summer months, the pots being plunged in Cocoa-nut fibre and the position being both sheltered and sunny. The flowers of many of the species are large and regular as Ox-eye Daisies, whilst their colours vary from white to yellow, crimson, magenta, purple, pink—almost all shades, in fact. To many of our readers the genus Mesembryanthemum is known only by the tiny trailing variegated kind used for carpet bedding, the annual tricolor, and the Ice plant; but here at Kew there are hundreds of dwarf shrubby sorts, others with thick watery leaves, and others small trailers, spreading and forming large patches, which, when in flower, are most attractive. It would be well worth anyone's while to look up these plants at Kew, and jot down the names of the kinds most desirable. Many of the sorts are most serviceable for greenhouse decoration.

Sweet Williams.—Some very fine sorts of these favourite border flowers from Mr. Caudwell, of Wantage, show what an advance has been made in their improvement of late years. We have now every shade of colour, from pinks to deep crimsons, besides pure whites and "eyed" sorts, and doubles and semi-doubles, so that there is abundant variety and beauty in Sweet Williams alone. We saw at Kew lately a plant representing a cross between Dianthus alpinus and the Sweet William (D. barbatus). It is quite a new break, larger and finer flowers, and a dwarfer and neater habit than ordinary Sweet Williams. Florists should follow in this direction.

Angræcum Leonis from seed.—It is stated in the *Revue Horticole* that M. Loury, of the Paris Botanic Garden, has succeeded in raising seedlings of this new Orchid. It appears that when M. Humblot introduced it, he gave several plants to M. Loury, who found on one of them a pod almost ripe. This being sown on Sphagnum, two little plants came up. This Angræcum has been compared unfavourably with its congener, sesquipedale, but M. Carrière thinks it will prove the more valuable of the two, as the flowers are produced in great abundance, and are, moreover, produced in succession through several months in the year.

Eucomis bicolor is quite as handsome and hardy a bulbous plant as E. punctata, mentioned by "G. J." last week; in fact, all the species of this genus are worth a place in a warm, well-drained border out of doors, and they number some half-dozen. Their flowers are not brilliantly coloured, but they are produced on stout erect spikes, and are arranged in a compact and dense fashion, so that their starry shapes are well seen. Green or yellow-green, with a reddish or brown margin, are the colours of the flowers; whilst the stout succulent scape is shining green and either spotted or peppered with chocolate-brown. The stems and leaves are, of course, only of annual duration, but the large fleshy bulb will keep all right in the ground if merely covered with a cone of ashes during severe weather. All these plants are natives of the Cape.

Erythrina Humei.—A beautiful-flowered shrub under this name is now in flower in the Palm house at Kew. It is about 4 feet high, branching at the base, the stem and leaf characters like those of E. indica, of which E. marmorata is a variety, plus some rather stout prickles on the petioles and stem. The flowers are on erect axillary racemes, about a score on each raceme, and they are as large as those of E. Crista-galli; their colour is a rich velvety crimson, richer and more attractive than any Erythrina known to us, not excepting even the popular Cockscomb Coral Tree (E. Crista-galli). There is a difficulty in making many of these large-growing Erythrinas produce flowers under cultivation, and we suspect that this small specimen now flowering at Kew is exceptional. The treatment recommended is exactly what suits best Allamandas, Bougainvilleas, and such like flowering plants, namely, liberal stove treatment in summer and absolute dryness and a low temperature with plenty of light in winter. An important point to be remembered is that the plants must not be cut back or pruned in any way in spring. E. Humei is a native of South Africa, and is probably the plant figured in the *Botanical Magazine* as E. caffra, which is the Kaffirboom of the Dutch.

Gentiana Olivieri.—Under this name Mr. Kingsmill sends us a rare Gentian. Its proper name is G. Fetisowi, figured and described in the *Gartenflora*. It differs from the true G. Olivieri in the calyx being inflated and in having short teeth on the top, while G. Olivieri has the sepals linear and free to the bottom. The habit of both is nearly alike. G. Fetisowi, like most other Gentians, loves a shady position; the leaves are tufted and the flower-stem procumbent, but it rises again at the point on which the flowers are collected in a loose head. They are of a pretty blue, but not so deep as that of G. verna. It is likely to become popular on account of the ease with which it may be grown and flowered.

Philadelphus mexicanus.—In your notice of this plant (page 30) from Mr. Walker's garden, the description does not apply to it as grown by me. I enclose two or three flowers of it, not in shape like Philadelphus coronarius, but more like a Hypericum or a small Rose, much larger also than P. coronarius. My plant has stood ten or twelve years against the house, facing south-east, and flowers freely. I enclose also a flower of Codonopsis ovata—rather an old introduction, but not much grown, I believe.—T. H. Archer-Hind, *South Devon.*

*** The flowers sent were too much withered for examination, and we should much like to see another specimen. If packed in damp Moss in a tin box it would, no doubt, reach us in a fresh condition.—Ed.

People's flower show in South London.—The Duchess of Teck has, we understand, consented to open a large People's Flower Show and Industrial Exhibition in South Lambeth on July 19. The exhibition is to be held at the Manor House, Priory Road, Wandsworth Road, and the promoters are desirous that it shall be in every way a success. Its object is to encourage the poor of that sadly overcrowded neighbourhood to grow flowers, and to teach them to cultivate that industry in which they take a special interest. About 200 money prizes are offered, amongst which are special prizes given by the Duke of Westminster, the Lady Emily Cavendish, Sir Donald Currie, and others. The entrance money is very small, and all competitors receive a free ticket for the distribution of prizes on Wednesday, the 21st July.

Veronica Kirki and V. salicornioides.—The first-named and larger-flowered of these two Veronicas came to me some seven or eight years ago from the late Rev. Harpur Crewe, and is now blooming for the first time with me. I think the violet anthers form a pretty contrast to the greyish petals on the first opening of the flower. It forms a neat bushy shrub, and is quite hardy here. The second named species is a curious little plant, of low-growing and spreading habit of growth, well suited for the adornment of a rockery, and in foliage most unlike nearly every other member of the family known to me, resembling more one of the smaller Cypresses than a Veronica. It came to me some four or five years ago from the Edinburgh Botanic Garden, and was, I believe, one of the many rare plants introduced by the late Mr. J. Anderson-Henry. It is very slow growing, seems perfectly hardy, and is now blooming here for the first time.—W. E. Gumbleton.

*** The flower-spray of V. Kirki sent with this note is extremely graceful and pretty, the dense racemes of white flowers being some 4 inches or 5 inches long, and the violet-tipped stamens Mr. Gumbleton alludes to add to their beauty. The foliage is intermediate between that of V. speciosa and V. salicifolia. Ed.

Indoor Garden.

THE GENUS ATACCIA.

(WITH A FIGURE OF A. CRISTATA.)

The very remarkable plant represented in the accompanying figure is usually known as Ataccia cristata, under which name it has been cultivated in English gardens since about 1840, when it was introduced from India to Kew, and under this name it was figured in the *Botanical Magazine* eleven years afterwards. But the name Ataccia is now sunk under Tacca, of which eight or nine species are known, and which, along with another genus, viz., Schizocapsa, form a separate Natural Order, with Amaryllids and Dioscoreas for its near neighbours. We only know of three species of Tacca in gardens, namely, T. artocarpifolia, T. pinnatifida, and that here figured, and although the two former are noble and well marked plants, they are not so strikingly ornamental as T. cristata is when grown as here represented. The characters of the genus Tacca, and particularly those of the flowers, are so singular as to be worth a word or two here. If we take the inflorescence of a Crinum or Pancratium, we find it composed of an erect leafless scape, bearing on its apex an umbel of flowers rising from between two usually large membranous bracts or sheaths, which fall off or shrivel before the flowers are over. In the genus Tacca these bracts usually number four or more; they are large in comparison with the flowers, and they are persistent—that is, they remain fresh as long as the flowers, or even longer. They are also handsomely coloured or variegated. Springing from the bases of these bracts are the numerous flowers, each on a short stalk; and in addition to these stalks with flowers upon them there are numerous others, which, however, do not bear flowers, but are sterile or abortive, and modified into long drooping filaments, 6 inches or more long and variously coloured. In the umbel of a Pancratium it often happens that numbers of the flower-buds never develop, but remain at the base of the others as tiny buds; but in the flowers of the Tacca these abortive flowers are made to add very considerably to the attractiveness of the plant. The perfect flowers have a shallow tube, six reflexed calyx-lobes, no petals, a ring round the mouth of the tube, inside which are the six short stamens and a short, thick, six-furrowed stigma. These characters show some affinity to the Amaryllis Order, although there is a very marked difference between the two in general appearance. On the other hand, they show that the Taccas have nothing to do with Aroids, with which they are usually classed in garden books. The homes of the Taccas are in the Malay Peninsula, India, Madagascar, and Tropical America, the three garden kinds being natives of the Malay regions. They all require moist tropical treatment.

Ataccia cristata. Grown at Belmont, Taunton. Engraved for The Garden from a photograph.

T. CRISTATA has a fleshy rhizome, from which spring the dark purplish green foliage, the blade being about a foot long, and the petiole about 4 inches. The flower-scape is erect, longer than the foliage, stout, angled, dark purple, smooth, and the bracts are arranged, one in front and one behind the flowers, these two being boat-shaped and without stalks; the other pair are placed side by side behind the flowers, and stand straight up, like the dorsal sepal of a Cypripedium; they are purple-brown below, green above, and their length is about 5 inches. The flowers are 1 inch across and coloured dark purple, the abortive ones, or filaments, being purple at the base and yellowish above.

T. ARTOCARPIFOLIA has a large tuberous rootstock bearing tall erect foliage; the petioles, which are over 2 feet long, are slender, brown, and bear a large blade of three divisions, which are pinnatisect, or like what may be seen in the well-known Amorphophallus. The flower-scape is about 6 ft. high, as thick as the little finger and brown; the flowers are very numerous, round, nut-like, green and brown, on drooping stalks 2 inches long, the filamentous ones being nearly 12 inches long and as thick as whipcord. The bracts are arranged in two series, three or four being narrow, lanceolate, 4 inches long, dark green, and hanging downwards, and three standing erect or forming a sort of canopy over the flowers; their length is 6 inches, width 2 inches, narrowing towards each end; colour deep green with streaks of purple-brown. It is impossible for this plant when in flower to fail in attraction, even for the most casual observer; its noble foliage and the tall stalked flower-heads, with their long, graceful filaments, drooping flowers, and singular bracts, are very uncommon. This and the following species may be seen flowering annually at Kew.

T. PINNATIFIDA.—This has a rootstock often as large as a child's head, and is cultivated in Malayan countries for the sake of the beautiful flour obtained from it by boiling, &c. The leaf-stalks are erect, about 3 feet high, grooved, purplish, and the blade is something like that of the last-mentioned species, except that the three divisions, instead of being simply pinnatifid, are divided again and again into irregular segments. The flower-scapes are 6 feet long and striped green and whitish; the flowers, filaments, and bracts are similar to those of T. artocarpifolia, but the bracts are more numerous and beautifully marked with pale purple veins. The three species here described flower in summer; during winter the two last should be kept almost dry and in a lower temperature, as they are thus induced to cast their leaves and go to rest, which has the result of making them throw up fine foliage and strong flower-scapes when they are again started in heat. Whilst growing they require liberal supplies of water.

CULTURE.—Mr. Lucas, the grower of the plant here illustrated, writes as follows concerning its

cultivation: The plant, which is growing in a 16-inch pot, measures nearly 3 feet across. When purchased a few years ago it was but a very small plant. As regards soil, it likes a compost consisting of good rough fibrous peat two-thirds and one-third of Sphagnum Moss, with plenty of charcoal and crocks and a good sprinkling of silver sand to keep it porous. As to temperature, it was grown in a house in which the day heat varied from 75° to 85° in summer, and it stood in the shady side of the house. It had plenty of overhead moisture, and plenty of water at the roots while growing. In winter it was kept drier at the roots, and the temperature ranged from 60° to 65°. Under the above treatment and after a good rest we find it to flower freely. W.

FREESIA REFRACTA ALBA.

I DO not know what the experience of others may be with regard to imported bulbs of Freesias, but I find that home-grown bulbs are much the largest, and consequently the best flowerers, the variety with yellow flowers being no exception to this rule. It appears to me that, like many other bulbous plants, these are weakened if kept too long out of the soil, and that no doubt is the reason why imported bulbs are weaker than home-grown ones. Our stock of bulbs, which were in flower in February in an intermediate house, were allowed to complete their growth in the same house, and by the middle of May, after standing in the open air for a fortnight, the leaves were quite yellow, and parted readily from the roots. I should, perhaps, mention that we made no attempt to hurry them to rest by withholding water; they had, indeed, as much water as was required to keep the soil moist. Under these conditions they went to rest at their own time, and the result is a greatly increased number of large plump bulbs; in fact, they must have increased at the rate of twenty-five per cent.; but this is not surprising, seeing that the strongest stems produced one or more bulbs in the axils of the leaves, while others ripened several pods of perfect seeds. Taken altogether, I do not know many plants which can be increased at such a rate as Freesias. On turning out our stock, I found that they had made a greater number of roots than I had supposed. They are not large, but very numerous. For the future I shall confine the number of large bulbs to eight for 6-inch pots. These will make neat specimens for table decoration or for vases, &c. I find the fragrance of these Freesias is much liked. The flowers also open well in rooms, and a plant will last in presentable condition for more than a week. On a limited scale we have proved that Freesias make capital specimens when grown in pans, with the flower-spikes neatly tied out, and we hope to increase their number by selecting pans about 14 inches in diameter and 6 inches deep. In these the bulbs will be distributed 2 inches apart all over the pan. In the matter of soil, Freesias are not very particular. With us they grow vigorously in good turfy loam in which there is a fair sprinkle of sharp sand. When potted, ours are placed in a cold pit, where they remain until the middle of October, when they will be introduced into a house heated about 10° higher than an ordinary greenhouse, and there they will remain until they come into flower.

TAUNTON.

SHORT NOTES—INDOOR.

Scarlet Geraniums for cutting in winter.—Henri Jacoby is one of the best varieties for the production of blossoms for cutting in winter. Cuttings rooted now will form bushy material that will produce a bright effect next winter. H. Jacoby is also an excellent bedding variety, having a compact habit and large well-formed lasting trusses of crimson-scarlet flowers. If plants of it are lifted in autumn and helped to regain their root action by genial warmth, they will begin flowering almost immediately.—E. H.

The Oak-leaved Geranium planted in a conservatory against a pillar or a wall, no matter how lofty it may be, is very pretty. It commences at the very base, and then inch by inch and foot by foot ascends, filling in all the space as it proceeds until the pillar or wall against which it has been placed has been completely covered with its leaves. Its flowers, too, in summer are sweet and useful in a cut state.

A MOIST BOTTOM FOR POT PLANTS.

THE progress that plants of most kinds that are grown in pots make when placed during the growing season on some kind of material that will hold moisture is such that it seems strange that the practice of placing them on moist surfaces is not more generally adopted than it hitherto has been. The saving thus effected of labour in watering alone is worth taking into account; but of even more importance is the influence that the moisture, which is continually rising from a damp surface beneath the pots, exerts on the growth, especially that of young stock. Dry air favours red spider and thrips but where there is moisture rising so as to condense on the under sides of the leaves, they seldom put in an appearance. The benefits that follow the adoption of a moist standing-ground are not confined to any particular section of plants; on the contrary, they apply to the various kinds of flowering and fine-leaved occupants of the stove, to Ferns and Palms, as well as to most of the hard and also soft-wooded greenhouse kinds, with the exception of such things as Epiphyllums, Agaves, and others of a succulent character that thrive in a dry atmosphere. Even Pelargoniums that succeed in a drier air than most plants make better progress if stood during summer on a medium that contains moisture than when on dry shelves or open stages, composed of strips of wood that admit of a current of air passing through them. Amongst those engaged in plant-growing there are none who are better acquainted with the advantages of keeping pot plants on a moist bottom than those who cultivate for the London market; with them it is now a rare occurrence to meet with anything on dry stages, and the plants which they grow in little pots are marvels of skilful cultivation alike for their healthy foliage and for the quantity of the flowers which they produce. T. B.

BASKETS AND VASES.

THESE should always form a part of the furniture of a conservatory, as they appropriately fit any style of house. Plain circular baskets, with no ornamental work projecting from the sides or bottom, are the easiest to fill, and look best when the plants have filled them, which they will do quickly, so as to completely hide all the wirework. The size of the baskets should bear some proportion to the size of the house, and although of plain outline, yet they should be strongly made, as thin wire soon rusts through when exposed to almost constant damp. Plants for baskets should be grown on in pots till they are strong and well established, and then they will feel no check, but will commence work at once. Ferns make excellent basket plants, especially those of drooping habit or which have creeping roots. In some cases it is an advantage to use a contrasting plant for the base of the basket. To make my meaning plainer, let me give an illustration. Polypodium aureum forms a striking plant in a basket. It has wide arching fronds of deep green, which keep their colour well in a greenhouse temperature, and may, if required, be taken into the house and hung up in the hall for several days at a time without suffering any injury. Asplenium flaccidum is equally effective, though distinct in character, but the effect in both cases is much enhanced if the base of the basket is covered with some creeping growth which will conceal the Moss and wires. There are many plants adapted for this, but my present purpose will be served if I only mention one, which is the hardy Sedum carneum variegatum. It is a very rapid grower, and will require pegging round the ball at starting, and it may then be permitted to grow as it pleases, hanging about gracefully in all directions. In filling a basket, I always provide a lot of this Sedum and similar things in small pots. I first line the bottom of the basket with Moss, and work in the little Sedums as the work proceeds at intervals up the sides. There is no occasion to place any in the bottom, as after the plants begin to grow they may be pegged to cover the bottom. Vases of different heights may often be usefully employed in an architectural conservatory to fill up centres, or to place in conspicuous positions where there is space for one handsome specimen plant, but it is quite possible to overdo it, as I think vases should be used sparingly. E. H.

NOTES.

SUMMER RAIN.—Gone are the weeks of hot, dry weather and vivid sunshine and dust, and now most welcome to the parched flowers is the soft, gentle rain which we are now getting. Everything seems grateful for it, and there is a general revival among the drooping leaves. Late and cold as the season has been, it has not been so deficient in flowers as one might have anticipated. Roses have been finer than usual, the bright, hot sun coming on the heels of a dripping spring time having brought out their flowers in abundance. Then a hot, dry time in early summer enables one to overtake the mowing and to deal death to the weeds. On hot, dry soils, or on hard caked lands which crack in the sunshine, this gentle rain will be welcomed heartily, and for a time at least the creaking rattle of the water-barrow is silenced by the coming of the showers. To-day (July 12) the soil is reeking with heat and moisture like a hotbed, and one result of this rain will be a rush of leafy growth of all kinds. Once more planting can begin again of all such seedlings or rooted cuttings that were safer left alone during the drought. Pipings of Pinks, Carnations, &c., may also now be made; indeed, there is no time so good for outdoor propagating as is the showery weather following on the heels of a period of hot, dry weather.

MUTISIA DECURRENS.—In habit this plant is somewhat like a Lathyrus, bearing Gazania like flowers, and climbing Marigold is a by no means inexpressive popular name for it to bear. The simple, strap-shaped glaucous leaves are decurrent, each terminating in a tendril at its apex. We have just now a strong plant of this species which has been planted outside for a year or more, and it is now showing twenty or thirty buds and flowers. It is in a warm and dry position in front of a greenhouse, a bundle of Fir branches affording it the means of climbing to a height of 6 feet or more. All the strongest growths of last autumn are now set with flower-buds, and it promises to be a showy garden plant, apart altogether from its botanical interest. Some difficulty in its propagation has always prevented this plant becoming common in even the best of gardens. Cuttings of the young growth will root under a handlight, and good seed germinates freely, but it is not very easy to procure. There are a dozen or more species of this genus for the most part confined to Chili and Peru, and they are related to Barnardesia rosea, another plant rather rare in collections generally. So far it seems Mutisia decurrens is the best of the whole set, and it has been figured in colour in THE GARDEN.

SWEET WILLIAMS.—There are many less enjoyable sights in even the best of gardens than a good broad belt or mass of seedling Sweet Williams. In the sunshine they are most bright and showy, and if you bend your face down among the clusters you feel them to be soft and warm, and their fragrance is delicious beyond mere words. They are of all colours, from white to deep velvety crimson, and the last named are, as I think, most effective, either in the open air or as cut and brought indoors for large bowls or vases. The Sweet William is so sweet and showy that it deserves to become again popular, and a packet of good seed sown now will not cost much for seed or for labour, and may afford much pleasure in days to come. This old-fashioned plant is not particular as to soil or situation if it has full exposure to the sun. I

saw a big bed of these flowers yesterday in an old cottage garden amid the hum of bees, and with butterflies fluttering all around them. The seed had been sown thinly, and the young plants were allowed to flower without having been transplanted. The bed was edged with a band of white Pinks, and I need scarcely say that the effect was good or that the fragrance was enjoyable.

Eryngium Oliverianum.—This is a good, strong-habited herbaceous plant well worth a place in all good gardens where it does not already exist. In good strong soil it grows a yard or more in height, and is now very effective, as its bracts are changing from grey to a steel-blue colour, whence, no doubt, originated its older name of Eryngium amethystinum. As seen in good strong clumps or masses it is a very attractive plant, and if its stems be cut before their fullest development they dry well and are by no means to be despised as arranged along with Typha rods, Pampas Grass, or other dried Grasses in winter vases indoors. It is a plant very readily increased by division, even thick bits of its fleshy roots forming young plants. Another species, E. giganteum, is also worth growing for the same purpose or for skeletonising. Seeds of this last sown as soon as they ripen in September form strong little plants, and flower where sown during the following season; and as the plant is bold and distinct in all its phases of growth, it is worth culture. It has also the merit of drying well if cut just before it flowers in June or July.

Canterbury Bells.—Will anyone be so good as to tell us why the numerous seedling varieties of Campanula Medium are commonly called Canterbury Bells? Just at the present time these biennials are very effective in the garden, especially where the partial shade of adjacent trees has prevented their big balloon-shaped blossoms becoming blistered by the hot sun. They vary in colour from pure white to deep purple, but none are prettier than the soft rosy or lilac kinds. Some of these new rosy shades are very beautiful, as are also the best of the Calycanthema or cup-and-saucer forms. Parkinson, writing in 1629, calls these plants Canterbury Bells, and also speaks of Coventry Bells, but does not enlighten us as to his reason for so doing. After the hot dry weather of the past few weeks, the present is a good time to sow seeds of these and other biennials in open-air beds. If sown on the approach of rain, the earth is now so warm and genial, that they readily germinate and soon make vigorous young plants for transplanting. The main point to observe is to sow very thinly, so as to allow ample room for after-development. As a general rule all annuals and biennials are sown much too thickly, and the result is wasteful of growth-force in all ways.

Wild Thyme.—This wild plant is now very pretty on dry sandy banks or rocky declivities, especially near the sea. It forms lovely carpets of soft, rosy lilac flowers here and there on dry banks, and seems to have a liking for stony places. In the midland counties of England, and notably in Leicestershire, the wild Thyme affects the little hills or mounds raised by ants. We all know Shakespeare's allusion in the "Midsummer Night's Dream"—"I know a bank whereon the wild Thyme grows," and, remembering the fact of its growth on ant-hills, Bacon's directions for its culture in gardens have an extra interest for us. "I like," says he, "also little heaps in the nature of mole-hills (such as are on wild heaths) to be set, some with wild Thyme, some with Pinks, some with Germander." Whenever I read this quaint conceit of Bacon's, my thoughts wander to the garden near the cottage at Weybridge, wherein the little hillocks are covered in the way above advised, if not with wild Thyme and Pinks, at least with Vinca, Woodruff, Acæna, Cerastium, Linnæa, and other interesting plants which seem to enjoy having a little raised mound, or hillock, all to themselves. I only once saw a good mass of wild Thyme in a garden, and that was on a heap of road scrapings. To grow this and many other beautiful wild plants well a little judicious starvation is necessary.

Morina longifolia.—A fresh green plant of Acanthus-like habit, just now bearing stout erect spikes of soft rosy or pink flowers which somehow irresistibly remind one of the Dresden china once so popular in high places. The plant was long ago introduced from the Levant, as mentioned by Miller in his "Gardeners' Dictionary," but it does not appear ever to have become a favourite in gardens generally. It grows best among stones, or planted near the foot of a wall, so that its spires of rosy blossoms lean out gracefully over the dark green Thistle-like leaves. The plant is quite easily raised from seeds, or old clumps may be carefully broken up and divided during wet weather. A good strong mass of this plant is always a sightly object, and its glossy foliage serves to set off any other flowers beside its own. Thus a few bulbs of Gladiolus The Bride planted near this plant, or the common Acanthus, have quite an added charm when the soft white flowers are seen near the Morina leaves. Once well planted this Morina thrives even in poor stony soil, or in waste sunny places where shallow-rooting plants do not luxuriate.

Lælia majalis.—This beautiful Mexican species is now flowering with us for the first time in a warm greenhouse. We have had the plant several years, but it never flowered before, although it has always grown freely. It is a good sized mass on a block of Apple wood, but two years ago quite a small plant bloomed in a neighbouring garden. This is the Mayflower of the Mexicans, and has with us been subjected to a very cool and airy climate. After its growth is made in autumn the plant is kept dry all the winter until young growth commences in April of the following year. Our plant has become stronger, although during winter air is freely admitted, and actual frost only is excluded from the house. A former plant absolutely died in the temperature of an ordinary plant stove. It is one of the most easily grown of all Orchids in the full sunshine of an ordinary airy greenhouse. Our plant is suspended near the glass, and bears one great rosy lilac flower of wax-like texture about 6 inches in length by 5 inches across. Plenty of water and sun-heat only when growing and absolute rest in winter seem to suit this shy-flowering species, and if more generally so grown, perhaps we should hear of its flowering regularly every year.

Fragaria indica.—This golden-flowered Indian Strawberry is very pretty as grown in wire baskets for greenhouse decoration. Its stolons droop on all sides, and as it has the habit of growing, flowering, and fruiting all the year round, it deserves notice as an easily grown plant, and one which is sure to prove attractive in most gardens. In some localities it is perfectly hardy, and is used in rock gardening for draping jutting boulders, but it is as a cool greenhouse or window plant that it shows to greatest advantage. This yellow-flowered Strawberry is, by Grant Allen, supposed to be a reversion towards the golden-flowered Potentillas, but, when writing on the subject of Strawberries in *Longman's Magazine*, 1883 (p. 314), he had overlooked this plant altogether, and on my drawing his attention to it, he dovetailed it into the article as republished in "Flowers and their Pedigrees" (pp. 98, 99), a book in which he tried to persuade his readers that "Wheat, by descent, ranks as a degenerate and degraded Lily!" We have now, however, to deal with what is, and not what was or what may be, and there is no doubt that, really well grown in a hanging basket, Fragaria indica is one of the prettiest and most interesting of all trailing plants that may be so used.

Alstrœmeria aurantiaca.—Wherever this plant is growing in clumps or masses, and flowering in the sun, there the garden seems to be on fire. No other plant is of such a fiery orange colour, if we except Lilium croceum, and for cutting this Alstrœmeria is to be preferred to the Lily. All the Alstrœmerias are very beautiful as seen well grown, but they are a little capricious, and so do not always succeed where planted. One way to establish this great orange-flowered kind is to sow its seeds as soon as ripe in positions where it is to remain, or its masses of thick white thong-like roots may be planted deeply in sand and stones with every chance of success. A dry, warm, and sunny position is essential to them, and they are grateful if a few coal ashes are spread over their crowns during the winter months. All the kinds are very useful for supplying good flowers for cutting when at their best, but lovely as are some of the other kinds, none grow so strongly or afford such a brilliant outdoor display as does this vivid orange-flowered kind.

Kniphofia (Tritoma) caulescens.—All the Torch Lilies are beautiful when well grown, and this is one of the finest of all in habit, with its broad glaucous leaves, almost Yucca-like in breadth and substance, above which towers its stout scapes of red buds and pale yellow flowers. It is with us one of the earliest of all the species to flower, for although T. media is more or less always in bloom, its flowers are more a survival of the late autumnal inflorescence than genuine products of the early springtime. Here we grow this plant at the foot of a sunny wall just in front of a heated greenhouse, its rootstock and collar being, during winter, protected by stones, filled in with dry sand. Thus grown it so far seems the most distinct of all the so-called species, and one that is worthy of a little extra attention. Can anyone tell us of the true T. pumila, as figured in the *Botanical Magazine* nearly a century ago? T. media often does duty for it in modern gardens, but as figured by Curtis it seems a most distinct and effective plant, and one quite different from any other Tritoma known to me.

John Rea's "Flora" (A.D. 1665).—I obtained the third impression of this curious old book (1702) the other day, and although the author tells us he has seriously considered Mr. Parkinson's garden of pleasant flowers, yet he does not sympathise much with that favourite old author. Rea deprecates the woodcuts in the "Paradisus," for, says he, "did his flowers appear no fairer on their stalks in the garden than they do on the leaves of his book, few ladies would be in love with them much more than they are with his lovely picture." This latter allusion is to the woodcut portrait of Parkinson as affixed to the first, or 1629, edition of his "Paradisus" before alluded to. Hence it would seem that the horticultural critic is not a mushroom upstart of to-day, but existed at least a century ago. Rea seems to have been a good practical gardener, since he alludes to the double Narcissus poeticus and its habit of failing to flower well, which, he says, it will do if transplanted every second year. He recommends it to be dug up in June or July and replanted in September. Rea seems to have been a little in advance of the garden art of his time, since he

tells us that he has seen "many gardens of the new model in the hands of unskilful persons, with good walls, walks, and grass-plots, but in the most essential adornments so deficient that a green meadow is a more delightful object." Again he says, "noble fountains, grottos, statues, &c., are excellent ornaments and marks of magnificence, but that all such dead works in gardens ill done are little better than blocks in the way to intercept the light, but not at all to satisfy the understanding. A choice collection of living beauties, rare plants, flowers, and fruits is indeed the wealth, glory, and delight of a garden." This old work of Rea's is rich in gossip and poetical allusions, and is worthy of a place among curious old books of the garden.

Senecio japonicus.—This big Groundsel from Japan possesses a twofold chord of interest, for it is distinct and effective in flower and in foliage alike. Its great palmate or deep-cut leaves are borne on fluted stalks 2 feet or more in height, while its flowers are like big Daisies of a rich old gold colour. Planted out in deep rich soil and in a sheltered situation it grows most vigorously, and is so distinct in habit that it rarely fails to attract the attention, even if not the admiration, of visitors. Another fine composite plant now in full beauty is Inula glandulosa, one of the finest of all border plants where it does well. It bears yellow flowers 5 inches across, the ray florets being narrow and rather thickly set together, and being more or less twisted they remind one of gold lace or fringe. Another fine Groundsel, viz., Senecio pulcher, is not quite so happy this year as usual, the hot, dry weather having been against its luxuriance so far, although, as a rule, it is one of the best of all our autumnal border plants, its rich lake-purple Daisies continuing to open until absolutely cut down by the first sharp frosts of winter.

Lathyrus tuberosus.—This is a gracefully habited Everlasting Pea, flowering after L. Sibthorpi with L. grandiflorus, and before L. latifolius and its beautiful white variety come into full flower. Planted at the foot of a hedge or a fence, this pretty little species scrambles over and about it in a pretty way, or, like the other Everlasting Peas, it may be planted in a bed on the Grass and allowed to arrange itself in its own way, which is sure and certain to be a pretty one. Growing here near a Holly bush it scrambles up its outer branches, and also twines very gracefully about the uprising leafy stems of the King's Signet or Solomon's Seal. Its slender stems bear axillary clusters of small, but shapely, red flowers, somewhat midway between pink and terra-cotta-red. L. grandiflorus is one of the most robust of the whole family, and just the thing to plant at the foot of a rough Hawthorn hedge or an open bush of any kind as a support. All are good as affording flowers in quantity, but none are more welcome in this way than is the white Everlasting Pea, which yields shapely white clusters of long-enduring blossoms.

Rubus odoratus.—A tall-growing large-leaved Raspberry with odorous palmate leaves and rosy flowers as large as those of a wild Rose. It is a vigorous-habited plant, taller growing than R. nutkanus, and as it extends itself rapidly by underground stolons, it is well adapted for naturalising in the open parts of woods and plantations, especially in positions near walks, drives, or roads. The golden-leaved and double-flowered varieties of the common Blackberry may also be grouped with them effectively for the sake of variety. As seen vigorous and healthy, R. odoratus is an effective shrub at all seasons, either as leafy in spring, flowery in summer and autumn, or as its warm brown stems stand up in the sunshine of a winter's day, with those of the white-washed Bramble for company. A good group or two of these strong-growing ornamental Brambles and Raspberries, if well arranged along copse margins, or even in out-of-the-way corners, now too often sacred to weeds, might really become a pleasant feature to have near a country house.

Linaria pallida.—This plant is either a pleasure or a curse, according to the position selected for it in the garden. No greater pest was ever unwittingly associated with delicate Androsace or dainty Primrose in the rockery or alpine garden. Once it gains a footing in good deep soil amongst stones, and its underground stolons begin to wander about and crop up in the most unexpected and unlikely places, and many a day's work is in store for those who feel bound to get rid of it. Like Arabis and some of the Saxifrages, the growth of this plant is slow and sure; it overwhelms everything less robust than itself, and if unchecked in time it will smother up and kill many a rare plant in its growth. There are some plants very lovely in themselves that are too luxuriant if unrestricted by artificial means, and others which are really beautiful only when starved into a dwarf and floriferous habit. This plant is one of them, and there are others of which the white and rosy varieties of Thymus Serpyllum, T. lanuginosus, many Sedums, Saxifrages, and Sempervivums may serve generally as examples. For such plants isolated mounds, beds on the Grass, or cemented pockets or niches in the rockery or wall-top garden are essential. So planted they are out of danger, and are even more beautiful than when doing mischief among other things.

Veronica.

RAISING HARD-COATED SEEDS.

I do not know of any tough-coated seed that comes up under six weeks, and some lie in the soil as many months before they germinate. Nearly, if not quite, all seeds of this description come up best if sown as soon as ripe. Christmas Roses, for example, rarely come up unless sown as soon as ripe, and I have never succeeded in raising tuberous-rooted Tropæolums when the seeds were held over till the following year. The soaking of seeds of this description for some hours previous to sowing has often been recommended, but I have found that I succeed just as well without doing so. My experience of soaking seeds is that unless very carefully managed more harm than good is done, and that a check to germination is more apt to take place than when sown in the ordinary manner and the soil maintained in a uniform state as regards moisture. An important detail in the raising of such seeds is covering them with soil sufficient to screen them from atmospheric influence. The great danger lies in the soil becoming dry during the first process of germination. When this takes place the seeds partially harden, and will then, in spite of good attention, remain months and sometimes a whole year underground before they come up. I have seen Cyclamen and other seeds come up on a rubbish heap long after the pots had been emptied, and when they had been given up as bad.

My plan is to well water the soil before sowing, not giving one heavy watering, which will render it somewhat too close, but rather giving two or three moderate doses at intervals of an hour or so. Then, a moderate watering after sowing will ensure moisture sufficient to act upon the tough coat of the seeds, and thus induce them to swell. If hard-coated seeds treated in this way are examined a day or two after sowing, they will be found to have considerably increased in size, and if from this time they are kept in an equable state as regards moisture, they will in due time come up freely. I have seen it stated that Cyclamen seed will lie several months before it germinates, but I get up 95 per cent. of it in six weeks from the time of sowing without having recourse to bottom heat, which from April until September is unnecessary. The seeds of the tuberous-rooted Tropæolums are considered to be unusually difficult to get up; but I have raised them in quantity by sowing as soon as ripe in the following manner: I well drained a box 4 inches deep, sprinkling some soot on the drainage to keep out worms, and after sowing in the manner just mentioned, I sunk the box to within 1 inch of the rim in the open air in a shady position. I should, however, state that the box was only filled with soil to within 1 inch of the top, so that the surface was level with the ground outside. The inch of space thus left was packed in with Moss and covered with a board. Sown in this way, there was no danger of the seeds becoming at all dry. In a general way they did not require looking to more than once till they came up, which was early in September. When the young plants were well through the soil, they were removed to a sunny situation and carefully attended to in the way of watering, and by the commencement of winter they had made 6 inches of growth. The following year they were treated in exactly the same way without removing them from the seed box, and most of them flowered well. That lovely little Tropæolum, T. azureum, so rare in cultivation now-a days, I raised in the same way, and I feel certain that it is the only sure method of doing so.

Christmas Roses are long in coming up; under the best treatment they do not appear until the spring following that in which they were sown. They will come up if sown as above described, but where any quantity has to be raised, a more rough-and-ready method may be successfully employed. A piece of good friable ground on a north border should be prepared and watered; the seeds should be sown as soon as ripe, and covered half an inch or more deep with leaf soil made rather firm. Water gently and cover up several inches deep with Cocoa fibre, or with anything that will ward off the summer heat, which is the thing to guard against till autumn. During a very hot time a little attention in the way of watering may be necessary, and in March, or later, according to the season, the young plants will appear almost all at once. The covering may then be gradually removed. Where this way of sowing is resorted to, it is well to mix a little soot with the soil, as that keeps down worms, which are sure to be attracted in numbers when the weather is dry, and however useful they may be as draining agents, they are not wanted amongst seedlings and cuttings. Hepaticas, which have hard seeds, may be raised in this way, and the Gentians can scarcely be relied on to come up by any other method. Perhaps the hardest coated seed produced by a soft-wooded plant is that of the Canna, and soaking in warm water for twelve hours before sowing is, I think, in its case conducive to success. Cannas, however, require a strong bottom-heat to bring them up; they rarely germinate with freedom under cool treatment.

Palm seeds are amongst those that require careful handling, and the germination of many of them is much assisted by having a portion of the tough coat pared off. Everlasting Peas do not come up very readily, and the pure white one seems to be more difficult to induce to grow than any, if I except the new scarlet Lathyrus Drummondi, which I hope some reader of The Garden will give me a hint as to its successful germination. The seeds are small and almost stony as regards hardness. Up to the present

this has baffled me, and I think that it is one of those things that will only come up if sown as soon as ripe. J. C. B.

THE DIVINING ROD.

There are still people who doubt the power of the divining rod to find water, but it is a fact, nevertheless, that wherever John Mullens sticks his peg there water will be found, although scientific people had previously declared that "owing to the lie of the strata no water could possibly collect at the spot indicated." "Now, then," I said to an experienced engineer and a constructor of reservoirs, "what have you got to say now?" when the water appeared where he had never thought of looking for it. His reply was, "Well, I am fairly puzzled." Now is the time to test the "water-witch," as the people about Grantham call John Mullens, where he has done so much good work. As he told the writer once—in a wet season one can find springs almost anywhere, but in a dry season only the permanent springs run, and when he found them people believed him. His proceedings when in search of water are frightfully unscientific. Armed with his Hazel or Thorn twig, John is always ready to prospect any piece of ground at a moment's notice, and the way in which the twig whips sharply round and stands stiffly erect above a running current of water is really the best thing in magic I have ever seen. There was a tradition here that an ancient culvert existed somewhere near the house, and that it had some connection with the drains, but it could not be found, although it had been searched for many a time. John Mullens found it in less than five minutes and set it out from end to end, and a grating ventilator now marks where he placed his middle peg exactly above the brick arch. He has, I believe, been also employed successfully in similar work by some of the London sanitary authorities. Allow me to propose that Mr. Mullens give a demonstration before the public at some great flower show. What an attraction the "water-witch" would be! I would suggest that a running current of water under dug or ploughed ground should be provided for the occasion, as if newly laid down on Grass land the drain would be seen Mullens to find it and peg it out. My impression is that natural springs or drains consisting of earthenware pipes are sooner detected by the twig than iron water pipes; although when Mullens was here he was so frequently stumbling over the numerous iron mains and branches from the reservoirs, which he found almost in every case, that our water-man had to follow and mark these to afterwards distinguish them from the natural springs.

S. W.

Everlasting Peas.—Of these there are several fine forms, and foremost among them must be put Lathyrus grandiflorus. It is a very handsome species, with flowers much larger than those of the ordinary Everlasting Pea; the standards are lilac and purple and the keel and wings white. Once planted, it will endure for years, making quick and rapid growth in spring, and flowering early and with great freedom. It is not very particular as to soil, but a somewhat open sunny spot should be devoted to it. The common bright rose-coloured Everlasting Pea is known to all, but there are some varieties of it a little larger and deeper-coloured than the type—the results of selection. —R. D.

Garden in the House.

SOLOMON'S SEAL INDOORS.

As pot plants for indoor decoration in late winter and early spring nothing is more useful than this graceful wood-plant. Its singular nobility, refinement, and delicacy, both of form and colouring, make it highly suitable as a room ornament. Flowered under glass, its leaves are more tender in colouring, and the stems rather slighter than in the natural outdoor state. Six or eight crowns potted in 8-inch pots in September and kept in a cold frame may be brought on in convenient batches in a moderate greenhouse temperature, so as to flower from Christmas onward. The engraving shows a potful so treated in an old embossed Venetian copper bucket.

Solomon's Seal as a room plant. Engraved for The Garden from a photograph.

Leaf ornaments for window screens.—The following may afford amusement and pleasure to those who take a delight in domestic decorations: An exquisite transparency may be made by arranging pressed Fern or other handsome leaves on a pane of window glass, laying another pane of the same size over it and binding the edge with ribbon, thus leaving the group imprisoned between them. Use gum-tragacanth in putting on the binding. It is well to put a narrow strip of paper under the ribbon. The binding should be gummed all round the edge of the first pane, and dried, before the leaves are arranged; then it can be neatly folded over the second pane without difficulty. To form the loop for hanging up the transparency, paste a binding of galloon along the edge, leaving a 2-inch loop free in the centre, afterwards to be pulled through a little slit in the binding. In halls a beautiful effect is produced by placing these transparencies against the side-lights of the hall door. Where the side-lights each consist of only a single pane, it is well worth while to place a single transparency against each, filling up the entire space, and thus affording ample scope for a free arrangement of Ferns, Grasses, and leaves, while the effect of the light passing through the rich autumnal colours is very fine. Leaves so arranged will preserve their beauty during the whole of the winter.

Kitchen Garden.

PEAS IN DRY WEATHER.

Last summer the Pea crop, after the produce of the early sowings had been gathered, was in most parts of England cut short by dry weather in a way that does not often occur. In the southern counties the rows were literally burnt up before the contents of the pods had reached nearly their proper size, so that by the end of July in many places Peas were over. The parched condition of the ground and recent intense sun heat make it look as if the present season, so far as relates to Peas, is about to be a repetition of the last. There is no vegetable of which gardeners find it more necessary to keep up a continuous supply for as long a season as possible than Peas. Those who have had to grow vegetables will not require to be told that there is even more difference in the length of time during which the Pea crop can be made to hold out in autumn in some places than there is in the time when the earliest Peas come in. The character of the soil has doubtless a good deal to do with this, for in some parts of the kingdom, under ordinary cultivation, mildew sets in early to such an extent that late Peas are unobtainable. In old gardens, where the soil is light and dry and contains much humus, in addition to being over-sheltered, mildew finds the conditions most favourable to its development. In places so circumstanced the crop is generally over long before it comes to an end in localities more suited to the growth of Peas. Yet something may be done to lengthen the supply, even where soil and other matters are not favourable. Plants that are subject to fungoid growths are less liable to their attacks when vigorous than when weak, and therefore the best way of preventing their attacks is to take means to secure strong healthy growth.

Peas are deep rooters, pushing their roots much lower down than many plants, and consequently they require the soil to be loosened deeply. In common with other things that make much growth in a little time, they cannot be kept moving freely in poor ground. To enable them to succeed in a hot dry summer their roots must find food wherever they penetrate, for though it is the numerous lateral fibres emitted from the main descending roots that principally sustain the plants, still the deeper the latter are induced to descend, the more feeding fibres they produce. The course some-

times advised of growing Peas without manure in ground that has been manured for a crop of some kind the year before may answer for early sowings, or in new ground that is more than ordinarily well adapted to the growth of Peas. But it is not the way to get the best results in the case of summer and autumn crops where the soil is of a light or ordinary description. My own practice with all except the earliest crop has been to open trenches similar to those used for Celery, and then to dig in a spit deeper a good dressing of manure, with where the soil was light 3 inches or 4 inches of marl. When the latter was unobtainable, clay pulverised by exposure was substituted. This with thin sowing, and the rows far enough apart proportionate to the height to which the varieties grow, good soakings with water during dry spells and mulchings with litter for about half a yard on each side of the rows, will keep Peas growing in hot dry seasons in such a way as to enable them to ward off the attacks off mildew, and secure a supply much later than could have been procured under the ordinary course of cultivation.

One of the commonest mistakes in Pea growing is thick sowing; where too much crowded in the rows it is scarcely possible, even with the help of water, to keep the crops going in dry seasons so as to admit of their lasting out as they should do. The roots crowded together as they are under such conditions have not enough good material within their reach to maintain growth, the result being that the crop, such as it is, comes in all together. I have said nothing about the difference that there is in the quality of Peas that have been grown freely and others produced under opposite conditions, but I may add that even the best varieties when indifferently grown are hard and often very deficient in flavour. T. B.

Late French Beans.—An early kind of dwarf habit, such as Newington Wonder or Osborn's Foreing, planted now will probably prove useful in the autumn if the frost should cut off the Scarlet Runners. They should be planted on a warm south border, where it would be easy to shelter them if required. By the aid of an old canvas blind I have often kept this late-planted crop of dwarf Beans going till quite late in the autumn. A slight framework of lath should be erected just before frost is expected, and an old blind or one of Brittain's nets may be drawn over it at night, and removed in the morning in a very few minutes. A very slight covering suffices to shelter tender things from early autumn frosts.—E. Hobday.

Summer-sown Carrots.—I was pleased to read Mr. Hobday's note respecting Horn Carrots. Gardeners, with their constant succession of crops and ample help in the way of labour, can easily find a patch of soil, if but half a rod in extent, upon which to make a sowing of Carrot seed now, and they have themselves to blame if from the middle of October till the end of the year they have not a liberal supply of delicious young Carrots, as well as a stock of larger ones for winter use. But it is a matter for surprise that market gardeners favoured with rich, light soil do not strive to obtain a good crop of these for the autumn. Just now, when early Potatoes are being taken up, the soil is left in admirable condition for receiving Carrot seed, and a few pounds mixed well with sand and sown thinly in drills 10 inches apart might yield a very profitable crop. It seems certain that we shall have plenty of all the Cabbage and Broccoli tribe, for plants of these have been put out largely and are doing well. The result, doubtless, will be a glut of hardy vegetables in the market. On the other hand, small Carrots, clean, young, and tender, would cost little to bunch, and, compared with Cabbages, would not be very bulky to market. Moreover, a Carrot crop so short a time on the ground would not absorb one tithe of the nutriment from the soil that Cabbages would do; hence all round it does seem as if summer-sown Carrots would prove a capital crop. Add to these winter Spinach, sown early, Rosette Coleworts, neat, firm, medium-sized Brussels Sprouts, and good late Cauliflowers, and really high class vegetables are ensured.—A. D.

PEA TRIALS.

In the following trials, made in Ohio, the Peas were sown on May 2 in drills 3 feet apart. The seed was placed 3 inches apart in the row and covered with 3 inches of soil. The season was very favourable, especially in the earlier part; hence the record of nearly all of the early varieties was uncommonly good. The following table is intended to show the comparative earliness of the varieties named. It does not show the first mature pods found upon the plants of any variety, but shows how many pods were fit to pick at a given date. The first picking was made in every case before any of the Peas were too hard to use, and all the pods mature enough to pick at that time were taken. In fact, the pickings were made just as though the Peas were intended for market or table use. This method shows just what it is desirable to know about any variety, viz., the length of season and time of largest picking. According to this method, the earliest variety is the one that shows the greatest number of pods at the first picking and yields its crop in the shortest time. The season being less favourable for the late than the early sorts, the former do not make as good a showing, comparatively, as the latter. The length of season or number of days in bearing given is undoubtedly too long for some of the early sorts and too short for some of the late, but the length of season seems to be quite variable with most varieties, and is influenced greatly by the weather, depth of planting, and time of planting. Before the picking was commenced twenty-five plants were counted off in each row, and the same plants picked from each time.

In the next table is given the whole number of pods picked from twenty-five plants, also the number of Peas. It will be seen that the relative weight of shelled Peas is much smaller in the smooth than in the wrinkled sorts, being from 15 to 20 per cent. greater in the latter than in the former, the only exceptions being the early wrinkled sorts; but even they stand higher than the smooth varieties. In some of the late sorts the shelled Peas weigh more than the empty pods, but in some of the smooth early sorts the weight of empty pods is more than twice that of the shelled Peas.

Name of variety.	First picking—days from planting.	No. of pods from 25 plants. First picking.	Second picking.	Third picking.	Fourth picking.	No. of days in bearing.

Of the early sorts, Cleveland's Rural New Yorker Everitt's, Maule's, Ferry's and Vick's Extra Earlies, Ferry's and Sibley's First and Best, Henderson's First of All, Livingston's First in the Market, Early Pearl, Early Philadelphia, Excelsior, Landreth's Extra Early, and 17th of June are essentially the same. Some of them may have been grown with greater care than others, but all of those named show careful selection, and all that is claimed for them as to earliness is true. Bur

pee's Extra Early was quite different from the others, being taller and more productive, but nine days later. It was the same as a variety under the erroneous name of Early Philadelphia from the same source. Stratagem maintains its reputation, and Alexander's Improved Stratagem seems really to be an improvement, so far as productiveness is concerned. Vick's New Dwarf is promising, and may prove to be superior to American Wonder. Bliss' Abundance is an excellent variety, but Bliss' Everbearing is a misnomer. It is only fairly productive, and yields its crop at two pickings. For a variety that continues long in bearing and yields heavily, Horsford's Market Garden seems to have no superior. It is unrivalled for family use. Smilax is very promising, also Early Pearl, if upon further trial it should prove to be as early as it appears to be.

TOMATO TRIALS.

In the following trials the seed was sown on a hotbed on April 20. The plants were once transplanted and put in their fruiting quarters on June 2. The Tomato is quite variable as to earliness; the variety that is earliest one season may not be so the next. It will be seen that Acme seed taken from the first ripe fruit produced plants that gave fruit earlier than that taken from the last ripe fruit. Doubtless, the plan of saving seed from the first good fruit, or from plants that give the most early fruit, is a good one. It has been observed that the finest, if not the earliest, fruit is secured by this method of selection. There was no difference observed between seed saved from fruit affected by rot and that saved from sound fruit. Seed saved from green fruit failed to germinate.

Name of variety.	First ripe fruit.	Number ripe August 14.	Number ripe August 21.	Number ripe August 31.	Average weight in ounces.	Average circumference in inches.

Trophy	12	9	9	20	6	9
Wonder of Italy	12	7	10	47	2	5

Advance is rather larger and not so rough as the Alpha, but not large and smooth enough to become a profitable market variety. Climax is a fine smooth-fruited kind, much resembling Favourite. Cardinal has fruit of good form and colour, but it rots quite as badly as Acme. It is not superior to that variety, except for markets where its colour is in its favour. Market Champion resembles Cardinal, and, whether identical or not, is a fine variety or strain. Optimus resembles Perfection in colour, and may be identical with that variety. Of Precursor the fruit is quite irregular, and scarcely better than that of Canada Victor. Of Rochester the fruit is quite large, but somewhat irregular, and ripens unevenly. Standard Market and Shipping regular and smooth, but resembling Perfection. The new Tree Tomato is identical with the Upright Red; its fruit is too rough and late. Wonder of Italy is small and worthless.—*Ohio Experimental Station.*

THE RIDGE CUCUMBER.

This is a crop which often repays a little attention. Up till the time of writing, the present season has not been very favourable to its growth. During the greater part of the month of June the temperature, especially at nights, was too low for any real progress. The last few days of the month and the early days of July have, on the other hand, been scorchingly hot. On the whole, however, where the plants were fairly well established before the spell of hot weather, and have been looked to since its commencement, there are marked signs of better growth.

Where the plants are not at once available, or already planted out, it will be too late in the season for much to be done during the present year, but where the plants have been grown and are placed by this time in the open, much will depend upon the subsequent treatment. With regard to raising the plants from seed, the precise time at which the seed is sown must be to some extent governed by circumstances, and also by the situation for which the plants are ultimately intended. Frost is the great enemy to be guarded against; therefore it is useless to set them out until there is reasonable ground for hope that the frosts are past for the season. Earlier than the middle of June for most positions I could not recommend for planting out. To obtain strong plants by this time it will be necessary to sow under glass during April. The way I generally proceed is to plunge some broad pans or boxes, 3 inches to 4 inches in depth, into a partly spent hotbed, and sow the seeds singly in these at a sufficient distance apart to allow of room for rooting and subsequent removal without disturbing the soil round the plants. The boxes or pans should, however, be drained, as the free escape of superfluous moisture is a great point towards securing healthy plants. As the season advances I remove the glass entirely during the daytime, and for the last week or so before planting out leave no protection but that of the frame itself.

In planting out, the selection of the site will have much to do with the amount of labour requisite to cultivate the crop successfully. With such a moisture-loving plant as the Cucumber, little or nothing can be done if there is not easy access to water in one form or another. A favourite spot of mine for raising ridge Cucumbers used to be some small beds in a back garden. These patches of soil sloped considerably to the south-east, and along the bottom of them there was a small mill stream, which, during the hottest season, afforded a supply of water. On the north and west on higher ground there was a small coppice, which afforded capital shelter. Towards the stream the soil was too moist to produce ordinary garden crops to perfection, if I except Runner Beans, which did remarkably well; but, on the whole, it was about the best spot for raising ridge Cucumbers that I have met with. In such a position, however, it was important that the ground should be ridged, otherwise the drainage would not have been sufficient. It is not always one has the command of a place so naturally favoured, and this season I am obliged to grow my Cucumbers on a spot in many respects just the reverse. The situation is high, the soil incapable of long retaining moisture, and the water has to be raised from a well. The best way for such sites I find to be to place some well-rotted manure in a trench, and cover it with soil 6 inches in depth, finishing off the soil at about the general level. If I deviate at all from this, I would prefer to have it below rather than above the surrounding soil, as to attempt to grow ridge Cucumbers on a ridge in such places would be an error. This season, however, I have had no opportunity of trenching the ground in this way, as the only place I had available was one which has all the spring been occupied as an old Cabbage bed, necessitated by my young plants being killed by the winter's frosts. To economise the space, I have loosened the soil as deeply as possible in spots some 18 inches or 2 feet in diameter, and worked it down to a fine tilth. In the centre of these spots I have placed my plants and worked in rotted manure round the margins of the little circular patches. In this way I have been able to save some of the Cabbage beds in the spaces between the plants, but they will, of course, be removed as the Cucumber plants grow on and need the room. I have my earliest row of Celery at one end of this bed. As raising water directly from a well and applying it at once to the plants did not commend itself to me, I have placed a large wooden trough in a convenient position on the edge of the bed, and into this have thrown several pailfuls of solid excreta from the pig-stye—the same kind of thing from the sheep-fold would be quite as desirable if to be had—and with this I daily mix enough water to supply my Cucumbers, Celery, and other plants which require stimulating.

The actual outcome will, of course, depend much upon the season, and the treatment will have to be varied accordingly, but unless the weather has been very abnormal I have never failed in getting a fair return for the trouble expended upon it. In growing ridge Cucumbers, as with others, there is very much to be gained by pegging down at the joints, and in thus getting them to take a new hold upon the soil. When a plant has to depend upon a single root, it is seldom it produces a very heavy crop. D.

5508.—**White Cucumbers** (*J. N.*, *p.* 22).—Cucumbers are not aquatic; consequently their roots under ordinary culture, do not require water every day. Your temperatures being right, the deficiency in chlorophyll or colouring matter may be due to incessant watering, combined with insufficient food. This, however, is only conjecture, as you omit the most important part of your case, viz., the compost in which they are struggling for existence and the mode of culture, whether in pots or on hills, in frames or a Cucumber house proper. Read notes on Cucumbers in this week's calendar, and if the remarks therein contained do not help you, examine the bed, as it is more than probable the soil has become sour, and the roots are unhealthy and incapable of performing their duty. Should this prove to be the case, cut off all the imperfect fruit, thin out the Vines and a few of the aged leaves to make room for fresh young growths, cleanse and limewash the structure. Meantime, prepare fresh compost, consisting of medium turfy loam, say five parts, rough charcoal one part, and old lime rubble one part; mix thoroughly, and place it in the sun to warm and sweeten. When ready for use remove the mulching, also as much of the old soil as can be taken away with safety, and top-dress with a layer 2 inches in thickness; make this firm, and water rather sparingly until the roots have taken hold of it. Renovate the fermenting material with Oak leaves, if available, to prevent the bottom heat from sinking below 80°, shade slightly if the plants show signs of flagging, and syringe twice a day with warm soft water. Avoid the use of all animal manure, but stimulate the foliage and roots by syringing every part of the house three times a week with very weak soot water, and give diluted liquid when the roots show on the surface of the new compost. Examination of the old compost having revealed the condition of the roots and drainage, your own judgment will be the best guide in giving water, both as regards quantity and quality. Constant saturation of the soil and daily driblets are alike pernicious, and heavy feeding, when roots are neither plentiful nor healthy, is worse than useless. Therefore to avoid these extremes water copiously when this element is needed, ply the syringe freely on non-watering days, and grow the plants without shading when they are re-established. If any of the compost remains over, cover it up with fresh stable manure

for future use, as all mixtures of this kind improve by keeping. Soot water is an excellent insecticide and stimulant when used in moderation, but, like all other powerful fertilisers, burns the foliage and roots when applied too strong and frequently. Old soot which has been kept for a time is less fiery than new, and for this reason should be preferred. Half a peck placed in a bag, and sunk in a tank containing, say, one hundred gallons, will make a supply which should be diluted for a few days at first, but when the tank has been once or twice filled up, it may be used without the addition of pure water.—W. Coleman, *Eastnor Castle, Ledbury.*

—— The reason why "A. N.'s" Cucumbers become white is probably because seeds of the white or cream coloured variety have been planted. White Cucumbers are seldom produced on plants consisting of the ordinary green-fruited varieties.—J. D.

Ferns.

INDOOR FERNERIES.

In the construction and arrangement of an indoor fernery, there is abundant scope for the exercise of taste and skill. There is no class of plants which submits so readily to such a variety of dissimilar conditions as Ferns, and the question of temperature has less significancy in their case than in that of most plants. It is true that to grow some species care must be exercised, but many of the so-called stove Ferns will succeed in a warm greenhouse, and all the greenhouse species will flourish in a warm house. Even hardy Ferns will acquire a freshness of tint under glass which does not always belong to them in the open air. Most Ferns are considered to do best in a shady position. To a certain extent this is true, but I am convinced that more shade than is necessary is frequently given them, especially if we want any of the fronds for bouquet making or for mixing with flowers, or if we wish at any time to move the plants out of the house in which they grow, which most people do at some time or other if grown in pots. Fronds grown in the shade in a high temperature heavily laden with moisture are of no use for cutting, nor yet are the plants grown under such conditions of any use for decorating rooms, for the least blast of cold air shrivels up the delicate pinnules almost immediately. In constructing a fernery, we must first take into consideration what is our aim and object. If we want plants to be moved into the rooms, or fronds for cutting to mix with flowers, they must have plenty of light and as low a night temperature as is consistent with healthy growth. If, on the other hand, we simply want to enjoy the plants as they grow without thought of removal, then the natural system of arrangement is decidedly the best. In such a case, pots and tubs may be dispensed with. The fernery should be as large and as lofty as the means will admit, for no fernery will contain a representative collection that does not include some of the Australian Tree Ferns, and these will require a considerable amount of space upwards and laterally, for their fronds are far-reaching. In a natural fernery the outline of the beds and borders should have as picturesque a surface as can be given in a limited space; winding paths will be formed of some sober coloured material, cement being very appropriate. The Tree Ferns may be grouped in the gullies or indentations, and lower growing species on the banks, which may be aided by naturally arranged rockwork. This plan will give more head room for tall species, and will bring small kinds more into prominence. Mosses and other creeping things will fill up bare space, and cover all with a living natural growth. In making the borders drainage is essential, and it will add much to the interest of the house if a quiet pool can be introduced at the base of a mound of rock, down the face of which a tiny stream might ripple. There should be no bare walls visible; in some way they should be clothed with suitable vegetation. Virgin cork is sometimes used for this purpose, but its chief fault is its lack of permanence. I have seen clinkers and large pieces of hard furnace coke covered with cement used with good effect; and there are creeping plants, such as Ficus repens and others, that will cover quickly any naked wall with living greenery, clinging to the stones in a natural manner without aid.

The culture of Ferns in pots is not attended with more difficulties than are found in the case of ordinary plants. If the fronds are required for cutting, which in most gardens some of them are, I have generally found that a proportion of loam in the compost gives strength and substance to them. Indeed, some kinds do best altogether in loam, and for greenhouse Ferns, especially for plants which are required to possess a good development for furnishing corridors, rooms, &c., and which must at the same time be grown in limited sized pots, loam as turfy and fibry as it can be had is the best material for them. It may be lightened with peat or leaf-mould if too heavy, and sand and charcoal dust will be useful if it lacks porosity, for in no case must stagnant water linger in the soil. It may be taken without saying that the pots must be clean and well drained, and the soil in a healthy condition when used. The ball of the plant must be neither wet nor dry. The best season to repot is in spring, just before or about the time when growth begins. At that season Ferns may be divided—may, in fact, be cut up into little bits and begin life afresh in the smallest of fragments, though in such cases a close moist shady place will be of great value in encouraging early root action, without which some may, perhaps, perish. Though the general potting should be done in spring, yet young growing specimens may be shifted at any time during summer.

Ferns in baskets look well, and this is an excellent way of growing all the naturally trailing or drooping species; indeed, all Ferns will grow as well in baskets as in pots, but it may not be either convenient or expedient to have too many grown in that way. Still, a few to hang about the house will improve its appearance, and they are very useful to move into the dwelling-house to hang up in the hall and corridors, &c., on particular occasions. The simpler the form of basket used the better, as whatever kind is employed, none of it should be visible when the plant which it contains is full grown. We make our own baskets of different sizes, to suit the different objects we have in view, due weight being given to the requirements of the plants. When the baskets are made at home the cost is very small, as wire is cheap, and a handy man, after a little practice, can make them on wet days, the only tools required being an implement to cut the wire and a pair of pliers to bend it in the right direction. Two sizes of wire are used, one stout to form the groundwork of the basket, and the other of lighter substance to bind all together; afterwards a coat of paint is given to preserve the wire from rust. E. H.

Egyptian Lotus.—Mr. Woodall (p. 40) is naturally surprised that I should have repeated in the catalogue of the "North" Gallery the error that the Lotus of the ancient Egyptians was Nelumbium, and so am I, because it was I who translated Schweinfurth's manuscript on the subject, which appeared in *Nature* in 1883. When I wrote the first edition of the catalogue I was unaware of the discoveries of archæologists, and the last edition was finished off so hurriedly, that I had not time to reconsider every statement. As long ago, however, as the time of Herodotus Nelumbium was probably cultivated every here in Egypt, and was then known as the Lotus; how or why the name was transferred from Nymphæa to Nelumbium is unexplained. I may add that Nymphæa Lotus is not blue, as stated by Mr. Woodall, but either white or some shade of red. The Egyptian blue Nymphæa is one of the varieties of N. stellata, and commonly known as N. cærulea. According to Schweinfurth, both N. Lotus and N. cærulea occur in the funeral wreaths of the very ancient Egyptians, though he identified the latter only in the mural paintings of the temples.—W. Botting Hemsley.

Garden Flora.

PLATE 553.

MALVA LATERITIA.*

Generally speaking, the Mallow family is not very popular in gardens, *i.e.*, if we take into consideration the number of species of which it consists; but this we know, that amongst the few that we cultivate are some of the finest of garden plants. These include the Hollyhock, the Hibiscus, the Abutilon, the annual Malope, and that charming little trailer, Modiola geranioides. Of the Malvas themselves much cannot be said, though what have we more beautiful than the white satiny-flowered variety of M. moschata? The Malva herewith illustrated is also a pretty plant, and one that we hope will become more generally known than it now is. It is uncommon, but cannot be called new, since it was first sent to this country from Entre Rios, near Montevideo, by Tweedie in 1836. Nothing more was heard of it until 1840, when Mackay, then of the College Botanic Gardens, Dublin, who had received seeds from the same source, flowered it in September. It is generally described as being only 6 inches in height, but with us many of the stems rise to the height of a foot or more after running as much or more on the ground. The flowers, as represented, are produced on long peduncles rising from the axils of the uppermost leaves. They are mostly set down as brick-red, but they seem to be flesh or salmon-coloured, and not unlike the flowers of Geranium lancastriense. The upper leaves are three-lobed, hard, and slightly rough to the touch. A light sandy soil and full sunshine appear to suit this plant either on a rockery or in a border, the former being preferred. There it should be allowed to ramble at will, without being crowded or shaded by taller plants, and if otherwise well attended to it will produce a profusion of its salmon-coloured flowers from June to September. It is easily propagated by means of the prostrate branches which often root as they spread, or from cuttings which can be had in abundance in autumn. It ripens seed but sparingly, unless in exceptionally warm seasons, and if sown when gathered it will furnish sturdy little plants by spring. The Callirhoes, of which there are three or four good species in cultivation, belong to quite a different type; generally they have a procumbent or prostrate habit of growth, and they are more suitable for a rockery than a flat border, as on rockwork their trailing stems and bright flowers can be shown off to much better advantage than on level ground. Modiola geranioides, or, more properly, Malvastrum Gilliesi, is also of this type. In low-lying localities it is often lost during winter, but in rich sandy soil on an exposed rockery it withstood the last severe winter uninjured, and is now beginning to flower as vigorously as ever.

D. K.

Sparmannia africana.—This old-fashioned greenhouse plant is not to be despised by those who want flowers during winter, and have not convenience for growing more delicate and showy subjects. In a fairly warm greenhouse it will begin flowering in autumn, and continue to do so until late in spring; in fact, it is hardly ever without flowers. We grow it in the shape of various-sized plants, ranging in height from 15 inches to 4 feet; but the larger the plants the more effective they are, and if their flowers are not striking, their formation is certainly singular. The young tops of the shoots strike root freely in spring, and they will succeed in any ordinary garden soil.—Taunton.

* Drawn in the Royal Gardens, Kew, by Miss Lowe, July, 1885.

MALVA LATERITIA

WORK DONE IN WEEK ENDING JULY 13.

July 7 to 10.

The drought continues, but the heat is not so intense; watering is still our principal work, but it is a poor substitute for rain, yet it must be done to keep the plants alive till such times as we are favoured with rain; all the recently planted winter Greens, Lettuce, and Celery have to be included in this category, and when time affords, Peas, French Beans, Onions, and Tomatoes also have their turn. Fruit trees on walls have a drenching once a week, and as all are heavily mulched this watering suffices to keep them in good condition. As a matter of course, the borders of fruit houses—inside and out—are never stinted of water, and in such weather as this all have to be done once during the week. For kitchen garden crops that it is not practicable to either mulch or water, deep stirring of the soil with hoes assists growth immensely, not to mention the destruction of weeds, so that as time can be afforded this work goes on. Flower gardening for summer and autumn effect we have to make a special study; hence this drought is causing us a serious amount of labour in watering to get the plants up to their usual summer standard of perfection. Cocoa fibre refuse is our friend, and we use it for mulching all small beds and plants, and so save a certain amount of watering, and yet the growth of plants continues. It is a grand invention for this purpose, being cleanly, of a nice colour, and the birds do not peck it about as they do other mulching materials in their search for food. Pegging and pinching of low-growing plants, and tying to stakes tall-growing kinds and keeping the turf edgings in trim order are jobs that in this department have been in the ascendant this week. Herbaceous plants, in spite of drought and with but a scant amount of watering, still present a gay appearance; for, now that Pæonies and Pyrethrums are nearly over, in their places we have the several varieties of Delphiniums, Veronicas, Potentillas, and Spiræas, and thus the round continues, not the least interesting part of the matter being the constant change or succession of flowers of various species of plants. Roses have had a hard time of it, for fierce sunshine, however liberal may be both mulching and watering, does not suit the flowers, and three days is about the utmost limit that they continue in fair condition. We cut them off as soon as over, and thus assist the plants to make an earlier growth, which ensures better autumnal flowering. Besides watering, the work connected with houses has been the keeping of laterals in vineries within reasonable bounds. Late vineries now make a great amount of growth, which we never like to cut or pinch back all at once, but prefer rather to do it at intervals of two or three days; thus we avoid a sudden check or derangement of the ordinary functions of the Vines, and thereby to some extent the disease called shanking, which, though it may be caused by other irregularities, such as cold currents of air, a stagnant atmosphere, and by attacks of mildew and red spider, I believe is most frequently caused by the wholesale removal of lateral growth at one time. Early Peaches have had their growth thinned out, the better to admit of sunshine to ripen the wood; the trees are well syringed twice a day, and the house constantly remains open during this hot weather, there being no prospect of immaturity of wood, else the house would be closed up early in the afternoon and fire-heat given, which we have sometimes to practise in respect of later houses to get the wood well ripened. To Melons and Cucumbers we apply the same rule as to the timely removal of lateral growths, as in the case of Vines, and once a week at least we find it necessary to go over these to pinch back and tie them to trellises. To Cucumbers in full fruit we give rich top-dressings, a little being added most weeks throughout the rapid growing season. Melons we grow in good loam, the only admixture being a few crushed bones, and the only top-dressing a little fresh droppings applied as soon as the crop of fruit has set. We never allow the soil to become dry, which state is a certain precursor of the loss of foliage, and it might as well be of fruit, too, for any good it is, so far as quality is concerned, for good fruit cannot be had without good foliage. Layering Strawberries for foreing, as well as for forming new plantations; potting Poinsettias, Gardenias, Eucharis, Tree Carnations, and Bouvardias, and keeping pinched out the side shoots of Chrysanthemums and the main shoots tied to strong stakes, and on this last-named date gave all houses a thorough clean out. Thus ends as hard a week's labour as has ever fallen to our lot, and till rain comes there is, unfortunately, in store for us the prospect of its repetition.

July 12.

The longed-for rain has at length and unexpectedly arrived, 0·48 being our register as having fallen since 9 p.m. yesterday to the same hour this evening. It made us extra busy between the showers putting out Broccoli, Cauliflowers, Savoys, and Curled Kale, also thinning out Leeks, Salsafy, Beet, Lettuce, and Turnips; pulled up second early Peas that were nearly over and planted on ground late varieties of Broccoli. The ground being free of weeds nothing needed to be done beyond the removal of sticks and haulm and the drawing of drills in which to put out the plants. The ground was trenched for the Peas, and as all the Cabbage tribe do best in firm land, digging was not necessary. Sowed Turnip Radishes and Black-seeded Bath Cos Lettuce on borders that had been cleared of early Potatoes, and sowed Turnips on an east border, the partial shade that such a position affords being helpful to this crop at this season of the year. Continued layering of Strawberries, tying Chrysanthemums, and stopping lateral shoots of Vines. Planted Capsicums in manure frames, after the fashion of Cucumbers, which is by far the most profitable way in which to fruit them.

July 13.

Fine, and warm as ever. We should have liked more rain—half an inch is but little on ground so parched; still, it has done an immensity of good, and it is worth something to get even one day's rest from watering. Rolled all walks, mowed flower garden, and cut turf edgings. Tied Tomatoes to stakes and thinned out the weakest shoots—a single branching stem produces the finest, and quite as much fruit as do several shoots on the same plant. Gathering fruit for preserving; Currants and Raspberries are abundant; Strawberries were so too, but the heat and drought have made the crop light, and now that they are over we have begun to weed the plots and to cut off runners, after which the mulching will be renewed. Except the work mentioned under yesterday's date, all other work in and about the houses has been of a purely routine character.

Hants.

FRUITS UNDER GLASS.

Vines.

Where the roots are well mulched and liberally supplied with water, fruits of all kinds under glass and in the open air are now growing with a rush, and bid fair to redeem the time lost during the cold weather which prevailed up to midsummer. These sudden changes from one extreme to another are not, however, good for trees or fruit, and great care must be devoted to Vines in every stage of their growth.

Early houses from which the fruit has been cut must be copiously watered inside and out, and well mulched with half-spent manure, old leaves, or litter to keep in the moisture and protect the young roots now working near the surface. If the Vines are old and weak, a good coating of rotten manure well washed in with the hose will be found a great help, especially where they have been touched by spider and do not show a disposition to break into a free and fresh growth of lateral. With the glass standing at 80° or more in the shade and a cloudless sky, all the doors and ventilators may be thrown open for at least twelve hours out of the twenty-four, and plenty of cold water thrown down in the passages through the day will keep the temperature down until the declining sun admits of a thorough leaf bath every evening.

Succession houses containing ripe Grapes will require still more careful management, as this tropical weather soon takes the colour out of black varieties, whilst it hastens the ripening of others before they have time to lay on the thick coat of bloom more frequently met with in good ordinary seasons. White Grapes of all kinds, especially early Muscats, on the other hand, enjoy all the sun, light, and air that can be safely admitted through the irregular breaks in the main foliage, and for this reason the Vines should be divested of all gross laterals where they intercept the sun's rays; while those on Hamburghs may be allowed to ramble provided they do not interfere with the principal leaves or check the circulation of air. Water, it is hardly necessary to say, may be freely used in succession houses, and, assuming that internal borders were thoroughly watered and well mulched when the Grapes commenced laying on colour, regular damping down two or three times a day and syringing the stems on fine evenings will keep the Vines fresh and healthy until the crop is cleared off. When July Hamburghs and Madresfields are quite ripe, and hanging for private use is not only desirable, but necessary, unless the foliage is close and good, slight external shade is sometimes applied with beneficial effect through the hottest part of the day. Various materials, including light scrim, are frequently used, but the shading of any particular section of a long range being extremely troublesome, I have found two or three thicknesses of ordinary herring netting most suitable, as they are not affected by wind, and the abundant, but subdued, light which passes through the meshes renders daily removal unnecessary.

Late houses.—Thinning in Lady Downes and the general Muscat house having been brought to a close, the Vines must be well watered and generously treated until the scalding period has been passed, when it may be necessary to run the scissors over all the varieties intended for hanging up to Christmas and cutting for bottling. Black Alicante, Gros Colmar, and Black Morocco this year promise to be very fine in the berry, and as yet have shown no tendency to scalding; therefore all doubtful or imperfectly fertilised berries should be removed with a careful hand. In order to economise fire heat in the autumn, and yet to insure the proper ripening of these varieties before the end of September, a night temperature of 70° with a corresponding rise by day should now be maintained in the houses—if with the aid of sun heat alone so much the better—but in the event of the minimum falling below 68° before morning and scalding setting in, gentle fires with a free circulation of air and a diminished supply of moisture will become necessary. When this danger is past atmospheric moisture in plenty must be resumed, and in order to keep spider in check, the stems and foliage, wherever a syringeful can be delivered without wetting the berries, may be carefully bathed about 7 p.m. Many growers never wet their Vines after the Grapes are set, but this is a season of extremes and admirably adapted to the spread of spider. Moreover, prevention being better than cure, a few gallons of cool soft water passed through a good syringe in dexterous hands will tell favourably upon the Vines and fruit until we have a change to cooler weather.

Pot Vines.

Fruiting canes intended for next year's forcing will now show signs of changing colour if they are not already ripening. This process, it must be borne in mind, must not be too rapid, as the main buds have to be properly fed and the embryo bunches formed before the leaves fall. If well plunged, or the pots are surrounded by leaves or litter, less water may be needed, but on no account

must the roots be allowed to become dry or the foliage to suffer through careless syringing. Air in abundance through the ripening stage is an important factor; indeed, the treatment usually accorded to early houses from which the Grapes have just been cut will suit pot Vines admirably. The general stock intended for planting or cutting back should be prevented from rooting through into the beds, much as one may approve the vigorous growth which they make when the first root breaks bounds. If not already stopped each leader may be pinched when the Vines have made 6 feet to 8 feet of growth, more or less according to their strength and the purpose or position for which they are intended. All laterals and sub-laterals, too, must be pinched to plump up the lower buds and thicken the canes near the base, but those which start near the top after the points are pinched out must be allowed to ramble as safety valves to the main buds when the lower laterals are entirely removed. The ripening process must be facilitated by gradually reducing the supply of water and increasing the circulation of air. Where old Vines have been forced hard with the view to replanting as soon as the Grapes were cut, the houses should now be ready for the young stock if they are not already planted. June is the best month for replanting with growing canes, but I have planted as late as the end of July and the first week of August and then they have topped the rafters. Weaklings, or canes that have been checked, it must be understood, will not do this, as one continuous growth from the bud to the finish is absolutely necessary; therefore, where Vines have not been properly prepared, either on cratches, squares of turf, or in good sized pots, July planting is best left alone. If, on the other hand, the Grapes are ripe, and perhaps partially used, and young Vines in good condition are ready, the work should be taken in hand at once and finished off quickly. Quickly, indeed! the inexperienced in these matters may exclaim. Vines in bad condition (no one would disturb them if good) must be made to ripen a crop of Grapes; these must be consumed, young ones must be struck from eyes, and new borders made, all in the course of nine months. Yes, the young Vines will be growing while the Grapes are ripening; if stopped once to keep them within bounds no harm will be done. The Grapes may be cut and bottled as soon as they are ripe, and new compost can be prepared ready for use as soon as the house is cleared of the old canes and properly cleansed. But what is to be done with the old borders—a ponderous undertaking when all hands are so busy? Why, leave the external border intact for removal at leisure, and cut a trench 3 feet in width out of the inside border next to the front wall plate if time presses. Otherwise remove the inside border bodily, correct the drainage, and form the foundation (3 feet will be wide enough) with fresh turves, grass side downwards, build turf walls clear of the undisturbed part of the old borders, and fill in with fresh compost. When finished the ridge may be 3 feet in width at the base, 2 feet 6 inches at the top, and 6 inches to 9 inches higher than the old to allow for settling. Shut up the house for a day or two to warm the compost, plant the Vines 3 feet apart, give a little water at 90° to settle the soil about the roots, and mulch with old Mushroom manure. Keep the house close and shaded to keep down the temperature, and syringe the paths, walls, and Vines three or four times a day until fresh root action sets in. This the crisp appearance of the young leaves will indicate, when the heavy shading must give way to canvas or tiffany for a time, but not longer than is absolutely necessary, as the Vines must be gradually inured to sunlight and air. When fairly established and the growth, which will be rapid, has filled half the rafter, pinch the points to thicken the canes near the base, also the lower laterals to plump up the buds, and allow those near the apex to ramble over the upper part of the trellis. As autumn draws on give more air and less water, and apply gentle fire-heat to ripen up the canes.

Figs.

Where November-started trees have been well managed, the second crop of fruit will now be ripe, and after the past hot weather the colour and flavour will be good. Second-crop fruit does not, as a rule, attain a very large size, and some varieties, including Brown Turkey especially, when trained on trellises, show a great deal more than they can carry to maturity. This may be prevented early in the season by pinching the points to swell up the fruit and induce fresh breaks; but it is now too late to pinch, as points so treated would most likely become blind and comparatively useless for next year's forcing. In order, then, to obviate this difficulty and still to retain the short-jointed points now drawing up to the glass, all intermediate fruits not likely to be wanted must be taken off, as their retention will only rob the second crop and keep the trees at work when they ought to be going to rest. Two crops are quite enough for one set of trees to carry, although I have made them carry three, but they have always squared the account the following spring, independently of the fact that the third crop comes in with larger fruit from walls and wall cases. Second-crop trees cannot easily be over-watered, even when the fruit is ripening, and they require good syringing wherever water can be placed without casting spray on Figs nearly ready to gather. From this time forward, every particle of spray should be constantly removed to let in sun and light, so essential to the ripening of the fruit and wood, and when the last Fig is gathered, the hose must be introduced to cleanse the foliage of filth and insects. All fruits at the same time larger than Marrow Peas may safely be removed for the benefit of those barely perceptible in the axils of the leaves near the points, as they rarely pass the ordeal of cleansing and the suspended flow of sap through the winter.

Late houses and wall cases.—Tie down to the wires the most promising growths before they touch the glass, and avoid overcrowding by thinning out side shoots and useless spray as the work is proceeded with; also thin the fruit where too thickly set, as one fine fruit is of more value than two of inferior quality. Keep the roots well mulched and copiously watered, syringe freely, and shut up early with sun heat on fine afternoons. Trees on walls enclosed by narrow glass cases require similar treatment, but being a greater distance from the glass the young growths should be more freely thinned, otherwise a great deal of heat will be lost, as water instead of warmth will be absorbed by the brickwork. Where pot trees are grown along the front of these structures—a suitable place for testing new varieties—they should be partially plunged in the soil and thoroughly well mulched to feed the fruit and economise watering. Free fruiting kinds like Osborn's Prolific, Brown Turkey, and White Marseilles do not make much growth; consequently they rarely require stopping. Young stock from eyes or cuttings must now be pushed along, as days will soon begin to draw in, and next year's success entirely depends upon the way in which the points are ripened. Weak plants that have not received the final shift should be potted before the end of the month, otherwise they will be growing when the young points should be ripening. As these will hardly form embryo fruits, they may be pinched a little later than others intended for forcing. A set of trees so treated last year and kept in a late house have made handsome little bushes, and every summer shoot is now crowded with swelling fruit which will ripen in August.

Cucumbers.

Although winter plants are not unfrequently kept doing good work throughout the summer, they cost a great deal in labour, and often become badly infested with thrips and spider. If these pests could be confined to the plants upon which they originated, their presence for a time might be tolerated, but unfortunately they migrate in hot, dry weather and get carried about by attendants whose duties take them into other houses. To obviate this and keep up a good supply of fine fruit, a sowing of Telegraph should now be made in 4-inch pots or squares of turf to secure strong plants for succeeding Melons. Where a little stable manure and a few fermenting Oak leaves are at command, a slight hotbed large enough for a two-light frame in which the young plants can be kept close to the glass will answer better than a larger structure. If portable, the frame may be placed with its back to the south, and 6 inches of old tan or leaf-mould spread over the surface of the manure, while keeping back rank steam, will admit genial warmth and suit them admirably. These plants must be shifted from time to time before they become pot-bound and trained to single leaders, with plenty of side room for the full development of the stem-leaves—a very important matter where canker is prevalent. Where space does not favour this mode of procedure and old plants must be retained, a portion of them may be divested of all their fruit and cut over. Slight shading for a short time, combined with frequent syringing with warm water, will soon cause healthy plants to break, when the bottom-heat must be renovated. When this touches 80° to 85°, not before, remove a portion of the old compost and replace it with a thin layer of fresh sweet turf, a dash of bone-dust and a liberal admixture of rough lime rubble. As growth advances, lay in young shoots full length for a time to cover bare stems, pinch the points to induce fruitful laterals, and crop lightly. In this way a house can soon be renovated piecemeal, but the better plan, where a compartment can be dispensed with, is to cut all the plants over at one time and renovate them under heavier shading, with an abundance of genial heat and moisture. Fresh top-dressing, little and often, should be added as soon as young roots appear on the surface.

Eastnor Castle, Ledbury. W. Coleman.

Fruit Garden.

GOOD STRAWBERRIES.

Hitherto the remarks made on Strawberries have been confined to a few well known kinds, but there are numbers of different sorts which, although not popular, are grown in various places because their flavour is found to be more agreeable than that of better known kinds. In this county, for instance, there is a garden in which no Strawberry is grown but Webb's Refresher, a kind preferred to all others on account of its peculiar refreshing flavour. It is a fairly vigorous sort, the fruit of which is large, but variable in shape, some being cockscomb and others roundish. In another garden Alice Maud has the preference; it is a second early, a fair cropper, and less acid than some kinds. What, I wonder, has become of that once favourite sort Mr. Radclyffe, a variety which produced large red fruit, with a flavour very little inferior to that of British Queen, and one which will thrive where that variety will not succeed. It is not so many years since it was to be found in many gardens, but it is now very scarce. Connoisseurs of richly flavoured Strawberries should grow Marguerite, a grand variety and a very old kind; but in a soil that suits it none are more prolific. The fruit, too, is both large and handsome. This sort is suitable alike for forcing and for outdoor culture, and it is a kind that travels well. It is somewhat capricious as to soil, which I believe is its only fault. What have growers who reside in chalky districts to say about Rivers' Eliza (not Myatt's)? When I grew this sort in a garden at the foot of the South Downs, it bore magnificent crops. Its fruit is medium-sized and the flavour good.

Less than twenty years ago Trollope's Victoria was much more cultivated than it is now. It bears a flat round fruit, not remarkable either for sweetness or acidity, but it has the merit of thriving in any kind of soil. This sort may be known from all others by its pale green leaves and short leaf-stalks. I should add that its fruit is not particularly handsome, being bright red on the sunny

side and lighter on the other. La Constante never made much headway, though sent out as a first-rate late sort, a character which I think it would have sustained had it been sufficiently tried and a little more patience exercised respecting it. Its habit is neat and dwarf, and its fruit possesses a brisk, yet not unpleasant, flavour. As regards the newer varieties, I have a number of them now on trial. The earliest is The Captain, which is only a day or two later than Black Prince, and it is superior to that variety in size and appearance. King of the Earlies, quite a distinct kind, ripens at the same time as the last-named sort. The wiry character of the runners and hairiness of the leaves seem to indicate that it belongs to the alpine section. Its flavour is quite equal to that of the best early kinds. Helen Gloede will not, I am afraid, prove hardy enough for any but the warmest and deepest soils. This I must reserve for another season's trial. Auguste Decaisne I think will prove a useful midseason variety. It is a vigorous grower, and throws its flower-trusses well up above the foliage; its fruit is both large and handsome, slightly acid, but with a fine aroma. Goldfinder is, I think, a local sort, but it so nearly resembles Loxford Hall Seedling, that it is not wanted.—J. C. C.

Alpine Strawberries.

These are so easily managed, that it is surprising so few grow them. Their size is certainly against them when they have to compete with larger fruit. While large fruits are not to be had, no one objects to Black Prince, but as soon as President or Sir Joseph Paxton becomes ripe, Black Prince is rejected. If we could get an alpine to ripen ten days or a fortnight before Black Prince—which is still the earliest of all Strawberries—no doubt it would be largely grown. During my experience I have, however, known instances in which alpines were highly appreciated. I remember on one occasion sending in a dish of them for dessert, and so much were they liked, that I had to supply plants next morning to four of the visitors who had partaken of them; this was in the month of September. In order to get good crops of alpine Strawberries fresh plantations must be made every spring, and all the first flowers should be picked off; indeed to get the fruit as large as it is possible to get it, all the flowers should be picked off up to the beginning of July. The ground, too, must be liberally manured and dug deeply during winter. If nothing is done to the old beds during autumn and winter, except clearing off weeds, there will be plenty of young plants ready for transplanting in spring. Early in April is soon enough to plant them, and they should occupy a fresh piece of ground every year. The plants should stand 1 foot apart each way. The best place for the beds is on an east or west border where they get shaded during a part of the day. The largest sort with which I am acquainted bears a white fruit with a tinge of pink on the sunny side, but the variety named Galande is decidedly the best in flavour. The fruit of this is dark red in colour and the flavour agreeable. I at one time grew all the kinds of Hautbois that I could get together, and the only sort I considered worthy of cultivation was one raised at Sawbridgeworth. This bore abundantly through August and part of September. The fruit was large and produced in erect trusses, and had a true Hautbois flavour. Fresh plantations of this sort should also be made every spring. Birds do not seem to like Strawberries in autumn; at least, they never interfered with our alpines.—Taunton.

Strawberry Trials.

Mr. Hobday's suggestion as to providing a garden in which all kinds of Strawberries would be grown is an admirable one, so far as it goes, but to make the suggested trial full and complete, the same thing should be done in some dozen parts of the country, and in diverse soils and positions, because it is evident that the Strawberry is affected by soil more than any other fruit. How often do we find growers declaring that certain kinds will not thrive with them at all, and yet they do well elsewhere and in different soil. It is to surmount the comparative unfairness which would follow were a trial of the kind suggested to take place in only one spot that it is advisable to have many. On the other hand, something is already done in this direction by growers of plants for sale, as these usually retain stocks of kinds that private growers may generally have discarded. If trade growers, who must have a wide and varied knowledge of the qualifications of Strawberries, would speak out, they might help this discussion very materially. Something, too, might, I should think, be done in the production of new and improved sorts, but for that purpose a small quantity of each one might suffice.—A. D.

President Strawberry and Mildew.

President is bearing a heavy crop with us this year, and the berries, individually, are very fine and comparatively free from mildew. Two things are absolutely essential to its well-being on our soil, viz., plenty of room and constant renewal; the first is necessary on account of its large foliage and the length of its fruit-stalks. The latter is a great drawback, especially in a wet season, as regards the fruit ripening and finishing well. With respect to its constant renewal, I find that two seasons are enough for it, and that plants put out in June this year should be destroyed in that of 1888. If with these conditions strictly adhered to it still, in average seasons, mildews badly, I shall be reluctantly compelled to discard it, as extra size is no compensation for a tender constitution. That it is peculiarly liable to mildew both in and out of doors we have ample proof. Plants standing in vineries side by side with Sir Joseph Paxton and La Grosse Sucrée are sometimes much affected, whilst the varieties just named are not touched. —E. Burrell, *Claremont*.

Strawberries Degenerating.

Do some varieties degenerate in certain districts? I have found that to happen here in the case of several sorts, notably Dr. Hogg, Mr. Radclyffe, La Grosse Sucrée, and, I am afraid, Loxford Hall Seedling. For four or five years these sorts produced grand fruit, but after that I had to discard them. As to British Queen, it is useless here. A few years ago I converted a meadow into a new kitchen garden, some part of which was as good loam as could be desired. On this I planted several rows of British Queen, but during the three years they were on the ground they did not produce three quarts of fruit. There are very few gardens in this neighbourhood in which British Queen is grown, while in a garden some 10 miles distant it does as well, or better, than any other variety. Our best bearing Strawberry is Vicomtesse Héricart de Thury, the next Sir Charles Napier; Sir Joseph Paxton is also very good. I find King of the Earlies to be a good bearer. We have the smallest crop of Strawberries in the open ground this season that I have seen for many years, owing, I think, to the crowns not having been properly matured last autumn, for our latest crops from pots have been very heavy. The best-flavoured variety that I grow is Loxford Hall Seedling, which is probably as good as British Queen. King of the Earlies, which is very good, is very much like Keen's Seedling. Sir Joseph Paxton is also very good. The Captain, like Vicomtesse Héricart de Thury, is a little acid. Our earliest Strawberry is King of the Earlies, a kind which ought to be planted extensively. The next is The Captain, then Vicomtesse Héricart de Thury. Pauline is said to be very early, but it has been a failure with me both in pots and in the open ground. The best late variety is certainly Loxford Hall Seedling, from which I gathered on the 14th of August eight pounds from forty-six plants, but my plants of it have not done so well this season and last as they did previously; perhaps their comparative failure is owing to their having been planted late in the autumn. If not, like some others, they are degenerating. Hélène Gloede is a fine Strawberry and late, but its quality is not equal to that of Loxford Hall. Anne de Rothschild and Unser Fritz are also good, but being shy bearers, I have discarded them. This is the best time at which to commence cultivation if Strawberries are to be grown successfully either in pots or in the open ground. I plant a plot each autumn, generally three rows on the side of a walk along which the water-barrel can be driven; they are planted 2 feet 6 inches apart each way. In spring all the flower-stems are removed. It is indispensable that early runners be got, particularly for pots, and I find those to be best which are taken from plants put out the previous autumn. They make better crowns, produce more and better fruit than those taken from older plants, and the earlier they are in the fruiting-pots, the growth made, and the crowns ripened, the better. I am of opinion that the best method is to layer the runners in 3-inch pots, of which there are generally plenty which have recently been emptied in the flower garden. Secure these plants in the pots by hooked pegs cut in winter from old birch brooms. I have tried layering them in their fruiting pots, but if heavy rain comes before the plants are established and the roots have filled the pots, the soil gets sodden and sour. I do not consider, moreover, that labour is saved by so doing. After they are placed in their fruiting pots they are put on strips of wood nailed about 2 inches apart on short cross pieces; these are placed on bricks on one side of the walk in front of the vineries fully exposed to the sun. Thus set, no worms can possibly get into the pots, and if any extra labour attends the method it is more than counterbalanced by the results.—David Walker, *Dunorlan, Tunbridge Wells*.

Strawberry Burghley President.

Mr. Richard Gilbert, of Burghley, contributes his item to the Strawberry discussion in the shape of some specimens of this Strawberry, which seems to us a very large and well coloured fruit. We shall be very glad if he will kindly tell our readers how far it differs in habit and productiveness from the older kind, and something of its origin and value.

FRUIT PROSPECTS.

The fruit crop throughout the country this season goes to confirm the proverbial uncertainty that is attached to outdoor cultivation in our variable climate. Apples are very thin in most localities in the southern parts of England, though there was sufficient bloom to lead to the expectation that there would be an average crop. The trees had made too much leaf growth at blooming time, a condition that as long as I can recollect has almost invariably ended in the fruit setting badly, and which this year's experience goes further to confirm, as there was not sufficient frost at the time of flowering to do any great mischief. Further north, so far as such parts of Yorkshire that I have had an opportunity of seeing, Apples have set better, but are so unusually late, that there are some doubts about their falling off, for it usually happens that when the time of blooming is delayed beyond what may be regarded as seasonable, even if the fruit sets, it often drops. Pears are seldom a full crop two years in succession, yet, notwithstanding that they were plentiful last year in the southern parts of the country, this year they again promise well. In such of the northern counties as I have seen, particularly Yorkshire, Cheshire, and the seaboard of Lancashire, Pears are set much fuller than usual.

Respecting Plums, it is even a rarer occurrence to have them in abundance two seasons together than in the case of Pears, but, loaded as the trees were last summer, they seem fuller of fruit this year; in many localities the branches are already bending under their load. In the Green Gage section I have never seen trees with more than half the crop that they are now carrying in many gardens for some distance north of London. The quantity of fruits is indeed such that where they are not thinned they will be small and poor. Plums, except the commonest hardy varieties, do not succeed nearly so well in the northern half of England as in the south, but

this season the crop appears to be a full one. Apricots, in common with other fruits that bloom early, were unusually late in the spring, and in parts of the north of England in which they succeed they appear to be carrying a heavier crop than ordinary; the same remark holds good with Peaches in all the gardens both north and south that I have seen, except a few places more than ordinarily exposed where the cutting frosty east winds that occurred at the time of blooming appear to have defied anything that could be done in the way of protection. Cherries in districts where they do best are again plentiful, and so far as I have had an opportunity of judging in localities where they do not succeed so well they are this year more plentiful than usual. Strawberries appear to be much below an average, generally speaking. In districts in Kent where such vast quantities are grown they are set down at about half a crop. The effect of this is seen in the much higher prices that Strawberries have this season fetched in London than for some time back, notably last year, when in the leading provincial towns to which the Kent growers send such quantities the prices realised were so low, even more so than in London, as not to cover the cost of gathering, carriage, and sale. As an evidence of the extraordinary lateness of the season, I may mention that a grower with whom I am acquainted got 10s. a pound in Covent Garden on June 19 for British Queens grown under glass without fire-heat. It is thus evident that within a week of midsummer there were no outdoor Strawberries, otherwise such a price could not have been realised. Raspberries, which vary less in yield from one year to another than most fruits, seem to be about an average. Gooseberries and Currants in all places that have come under my notice are plentiful. White Muscadine Vines growing on the south side of a house within half-a-dozen miles of London, well sheltered and fully exposed to the sun, were not in bloom until the 5th of July; while last season, although late, they were nearly three weeks earlier. As to the fruit ripening, it is out of the question, as, however protracted the summer may happen to be, the time is too short. T. B.

WOOD ASHES AS A FERTILISER.

Some of our fruit-growers, says the *Pacific Rural*, are making good use of wood ashes, both as a source of home-made lye for washing fruit trees for insect pests and directly as a fertiliser. When we consider how large an amount of vegetable matter is represented by a small amount of ash, the value of wood ashes for manure becomes evident. Thus only ten pounds of ash remain from the combustion of a cord of hard wood, and only five pounds from a cord of soft wood. Eleven tons of Gooseberries, Grapes, Blackberries, Peaches or Apples would each contain only 100 lbs. of ash. Seven tons of Cherries, Plums or Raspberries contain only 100 lbs. of mineral matter. This gives some idea of the large amount of orchard produce represented by a small weight of mineral matter. But small as is the amount of ash, it is still indispensable for the production of fruit and other crops, and must be present in the soil in available form before profitable cultivation is possible. Let it not be supposed that the ash in all these crops is identical in composition. The ash of each class of plants has a composition peculiar to itself, differing in some respects from that of other classes; yet there is a certain similarity in the ash of all cultivated plants. When the ashes of vegetable substances are served up for any plant by mixing them with the soil, such plant does not of necessity require every item on the bill of fare, but selects such materials and in such quantities as are adapted to its wants, and leaves the balance for some other guest. If any soil is naturally deficient in any of the ash constituents, or has been impoverished by excessive cropping, the restoration of these materials in the form of wood ashes appears to be a natural and safe process, because they contain all the minerals of vegetable growth.

Hard wood ashes were taken from our kitchen stove, the fuel being a mixture of Beech and hard Maple. Small fragments of charcoal were scattered through the ashes and a little sand from dirt adhering to the wood. Ninety-three per cent. was soluble in dilute hydrochloric acid; the potash constituted 12¼ per cent. and phosphoric acid 6 per cent.; of soft wood ash 50 per cent. was soluble in acid, and so much soluble silica was in the ash that, when treated with acid, it formed a jelly-like mass of precipitated silica; the ash contained 12 per cent. potash and 4 per cent. phosphoric acid. In general terms it may be said that the ashes of wood and of plants of every kind are of value for manure on every kind of soil which has been reduced by cropping; but the greatest benefit is shown upon sandy and porous soils. On these light soils crops of every kind, but especially root crops, will be benefited by a dressing of wood ashes. Fruit trees and fruit-bearing plants having a woody structure will be benefited by wood ashes. Thirty to fifty bushels to the acre of fresh ashes will be a full dressing, and three or four times that amount of leached ashes may be applied with permanent benefit.

Old Apple trees and drought.—Apple trees suffer more from drought than either the Pear, or Plum, or Cherry. In many gardens and orchards last year the Apple trees—especially old trees—received a severe check, owing to the dry weather which prevailed last summer. The drought of the present season, though less pronounced as yet, has made its mark. This may be seen by the smallness of the fruits and the almost entire absence of young growth, and they have a starved, impoverished look. It will be better to leave the old trees unpruned this year and encourage them by giving them liquid manure. The best way in which to apply rich liquids is to make holes with a crowbar a foot deep and 3 feet apart, and widen them till they are 6 inches in diameter at the top. These should be made all round under the tree as far as the roots extend, and they should be filled up with liquid manure three or four times a day till the whole soil has become saturated. Such treatment cannot fail to invigorate anything not gone too far wrong. But, let me remark, we have far too many old trees, and such young ones as are planted are often too carelessly dealt with, both as regards the preparation of the land before planting, and also the attention given afterwards. —E. Hoeday.

Premature ripening in Vines *(C. R., p. 22).* —It is no unusual occurrence for the foliage of Gros Colmar to lay on the autumn tint early in July in hot seasons, neither is it surprising to hear that a few of the lower leaves have already fallen. If the Vines in question and their roots were not thoroughly ripened before they were so severely pruned back to within 1 foot of the soil in December, it is more than probable that the shock caused many of the soft roots to die back during the three months they were dormant. The natural consequence would be a weak, or a comparatively weak, start, but the rods would gradually improve as the season advanced, and possibly stopping at 10 feet would cause them to thicken to an extent which would force the first formed leaves from their holding. Then, again, the weather has been intensely hot; the border at some period may have been allowed to become dry; and the heat—70° by night, 80° by day, and 90° after closing—to say the least, has been high, certainly higher than I should care to recommend through the early stages of the growth of this variety. When young Muscat Vines are forced from moderate into strong growth as the season advances they sometimes behave in the same way, but no serious mischief follows. Keep the border well mulched and moist, and do not let the roots feel the want of water. If laterals exist where the main leaves have fallen or show signs of ripening, carefully preserve the young leaves in a fresh healthy state to draw the sap into the base buds, as this is your only chance of getting them properly formed and fed through the autumn. If the Vines generally show a disposition to ripen, and the canes are turning to a nut-brown, give more air through the day and close later. Syringe well to keep the foliage fresh and clean, and having plenty of time before you give night air to favour steady and perfect maturation of the wood and foliage. As this process goes on give sufficient water to keep the border moist and in a growing state, and place more light non-conducting mulching on the surface.—W. Coleman, *Eastnor Castle, Ledbury.*

FLOWER GARDEN.

CANTERBURY BELLS.

When, some few years since, the curious cup-and-saucer or Calycanthema forms of these flowers were introduced they were not only limited to white and blue colours, but of the ordinary forms we had then only singles, and those limited to the colours just named. The Canterbury Bell has progressed or, more properly speaking, developed since those not very remote days, and now we find form remarkably varied and hue of colour of the most varied character too. I have for several years tried to keep both ordinary and Calycanthema forms distinct, but circumstances are against my doing so. The old single forms have developed doubles of the most absolute kind, and many of the Calycanthemas are also double whilst still retaining the hooded calyx. Not a few of the flowers found in this latter section are remarkable both for size and form, and are far ahead of those which when originally shown obtained for the raiser a certificate of merit. In the original strain some of the finest bells are those of a semi-double form, that is, having one bell fitting closely within the other, but with the edges overlapping. Some have three or four bells, thus producing elongated flowers, whilst, again, others have the bells so crowded within the outer one that they are very massive and solid. These latter, owing to the choking or disruption of the organs of fertility, rarely seed, and I invariably select from the best semi-double flowers only, because these seed freely and also give me all the variety which may be looked for. Plants producing these double flowers often need support, as they are so heavy. They are now absolutely portions of the strain, and apparently cannot be got rid of if desired; still many are pleased to have them. Since the beautiful rose coloured form was introduced many variations of colour have followed, and between pure white and purplish blue we find probably a dozen diverse shades, perhaps more, and these hues are gradually increasing. Probably very many who have gardens and have dawdled along with the old blue and white singles have any conception of the grand forms and variations now found in a good strain. Whilst some plants will bloom two years in succession yet few can be trusted to do so much; hence it is wisest to sow seed every year and thus raise a stock each season. I sow seed always under glass, although so much trouble need not be taken in every case, as in some fine soils small seeds will germinate freely enough in the open ground. My soil is not of a character to encourage me to do so much; hence I prefer to sow seed in shallow boxes and raise it under glass. Sowing is done in April, and as the boxes are placed in the open after the plants are strong they transplant readily into the open ground, where summer showers favour the planting. If not convenient to plant out where they are to bloom at once, then the plants will transplant with the aid of a fork in the autumn. Few garden biennials show such remarkable advance as do Canterbury Bells. A. D.

Cornflowers in masses.—I have seen nothing prettier in the way of hardy flowers this year than some large bush-like masses of variously coloured Cornflowers in a cottager's garden. It often happens that the happiest effects in the flower garden are obtained in a chance way, and in this instance the careless throwing about of some plants with seeds on them in autumn gave a

large number of seedlings, which were strong ere winter set in, and which increased exceedingly as the days grew longer. These plants have for a long time been a mass of charming colour, and as they have grown to a height of quite 4 feet, they are very effective. Cornflowers sown in spring cannot compare with those sown in autumn, and a few weakly isolated specimens give no true idea of the charms of this hardy flower when proprely treated. What a grand contrast is afforded by a plentiful sprinkling of blue Cornflowers amongst crimson Clover, the two colours setting off each other to advantage.—J. C. B.

SILVERY-LEAVED ALPINES.

People who have travelled on the Alps, or passed the winter in the Mediterranean region, are always struck with the green appearance of plants in our gardens that with them are quite silvery. Our climate doubtless does something towards effecting this change, but we are inclined to believe that the manner in which such plants are treated has most to do with it. Potentilla nitida is a good example of what is here meant. Plant it in a rich border, and the result is luxuriant foliage, but wholly or almost green, and of flowers there will be few, if any. Ram it tight between the bricks or stones of an old wall, and it will become bright and silvery, and bear flowers in profusion. There are not, of course, old walls in every garden, but a substitute for them, in which the presence of old lime rubbish and broken bricks should form the major part, can be as readily made as a rockery. This done, the conditions to provide the desired effect will be within measurable distance of attainment. Silvery-foliaged alpines for rockeries have been almost wholly neglected—not that we are without such plants, but they do not receive proper treatment. A dozen or more kinds with variously cut or shaped leaves occur to us at the moment, hardly one of which we ever see in perfection, and yet they are very effective in brightening up our rock gardens and old walls. The plant here represented, Artemisia mutellina, is much more in character when found growing on limestone than when in ordinary garden soil; and the same may be said of A. glacialis, argentea, maritima, discolor, and many others. Salvia argentea, if the flowering shoot is kept pinched, makes an excellent silvery-leaved plant, as do also Tanacetum Herderi, nubigenum, bracteatum, &c.; Cerastium tomentosum and Boissieri, Achillea umbellata, Anthemis Aizoon, Helichrysum serotinum, litoreum, &c.; many of the Gnaphaliums, Pyrethrum cinerariæfolium, Antennaria tomentosa and the Aizoon section of Saxifrages, many of the Sedums, and a few of the Sempervivums; while Onopordon, Cnicus, &c., supply specimens of a larger type. D. K.

Artemisia mutellina.

Ranunculuses resisted the intense heat and drought lately experienced better than many hardy plants. Some I noticed bore expanded blooms in good condition quite a fortnight, although not watered and growing in rather poor soil. It is seldom that one sees this really fine flower well grown now-a-days; indeed one may go into many gardens without seeing either a Turban or a Persian Ranunculus. The named kinds are many of them rather dear, but good seedlings can be bought so cheaply, that a good sized bed can be had for five shillings. I bought some this spring at the rate of five shillings per 100, and they turned out very satisfactory; they were, I believe, imported roots. A mistake that many make in the culture of the Ranunculus is leaving the roots too long in the soil after they have flowered. They ought never to feel the influence of the autumn rains, as they then plump up again and throw out roots, and, unlike many hardy flowers that die down after blooming, they should not be left in the ground all the winter. As soon as the foliage dies off they should be lifted and stored away in a dry, cool place until planting time. Ranunculuses require a good friable soil and well rotted horse or cow manure that has been turned over and over for a year or two. Rank manure would be almost sure to cause the foliage to turn yellow, especially in wet weather. In the case of stiff soils it is well to draw deep drills and fill up with light mould.—J. C. B.

NOTES ON HARDY PLANTS.

Pinks.—It would indeed be hard to even imagine a more handsome or more serviceable Pink than Dianthus alpinus. D. neglectus and glacialis rival it, but until we learn generally how to grow them into larger specimens than is generally seen, they are not likely to place alpinus in a second, much less a third-rate position. There are, however, several less known kinds worthy of note. The slender-stemmed and small-flowered D. pulchellus is a pleasing Pink; it has white flowers of good substance, with a distinct maroon star-shaped eye. It grows 6 inches or 8 inches high. Another form, kindly sent to me by Mr. Wolley Dod, is an effective and most enduring flower. It may be described as a magnified form of D. neglectus. With me, grown in a pot, it is about twice the size of that kind. It reproduces itself by underground stems of moderate vigour. Even in hot sunny weather the flowers have kept fresh and good for ten or twelve days. Another kind somewhat in the same way, but still larger and with higher coloured flowers, is grown under the name of D. superbus Hæltzeri. It is a very desirable Pink for the rock garden. The flowers are nearly 2 inches across and extravagantly beautiful, the intensely crimson petals being deeply lacerated, and fall like a fringe. Then there is the little white D. fimbriatus, with arching stems like a thread; let the florist try these flowers in an epergne or bouquet; for delicacy or perfume few flowers are better. In cultivation the plant is free from all the weaknesses which characterise the neglectus class, and its neat grassy cushions keep perfect for years, one here being five years old and nearly 2 feet across. The gay Maiden Pink (D. deltoides) is now a host of beauty in itself, owing to the myriads of flowers which it produces. The latter range from white to crimson. It makes a good decorative plant for walls and the rock garden in July. On old walls it seeds freely, and if there are ledges connected with them ever so narrow, there will appear seedlings by the hundred. In such positions during very hot, dry weather a little water should be given it, or it may perish. Of course, much will depend on the aspect and amount of *debris* with which the ledges are filled. The Cheddar Pink (D. cæsius) is not only well adapted for similar situations, but the typical form of it is, perhaps, the most fragrant of its family. I say type studiedly, because there are several dwarfer varieties of it which do not so well develop this desirable quality.

Saxifraga tricuspidata is an intermediate species, so to speak, between the rigid and pointed forms, such as Burseriana, and the smaller mossy kinds. Its habit is neat, but it is a slow grower

and sparse flowerer. The cosy way in which it adapts itself to the stones in rockwork, and the pleasing tints which it develops in summer, most commend it. Just now, the tiny three-pointed leaves are becoming a fairly good yellow tipped with red. The plant reminds one of some of the Drabas. Moreover, it is one of the least common of the numerous family to which it belongs.

Rosa minima.—Under this name I received a charming little double Rose—the smallest plant and smallest flower I ever saw. Its colour is varied like that of centifolia; the petals are pointed, and the scent spicy and strong; my specimen of it, which is flowering a second time this season, does not exceed 3 inches in height. It grows bushy from the base, and the flowers are produced singly. I have only as yet tried it in a pot in a cold frame on which air was left all last winter, and where several times its roots must have been frozen hard, for the pot was not plunged. If it should prove hardy it will be a gem for the rock garden.

Codonopsis (Glossocomia) ovata.—This is a little tuberous-rooted Bell-wort, with greyish downy foliage set on slender stems. Its big bells, which are produced singly, are leaden blue in colour and prettily veined. Its structure and painting inside are indeed a study, being wondrously beautiful. I will not try to describe the ivory-capped columns, or the angular rings of rich colours at the bottom of the cup, but I would urge all to grow it, for it is perfectly hardy; use plenty of splintered or sharp wood charcoal, for this, I fancy, keeps ground pests from eating its long tuberous roots. I also find that in light soils it has the habit of drawing itself down deeper and deeper every year. Whether this is for it or against it I cannot say, but in three years it gets to a good depth, though originally set near the surface. Some roots kept in small pots were so persistent in this habit, that they deviated from the erect position, bent themselves round the bottoms and escaped by the holes tail first. This sort of thing occurs in many Liliaceous plants Alstrœmeria lutea being a notable example.

Ramondia pyrenaica.—Last year I spoke about rooting the leaves of this choice alpine. I have just been going over some that were inserted as cuttings two years ago; they lifted with a nice tuft of roots attached to them, and they had thrown up from two to four young leaves, the cutting leaf being still green. They were pricked into decayed Cocoa fibre, sprinkled with a few seeds from the short velvety wall Moss. The latter soon germinated and formed a nice mulching, and, as I suppose, helped to keep the little pan of leaves cool and moist. Just about a year ago a friend sent me a handful of seedlings of this plant in some nice fresh Sphagnum. My man seemed to care more for the Moss than the Ramondias, so he had the Moss, but in it he took by accident one of the plants, which, together with the Sphagnum, was placed on the surface of a basket of Stanhopea, and, of course, hung up in the stove near the glass. After a week or two it made rapid growth. It remained in that position, and it is there now, healthy and strong. This Ramondia is found wild in cool, deeply shaded places, while the position into which this plant has got is just the reverse, but, of course, very moist, and this evidently balances the other conditions.

Papaver bracteatum and orientale.—The distinctions between these are such that no one could mistake them after once seeing them. The colours form the chief distinguishing points, for though there are others, they are not always reliable. As, however, it seems desirable that, if possible, the two kinds should be identified when not in flower, one or two features may be noticed. The leaves of bracteatum begin to appear earlier than those of orientale; they are more sparsely covered with grey hairs and more erect; they begin to grow freely in winter, and, like the flower-stems, are stouter and more erect than those of orientale. In the matured state, indeed, the leaves are a grass-green compared with the greyish green of orientale. When in flower the stalks of bracteatum are not only stouter and more erect, but they are better furnished with foliage; they support the flower in an upright position, never bell fashion or looking sideways, as in some varieties of orientale; the leaf-like bract immediately under the big crimson flower is never absent. This, however, is sometimes present on the orange-red flowers of orientale, but it rarely occurs on all the flowers alike of the same plant. It is on account of this bract in orientale or some of the varieties which run rather close to bracteatum in all but bloom colour that many become puzzled. I may also mention that from five different sources I had orientale sent me for bracteatum, and I believe the latter (true) is not generally yet in cultivation. Another striking distinction is the fact that the flowers of bracteatum last twice as long individually as those of the oriental species, and each petal, by comparison, may be termed wedge-shaped, whilst those of the latter may be called balloon-shaped in outline. The capsules, too, are markedly dissimilar; the seed-head of bracteatum is wineglass-shaped, that of orientale more round.

The Dryases are just now in very happy form, having made new and shining foliage which has just become sufficiently ripened to show its true character. Some fine flowers are still to be seen, and the seed-heads both in the twisted and downy condition are also present. D. Drummondi is the largest, but though its flowers are yellow and therefore desirable, it is not so free nor is its habit so pleasing as that of octopetala, which, taken altogether, is by far the best and most useful. Octopetala minor is a counterpart of the type, but more shy as regards bloom and smaller in all its parts. Its tufts of foliage are very pretty and make a dense mat. Much difficulty has been experienced in establishing fresh patches with material taken from the old plants. I do not think such would happen if an effort were made to secure it at the present season. Just now the new growth has become set and partially ripened; last year's wood has sent down its rootlets, and if rooted twigs were slipped off now they would start into growth at once. The foliage should not be turned wrong side to the sun. A little later on will not do so well as now, because not only will the second growth have begun to lengthen, but there will hardly be time enough for the plants to make as many roots as they will require with which to pass through the winter. Place the rooted twigs on moist peat and loam, scatter over them a good covering of the same, and lay a heavy stone over the roots, then give one good watering and leave them alone.

In the pot culture of alpines wild Spergula is a plague. There is one little matter which I would like to point out in reference to this Spergula or Spurry. Owing to its small size it is not objected to until it has made itself a nuisance; people then begin to pull it out as well as they can. Now where it has grown freely it is not enough merely to pull it up; let anyone turn the soil out of the pot and it will be found that a paper-like mat of its roots will have been formed between the soil and pot, greatly to the injury of the roots of the rightful occupant, and if such is not removed the plant never thrives as it otherwise would do. Therefore, if Spurry is growing among alpines in pots, remove it, and be sure you clear the soil of its roots.

Some Gentians may be propagated by rootlets, the stronger kinds, for instance, such as lutea, punctata, purpurea, &c. I noted this fact in the case of the latter where a rather strong plant had been starved in a small pot; the roots had run round and cropped above the morsel of soil where an eye formed, and when taken off it grew freely. As regards lutea, I have cut its roots like those of Seakale, and made plants from them in moist sand and peat.

Saxifraga ohioensis is as pretty when in flower as it is uncommon. It belongs to the same section as rotundifolia, having roundish, but largely toothed, leaves, which, however, are not thick or downy, but thin, somewhat leathery, and glistening; the leaf-stalks are very slender, and the little plants when in flower do not exceed 6 inches or 8 inches in height. The flowers are of crystal whiteness, small, and borne in lax spreading panicles. It is a gem for rockwork, and during these past four years it has withstood the severity of our winters.

Aster alpinus and its varieties.—Unless these are constantly propagated from cuttings like Chrysanthemums no idea can be formed of the beauty and size to which the flowers may be grown. The plants will be in their prime the second summer from the cutting stage, and it is a mistake to place them in the poor worn-out soil of rockwork, where they often get, and which is, moreover, too dry. Under liberal treatment the flowers are not only better as regards size and colour, but they last longer. The white variety is especially amenable to high culture; it then becomes larger than the type and the ray florets trebled, thus giving this shorter-stalked variety a massive effect. We have noted also the ruby coloured kind under the name A. alpinus ruber, but my experience of it is so brief, that I can only say it is very hardy and a robust grower.

J. W.

LILIES IN FLOWER.

IN order to form some idea of the beauty and variety to be found among Lilies, a collection of them should be inspected now when the majority of them are in bloom. L. Thunbergianum or elegans and its different varieties make a goodly show, and, what is more, they supply a wide range of colour, varying from the orange-buff tinted Prince of Orange to the deep blackish crimson-coloured cruentum or hæmatochroum. This last is the deepest coloured of all Lilies, that known as the Black Lily excepted, but that by some is classed with the Fritillaries. Other desirable forms of L. Thunbergianum besides the two just mentioned are bicolor, a large bold reddish apricot-coloured kind; Van Houttei, rich crimson; and sanguineum or biligulatum, brownish red. L. bulbiferum is a pretty Lily with erect heads of cup-shaped, reddish orange flowers. This species is readily distinguished from all others by the small bulbils that are produced in great quantities in the axils of the leaves. The common Orange Lily (L. croceum) is just now at its best, and when seen in a mass a fine display it makes. The old White or Madonna Lily (L. candidum) is known to almost everyone, and, though so common, is second to none as regards purity and beauty. When once established it dislikes being disturbed, a remark which also applies to L. chalcedonicum, one of the Turk's-cap section, with intensely bright scarlet-crimson blossoms. This kind will often absolutely refuse to grow the first season after being planted; the bulbs remain in the ground throughout the winter, and flower the following year. The brightly-coloured L. pomponium verum has been very fine, but it is now past its best. It is a most effective early-flowering Lily, but has such a faint smell that it cannot be used in any way for indoor decoration.

Several of the North American Lilies are now in bloom, notably the Panther Lily (L. pardalinum), L. parvum, and Humboldt's Lily (L. Humboldti). Variable as some Lilies are, this last is even more so than usual; some blooms of it, except towards the tips of the petals, are thickly studded with small dots, while in others they are fewer in number, but become comparatively large blotches. The extreme form of this latter is often met with under the name of L. Bloomerianum, and an extremely pretty variety it is. Another North American kind is L. Parryi, the beautiful golden blossoms of which, delicately poised on a slender stem, are admired by everybody. The white trumpet-shaped blooms of L. longiflorum and its varieties are just commencing to expand. Harrisi, eximium, and Wilsoni are all too much alike, but a pretty form of longiflorum is albo-marginatum, in which the leaves are broadly margined with white. The fragile-looking L.

Krameri is most deceiving in the size of its bloom; its appearance during the earlier stages of growth would lead one to expect but a miniature flower, but in reality the blossoms are comparatively large. The delicate pinkish hue of the majority of them is most pleasing, but unfortunately it is a difficult Lily to keep in health—so, at least, I find it to be, but I hear of others who grow it most successfully. Here, in rather a light well-drained soil, imported bulbs flower well the first season, but less satisfactorily the second, and by the third year few indeed will bloom. The beautiful L. Browni, with its large tube-shaped flower suffused heavily on the outside with chocolate, is just opening, and revealing the waxy white interior. When fully expanded the dark-coloured anthers are most conspicuous, contrasting strikingly as they do with their delicate surroundings.

Of the Turk's-cap Lilies, mention may be made of the ordinary form of L. Martagon, with its spike of gracefully reflexed purplish blooms; but the finest in this class are L. Martagon dalmaticum, a variety in which the flowers are of a deep shining crimson-purple, and album, with pure white blossoms. Some forms of these two last-named Lilies are greatly superior to others. Another nearly allied to the Martagon is the Japanese L. Hansoni, but its rich golden-coloured blossoms being earlier in expanding than the others are now past their best. L. monadelphum I take to be a remarkably fine Lily—that is, when it does well, which is not always the case. My experience is that it is useless to expect a good show of bloom during the first season, for, generally speaking, many of the plants do not appear above ground till the second year. Its blooms are borne on large pyramidal-shaped spikes, and are most gracefully reflexed and delicately tinted. Their colours vary from deep yellow to pale whitish sulphur, and they are more or less studded with small dark coloured dots. L. testaceum, which when growing reminds one to some extent of L. candidum, is a fine Lily, and especially noteworthy from the distinct nankeen tint of its gracefully reflexed blossoms. They may be used in a cut state, as their scent is agreeable and not too powerful. No notice of Lilies would be complete without mention of L. auratum, the earliest blossoms of which are just expanding. Like most of the others, this Lily is very variable, some forms of it being greatly superior to others.

Alpha.

BORDER FLOWERS AND HOT WEATHER.

The recent hot weather has been most trying both in the kitchen and flower garden. The ground was dry before it set in, and after that everything suffered. The plants first affected were those in herbaceous borders, such as Phloxes, Pyrethrums, Irises, &c.; in fact, the leaves of the Irises became yellow. I visited a garden ten days ago containing thousands of English and Spanish Irises during the hottest part of the day, and their flowers were in a sad plight; they were drooping in the bright sunshine, and the heat reflected from the hot, dry red earth was even trying to one's eyes. A surface watering under such conditions would have done little good—indeed, might have done harm. We cannot avoid the blaze of sunshine, even if desirable, but we can maintain a moist condition round the roots of these and all other plants by giving a thoroughly good watering, and immediately thereafter mulching the ground with Cocoanut fibre refuse, or short manure if well decayed. Watering in dry, hot weather should be done thoroughly. Enough should be given to reach, if possible, all the roots, and to prevent evaporation mulch with something.

Roses suffer very much in dry weather if the soil is light and the subsoil gravel. They cannot be maintained in good health unless they are kept growing. I have seen them with the sap almost dried up, so much so, as to prevent the bark from rising when slit with a knife for budding. Such Roses become a prey to green fly, mildew, and even red spider. This last is the worst of all, as it causes the leaves to become brown, and ultimately to drop off. Such disastrous results would not happen if the ground in the first place was trenched and manured, and also mulched in winter with manure, and again in summer as soon as hot weather sets in. Syringe well overhead at night, and then in the morning every leaf will be furnished with a row around it of glistening dewdrops—a healthy sign either under glass or out of doors. Perhaps none of our choice garden flowers suffer sooner from the lack of water than Gladioli; they require the same treatment as Roses; they should never be allowed to get very dry at the roots. At one time I used to grow thousands of named varieties and seedlings. Our plan was to give them a thoroughly good watering twice a week, and every hot day they were well watered overhead with the garden engine. If this was not done, red spider would attack the leaves and cause them to become brown. Syringing, however, does not dislodge the maggots which inhabit the axils of the leaves, crawl out at night and devour the flower-buds. They can be discovered in their hiding-places by day, or, by the aid of a good lamp, be found feeding at night. Phloxes ought to be well watered and mulched, and the same advice should be followed in other cases. It is a good plan to plant some spreading low-growing subjects to cover the surface of the ground in mixed herbaceous borders. This retains moisture and has a pleasing appearance.

J. Douglas.

Trees and Shrubs.

TREES AND SHRUBS FOR WATERSIDE.

In planting near water the following shrubs may be named as suitable for planting in the neighbourhood of water. The Alder, kept low by occasional cutting, makes a fine fringe, and forms a strong barrier for the margins of water when the current is liable to wash away its banks. The common Whitethorn, Bramble, hedge Rose, red Dogwood, Honeysuckle, and Blackthorn, afford proper marginal decoration for water in natural scenery. Trees best adapted for positions nearest the water, where the ground is liable to be moist, must consist of the common Alder, various kinds of Willow (including the Weeping and Rosemary-leaved Willow), Alnus cordifolia, Norway Spruce, deciduous Cypress, and Hemlock Spruce. Such trees are also quite proper for the islands; but in order that the roots may not lodge too much in the water, the parts of the islands to be planted should be raised irregularly, or in a natural manner, with stones, roots, sods, &c., mixed with suitable soil, a few feet higher than the level of the water. The five last-named kinds of trees are most appropriate for beautifying water in well-kept grounds.

Amongst the larger trees employed, not exactly for fringing the margin, but at a moderate distance from the water, the Wych Elm is the most elegant, and should always be planted in extensive places; its elegant massive twigs and pendent branches entitle it, above all other large trees, to this distinction. Nevertheless, the English Elm, Lime, Beech, Weeping Birch, and Larch would be appropriate. Every kind of Poplar should be excluded, except, indeed, the Lombardy, of which two or three may be planted so as to rise out of the midst of masses of other trees. In planting, room should be allowed for walking near the water's edge; sometimes close to it, and at other times with a bush or group of shrubs interposing. Swans, by all means, must be introduced, as well as other water fowls.

W.

Elder and Dogwood.—Just now the most noticeable tree in flower in the hedgerows is the Elder, and abundant as the blossom of this tree generally is, this season it seems to be unusually profuse. By the roadsides it is seldom the hedges are allowed to grow on long enough for the trees and bushes of which they are composed to approach to anything like perfection or maturity of growth, but in some places in this neighbourhood there are hedges which have not been cut for many years, and in these the Elder seems to have supplanted many other species. Where these large bushes occur at very frequent intervals for long stretches on each side of the roadway they present a vista of masses of flowers seldom equalled except in positions which have been arranged for the sake of the effect. Hereabouts there is another hedge bush which grows largely by the roadside, the common Dogwood (C. sanguinea), and this is now showing a great mass of blossom, and very often comes into the view with the Elder.—D.

Rhus radicans is a very suitable shrub plant for the woodlands; when allowed its own way it will climb among shrubs and low trees, and take perfect care of itself. In sheltered places its leaves do not change colour, but more in the open they turn bright yellow in autumn. I remember seeing a plant which had climbed among the branches nearly to the top of a tall Cypress, at the edge of a wild piece of shrubbery. It formed a perfect picture, its large, bold foliage being set in a framework of glaucous green.—G.

The Washington Cedar.—As is now tolerably well known, the Mammoth tree of California—Sequoia (Wellingtonia) gigantea—was at first supposed to be a new genus, and named Washingtonia by Dr. Kellogg. Lindley also supposed it to be distinct, and, either ignorant of or ignoring Kellogg, named the supposed new genus Wellingtonia. But neither of these determinations stood the test of botanical rule, and the plant was finally referred to a genus already established, namely, Sequoia. Dr. Kellogg, however, claims, at least, priority for his common name, Washington Cedar. He says, "As historic truth demands it, it is but just to state, I, myself, took Mr. Lobb to the California Academy of Sciences, and showed him the first specimens he ever saw of this marvellous, now world-renowned, Washington Cedar, which was so named by me before he ever saw the tree. The fact is well known to the old charter members of the Academy, several of whom are still living. It is, therefore, the earliest among common names, and claims precedence, by all courtesy, in point of time, as also in appropriateness of honour. Our relations to its earliest identification we leave to the historian of the future."

The Judas tree (Cercis Siliquastrum).—This tree is indigenous to Turkey, Greece, and Judea, where its flowers, owing to their agreeable acidulous flavour, are highly esteemed for mixing in salads, and they are also frequently pickled for use in the same way when fresh flowers cannot be had. Its foliage is very distinct from that of most other trees in shape and colour, the latter being bluish green on the upper surface and grass-green underneath. When old, the Judas tree forms a broad, round, flattish head, somewhat similar to that of an Apple tree. The wood is not considered valuable, although it is hard and capable of taking on a good polish. As an ornamental tree in spring, it ranks as one of the most attractive, owing to the singular and beautiful appearance which it presents when its old, as well as young, wood is literally covered with its purplish pink blossoms clustered together in small bunches before a leaf is visible; and when associated with Laburnums, Lilacs, Flowering Currants, Azaleas, and other spring-blooming subjects, it forms a charming contrast in colour, blooming, as they all do, at the same time. The Judas tree is also well suited for planting on a lawn, either to form a standard bush or as an isolated specimen.—G.

Pruning Picea Nordmanniana.—This Conifer is inclined to produce strong side-shoots, frequently stinting the growth of the leader to 1½ inches in height per annum. Seedling plants of P. Nordmanniana rarely put up more than one leader, and it is wrong to allow this leader to be robbed by the superabundant growth of the side-branches, now that it is shown that no harm will accrue from a judicious use of the knife. During the period when the P. Nordmanniana was scarce, the plants were generally increased by cuttings, grafts, and layers. This pruning was unintentionally the means of causing the leaders of the original plants to assume an upward growth. It is surprising to

see many of the early produced plants from cuttings, grafts, and layers, although eighteen or twenty years told, growing procumbent, and, if upright, somewhat fan-shaped. The only way to induce a leader on such plants is to cut off all the branches and peg the stump firmly to the ground. By this means, one, two or more leaders will be produced from the lower part of the stem. By the removal of all but one, it will in time become a well-set leader, and ultimately make a vigorous tree. The leading shoots removed will make excellent cuttings or grafts, by retaining their leaders, which is not the case with the points of side-branches. The same remarks are, I find by experience, applicable to many other species of Picea when produced by cuttings and layers, such as P. nobilis, P. robusta, P. amabilis and P. grandis.—J. M.

The Spruce.—There is not a more elegant tree, I consider, than the Spruce Fir (Abies excelsa), which, planted in a northern exposure towards the foot of a hill where the soil is loamy and damp, presents a most beautiful appearance, its horizontal branches touching the ground, laden with its large handsome cones in the proper season, and displaying such a lovely mass of green foliage from growing so closely that its stem cannot be seen, and which, if left untouched, will remain so for sixty years. But plant a Spruce upon a dry sandy soil that would be appropriate for a Pinaster or Scotch Fir, although it may possibly thrive for five or six years, when it has attained an age of twenty years, its under-branches will be found withered and destitute of foliage, the bark covered with Lichen, and the whole tree at a complete stand-still.—W. H. A.

Erica cinerea.—Of this pretty Heath, which does not seem to feel the effects of drought, there are several varieties, some of them differing widely from each other, and also from the type. For instance, in atro-purpurea the flowers are much richer in colour than the ordinary form, while in alba they are pure white, thus contrasting well with the preceding. In pallida the colour of the blossoms is of a pale reddish hue, and in coccinea they are a distinct shade of crimson. The St. Dabeoc's Heath (Dabœcia polifolia), with its spikes of comparatively large bell-shaped blossoms, is also in flower, and with it the two varieties, viz., that with white flowers, and the other in which the blooms are parti-coloured.—H. P.

The Beech in Denmark.—It may interest your readers to know under what circumstances the Beech (Fagus sylvatica) grows here in Denmark. The Beech is the commonest and at the same time the most beautiful forest tree with us. Fascinating and lovely beyond all description is a Beech forest, or even a single tree in early spring, when the delicate, glossy, bright green foliage has just unfolded itself on the graceful, hanging branches. Formerly the Oak (Quercus Robur) predominated in the Danish forests, but are now fast disappearing for the Beech. Young self-sown plants of this beautiful tree grow very luxuriantly even if they are quite overshaded by the crowns of the Oaks, and when they grow larger the Oaks must give place to the Beeches. The European Beech (Fagus sylvatica) is, however, distinguished from the common American Beech (Fagus americana or F. ferruginea) by a more slender growth, with more hanging branches and smaller, but more glossy and bright green foliage, and very likely its claims to soil and situation are also a little different. The Beech in this country grows best in a somewhat heavy clay and chalk mixed mould with a moderately moist subsoil. When these conditions exist the tree reaches its finest development. It also does better in low places in the neighbourhood of lakes and rivulets and on northern slopes than in higher localities and on southern slopes. In sandy soil deprived of chalk and in a dry situation it will either not grow at all or it becomes stunted in growth. A soil and situation that is favourable for the growth of Evergreens in general will also be suitable for the Beech.—R. H.

GRAFTING CONIFERS.

As the season for grafting Conifers is at hand a few words upon the subject may be useful. Conifer grafting may be performed either about the month of August or early in spring. For this purpose two-year-old stocks are preferable, as it is desirable that the stock and scion should be as near of a size as possible. They should be established in 3-inch pots, and if it is intended to use them early in the spring they should be kept during the winter in cold frames. There are several methods of grafting Conifers, but ordinary side-grafting is in most cases the best. This operation consists in making a clean cut in the stem downwards about an inch in length, then at its termination making a transverse cut, thus removing a piece of the bark-wood clean away from the side of the stock. The scion should be cut off clean and square at the end, and a piece of the wood should be shaved off about equal in length to the cut on the stock. The butt-end of the scion should then be placed upon the notch cut in the stock, taking care that the bark on one side meets exactly the whole length of the cut. The great aim in this operation is so to cut the scion and stock that the former when fitted on nearly replaces the piece removed. The scion being thus fitted must be held firmly in its place by the thumb of the left hand and tied on with bast or wool so that it does not afterwards shift. When the scion is very small, or the stock much out of proportion to it, another method may be practised. This consists in simply making an incision obliquely in the stock, the scion being so cut that one side of it forms a sharp edge, in order that it may be easily inserted therein, the bark of the scion thus coming level with that of the stock. This is a neat and expeditious method, as when united it is difficult to perceive the union. The cuts must be cleanly made with a sharp knife, and the incision in the stock and the cut on the scion should correspond in length as nearly as possible. This latter method scarcely needs tying, for if properly done the scion will not easily move, and it quickly unites to the stock. W.

Berberis concinna.—Now that nearly all other Barberries are out of bloom this species is in full flower. It is a dense compact evergreen bush, at most not more than 2 feet high, with light green leaves, the undersides of which are of a silvery whiteness. The flowers are of a pale yellow colour, and borne as freely as those of the commoner kinds. This Barberry is well worthy of a place among the more select shrubs; indeed, it is not vigorous enough to be associated with strong-growing subjects, but needs rather a good position in front of a shrubbery border or a fairly sunny spot on the rockwork. It is a native of the Himalayas, but quite hardy in this country, except during very exceptionable winters. Another Barberry rather variable in its time of flowering is B. aristata, some individuals of which are now in bloom. It is a vigorous growing kind, reminding one to a certain extent of the common Barberry, but differs widely in its time of flowering. From the reddish colour of the bark it is a conspicuous object in winter when devoid of foliage, for it belongs to the deciduous section, while B. concinna is nearly, if not quite, evergreen. B. aristata is also a native of the Himalayas.—T.

Birds and Holly berries.—In March this year there were some observations in The Garden from one or two persons about "Birds and Holly berries," and I mentioned that here, at Tunbridge Wells, where the Hollies had borne an unusually heavy crop of berries, that they were then losing their berries, which were lying on the ground thickly beneath them. One tree, however, in the garden of a friend of mine has not done so, and still retains its berries. Is it not a very unusual circumstance for a Holly to be covered with berries at this time of year? This tree forms a very striking object among some deciduous trees among which it is planted.—G. S. S.

Pernettyas in flower.—Everybody admires the Pernettyas in berry, but few seem to notice their flowers; yet just now the myriads of tiny wax-like flowers have a beautiful effect. Though the most attractive stages of the Pernettyas are in summer when in bloom, and in winter when in fruit, yet at all times they hold a high place among neat growing evergreen shrubs, irrespective of any other conspicuous feature. As so many new varieties have been raised recently, and a wide range of forms exists from a fruiting point of view, it would be as well to devote a certain amount of attention to the flowers, as some might be obtained giving a greater variety in this respect.—H. P.

The Rose Acacia (Robinia hispida).—This lovely shrub or small tree is at its best when Thorns and other early summer trees and shrubs are over. Its clusters of large deep rose-coloured flowers are very beautiful, and no other shrub of its class can vie with it. It is not very particular as to soil or situation, but will thrive in dry sandy spots better than most shrubs, for though when grafted it acquires a tree-like habit, yet it is more adapted for associating with the larger shrubs than with vigorous trees. When on its own roots this Robinia forms a loose, straggling specimen of bush-like habit, but, grafted standard high on the common False Acacia, it soon acquires a good-sized head, and flowers most profusely. An additional merit is that a second crop of flowers is often borne towards the end of the summer, at which time they are extremely welcome. There are several varieties of the Rose Acacia mentioned in various catalogues, but the finest of all is macrophylla or grandiflora, the flowers of which are larger and deeper coloured, while the foliage is also bolder.—T.

Where to plant Laburnums.—A few weeks ago, in going through a place, I was much struck with a group of Laburnums on the edge of one of the lawns. The background was a large mass of Beech and other trees of the same class, and the Laburnums were just in flower. Being a group of a considerable size and pendulous in habit, I think the effect was better than any I had seen produced by this tree before. As is well known, the form which the Laburnum assumes as an isolated tree, if left to grow on naturally, is such as to render it somewhat unsuited for lawn-planting, but here this loose and straggling form was turned to good account through their being placed in a mass. I have seen many Laburnums, which have been trained to a single stem and periodically cut back, form a good regular head, but the result is too stiff. By planting them in masses, as suggested, pruning becomes unnecessary, and being left to themselves the trees soon intertwine and make a capital flank or screen on the margin of a lawn.—D.

The Jerusalem Sage (Phlomis fruticosa).—This is not usually considered a handsome flowering shrub, yet it is when in bloom, and, moreover, is distinct from all others. It is now in flower and seems to defy drought; indeed, it thrives best in hot sandy soils where few other shrubs can grow.—T.

Cut-leaved Alder.—I shall be glad for information regarding the Cut-leaved Alder. Is it easily blown over by the wind, and is it suited to an exposed situation?—F. W.

*** The Cut-leaved Alder is not a tree suited for a very exposed situation. It never flourishes so well as when planted in a low-lying spot near water, near enough for the roots to derive abundance of moisture therefrom. In such situations it is not liable to be blown over, as its roots spread widely and obtain such a firm hold of the soil. In poor soil on on exposed situations half its beauty is lost.—Ed.

SHORT NOTE.—TREES AND SHRUBS.

Carpenteria californica is now in flower in my garden. I bought the plant three years ago from Messrs. Rodger and McClelland. It is quite hardy here.—T. M. Bulkeley-Owen, *Tedsmore Hall, Westfelton, Shropshire.*

SOCIETIES.

ROYAL HORTICULTURAL.

July 13.

A better meeting than this has not been held here this season. There was a capital fruit and vegetable show—could hardly have been finer; hardy flowers were neversh own more extensively nor of greater excellence, and added to these were a large gathering of cut Roses and a miscellaneous display of plants, including Orchids and new and rare plants. These latter were more numerous than usual, and no fewer than thirteen plants were certificated. First-class certificates were awarded to the following:—

Dendrobium Williamsianum.—This, the rarest and most beautiful Orchid shown, has long been heard of, but seen in flower by very few. It is a New Guinea plant, belonging to the group of which D. bigibbum is a familiar example, but it is different from any other in cultivation. Its growth is most like that of D. bigibbum, but more slender. The flowers are about 2 inches across, with pure white sepals and petals, and a shell-like labellum of the richest royal purple colour. Such an extremely beautiful Orchid attracted much attention. It was exhibited by Mr. B. S. Williams, who introduced it some years ago, and after whom Reichenbach named it.

Odontoglossum crispum Hrubyanum.—An extraordinary variety of the spotted-flowered or guttatum group. It can only be compared with such as Veitchianum and Sanderianum. The flowers are large and finely shaped; the broad sepals and petals are white and very heavily marked with irregular blotches of a rich chestnut colour. The plant was shown by Baron Theodor Hruby, of Austria, and bore several flowers on a long, graceful spike.

Odontoglossum crispum Mrs. Dorman.—A lovely variety, very similar to an older one called virginale. It has large and symmetrically formed flowers, and spotless white sepals and petals. Exhibited by Mr Dorman, The Firs, Lawrie Park, Sydenham.

Phaius Humblotii.—A new species from Madagascar, resembling the better-known P. tuberculosus, and though not so beautiful as the latter is a very showy Orchid. The flowers, produced on erect spikes, are about 2 inches across, with pale claret petals and sepals, while the large and broad lip, quite an inch across, is white on the upper part, the lower lobe being stained with a deep port-wine colour. The spikes are few-flowered and about a foot high, and the foliage is long, narrow, and ribbed. Shown by Sir Trevor Lawrence, Burford Lodge, Dorking.

Oncidium macranthum (Southgate's variety).—This closely resembles, if not the same as the variety named Williamsianum by Reichenbach some time ago. It differs from the typical form in having the petals stained with a large irregular blotch of purple. It is the handsomest and most distinct variety of this Oncidium yet seen. Shown by Mr. Southgate, Selborne, Streatham.

Impatiens Hawkeri.—A marvellously fine new Balsam, somewhat in the way of the popular I. Sultani, but greatly superior to it both in the size of its flowers and their colour, a brilliant carmine-crimson. It appears to be quite as free in growth and bloom as I. Sultani, which it will no doubt supplant in course of time. Exhibited by Mr. W. Bull, of Chelsea, who recently introduced it from the South Sea Islands.

Aphelandra chrysops.—A handsome plant resembling A. fascinator. The leaves are broad, of a deep green, and marked with parallel bands of silvery white. The flowers are produced in a dense terminal spike about 6 inches long, and these, as well as the bracts, are of a clear canary-yellow. Exhibited by Mr. W. Bull.

Pteris serrulata (Naylor's Crested).—This is different from the numerous crested forms of this Pteris previously raised, the fronds being more finely divided; indeed, the plant looks more like a tuft of translucent seaweed, as finely cut as garden Parsley. It will prove a specially valuable plant for the market grower. Shown by Mr. Naylor, Harrow.

Pelargonium Eden Marche.—A new French variety of the double-flowered Ivy-leaved class in the way of Mons. Crousse, but with larger, more double flowers. It is free in growth and very floriferous. Shown by Mr. W. Bealby, Roehampton.

Papaver nudicaule miniatum.—A brilliant orange-red-flowered variety—a beautiful contrast in colour to the yellows and the whites also found among seedlings of the Iceland Poppy. Exhibited by Mr. T. S. Ware, Hale Farm Nursery, Tottenham.

Rose Grand Mogul.—Said to be a seedling from that splendid Rose, A. K. Williams. The flowers of the Grand Mogul have the size, form, and substance of petal of the older sort, but the colour is much deeper and, if possible, richer. It is sure to become as popular as A. K. Williams. Some superb blooms of it were shown by Messrs. W. Paul and Son, Waltham Cross.

Stock Snowflake.—A Ten-week Stock with dense spikes of flowers, very double and pure white. Shown by Messrs. J. Veitch and Sons, Chelsea.

Among other exhibits the most noteworthy was a group of Orchids from Sir Trevor Lawrence, which was composed for the most part of species not often seen, and a few extremely rare. Besides the Phaius Humbloti certificated, there were the following: Spathoglottis angustorum, a beautiful terrestrial Orchid, with long, narrow, plicate leaves and slender flower-spikes some 2 feet high, terminated by crowded clusters of about a dozen flowers. These are about 1½ inches across of a delicate blush pink. Trichopilia Galeottiana, a distinct and very fine flowering species, a good deal like others in the shape and size of flowers, which are yellow blotched and spotted with brown on the labellum; Aerides roseum, in the way of A. Fieldingi; Masdevallia Dayana, a very rare species, more curious than showy; the flowers resemble snake's heads, and are creamy white chequered with brown, like a Snake's-head Fritillary; and M. infracta purpurea, a very fine variety of what is generally regarded as an unattractive species. In addition to these the Burford garden contributed a plant of Cypripedium caudatum with three flower-spikes, which the committee considered worthy of a cultural commendation, inasmuch as the plant had been grown in a cool house. A variety of Odontoglossum vexillarium was shown by Mr. Hollington, Forty Hill, Enfield. It was named Hollingtoni, and differed from ordinary forms in having the lateral petals broader than usual. Baron Schroeder showed a plant of the old, but rather rare, Galeandra Baueri, which is the way of the commoner G. Dayana, but has yellower flowers and a deeper stained lip. From the Earl of Fortescue's garden at Castle Hill came a very fine spike of that showy Orchid, Renanthera coccinea, which so few can grow and flower successfully. Col. Berkeley, of Market Harboro', sent a fine flowering specimen of Phalænopsis speciosa, one of the small-flowered group after the Luddemanniana stamp, and with bright carmine-purple flowers. A choice group of plants of Odontoglossum crispum came from Mr. Dorman's collection, all being of the finest type as regards size and form of flower. Mr. Measures sent from his garden at Cambridge Lodge, Camberwell, a large and select group of Orchids, consisting chiefly of Cattleyas, Odontoglossums now in season, besides a good many out-of-the-common things, such as Lælia xanthina, Cypripedium concolor Regnieri, C. Parishi (a fine specimen), C. Godefroyæ, and a wonderfully fine variety of that little-known species, Oncidium stelligerum, remarkable for its large showy lip, white and claret colour. Some seedling Poppies, varieties of Papaver Rhæas, raised by the Rev. W. Wilks, of Shirley, Croydon, attracted some attention, as they were so beautiful, the crumpled and satiny petals of their flowers being of all colours, from white to deep crimson. The delicate Roses and Pinks were very lovely. Messrs. Veitch showed a small group of seedling Gloxinias, which made an attractive group. Out of the eight or nine sorts shown, we thought that Irma, brilliant scarlet; Vestal, delicate pink; Lucinda, frecked purple; The Moor, deep purple, and Ruby were the finest. Messrs. Veitch likewise showed a pretty Carnation named Mrs. Mason, a sort of salmon-pink colour, and an extensive collection of Iris Kæmpferi varieties, which included some wonderfully fine sorts, some with flowers 8 inches and 9 inches across. Mr. Gordon, of Twickenham, also showed some good sorts of this Iris. Messrs. Carter showed some well-flowered plants of their new double-flowered Silene pendula compacta, which promises to become a valuable plant for borders. A finely-flowered specimen of Fuchsia General Roberts was shown by Messrs. Cannell, who had with it a bunch of that most beautiful of all yellow Carnations, Pride of Penshurst. A fine Hybrid Perpetual Rose named Eugène Furst was shown by Mr. T. Bunyard, of Ashford. It is of a dark crimson colour and with blooms of good quality. Mr. R. Dean, of Ealing, exhibited some spikes of Ten-week Stocks, the sorts being Giant Crimson and Mauve Beauty—the latter a most beautiful sort of a soft mauve colour. He also showed a pale pink variety of the Everlasting Pea named Delicata, the white Musk Mallow, and a new Carnation of a flesh pink colour named Effie Dean. Messrs. Vilmorin, of Paris, sent a gathering of their mixed seedling Carnations representing all colours, and some as large and double as named sorts. Some seedling Pelargoniums were sent by Mrs. Kingsbury, Bevis Valley Nursery, Southampton. One was named Mrs. Parker, with silver-edged leaves and double flowers of a soft pink; the other, Kingsburyana, with silver-edged leaves and double scarlet flowers.

Roses were plentifully shown by Messrs. W. Paul, of Waltham, and by Messrs. Paul, of Cheshunt, who had blooms even finer than at the great Rose show a week previous, and a multitude of first-rate sorts were represented in perfection. Among the new sorts shown by Mr. W. Paul was a white sport from Catherine Mermet which we thought excellent, and a new Hybrid Perpetual named Silver Queen, pale pink with deeper centre. The new Madame de Watteville was also splendidly shown.

Hardy flowers were also abundant, large and varied collections being shown by Mr. Ware, Messrs. Paul, Messrs. Kelway, and Messrs. Barr. The first prize for the finest collection was won by Mr. Ware, with a group as fine as he has ever shown at South Kensington. Lilies were its chief elements, and of these there were huge masses of tall spikes showing the natural grace of Lilies to perfection. The most noteworthy among them were L. candidum and its striped variety (striatum), testaceum, the nankeen-coloured Lily, croceum, pordalinum, Parryi, Humboldti, columbianum, lucidum, Martagon dalmaticum, canadense, besides large gatherings of early Gladioli and other bulbs and a choice selection of hardy perennials. Messrs. Paul's group was a very fine one too, and most effectively arranged. They had great masses of showy things like Lathyrus latifolius varieties, Centaurea montana and the golden macrocephala, Erigeron glaucus, Spiræa palmata, Phlomis Russelliana, Lythrum Salicaria superbum, Campanula turbinata, and a host of other alpines and Lilies. Messrs. Kelway's group consisted chiefly of Pyrethrums, Gaillardias, Alstromerias, white Agapanthus, Phloxes, &c. Messrs. Barr excelled, as usual, in bulbous flowers, of which they had an extensive collection.

Fruit.—With trifling exceptions, rarely has there been a better display of fruit at any summer show than was to be seen here on Tuesday. There were about a dozen classes, and the competition generally was good; in some instances unusually so, and if the remaining shows of the season present the same admirable features, they will prove worthy of the Society. Grapes were excellent, especially the black kinds; the best three bunches of Black Hamburghs, stout, handsome, and well finished, came from Woolmer Forest and from Sir A. Macdonald's garden, so admirably managed by Mr. Taverner, who generally turns out Grapes well. Other good samples came from Elvaston and Bickley Park. There were eight lots in the class. But the class for any other black kind had most interest, because it brought some grand bunches of that delicious Grape, Muscat Hamburgh, superbly finished, and as good as usually seen, from Mr. Goodacre, who merits the highest praise for this exhibit. Gros Maroc, from Mr. Miles, of Wycombe Abbey, medium bunches, but very handsome, if not quite up to size in berry, and what would in another month be superb Alicantes, from Chertsey, were the pick of this class. It was a surprise to find so late a

Grape as Alicante shown so early, but in no case was it fully coloured. Muscat of Alexandria came up moderately. The best were still lacking colour, and the second best, though good bunches, still pale green. It is very rare indeed that good examples of this fine Grape are seen early. Peaches were in grand form; the Grosse Mignonne sample from Mr. Seymour was as fine as could be wished for; and Mr. Wallis, of Keele Hall Gardens, had rich-coloured Crimson Galande that were perfect. Not only other Grosse Mignonne, but Violette Hâtive, Sea Eagle, Royal George, and Barrington were well shown in the fourteen dishes staged. Of Nectarines, finer than the dish of Lord Napier, from Mr. Roberts, of Gunnersbury, have rarely been seen—quite up to Peach size and richly coloured. Pitmaston Orange was also well shown; there were thirteen dishes of these. Cherries were fairly good generally, but Mr. Hudson's two dishes of Black Circassian and Bigarreau Napoleon could hardly have been excelled, they were so fine, glossy, and superbly coloured. Mr. Roberts had good samples of the latter and Black Tartarian; and amongst others shown were Elton, May Duke, Black Eagle, and Governor Wood. Some capital Pines came from Wycombe Abbey, the pair of Queens staged by Mr. Miles weighing 10 lbs., and they were handsome, well coloured, and even. The first prize Pine, which also came from the same exhibitor, was not less good, and weighed 5 lb. 2 oz. Queens were most favoured, only one lot of Smooth Cayenne being shown. Melons were plentiful, sixteen pairs being shown, but were a singularly uneven lot as far as size was concerned, and even the first prize brace, Blenheim Orange, was not first-class, though handsome. Hero of Lockinge, Sea let Premier, Imperial Green Flesh, and Read's Scarlet Flesh were well shown. Some very fine brown Turkey Figs came from Woolmer Forest; indeed, of the eight dishes staged this kind largely predominated. Strawberries were very fine, and gave little indication of the drought which so recently prevailed. There were ten pairs of dishes in the one class, and fourteen single dishes, the British Queens and Dr. Hogg from Greenford showing how admirably the soil in the fertile valley which lies between Ealing and Harrow suits these uncertain, but delicious kinds. Mr. Garlandvoy always does Strawberries well. Curiously enough in the single dish class, fine British Queen from Gunnersbury Park, and Dr. Hogg from Bickley Park, were the best dishes. Of other kinds shown well were President, Eleanor, Sir J. Paxton, Sir C. Napier, and Eclipse. Of miscellaneous fruits there were furnished by Mr. Ross, Welford Park, a seedling Grape very much resembling Muscat of Alexandria, but said to be a seedling from the Black Monukka. It has fine berries and received a commendation. Also from the same exhibitor dishes of Duke of Devonshire, Sturmer Pippin, and Alfriston Apples and Catillac Pears fairly well preserved; also a basket of fairly good Backland Sweetwater Grapes; and from Mr. E. D. Lee, Aylesbury, a basket of Lord Napier Nectarines of fair size and colour.

Vegetables were also remarkably good, and no less than ten collections of eight dishes were staged, the best growers competing. The honours in this case worthily fell to Mr. Richards, of Somerley Park Gardens, though run very close indeed by Mr. Miles and others. The leading kinds were London Cauliflowers, Telegraph and Telephone Peas, Perfection and Stamfordian Tomatoes, Snowdrop Potatoes, New Intermediate and Matchless Scarlet Carrots, White Elephant Onions, Globe Artichokes, Asparagus, and Moore's Cream Marrows. In other collections were beautiful Nantes Carrots, Pen-y-byd Marrows, Duke of Albany Peas, in several collections and very fine; Leviathan Long-pod Beans, &c. The best dish of Tomatoes, of which eight lots were staged, came from Mr. Farrance, Chadwell Heath; in it were fine Trophy, and Stamfordian, a beautiful sample, coming next, and Hackwood Park third, whilst Acme, Reading Perfection, and Trentham Fillbasket were also good. Cucumbers were but moderate in quantity and quality—Purley Park Hero, Model, and Telegraph coming in this order.

Special prizes.—Messrs. Carter offered for competition on this occasion some valuable prizes for their undoubtedly fine Peas, Telegraph, Telephone, Stratagem, and Pride of the Market, ten collections, generally fine samples, being staged. It was rather odd that Messrs. H. Marriott, sen. and jun., of Boston, should have come in first and second, and the samples were throughout literally as like as two Peas. It is due to the Royal Horticultural Society that Messrs. Carter and Co. should satisfy themselves that these exhibitors are distinct, and grow their samples in different gardens. In the class for a single dish of House's Perfect Marrow—prizes given by Mr. House, of Peterborough—only six dishes were staged, the Marriotts coming first and third with fairly even samples, another Boston grower, Mr. Cook, taking second place. This Pea is somewhat of Veitch's Perfection shape and style. For Messrs. Webb and Son's prizes for Wordsley Wonder Pea there was poor competition, the samples being rather small and sword-shaped. Whatever may be its cropping merits, it is not a striking Pea on the exhibition table. Mr. J. C. Mundell, of Moor Park, Rickmansworth, showed several dishes of Peas, fairly good samples, including the old Bunch Pea, put up as the Egyptian Mummy Pea. Mr. T. Laxton, Girtford, showed a collection, including such good kinds as Ameer, Walton Hero, Sensation, &c., chiefly his own kinds. From Messrs. Carter came a collection of about eighty dishes, including all the best kinds in cultivation. The finest of these seemed to be Alfred the Great, Duke of Albany, Telegraph, Pride of the Market, Prodigy, and Telephone. A quantity of Sweet Pea flowers in bunches seemed to prettily decorate this exhibit.

Fruit committee.—The chief exhibits consisted of new Melons, a crop of seedling sorts, sent by various growers for the opinion of the committee, but none were considered superior to old sorts. Mr. R. Gilbert, of Burghley, sent one called Her Ladyship's Favourite. Mr. Ross, of Welford Park, sent one called General Gordon, and another named Semper Fidelis; and Mr. Howe, of Benham Park, showed his Pink Perfection. Messrs. Viccars Collyer and Co., Leicester, sent some excellent specimens of the new Blackberry, named Wilson Junior, which were quite equal in size and productiveness to the illustrations that have been published of it. Mr. Barron exhibited, from the society's gardens, Chiswick, a dish of a handsome Strawberry named Waterloo. The fruits are large, round in shape, and of a deep blood-red colour, and of good flavour. Some fine Canadian Apples were shown in good preservation, the sort King of Tomkins County being the handsomest. Some excellent Lord Napier Nectarines and Royal George and Noblesse Peaches were shown, and Mr. Ward, of Longford Castle, showed some capital samples of Webb's Chancellor Peas, and Mr. Turner, Tonbridge, furnished four dishes of Carter's Peas, Telegraph, Telephone, Stratagem, and Pride of the Market. A silver Knightian medal was awarded to the commissioners for the Cape of Good Hope colony for a fine selection of dried fruits, including Peaches, Pears, Apricots, Apples, Raisins and Cape Gooseberries. The stewed Pears prepared from the dried fruits were delicious, scarcely distinguishable from fresh fruits.

Scientific committee.—The following were the chief subjects of interest discussed at this meeting:—

Rhododendron ponticum var. myrtifolium.—Mr. G. Maw doubted this being a true native of Gibraltar, as stated at the last meeting. At the same time Mr. Maw mentioned that R. ponticum was wild at Algesiras, where it grew in company with Balantium Culcita, both cases affording instances of isolation.

Cistus ladaniferus.—Mr. Maw remarked that plants of this with blotched flowers grew in Spain in company with others in which no blotch was perceptible. He had also seen a few instances of blotched and unblotched flowers on the same plant. Mr. Maw also suggested that Digitalis lutea and grandiflora might be dimorphic forms of one and the same species.

Daffodils.—Mr. Maw reported on the occasional occurrence of erect flowered Daffodils. He also stated that N. minimus of *Botanical Magazine*, t. 6, was identical with N. minor, and abundant in Central Spain at high elevations. Drawings of various hybrids were shown, and the opinion expressed that N calathinus and triandrus were one and the same species.

Masdevallia Dayana.—Mr. O'Brien alluded to this interesting species, in which the three sepals cohere by their tips, leaving, however, lateral apertures through which insects may enter, as in M. fenestrata. The peduncles originate from the top of the shoot, and not from the base, as in others of the genus. A botanical certificate was awarded to the plant.

Fungus on Mangoes.—Mr. W. G. Smith alluded to a fungus, Capnodium mangiferum, which he had received from Mr. G. S. Jenman, of Demerara. The fungus occurs also in India, but there attacks the leaves only. In Guiana it bursts through the bark of the trees.

Selenipedium and Uropedium.—Dr. Masters exhibited a drawing by Mr. W. G. Smith of a specimen, interesting as confirming the notion that Uropedium is a monstrous state of Selenipedium; and a monstrous form of Cattleya Loddigesi was also shown; and Dr. Masters showed a spray of Mistletoe with ripe berries.

Fire blight in Pears.—Dr. Masters exhibited specimens of this disease received from Professor Arthur, of New York Agricultural Station. The disease is attributed to Bacteria, and happily has not yet been noticed outside the United States. To the naked eye the young shoots look dry, shrivelled, and black as if scorched by fire.

A prize list will be found in our advertising columns.

Strawberry Laxton's Noble.—Mr. Laxton, of Girtford, reminds us that we omitted to note the fact that his new early Strawberry named Noble was awarded a first-class certificate at the Royal Horticultural Society's recent show at Liverpool.

Cabbage grub (*B. W. H.*).—Allow me to make a slight correction, as the alteration of one word makes a good deal of difference to my meaning. I wrote (perhaps not very legibly), "however, it should be known as the Cabbage-fly, as it is *really* the same as the Cabbage-fly," but in print it reads, "as it is *nearly* the same."—G. S. S.

Alnwick Seedling Grape.—Just at the moment I cannot with certainty inform "W. I. M." where he will see examples of this Grape that have been set by means of the syringe, but the best and evenest bunches of this variety that I have seen were syringe-set, and I cannot understand how "W. I. M." has failed in setting it by this method.—T. B.

QUESTIONS.

5508.—**Slugs.**—What is the best way to get rid of slugs in Strawberry beds? Perhaps some reader of The Garden will kindly say.—Fawley.

5509.—**Crickets.**—I am very much annoyed by crickets in my greenhouses, Melon houses and vineries, and I shall be glad to hear of anything to destroy them.—F. M. T.

5510.—**What to grow profitably under glass.**—I have a heated span-roofed house 60 feet by 11 feet, thirty miles from London and eight miles from a railway station. I should be glad to know what I could plant it with that would be easy of culture and realise the most money. Will some reader of The Garden kindly assist me in this matter?—H. W.

5511.—**Orchid spot.**—Will some Orchid grower kindly help me under the following circumstances: I have a very fine plant of Cymbidium eburneum which flowers freely, but unfortunately the tips of the leaves as soon as formed become spotted and gradually die back, rendering the plant when the decayed parts are cut off, to say the least, unsightly. I have also in the same house Pleione lagenaria, maculata, and Wallichiana which go in the same way, but in their case the bulbs do not grow, I think, to their full size, nor do they properly ripen. They are shaded with canvas blinds when the sun shines; the night temperature is 70°, and the atmosphere moist. The Cymbidium is potted in Fern fibre, fibry loam and Sphagnum, mixed with crocks and charcoal.—J. E. R.

Names of plants.—*W. R.*—1, send better specimen; 2, Spiræa ariæfolia; 3, Spiræa callosa alba; 4, Sedum spurium, ——*C. F. J.*—1, Cassia corymbosa; 2, Diplopappus chrysophyllus; 3, Staphylea pinnata; 4, Polystichum angulare var. ——*M. Shelberton.*—1, Cyperus longus; 2, Holcus mollis; 3, Festuca elatior; 4, Hordeum murinum ——*L. Rondebosch.*—1, Crassula Septas; 2, Phylica stipularis; 3, Brunia sp.; 4, Erica Thunbergi; 5, Struthiola longiflora; 6, Aristea. All these except No. 4 were named by us for you last year.—— *E. Cox.*—Aeokanthera venenata.——*Sanguinea.*—Elæagnus hortensis.——*A. K.*—1, Milla Murrayana; 2, Datura, too much withered to name. Please send leaves also.——*R. M.*—1, Cephalaria tatarica; 2, Iris sibirica.——*E. Beveridge.*—Oncidium dasytyle (true).——*R. L. B.*—1, Adiantum formosum; 2, apparently A. concinnum latum; 3, Onychium japonicum.——*R. M.*—Next week.

WOODS & FORESTS.

PEELING STANDING TIMBER.

In some parts of Yorkshire Oak trees are all peeled standing, and hardly anything would persuade either woodmen or purchasers accustomed to the practice to adopt any other plan. Marshall, writing on the subject about 100 years ago, speaks of barking trees standing as having much to recommend it, but tedious and troublesome. As to the cost of the work, I am not sure that the labour or expense is greater, while there can be no doubt about the advantage to the timber, and we are familiar with both methods. Most of our timber here is sold standing, and the purchasers, who have the option of peeling and felling it in their own way, always peel it standing to the extent of many thousands of feet every year. The men understand the work, and there are besides people in the district following other occupations during the rest of the year who are expert peelers and always attend the bark harvest. We have had about thirty-five such men employed this season; they began in May and peeled, according to the weather, till the end of June, and some of them later. One man will contract for so many tons, or a certain portion of a fall. These men this season have paid their assistants from 3s. 6d. to 5s. per day, and made a good thing of it themselves, the trees and poles being, on the average, rather small. Thirty-five shillings per ton is the price this year agreed on for peeling—including stacking, 36s. 6d. This is considerably higher than in most other parts of the country, but it is in proportion to the general run of wages in the district; and if the trees are felled first and peeled afterwards, the price would just be the same. The figure does not leave a broad margin for the bark seller at £3 10s. or less per ton delivered in the rough, but large purchasers say that it pays them to peel Oak timber standing if it does no more than cover expenses and perhaps pay for the felling. The advantages of peeling the trees standing are that the timber is much better and sooner seasoned, looks better, is cleaner, does not rive with the drought, and is more saleable. In dry weather Oak peeled after felling cracks and splits in a way that sometimes renders it useless for some purposes. Left standing this does not happen, and it can be felled when wanted. Lastly, the weather has been extremely bad for felled peeled timber. In peeling standing timber the workman begins at the top and strips the trunk in a few sheets in a wonderfully short time. The small boughs are lopped off and peeled on the ground. During the the present bark harvest the quantity got has been about 200 tons. Timber felled and peeled afterwards has to lie where felled till a purchaser is found, unless the forester or the purchasers choose to have it dragged out and lotted, which means additional expense. Acquaintances of mine who fell and peel always sell the timber as it lies—if possible at the purchaser's risk. Felled timber does not peel so readily as standing timber, nor does the season last so long. We have this year peeled down to July 5. Much depends on the weather. A cold day or two will arrest operations; and, on the other hand, when the weather is warm and favourable to the run of the sap, the peelers cannot make too much haste, as it is between the first move in the sap and the full leafage that the work must be completed. Old peelers profess to distinguish between the first and the second sap. The trees are said to be in their first sap when the sap begins fairly to rise before the buds burst, and in the second sap after the leaf is out. Hardly two trees are exactly alike as regards condition for peeling at the same time. One of the most experienced men goes before the others and tries and opens the trees that are "on the run" until the fall has been gone over the first time, when they begin at the beginning again and peel those left. Timber that is peeled standing has another advantage over felled timber, inasmuch as it is not so heavy when felled, and the teamsters can load more feet of it than they can of timber that has lain long, perhaps, on the wet ground and got wet and heavy. All timber merchants I have spoken to on the subject prefer timber that is peeled standing, and that is perhaps one reason why we have for many years been able annually to sell such large quantities of Oak at a fair price when the market was almost glutted with it.

YORKSHIREMAN.

DRAWBACKS TO TIMBER CULTURE.

Although I have had a good deal of experience of buying and selling timber, and have studied the means of producing it—in short, all aspects of the forestry question—I do not think that we have really reached the true issue, or clearly determined why it is that timber culture is not more largely attempted in this country. It would be a great point to be satisfied as to what the real drawbacks are. We here and there see this side of the problem touched upon in a casual manner, or spoken of in connection with other parts of it, but it never seems to be gone into exhaustively.

There is no doubt that the difficulty of fixing upon the real reasons has much to do with the subject being shelved, or it may be that they are so clear to the majority, that they do not deem it necessary to discuss them. If this is so, there are some, I have no doubt, who, like myself, are not altogether clear about it. There is one reason which is occasionally brought to the front, and which has a certain amount of plausibility about it, and that is, that the individual who plants timber trees will hardly ever get a return upon his outlay in his lifetime. In ordinary cases this is true, but the objection is more apparent than real. If the property upon which planting is done passes on from one member of the family to another, where is the difference, whether the owner hands down the bare land and a certain amount of stocks and shares, or whether he invests a proportion of hard cash in young woods and plantations? It is obvious that in the latter case the planter is deprived of the income which would arise from the hard cash invested in enterprises which would be immediately interest-paying; but, on the other side, he would be placing a certain amount of capital in the hands of his successor in a perfectly sure way, and, as the history of families shows plainly enough, it is no small advantage to bequeath wealth in a form which cannot be too readily realised. It is not, however, every would-be planter who would wish to bind himself to the idea of passing on his estates in due succession. If this is so, the conditions are virtually the same, as, when plantings have been made, they are each year increasing in value, and if at any time the property upon which they have been established is placed in the market, its value will be increased in proportion. I cannot, therefore, think that the mere fact of the improbability of the planter himself felling the trees which he propagates is the reason why larger acreages are not laid under wood. It is, I think, on more purely economic grounds that the hesitancy to plant must be sought for, viz., that the ultimate return from the timber crop will not be in proportion to the outlay and the lost interest on capital. This, at least, is the only way in which I can account for it. Taking the present position of the markets, it is not to be wondered at, and I fear that, under existing conditions, the advocates of more extensive planting have rather a thankless task. There are plenty, it is well known, who build up superstructures of figures, showing that in such-and-such a time all forests will be exhausted, and those who now take time by the forelock will then be well repaid. It is an old adage, that "one should not prophesy unless they are sure," and this prophecy as to the exhaustion of what may strictly be termed timber-producing forests seems to be a little before its time. That certain contingencies may occur it cannot be denied, but hap-hazard assumptions are scarcely good enough ground upon which to rely. I conceive that a much more rational way would be to take the averages of the figures of the last two or three decades, and sift out, as satisfactorily as may be, the prospects of return on present outlay. That prices will, by the time that timber crops planted now mature, attain a much higher level than the averages of the last twenty or thirty years, there seems but little foundation to believe.

Timber planting is not likely to be undertaken as a simple act of patriotism, as there are so many directions in which this spirit may be worked out and receive recognition. As has been said, it is upon economic grounds that the question must either stand or fall. Admitting this, and also that the current average figures are not likely to be much exceeded, we are narrowed down to the point of whether the cost of growing and working up can be cut sufficiently low to compete with the imported productions of natural forests. A step towards it I have over and over again urged, and that is a better appreciation of home-grown woods by the producer for his own wants. It is a plan, however, which does not seem to be greatly favoured by the most enthusiastic of would-be planters, and this leads me to think that many who take the subject up do so more on sentimental than practical grounds. A writer remarked some time ago that the amount of wood required for estate use was comparatively very small. On densely wooded places, where the acreage in proportion capable of pasturage or cultivation is consequently reduced and the wants less, this may be true, but on the great bulk of estates I believe that if the timber account was balanced it would be found that there is as much paid out yearly for timber as there is received. It may be done unconsciously, but it is nevertheless a great drawback to timber culture. Although the market quotations are low enough in all conscience, by the time it gets to the place where it has to be used there is not a very large pile of foreign wood for £20, but when a sale has to be effected a pretty good bulk has to be parted with to make this sum. I do not by saying this mean to imply that the merchant takes an unfair advantage, but it is the cost of transport which is the dead loss, and to cover this very heavy item it is necessary to part with about two or three times the bulk of home-grown for the same value in foreign wood. I do not overlook the item of labour for sawing our own produce. This is generally too heavy, and needs to be greatly curtailed. Taking into view the multiplication of labour-saving machinery, I think there is a hope that this item will become less and less, and that ultimately what is now most certainly a great drawback to our timber culture will be very materially modified. A few years ago a portable saw-mill was almost a novelty to the average countryman. Now they are becoming more and more common.

D. J. Y.

British veneer woods.—The reason why woods are cut into veneers is obviously on account of their scarcity and consequent value. When a

wood is abundant, it need hardly be said that it is infinitely better that the article for which it is to be used should be made of the solid material. Amongst British woods the Oak is probably the most used for veneer. This, of course, is not because the wood as a species is scarce, but because there is only here and there a tree which possesses some especial quality, such as a peculiar colour or working of grain which it is desirable to make the most of. The red or brown Oak, which, as understood by cabinet-makers, does not refer to any particular species botanically, but to the colour which a tree of the common Oak now and again assumes, is an example of the kind. Being comparatively rare, it is unusual for it to be used in a solid form, but is cut up into fliteches for covering less valued woods. When the Walnut was a fashionable wood, it was very generally cut up into veneer, and, fashion notwithstanding, it probably is to some extent up to the present time. There are also other comparatively rare British trees which are either used for veneering, or for inlaying in woods of other kinds. The Yew is an example of the kind. When polished its dark colour when placed in contrast with some light wood like the Sycamore has a very good effect. I remember some time ago being shown some specimens of work in British woods, and I was especially struck with a panel of Sycamore, which was bordered with a margin of Yew. In this way there are many woods grown here which make really splendid articles of furniture. It is, perhaps, hardly the place to refer to it here, it being rather a matter of artistic taste than of special forestry interest, but I cannot but think that a very grave mistake is committed in concealing or attempting to conceal the true colour of the wood by means of foreign substances. There are, no doubt, many reasons why a polish is admissible, but beyond this, as a rule, foreign substances on what are of themselves beautiful woods are simply abominations.—D. J. Y.

RUSTIC SEATS FOR WOODS.

These ought to be good and durable and look as natural as possible. For the purpose I know nothing better than seats, whether portable or fixed, made of peeled Oak boughs from 1½ inches in diameter up to 4 inches or 5 inches. Such materials are plentiful at this season, and they ought to be collected and stored in a dry place where the men can use them in stormy weather during winter and on wet days. Crooked and straight of all sorts should be gathered, as every piece will come in useful. Straight thick pieces provide the framework for the seat; the large bent elbows make arms and legs in one piece; the straight smaller pieces provide the cross-bars for filling in the seat bottoms laid close together, and the crooked pieces make the backs and fronts. Mostly all our seats in the woods are made of these materials. Some hold only one person, and can be lifted and moved about; some can hold seven or eight easily, are also portable; and some placed round old tree trunks and at walk-sides hold many more. Ordinary woodmen make and repair them all, and it is surprising how soon a handy man will put a large chair together. In putting a seat round a large tree trunk, the arms and legs, consisting of one piece with a good round knee, are set up first; next the bearers are put in between back and front, and the seat-bottom filled in with the small pieces laid across and sawn off flush with the bearers. Then the back, pretty well elevated perhaps to the height of the shoulders or head—is constructed of what remains, mostly crooked pieces placed crosswise with each other, just as they come in, and topped with a stouter frame of the same pattern. The result is always a rustic-looking, comfortable, and capacious seat. No man who is the least handy need hesitate to construct a seat of this description. Given the materials, which, if promiscuously gathered and plentiful are sure to be right, he has only got to decide the dimensions and begin, and as he proceeds bit by bit he will find the task easy enough. General symmetry of appearance need not be neglected, but uniformity in the corresponding parts is neither necessary nor desirable. Perhaps such seats look most natural when not painted or stained in any way after they get weather-beaten, but a coat of transparent varnish annually makes them last longer. At this season we go over all the seats and repair them where needful, and in this way they last for ever. As for those places of public resort—that is, in places open to the public certain days in the week—the seats are of simpler construction and stronger, consisting generally of a stout tree-trunk cut flat by the axe on one side and nailed on to two upright pieces—one at each end—sawn off and set on end. On any new seat of this kind the visitor at once begins to inscribe his initials with a knife, but the structure is too stable to be much affected by such carving. Yorkshireman.

TIMBER TREES AND SOILS.

The question as to what trees to plant and where they should be planted appears to be yet imperfectly understood. There can be no doubt that the subject is a wide and complicated one, and that very perplexing diversities of growth occur with the same kinds of tree upon what to all appearance is the same kind of soil. There are, of course, other considerations beyond the soil itself, as elevation and aspect, and whether inland or on the coast, which have to be taken into account, but there should be little difficulty in supplying enough of these particulars to render the reports reliable. Such statements do now and then appear in The Garden, but I think there is much room for their extension. Matter of this sort from various districts would be of almost universal interest, for when sifted and compared they would afford valuable data to planters. As an illustration of what I mean, we are here a distance of some forty or fifty miles inland and several hundred feet above the sea level. The soils consist of the different strata of the middle Oolite and within a short distance some strata of the lower group occur. Towards the hills in the opposite direction we have the green sand, and then again the chalk. Taking, for instance, the upper stratum of the middle Oolite, that is, the coral rag, a study very interesting in itself, as well as of real value from a forestry point, could be commenced, viz., that of determining what trees thrive best upon it. As this is a stratum which runs for a considerable distance, and at various elevations and positions, with respect to the sea, it would be of great interest to learn what difference in the species of trees upon the various districts of it can be noted. The nature of the subject would preclude a single individual travelling over the areas to ascertain the facts for himself, but the thing could be easily done if observers at different points would record the result of their observations. That soil has much to do with the quality and progress of timber cannot be disputed. The variation in certain trees, say, between the coral rag and the Oxford clay, next in order to it and here adjoining it, is in some cases very striking. I do not here propose to give any account of the particular trees in which the most noticeable differences occur, or to make a list of those which are common to the soils, but merely to raise the whole question to ascertain the views of those to whom such subjects are both a recreation and a serious study. As a great enquiry like this must be in some way subdivided, so that it shall be intelligible and unmistakable—a common language, so to speak—to observers wherever stationed, I do not see any better basis than that of the geological strata. It is a thing which I have long desired to see taken up and treated in a thoroughly exhaustive manner, and I cannot conceive a better channel of communication than through the columns of a journal like The Garden. The information elicited would without doubt be of as much value to the gardener pure and simple as to the forester. There has been so much said and done on the forestry question, which is so wide of any practical purpose (note the paragraph, p. 42, on the evidence given before the forestry committee), that it would be a relief to get upon some fresh ground from which data could be gained, which would be permanent and reliable. I do not now intend to pursue the matter further, but shall be glad to hear opinions expressed as to the practicability of some such plan.

D. J. Yeo.

THE BEST WOOD FOR POSTS.

Can you inform me (1) which may be considered the best British grown wood for posts, and (2) what kinds would be likely to last for a fair length of time without the use of any protective agent? —W. H. L.

*** By far the most widely used British wood for the purpose of posts is unquestionably the Oak, and there is a general agreement amongst men of experience that it is the most durable. On the other hand, there are men who are intimately acquainted with woods and their uses who prefer the Spanish Chestnut or the Acacia. The comparative scarcity of both these trees, however, precludes their being very largely used. With regard to the durability of the Oak, much will depend upon the age of the wood, the soil upon which it grew, and its freedom from sap-wood. For common mound posts, *i.e.*, such as are used for fences for the protection of young hedges, &c., the smaller branches of the Oak, if there is a fair proportion of heart-wood, will, in most cases, last as long as they are required. Small sapling trees may also be used, and they are generally straighter, but, on the whole, I would prefer the tops of more matured trees. As to the second part of the question, there is a very wide selection of woods which are used for posts, but next to the Oak the Larch is the most common. Scotch Fir, too, is sometimes employed, but I cannot very highly recommend it. It is only fit for temporary purposes. Now and again Elm is used when other wood is not to be had, but it is not well suited to the work. Ash and Beech should be quite avoided, especially the latter. There are other hard woods which may be used under certain circumstances, such as the Maple and trees of that class. In other cases large Willow sets may be made to answer, as they will often grow on instead of decaying. These, however, are matters more for individual decision than for especial recommendation. When it is considered what a very wide range of ground the term post covers, it will be seen that unless it was definitely stated the nature of the work for which they were required, it would be impossible to say precisely what would be the most suitable material. If you could inform me whether the posts are for a building or merely for fencing, and the kind of soil, I could probably assist you further.—D. J. Yeo.

Waste land in Scotland.—"Be aye sticking in a tree, Jock," was the Laird of Dumbiedyke's advice to his son, and the advice should not be lost upon the present generation of Scotchmen who, by adding to the Fir woods of their country, enhance the value of the cultivated land, and add also to the beauty of the district. The rapid growth of the Scotch Fir where it has been extensively planted in the north is a proof of what I state. It is impossible to conceive the extent of the ancient Scotch forests until one carefully examines the mountains and hills now bare and treeless, where the relics of the trees that once flourished upon them lies concealed in the soil or peat; and it is very evident that if these extensive wastes are to be clothed with verdure, the hand of man must do it.—J. T.

Trees for towns.—It has been found that the Plane, which does better that any other tree in London smoke, will not grow at all in that of Lancashire; but, on the other hand, the Beech, Sycamore, Birch, Wych Elm, and Turkey Oak thrive well, but the Lime does best of all.

No. 766. SATURDAY, July 24, 1886. Vol. XXX.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

BORDER CARNATIONS.

It is satisfactory to see these beautiful midsummer flowers becoming more and more popular. But a few years ago what are now called border Carnations were comparatively but little known and as little sought after. They were thought to be so inferior to the orthodox Carnation of the old school florists, that they were considered unworthy of attention. They were held to lack size, symmetry, and refinement. The border Carnations of to-day are, however, very beautiful, and popular opinion respecting them is changed from what it was; it seems probable, indeed, that in course of time they will quite supplant the old show sorts, notwithstanding the fact that their blooms are faultless in form. The once-despised border varieties, or at least their descendants, have developed into a most important, and in fact indispensable, class of open-air garden flowers. Since the raisers of new varieties began to meet the demand for new kinds the list of first-rate sorts has lengthened considerably, and every season brings with it a crop of novelties superior in some way or other to older kinds. Every year one may see during the end of July and beginning of August a grand display of all the sections of Carnations and Picotees in the Royal Exotic Nursery, Chelsea, which is the more remarkable because the plants are grown in a populous neighbourhood, where one would imagine that open-air flowers would have but little chance. The Carnation is, however, proverbially one of the best town flowers one can grow, especially those vigorous border kinds which can withstand a town atmosphere better than the more refined, but much more delicate, show varieties.

The Chelsea Carnation show this year is indeed very fine, notwithstanding the fact that the season has not been one of the best for Carnations. The cold dry winds which blew so long in April were much against them, and before they had recovered themselves there came the dry, hot weather which we had a few weeks ago. The result is that some of the more delicate sorts have not been able to cope with the weather, and this is especially noticeable with the yellow-flowered sorts, nearly all of which, strange to say, are much less robust than the whites, or high-coloured kinds. The Carnation ground has a finer effect than usual, we think, because sorts of like colours are planted in large masses, which brings out the contrast of colours more strikingly. Besides a full collection of what are called border sorts, there is to be seen here a large selection of the very finest show sorts—flakes and bizarres, and all the finest Picotees of their various sections. But it is to the border sorts that we wish to direct most attention, because they are most popular, and because so much is said and written about the show section now that the Carnation show season is at hand. Messrs. Veitch, as we have said, group their border kinds into sections, according to their colours. There are white, yellow, scarlet, crimson, purple, pink, and rose selfs, besides a class for fancy varieties, that is, those sorts which have a mixture of colours in their flowers. Of whites there are about a dozen named kinds, and these seem to be all so good, that it is a difficult matter to say which is best, but, speaking as we saw the sorts together, we thought the best white was Duchess of Connaught, the flower being good and pure, and the growth excellent and floriferous. The favourite, W. P. Milner, so long considered the finest, is well represented; while other first-rate whites are those named Miss Marianne North, The Bride, Ossian, and Virgo; the latter quite a gem, the flowers being small, very compact in form, and snow-white. Gloire de Nancy, the white Souvenir de la Malmaison, is a first-rate white, especially considered as a large flower, but it is not nearly so floriferous as the smaller sorts. Among deep crimsons there is still nothing finer in flower or habit than the old Crimson Clove, of which there is a great mass, but for brilliancy it is eclipsed by a new sort much of the same stamp as regards habit of growth. This is called Masterpiece. Its flowers are smaller than those of the old Clove, more refined, and of a vivid blood-red colour, which, seen *en masse*, is very striking. Masterpiece is bound to make a way for itself among the finest border Carnations. Another good crimson self is General Stewart, which is thought very highly of, and favourite sorts still are Robert Burns, Sparkler, and Sambo. Scarlets are numerous, and perhaps beyond all others the most effective, the great masses one sees of them here being very brilliant. There are about a dozen and a half sorts represented, but even among such a number it is not difficult to single out those which make the greatest show. Brigadier is about the best, being the freest in bloom, and one of the most brilliant in colour. Then follow Fire-eater, Illuminator, The Lord Mayor, Vivid, and Lucifer. To our mind the very best is Magnum Bonum, which, moreover, is the most distinct of all. No one can mistake it, for it has such a dwarf, compact habit that you can discern it a hundred yards off. It is also most floriferous. This is the stamp of Carnation that raisers should improve upon. Being dwarf and stocky in growth, the plants want little, if any, support, and it must be owned that one of the drawbacks to border Carnations is the number of stakes with which they are associated in nine cases out of ten. Beauty of Whitby is another new sort, a brilliant scarlet, which is superior to some of the others.

Passing to the pink and rose sorts, the queen of the group is Celia, which everybody says has eclipsed that popular sort Mary Morris, which it most nearly resembles. The flowers are very large and full with smooth petals (always a point with florists), and the colour is a most exquisite clear rose-pink; a bed of this is one of the chief features in the Chelsea collection, and as it may be seen by Mary Morris's side, one can judge for oneself. Other pink or rose sorts of superlative merit are Gertrude Teigner, Elysian Beauty, Queen of the Roses, Corsair, Cornelius, and Blush Clove, the latter a sport from the old Crimson Clove. Its flowers are large, and the colour, a delicate blush-pink, which, combined with a spicy fragrance, makes it a much-prized sort.

Purple selfs are not numerous, only about half a dozen sorts being catalogued, but most all of these are good. There is none finer in our opinion than one called Walter Ware, which has smallish flowers, compact and of good form, and of a brilliant purple. It is extremely floriferous; in short, we should rank it among the most select of border Carnations. In a similar way is Royal Purple, while others to be recommended are Auctioneer and Improvement, both first-rate.

Coming to the yellows, we can say the least about them, for, as we before remarked, they have been almost a failure at Chelsea this year; they seem to be different from the whites and coloured sorts, more delicate in constitution, and altogether more capricious. There are but few decent beds of yellows; some of these consist of an apricot-yellow sort, named Florence, which is unquestionably first-rate in every respect, and one can overlook its undefined colour when its growth and floriferousness are considered. Among the clear yellows is Primrose Queen, which in a good season would have made a very effective bed. Of the new Pride of Penshurst there is a bed, but the plants have done but indifferently; perhaps other causes besides the weather have brought this about, for of new sorts nurserymen cannot usually afford to keep large plants long without mutilating them for cuttings. The new Belle Halliday is perhaps the best of all the yellows now in bloom in this nursery. It is of good dwarfish habit, very free in flower, and of a soft sulphur colour. Everybody who sees this variety likes it, which is a pretty good indication of its beauty. Among what are called fancy varieties there are few really fine kinds, the best, we think, being Sir Beauchamp Seymour, a sort raised by Messrs. Veitch at their Langley Nurseries. It has large, full flowers of a flesh-red colour, mottled and streaked with lighter and darker hues. In a similar way is Sir Frederick Roberts, also first-rate. The Earl of Beaconsfield is among the cream of the collection. Its large, well-shaped blooms are bright scarlet, flaked with crimson, and, moreover, it is very floriferous and of good habit. The above are some of the best of the border varieties; but we do not mean to say that they are the only kinds of Carnations and Picotees suitable for borders, as there are scores of sorts, bizarre and flaked, as well as of Picotees that are quite as beautiful, but far less effective in the open borders; in fact, their bizarred colours produced an undecided effect, and in order to be enjoyed must be inspected closely. One may see in this nursery a selection of the finest sorts side by side, so that one can compare their merits. In addition to the Carnations, there is a Pink to which we should like to direct attention, as it is the prettiest self-coloured sort we have seen; indeed, it is said to be the only self Pink yet obtained. It is named Rose Perfection; its blooms are bright rose, and produced freely. A mass of it is quite as effective as that of some of the Carnations.

FLORISTS' CARNATIONS AND PICOTEES.

We are now upon the threshold of the two southern exhibitions of this favourite flower, one of which takes place at South Kensington on Tuesday next, and the other in Mr. Dodwell's garden at Oxford on August 3. The latter will include flowers from districts further north than the show at South Kensington. I have not yet learned the date of the Manchester exhibition, but it will in all probability be a week or ten days, at least, later than the Oxford meeting, for the flowers are very late in blooming in the north. At the Royal Nursery, Slough, there can be seen some 2600 plants now under glass, and the fine head of bloom can now be seen pretty well at its best, being protected from damage through rains. The plants are singularly clean and vigorous in growth. There are three classes of bizarre Carnations, the scarlet, crimson, and pink and purple; the two last so nearly approach each other, that it almost requires the knowledge of an expert to separate them. The bizarres have two and three colours on a white ground, and the scarlet bizarres are of the highest value and most striking, being extremely showy, and when in good character very beautiful. The flaked flowers have, in the case of purple flakes, dashes of this colour; scarlet flakes, scarlet; and rose flakes, rose, on white grounds. The purple-flaked flowers have the highest value; the scarlet flakes are singularly bright and effective; and the depth and brightness of colour in the case of some of the rose flakes cause them to very nearly approach the scarlet in colour. Picotees are divided into three main divisions: red edged, purple edged, and rose or scarlet edged; in each case there is a beading of colour on the margins of the petals; these are again sub-divided into heavy and light edges, according to the density with which the colour is laid on. There is a fourth class of Picotees, the yellow grounds, in which the colour forming the edge varies, and while some of the petals are of a pale yellow colour, others are deeper in tint. A statement of these divisions will, perhaps, enable the visitor to a Carnation and Picotee show to understand the classes in the schedule of prizes and the flowers exhibited in them.

The following are now in fine bloom in the Slough collection—Scarlet bizarres: Robert Lord, James McIntosh, Master Stanley, Lord Napier, Charles Turner, and Arthur Medhurst. Crimson bizarres: Rifleman, Harrison Weir, Crimson Banner, E. S. Dodwell, and Mrs. Maclaren. Pink and purple bizarres: Twyford Perfection, Sir

Garnet Wolseley, H. K. Mayor, Sarah Payne' Squire Llewellyn, Falconbridge, Princess Beatrice, and Joe Bogstock. Purple flakes: Sporting Lass, Juno, James Douglas, Mayor of Nottingham, and Florence Nightingale. Scarlet flakes: Royal Scarlet, Figaro, John Bayley, Dan Godfrey, John Ball, Jupiter, Henry Cannell, Scarlet Keet, and Bailey, junior. Rose flakes: Lady Gordon, Lord Chelmsford, Miss Erskine Wemyss, James Flowdy, Rob Roy, Stapleford Hero, Mrs. Matthews, Mrs. Tomes, Sybil, John Keet, and William Newman.

Picotees — Red-edged: Blanche, Princess of Wales, Dr. Epps, and William Summers. Purple-edged: Norfolk Beauty, Her Majesty, Princess Dagmar, and Clara Penson; the latter has a fine broad petal and delicate edge of purple. Rose and scarlet-edged: Evelyn, Louisa, Miss Horner, Constance Heron, Duchess, and Favourite, the latter a somewhat new and beautiful variety.

The fancy Carnations and Picotees are so brilliant in colour in many cases, and so handsomely marked, and the self-flowers are scarcely less attractive, that it is not to be wondered at they have become such great favourites. Many of these are what are known as "run" flowers; that is to say, the flower of a Carnation, instead of becoming a bizarre or a flake, as is its proper character, becomes self-coloured, or the white ground is rose, scarlet, &c. It is difficult to account for the phenomenon of running; it is one of those subjects that seem to defy explanation; but it is generally thought that soils, more than anything else, have to do with it. Run flowers seldom revert to the proper character, and therefore they are not propagated by nurserymen, except to preserve the particular sport.

Just now there is also a good bloom of Carnations and Picotees in the open air. I have a bed of seedlings of a very attractive character, and I am pleased to find among them some flaked flowers of excellent quality. The flower-stems should be tied securely to stakes, and the numerous buds thinned out a little; the former to keep the blossoms from being damaged by wind; the latter, that the plants may carry only a reasonable number of flowers of a good character.

R. D.

NOTES OF THE WEEK.

A Helianthus from Japan, shown the other day at South Kensington, and which we suspect is H. japonicus of botanists, is one of the finest Sunflowers introduced of late years. The colour of the flowers resembles that of H. cucumerifolius, but this new species has the advantage of being a perennial. It grows about 2 feet in height, sturdy, and bears a profusion of bloom.

Ornithogalum aureum.—It is to be regretted that this is not hardy or capable of being cultivated with the aid of protection during winter. We have nothing in the open air at this season to compare with it, unless, indeed, it be Cyclobothra pulchella, and that does not always grow satisfactorily. O. aureum is well worth growing by those who have accommodation for it, its flowers, both in colour and quantity, being all that could be desired.

Statice Suwarowi, as we saw it the other day, both in the Cape house and on the rockery at Kew, is likely to be a favourite when better known. It grows ordinarily from 1 foot to 2 feet in height, with branched spikes of charming rose coloured flowers, set as closely together as they can be on the spike. Half-a dozen plants together of this Statice have a grand effect. It seems better adapted for pot culture than for planting out of doors.

Inula glandulosa.—This is undoubtedly the best of this genus for ordinary garden purposes. The flowers are much larger, and the colour if anything better than that of the now popular Rudbeckia speciosa, and the plant, to all appearance, is just as easily propagated. One thing must be guarded against, however, and that is, in light sandy soils, its dislike to sunshine. In heavy land we have seen it do well in the full blaze of the sun, but in light soil it needs shade.

Sidalcea candida.—The recent dry weather, however unfavourable it may have been to the generality of herbaceous plants, seems to have suited this and S. oregana, both of which have thriven wonderfully under it. A good fresh bunch of S. candida was shown at South Kensington the other day, and it seemed to be quite a match for its rival, Malva moschata alba. The latter has the largest flowers, but they are less substantial in texture than those of S. candida. Both are, however, worth noting, the Malva being easily procured from seed.

Alstrœmeria Pelegrina.—Mr. Rawson sends us from Windermere the best bloom of the white variety of Alstrœmeria Pelegrina we have seen. It is large and quite devoid of that greenish whiteness the flowers usually have. Mr. Rawson recommends it "as being amongst the prettiest and most lasting of greenhouse flowers." He adds, "I think that these Alstrœmerias are not known enough, and their culture is simple." A flower of the typical form of A. Pelegrina is also sent. Its colour is pale rose with markings of deep red.

Codonopsis clematidea.—Mr. Bartholomew sends us a specimen of this pretty hardy perennial so seldom seen, except in botanical gardens. It is so much like a Campanula, that many would think it is one. It has slender stems, bearing small opposite leaves, and terminated by a flower somewhat larger than a full sized thimble. This is pale mauve coloured, with yellow and black markings at the base. It grows best in a light soil in a well drained and sunny spot, and all the better if its shoots can fall over a ledge, so that the interior of the flowers can be seen. It is also known as Glossocomia clematidea.

Phalænopsis Mariæ.—Mr. Measures, The Woodlands, Streatham, is the possessor of two plants of this scarce and beautiful Phalænopsis. One is a large plant, bearing two spikes of bloom with thirty flowers; the other, a smaller plant, with six flowers on a spike, is a much better variety. It has clear white sepals and petals, marked and barred with rich crimson-maroon. It seems apparently to be between Phalænopsis sumatrana and Luddemanniana. Both plants are thriving well along with the varieties Schilleriana, amabilis, and grandiflora in a low west lean-to house, in which they evidently delight.

The Bridal Wreath (Francoa ramosa).—A very fine specimen of this elegant plant, measuring nearly 6 feet high, has been sent to us from Mr. Renshaw's garden, The Hall, Catford Bridge. The tall, wand-like flower-spikes are 5 feet or more high, branched in the upper parts, and wreathed with crowds of snow-white flowers. Such a specimen as this has a very fine appearance in a greenhouse, and the wonder is that it is not more often grown, especially as its culture is so simple. All the Franceas are nearly, if not quite, hardy, but they are most satisfactory when grown in pots.

Cape bulbous plants.—Some flowers of a fine choice bulbous plant have been sent to us by Mr. A. C. Bartholomew, of Park House, Reading. Among the prettiest are Lapeyrousia corymbosa, very elegant in growth, the slender flower-spikes being crowded with small blue flowers furnished with white markings; Hesperanthera graminifolia, flowers small and pale yellow; Geissorhiza roeheasis, dark blue and scarlet; Ixia monodelpha, violet-blue, with a purple centre; I. conica, yellow, with a dark centre; and Gladiolus ornatus, with small rose-pink flowers. All these are choice little plants, hardy enough for frame culture, and which, in warm places, may be even grown in the open border, if protected, during winter.

New Roses.—Messrs. Paul, of Waltham Cross, send us flowers of four new Roses, named Grand Mogul, Florence Paul, Lady of the Lake, and Silver Queen. It is a difficult matter, without means of actual comparison, to say in what way these new sorts differ from others possessing similar colours, and as we have no notes on their habit of growth or other points, we can only say that the blooms represent four beautiful varieties, the best being, in our opinion, that named Grand Mogul. This is said to be a seedling from that popular favourite, A. K. Williams, and its flowers and foliage partake strongly of the characters of that variety. The flowers are large and beautiful in form, with thick-textured petals of an intensely deep, rich, velvety crimson, yet glowing with a scarlet shade in strong light. The sorts Lady of the Lake and Silver Queen are both delicate pinks; Florence Paul is bright crimson-scarlet, and has numerous reflexing petals.

New recreation ground.—During the week the Baroness Burdett Coutts has opened a recreation ground at Sayes' Court, Deptford, the gift of Mr. W. J. Evelyn. Sayes' Court is an old square red-brick building, which is the site that was once the residence of Peter the Great when he was learning shipbuilding in the English Royal Dockyards. The estate, which has been in the possession of the Evelyn family for upwards of two centuries, consists of about ninety acres, the greater part of which has been built upon. A portion of the remaining open space has been generously bestowed upon the public, and yesterday was consecrated to their use. Tastefully laid-out grounds have been formed by the members of the Kyrle Society, and embrace flower beds, gravel walks, a kiosk, and numerous seats, forming a pleasant retreat for the mechanics and their families after a long day's labour. This is an example which might suggest imitation to some of the more wealthy proprietors of property in and about London.

Bulbine bulbosa is one of several species of this genus which are natives of Australia, the bulk of the number being found at the Cape. The above was obtained from the Darling Downs, in Queensland, where it was found along with Calostemma luteum, the Australian Daffodil. The leaves of B. bulbosa are almost fistulose, as in the Onion, 15 inches long, and they spring from a rhizome. The flowers are on erect spikes, 2½ feet high, the upper foot bearing numerous star-shaped flowers 1½ inches across, bright yellow in colour, and sweetly scented. All the Bulbines have the filaments of the stamens hidden by a covering of long hairs, and most of the kinds are fragrant-flowered. B. latifolia and B. narcissifolia are sometimes met with in gardens. These three species may now be seen in flower at Kew.

Hemipilia calophylla is a small terrestrial Orchid with the habit of an Ophrys, and related to the Satyriums and Habenarias. It has a fleshy tuber as large as a Date stone, and a cordate solitary leaf about 3 inches long, beautifully mottled and netted with brown-red. The flowers are produced on an erect, thin peduncle, 6 inches long, and bear about half-a-dozen flowers, each as large as the flower of Ophrys apifera, the sepals and petals white with green tips, and the large flat lip a beautiful amethyst-purple. There are two species of Hemipilia, both natives of India, the above being found on limestone rocks in Moulmein, from whence tubers were obtained for Kew about two years ago. Our description is made from one of these which we saw in flower a few days ago. The species is not big, but its flowers are beautiful jewels, and the leaf is as prettily marked as that of an Anœctochilus. It thrives in a loamy soil, planted in a pot, and placed on a shelf in a warm house.

Huernia brevirostris.—The Huernias were once called Stapelias, but they are now in a genus by themselves; and, if on no other account, they deserved to be taken out of the company of the vile-smelling Carrion plants as Stapelias are called—because they have lost, or never had, that objectionable character found in all true Stapelias. In form the Huernias differ from Stapelias in their shallow bell-shaped corolla tube. They are all large flowered and very prettily marked, H. oculata, which has an almost black velvety flower with a pure white eye, being one of the most gem-like of all. H. brevirostris has short, thick, five-angled stems with serrated angles; the flowers are 1½ inches across, five-lobed, and in form suggestive of a Primula; the colour is yellowish white, with numerous small brown spots and papillose hairs, the stigma at the base of the bell being five-rayed, black, and set in a disc of purple colour.

Nymphæa biradiata.—This rare Water Lily is now in flower in the Water Lily house at Kew. It is a variety of our own native species (N. alba), and is found only in Central Europe. As a garden plant it does not equal the beautiful variety known as N. candidissima, nor is it superior to the plant which grows in our own ponds. Its chief interest lies in the number of its stigma rays (five to eight), and in the stellate blotch which is found in the centre of the flower. This blotch is composed of numerous small purplish glands on the surface of the lower half of the rays, the upper half being

bright orange; and it is owing to the kind of double star thus formed that the name biradiata has been given to this variety. In size the flowers are not so large as the common English Nymphæa; the sepals are very broad, green below, whitish above; the petals are correspondingly broad and pure white, and the stamens are bright yellow. The leaf is 7 inches long by 6 inches wide, the sinus at the base being about 2 inches wide, narrowed to a point where it is attached to the stalk.

Phœnix hybrida.—Mr. Bull exhibited a Palm under this name at South Kensington on Tuesday last, the same plant, or one under the same name, having been exhibited by Messrs. Veitch about a month previous, when it was certificated. We should like to know the history of this Palm. Is it one of the hybrid Date Palms raised in Calcutta by Mr. Scott? or does it belong to the numerous forms of P. spinosa now known, and of which P. leonensis and P. canariensis are examples? There is a close resemblance between this last-mentioned kind and P. hybrida—so close, indeed, that we suspect they are one and the same plant. He would be a bold man who tried to set the names of the different Phœnixes in order, but we are not quite sure that the name hybrida is not another addition to the synonymy of these plants.

The Garland Flower.—When treated liberally, the Hedychiums grow into very large specimens, their tall leafy stems springing up in great profusion from the underground rhizomes, and each one bearing a large head of graceful Orchid-like flowers having a delicious fragrance, and always delicately coloured. The commonest of them is the almost hardy H. Gardnerianum, which is beautiful both in flower and fruit, and even the leaves have a freshness and thrifty look which is valuable in large houses. The more tropical kinds and those best known are H. coronarium, whose enormous heads of ivory-white flowers are all grace, fragrance, and beauty; H. flaveseens, with pale yellow flowers; and H. thyrsiforme, which may be called a canary-coloured coronarium, its flowers being as large and as fragrant as those of that species, the habit of the two kinds also being the same. These three species may now be seen in flower in the Water Lily house at Kew.

Thunbergia affinis.—The genus Thunbergia, including Meyenia and Hexacentris, contains about 30 species, most of which are handsome garden plants, a few of them being amongst the most popular of stove climbers. H. affinis deserves to be added to this select few, as it is a free, clean grower, has foliage of a good green, and bears large violet-purple flowers. In T. laurifolia, T. Harrisi, and T. mysorensis the flowers are developed on the ends of the shoots, but in T. affinis, T. natalensis, and one or two other cultivated kinds the flowers are borne singly in the axils of the leaves. The two last named kinds may be called climbing Meyenias, the leaves and the flowers being similar, but much larger than in M. erecta. The calyx of T. affinis is green and large, and the corolla tube is 2 inches long, with a spreading limb of over 2 inches in diameter, the whole being of the same colour as the flowers of Clematis Jackmanni, with the addition of a blotch of yellow in the throat. There is a plant of it in the Palm house at Kew, and this, along with T. natalensis, T. alata, and T. erecta, are now in flower.

Ipomæa Bona-nox.—The Moon Creeper, or Good Night, is a beautiful plant which should be grown in every stove, because of its peculiar habit of opening its flowers only in the evening, to remain expanded till the following morning. The Bindweeds generally close their flowers as soon as the sunlight leaves them, the name "Morning Glory" no doubt having originated in the habit of the flowers opening to the morning sun. I. Bona-nox is the largest flowered in the genus, which is saying a great deal for it. We saw a plant of it in flower at Kew a few days ago, and on measuring one of the blooms it proved to be 6½ inches across, the length of the tube being about the same. If a circle is drawn with a diameter of 6½ inches, the size of these flowers will be better understood. The pure white and fragrance, together with the size and the night expanding habit of the flowers of this plant, invest it with an interest and value as a garden plant, and we should recommend everyone who has a stove to grow a plant of the Moon Creeper, which is as common in India and other tropical countries as the white C. sepium is in our own hedgerows.

Lourea Papilio is a new name for an old garden plant, well known to botanists as L. vespertilionis, or the Bat's-wing plant. An example of it under the new name was shown at the last South Kensington meeting, and the only excuse we can find for the substitution of the former name for the latter is that it is shorter and quite as descriptive of the appearance of the foliage as the other. Still, the practice of changing names is a bad one much too freely followed now-a-days. There are two or three species of Lourea, and they are common roadside weeds in many parts of Asia and Australia, just as the Sensitive plant and the Telegraph plant are. Like these, too, the Loureas are Legumes, annual, small, and have curiously formed leaflets. The species named above has a large terminal leaflet 2 inches wide, and shaped just like a common butterfly when its wings are spread out; it is coloured green with stripes of brown-red along the principal nerves. The flowers are of no account. As a curiosity, L. vespertilionis is worth a place in a collection of stove plants.

New Lachenalias.—Amongst the collections of Cape bulbs distributed and sold from the Botanic Gardens at Cape Town last year were some unknown Lachenalias, numbered from one to six. A set of these was obtained for Kew, and four of the kinds have just pushed up flower-spikes. Mr. Baker has named these as follows: No. 1, L. fistulosa, leaves two to each bulb, erect, green with slightly spotted bases; flowers on erect scapes 9 inches high, bearing about twenty flowers, in which the segments are equal, half an inch long, and coloured rose with purple tips. No. 2, L. orchioides, a yellow-flowered form of it, the most attractive one being that known in gardens as atroviolacea, in which the flowers are dark purple. No. 4, L. contaminata—this has tufts of grassy-green leaves and short scapes of white flowers with brown tips and orange anthers. The segments are equal in length, but only about quarter of an inch long. No. 6, L. unifolia—as the name denotes, this species has only one leaf to a bulb, and this has incurved edges, and is green above, zoned below with brown on a white ground. Flowers on an erect slender spike, rather sparse, nodding, pale rose at the base, then white, the tips being green. As garden plants these four Lachenalias are not in themselves of much value, but they are worth the attention of such cultivators as Mr. Cam, Mr. Rawson, and M. Max Leichtlin, who, we believe, are crossing the various species of Lachenalia with a view to obtaining more variety both in form and colour.

A useful insecticide.—As considerable difficulty is sometimes experienced in finding an insecticide that is not injurious to foliage and at the same time is destructive to insect life, I send a recipe that came under my notice some two or three seasons back, and which has been used ever since with excellent results. Put half a pound of soft soap in one pint of hot water, and stir until it has dissolved; add one pint of paraffin; when that is thoroughly incorporated, add similar quantities of water, soap, and paraffin, and mix until all traces of soft soap have disappeared. The mixture will then be of the consistency of thick cream; then add two more quarts of water, place it in a jar and cork tightly. Our dose is one 3-inch (small 60) potful of this mixture to three gallons of water, and this we have found to be perfectly harmless to all outdoor foliage, while at the same time it is certain death to all forms of aphides, thrips, and red spider.—B.

Lace-winged fly.—I send herewith some leaves and stems of a plant on which you will observe long hairs ending in a small whitish substance attached to them. Is this a fungus, or what? I have not found it on any other plant, and but little on this. The plant is very much shaded by an Apple tree.—T. Palmer, *Kingston Hill.*

*** The long hairs attached to the plant you forwarded are the eggs of a very common and most useful insect, the lace-winged fly (Chrysopa perla). This insect, when about to lay its eggs, settles on a leaf or stem, which it touches with the end of its body, from which exudes a viscid fluid, which hardens very quickly on exposure to the air; then, raising its body, a thread is formed of this secretion, at the end of which an egg is laid. It is the empty egg-shells which you have noticed at the end of the threads. The grubs hatched from these eggs feed upon aphides and destroy great numbers of them. The lace-winged flies should always be encouraged; they do not fly well, although they are provided with two pairs of large greenish gauze-like wings. They almost always lay their eggs on plants infested with aphides.—G. S. S.

Indoor Garden.

BERRIED PLANTS FOR WINTER.

Berry-bearing plants are very handy, either for the decoration of the conservatory or sitting-room, and have the advantage of lasting in beauty for several weeks, and not unfrequently months, in succession. They are, as a rule, very easily grown, and form an agreeable contrast when grouped tastefully with Chrysanthemums, Cyclamens, scarlet Salvias, and Ferns. Some are well adapted for cutting, and help to create variety in the drawing room vase, while their value in church decoration of all kinds is well known.

Aucubas.—These, when covered with a crop of shining scarlet fruit, make fine winter decorative plants, and they are easily grown. In mild sheltered localities, small bushes in the shrubbery or private nursery may be fertilised, when in flower, by pollen from the male plants, and these can be taken up and potted in the autumn. Plants in pots generally flower more freely than those planted out, and are handier than the latter for fertilising purposes. Large plants in sunny positions outside have a beautiful appearance when fertilised—an operation which is most readily done, either by grafting a male branch into the female tree, or by setting a male plant in flower in close proximity to a female one. We have now numerous varieties, both green and variegated, which form noble winter decorative plants. Aucubas, like all other smooth and glossy-leaved plants, do well in towns and smoky districts, simply because they are readily cleansed by every passing shower.

Solanums.—These are well-known plants, which are easily propagated either by means of seeds or cuttings in the spring. Young plants may be planted out in a warm sheltered border in May, and if liberally supplied with water, will make clean, fresh, little specimens for decorative purposes during the ensuing winter. They should be carefully lifted and potted in October for removal indoors, and if taken inside and kept in a moist close atmosphere for a week or so, they will establish themselves and ripen off their bright orange fruits without losing a leaf. S. Capsicastrum and S. pseudo-Capsicum are the most useful, but Yellow Gem is very distinct and effective when well grown, bearing large ribbed or contorted fruit of a bright glossy yellow colour. The Egg plant is very ornamental, and grows well in an ordinary frame or greenhouse. There are both white and purple varieties.

Capsicums.—These, although generally grown for culinary purposes, are far from being uninteresting as decorative plants. We have several species in our gardens, all bearing bright scarlet or yellow fruits, which contrast well with their deep green foliage. Care must be taken to syringe these and Solanums freely when growing, in order to keep red spider in check, a pest to the attacks of which they are very liable.

Skimmias.—These are dwarf shrubs with broad lanceolate smooth foliage, and bear clusters of small Holly-like berries. S. oblata and S. japonica are both well adapted for pot culture, and look well all winter in a cool house.

RIVINA (HUMILIS) LEVIS.—This well-known stove plant bears small inconspicuous white flowers and drooping clusters of shining berries. Small plants of it in pots are very pretty, or it may be trained up the back wall of a stove, where it will grow, flower, and fruit all the year round, forming an interesting object of permanent beauty. A bright yellow-fruited woolly-leaved species of Rivina was introduced by Bowman a few years ago, but it appears to have been lost.

NERTERA DEPRESSA.—This is one of the smallest, and at the same time most interesting, of all berry-bearing plants. In habit it is very dwarf and spreading, rarely exceeding 1 inch in height; indeed, it may not inaptly be compared to a plant of Selaginella densa, sprinkled with coral beads. The foliage is of the freshest green imaginable, the berries being of a brilliant orange-scarlet. It is readily grown in a light compost of peat and sand either in the stove, greenhouse, or under a glass shade or Wardian case in the sitting-room.

COTONEASTERS.—These include some of the finest of all hardy berry-bearing shrubs for planting along a sunny wall. C. Simonsi, trained up the front of town houses, along with small green-leaved or gold and silver variegated Ivies, forms a brilliant picture in the autumn and winter when studded with bright scarlet berries, the latter being very freely produced along its slender branches. C. microphylla, a well-known small-leaved evergreen species, bears berries of a deeper crimson, and is one of the most useful wall shrubs we have. Trained up the front of a house, or over the porch or balcony, it has a cheerful appearance even in the depth of winter, and is particularly beautiful when the ground is covered with hoar frost or snow. It also does well as a low bush on the lawn if cut in closely every year. Of this, Lindley says, "Its deep glossy foliage, which no cold will impair, is, when the plant is in blossom, strewed with snow-white flowers, which, reposing on a rich couch of green, have so brilliant an appearance that a poet would compare them to diamonds lying on a bed of emeralds."

ARDISIA.—This is one of the prettiest of all pot plants when well grown. It is easily propagated by means of seed, and plants about a foot high bear nice crops of berries the second year. Seedlings should be potted off in loam, leaf-mould, and sand, and if placed on a shelf near the glass in a moderately warm greenhouse temperature, they make dwarf vigorous little plants. Even when not in fruit the plant is ornamental, its oblong foliage being of a rich glossy green colour, elegantly wavy or crenate along the margins. The species common in gardens is A. crenulata, bearing bright scarlet or crimson fruit the size of Peas. There is, also, a yellow-fruited variety, well worth growing for variety, although not so effective as the normal kind.

PERNETTYAS.—These are pretty little shrubs for pot culture; in habit they closely resemble the Cotoneasters, and, like those plants, have deep green glossy foliage and a rich profusion of berries during the autumn and winter months. For greenhouse, conservatory, or drawing-room decoration they are invaluable, taking the same place indoors that the Cotoneaster occupies outside. I have only seen three species, all of which are beautiful. P. mucronata bears deep crimson berries, something like those of Cotoneaster microphylla in both size and colour. P. microphylla bears immense crops of purple or lilac berries, and is, perhaps, the most distinct and ornamental of the whole group. P. speciosa is very dwarf and compact in its growth, and bears deep crimson berries.

CRATÆGUS PYRACANTHA (Pyracanth or Fire Thorn). For covering the fronts of town houses, or the side walls of greenhouses or stoves, nothing can be prettier or more effective than this plant, especially if trained among gold, silver, or green leaved Ivies. It may be freely propagated by means of layers, and small plants from 2 feet to 3 feet high bear heavy crops of brilliant scarlet berries. Nearly all glossy-leaved plants do well in towns for reasons already stated, and for such purposes this plant is one of the best.

CALLICARPA PURPUREA.—This is an old greenhouse plant, well deserving cultivation, although rather straggling in habit. Its shoots are clothed with opposite serrate leaves, and it bears axillary clusters of small purple or amethyst coloured berries very freely. It may be propagated freely either by means of seeds or cuttings, and young plants grown as recommended for Ardisias are best; old plants lose their bottom foliage, and become "leggy" and unsightly.

LEUCOCARPA ALATA.—If grown in a poor, sandy soil, and fully exposed to the light, this makes dwarf plants 1 foot to 18 inches in height and as much through. It has light green foliage and thick winged stems, and, when well grown, bears heavy crops of white berries. If grown in rich soil it is little better than a rank-growing weed, but, treated as above, it makes a variety—white-berried plants being rather scarce.

BERBERRIES.—Among other large-growing hardy berry-bearing shrubs we must not forget the common Arbutus, with orange-scarlet, and Berberis Aquifolium, with bluish purple fruit in massive clusters. B. vulgaris, having elegant drooping clusters of bright scarlet oblong berries, forms a noble object on the margins of shrubberies in warm sandy soils during the autumn months. The berries of both the last-mentioned species are often preserved in syrup, or in salt, for garnishing purposes during winter. Hollies are too well known to need much comment, but small bushes, 2 feet to 3 feet high, may be grown in pots, or taken up from the outside and potted, when they come in usefully for the decoration of churches, front halls, conservatories, or even for ordinary apartments during the Christmas season. The common Snowberry bears heavy crops of large pearly-white fruit in some districts, and these cut from the plant and tastefully grouped in bunches, wreaths, or vases, along with the fruit-bearing branches of Hollies, Berberis, Solanums, Cotoneasters, Cratægus, and the bright-coloured autumnal foliage of Maples, Berberis, and Oaks, have a highly pleasing appearance, while they are specially valuable for church decorations of all kinds. We have many other fruit-bearing plants, but the above list comprises the best known for decorative purposes during the winter season. B.

VIOLETS FOR WINTER FLOWERING.

THESE require careful management at this time of year, and if they do not receive it no amount of attention when they are required to flower will induce them to do so. Assuming that young plants were put out in April, they will now be making rapid growth, and pushing out runners in abundance. Now, it is of the utmost importance that these runners be removed at once, for if allowed to extend they soon monopolise a large share of the energies of the plant, and the crown does not swell up thick and ready to burst with flower-buds as it does if the runners are kept closely cut off. The best implement for removing them is a pair of Grape scissors. The plants should be gone over several times during July and August, and also frequently surface-stirred with the hoe, and if the weather is dry a good soaking of water should be given, and after hot days a good drenching overhead will help to keep red spider in check. Liquid manure is of great assistance at this stage of growth, and in showery weather a little dry powdered manure shaken on the surface to be carried down to the roots by rain will help to keep the plants healthy and growing vigorously, as it is when growth is checked that red spider attacks them. Soapsuds, a good homely remedy for spider, should be applied copiously about this date. The new double white Comte Brazza's Violet appears to be a robust grower, producing large healthy foliage; the older Marie Louise, too, is still one of the most useful of Violets, and has to a great extent superseded the Neapolitan. J. G. H.

Æchmea fulgens.—Many Bromeliads are extremely elegant in habit, require but little attention to grow them in perfection, and form very effective decorative plants for the greenhouse, stove, or drawing-room. Some species are very hardy in constitution, and remarkably tenacious of life; indeed, they may be grown with less trouble than any other class of plants, if we except succulents. The leaves of Æ. fulgens are bright green, robust in character, and gracefully recurved. Its flower-spikes continue in perfection for several weeks at a time, and form conspicuous objects. Nearly all the Bromeliads grow vigorously in good sandy loam, to which a little leaf-mould may be added, and they should be liberally supplied when growing with water at the roots. A little clear manure water, too, strengthens them in a marked degree, and assists them in producing strong flower-spikes. Bromeliads are easily propagated by taking the offsets produced by the old flowering plants, and potting them at once in small pots, which may be plunged in a gentle bottom heat until well rooted, after which they may be encouraged to make good growth, and will generally produce flowers the second year; but, for decorative purposes, this plant is always handsome either in or out of bloom.—Q.

FRUIT TREES IN VILLA GARDENS.

BEFORE many years have passed I feel sure that fruit trees of various kinds will be much more freely planted in ornamental grounds than they hitherto have been. The old prejudice against anything of a useful character being introduced into the ornamental portions of the garden is rapidly vanishing. In suburban gardens especially fruit trees may already be seen on lawns—remnants of old market garden orchards now converted into villa gardens. These old fruit trees yield both shelter and shade, and impart a cheerful, furnished look to grounds that would otherwise be comparatively bare—at least as far as ancient trees are concerned. I have lately seen several gardens in which all the trees of any size were old orchard trees, promoted in their old age to the rank of ornamental trees, and right well they looked amid their new surroundings. In one garden rustic seats had been put around their trunks, and their wide-spreading tops furnished ample shade, that in summer was most agreeable, and a plentiful supply of Apples in autumn, as well as rosy blossoms in spring. Pear trees of the ordinary orchard kinds also make noble specimens either on Grass or gravel; Cherries, too, do especially well on turf, as they dislike having their surface roots disturbed. Plums, including Damsons and Bullaces, are all available for the same kind of decoration. In fact, after the first few years, there can be no doubt that all these fruit trees are benefited by having turf permanently over their roots. Mulberries, Medlars, and Figs make capital lawn trees, and on the south coast very fine examples of the Fig may be found fruiting freely as standards, and even against walls they make fine-foliaged plants. Boundary walls indeed of villa gardens are everywhere being more generally covered with fruit-bearing trees than hitherto, displacing even in some instances the Honeysuckle and Jessamine. Hardy Vines are, I need scarcely say, both useful and ornamental, their fruit over a great portion of the kingdom arriving at maturity. Red, White, and Black Currants and Gooseberries make good and fruitful covering for walls, and give but little trouble. The walls should be wired, and the main shoots securely fastened thereto with tar string. Crab Apples make beautiful colour-pictures in autumn. In fact, with a little care in selection, one might combine beauty and usefulness to an extent hitherto unthought of in this phase of gardening. JAMES GROOM.

Striped Provence Rose.—In my collection of old-fashioned Roses I am happy to say I have this one. I was fortunate enough to meet with a plant of it last year, after having lost sight of it for a very long time. It has all the characteristics of the Cabbage Rose, except scent, and may be described as a striped variety of that Rose. The prevailing colour is white, with delicate stripes and splashes of pale pink. The flowers are very full, but do not expand well, which I attribute to the weak condition of my plant, which is as yet rather small.—C.

Rose Garden.

A BUNCH OF TEA ROSES.

Many are the beautiful forms that have been produced in this lovely section of our cultivated Roses; their beauty is undoubtedly of a more refined order than that of the Hybrid Perpetuals, while their individual characters are, as a rule, more clearly marked. Triomphe de Rennes, the subject of the present engraving, is a Rose of eminent merit, excellent in form, most delicate in colour—warm white deepening to full lemon colour—and unusually distinct in foliage. The leaves are deeply toothed and of a dark glossy green, with a characteristic waving or twisting, so that the identity of the bush cannot be doubted when out of flower; these features also give it a distinctly ornamental aspect. Its high value as a cut flower when easily arranged in a simple glass may be seen in the engraving. To be quite correct, Triomphe de Rennes is a Noisette, a subdivision commonly classed under the head of Tea Roses.

A bouquet of Tea Roses (Triomphe de Rennes). Engraved from a photograph for The Garden.

Large-headed Roses.—As a rule, I dislike standard Roses; their heads as usually seen are too meagrely furnished to be effective, and, in most instances, they are too short-lived. We do not care to lose our Roses almost as soon as we make their acquaintance; there is, however, no rule without an exception, and in the present case we would carefully preserve those kinds which develop large spreading heads. A standard Rose with a wide-spreading drooping habit always forms a pleasant picture either singly on Grass or in borders. Doubtless, some of the new Roses are capable of fulfilling these conditions, but all the Roses I know of large size and wide-spreading habit are old-fashioned ones. Gloire de Dijon is always good everywhere. Aimée Vibert, with its large clusters of white flowers, makes an effective standard, even though the individual flowers are poor. Bouquet de Flore is another good growing free-blooming clustered Rose, that quickly assumes large proportions. Jules Margottin, La Biche, and Céline Forestier are also suitable for standards, and all are hardy enough to withstand our severest winters. They should be budded on sound, healthy Briers, from 4 feet to 4½ feet high. If taller than this they are liable to be injured by wind. E. Hobday.

York and Lancaster Rose.—Amongst Roses now in flower, none, in my opinion, are more pleasing than this old semi-double striped variety. It is growing in a neglected border, and the position being somewhat shaded, the blossoms appear to come with a greater depth of colour than when the situation is fully exposed to the sun. When the flowers of this Rose are about half expanded, there is a beauty about them peculiarly their own: the two colours (white and pink) blend so well together, that no one fails to admire them.—J. C. C.

ROSES IN SOMERSETSHIRE.

Our best Rose this year has been Souvenir de la Malmaison. Contrary to previous experience, this fine old Rose yielded a great number of the most perfect blooms I have ever seen it produce in the month of June. They possessed the usual plate-like flatness common in the flowers of this Rose; but they were both large and full, and the petals expanded so as to show the most perfect outline. This Rose has thus shown its gratitude for an increased amount of good soil which we gave its roots eighteen months ago. Comtesse de Chabrillant is an old Rose, but exceedingly beautiful this season. The flowers have been large, finely cupped, and full of petals. It has been the nearest approach to a good pink that ever I saw. Its fragrance is not the least of its merits, there being not many sweet-smelling pink Roses. In Merveille de Lyon the colour is a little variable. Our earliest blooms came tinged with pink, but the later ones have been sufficiently pure to be pronounced the best white we have. They are very large on strong plants, and their form excellent; but I am afraid that it will prove to be a fine weather Rose. Captain Christy is another fine weather Rose. Therefore, taking into account what wonderfully warm and dry weather we have had for the last fortnight or so, there is nothing perhaps remarkable in its being so fine this year. In a general way one downpour of rain, and a day or two of low temperature just before the flowers are ready to expand, are sufficient to wholly spoil them. The fact is, the flowers are too full to be reliable during all weathers, although I admit that, when in good condition, few Roses of the same colour surpass it. Queen of Queens proves to be a grand Rose, vigorous in growth, ample in foliage, and a thorough perpetual. Notwithstanding the number of pink Roses which we now possess, this sort stands out conspicuously. It is bold in port, and I shall be surprised if it does not take a foremost place as a garden Rose. It is not an early Rose; but that is perhaps in its favour, and, being a full flower, it no doubt opens better in dry seasons than in wet ones. Its blooms are not so perfect as those of some kinds, but a peculiar blush shade pervades them that is both distinct and pleasing. Madame Sophie Fropot is a reliable Rose, and a most useful one. It grows well on the Manetti stock, and flowers with great freedom. Its blooms are above the medium size, moderately full of petals, and the form is excellent. The colour is a soft rosy pink, which, when looked at from a short distance off, has a satiny appearance, which is quite charming. In our case it has proved, amongst rose-coloured sorts, to be the finest Rose of the year. Ulrich Brunner has been grand in growth, foliage, and blooms. The latter have been exceptionally large, one, when fully expanded, measuring 17½ inches in circumference, and the colour a clear and bright cerise. Seeing that it is a seedling from Paul Neyron, the size of the flower is perhaps not noteworthy; but size, taken in conjunction with its other qualities, is a recommendation to those who are fond of large Roses. Marie Baumann, no experienced rosarian will be surprised to hear, has been in its best condition, and certainly one of the most beautiful Roses in our collection this year. Grown as dwarf plants, which most of our Roses are, this variety rarely grows satisfactorily, but this year it has done well and produced many perfectly-formed flowers. The colour, too, has been most brilliant and the individual blossoms large. It has certainly

this year made up for its disappointing behaviour with us in previous seasons. Pompone Blanc Parfait is a miniature Rose, remarkable for the exquisite form of its flowers and the freedom with which they are produced. We have it growing on a low warm wall, and it has been quite a sheet of white, so numerous have been its flowers, which are produced in large clusters on short, sturdy branches. They are pale flesh-coloured, quickly passing to pure white. For button-holes or for the boudoir this little Rose is well suited. Duke of Albany, without doubt, is one of the grandest of dark Roses of English origin. It is probable that its flowers may be too full to open satisfactorily in wet cold seasons; but one can afford to wait a year or two, if at the end of that time we can obtain a few perfect flowers of this Rose. It is large and excellent in form, and the plant is a fairly good grower—altogether a grand Rose. Abel Carrière has been the best amongst kinds having maroon-coloured flowers. The latter are produced with great freedom, and in form perfect, the substance of the petals being all that could be desired. Mrs. Baker this season has been unsurpassed in its particular line of colour. Not only have the flowers been exceptionally large, but their lively carmine-red colour has been more conspicuous than I have ever seen it before—a circumstance which shows that Roses of this colour do not object to heat if the roots are well supplied with moisture. This Rose has always been such an indifferent grower with us, that one cannot fail to notice its changed condition this season; it is clad in large and healthy foliage, and is making very satisfactory growth. J. C. C.

NOTES.

"Grim the Collier."—Miss H. Gatty in writing the life of her sister, the late Mrs. Ewing (author of "Jackanapes" and other stories) says, "One of the unwritten stories which I most regret is 'Grim the Collier;' this was to have been a romance of the Black Country of coal mines in which she was born, and the title was chosen from the description of a flower in a copy of Gerard's 'Herbal,' given to Mrs. Ewing by Miss Sargent." This, according to Gerard, is the English name of the plant we now grow as Hieracium aurantiacum, but which Gerard calls H. hortense latifolium *sive* Pilosella major, golden Mouse-ear, or "Grim the Collier," and he further states that "the stalks and cups of the flours are all set thicke with a blackish downe or hairinesse, as it were the dust of coles; whence the women who keepe it in gardens for noveltie's sake have named it 'Grim the Collier.'" It was Mrs. Ewing who formulated the aphorism, "a garden of hardy flowers is essentially the garden for cut flowers," and in one of her last "Letters from a Little Garden," in "Aunt Judy's Magazine," speaking of amateur gardeners, she said. "Others, again, among whom I number myself, love not only the lore of flowers, and the sight of them, and the fragrance of them, and the growing of them, and the picking of them, and the arranging of them, but also inherit from Adam a natural relish for tilling the ground whence they were taken, and to which they shall return." The above has given to me quite a new interest in a plant, the colour of which is, I believe, unique, an indescribable sort of reddish orange, and whenever I look on a plant of "Grim the Collier" I shall think of "Jackanapes," and regret the unwritten story of the mines.

The divining rod.—I neither affirm nor deny what has been said from time to time in the gardening periodicals under the above head, but I agree with "S. W." (p. 49) that a seance by Mr. John Mullens would be an agreeable addition to the usually prosaic trials which take place at our horticultural exhibitions. I should also like to ask wherein lies the supposed power of the stick? For example, any sort of rod, Hazel or Thorn, seems equally suitable to Mullens, so that I presume the power is in the man rather than in the rod employed. But can any man use the rod successfully, or must his name be Mullens? I should like to be one of a jury of twelve to test this water witchery, believing as I do that miracles of this kind are explainable on purely physical grounds. I do not doubt what "S. W." says, but I wish to know how the stick and the man and the water act or re-act on each other. Could "S. W." hold the stick as Mullens held it and find water, or did he try and fail? I certainly second the proposal that Mr. Mullens be invited to some horticultural exhibition, and that he there do display his water-finding powers. An irresponsible person at my elbow suggests that if the water was not found at such a trial, Mullens and his stick might be made to re-act on each other in some other amusing way! Seriously speaking, if "S. W." believes in the water magic of Mullens, he ought at least to afford us his opinions as to how it is done, or, better still, perhaps Mr. Mullens will himself explain.

Geranium sanguineum.—As a rule, our native plants are neglected in the garden. This Geranium, however, is quite beautiful enough to become a marked exception to the rule. On dry, rocky banks near the coast, where it is starved into dwarfness and coloured by a blazing sun, it is difficult to picture any alpine plant more beautiful than is this native of our own seashore. It is really a plant well worthy of careful culture in the garden, but like many other of our wildings it loses in beauty by being planted in deep, rich soil, and a system of judicious starvation is necessary if its fullest and richest beauty be desired. This is one of the secrets of the rock garden, and more especially of the pockets of the wall top garden, wherein the plants are fully exposed to sun and to wind, and are not overfed into leafy exuberance. Let us take the Edelweiss, for example. Planted out in a deep, rich border, you have a mass of leafy growth, and great bracts are the result, but the silvery beauty is gone, and this alpine is not more beautiful than a tuft of Sage leaves. On the other hand, plant it in sandy loam and lime rubbish on the top of a wall, and its bracts become as silvery as if from the limestone crags of its sunny home in the mountains. It is especially so with many of our native plants, which require full exposure and a hard diet in the garden in order to develop their highest beauty, as we see it by the roadside or among the stones of the mountain-side. As planted amongst stones, old lime rubbish, or granite rubble in full sunshine, Geranium sanguineum is one of the best of garden plants.

Lilium testaceum.—No Lily now in blossom surpasses the pure white L. candidum, but it is not always an easy plant to grow. One little secret in its culture is to transplant it soon after its flowers fade away, as so treated every two or three years we find it by no means hard to manage. One of the tallest and best of all good strong growing garden Lilies, however, is L. testaceum, as seen 8 feet in height, with from twelve to fifteen of its buff-reflexed bells on a stem. It is a good example of the added vigour sometimes observable in hybrid plants, for, as is well known, this variety is the result of a cross effected between the common Madonna Lily (L. candidum) and the scarlet Turk's-cap (L. chalcedonicum) (see "Flore des Serres," vol. i.). We are pretty sure of this parentage, since Col. Trevor Clarke has repeated the cross, and, as a scientific resurrection, raised L. testaceum over again. As a good serviceable garden plant I consider L. testaceum one of the best, since it grows well almost anywhere, and increases quite rapidly from its bulb scales which form flowering bulbs in two or three years, besides which its usual rate of bulb increase renders division absolutely necessary every other year. Some good masses of this Lily are now opening their soft elegant shaped flowers, and being backed by the towering stalks of some dark blue Delphiniums they show themselves to the best advantage. The dark claret-purple Martagon is also in flower (L. dalmaticum Catani), and is most beautiful. A good mass of it along with the ivory-white flowered kind would make a picture fair to see even in the time of Roses.

Gladiolus Colvillei albus.—It is not too much to say that this is one of the most beautiful and serviceable of all the flowers which can grace a garden. If forced, now is the time to pot up bulbs for flowering next March or April, after which the outdoor bulbs begin to flower in May in warm positions near sunny walls, while they linger on through June and even into July in cool and open or in shady places. Less than ten years ago this plant was well-nigh unknown in gardens; now it is grown by tens of thousands every year. Who can tell us the history of this white Sword flower? Parkinson mentions a Corn Flag with snow-white flowers in his "Paradisus," but it is doubtful if it is referrable to our present plant. All the early flowering Gladioli force well, but there is unfortunately a dearth of white-flowered varieties among them; but this is a drawback which the Dutch bulb growers may remedy for us at no far-off date. The Corn Flags as a class are woefully neglected in many of our best gardens, although wherever a collection is grown some of them will be in bloom for at least nine months out of the twelve. One very useful variety at least, viz., Gloire de Versailles, may be had in flower all through November and December, along with the Chrysanthemums, but of the whole genus as at present known none are more welcome than G. Colvillei albus, surnamed The Bride.

Daffodils.—Now is the best time to plant or transplant these bulbs if the best results are expected next spring. With home-grown stock this is practicable, but it is by no means easy to obtain bulbs thus early from the shops, and so much valuable time is lost to those who like to keep ahead of their planting work. Bulbs of any of the really good sorts, such as N. Horsfieldi, N. princeps, N. obvallaris, N. maximus N. Regina Margherita, N. pallidus præcox, or even N. nanus, may now be potted and placed under ashes in an open sunny place, and such bulbs may be expected to flower during next February and March at the latest; indeed, N. pallidus præcox, N. Regina Margherita, and N. Ard Righ, or Yellow King, might be forced into bloom soon after Christmas Day. As a rule, however, the less fire heat used in forcing these golden flowers of spring the better. All that is requisite are good, sound, early ripened bulbs—if from Italy or the south of France so much the better—and these in a sunny frame or greenhouse only will be in flower weeks before their namesakes out in the open borders. Good, strong, well-bloomed pots of Daffodils are always welcome indoors in spring, and now is the time to make preparations for such a floral display.

Calystegia sylvatica.—This is a strong-growing Convolvulus with white flowers, and is sometimes known as the Hungarian Bindweed. When established in good rich soil it will grow to a height of 20 feet to 30 feet in a single season, forming a fresh leafy mass or screen of growth, covered with great bell-shaped flowers. Beautiful as it is, however, beware where you place it in a garden. At the foot of a dead tree or near railings on the Grass it soon becomes at home,

and the mowing machine or the scythe keeps it within bounds; but if it once gets into a deep, rich border, among other things, it becomes a pest difficult to eradicate, and proves most destructive amongst other flowers. Planted at the foot of an Ivy-covered wall, it cannot do any harm, and its white bells are very beautiful from this date until the frosts of November cut down its stems. Three or four years ago we planted a few of its roots at the foot of a dead Fir tree in a corner, and the result is a leafy column 30 feet in height every year. This corner is devoted entirely to such troublesome, albeit beautiful, plants such as Musk, giant Hemlock, Comfrey, Oriental Poppies, &c., and the effect of all these massed together is a good one for the most part of the year. There is also a rosy-flowered Calystegia which is well worth a place with this giant kind.

Meconopsis Wallichi.—The blue Himalayan Poppies are again in blossom, but not nearly so fine as in former years, owing, doubtless, to the incessant hot, dry weather of the past five or six weeks. These Indian Poppies are never quite happy with us, except during a wet season, when they grow 6 feet or 7 feet in height, and are striking objects covered with their soft blue flowers. The yellow variety, M. nepalensis, is a very good companion for the above, but both are a little capricious, and can only be well managed by rearing seedlings every year. The seed itself is not easy to procure, and does not germinate equally well, even although sown as soon as the pods open at their points. It is a curious fact, that although seed ripens here quite freely, I never could raise plants from it; whereas that ripened in the Edinburgh Botanic Garden invariably yields us a good crop of healthy seedlings. When well grown we have no Poppies quite so delicately lovely as are these Meconopses with their satin-lined cups in which the golden anthers tremble at a touch, or as moved by the lightest breeze. They are biennials and die away after flowering. The smallest seedlings sometimes stand over until the third year ere they bloom, a by no means undesirable thing, seeing that these plants are very pretty in their rosette-like or leafy stages of growth.

Iris aurea.—A tall-growing rhizomatous or Flag Iris which, in stately habit of growth, reminds one of I. ochroleuca (=I. gigantea of some gardens), but its flowers are of a clear pure bright yellow colour, poised like great butterflies on leafy stems or stalks fully 5 feet or 6 feet in height. Iris ochroleuca is also a fine Iris wherever it grows well, its flowers being white, with a yellow disc or blotch on its fall petals. Both deserve a place in deep rich borders, since they flower at a time when other rhizomatous kinds are past their best. I give the palm to I. aurea, because it flowers quite freely every year, while its congener above alluded to is more chary of its beauty, perhaps, however, because our soil is too light and dry, for I have seen great clumps and masses of it quite showy about this season on the stiff clay soil of the Thames valley. Both species are strong and free growing, and are readily increased by division in August after flowering, or in spring before their growth is far advanced. Some Irises are much more floriferous if divided every second or third year, as they soon exhaust the soil near them, and it is a good plan to divide some of the Flag Irises every year. This season some of our old-established clumps did not bloom, while quite small divided plants did so. This is a hint we shall remember.

Dipsacus laciniatus.—Wherever tall and stately habited foliage plants are admired this is well worthy of a place. It is, perhaps, the most beautiful of all the Teazles, easily reared from seeds, and in deep rich soil it attains a height of 8 feet or 10 feet the second year. The opposite leaves are cut or lobed in a pretty way, and are connate at the base, forming a cup around the fluted prickly stems. These cups are full of water after every shower, although the utility of these natural water tanks, or reservoirs, is not quite so clear, unless, as in the case of some Bromeliads, they serve to isolate the flower-stems, and so prevent useless, or it may be injurious, creeping insects from reaching the blossoms. All the Teazles are interesting plants, and the Fuller's variety (D. Fullonum) is more especially so since its hooked bracts serve a particular purpose in cloth-dressing, and, so far, all attempts at imitating their action by mechanical means have failed. If seeds are sown as soon as they ripen, the young plants may be transplanted the following spring to the positions where they are to flower, or seeds may be sown at once in such places, care being taken not to leave the plants in too crowded a state. The flowering stems, if cut and dried, are useful for grouping along with dried Grasses, &c., for the decoration of large vases indoors during winter.

Veronicas.—All the Veronicas are good garden plants when well grown; even the Germander Speedwell is worth a place in the garden, or its seeds may be scattered in meadows near the house for the sake of its Forget-me-not-like blossoms among the Grass during May-time. On a dry and sunny bank this plant will make a lovely cloud of blue, and if planted in the garden, let it be in amongst stones where it may not grow too rampantly into mere leafage instead of flowers. Just now one of the most effective of all the species is V. exaltata, an herbaceous species with erect plumes of soft lilac-blue flowers. As seen in masses along with taller and deeper hued Bee Larkspurs it affords a perfect harmony in blue. The numerous forms and hybrids of the V. Andersoni section are well known and are useful shrubs in mild seashore localities, and then of late years we have quite a collection of species from New Zealand, some showy in flower, and others curious in habit. The golden green V. salicornioides looks much more like a Thuja or Retinospora than as being anything related to our native Speedwells, and there are others which remind one of Ericas or Epacrids in their habit of growth. One of the prettiest of all for the alpine or rock garden is V. Lyalli, forming masses of white or lilac flowers. V. saxatilis is also a beautiful blue-eyed species, quite at home among half-buried stones.

Actæa racemosa.—This plant is not at all common, although long ago introduced and grown in gardens under the name of Cimicifuga racemosa. It is now very striking, as its feathery white plumes stand up among the blue spires of its first cousins, the Delphiniums, and the Aconites or Monkshoods. Planted out in a deep, rich, partially-shaded border, this plant forms masses 6 feet or more across. Its leaves are of a fresh green colour, and above these rise the slender, Spiræa-like spikes to a height of 5 feet or 6 feet. It is especially useful, as it succeeds Spiræa Aruncus and its varieties, which are of somewhat similar port and effect. Our present plant, however, belongs botanically to the Buttercups; and its allies, the soft, yellow-plumed Thalictrums also deserve notice, since they are now most effective, as contrasted with Lilies, Foxgloves, and tall Mulleins, of which by far the best is just now Verbascum olympicum. All the above are worthy of a note, being in their way strong growing and effective plants for a shrubbery border, where there is ample space for their due development. Actæa spicata is readily increased by division, but as it takes a season to become well established, we generally adopt the old-fashioned plan of dividing one plant or two only every year. This is a good plan to adopt in dividing all sorts of garden plants, and may be taken as another reading of the old adage, "Don't place all your eggs in one basket."

Spiræa ariæfolia.—Either as a wall shrub or as a bush on the open lawn this Spiræa deserves culture as a beautiful thing. It is just now at its best, covered with oatmeal-coloured flowers forming feathery plumes as graceful in their way as an ostrich feather. The motion of these plumes in the wind is most interesting. I remember once a writer describing the plumes of this Spiræa as being as white as snow, and a friend replied at once that the whiteness, if that of snow, was of snow before a broom! Cuttings of the young wood planted in autumn root freely, and soon form strong plants, or if a plant be cut down it suckers up from the roots so freely that there is no great difficulty in obtaining stock. Planted judiciously, this shrub is most effective in the garden, especially so as contrasted with the purple-leaved Hazel or Beech. If it be so planted as to escape the mid-day sunshine, its feathery plumes will not fade so soon as they usually do. This is, indeed, the one great drawback to all the Spiræas, their fading so quickly if exposed in a hot position. Planted on an eastern or northern wall it grows well. A well-flowered mass of it on a wall here, topped with crimson Snapdragons, has been much admired.

Centaureas.—In the days of Parkinson and of Rea these plants were known under the homely name of Blewbottles, and some of the blue-flowered species are pretty enough in their way. Still more uncommon, however, is C. glastifolia, the half-developed flower-buds of which are just now of a silvery grey colour, glistening in a manner reminding one of large grey pearls. To my mind, it is more beautiful in this state than when its shining involucral bracts are hidden by the yellow flowers. The plant has hoary leaves, and its flower-stems are branched and about 2 feet in height, each branchlet tipped by a great silvery bud. A handful of these pearl-tipped stems form a really unique ornament. Another robust-habited species now in flower is C. macrocephala, which bears golden brush-like flower-heads 3 inches or 4 inches in diameter. Planted in deep, rich soil, the whole plant grows 6 feet in height, each leafy stem bearing at its top the bright yellow, boss like flower-head. The first-named plant is really well worth growing in quantity for cutting, but the latter is best adapted for some out-of-the-way corner, or for a sunny nook in a shrubbery border, where its rampant growth may not be a danger to plants more delicate. Both are easily propagated, either by division or by seeds sown as soon as they ripen.

Wall-top gardens.—Wherever low dividing or retaining walls exist, or are necessary in gardens, there may provision also be made for the growth of many pretty alpine plants. Bare topped walls are never strikingly beautiful, and there is in the garden no necessity for their existence. Among the plants which naturally enjoy growing on rough walls are Arabis, Aubrietia, Erinus, Corydalis lutea, Wallflowers, Snapdragons, Valerian, and a host of other things too numerous to name. All these, however, will establish themselves on any ordinary wall from seeds quite readily. Other good wall plants are the Sempervivums and many Sedums. There are many less effective plants in our gardens than Sedum acre and its golden variety. A good clump or mass of the common Houseleek (Sempervivum tectorum), made firm on a wall or ridge

of the roof with a little mortar, will grow and flower freely for many years. But wherever a little trouble is taken to form pockets of rough stones on the tops of low walls in gardens, there one may grow not only Cacti and succulents of many kinds, but also some of the choicest of all the alpine flowers. The Edelweiss is quite at home on such a wall, so also is a mass of Ramondia pyrenaica, which bore in all over seventy blossoms, and some of the Fig Marigolds in seaside localities grow and flower on such dry walls better than they do in pots indoors. I saw the crimson Valerian glowing like fire on the old walls of Conway Castle the other day, and in Anglesey the Foxglove was of a vivid ruby-crimson colour on the old walls and among the boulders on the Grass; and so in the garden some plants are much improved by the semi-starvation of a garden on the wall.

Seed-sowing.—A good deal of trouble would be saved in gardens if wooden boxes were substituted for the pots or pans in which seeds are sown. Again, whenever practicable, seeds should be sown at once as soon as gathered, and for hardy and many half-hardy plants the best seed bed is one specially prepared in the open air. A bed of 4 feet wide and any convenient length can be framed with boards and filled with the refuse soil from the potting benches, or with garden soil to which a little sand and leaf-mould have been added. In such beds the seeds can be sown in rows and, as a rule, germinate better and grow more vigorously than when coddled in pots or pans. We have two or three of these seed beds, and seed-sowing goes on in them all the year round. As one batch of seedlings is planted out a little fresh soil is added, and the whole is freshened up with a fork and raked level, and then in go more seeds. Now and then a batch of seeds does not grow, and that patch is forked over, and in go some other seeds, and it not unfrequently happens that after this stirring the original crop appears. The old plan of saving up a lot of dry, dusty, and worm-eaten seeds from summer until the following spring should by this time be an obsolete practice in the garden; better results will be gained by sowing all flower-seeds at once as soon as they ripen. There is no comparison between seedlings raised in these open-air beds and those coddled in pots and pans in a frame; the gain is in quantity as well as in quality, and the trouble is lessened considerably.

Iris juncea.—My experience of this lovely bulbous Iris is that it likes a warm, dry, sandy border, in fullest sunshine, and ample time to establish itself before it flowers. I saw it glorious in the sun on the rockery at Knockmullen, and on the 15th day of August, 1884, my friend, Mr. Peter Barr, sent me three bulbs in a match-box, which were at once planted as above described. I never saw any sign of growth until this year, when four strong-flowering stems appeared, each bearing a pair of blossoms, the brilliancy and richness of yellow colouring in which defy description. Of course, it is most probable that these bulbs produced leaves in 1885, but they are so slender that one might easily miss seeing them amongst other things unless one especially looked for them. Ordinary yellow Spanish Irises look quite pale and washed-out beside this Rush-leaved species, which is a gem of its order well worth a good place in the best of gardens. Another distinct Iris of this Xiphion group is I. filifolia, bearing flowers of a rich blue-purple colour, with a blotch of orange on the bent portion of the falls. In general appearance, especially in colour, it recalls I. reticulata Krelagei, but is, of course, taller and quite different in form. The English Irises have been very fine this season, although very short-lived on account of the drought. Best of all is the larger pure white variety, which is quite as fine in its way, as is Cattleya Trianæ alba. For cutting all these bulbous Irises are most valuable, the delicate satin-like texture and sheen becoming quite delightful as seen near to the eye indoors.

Veronica.

Flower Garden.

WHITE LILIES.

These seem to be blooming this year with an exceptional amount of freedom and vigour. In almost every garden in this neighbourhood one sees them in full beauty, their pure white flowers carried on stems 6 feet or more in height and as thick many of them as a good-sized fishing-rod. This is one of the noblest of hardy flowers when it does well, and I have often wondered whether we get it in its normal vigour in this country. We hear a good deal of the conditions in which L. auratum thrives in its native land, but I never remember to have seen anything on this matter respecting the old white Lily. If we knew the exact natural conditions in which it is found at home, we might possibly manage to make it flourish better than it now does in a general way in this country. This Lily being a native of the Levant, I have hitherto thought that, as in the case of many other Lilies, our damp, cold winters and changeable springs were the cause of the failures which so often occur in its cultivation. I fancy, however, that this is not the true solution, and that the cause of failure lies chiefly in the absence of sufficient warmth to mature the bulbs after they have bloomed. Last summer was exceptionally dry and the autumn was moist, so that after a longer period than usual of inactivity a free strong growth was made. It would be an easy matter to arrive at some satisfactory conclusion in this matter by planting bulbs in various positions, putting some where they would get the full force of the sun, and others in more or less shady situations. It would also be well to vary the depth at which the bulbs are planted, so as to see whether those nearest the influence of the sun bloomed better than those more away from it. This old white Lily is such a grand thing when it does well, as to make one regret that it should be so capricious. There is one way by which this Lily may be grown so as to ensure its blooming well. If good strong bulbs are put into 8-inch pots in good loam, potting firmly and not disturbing them for a season or two, they will throw up well. Some market growers do it in this way, and if well attended to no other Lily can match it in nobility of aspect. The wonder is, considering how long it has been in cultivation, that its merits as a pot plant have been so tardily recognised. Wherever the white Lily does well I would recommend its being planted in bold groups in conspicuous positions. Unlike most other Lilies, it does not seem to crave for shelter, the flower-stems being so strong as to defy the battering effect of rain and wind. The hardier kinds of Lilies are far too little employed in this way; their true worth is scarcely realised unless they are planted somewhat thickly. I fancy, too, that they do better in this way than when isolated.—Byfleet.

—— What a glorious display of white Lilies there has been of late in gardens of all kinds. The masses of them that one finds in cottagers' gardens that have not been disturbed for years testify that light well-drained soil will keep them in perfect health without any special attention. Those who wish to get a fresh stock should transplant about the end of this month, or as soon as the foliage decays. There is a great demand for the bloom spikes of this Lily for indoor decoration, and most lovely they look in large vases cut with good long stems and dropped in with the addition of a little foliage. We grow the majority of our stock of this Lily under the partial shelter and shade of fruit trees, as in this way we get a longer flowering season than when fully exposed. I may add that shell snails, slugs, and other garden pests are very fond of the leaves of this Lily, and will strip the stems quite clear; care should therefore be taken to plant it as far away as possible from hedgerows, Ivy-covered fences, or other places where such things find shelter. In places where the soil is naturally heavy road scrapings, leaf mould, or sand should be added to it. In this part of Hampshire this Lily grows with the greatest freedom in soil by no means rich, but very sandy and friable.—J. Groom, *Gosport*.

—— White Lilies are now just at their best, but with us they are scarcely so fine as last year. I have planted them in various situations, but they are most effective, I find, in large masses in mixed borders with their stems hid by other plants. They look well against a background of evergreen shrubs. We have them dotted about a large bed of Heliotropes, in front of a Cedar of Lebanon, and they look very well there, but still they seem more at home in the old-fashioned mixed border, sheltered from wind by other plants. They transplant best about the first week in October, especially if the bulbs are to be singled out. I have moved large clumps of them with success from one part of the garden to another in spring. I lifted them with a spade, and carried along with them all the soil that would cling to them, and planted them with as little disturbance as possible.—E. H.

PROPAGATING HOLLYHOCKS.

Summer is the best season in which to propagate named varieties of Hollyhocks. Striking them in heat in spring tends to weaken the stock. The flowering side shoots taken off now make excellent cuttings. Some judgment is required in their selection. If the wood is too soft they will damp off, and if too hard and fibry they may not start at all. They should be taken when half ripe—a condition reached about the time when the blossoms are opening. Where considerable numbers of plants have to be raised, the cuttings will do best in a frame under glass. Place a layer 2 inches thick of old manure or leaf-mould in the bottom of the frame; press it down, and then put in 3 inches of light sandy soil, and on the top a sprinkling of sand. The whole should then be made moderately firm by placing a board on the surface and applying pressure; then water with a rosed pot to settle the whole. Most Hollyhocks, besides sending up a main central flower-stem, throw out from near the bottom other stems. These side stems make excellent cuttings when the wood is getting firm. In the axils of most of the leaves there is a latent wood bud which, under suitable conditions, may be forced into growth, even though it might not under ordinary circumstances start into growth at all. In making the cuttings, first trim off all the leaves, leaving about an inch of the leaf-stalk; then begin at the lower end and cut up the stem into single joints or eyes, leaving about an inch of the stem below the bud and a quarter of an inch above it. The knife should be sharp enough to make a clean cut through the stem. Lines should be made across the bed in the sand 2½ inches or 3 inches apart, and in these lines the cuttings should be thrust up to the shoulder 2 inches apart. When thrust in the bed in this way the base of the cutting rests on a firm foundation, which might not always be the case if the cuttings were planted with a dibble. As each batch of cuttings is inserted, water to settle the soil, and shade if required. In bright weather, if the sand at any time looks dry, slightly dew it over in the afternoon with a fine-rosed pot, but too much water must not be given till it is ascertained that the cuttings are pushing roots. When well rooted they should be lifted carefully and potted singly in small pots, and placed in a close frame for a time to encourage root action; afterwards shift them into 5-inch or 6 inch pots, and encourage them to grow strongly. They should be wintered in a turf pit, or where some protection

can be given. If all goes on well, roots will be forming and the buds breaking through the sand in the course of three weeks or a month after the cuttings are inserted. Air should then be given and shading discontinued. In a general way seedlings make the strongest and most vigorous plants, and when seeds are saved from a good collection, the seedlings are invariably good, but it is obvious that, in order to preserve the best varieties, they must be increased by means of cuttings. All who grow a good collection of Hollyhocks, of course save seeds from the best flowers, and if sown in pans under glass, the plants will flower the following season. Even if sown now in a bed in the open air, they will flower next year. Sow in shallow drills 9 inches apart, cover lightly with light, sifted soil, and shade the bed with Rhubarb leaves laid flat on the surface till the seeds begin to germinate. E. Hobday.

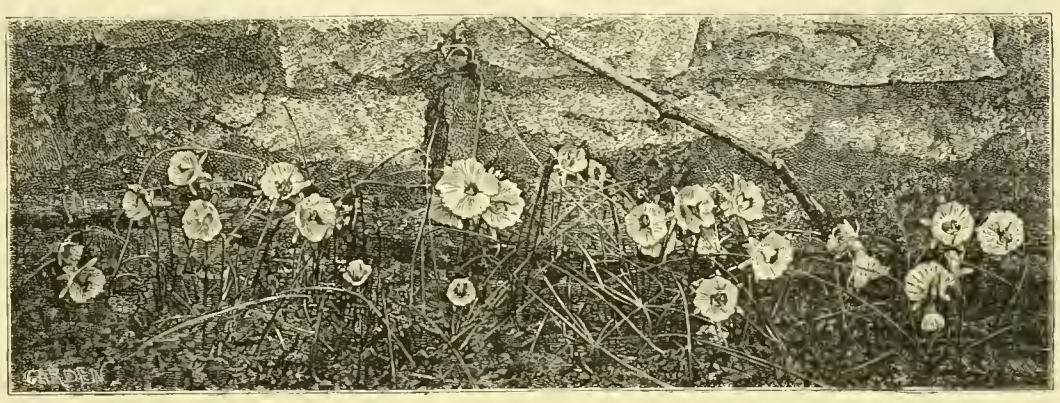
Climbers on trees.—I lately saw a very pleasing effect produced by covering naked tree stems with Virginian Creeper. The trees in question were Firs and Chestnuts, which had clear stems 30 feet or more in height, and which from the base upwards were completely covered with luxuriant foliage. Ivy-clad trees are common, but one does not often see free use made of the other strong growing climbers in a similar way. There is no lack of material for employment in this way, for in addition to the Virginian Creeper there are Aristolochia Sipho, Menispermum canadense (both of remarkably vigorous growth) such Clematises as montana, Flammula, the Traveller's Joy, and even some of the strong growing evergreen Roses might be thus used. The principal point is to get them well established by giving them a barrow-load or so of good soil to start in, and a good watering occasionally the first season; afterwards they would take care of themselves. In most gardens there are naked tree stems, the draping of which imparts an additional charm.—J. C. B.

Cornflowers.—Which is the true Cornflower, the blue Centaurea Cyanus or the yellow Chrysanthemum segetum? Both are variously termed Cornflowers, but, on the other hand, captious persons term the blue Centaurea the Cornbottle, which is, I believe, its correct appellation. We have few better blue hardy flowers for cutting from than the Centaurea just named, and I wish the lovely yellow Sweet Sultan was equally hardy. I greatly doubt whether amongst yellow flowers specially suitable for table decoration and similar purposes we have any more lovely or pleasing flower than the Sweet Sultan, and yet it is but little grown. The yellow Cornflower, since its adoption in gardens, has made considerable progress; the flowers are now often double the size of those found in the fields, and less formal because the petals are so much larger. I have found blooms 3 inches across. Once established in gardens, it gives ample plants yearly, and is less difficult to eradicate than Centaurea Cyanus, which seems to seed so abundantly, that no sooner is one lot of seedlings removed than others burst up. For this reason the Cornbottle should be restricted to some out-of-the-way corner where it can bloom and seed as it will from year to year. Without doubt in its case plants that have stood the winter give by far the best results. They are very hardy, which is more than can be said for those of the Chrysanthemum.—A. D.

CORBULARIA MONOPHYLLA IN THE OPEN AIR.

This, the most beautiful of the Hoop-petticoat Daffodils, as a hardy plant has been somewhat of a puzzle to cultivators. Not that it fears cold, for its home is in the snowy heights of the Little Atlas, but the difficulty in our climate is that it does not get the thorough dry ripening that is needful to its well-being.

In the case of the garden from which the subject of the engraving was taken, the difficulty was met by planting the bulbs at the foot of a west wall covered with Vines. The Vine foliage roofs the space where the bulbs are, so that no rain reaches them throughout the summer. By the end of October the leaves are off the Vines, the ground becomes moistened and the bulbs start. Snow lay on them last February, but the little flowers came bravely through, growing into full beauty as it melted. Probably the soil and situation (a warm sand, at 400 feet elevation in a southern county) are conditions unusually favourable; certainly the result has been most



White Hoop-petticoat Narcissus at foot of south wall in a Surrey garden. Engraved from a photograph for The Garden.

encouraging, and other tender Corbularias and the less hardy Narcissi are being tried under the same conditions.

Irises.—Both Spanish and English Irises are now well in flower with us, and very pretty many of the varieties are, especially amongst the Spanish section. The lemon and orange-coloured sorts contrast strikingly with the bright blues and purples. Some of the colours are also quaint, more particularly those with dark puce shades. I am somewhat disappointed, inasmuch as I have not a pure white variety amongst the Spanish sorts. The nearest approach to white is one named La Vestal, but this is by no means pure. It is also the weakest sort amongst them, not being more than 9 inches high, while some of the others are 2 feet. The English sorts are much more vigorous than the Spanish, and their flowers are also larger. The nearest approach to white in the flowers of this section is Mountain of Snow, but it is hardly so pure in colour as to justify its name. Still, it has bold, well-formed flowers. These Irises are not particular as to soil, provided it is fairly dry in winter and not too heavy. Ours were planted last September, and they have given us no trouble since.—Taunton.

Show Pelargoniums out of doors.—I recently saw a good sized bed of these treated exactly the same as ordinary zonal varieties, *i.e.*, old plants were carefully hardened off in spring and planted out in May, with the result that they had grown into fine bushes, and were covered with hundreds of lovely blooms and buds that promised to last for a long time to come, the increased root space having promoted both successional growth and bloom. We have long had such kinds as Lady Scott, Pretty Polly, and Unique out of doors, but the beautiful soft colours of the show varieties are but seldom made use of in that way. In fact, it is more the result of accident than design that one does find them thus employed. I have sometimes planted them in large rustic baskets, in which they look well in pleasure grounds, and I feel sure that a more general use of this kind of Pelargonium would add quite a fresh charm to our flower beds in summer. I need scarcely say, that if intended for open-air bedding they should be kept as cool as possible during the winter and spring, so that they may not be too far advanced at bedding-out time. There is amongst them such a variety of colours, varying from the clearest white to the most intense crimson and rose, that a really effective flower garden might easily be made by means of these Pelargoniums alone.—J. G., *Hants.*

CROSSING SWEET WILLIAMS.

Notwithstanding suggestions made respecting the intercrossing of Sweet Williams with other members of the Dianthus family, certain it is that our old garden favourites will long yet remain much in their present state. But without the aid of intercrossing, Sweet Williams have not stood still; indeed, a good strain now-a-days exhibits a vast improvement on the strains of twenty years ago. Sweetly scented as Wallflowers, Violets, Pinks, Stocks, and similar old-fashioned flowers are, it would be difficult to imagine an old garden without Sweet Williams. Whether, however, in old gardens or in new ones, Sweet Williams are ever in place. Old strains were prolific in the way of dark colours; in modern ones lighter hues prevail; but still the dark hues may be had if need be. Light flowers show a greater variety of marking than dark ones. No one could describe fully the variations to be found in the colours and markings of Sweet Williams now-a-days. Auricula-eyed flowers may have white eyes, and red, carmine, purple, violet, or some other coloured ground, and a thin margin of white. There may, moreover, be ringed forms, as in Hunt's strain, the ground colour being more narrow and bordered by a broader margin of white. There may also be found white, pink, red, scarlet, crimson, or purple selfs, but far beyond these come the mottled or flaked flowers, which are almost endless in variation and yet very beautiful. These mottled flowers are, I think, the most striking of the whole. In any case a good strain should have the greatest variety allied to size and quality and broadness of truss. Plenty of kinds now have pips 1 inch across; any good strain, too, will produce some double flowers, but these are more curious than beautiful, and can never take the place of good singles in a stand of Sweet Williams at a show. It is pleasant to find Sweet Williams so widely encouraged at summer shows as they still are. As to seed-sowing, my own practice is to sow towards the end of April in the open ground, and I am now awaiting a little more rain to enable me to plant out about a thousand plants from such sowings

into beds consisting of five rows each, so that they may grow together in masses, and thus when in bloom serve to hold each other up. Plants put out now, if strong and in good soil, will throw up some half-dozen or more heads of bloom, and thus form an almost solid mass of flower. One drawback incidental to hybrid Dianthuses is that they fail to give us seed, or, if they do so, in no great quantity. The old mule Pink furnishes evidence of this defect. One of the prettiest Pinks we have is the single form of Dianthus plumosus, the flowers of which have deeply laciniated edges and ringed or coloured centres, the ground hues being white and pink. This seeds freely and is well worthy the attention of all who have to decorate vases, epergnes, &c. For this purpose it is one of the lightest and most elegant of flowers. I propose to see how far it may be possible to engraft the rich hue of Dianthus Heddewigi Brilliant upon this hardy perennial. Could we get rich-hued flowers upon it, I am sure that it would prove to be one of the most popular of border plants. A. D.

NOTES ON HARDY PLANTS.

Œnothera macrocarpa.—This is one of the neatest and showiest of the evening Primroses, and one which deserves to be largely grown. It is not, however, at all common, and one often hears complaints that it cannot be increased very readily. That it is not easily divided is true, but besides seed raising, it may be got in quantity from cuttings. These should be taken, slip-fashion, from the crown before the growths get long or show buds. On strong plants many shoots will now be 3 inches or so in length, and just suited for rooting. If put in a close frame for a week roots will be made, and there is plenty of time to grow them into strong plants before winter sets in.

Lithospermum petræum is a brave little shrub in our trying climate if the plants are grown strongly before they are exposed. Its exquisite flowers need no praise, but are, alas! too seldom seen. It loves the sunshine and the breeze; one or two plants of it forwarded in shelter are promising seed. On this, however, we are not alone dependent, though it is said cuttings are hard to strike, but in my opinion they need not be so; the mistake too often made is that they are kept close and moist in the same way as most other cuttings. The foliage of this species will not stand moisture scarcely two days without injury: the coating of adpressed hairs turns soft, and the leaf is soon covered with fungoid growth. The better way is to take short, but firm, young wood with a "heel;" such cuttings or slips should be set firmly in sandy soil and in a warm place; the leaves will flag and perhaps shrivel, but the results are better than are obtained under confinement and moisture.

L. graminifolium.—This is a distinct and charming species with a spreading or forked raceme of highly coloured flowers, not unlike those of L. petræum. It stood last winter well in the open, and may therefore be considered to be fairly hardy. It makes Grass somewhat freely, and it may be increased by division as readily as the summer Forget-me-not.

The Ferulas.—In planting these conspicuous and showy foliaged plants it is as well to study their leafing and fading periods, or objectionable gaps may occur just when and where one would least desire them. We are all delighted with the early verdure of F. communis, but it does not last through a dry summer. The variety gigantea is scarcely more reliable. The foliage of tingitana is not so finely cut as that of the two former, but it is both bold and lasting. Why are not the Fennels more grown in borders and shrubberies than they now are? They belong to that class of garden objects which, when once tried, are felt to be indispensable.

Primula Rusbyi, referred to but a week or two ago in these notes, is found to be a successional bloomer, a feature in a Primrose which, at this advanced season, is worthy of note. The smallest plants seem to be floriferous, sending up mealy scapes and violet-purple, but spare-flowered, heads more freely than capitata. The scent is rich and agreeable.

P. obconica may not be hardy enough for the open air all the year round, but I find that self-sown seedlings of it under hardy conditions grow as freely as weeds, and it will be interesting to watch if these plants stand the winter any better than those otherwise raised and nursed.

Æthionema coridifolium.—This stood out all last winter in pots plunged in sand, but otherwise quite exposed. Our plants of it, now three years old, are finely in flower. I have always found the age of plants belonging to this genus to be a chief point to be observed, as there is a tendency amongst them to be biennial. Anyhow, so far I have always found it best to raise plants from seed, and treat them as we do Wallflowers.

Campanula valdensis.—This is a most desirable variety. It is early, showy, and lasting. It may be described as intermediate between C. cæspitosa or pusilla and rotundifolia. It is about 6 inches high and the perfection of neatness. Its stems are numerous and slender, but though the glistening pale blue bells are large for such a small plant, they are always well held up. It has none of the weedy habit at the root which characterises rotundifolia; in fact, though free the growth is but moderate, and in dryish, sunny places, which it seems to enjoy, it proves a model alpine, so far as cultivation is concerned. Its flowers have been open five weeks and are still in good condition. I should say that few things are better suited for exhibition in pots or pans than this Bellflower. Hitherto I have always divided it as soon as done flowering, placing a pinch of the roots in 3-inch pots, with some grit and leaf-mould; the pots soon fill with roots, and the plants flower well the following season.

Calceolaria Kellyana.—What a grand little plant this is for a cool, moist crevice in rockwork, or to place between taller plants with sparse tops and a compact habit. It thrives in a stiffish loam and flowers more or less from June to September. I used to winter some plants of it in a frame, but from some cause or other they did not thrive there so well as in the open ground, where, in the worst of winters, I have always found this Calceolaria alive, though sometimes much injured.

The Master-worts (Astrantias) are fast becoming favourites; the flowers of even the commonest seem to be liked where cut material not of glaring colours is in request. The clustered varieties mix well with leaves, and the one or two-umbelled stems of A. maxima associate charmingly with Grasses. I mention this use of the flowers, because in the borders they are anything but effective, and there, if allowed to seed, they soon become trying weeds. I find also that the flowers develop best in partial shade, and therefore it might be as well to give them a suitable corner to themselves, or associate them with plants of similar requirements. The tips of the involucral leaves are very liable to turn brown; an umbel will last in good condition for a week or a fortnight, but often on the second day these blemishes will occur. It is a good plan to cut the flowers early; if before they are quite open, no matter, they will expand in water.

Gillenia trifoliata.—This, as seen in flower, nodding between some Hollies, which protect it from the midday sun, but which do not overshadow it, is much fresher and fairer than when more exposed. If not a showy plant it is both effective and beautiful, especially when cut for the table. Unless sheltered in the way just stated, it does not grow freely, and the flowers and leaves are wanting in size and freshness. J. W.

Monstrous Foxglove (*F. C.*).—The bell-like flower of the Foxglove sent is a monstrosity, not unusual in the case of the Foxglove. It is no doubt caused by the fusion of several flowers into one at the termination of the spike. We need hardly add that the occurrence has nothing whatever to do with the Campanulas that grow, as you say, amongst the Foxgloves.

GLADIOLUS COLVILLEI ALBUS.

Frequent complaints are made that this Gladiolus cannot be induced to flower properly; but such complaints only show that the treatment is wrong. No plant can be more easily cultivated successfully than this when its requirements are understood. The chief, and probably the only, cause of failure arises from keeping the bulbs too long out of the ground. In the case of imported bulbs, they should be obtained along with Hyacinths in autumn, and potted as soon as they come to hand. Continental bulbs complete their growth earlier than those of English growth, and that being so, they suffer from long confinement in drawers or paper bags. The first lot of roots of this Gladiolus I ever dealt with came from Holland in January in the shape of dry bulbs, but they had grown out in some cases as much as 4 inches, and all had started into growth more or less. As I wanted them for flowering in the open ground, I had them potted at once, putting seven bulbs in a 6-inch pot and then placing them in a cold pit, where they were secure from frost. There I allowed them to remain until the middle of May, when they were planted out where they were to flower. Even under this kindly treatment they did not, however, flower so satisfactorily as home-grown bulbs. When one has once got a stock of this Gladiolus, it increases rapidly, and if it is to be grown altogether in pots, it must have plenty of root moisture until the foliage gets quite yellow. The best place for it to stand during summer is in a cold frame, from which the lights are removed during fine weather. When the leaves have died down cut them off close to the pots and pack the latter away somewhere under cover, for if moisture gets into the soil they will start into growth again in September. They will not sustain any harm if kept dry until the end of October; but they must not be neglected at that time, or the bulbs will be weakened. They must have fresh soil every year; therefore, all the old material must be shaken away from them. If the plants are taken to a warm greenhouse early in April, they will be in flower by the end of May. In some gardens this Gladiolus will live in the open if planted near a warm wall and the position is somewhat sheltered. But I find if it is planted in exposed beds, that if a warm moist time occurs after it has rested a few weeks, it commences to grow again, and if a hard winter follows, the growth thus made is killed and the bulbs permanently injured. If, however, I take the bulbs up early in September, and keep them dry for about two months, and then put them in pots for the winter, to be transferred to open beds late in the spring, they succeed satisfactorily. J. C. C.

Diseased Humeas.—I send you a stem of Humea elegans killed by some disease, concerning which I know nothing. Can you kindly help me in the matter? I have grown Humeas for over twenty years as easily as we grow Cabbages, and almost to any size, but for these last seven or eight years I have not been able to grow a decent plant. Our treatment and soil have been the same from the first. The plants show signs of distress just as they begin to flower, and, finally, go off altogether, which is a great loss to us, as we grow them specially for standing under a large front portico, and for that purpose, when well grown, they are most graceful. For any information respecting the cause and remedy I shall be greatly obliged.—William Sangwin, *Trelissick, Truro.*

*** We regret our inability to explain the cause of sudden death in Humeas. Their disease and death are, however, but too well known to cultivators of these plants. We have repeatedly examined examples under the microscope, but have never seen either fungus, insect, or nematode likely to be the depredator. We have never seen anything like a Peronospora; the fungus threads (sometimes present) belong to acremonium. Death arising from this disease in Humeas seems to be simply a sudden failure of vitality. When we get the plants for examination, all parts, from the tips of the rootlets to the tips of the newest leaves, are

quite dead. If our correspondents would send us examples just as the disease is putting on its first appearance, some cause might be found, but this possibility is, to us, doubtful. It is a case of sudden and complete disorganisation and death of the tissues, possibly brought about by bacteria. We have seen the same state of things in other plants, as, for instance, in Violets, but the cause has in all cases eluded us.—W. G. S.

Trees and Shrubs.

LAWSON'S CYPRESS AND ITS VARIETIES.

No better proof of the qualifications of Cupressus Lawsoniana as an ornamental evergreen tree can be given than when it is stated that in Britain it is annually raised from home-grown seeds by the million, and that it is to be met with almost everywhere, in place, and out of place, in the gardens of the poor as well as in those of the rich—here as a single specimen of almost unrivalled grace and beauty, there in groups, or adding variety to the mixed shrubbery; and often, but as yet not too often, forming beautiful and ornamental hedges. So accommodating is it as a stock, that not only are all its own distinct varieties grafted on it, but also other species of Cypress and members of very distinct, but, of course, of cognate genera. Singular, however, as it may appear, it will have little or nothing to do with what botanists consider its nearest blood-relative—C. nutkaensis, though the latter, as a scion, unites kindly with C. Lawsoniana, but the union is not a happy one and very soon comes to an end through the death of the scion. C. nutkaensis makes a perfect and lasting union with Juniperus virginiana and J. communis.

Mr. Murray, who originally discovered the Lawson Cypress, found trees of it in Upper California, in some instances upwards of 100 feet in height, with trunks 2 feet in diameter. In this country it has already attained a height of from 20 feet to 30 feet; but although its timber is said to be good and easily worked, it will never, I fear, excel as a timber tree with us in Britain. Its proper place is as an evergreen decorative plant, and as such it has, at least among Cypresses, few if any equals. Being perfectly hardy, and not too particular as to soil, it luxuriates almost anywhere, but prefers a rather heavy, damp soil to a light or dry, sandy one. In the latter it is subject to premature sickening of the leaves, and, ultimately, defoliation. But this Cypress, like the majority of coniferous plants, is less fastidious as to soil than it is to climate; it delights in shelter rather than exposure to cutting winds.

As a cheap and ornamental hedge plant it has few equals. Its shade of green is more cheerful than that of any other plant at present devoted to such a purpose; and its gracefully recurved feather-like branchlets form a pleasing relief to the rigid shoots of the Holly and even the Yew. Plants of large size may be advantageously used for this purpose, but small ones, say from 18 inches to 4 feet in height, are preferable, as they can be clipped and headed back until a proper base is formed on which to build the superstructure. A distance of from 12 inches to 18 inches apart (according to the size and habit of the plants) will be found sufficient; but of course a greater distance is requisite where large specimens are required to screen unsightly objects. About the beginning or not later than the middle of September, and again in spring when the shoots show signs of new life, are good times for clipping; but of the two early autumn is probably the better time, as the shoots then clipped are not so liable to be displaced and bent down by snows in winter, which would, were the shoots left untouched, give the hedge an irregular and ragged appearance.

This Cypress is often seen of a sickly hue and partially defoliated; and people very naturally attribute such a condition to the occurrence of some constituent in the soil that does not suit the plants. It will, however, generally be found that mishaps of this kind are the result of poverty at the roots, and will in nine cases out of ten disappear after a generous top-dressing of well-rotted manure. Many plants when under diverse cultivation present a greater or less degree of variation from the normal type, and particularly is this the case with the Cypress under consideration. In the short space of time during which it has been under cultivation in Europe many very distinct varieties in habit and colouration have been obtained, and are now extensively cultivated. But, unfortunately, all the varieties named in trade lists do not deserve the consideration of planters; I shall, therefore, briefly describe a few of the best.

Varieties.

Erecta viridis.—This in an erect, tapering tree of moderate growth, thickly and closely inlaid from base to top with compressed twiggy branches and branchlets of the richest green; indeed, it is quite unique as regards beauty, and never needs pruning or clipping.

Argentea.—In this we have a dense, oval shrub of a silvery bluish green, with the points of its branches gracefully recurved. It is of moderate growth, and doubtless never will attain any great size; it is therefore a suitable subject for planting in small gardens.

Gracilissima.—This has the same habit of growth as the preceding, but is characterised by thinner and more twiggy branchlets; it is also of moderate growth.

Alba spica.—This possesses a dense, pyramidal habit of growth, with the bark and leaves of the vegetating shoots of a chalky whiteness. Although of good colour when exposed to the sun, it will, unlike golden variegated Conifers generally, be improved by being planted in shady positions.

Albo-variegata.—This is of an upright habit, without ever reaching to any great height, with branches almost regularly blotched and striped with yellowish white. It is consequently rather pretty and a most befitting subject for enlivening a shrubbery.

Aureo-variegata.—This differs from the preceding in its branches being loosely spreading, and in the variegation being of a golden yellow.

Filifera.—A form remarkable for the long attenuated branchlets, which gives it a pendulous habit of growth.

Intertexta.—In this the growth is more robust than usual, and the foliage possesses a peculiar glaucous tint.

Gracilis pendula.—This is of an elegant pendulous habit on account of the branches being long and slender.

Argenteo-variegata is a form having creamy-white foliage intermixed with the deep green branchlets. It is a handsome variety, and particularly suitable for small gardens.

Flavescens differs from lutea in having pale greenish yellow foliage, but it is not nearly so effective as that variety.

Nana.—This form has been in cultivation almost as long as the species, and yet is seldom to be seen over 2½ feet in height. It is of an ovate shape, with stiff, erect, flattened branches and branchlets. It is represented by two distinct seedlings, the one bright green and the other bluish green; the latter is the best. Its synonyms are pygmæa and minima. There are two forms of nana, one called alba and the other glauca. The former has yellowish white foliage, and the latter is very glaucous.

Lutea.—The peculiarity of this form is its colour, which is throughout the growing season a rich golden yellow, and even in the autumn and winter months it is only slightly converted into greenish yellow. It is of good form and vigorous, and indeed all that can be desired for relieving the monotonous green of our shrubberies; but to do it justice, it is necessary that it be fully exposed to the sun. There need be no fear of it being scorched, for it is as immutable as the parent. It is also called aurea.

Stricta.—This is a most distinct form as regards the habit of growth, which is columnar, similar to that of the Irish Yew. It is one of the most desirable of the varieties.

There are other varieties, but the foregoing are the most distinct. This list will no doubt be much extended, as every bed of seedlings invariably yields forms more or less distinct. W.

Lebanon Cedars for churchyards.—Why are not Lebanon Cedars planted more frequently in cemeteries or churchyards? For the higher grounds of our country churchyards, many of which are so picturesquely situated, this Cedar seems to be well adapted. In rapidity of growth it far exceeds the Yew, and probably it yields very little to it in point of longevity. The slowness of the growth of the Yew, especially in the open spaces generally devoted to the burial of the dead, is probably the principal reason why so few are now to be seen springing up to take the places of those falling into decay.

Lawn trees.—In The Garden (p. 60) "D." observes that Laburnums are "somewhat unsuited for lawn planting." I have one planted some twenty years ago. I raised it from seed, and carefully trained it to a single stem. I never cut back the leading shoot, and simply cut away straggling side shoots. The result has been a very handsome tree with pendulous branches, which hang down almost to the ground. Care must always be taken to destroy the seed-pods by cutting them off immediately the flowers are over. Thus, and thus only, a handsome show of flowers will be insured for the next year. Any tree allowed to ripen its seeds will be a failure in the next flowering season. I remember seeing some years ago, on an old-fashioned garden lawn, a very fine Elder tree. It had been grown to a single stem, and had attained a great size. Its trunk was as large as an ordinary orchard Apple tree. It was annually covered with a profusion of flowers, and formed a lovely object. In the autumn its huge bunches of fruit quite weighed down the branches. It was really a sight worth going some distance to see. The age of the tree must have been considerable. Surely the example might be followed, and the lawn adorned with a handsomely grown Elder tree?—Richard Hooper, *Upton Rectory, Didcot.*

Cut-leaved Alder.—Only those who have been fortunate enough to see a really fine plant of this tree (Alnus glutinosa laciniata) can form a true idea of what a noble specimen it makes when it finds itself in a locality to "its liking." Near here there is an exceedingly grand plant of it growing within 10 feet of a small river, upon soil only about 18 inches above the surface of the stream; its lower branches overhang the water, and are just high enough to walk under on one side, while on the other side they feather to the ground. The expanse of the branches measured 36 feet in one direction, and in other directions nearly as much; and the height was found to be about 47 feet.—W.

Cryptomeria elegans.—This differs extremely in habit and general appearance from C. japonica, but produces cones which—as we learn from Veitch's "Manual of Coniferæ"—are indistinguishable from those of that species; C. elegans is in many respects a more desirable tree. In the first place it is much hardier than its relation, and will succeed in places where the other almost refuses to exist. The remarkable change in colour from the bright green of the summer months to the bronzy crimson of the winter, and its pleasing habit of growth, place this tree amongst the first rank of ornamental subjects of

small proportions. In Messrs. Veitch's manual there is a good illustration representing a fine specimen at Linton Park, near Maidstone; this was 20 feet high in 1881; it would be interesting to have the present measurements together with the history of this tree. To the late Mr. J. G. Veitch is due the credit of having introduced this useful tree; he sent it from Japan in 1861, but never found it in a wild state; according to the work above quoted, it was only met with in cultivation in Japanese gardens.

ORNAMENTAL JUNIPERS.

Among the Junipers are some of our most ornamental as well as useful shrubs. Upwards of twenty species are known, most of which, like our native Junipers, are of low stature, although a few species often attain the height of ordinary trees, and afford welcome shade, as in Syria and several other warm countries. The common and dwarf Junipers (J. communis and J. nana) are the only species indigenous to Britain, of which, however, several well marked and distinct varieties are commonly cultivated.

The common Juniper (J. communis) is chiefly found growing in England on sandy or chalky soils or on open downs, while in Scotland, its native home is amongst the granite or trap hill and mountain sides. It is, with us, usually low and small, seldom much larger than the Furze; but where it attains some size the wood is very fine and compact. It is now seldom used, although in former times spits and drinking vessels were made of it, as it was thought to impart a pleasant flavour to meat or liquid.

The dwarf Juniper (J. nana) is a very distinct and pretty plant, seldom found over a foot in height, but more commonly half that size. It is of a low, dense mode of growth, and soon spreads to a great width in proportion to its height, thus rendering it a plant well adapted for rockwork. It is less common than J. communis. On the high Welsh rocks above Ogwen Lake I have frequently met with this plant, but never very abundantly.

The Irish Juniper (J. cemmunis hibernica) is a most desirable and highly ornamental variety, and of inestimable value in landscape gardening generally. The growth is close and compact, as in the Irish Yew, and the foliage of a peculiar silvery-grey tint. It succeeds best on rather damp soils; indeed, the finest and healthiest specimens with which I am acquainted are growing on well-drained peat soil, on an estate in the north of Ireland. A dwarf and very compact variety of this Juniper, named compressa, is extensively used for rockwork planting.

The Weeping Indian Juniper (J. recurva) succeeds well at Penrhyn, and frequently attains a height equal to that in its native habitat. At Brynmeirig, near the Penrhyn slate quarries, there is a number of this gracefully-drooping plant, which, for size and healthy appearance, are perhaps not excelled in Britain. The soil is composed of loam and peat in equal preportions, and resting on shaly slate rock. The situation is shady, and has a northern aspect, which, by-the-by, seems to suit not only this species, but the male form (J. recurva densa) as well. This ornamental shrub deserves to be cultivated more extensively than it is at present, especially where a suitable soil and situation can be conveniently provided. It should, however, never be planted on dry warm soils, as in such situations it presents a miserable dusty appearance, and soon dies out.

The winter-flowering Juniper (J. chinensis).—This is certainly the most ornamental of the genus; indeed, in this respect it is perhaps not excelled by any evergreen shrub in cultivation. During winter or in early spring, when covered with its golden male flowers, this shrub is particularly beautiful. It is perfectly hardy and of the easiest cultivation, succeeding well en good loamy soil and in a partially sheltered situation. Several beautiful and distinct varieties of this plant are in cultivation, amongst which the golden and silver variegated forms are well werth a place in any collection.

The Frankincense Juniper (J. thurifera).—In this species we have another distinct and highly ornamental plant—or rather tree—for in its native country it frequently attains a height of 40 ft. As a lawn specimen it is invaluable, and frem its dense, conical shape associates well with trees of a more loose and spreading appearance. It should be extensively planted, for, apart from its value as an ornamental tree, it is uninjured by any amount of frost in this country.

The Prickly Cedar (J. Oxycedrus) is by many writers supposed to be the tree rather than the so-called Cedar of Lebanon, from which the Cedar-wood, so famed in former times for its durability, and of which statues were made before the use of marble was introduced, was obtained. It is found plentifully along the Mediterranean coast, and is highly valued, as well for its ornamental appearance as effect for planting in greups. Perhaps, amongst the whole range of Junipers none is more highly esteemed for its utility than

The Red Cedar (J. virginiana).—It is of the easiest culture and seems to succeed in almost any situation, though attaining greatest perfection when planted near the sea-coast. It is a native of North America, where it becomes a large tree, with a bright red, aromatic wood, the value of which is well known from its use in cabinet work and the manufacture of pencils. A. D. Webster.

Wellingtonias as nurse trees.—I should like to see the Wellingtonia planted as a nurse tree, as bas long been done with the Larch. Independently of seeds, which can be got and often imported in very large quantities, no tree of recent introduction can be propagated faster, as it grows very readily from cuttings, which soon make proper and handsome specimens. From what I know of the Wellingtonia I feel satisfied that if planted and brought up amongst other trees it will do better than planted singly on Grass lawns, as we are accustomed to see it. It is said that the wood is soft on account of its free-growing nature; this may be the case in its native country, but in a climate like this it grows more slowly, and its wood, in consequence, may be fitted for many useful purposes.—J. M. N.

Poplar hedges.—The black Italian Peplar is admirably suited for a fence in moist soils. Plants one year old, which are generally about 4 feet in height, will form a tolerably good hedge the first year. If the soil is dug over and manured several months previous to planting, strong cuttings may be inserted about a foot apart, and these will make shoots varying from 3 feet to 5 feet in height during the first season. At the end of the second year, during the month of November, the top of the fence should be regularly reduced with a hedge-bill to the height of 5 feet. This will strengthen the sides of the fence, and consequently increase the stability of the stems. A very good plan is to tie rods of wood to the young trees at 2 feet or 3 feet from the ground until they have become sufficiently strong of themselves to resist the pressure of cattle. When properly attended to, by keeping them free from weeds and trimming them regularly every autumn, these fences become highly useful and ornamental, and are at once amongst the cheapest and readiest of any that can be raised. The form of the hedge should be the same as that of the Hawthorn, only a little wider at bottom, and trimmed up in a wedge-like shape, which renders it firm and neat in appearance.—J.

Planting trees on mounds.—It is somewhat remarkable that even practical men of experience advocate the method of planting trees on mounds. I maintain that it is altogether unnecessary as far as success in planting is concerned, although it may with advantage be carried out on a modified scale on naturally wet, stiff, clay soils; on dry, light soils, mounds are wholly unnecessary, particularly abrupt, high mounds, which would be detrimental rather than otherwise by encouraging the evaporation of moisture from the roots, which, probably, during an extremely dry, burning summer, would suffer so much from drought that the trees would be found to die outright. There is no better plan for planting ornamental trees and shrubs than turning the soil and subsoil to a depth of at least from 18 inches to 24 inches, and a yard or two more in diameter than is required for the roots when planting, turning out stones, roots, on very bad subsoil, and replacing them by fresh soil or turf, well chopped up and stirred in with the original soil. On stiff clayey lands inclined to be wet, the trees should be planted on the surface, covering the roots with fresh soil so as to form a slightly raised mound over the roots, and outside or beyond the latter, not less than a yard or so. The method of surface-dressing trees every few years with turf, leaf-mould, or other enriching material and gradually forming easy mounds, is preferable to planting on mounds at the outset.—O. F.

GARDEN FLORA.

PLATE 554.

HARDY HYBRID GLADIOLI.*

The accompanying plate represents two and a glimpse at a third variety of these most free-blooming, easily cultivated, and very beautiful hybrids, which have been all raised by M. Victor Lemoine, of Nancy, from seed obtained from a variety of G. gandavensis as seed parent fertilised with the pollen of the hardy species known as G. purpureo-auratus, and sent out by him during the last five or six years in batches of from eight to ten varieties each year. As to the respective merits of these beautiful Gladioli, I have furnished the result of my observations and comparisons in a series of descriptive notes contributed to the columns of The Garden during the autumns of the last five or six years. For full descriptions of the varieties here figured, I may refer your readers to Volume XXVIII. of The Garden, page 364, for the two first named, and fer the third to page 314 of Volume XXVI. As to culture, I find the following simple method answers best. Never dry off the bulbs, but plant again the same day as they are taken up (for the removal of offsets and spawn bulblets which are most abundantly produced) in a bed of light rich compost made up of leaf-mould, sod mould and a little sand. They increase very rapidly, both by offsets and seed, the production of which does not seem in any way to weaken or fatigue the bulbs. I have never known them to be affected by any kind of disease, and they bloom in so small a state, that frequently small offsets forgotten in the bed send up nice flower-spikes the following year. The best time for taking up and replanting I find to be from the middle to the end of the month of October. My first flower to open this year is Cléopatre, which expanded its first bloom yesterday, and from this onwards for the next six weeks or thereabouts I hope to have a succession of beautiful blooms. The set of novelties for this year is an unusually large one, numbering no fewer than thirteen varieties, as to which I shall hope to have some descriptive notes to send to The Garden about October. W. E. Gumbleton.

Belgrove, Queenstown.

Camellia General Pescette.—In the journal of the Royal Tuscan Society of Horticulture is published a coloured plate of a new Camellia named General Pescette. Signor M. Grilli, who describes it, states that it is "floriferous, and has the merit of constantly maintaining the characters that distinguish it; every flower opens regularly and presents the same form and dimensions, the

* Drawn in Messrs. Veitch's nursery, King's Road, Chelsea, Aug. 25, 1885.

NEW HYBRID GLADIOLI

1. LA FRANCE. 2. L'ALSACE. 3. MASQUE DE FER.

same streakings with red and carmine on petals with a flesh coloured ground." He strongly recommends this variety, which he terms a grand acquisition, and urges that Camellias as a class are more worthy of special attention than Chrysanthemums, which just now find so much favour.

Flower paintings.—The practice of offering prizes at flower shows for flower paintings by amateurs, especially ladies, merits much wider adoption than it has hitherto done. From the first establishment of the Chiswick Horticultural Society prizes have been offered for paintings, and the competition has been invariably good. Fruits and foliage as well as flowers are invited, but of fruits few have been shown. Probably it is more difficult to depict fruits well than flowers. At a recent exhibition of this society about a score of plates, tiles, vases, &c., were submitted for competition. Some few were of a rather elementary school-of-art-instruction kind, and showed none of the finish of the real advanced artist. The colours were laid on too thickly, and in some instances were what may be termed dauby. On the other hand, some were admirably done, notably a large round platter, painted by Miss A. Finch, of Wimbledon, but which was by the art connoisseurs, who acted as censors, put third. This artist had selected white Clematis flowers associated with foliage of one of the spring blooming kinds, and added autumn-tinted sprays of the foliage and vine of the Virginian Creeper; the combination naturally was incongruous, but artistically it was charming. The first prize went to Miss Matthews, of Richmond Hill, for a very faithfully depicted portrait of Lælia purpurata, stiff, but true, even the spots on the leaves of a badly grown plant being rendered. Mrs. Harry Turner, of Slough, worthily came second with a fine vase, upon which was beautifully depicted flowers and foliage of a mauve Clematis.—A. D.

NOTES FROM KNOWSLEY.

Orchids, notably Odontoglossums and other kinds that thrive best in a comparatively cool atmosphere, are cultivated here by hundreds. A lean-to house attached to a north wall would appear to suit them best, the staging or shelves facing the south, and as most of the species require but little space, quite a small house holds a large quantity of plants. A few good Cattleyas and other Orchids were blooming strongly in a mixed plant stove, conspicuous among them being a good plant of Oncidium crispum. This had formed a strong erect spike bearing about thirty-six large coppery red blooms, and was very handsome. No drying off is advisable with this useful Orchid, and, in common with several of the Oncidiums, it well repays any trouble taken with it. A small-flowering plant of Epidendrum radiatum quite scented the whole house, and is worthy of cultivation for that property alone.

Jasminum gracillimum.—A good many growers have failed to properly manage this lovely and most useful stove Jessamine, but at Knowsley no such difficulty has been experienced. One large plant of it trained over a balloon-shaped trellis is never out of flower, and its trusses of large pure white blossoms, expanded at the time of my visit, were stronger than with us. It delights in a rough peaty soil, and the less fibre there is in the lumps the more need of a plentiful admixture of charcoal and large crocks. The plant just mentioned is growing in a large, well-drained pot, and this would appear to answer better than small brick pits. Fragrant white flowers are always in demand, and those who have hitherto failed with this Jasmine ought yet to give it another trial.

Eucharis amazonica.—An extra large quantity of this is grown, and all are in a very healthy state. They are repotted rather oftener than many may think advisable, but this does not prevent their flowering as often as they do anywhere. It seems to me that if kept free of disease, and rooted in a fresh loamy mixture, no difficulty whatever would be experienced in flowering it when most wanted. It likes plenty of water when growing freely, but this must pass away readily, or many of the roots will perish. Here it is, I believe, repotted annually, and it is never dried off. Before flowering, rather less water is given than at other times, and this induces the formation of flower-spikes, which either an increase in the water supply or a slightly raised temperature fully develops. Many of the plants have been recently repotted, not necessarily shaken out and divided, this being practised only when the pots are getting too crowded with bulbs.

Table plants.—Large numbers of these are required, and abundance of very suitable plants are prepared for such purposes, amongst which many narrow-leaved Crotons, one of the best being C. interruptum aureum, are now in capital colour, yet the majority of them have been propagated quite recently. Strong, moderately firm tops are taken off and placed singly in small pots, then they are placed in a close, hot frame, where, if kept shaded from bright sunshine, they strike root in a very short time. They do not lose their lower leaves, and are therefore nearly large enough for table work directly they are rooted, but a small shift further improves them. The tops of Draccenas can be converted into handy little plants in a similar manner. The elegant Reidia glaucescens is much liked for table decoration, and when well grown it certainly is a most desirable plant for such purposes. Strong tops of this are also rooted in heat, and this is a much quicker and better way of securing serviceable plants than by raising them from root-cuttings, or even side-shoots. Pandanuses, Geonomas, Cocos Weddelliana, and other elegant Palms, Ferns in variety, and large quantities of the pretty close-growing Selaginella apoda are all prepared especially for house and table decoration, and are all in excellent order. They are not crowded amongst larger plants, but all receive fair play, and are in a presentable condition accordingly.

Greenhouse climbers.—There are few good gardens in the country where an attempt has not been made to grow Lapageria alba, but in very many cases the result has been anything but encouraging. It is a lovely flower, and ought to be in every conservatory or greenhouse in which climbers are grown. At Knowsley it is equally as vigorous as the red variety; in fact, the two are indistinguishable except when in bloom. Lapagerias are really shade-and-moisture-loving plants and should be treated as such, and not placed on a dry shelf and in full sunshine, as is too often done. Two years ago several were planted against the north wall of a cool house, the roots being confined to a narrow raised border, and already the wall is fairly well furnished, the young growths now forming being exceptionally strong. Another example, planted three years, now well covers a roof area 15 feet by 6 feet, and blooms most abundantly. This plant is rooting in a small brick pit. Lapagerias must have abundance of water at the roots, but anything approaching stagnation sours the soil and ruins the plants. Only the most fibrous portion of either peat or loam should be used, the two in about equal portions, and to this should be added a good sprinkling of charcoal, broken crocks, and half-inch bones. Lumps of sandstone also serve to keep the compost open and sweet. Lonicera semperflorens is rarely out of flower at Knowsley, and this also is worthy of more extensive cultivation. With us it is much liable to be infested with small green and black aphides, but here it is clean and healthy, although growing in the neighbourhood of decorative Pelargoniums and other conservatory plants. It is very elegant and showy, and particularly good in a cut state.

Justicia flavicoma.—It is not often that this old-fashioned greenhouse flowering plant is met with in good condition, but at Knowsley it is grown extensively and well. It produces its bright yellow plumes or spikes of bloom for at least four months during the very dullest part of the year in an ordinary greenhouse temperature. Cuttings of young wood strike freely in heat, and these after being stopped once or twice make neat plants the first season, but are more useful the second year. At present the whole batch of plants is growing freely in frames, where they will remain till late in the autumn.

Cannas. In this country these are not largely cultivated for the sake of their flowers, but at Knowsley they are employed extensively in the conservatories. They appear to be particularly well adapted for mixing among Camellias, Palms, Ferns, and other flowering and fine-foliaged plants; either planted out in large beds or grouped on the ground level, Cannas are not to be despised as fine-foliaged plants, but some of the newer varieties introduced by Continental nurserymen also flower freely and continuously for several months, the spikes being strong and branching, while the Gladioli-like flowers are large and handsome. C. Noutini with rich crimson blossoms is the best I have yet seen, and C. Ehemanni is also very fine. The latter has Musa-like foliage and deep crimson flowers, while C. grandiflora picta with yellow flowers is also effective. To these several other new sorts may well be added, and even some of the older varieties grown for open border decoration may be given a trial. They pot up safely from the open borders, and in an ordinary conservatory temperature will flower for several months. They delight in a rich loamy soil and require plenty of moisture at the roots.

Ivy-leaved Pelargoniums.—We are often informed that these are particularly well adapted for hanging baskets, but we rarely meet with them in good condition. At Knowsley not only are baskets well covered with their growth, but the suspending wires are also beautifully furnished with them; and a series of baskets in full bloom hanging round one compartment of the conservatory proves most attractive. All are semi-double sorts, which never fail to bloom well when given plenty of light and air. Under these is a good assortment of noble conservatory plants.

Foxgloves in shrubberies.—A long walk leading from the mansion to the lake was at one time most monotonous, but near this has been placed at intervals large beds, and these are planted with a great variety of handsome, rare deciduous and evergreen shrubs, amongst which are interspersed Foxgloves, and very effective they now are. Seedlings raised early this year grow into strong flowering plants for the following year, and with a very little trouble they are thus made to beautify the shrubberies.

Grape-growing.—Of Grapes a supply is maintained all the year round, and several well-designed vineries as well as some that are very old-fashioned are devoted to their production. In one of the earliest houses Black Hamburgh and Foster's Seedling are bearing grand crops, both bunches and berries being good and well finished. Muscat of Alexandria, Alicante, Lady Downes, Gros Maroc, and Madresfield Court are the sorts principally grown for the later supplies. For bottling, Lady Downes is the favourite, and for this purpose rather small, well-thinned bunches of this firm, long-keeping sort, as well as of other late varieties, are much the best. All at different times have undergone a renovating process in preference to a complete change of both border and Vines. Those that last autumn had their roots lifted to within about 3 feet of the stems and relaid in a nearly fresh compost are cropped lightly this season, and have formed remarkably good wood, which should produce extra fine crops next year. Where the sorts are worth preserving this plan of thoroughly renovating Vines both at the roots and top is preferable to a complete clearance followed by the formation of new borders and the planting of young Vines. It is much the cheapest, and by no other plan can a whole house of Grapes be so quickly and simply secured. If done properly early in the autumn while the foliage is green and sound, a light crop may safely be taken from them the following year, and a full crop the next. The best of borders and the best of Vines wear out in time, and Mr. Harrison's method of renovating just recorded should

commend itself to other Grape growers who find their crops falling off both in weight and quality.

THE PEACH AND NECTARINE trees at Knowsley are the largest and best I have yet seen. There are several fine Peach houses, and throughout the trees are good, and the crops, where still ungathered, perfect in every respect. Every year the whole of the trees are partially or wholly lifted, commencing with the earliest some time in August, and finishing all before the leaves lose vitality. Being an annual proceeding, the trees do not receive a very severe check, as all are furnished with abundance of fibrous roots about the reserved balls, or say at about 4 feet from the stems, more or less according to the size of the trees operated upon. Very little fresh soil is added to the borders, the principal motive for lifting being to loosen the soil, though the operation is accompanied by other good results. It may seem strange to advocate looseness of soil for Peach and Nectarine trees, but Mr. Harrison is of opinion that when a border becomes close and hard it cannot be sufficiently moistened to meet the demands made on it by the roots—it becomes impervious, in fact, to both air and water; whereas a loosened border absorbs moisture readily, including fertilisers. The lifting of Peach trees annually is new to me, but the results fully bear out what has been said about its efficacy. Grossness is nowhere apparent, yet some of the young growths are a yard long or more, and the foliage is remarkably good. One of the finest trees, a Violette Hâtive Peach, occupies a trellis space fully 24 feet by 14 feet, and several others are nearly as large, all being well furnished throughout. A seedling Peach placed nearly three years ago where it is now growing covers a space 14 feet by 14 feet, and would, if permitted, soon fill a large house.

FIGS AND OTHER FRUITS.—A range of lofty and wide lean-to houses is devoted to the culture of Cherries, Plums, and Figs. The bulk of the trees are bush-shaped, and these are kept clear of each other, all perfecting heavy crops of good fruit. One house of Cherries had been cleared, but the trees in the next compartment presented a most beautiful appearance. Under good treatment failures never occur, and what is more tempting than a handsome dish of choice Cherries? There are also numbers of bush-shaped Fig trees which are always fruitful. Given a roomy house and a fair amount of space, these bushes are more profitable than trees trained either on the roof or up the back walls.

YOUNG CARROTS AND WATERCRESSES.—I have linked these together simply because they are both cultivated in one quiet corner. A long row of frames is first cropped with early Potatoes, and as these are cleared off the frames are sown with French Horn Carrots, the latest being now just coming up. Watercresses are cultivated here in ordinary frames, and at the present time these present a rather seedy appearance. A short time before the Cresses are wanted in the autumn the beds are taken in hand, and a cleaning over and a good soaking of water quickly put new life into the plants. Any fairly rich soil will grow them, and they like plenty of moisture at the roots, but there is no necessity for them to be constantly in water. In these frames the Cresses grow quickly, are perfectly clean, and are most tender. They can be easily raised from tops, root cuttings, or seeds, and there is no reason why every private establishment in the country should not be well supplied with Watercresses, even although there is no running water in which to grow them.

W. I.

Choice bulbous plants.—A gathering of flowers of various bulbous plants sent to us by the New Plant and Bulb Company, of Colchester, includes the uncommon little Gladiolus biflorus, not showy, but interesting; the Fire-cracker bulb, Brodiæa coccinea, a really showy plant, easily grown, and quite hardy in light soils in the south; B. ixioides, with heads of small yellow flowers, not a plant for general culture; Calochortus venustus citrinus, a most lovely Butterfly Tulip with bright golden yellow cups 3 inches across and blotched with brown; Sparaxis grandiflora varieties, all beautiful and worth growing in a frame or pots for the greenhouse; Ixia conica, bright yellow, blackish centre; Babiana rubro-cyanea and B. disticha, both excellent bulbs, especially the former.

WORK DONE IN WEEK ENDING JULY 20.

JULY 14 AND 15.

SUNNY and drying, and the half-inch of rain that fell but a couple of days ago seems to have done little good other than affording a day's rest from the labour of watering, which work we have still to continue. Wall fruits and recent plantings of winter Greens, Broccoli, and transplanted Lettuce have already had renewed soakings of water applied with garden hose, besides which, and the gathering of small fruits for preserving, little other outside work has been done. There is little change as regards work in the houses; watering and syringing form the great bulk of our daily labours, the little intervening time being made out in keeping Chrysanthemums tied to their supports, layering Strawberries, potting on Poinsettias, Primulas, and Cinerarias, putting in cuttings of Pinks, Carnations, and Roses, and thinning shoots in Peach houses; only sufficient is left for next year's fruit-bearing, and being thus exposed to full light and sunshine thorough maturity is a certainty.

JULY 16 AND 17.

The heat is still great, and the rain, too, in districts near us, but none comes here; hence we keep on watering and plodding away at such work as hoeing and carthing up of Brussels Sprouts and French Beans, and staking late lots of Peas, and cleaning up and cutting the Grass edgings of coach roads, and cutting back overhanging Laurels, Rhododendrons, and branches of trees that are getting too low for the safety of drivers. Pegging out plants in flower beds, and spreading out Sedums and other groundwork plants in coloured foliage arrangements by a gentle pressure with the hands. The growth of all plants is this season most satisfactory, and for once we seem likely to have summer bedding plants in perfection by the end of July. Herbaceous flowering plants have long been so, but their beauty is now waning, but in their place we have now beginning to flower Stocks, Asters, Zinnias, Salpiglossis, Scabious, seedling Verbenas, Petunias, annual Chrysanthemums, Everlastings, &c. Roses we have cleared of all faded flowers, and thoroughly drenched both plants and soil, which will help to start them into new growth and early autumn blooming; some of the longest shoots have been partly cut back and others pegged down to fill out blank or thinly furnished places in the beds. Completed the layering of Strawberries, and those first layered are already sufficiently rooted to be severed from the parent plants, but the work will be postponed till we get rain or a dull time, as exposure to heat when first cut off would so check growth as to take several days to repair the damage. The sun is so scorching that we have again had to apply shading to vineries and to all Pines, as even the most robust plants are getting browned. Scalding of berries has begun on Lady Downes Vines, and preventive measures have been taken to stop it; abundant ventilation night and day, a little fire-heat by night, and but slight atmospheric moisture never fail in staying the injury in this direction. Other work has been of a routine description.

JULY 19 AND 20.

Another 0·42 in. of rain on the evening of the 19th has revived everything, and we have on this latter date been busy planting out the remainder of Broccoli; thinning out Parsley, French Beans, Lettuce, and Endive, and cut the first-layered Strawberries away from the parent plants, and which for the present are stood closely together in a half shaded position. Our oldest plot of Strawberries we have cleared off with spades, and after drawing drills between the lines where once grew the Strawberry plants we have planted out Autumn Giant Cauliflower, Snow's Winter White Broccoli, and late Savoys. Pulled up Shallots and Garlic, and on ground lately occupied by them sowed Endive, early Cabbage, and Coleworts. On the first-named date all hands were employed with Pines, some potting and top-dressing; others clearing out the plunging material, and adding to it fresh leaves and litter, the walls meanwhile having been given a coating of limewash. There is a quantity of Queens in flower, and, warm as it was, we thought it wisdom not to let them be exposed to the air whilst the clearing out of beds and limewashing of pits were going on, and therefore they were stood in vineries till needed for plunging in beds. Fruit near the ripening stage we have put in the warmest vineries to complete their ripening; thus our arrangement of plants in Pine pits will not be interfered with for a considerable time. Other work has been the same as for some days past.

HANTS.

FRUITS UNDER GLASS.

FRUITING PINES.

THE weather of late having been favourable to liberal ventilation and closing at a high temperature from solar heat alone, the frequent use of stimulating liquids will have told upon the fruit without forcing the crowns into an elongated growth, as is too often the case in dark, dull seasons. When Pines are deeply plunged in fermenting beds of tan or moist leaves, their succulent nature does not render frequent waterings necessary; but when the roots do require feeding, mild stimulants, including clear diluted liquid guano and occasionally a dash of soot water, should be given in sufficient quantity to thoroughly moisten every particle of soil quite down to the crock roots. The time generally devoted to watering is the hour preceding closing for the day, as the ammonia from the stimulants used is then confined in the structure, when the fruit and foliage as well as the roots receive the greatest possible benefit throughout the night. On fine, bright non-watering evenings the atmosphere should be charged with ammonia by syringing a little warm liquid into the axils of the lower leaves and over the surface of the bed, care being observed that the spray does not reach the fruit. Overhead syringing or dewing at closing time with pure soft water will also be necessary; but this should fall very light, as getting the plants too wet about the collar is no difficult matter even at this season. When the fruit begins to show signs of changing colour, remove the plants, if in pots, to a drier and cooler house—a vinery, for instance, in which ripe Grapes are hanging—where they will ripen gradually and keep for a long time if not wanted for immediate use. Queens ripened in this way will keep good for three weeks, and Smooth Cayennes nearly double that length of time.

Successions.—If any of the plants intended for starting early in the spring have not received the final shift, they should be taken in hand as soon as the state of their roots will admit. Of two evils, over or under-potting, the last is the least; therefore lest any of them should persist in growing when they ought to be partially resting, it will be safe practice to err on the side of small pots, which they can fill with roots before the end of the year. Give established plants plenty of room, and gradually inure them to as much sun and light as they can stand without becoming too brown in the foliage. Ventilate freely to keep them dwarf, broad, and fleshy in the leaf, and supply mild stimulants as often as the pot-bound roots require feeding. Where the good old Black Jamaica is still grown for winter use, extra small pots well crowded with roots always furnish the finest fruit. Pots 9 inches in diameter are quite large enough, and enjoying, as the plants do, an abundance of bottom heat and light, they should always be plunged in the hottest and driest part of the house. Remove the strongest suckers from old stools and pot them at once in 7-inch pots.

Use the soil rather dry and rough, ram well with the potting stick, and plunge to the rims in a bottom heat ranging from 85° to 90°. When plunged, give a little warm water to settle the soil. Keep them rather close in a pit or frame in preference to a large house, and shade for a few hours on bright days. If the plunging material is moist, no more water will be needed until the suckers are rooted, but a light dewing overhead and damping the sides of the frame as well as the surface of the bed will be necessary on bright afternoons at closing time. Stools of the true Smooth Cayenne, always shy, can often be induced to throw a few suckers from latent buds if shaken out and laid in in a bed of warm fermenting leaves, or, divested of all their foliage and buried as close as they will lie together in shallow boxes filled up with sandy soil, peat, or leaf-mould, a fair percentage of the buds will start and grow into useful stock for potting off in the spring.

Melons

have had a good time of late, and the rapid growth of vine and foliage under a bright sun has favoured the quick development of clean, handsome fruit. When Melon plants grow quickly and set freely insect pests do not make much headway, but it is well to be always on the alert, as green fly spreads rapidly through the early stages, and spider soon destroys the lower leaves when the plants begin to feel the strain of the crop. Smoking if possible should be avoided, but prevention being better than severe remedies, the appearance of the first fly should be the signal for fumigation in a very mild form. When smoking has been decided upon the house should be freely ventilated and kept open rather later than usual to ensure the foliage and atmosphere being perfectly free from moisture and as cool as may be consistent with safety. Reduced to this state, a very light volume of smoke will stupify the insects, and good syringing with clean soft water before the sun strikes the roof the following morning will cleanse the foliage and render heavy shading unnecessary. The best preventive of or remedy for spider is good syringing with pure water every fine evening until the fruit has attained its full size, liberal feeding during the time it is swelling, plenty of fresh air and early closing with sun in preference to fire heat. Another important point is the preservation of all the old leaves from the base of the pots or bed upwards, and a liberal allowance for settling after the vines have taken to the trellis. Some houses, it is true, are pronounced subject to canker, and syringing is suspended; but in nine cases out of ten it will be found that ventilation on the level of the bed has been overlooked, the thick fleshy leaves have been mutilated, or the settling of the bed has tightened the main stems to the tension of fiddle strings. One of these defects is quite potent enough to produce an attack of canker, but when all three are in full force, it would be matter for surprise if some of the plants did not suddenly collapse, or ripen their foliage before the fruit was fit for table.

Late Melons.—Young plants raised in accordance with my last remarks will now be taking to the trellis, over which, aided by fermenting leaves, they will travel rapidly. If in pots they will most likely show and set plenty of fruit before they reach the extremity, otherwise constant pinching and keeping the roots slightly on the dry side will soon produce the desired effect. Two to three fruits to each pot plant will be found quite sufficient, and these should be of uniform size at the outset, to insure their swelling away evenly together. When the size of pigeons' eggs, top-dress with fresh loam and bone dust, water copiously with diluted liquid, shut up and syringe in time for the temperature to touch 90°. Plants from which the latest crop of fruit is to be cut should always be grown in pots, or on very small hills placed immediately over the hot-water pipes, from which they will derive great benefit through September and October. For the present, fermenting material, consisting of leaves and a little short stable manure, will produce a moist genial heat which will rush them on rapidly, and insect pests will hardly put in an appearance.

Pits and frames.—One of the great secrets of success in the management of the frame ground is the performance of every operation at the proper time. Earthing up, for instance, should be completed as soon as the young vines have started away freely and the roots begin to creep through the sides of the hills. If the latter are in a moist growing state from a preliminary watering, rather dry soil which will stand firm ramming may be kept sufficiently moist by daily syringing until the new roots begin to work through it, when tepid water in moderation will produce fine wiry growths, whose first break of laterals can hardly fail to set a plentiful crop of fruit.

The Cherry House.

If the long spell of hot dry weather did not necessitate the removal of the roof lights from the Cherry house proper, they should now be taken off to give the trees the benefit of cool refreshing dew and summer rains. Water in moderation must be given to the borders, and the latter should be well mulched with manure, rich or poor, to keep in moisture and prevent the roots and foliage from ripening prematurely. Cleanliness and freedom from spider are, of course, important factors, as the annual forcing of an excitable tree like the Cherry produces a tendency to autumn flowering. These, then, must be secured at any cost by a liberal use of the hose after sunset, or an occasional washing with soapsuds from the laundry. If any of the pot trees require a shift, this is a good time to take them in hand. The compost which suits them best is sound calcareous loam, rather inclining to heavy than light, but where this cannot be obtained lighter soils can be corrected by the addition of marl, burnt clay, and old lime rubble. The principal points to be observed are well-moistened balls, good drainage in clean dry pots, and firm ramming to prevent the possibility of the escape of water. If the trees can be kept under glass for a fortnight where they can have slight shade and daily syringing the roots will soon take to the new soil, when they will be fit for plunging in the open air for the remainder of the season. Trees which do not require repotting should be taken out of the house as they are cleared of fruit, well washed with the hose, and while lying on their sides examined to ascertain that the drainage apertures are not clogged. These also may be plunged in the soil to keep the roots cool and moist as well as to economise watering, and old trees crowded with spur wood will take no harm from a surface covering of rotten manure.

Early Plums

from which the fruit has been gathered may be treated precisely the same as Cherries not only through the autumn and winter, but quite up to the flowering period next spring. When pot Plums become aged they make very little wood which requires pinching; consequently the spurs increase and require annual thinning. The dormant season is generally considered best for this operation, but I prefer thinning as soon as the fruit is gathered, as the spurs left then have the benefit of exposure to sun and air and the flower buds fill up and ripen well. When early and mid-season sorts have been removed, the late varieties, which have not been allowed to root into the borders, can be re-arranged, top-dressed, and well fed until the fruit is properly coloured. Then, if kept moderately moist at the root, in a dry atmosphere and safe from birds, Golden Drop and some others will hang for a long time and improve in quality.

Strawberries.

If runners that were pegged down on the fruiting pots early in the season are still attached, all that have made good progress should be removed forthwith to their ripening quarters. It is not a good plan to detach them too soon, as they derive great assistance from the parent stools, but unless they are quite clear of shade and convenient to water, strong growth will be no advantage where perfect maturation of the crowns is doubtful. The station for these plants should be high and dry, fully exposed to sun and light and worm-proof. We sometimes see long rows of plants placed near the margins of garden walks, and very nice they look, but gravel kept constantly moist by frequent waterings soon becomes infested with worms, ever on the outlook for good living. This all good Strawberry composts contain, and soon they will pass the slight barrier of soot placed over the crocks, unless measures are taken to circumvent them. An occasional soaking with soot or lime water will most likely have the desired effect, but the best way to escape these enemies is to avoid them by placing the pots on blocks on properly prepared stations. When arranged with plenty of room for the air to pass through the lines of pots and the foliage to assume its flat natural habit of growth, they must be kept free from weeds and runners. In course of time, a general turn over to give them still more room and prevent the crock roots from striking into the bed of ashes or gravel will be necessary; indeed, where time admits, the more frequent the change of position, not only of Strawberries, but of all other pot plants, the better. Watering is, of course, a very important operation, as Strawberries are great lovers of moisture, and should never feel the want of water from the beginning to the finish. This element, then, must be given with a liberal, but careful, hand—never in driblets, but thoroughly and effectually when needful, and as often as the state of the weather renders necessary. Evening watering, after the sun has gone down, answers best through July and August, and the watering pot is more suitable than the hose, as wetting the foliage in hot weather can be avoided.

Eastnor Castle, Ledbury. W. Coleman.

Fruit Garden.

GOOD STRAWBERRIES.

With new varieties of Strawberries, as with most other fruits, the general tendency for a long time has been to attach importance to size, and weight of crop, rather than to good edible properties. If a new variety is raised that produces fruit unusually big and good looking, it comes out with a glowing description. Numbers of people are tempted to procure it; the fact of its being new is sufficient, even after it is tried, to cause many for a time to overlook what defects it may have. Strawberries being so easily raised and taking so little time to come to a bearing state, coupled with the rapid rate at which they increase, have resulted in the numbers of acid, flavourless varieties that now abound. The descriptions that are usually given of much the greater number of the sorts now grown, and which in reality have nothing except appearance to commend them, are that they are pleasantly acid, brisk in flavour, and the like. When anyone names a new Strawberry to me, I ask, is it sweet when fully ripe? As they now exist we have a great deal too many varieties that require sugar when eaten, which, in my estimation, is sufficient to condemn them, as most of the natural flavour is thereby destroyed, and though tastes differ in the case of this, as in that of other fruits, most people that I have met with who have had sufficient opportunity of judging of the merits of fully ripe fruit of good kinds think as I think. A Strawberry that needs sugar is not worth growing for anything, except cooking. Unfortunately with Strawberries, as with most other fruits, good varieties are less easily grown than inferior ones. Strawberries are more affected by the nature of the soil than most fruits, particularly the best sorts, which are less able to thrive and bear well in all sorts of soil than most things. Take, for instance, British Queen—the variety *par excellence*; it is not nearly so accommodating as the generality of kinds. Proverbial as Strawberries are for liking strong heavy soil, this variety seems to be least able to thrive where the soil is light, unless in the case of land that is newly broken up. In such the Queen will usually be

found to answer for some years, provided it is replanted as often as required. But it is only for a limited time that it will succeed in light land, the plants beginning to die off, and those that live not bearing as they should; whereas if the soil is heavy enough—the heavier the better—it will continue to thrive and bear well. In this locality the soil is a heavy tenacious yellow clay, that when newly dug, even after being broken up for many years, looks more like earth about to be prepared for the brick-maker than anything else. As an evidence of how the variety named will continue to answer in such land, I may mention a field in the hands of a market grower that has been eighteen years occupied by this sort with no change of crop, the old plants being destroyed when they showed signs of weakness, the ground re-trenched and again planted. In another field near the one just mentioned, after being broken up from Grass, the first lot of plants put in stood for eleven years before they were renewed, and, needless to say, those who grow for market do not indulge in fancies or put off clearing away anything that has become unprofitable.

From the time that the British Queen became fairly known I always grew it, in old gardens where the soils varied from light sandy loam to such as was of a black description, approaching to peat, and never until I came to this part in soil that was naturally suited to Strawberries. Yet we continually hear people saying that they have been obliged to give up growing this finest of all Strawberries on account of its refusing to thrive, and not unusually complaining that other sorts that at one time answered well do but very indifferently. The fact is that, except where the land is not more than ordinarily heavy and adapted for Strawberries, new material must be added if the Queen and others of the best sorts are to answer as they should do. What I have used was marl where I could get it, and where not, clay. There are few places where the latter cannot be had at little cost in sufficient quantity for the requirements of Strawberry growing in private gardens, and clay is so little inferior to marl in its effects on the soil in old gardens, that it is not worth while incurring much expense in procuring marl. Five or six inches of clay should be laid on the surface, either in winter or before the plantations are made, and allowed to lie until it has become mellowed by the weather; then the March winds or summer's sun, followed by a little rain, will soon pulverise it sufficiently, when it should be forked in and mixed with 6 in. or 8 in. of the top soil. Before the clay is put on, the ground should be dug deeply, putting in a good dressing of manure. At the same time, the fact of Strawberries liking heavy land points to the necessity of their having the soil made solid; this will be best done by treading the surface before planting until it is close and hard. A dry time must be chosen for this as well as digging in the clay, otherwise, instead of its mixing evenly with the soil, it will lie in large soft lumps that the roots of the plants will not enter so freely as they should do. Those who have not tried, or have not had an opportunity of seeing what can be done in growing Strawberries in old gardens, where the soil is light, by clay dressings, may rest assured that the little cost and labour involved will be repaid to an extent that they could not have looked for. I may, however, say that it would not be reasonable to expect that a dressing of this kind will enable a plantation to last so long as it would do in land that was naturally heavy. Three years will usually be found long enough to allow the plants to remain, when they may be cleared off and the ground replanted after being re-dug, but not deeply, unless more clay is added, or that which is already present will get down too deep to be within reach of the best roots. It is scarcely necessary to say that in light, hardworn soil, such as that under notice, it is good practice, each time a new plantation is to be made, to prepare a fresh piece of ground in the way advised. By this means a garden in time can be renovated in a manner that will effect a marked improvement in other crops as well as Strawberries. In dry summers Strawberries suffer in light land unless means are taken to water them. Where the leaves flag from want of moisture, as is sometimes seen, it is not to be wondered at that the plants go off where the soil is light and has been subjected to a long course of cropping.

Those who grow Strawberries for market give preference to the kinds that have big, good-looking fruits and that are the freest growers and heaviest croppers. In addition to this the fruit must be hard in texture, so as to bear packing and carriage without bruising. Needless to say, these properties are much seldomer present in sweet, high-flavoured varieties than in the coarser acid sorts. Those who do not grow their own Strawberries, and consequently have to procure such as they require from the ordinary sources, may be said never to taste the fruit in the condition it should be in, as, even if the varieties obtained are good, the fruit is gathered before the full amount of flavour and sweetness natural to it is present, and which it only acquires in the last stages of ripening. When Strawberries have arrived at this state they are too soft, and too near the stage when decay begins to be of any use to retailers.—T. B.

Strawberries for Forcing.

Opinions differ as to whether it is best to grow Strawberries for forcing in large or small pots, but, according to my experience, pots of fairly large size are better than small ones. I do not object to 5-inch pots for the earliest crop, which ripens at a time when there is not much solar heat to dry up the soil, but unless there is an unlimited supply of labour it is better to have larger pots; they hold a greater amount of soil, and consequently do not require watering so often as pots of smaller size. These are considerations which should influence the cultivator according to the circumstances under which he is placed; for the most part, growers who advocate the use of small pots are those who do not find any serious difficulty in keeping them well supplied with water during the trying months of April and May. Those who want large fruit and desire to keep their houses clear of red spider should use 6½-inch or 7-inch pots, and should put two plants in each pot unless they can comfortably command sufficient labour to keep the watering-pot going. We had a number of plants fruiting in 4½-inch pots in May last, and although in bright weather they were watered twice a day, the number of fruit which they bore was not in proportion to the amount of labour involved compared with those in pots 2 inches larger and with two plants in each pot. We are now engaged in preparing our stock for next season's forcing, and are only using 6½-inch and 7-inch pots. Instead of putting the plants in the centre of the pot we put them on one side, about 2 inches apart, so that when in fruit the trusses may hang over towards the light.—J. C. C.

Different sorts of Strawberries.

I have sent you a collection of Strawberries, some of the varieties of which are neither so well known nor so generally cultivated as they ought to be. Some of the earlier well-known kinds are past their best. Just now we have Crimson Queen, Dr. Hogg, Unser Fritz, and John Powell at their best. I place the fourteen kinds cultivated at Gunton thus as to ripening, viz.: Mr. Radclyffe, Sir J. Paxton, Vicomtesse Héricart de Thury, Countess, and President, followed by Auguste Nicaise, James Veitch, and the Comte de Paris, the rear being brought up by Amateur, British Queen, Sir C. Napier, Dr. Hogg, John Powell, Unser Fritz, and Crimson Queen. The varieties just enumerated are all so good, that I should scarcely know which to discard if called upon to do so, every one of them being prized either for size, colour, or flavour. As to the last, which is to many the most important desideratum, I would place, first, Vicomtesse Héricart de Thury, Mr. Radclyffe, President, Sir J. Paxton, Countess, British Queen, and Dr. Hogg in their order of ripening. If one would keep up the fruitfulness of one's Strawberry plantations, it seems a mistake to layer young plants from any but those full of fruit. Blind plants generally give the strongest runners and should be avoided. When I first cultivated James Veitch, 50 per cent. were blind or barren; while, from observing the above rule, out of a hundred plants this year I have only noticed one barren. I would also suggest to those who have failed with British Queen, from the soil having proved to be too light, to try the following: clay, dried and reduced to powder, and then applied as a top-dressing to the quarter or piece of ground intended for its cultivation. I have found most beneficial results from this practice, British Queen and Dr. Hogg fruiting as freely under such circumstances as other varieties, whilst formerly they proved to be very shy croppers. Our Strawberry crop this season has been unusually fine. Of fruits of James Veitch and President, the first weighed 3 ozs. and the last 2 ozs. each. Through mulching when in flower, and giving a good soaking of water before the nets are put on, they have not suffered from drought. I ought to have stated earlier that Mr. Radclyffe and Countess are nearly over, and that the fruits sent are only one-third the size of those of the first picking. These two Strawberries are not much grown, but they, nevertheless, deserve a place in every collection where earliness, colour, and flavour are desiderata.—Wm. Allan, *Gunton Park, Norwich.*

*** Mr. Allan sends us a most interesting contribution to the Strawberry discussion in the form of some fine specimens of kinds little known, for which we thank him very much. Like all his things, they show cultivation of quite an exceptional order. We have never seen more remarkable or more perfectly ripened fruit. Mr. Radclyffe is not a large fruit, but possesses a pleasant and distinct flavour. Auguste Nicaise was not so ripe as the other samples, and therefore we could not judge of it fairly. Countess is very well coloured, moderate in size, fairly well flavoured, with not much acid. James Veitch is large and fine, but in this case flat and dead in flavour. Dr. Hogg is large, almost a monstrous fruit, angular in form, and though occasionally with an agreeable acid, has an unpleasant after-flavour. John Powell is a big well-coloured fruit, rather monstrous, but decidedly not well flavoured—a somewhat unpleasant acid. Crimson Queen is highly coloured and large, with a pleasant flavour, and without the subtle acid noted in some of the other kinds. Unser Fritz is well coloured, well grown, large and wedge-shaped, rarely monstrous. The flavour of this is decidedly on the good side, with the faintest suspicion of after-flavour; on the whole, it is a kind which we should like to taste when quite fresh and compare with others, though it seemed not quite so good in flavour as Crimson Queen, which we happened to taste before it. Lastly, comes the British Queen, which, though a little past its best, consists of the finest specimens that we have seen this year. Mr. Allan's hint on the cultivation of this will be most valuable. Every gardener should try all he knows to grow the British Queen. It is the best of all Strawberries, and it is useless to say anything about its high flavour, which can only be known to those who get it in good condition. If our powers were extensive enough, we should set all those who are spoiling the Tomato by raising new and monstrous varieties, sending out what they call seedling Melons, one worse than the other in flavour, and crossing the distinct delicate little Brussels Sprout with the flat Dutch Cabbage, to raise a few Strawberries as worthy of English gardens as the British Queen. The fact is, the monotony of the common market Strawberry is intolerable and the flavour poor. If we cannot go forward to better things let us go back a bit towards the varieties that are even possible to us with our present knowledge of Strawberries. The little despised Four Seasons Strawberry, so seldom grown, has a better flavour than most of those commonly grown for market.—Ed.

Loxford Hall Seedling Strawberry.

Mr. Walker sends from Dunorlan some notes on Strawberries, and at the same time some speci-

mens of the Loxford Hall Seedling, not in quite such good condition as those referred to above. The fruit seems to be seedy, but on the whole we think distinctly an advance in flavour, and well worthy of trial. If one gets delicate and good flavour, little defects, such as green points, are not of much account. The British Queen itself has a greenish point.—Ed.

PEACH BUDS DROPPING.

Anyone who has watched the behaviour of Peach trees in different soils and climates will have noticed that there are other conditions besides dryness at the root during winter that cause buds to drop just as they are on the point of opening, and an observant cultivator will have no difficulty in assigning one cause at least to be a rich border, and its attendant results in the shape of gross wood, which scarcely ever gets ripened. From such wood buds invariably drop. How, therefore, to prevent this grossness in the wood should be the aim of every Peach grower. It is well to remember, too, that vigorous immature wood is more liable to be injured by severe frost than smaller growth that has been properly ripened. There is, therefore, more than one reason why the condition of the roots, as indicated by the growth of the branches, should be carefully noted, and any undue luxuriance checked by timely attention. In the case of trees carrying good crops that are producing stronger wood than is desirable, some of the vigour may be taken out of them by allowing them to carry a greater number of fruit than would be allowed on weaker trees. The advantage of this will be manifest later in the season in a more even growth, and better ripened wood. Peach trees are sometimes encouraged to make too much growth through the application of rich mulchings. The latter should not be applied to young, vigorous trees. Old Peach trees are very different, especially if carrying a good crop. In that case, a rich mulch over the roots not only increases the size of the fruit, but assists in sustaining the vitality of the tree. It should be as much the business of the cultivator to nourish and take care of the branches that are to furnish the next season's crop as it is to take care of the fruit of the present year. Only by such a course can one hope to meet with uninterrupted success. In some gardens a too free use is made of liquid manure—*i.e.*, old and young trees are alike treated to regular supplies of it regardless of growth. Young trees occupying newly made borders are induced to grow much too vigorously, and owing to such growth being immature at the end of the year the buds are imperfectly nourished, and fall off just when they are expected to open. In dry, hot weather young trees may require root moisture as well as old ones, but the condition of the growth should decide whether it should be liquid manure or clear water. There is no more trying time for Peach trees on open walls than the month of August; many sorts during that month will have finished stoning, and the fruit will be swelling fast. It is at that time that there is the heaviest strain on the tree, and any assistance that can be given then in the shape of root moisture, or surface mulchings, should be given with no sparing hand. Much also may be done to help the trees by the judicious removal of weak and useless wood. In many cases short branches of last year's wood on which there are no fruits may be cut out, and the strongest of the young growths made to take their place. It is timely attentions of this kind which go far to secure success. Deep borders in which the soil is naturally strong have more to answer for when the buds of Peach trees drop than some are willing to acknowledge, especially in the early life of the trees. When the roots work deeply in a good soil, the growth is always stronger than when the soil is not so rich nor so deep, and for that reason judgment is required in the management of both roots and branches. I am far from advocating a poor medium for the roots; on the contrary, I prefer giving them 2 feet in depth of the best loam I can get, and this I like to get firm about them, and not to disturb them in any way afterwards; but a greater depth than 2 feet is not required for the production of medium-sized branches, and as regards strength of wood, that is all that should be aimed at in Peach culture. As regards root moisture, more trees suffer from want of it than from its excess in ordinary seasons. While borders are cropped with vegetables to within a foot or two of the trees (no uncommon occurrence) no one can feel surprised if the trees do not thrive satisfactorily, for it is impossible for the roots to get either the warmth or the moisture that they require. Under such circumstances if the buds do not fall off, they get so weak that they cannot stand the trying spring weather. Red spider is a serious enemy to Peach trees, and if allowed undisputed sway it not only injures the present season's crop, but the succeeding one; for if the leaves get much infested by it, they fall off prematurely; the consequence is, the bud to which they were attached does not become properly mature, and then it falls instead of opening. In the management of Peach trees it is not safe to wait until red spider appears before the remedy—syringing with water—is applied. "Prevention is better than cure," and if the trees are syringed on the evenings of fine days from the beginning of June onwards, red spider will not effect a lodgment, and buds falling from that cause will thus be prevented. J. C. C.

Ranunculus glacialis. Flowers yellow.

Reinette Abry Apple.—This is a local kind which appears to have originated in the neighbourhood of Montlignon. It is said to be exceptionally fertile, and the quality of the fruit, which is of moderate size, is stated to be excellent, the flesh being white, tender, juicy and very agreeably perfumed. The tree is a vigorous grower, but naturally assumes a compact form, and for that reason it is recommended to be employed where double grafting is necessary.—J. C. B.

ALPINE CROWFOOTS.

With the exception of the Primrose, perhaps no genus represented in our native flora is more familiar to us than the Buttercup, which is a good example of the Crowfoot family. The genus taken as a whole is an extensive one, being represented largely in nearly all temperate countries. The prevailing colour of the flowers is yellow, but there are also some good whites, of which R. alpestris may be taken as an illustration. Some are dwarf and creeping and well suited for rockeries; others are large and well adapted for flower borders and beds; under this head may be included the Persian Turbans, amongst which are some of our choicest flowers, and although rather difficult to manage successfully, we have nevertheless seen very creditable shows of them in many places, even in the neighbourhood of smoky London. Some also do well as bog plants, including that New Zealand wonder, R. Lyalli, which has flowered at Kew in a cool house, but we believe it also shows signs of blooming in the open air there. The water-section of the genus which inhabits our lakes and streams, and clothes them with sheets of white flowers during summer and autumn, is well worth the attention of all who have artificial waters. The species known as Bachelor's Buttons (R. aconitifolius) may be seen of various sizes in almost every cottage garden, as well as R. asiaticus, of which there are a few really handsome forms. The alpine section, including R. glacialis, the species here represented, is largely grown in our gardens, so much so that we could ill dispense with it in spring. The great difficulty with alpines generally, and Ranunculi in particular, is the want of pure air, a want of course most felt in the vicinity of large towns, and, what is just as important, keeping them in a comparatively dry state during winter. Choice of a position should be carefully made; the highest and driest fully exposed situation has proved to be the best. In the soil, which should be gritty, sand should predominate. Many alpine Ranunculi ripen seed with us, but the readiest way of increasing them is by division, which they stand to almost any extent. Autumn, after the leaves have become brown, is the best time for the operation. The divisions should be simply dibbled in at the required distances apart; care will, however, be needed in the case of R. glacialis; it forms finger-like tubers that are readily damaged. R. amplexicaulis is a very ornamental species, and a very desirable one; it grows about a foot high; the upper leaves, which are of a pretty glaucous colour, clasp the stem, which is surmounted by large delicate white flowers. It is a native of the Pyrenees and flowers in April and May. R. anemonoides, which is rather a new species and dwarf in habit, has finely divided leaves, which, forming as they do a dense tuft, are of themselves ornamental, and the flowers, which are produced freely, often measure over an inch in diameter. They are white tinged with purple or rose, and very handsome when

about to open. This species, which flowers in early spring, does well on rockwork in a light position in fine gritty soil. R. montanus is a well-known garden plant of dwarf growth, very easily managed, and well worth growing in large quantities. It has large yellow flowers and forms a good companion to the fine white-flowered R. alpestris. Amongst others may be named R. ophioglossifolius, parnassifolius, rutæfolius, and Thora. K.

Kitchen Garden.

POTATOES, EARLY AND LATE.

At present it is doubtful whether or not we shall secure very good crops of Potatoes. Many of the second early sorts especially are ripening prematurely, and the very latest, notably Magnum Bonum and Scotch Champion, are, as a rule, making poor progress. The weather at the commencement was very much against them, the ground being both wet and cold, and then before they had properly recovered a long spell of hot and dry weather completely stopped their growth. In our district we have not yet had sufficient rain to well soak the ground, and unless we get more soon the tubers generally will be much smaller than usual. In many cases the rain came too late to benefit early and second early varieties; in fact, it has done more harm than good, as where left undisturbed they commenced growing again, and two crops of tubers together is almost worse than disease, as they cannot be separated; nor are they really fit to eat. Our plan, and one which others should also adopt, is to anticipate the second growth, either by lifting or storing at once, or by drawing up the haulm—the former preferably, as, if they have already started, drawing up the haulm may not completely check the tendency to grow again. The worst offender in this respect is the Edgcote Purple. On examining the rows of this variety about three days after the rainfall on July 12, we found that the majority of the tubers had already sprouted badly. In the southern and midland counties I should say all early and second early Potatoes may now be safely lifted and stored for future use, as they are sufficiently ripe, and if left on the ground are both liable to become diseased and to form a second growth. According to my experience, Potatoes never were better in quality; even the soapy American varieties, including the old Early Rose, which some of the cottagers still cultivate, are fit to eat. Particularly good are the Ashleafs, and on the whole these are the most profitable; we have this season some of them even larger than we care to send to table, and all of them are cropping heavily. Where garden ground is of limited extent growers will do well to plant the Ashleaf varieties extensively; they require but little space, mature early, and keep well. We have had them of excellent quality at midwinter, and so convinced are we of their superiority that each season a larger piece of ground is planted with them than previously. True, they are more liable to disease than sorts with stronger haulms, but it frequently happens that they are ready for lifting before disease makes much progress. By early lifting we avoid the evil, and the ground is ready for being planted with Strawberries, Broccoli, Savoys, and winter greens, or for being sown with Turnips, Spinach, Endive, Lettuces, and other quick-growing vegetables.

Home-grown seed best.—Many advocate a change of seed, and in the case of the rounds and late sorts generally it may be an advantage, but I much prefer to save my own sets of the Ashleafs, as well as of Lapstone Kidney and any sorts resembling that good old Potato. Trade growers necessarily store in large heaps, and consequently the valuable first sprouts are spoiled, or if stored thinly they cannot, or do not, attempt to preserve the sprouts when packing the tubers. We always try to plant the kidneys just named with the strong central sprout intact, all others being rubbed off, and if this is not injured by frost an early and extra good crop is the result, while if damaged by frost it yet recovers, though a lighter crop is the consequence; this, however, is superior to that obtained by planting sproutless and previously weakened sets. My advice, therefore, is to save as many of the medium-sized tubers of the Ashleafs as can possibly be spared, or if these be scarce to buy at once while they are yet cheap and plentiful, and to store them thinly in boxes or on shelves in a light airy shed or room. No attempt to green them by laying them on the open ground for a few days should be made, as if disease is at all prevalent it may affect them, and, besides, nothing is gained by greening sets. If the old Ashleaf can be procured, that is the best for frames and early borders, and this season it has been remarkably good both as regards weight and quality, but this good old sort is not fit for use long after it is lifted. The next best for frames, warm borders, and open quarters is Veitch's Improved Ashleaf, and of this well-known sort we have lifted six sacks of tubers for use and seed purposes. Myatt's Ashleaf is usually a heavier cropper than the last named, but this season the tubers are somewhat smaller. They are, however, still quite large enough, as we always prefer medium-sized tubers of any variety to large ones, unless they are to be baked. If the true Myatt's Ashleaf is obtained it is sure to give satisfaction; both this and the old Ashleaf have been cultivated in a large garden near here without a change of seed for fourteen years, and the crops are as heavy and good as ever. According to my experience, Mona's Pride and Veitch's Improved are synonymous, but an experienced cultivator assures me that they are quite distinct. Mona's Pride is a great favourite with him. Of early rounds I prefer Early Border; this forms but little haulm, and produces a good crop of handsome tubers of excellent quality. Sutton's Early Regent, as a successional variety, is also worth cultivating, as it matures early and the tubers are of extra good quality. The Dean, a round purple-skinned kind, grown for the first time this season, is cropping heavily, and the tubers are very handsome. Amongst new sorts it is one of the most promising, and if it proves of good quality it should be grown extensively. The well-known Reading Russet has also done remarkably well, and we have abundance of handsome tubers of it fit for exhibition. Lapstone, Cosmopolitan, Welford Park, and Woodstock Kidneys are all clean and good this season, and if our later sorts turn out equally well we shall have no reason to complain.

Successional crops.—Our late varieties of Potatoes are cultivated principally outside the walls, and are liable to be attacked by all sorts of game and vermin; only the early and second early sorts occupy ground that has to be cropped a second time in the same season. The Ashleafs are in rows 3 feet apart, and between some of the rows are planted Broccoli of different sorts, while the stronger growers just mentioned are given another 6 inches between the rows. Between the latter also we plant winter produce, principally Broccoli, and directly the Potatoes are lifted, if the weather is dry, the Broccoli receive a soaking of water (liquid manure might be given with advantage on poorer ground than ours), and they are then heavily moulded up, which serves to preserve the moisture and to steady the plants. Then, as the Broccoli do not require all the space, the ground previously occupied by Potatoes is planted with a row of either early Savoys or Coleworts. These, as well as the Broccoli, derive much benefit from a sprinkling of superphosphate, which was given to the Potatoes when planted, and which has not been much exhausted. Our successional crops are really of more value than the Potatoes, but they take more out of the ground, and this fact must not be overlooked by those who are anxious to maintain their garden in a fertile, and therefore profitable, state. Where it is intended to follow early Potatoes with a new Strawberry plantation, all that is necessary is to level the ground as the crops are lifted, breaking it up finely and clearing off all rubbish. Then if the ground is well trampled, shallow drills can be drawn, which may be filled with water if the ground is dry and "nubbly," and in the course of a few hours the plants may be planted firmly and properly. This will be found a better plan than manuring and deep digging at this time of year, as what manure the Strawberries eventually require may be given in the form of mulchings and top-dressings. Ground just cleared of Potatoes is usually very dry, and when sown with seeds of Turnips, Lettuces, Endive, and Spinach, much time will be gained by well watering the drills prior to sowing the seed. This insures a good even start, and is much preferable to watering after the seed is covered.

Somerset. W. I. M.

WINTER SPINACH.

Next to a good breadth of Brussels Sprouts for furnishing a supply of green vegetables during winter is a corresponding space devoted to winter Spinach. For this an open position is desirable, as drip from trees is very injurious to it in winter; a moderately rich and deeply moved soil is also essential. In naturally retentive soils it is desirable that means should be provided for allowing surface water to get freely away, for ground under Spinach is necessarily much trodden upon in all weathers, and if very moist it becomes pasty and unfit for root growth. In the early part of my experience I used to sow my winter Spinach in drills 1 foot apart, but in strong ground I found that width to be a mistake, as the leaves extended on each side of the rows so far that it was impossible to get between them without injury, which, in winter when the plants are growing slowly, is a loss. When, too, the rows are so close together the leaves have not room to grow so large as they would otherwise do, and at any time one large thick leaf is better than two small ones. I now place the drills 16 inches or 18 inches apart, according to the character of the ground, and I get more satisfactory crops every way. With regard to the time of sowing, there should no doubt be a difference between the north and south of the kingdom. For the latter the 12th of August is the old-fashioned date, but I need hardly say that a few days either way—before or after—do not make much difference, and no doubt a week earlier than the date just given would best suit the north. From experience I am satisfied that where there is a large demand it is best to have two sowings, one a week later than the other, the first in the open quarters and the other on a border facing the west. That in open quarters should be the first to be used, while that on the border should be reserved for use early in spring. I like a reserve in a sheltered place; although frost does not, as a rule, injure the plants the cold north and east winds do, and often so wither up the leaves as to render them useless. A border facing the west and sheltered by a good wall will often furnish a supply of Spinach when there is not a green leaf on more exposed plants. If ground on which it is to be put has been recently dug up it is best to tread the surface along the lines where the rows are to be in order to firm the soil, as if the surface is loose and the weather dry the seed would be long in ger-

minating. The plants should be thinned as soon as they are large enough to handle. I like them to stand 6 inches apart. In gardens in which wireworm is troublesome it is a good plan to sow a little soot along the bottom of the drill before the seed is put in. If soot does not drive them away altogether it at least checks their attacks. The variety of Spinach with prickly seed is supposed to be the hardiest; I have, however, tried both that and the round-seeded sort, and I have not found any difference between them.

J. C. C.

TOMATOES AS CORDONS.

After trying various plans with Tomatoes, I am decidedly in favour of the single stem, or cordon, which does away with the growth of useless wood and leaves, and thus concentrates the energies of the plant on the crop. If all side shoots are kept cut out directly they are large enough to get hold of, nothing is left but stout single stems clothed with large leaves from base to summit; after these stems attain a height of about 2 feet they cease to grow rapidly, but make very short joints, at each of which there are bunches of flowers, so that there is no difficulty about getting the requisite quantity of fruit. Few crops are more easily grown than Tomatoes, which come in well for filling up glass structures that may not at the moment be required for other purposes. Our plan is to sow the seed in February, and to grow the young plants on in a genial temperature until they are in 6-inch or 7-inch pots and beginning to set their fruit. We then fill boxes of any kind with rich soil, and, after making the drainage hole at the bottom of the pot sufficiently large for the roots to pass readily through, we plunge the pots half way into the soil, and by this means can get a good crop on stages, or in any position where it is not possible to plant out in regular borders. It matters not what the receptacle into which they are plunged is so long as a good rooting ground can be provided for them. We have a double row of huge plants in 7-inch pots, rooting through into large flat baskets filled with rich soil, and as a catch crop I do not know of anything so useful. We have several varieties, both new and old, but the main thing is to get a good large, smooth Tomato without the deep furrows so conspicuous in the imported kinds, and in this respect we do not find many to excel a good selection of the old smooth Red. It is good in colour, and all that can be desired as regards quality when well grown. Tomatoes are not usually difficult subjects to keep free from insect pests, but a sharp look-out should be kept to check the first symptoms of aphides, as it is surprising how soon they disfigure the young fruit if they happen to get established on the plants while the fruit is small and tender. "Prevention is better than cure," and, therefore, slight fumigations should be given before any fly is visible. We find liquid manure from the stable or cow house to be one of the best and safest stimulants that can be given for increasing the weight of the crop; failing this, a sprinkle of guano or of any highly concentrated manure sold in a powdered state, and watered in, will be of much benefit. As regards water, Tomatoes like an unlimited supply during bright weather. Of new sorts that promise well may be mentioned Earliest of All. This crops well under glass, and it is also said to be exceptionally well suited for open-air culture, but of this it is too early yet to speak.

Gosport. J. Groom.

Peas, old and new.—I am this year growing amongst other Peas some Champion of England. It is not long since this Pea ranked amongst the best and most popular. Now it is seldom grown, a circumstance not to be wondered at when we compare its pods with those of the newer sorts. It is as prolific as the best as far as number of pods is concerned, but we want bulk as well as number now-a-days, hence in Telegraph, Telephone, Duke of Albany, Prodigy, Giant Marrow, President Garfield, Reading Giant, and other tall Peas we find in addition to fair quality in some really excellent quality in others, all having fine pods. Duke of Albany has been shown on several occasions in very fine form, and it seems to be a first rate Pea. Mr. Eckford has recently come to the front as a Pea raiser, and has produced some fine kinds, both tall and dwarf. Mr. Laxton has given us quantities, good and otherwise; and Mr. Culverwell some superb Peas; therefore, there is no lack of sorts difficult to excel, and I feel sure that all Pea growers will say that for all purposes their pods are big enough; indeed, if varied at all, they may be if longer rather thinner, as big Peas in the pods are not desirable. It is strange that in the matter of first early kinds for general cultivation we should have made so little progress. I find that market growers who have tried the later novelties all complain that the pods are too small, and that none are so good as a well-selected stock of Sangster's No. 1 for their purpose. It is of little use to provide small podded Peas of which so many are required to fill the bushel.—A. D.

WASTE OF GARDEN PRODUCE.

At the present time, when things are ripening off so rapidly in the kitchen garden, it may be well to remind our readers of a fact to which we have before drawn their attention—that is, the great loss of vegetable produce in its best state, owing to our habit of not cutting things when they are ready. We think people would be surprised if they knew the amount of loss that takes place owing to this. Even in the small gardens of poor people one sees lines of Peas and other valuable produce allowed to ripen off and become useless. It is too often the custom not to cut the crop until it is too large, and inasmuch as two or three hot days suffice to make it useless when it arrives at that state, the major part of many crops is often lost. The remedy is, we think, to use things generally in a much younger state than is commonly the case. Many things are not half so good in quality when allowed to get old as when young—Radishes, Cauliflowers, Cucumbers, Peas, and Beans to wit. But even this way of using things when very young is not enough. We think that in many cases the only way out of the difficulty is to gather all the vegetables ready, whether they are wanted or not. To merely depend on the order of the cook or housekeeper for what is to be gathered is a mistake; she may not know what is in the garden. No amount of care in urging on gardeners that things should be eaten young will suffice. If we wanted to eat gardeners or human beings, it would be easy to convince people that three-year-old babies were more toothsome than old tough adults; but it is extremely difficult to explain to them that the difference between young and old vegetables is quite as important. We have known men lose their places because they would persist in sending up things when too old. The whole thing is bound up with the ridiculous false estimate as to the value of size and weight. The best plan is to lay down a rule that in summer time all crops that quickly perish should be gathered daily, whether wanted or not. In large places it would be well worth while to have a woman or boy continually engaged in gathering the produce, which should be placed in some cool or pleasant place in or near the house, and submitted to the cook. Then, after she has taken all she wants for the day's supply, it will be better to give the rest away as presents, or to adopt some such mode of preserving green vegetables as the Dutch do, than to let it destroy itself in the garden. It is not only the loss of the present day's crop that is to be deplored when daily gatherings are not made, but there is the injury to the successions which should follow, because, if we allow vegetables, such as Marrows or Peas, to ripen, there is little left in the plant for the young crops. Readers who have any doubts in the matter could probably soon set them at rest by making a few experiments in the garden.—*Field.*

Tomatoes for winter.—This is a good time to put in cuttings to make plants for bearing early in the new year, as unless well attended to old plants that bear heavily all through the autumn will be exhausted by Christmas, and under any circumstances I would rather begin the year with young vigorous unchopped plants than old ones. Insert the cuttings, which should be taken from strong leading shoots, in small pots singly, using light sandy soil, setting the plants in a close frame, and shading them till rooted. Shift them into larger pots as required, and keep them in a sunny position in the open air till the end of September; they should then be placed in a warm greenhouse and trained near, *i.e.*, within 12 inches of the glass. During the time when the plants are going through the preparatory stage in the open air, a stake should be placed to each plant, as if blown over and the stem injured the growth will be weakened.—E. H.

BUSH VEGETABLE MARROWS.

It is singular how slowly really good things spread amongst horticulturists, while worthless novelties are found all over the kingdom in a very short time after their introduction. This variety of Marrow is not new nor rare, but it is apparently very little known. During the past season I have received scores of inquiries as to where it can be procured. I do not mean to say that it is better than other Vegetable Marrows, but I can safely assert that it possesses qualities that commend it for general use. In the first place, I have proved it to be the hardiest Marrow I have grown. This spring we have put out plants of this variety, the custard, the long white, and the green striped; the nights were extremely cold and the days parchingly dry; consequently Marrows made slow progress; a good many, indeed, of the three just named died outright, and the rest looked more dead than alive until a sudden outburst of tropical weather infused fresh life into them; but during the whole time the Bush variety made steady progress, and anyone, even at a distance, could tell by its dark green look that it had withstood the chilly blasts much the best; moreover, as soon as warm weather set in, we had plenty of Bush Marrows fit to cut, but it will be some time before fruits of the other varieties are fit for use. Thus much as to hardiness, and I find its ability to withstand heat and drought is just as great. Last season when we had a vegetable famine by reason of the protracted drought, Vegetable Marrows were the only things we could get at a price to suit all-comers, and the Bush variety was then brought prominently into notice through great quantities of it coming into market. It is grown here in the open fields without any ridges of manure or special preparation, but simply planted between rows of early Peas about 4 feet apart each way. The Peas give shelter during the early stages of growth, and when cleared away the Marrows soon form large tufts of leaves resembling at a distance Rhubarb clumps. This variety does not send out running shoots; on the contrary, the fruit is borne in clusters, lying in heaps around the stem on short stubby shoots. For anyone desirous of growing a full supply of a good hardy vegetable capable of withstanding the trying character of our fickle climate, I can safely recommend the Bush Marrow. For amateurs with limited convenience as regards glass structures, or for growers for market, it is of the utmost importance to have vegetables that can be grown fully exposed after the middle of May; this season, however, those who exposed ordinary Custard or long Vegetable Marrow before the end of June found them to make but little progress. Marrows of any kind do not require nearly so much manure as is generally supposed they do; they are, in fact, more fruitful on good kitchen garden soil than on a manure heap. They should be planted in good soil and mulched with half decayed manure, which keeps the roots cool and moist, and helps the swelling crop.

Gosport. J. Groom.

American Tomatoes.—In the account of the American Tomato trial published in The Garden last week quite half the sorts were unknown to me. Some of these at least must be good, judging by the results of the trial. Would it not be worth while for some of our seedsmen to introduce some of the best sorts there named?—G.

MARKET GARDEN NOTES.

HYDRANGEA PANICULATA GRANDIFLORA.—One of the finest floral displays that I have ever seen was a large houseful of this Hydrangea in fine bloom last May. The plants were in 6-inch pots about 18 inches high, were furnished with well developed foliage to the rim of the pots, and carrying from two to four large heads of pure white blooms. As regards perfection of growth, each plant was the counterpart of its neighbour, and the effect of this mass of white blossom was almost indescribable. This Hydrangea is propagated from cuttings of the partly ripened wood, taken off in August, and inserted a dozen together in 6-inch pots in sandy soil, placing them in frames or in a cool house, giving a good bit of air in the morning when mild, and at night in very hot still weather. In this way ninety per cent. of the cuttings strike, and being wintered quite cool they are potted off the following year and grown along in the open air, becoming well established by the autumn in 4½-inch pots. Early in the year they are pruned in rather hard, and when they come into growth are shifted. During the early months of the year a temperature sufficiently high to keep them moving is maintained, and when the days increase in length they get from 65° to 70° by day, according to the weather. At this time and especially when developing their flower trusses, they require abundance of water, and from the time the roots touch the sides of the pots they get constant supplies of weak liquid manure. Without this constant feeding such a vigorous habited plant as this Hydrangea could not be grown to such large dimensions in small pots. Managed in this way, plants are in fine bloom ready for market by the end of May. As the flowers of this Hydrangea are very persistent, it is not so necessary to keep up a succession of bloom by the introduction of fresh batches of plants into heat, as is the case with many other flowering plants. If a portion of the plants are removed to a cooler house as soon as the flowers begin to expand, and especially if they are shaded from hot sun, the season of blooming may in this way be extended over a period of two months or more. Another mode of propagation is to take the tips of the growing shoots made in warmth in spring. In a good bottom-heat these will make roots in the course of a month, and if they are potted off and grown along in a genial temperature till June, hardening off gradually and getting them into the open air about the middle of that month, they will make nice plants by the end of the season. Good loam, with a liberal admixture of rotten manure, is the most suitable compost, which should be pressed in firmly.

NEW YELLOW CARNATION.—I lately saw in a large London market garden a yellow Carnation, which has undoubtedly a great future as a market kind. I cannot give its name, as this is kept secret; but I know that £30 was given for half the stock, which is a sufficient proof of its superiority. The habit is good, the flowers are large and of a bright clear yellow, and it is said to bloom more freely and continuously than any other yellow Carnation now in cultivation. The grower alluded to is increasing it for the express purpose of growing it in pots for cut bloom for Covent Garden in winter. Up to the present time no yellow Carnation has quite fulfilled the requirements of market growers, but this one is said to do so, and to be the very thing so much wanted.

CARROTS.—These, the dry weather notwithstanding, look uncommonly well. In most of the large breadths of Long Surrey Carrots grown in the neighbourhood of Weybridge and Byfleet, in Surrey, the plants are set out, and one may go over many acres of them without finding a thin place. During the last few days there has been a welcome change in the weather, and refreshing rains have exercised their usual effect, and the long rows of tender green leafage have a pleasant appearance and indicate, by their perfect verdure, a crop of good roots. Nothing is more wished for by the grower of Carrots for market at this time of year than good rains, as these give the young roots a start which in a short time places them beyond the reach of the grub, which is their arch enemy. If the weather is very dry during July the roots remain so small, that a single grub will destroy a dozen or more of them the course of a week. Although the Carrot grub has always been known, its ravages have increased wonderfully during the last few years, and it is now by no means uncommon to see a field in which two-thirds of the crop are destroyed. This is, of course, a great loss, as the hoeing and thinning out of Carrots is a costly affair, involving an expenditure of £2 per acre. There is no remedy known to growers at present but hand-picking, which is, of course, a tedious process, and is performed by taking the rows through, passing the finger round the crown of each plant just underneath the soil, as it is just at the union of the leaves with the bulb that the grub makes its attack; did it work from the point of the roots upwards, there would be no means of grappling with it. At one time Carrots were "cut out" to nearly 6 inches apart; now they are left very much thicker, so as to allow for loses; and some growers endeavour to make sure by not thinning out at all, merely going along and pulling the weeds out of the rows after they have been "flat hoed." The roots do not, of course, come so large as when each plant gets more space; but better a crop of small roots than none at all. Moreover, big, long Carrots do not take the fancy so much as formerly in the London markets. A few years ago it was useless to take anything but long, straight, bright-coloured roots into London; now consumers have found that the eye may be gratified at the expense of the taste, smaller kinds, such as the Intermediate, being of better quality.

PEAS.—Pea culture this year is not likely to have proved satisfactory to market growers. The inclement winter was against the early sowings, the majority of which were complete failures, owing to the melting snow, which kept the soil in a sodden condition during the first two months of the year. When Peas are once through the soil they are able to take care of themselves; it is just when they are swelling that they are in danger, a period of cold, very damp weather at that critical time being fatal. The unusually unfavourable weather had the effect of throwing the season back quite three weeks, and it is probable that for many years London has not been so badly supplied with Peas from the middle of May till the end of June as this year. Those who happened to sow later were this year better off, and there were plenty of buyers for moderately well-cropped breadths at £7 per acre. The Peas which supply the London market are partly grown by market growers and partly by agriculturists, who do not market them, but sell to the middlemen, who furnish the pickers or "podders," as they are called. As times go, the price above named may be considered to be good, as the vendor has the haulm left, which makes good feed in winter for the cattle. A Pea crop at from £6 to £8 per acre will certainly pay better than any Corn crop that can be grown at the present time, although it should be borne in mind that Peas are an uncertain crop. Still, if a Pea crop fails there is always time to get in some Turnips or Swedes, so that the season need not be lost. The hot, dry weather of late has been against late Peas, which are likely to be scarce. During the last year or two a considerable quantity of late Peas has come into London from the northern counties, principally from Yorkshire. Last year on one day 500 bushels came into Covent Garden from there. It is useless sowing late Peas on any other than good holding ground; in light soils they go off before they can turn in. J. C. B.

Paris Daisies.—I grew this spring plants of Etoile d'Or in 4-inch pots 18 inches through, and they carried continuously for three months from two to three dozen good blooms, and from a plant in a 6-inch pot I should think that I cut during winter and spring nearly 500 good blooms. I may add too that the colour of this variety much depends on the culture and feeding which it gets. Starved plants give pale straw-coloured blossoms, but in the case of liberally grown specimens they become almost golden.—J. C. B.

Books.

HOW I MANAGED MY ESTATE.*

THIS is a more than ordinarily useful little book, and one which deals with many things likely to interest our readers; the author seems to understand what he is writing about, and the only fault that we can find with the book is, that there is not nearly enough of it. Notwithstanding the use of what printers call "bumping out" and of large type, it is only a small book, consisting of little more than a hundred pages, in which many subjects that would prove useful to country people are left untouched. The author seems to have done very well with his estate after improving it for some years; but this, in times when estates generally are going down in value, is doubtless a matter of luck. He was fortunate in getting a good price for his timber and in making things pay. We quote the chapter on timber as a sample of his work.

There are three principal points to be regarded in the management of the large timber of an estate—ornament, profit, and the way in which it affects the profit of underwoods; and as my timber was thick where it should have been thin, and thin where it should have been thick, I was compelled to consider these points well. The planting of thin wood for timber is involved in planting up the underwoods; the healthiest young trees being left, when the first crop of underwood is cut, at intervals of from 20 feet to 25 feet apart. The relative values of timber and underwood differ greatly in different parts of the country. In Hop-growing counties like Sussex the underwoods are of more consequence than the timber; and, therefore, as a rule, the Sussex woods do not bear much more timber than is necessary to make them look like woods. Nothing could look more rich and beautiful than my woods, yet the large timber averaged only about £24 an acre. An acre of land, however, under the best circumstances of soil and aspect, and if planted all at once and kept duly thinned, ought to carry eighty Oak trees, worth £10 each, at the end of about fifty or sixty years; that is to say, the crop would be worth £800.

Such crops have been in England; but they will probably never be again, for no one in his senses would dream, in a state of political instability like ours, of planting any of his land in this way. Oak timber is, indeed, quickly disappearing, and fast-growing "soft wood" taking its place. An Oak tree which at fifty years might be worth £10 is probably not worth above a shilling at twenty; but Fir poles are useful at all stages of their growth. People in general do not know how quickly the destruction of Oak is going on, for the reasons I have just noted; there is little difference in external appearance between an Oak wood worth £24 an acre and one worth £800.

Sussex Oak rarely grows large, but in quality it is the finest in England. I have seldom seen a Sussex Oak so large as one which grew on my ground. It was 13 feet round; but this would not be a great size in some parts of the country. Not only is Sussex Oak exceedingly sound and hard, but it is fast-growing during the comparatively brief period it takes to ripen in this county. I felled one Oak which was more than 7 feet round at 5 feet from the earth, and there were only thirty-five rings of annual growth in it; two or three of these rings indicating a growth of more than 2 inches in the diameter of the tree in one year. In some years the growth of timber, as tested thus by the rings, is three or four times as great as it is in others.

Very interesting statistics, concerning the growth of timber and its relation to weather and soil and other conditions, might be arrived at by the simple method of collecting and polishing discs out of the trunks of various trees, dating the rings and comparing their breadth with the meteorological records of each year. For aught that I know, this may

* London: George Bell & Sons, York Street, Covent Garden.

have been done in Germany, where woodcraft is a science; but I have never heard of its having been even suggested.

The action of Ivy in diminishing the size of timber is very great. A heavily Ivy-bound Oak loses about one-third of its natural power of expansion. Few woodreeves attend to this. I did so myself, going through the woods with a bill-hook and chopping through the Ivy-stems carefully, so that the bark of the tree should not suffer, as I found it often did when I left this work to others.

Another work I found it expedient to take into my own hands was the measuring of the timber. The usual way, I found, was for the woodreeve or bailiff and the timber merchant to go over the timber together, the merchant measuring the "girth" with his own string, and the bailiff taking note of the size and marking the trees. In selling some timber, I myself accompanied the party, and observed that there were several disadvantages in this plan. The merchant's measuring-string was an old and very much frayed cord, which would stretch 2 inches or 3 inches in as many feet if tightened strongly; as I fancied that it was when applied to the tree, but not when applied to the measuring rod or line. Again, there was generally a dispute about the quantity of timber in the "head" of the tree—that is to say, above the point at which the "girth" of the trunk is seriously diminished by the departure of the first large branch. This part of the tree, which often contains a considerable proportion of the whole contents, is always measured by sight; and the eyes of the merchant generally saw less timber than those of the bailiff did. So I resolved to dispense, in measuring and setting value on the timber, alike with bailiff and merchant. I went through the woods with someone to hold my measuring rod—a lath of 18 feet or 20 feet long, used to ascertain the height of the main trunk when it is above reach—and the little sliding-rule which gives the cubic contents of the tree from the measure of the circumference; marked the trees, put the numbers and sizes in my note-book, set my own price upon them, and found that I had never any difficulty in getting it.

Not only did I thus sell the timber at my own measurement, but I found that, somehow or other, timber-buyers would always give me some twenty-five per cent. more than they gave to big proprietors in the neighbourhood, who left the transaction wholly in the hands of their reeves. I never had any personal haggling or any other direct communication with buyers. I gave my bailiff my notes of measurement and price, and the merchant took or refused the offer as pleased him best. The price of standing Oak at the time I am writing of was about 3s. 6d. a foot, but I believe that it is less now; not, probably, through any legitimate fall in its value, but through a better understanding—such as now prevails among butchers—between the purchasers of timber.

A ripe Sussex Oak seldom exceeds in its contents a "load" of 50 cubic feet. By the time it has reached that size, in my part of the county at least, of which the substratum is the "Hastings sandstone," its roots are commonly checked and probably more or less poisoned by the "iron pan," which usually intervenes between the soil and the rock. An intelligent and somewhat practised eye is required to decide upon the fitness of an Oak for felling. A tree with only 10 feet of timber in it may have quite done growing, while another of five times the contents may be putting on a great bulk of wood every season.

A "ripe" tree has always a "stodgy" appearance, especially about the topmost branches, among which small leafless twigs will begin to show themselves. If the work of selecting trees for felling be left to subordinates, the biggest, not the ripest, trees will generally be chosen. But this involves very serious loss; for the larger a tree is the more wood it will put on every year, if it is still "growing;" and, since an Oak is usually not timber at all until it is twenty-five or thirty years old, every additional year's growth, up to fifty to sixty years of its age, ought to be reckoned as containing two years of its entire increase.

Another point requiring the eye of the master is the thinning of trees when they stand too close together for free growth. I found this a serious problem sometimes. There were belts of Scoth Firs, Spruce and Larch extending for about half a mile on either side of the high road. They had been planted about fifty years before I came into possession, and had never been properly thinned. They had therefore run up to a great height, but three out of four of them were fit only for scaffold-poles. The stronger trees would have still grown into good bulk had it been safe to thin them; but I found it best to leave them alone, for I had quite ruined a two-acre plantation of similar trees by the attempt. The mass of tall thin trees was able to resist the south-westerly storms only so long as it stood against them altogether. As soon as I had removed a few of the trees from one corner, the wind got in amongst the rest; and the whole plantation had to be felled, much to the disfigurement of that part of the estate and of the view from the house.

There are comparatively very few well-timbered woods in Sussex. They are commonly either grievously under-timbered or as grievously over-timbered. One healthy tree, fifty or sixty years old, standing with a clear space of 25 feet about it, will probably be worth ten times as much as ten trees growing together upon an equal area. When a public road runs through an estate, it is a considerable point of economy as well as beauty that belts of timber shou'd run alongside of it. The trees throw their roots to the centre of the road, and utilise the ground as effectually as if it formed part of the estate. A mile of road means probably five acres of land, and these may be considered as being practically added to the property by timber so planted. I acted upon this consideration in my planting operations. A stream, like a road, may be made very productive in timber. The white Poplar sells at a high price, and grows at a wonderful rate in good soil and near a stream in a sheltered position. I sold one only thirty-five years old for £10, but I did not plant any, because they spoil the look of the adjacent timber, soon overtopping and dwarfing all other trees with their great sparse-leaved grey heads.

Grubbing timber is a matter of considerable importance in the management of a heavily wooded estate—especially at this time, when everything tends to render the retention of woods immediately unprofitable, and we see grubbing operations going on everywhere on a large scale. The process will not improbably, and at no distant period, end in practically denuding England of its woods, and in changing its climate very much for the worse, as has already happened in large tracts of Spain and other countries—tracts which have been converted into deserts by the loss of the moisture-absorbing and moisture-supplying power of forests.

This fatal wood-destroying process received a strong impulse from the strange and most ignorant legislation in the matter of woodlands some dozen years ago. I remember well the character of the debate, though I do not remember the year of it. It ended in rating woodlands—which, for good reasons, had not been rated before—at the agricultural value of the circumjacent land which was under culture. Had a single sensible woodreeve been among the members, he could have turned the debate. He could have told the House that many thousands of acres of woodlands do not pay one penny to the proprietors, being in such low condition that they do not return the expense of hedging and ditching. "Why," the inveterate Cockney would have asked, "not put them in better condition?" Because it involves a large outlay, for which not a farthing can be expected to come back for at least twenty-five years, at the end of which no one knows what will have become of the land. "Why," responds the Land Reformer, "not grub your unprofitable woods and put them under the plough?" Because, answers the woodman, to do so would cost, in many cases, the fee-simple of the land, of which in many parts of Sussex the agricultural value is not £10; and, furthermore, because a large proportion of woodlands is upon hill-sides and rough ravines, old quarries or gullies, or other uneven places, where nothing else would grow.

But there was no woodreeve in the House of Commons, and so the English woods were voted to destruction.

FERNS.

TASSELLED AND CRESTED FERNS.

I am somewhat at a loss how to account for the abnormal forms among our native Ferns—forms which we do not find among exotic species. What, therefore, causes Ferns that grow in British soil and in a British atmosphere to sport in the remarkable manner in which they have done with us during the last fifty or sixty years? These are questions difficult to answer in a satisfactory manner. I have heard it asserted that we at home are not in a position to say, with any degree of accuracy, that foreign Ferns do not sport into the crested and tasselled forms to as large an extent as our indigenous species do, because their habitats have not hitherto been so thoroughly explored by collectors as those of our native Ferns, a statement in which there is certainly some truth; but it is not sufficiently convincing to satisfy me, for, having had frequent opportunities of examining large herbaria, I cannot bring myself to believe that exotic Ferns (although subject to great variations) are liable to become altered in form to the same extent as our native kinds are, or we certainly should have received some of them from our numerous plant collectors long ere this. This fact was deeply impressed upon my mind a few years back during a walk over hill and dale between Halifax and Todmorden, especially in the neighbourhood of Luddenden Foot; there I saw Ferns growing everywhere, particularly Athyrium Filix-fœmina, but although any amount of varieties were to be found, it was quite an exception to see the recognised normal state of the plant; there were forked fronds, tasselled fronds, depauperated fronds, miniature fronds, and gigantic fronds; it, therefore, occurred to me that if exotic Ferns varied to this extent we must have received abnormal forms from our collectors, who are ever on the outlook for new plants of commercial value. Some assert that we are indebted to the Fern cultivator for the numerous varieties of British Ferns which we possess, and to some extent this is true; but yet some of the most beautiful and distinct of our crested and tasselled Ferns have been originally found in a wild state, the same form, in some instances, occurring in widely separated localities. I have previously stated that I am inclined to believe that the majority of these forms have sprung up during the present century; and one of my reasons for this belief rests on the fact that old British botanists are silent upon the subject. Had such varieties been known to them, some records of them would have been left behind. True, some few varieties of British Ferns are noticed; but that only serves to strengthen my supposition in regard to the non-existence of the great number of varieties which now serve to beautify and adorn our rocks and glens, and which, when tastefully arranged, produce such a charming effect in our rock gardens during the summer months. Another remarkable fact, and one which goes far to support a notion which I entertain that changes in form, such as have been recorded, are brought about through some peculiarities existing in the atmosphere or soil, is that in other parts of Europe these self-same species do not acquire such protean forms as are to be found in our own country. Again, the majority of exotic kinds which are crested and tasselled are the results of home cultivation, and have not been introduced, but have originated in our plant houses. G.

Woods & Forests.

PINES FOR PROFITABLE PLANTING.

Our knowledge of the qualities of the Scotch Fir is not limited to twenty, thirty, or even to one hundred years, and our opinion of its utility in the economy of our timber produce is immutable, as it is amongst the oldest and most tractable of native trees, and has been and is still among the most valuable of Firs which the British timber-grower can plant, when planted in certain soils, &c. Rich soils are not essential to its best development. Whatever "Yorkshireman's" acquaintance with the Scotch Fir may be, it is not so comprehensive nor so conclusive as to prescribe this tree to exclusion from a place in the plantations of the future ; and it is not likely to be less planted, in spite of all the excellent qualities "Yorkshireman" says the Corsican Fir has to commend it to culture. Thirty years is the very limit of "Yorkshireman's" experience of the Corsican Fir, and from that experience he has reached the conclusion that the Corsican Fir is better fitted to realise the consummation of a timber tree and the incongruous states that belong to our woodland areas than the Scotch Fir.

"Yorkshireman" does not state what is the nature of the moorland soil in which the Scotch Fir fails to grow in the highlands of Yorkshire. It is in vain so far that this information has been solicited. The Scotch Fir does not require to be pampered in a secluded corner of a garden to attain its finest dimensions ; nay, almost the most meagre of Scottish moorland soils will suffice. The Corsican Fir, on the other hand, delights to live on richer fare. As a tree for general planting, the Scotch Fir has no equal among the Pines, and its value in that sense is of the utmost moment to the British timber grower.

As a tree for local areas and favourable situations, the Corsican Fir will also become a tree of profit to the timber grower, but to say that it will accommodate itself to all conditions under which the Scotch Fir flourishes would be making a statement without facts to prove it.

It appears that "Yorkshireman" has converted a hitherto sceptic nurseryman to his views respecting the excellent attributes of the Corsican Fir. Well, that is no matter of ours ; still, this said nurseryman may not be deaf to a word of warning probably, or if he be, it is just possible he may find himself in the same fix as the other nurseryman found himself concerning the Douglas Fir. He had been told that the Douglas Fir was to take the place of this, that, and the other tree, and that the man who had the largest stock of this Fir for sale would make the largest fortune. It all looked very promising, so he went on multiplying his stock of the Douglas Fir until he had at last a vast and excellent stock. But, alas ! the vicissitudes that intervene in the way of demand and supply are perplexing. So it was in that case ; the supply was profuse, but the demand was next to nothing. It is not insinuated that "Yorkshireman's" nurseryman will find himself in the like predicament. Perhaps "Yorkshireman" will point out where "J. F." has said that the Corsican Fir is more ornamental than the Scotch, for his opinion of that tends, too, in favour of the Scotch Fir. J. F.

The Sweet Chestnut.—It may not be generally known that the seeds of the Sweet Chestnut should never be sown in autumn, as the germinating power is apt to be destroyed by the frosts of winter. The best course is to place the nuts intended for seed in layers of sand in a dark cellar, and then to plant them out in spring as soon as all danger from frost is gone. The best seeds for planting in the British Isles are those produced in Devonshire, and next to them German seeds may be recommended. French and Italian seeds do not produce good trees in this country. The best German seeds are grown in the valley of the Neckar and in the vicinity of Heidelberg. The trees produced from seeds yield only small nuts, and to obtain good fruit they must be grafted upon Pear, Apple, or Cherry trees.—W. H.

GATES AND STILES IN PLANTATIONS.

Where there is a public footway through a wood or plantation gates should always be used. Where a public pathway exists, if it is at all practicable, the sections of the wood should be fenced off, and only the pathway itself left open to the public. In some cases the operation would be too costly, as the distance to be fenced would be too great. What advantage there was to be gained by privacy would be more than counterbalanced by the too great outlay. Whether fenced off or not, if the owner's necessities do not render it imperative to have a horse or carriage entrance where there is a public footpath I should always prefer a stile to a gate. The particular form which it should take would, of course, be decided by circumstances ; but it is always unsatisfactory to leave an unlocked gate to the caprice of the public. In all cases even a lock is not altogether a guarantee that the gate will remain closed, as there is often ingenuity enough abroad to either knock it off, or to lift the gate from its hanging post. When a strong stile is erected in the place of a gate this anxiety ceases, as there are few who would so far trouble themselves to lift a structure of this sort bodily out of the ground. On the other hand, in such places as this, where a public right of road exists, it is well that a little thought as to general convenience should be given. The real object of the barrier at all in such instances is of course the prevention of trespass by cattle. When the path is completely fenced in for the whole distance the form of stile is not so great a consideration, but when the interior of the wood or plantation is entirely unprotected, it becomes imperative that the barriers at each end should be capable of without any doubt answering their purpose. In the first case, what is known as the "Yorkshire" stile, formed of two almost vertical, but slightly curved, posts, will answer as well as anything, but in the case of the open interior, a thoroughly substantial barrier can only be made of strong vertical posts and horizontal rails. The less sawn wood there is used in erecting stiles the better. To have sawn posts is quite unnecessary. Sawn under rails may be used, but I prefer a round or a half round rail for the top—if the latter, with the round side uppermost. Any knots or excrescences should, of course, be removed, and the surface made as smooth as possible. Stiles made in this way often last for very many years, and when it is necessary to replace a rail it can be done with little difficulty.

Gates require to have more labour expended upon them, and when made entirely of horizontal rails all the wood must be sawn. When vertical pales are added—and it is necessary they should be for plantation gates—it is optional whether the framework only be sawn or the pales as well. In any case the framework must be. With respect to the vertical pales, these may either be sawn out about an inch in thickness, or they may be made of half-round sections of Larch poles. For plantations this does very well—in fact, being so finished, with the rough bark upon the poles, is often preferable to sawn and painted work. The size and, to some extent, the form of gate must be regulated according to what it is wanted for. For a mere bridle path, a gate wide enough to comfortably allow a horse and horseman to pass through will be quite enough. Where carts and wagons have to enter, of course a much wider gate will be wanted. If the traffic is at all considerable, it is very often better to have a pair of gates instead of a single long one. As a rule, any entrance over 10 feet should be supplied with double gates, as the strain upon a single post and a single set of ironwork becomes too much. A short stump post in the centre of the gateway is the only objection to double gates, and this is a decidedly smaller one than that of the heavy strain upon the single post. D. J. Yeo.

GAME COVERT IN IRELAND.

In Mr. B. Hartland's pamphlet on reafforesting Ireland he gives some pertinent remarks on the game coverts. He says: "Beyond doubt our country, if planted, would form the most valuable coverts for game in the kingdom. In passing from Killarney to Kenmare before daybreak, over the mountains near the Upper Lake, I saw in the early dawn large numbers of deer ; they were in front, crossing, and at both sides, bounding to the woods. On Mr. Buckley's splendid preserves I have seen whole herds ranging the lofty mountains, pheasants abounding in the lowlands, and crossing your path at every turn, while hid among the covert, with abundance of running streams, the cocks flock in surprising numbers, ranking the Galtee Castle preserves among the finest and most valuable in this country. Again, Sir Henry Beecher's famous duck preserves, with flocks which positively darken the sky when hovering round, are another illustration how waste moor lakes can be converted into grand preserves by planting.

"It is only necessary to name the splendid cock woods at Muckross (Killarney), Glenbower (near Youghal), Castle Cooke (near Kilworth), as they are each famous for the numbers of birds that are annually shot, and are commercially of great value. Unquestionably our hill-sides and sheltered glens, abounding in running streams, if planted, would in a few years give shelter to the immense flocks of cocks which every winter pass over our island to the French and German woods, and alighting here would afford the most magnificent shooting, and prove a source of very large revenue to the owners. I speak from experience, having many a time at dusk, or at night, watched great flights of these birds, positively countless in number, passing low and noiselessly away to the south, and doubtless the waste and barren state of our country drove them to better sheltered lands. The reader will pardon my laying so much stress on this subject, but I believe it to be one of far greater importance than is generally supposed. Our winter climate being so mild, and feeding grounds abounding everywhere, Irish cock preserves would soon rival our neighbours' grouse moors, and could be annually let for very large sums. A few years ago I was asked to purchase a winter's shooting, and £300 was paid for a very indifferent one in Kerry, and for another small one near me the same party paid £80 a year during three years, but here the woods, though not extensive, afforded excellent sport."

THE SCOTCH PINE.

My opinion is that if the cold and wintry uplands of the north are to be brought into cultivation, it will be by the aid of this tree, either in hedges or strips, or in larger masses as nurses to other trees. In no soil does it refuse to grow. In peat, sand, gravel, granite, and all thin soils it rises rapidly, and forms a strong rough fence in the course of six or seven years. In the neighbourhood of Thetford and Newmarket, in Suffolk, where the soil is miserable, it is quite common as a hedge tree ; but in those places it is pruned in the same way as the White Thorn, which is certainly disadvantageous, it being well known that of all trees the Pine is the most impatient of the knife. It is only where a better tree, as a fence, will not grow that I am led to recommend the Scotch Pine, and this I do, as already stated, because it is admirably adapted for ameliorating the climate in exposed situations previous to the introduction of others. My plan with this tree is as follows : The soil requires no preparation whatever. The plants to be used should be four years old, and they can be had of nurserymen for 4s. or 5s. per 1000. Those plants

I insert in a straight line at 2 feet apart from each other, so that when they get up, the stems may form the chief part of the fence. Planted at this distance, there will be very little room for branches between the trees in the lines, but they will push out luxuriantly on each side and produce sufficient spray to keep the plants in a healthy state. The tips of the strongest side-branches should be cut off, so as to induce smaller ones to break forth, but no regular system of pruning should be adopted. Another parallel line is to be formed and planted in like manner, about 6 yards distant from the other; this distance I adopt so that the roots of the trees may not impoverish or reach the soil in the centre, which, at the proper season, should be planted with the White Thorn or Beech after the ground is trenched in the usual way. Between the parallel lines, at considerable distances, there should be cross lines planted so as to break any currents of wind, which are oftentimes hurtful in open avenues of this description. If the soil is tolerable, and the climate permits, the White Thorn hedge may be introduced three years after the planting of the Pines; but in the more exposed places it should be deferred for a year or two longer, when the screen on either side will be in a more complete state to protect it. At the end of the three years the Beech may with every prospect of success be introduced. J. M. N.

THE CARE OF UNSAWN TIMBER.

The preservation of timber from the time it is felled until wanted to be sawn for use is a matter of importance. After it is sawn, it is of course requisite that still greater care should be taken of it, but it is not to this part of the work I now wish to direct attention. The time which trees have to lie before they are brought to the saw will vary very much according to circumstances. It is certain that a proportion will have to remain unsawn for many months, and some, perhaps, for years. The amount of wood in this country, which lies long enough as it fell to be absolutely spoiled, is probably not very large, but there can be no doubt that an appreciable quantity has each year to be assigned to the fire, on account of its being too long neglected to be of any value for other purposes. This probably arises from the falls being, from some cause, too heavy to be grappled with in due time, or from a customer not being forthcoming at an acceptable price. When it is known that timber has been lying an abnormally long time in this way, or is likely to do so, the difficulty may be overcome by giving close attention to the kinds most likely to receive damage, as well as a general eye to the whole.

The Oak is, without doubt, the tree which will lie longest with impunity, but even this will not remain unscathed for an unreasonable length of time. Much depends upon its age and condition when felled. A young sapling Oak which has been cut down in the spring and deprived of its bark is anything but a durable article, and, if left about simply because it is Oak, it will very soon become useless, as decayed Oak sapwood generally makes a very poor fire-wood even. The time for which small trees of this class—composed as they are of very little but sapwood—may be left, before they become unfit for any useful purpose, will, however, vary considerably according to the soil upon which they grew and the position in which they are left. Although a strong, heavy clay produces Oak of capital quality, when young sapling trees grow upon it are left to lie upon such retentive soils, their durability will be much lessened. Remaining continually in the damp, and on the soils of which I have spoken, the wet has little chance to escape; it will only be a matter of a few months before irretrievable mischief has been done. On the other hand, where the soil and subsoil has been open, and the water consequently has had the opportunity to drain off, I have known sapling Oaks lie for two or three seasons without suffering greatly. In these cases the abundant summer growth, which is generally found in plantations, has served to protect the wood, and in some measure supply the place of the bark, and, perhaps, answer better, as it would not be close enough to the tree to retain the damp. On the whole, to keep this class of wood for any length of time, if, as I said, the soil is free and open, I would prefer to leave it in the covert lying scattered as it fell, than to draw it out to the covert side. In these cases, however, it is well to be clear that there is no probability of its being wanted during the resting season, otherwise, it would be very awkward to get at. With Oaks which are larger in size, and consequently more matured and with less sapwood, so much care is hardly necessary. With regard to this, however, it is unsatisfactory to leave it too long in the damp, and, on the other extreme, to expose it too much to wind and sun. The damp would certainly be detrimental to what sapwood there may be upon it, and the sun and wind would most likely crack and split it. This is, perhaps, not so important as with some other wood to which reference will be made; but it is, nevertheless, worth attending to if circumstances admit of it. In drawing trees together, from the covert or the field, it is also well to take the precaution of having some transverse logs laid upon the ground upon which the first layer of trees may be placed. When the soil is very dry and it is not intended for the trees to remain during the winter season, this may occasionally be dispensed with, but in addition to keeping the timber off the too moist soil, it greatly facilitates subsequent removal to have them a few inches off the ground. The same fact would, of course, be true of other trees than the Oak.

With regard to the Elm: although a tree which would not stand so long neglect as the Oak, there is a wide difference in the length of time it will lie unsawn without being appreciably damaged. A very material thing in its favour in this respect is the season at which it is almost always felled. There are two advantages in this direction. As the bark has no commercial value, there is no reason or necessity for waiting until the sap rises, therefore it is cut when there is little or no activity in the sap, and what is, perhaps, more important, the bark itself remains upon it and serves to protect the wood. It will have been observed by those who have given attention to the point, that merchants and others, who have to keep unsawn timber for any length of time, are always particular to preserve the bark entire as long as possible. It will in almost all cases become loosened after the first season, but so long as it covers the wood it saves it from the effects of sun and air. In this connection a word of caution may not be amiss, and that is that whenever possible, Elm timber should either be drawn to the yard, where it has to be sawn, when it is green and the bark firmly adheres to it, or if it is left until the bark has become loose, and a large proportion will be detached in transit, it should be sawn up immediately it is brought in. A couple of months' exposure in the yard, with the bark absent, would probably harm the wood a great deal more than a whole year with the bark upon it. There is not only this, but the condition with respect to age and soundness to be looked at. If a tree is in a vigorous state of health when felled, it may safely be left a longer period before being sawn than when it has passed maturity and has begun to show signs of incipient decay. I am not sure that this rule would hold good with very young trees, but even with them I would prefer to run the risk, to having to do so with very old timber.

The Ash in many respects is a different tree, as although it very soon damages under unfavourable conditions, and becomes split and torn with the weather, it will remain unsawn a very considerable time without actually going to decay. As with the Elm, it of course makes a very appreciable difference whether the tree is in health or is on the road to decay. In the latter case a little lying about is the last blow to its usefulness. I have advised, where the situation is dry enough, the leaving of Oak in coppice or covert, and I think the same treatment would apply to the Ash. A very great protection to it is its bark, which the Oak ordinarily does not possess; but screening it from the direct effects of sun and air by means of foliage is an additional advantage. Where this is not possible, in open yards for instance, I have often seen the practice of white-washing the butts adopted. This may do if we lack anything better, but on estates it will be seldom necessary to resort to this. If the trees cannot be kept in the covert, there is generally an abundance of branches and other green stuff which may be thrown upon the trees during especially trying weather. Such a plan as this could not of course be very largely adopted, but occasionally a single day's work for a woodman may be the means of saving ten times its cost.

The Beech is a capricious wood to deal with as regards keeping in the round state for any great length of time. If necessity compels it, however, it should, if possible, be kept either wet or dry, that is to say, not in a moist position or where it will be alternately wet and dry. I do not in this sense speak of the alternate wetness and dryness caused by rain, which of course cannot be prevented out of doors, but of its lying in low, moist spots where water may sometimes collect, and at others be absent. Kept entirely under water Beech would probably last for an indefinite length of time, but this plan would be impracticable beyond here and there a log. I remember the case of some Beech trees a few years ago which were left for perhaps a couple of seasons in a small watercourse. One section of them was completely buried in the grit and soil of which the bottom of it was composed, whilst the upper section was alternately wet and dry, as it was only after rains and in the wet season that there was any water in the ditch. The result was that the sections which had been buried and were kept from the action of the air were tolerably sound, whilst the upper parts of the trunks were entirely decayed.

The Sycamore belongs to still another class, viz., one where the colour of the wood being preserved is a great consideration, and if this is lost the value of the timber, if otherwise sound, falls very materially. This being so, it is well to make fairly sure of a market before the felling is effected. It has been said by some one that from the way Sycamore often lies about, it would appear that it cannot take much damage in this way. From this I differ, and I have no doubt that on offering it for sale the vendor would readily enough discover the fact that Sycamore which has laid about long will most probably have lost almost a half of its value. The use the Lime is generally put to does not make it quite so important that the colour be preserved; still, for the most choice uses, if it is discoloured and otherwise damaged, it cannot be expected that so much will be realised for it. The Plane falls into something the same group, but commercially this and the Lime are not so important as the Sycamore, as the character of the woods make them unsuited to many of the purposes for which Sycamore is used. Another important group,

the keeping qualities of which have to be considered, is that which comprises the Larch, Scotch, and Spruce, the type of Conifers which in this country have a timber value. So much has been said and written about them—too much, probably, in comparison to the attention given to our common British woods—that it will not be necessary to dwell at length upon them, but the question of preserving the trees in the round, between the time they are felled and when they are sawn out, is worth attention. The Larch as a timber tree undoubtedly comes first, and no doubt the amount of exposure it would bear before it becomes damaged is greater than either of the other two; but it is a mistake to assume, merely because Larch timber has been known to last a long time, that it has a complete immunity from the action of the weather. The reverse is true, especially with young poles, and if they are left as they fall for a season or two in many cases they will be spoiled. I have had plenty of such cases come under my notice. Larger trees, where the wood has matured, will generally stand a longer delay in cutting up. Between the Scotch and the Spruce in the matter of damage by lying about, I should not like to draw too marked a line, as I believe the difference in positions which they may respectively occupy, their age, and the soil upon which they were grown, would be quite enough to make any remarks which may be made upon them interchangeable, or, in other words, that sometimes the Scotch would decay before the Spruce, and *vice versâ*. In this glance at the keeping qualities of woods, I suppose it would be unfair to pass the Acacia entirely unnoticed, as though so comparatively rare, there can be no gainsaying the fact that it lasts for very long periods under very trying conditions. Besides all that has been written about it, I have had enough personal experience of the wood to know that it merits a great deal of what has been said about it in respect of its durability.

A totally different class of woods are the Poplars and Willows, and although they are looked upon as very second-rate kinds of timber, the length of time they will sometimes keep sound after being felled is rather surprising. I do not mean to imply by this that they may safely be left for an unreasonable time lying about haphazard; but I have met with trees of Poplar and Willow which have lain for years apparently without serious injury. The Birch and the Alder do not generally attain a very large timber size, but generally go off as poles. Their character is somewhat analagous to the Poplars and Willows, and in respect to the time they will remain uninjured are practically the same. Such woods as Walnut, Apple, Pear, and Cherry vary considerably, but each of them will stand a fair amount of keeping, the Walnut probably the most, as the sap-wood, being of comparatively little worth on account of its lack of colour, may decay, but the heart-wood will be intact. If possible, however, the bark should be kept on to prevent its splitting. D. J. Y.

Warm coverts.—I am afraid that the stumbling-block of many keepers, and not a few woodmen, in the matter of providing shelter for game, especially pheasants, the most expensive to rear, is the want of a little knowledge of the natural history of the subjects they have to provide for. I believe that on gentlemen's estates where pheasant rearing is carried on extensively, the success attained varies very greatly, all things being equal, except covert, and perhaps soil and situation. There is not much difficulty in keeping pheasants and other game in any wood in the summer time, but when the deciduous trees shed their leaves the game will not stay in it of their own accord, unless it has plenty of evergreen shelter in the shape of Spruce, Holly, Yew, and other evergreen trees, nor will they remain long in a wood lying in a northern aspect. At this season of the year it is warmth the birds are in search of, and where they find that they will find also most natural food. In planting for covert, therefore, Evergreens should always form a large portion of the wood, and it should be well distributed throughout its extent, and occupy the warmest spots as well as shelter the cold ones. The birds come to the sunny margins of the coverts at this season to bask in the sun when there is any, and to seek warmth, and whole coveys may often be found at such places when few are seen anywhere else in cold weather.—Y.

WOOD FOR RUSTIC WORK.

There is a considerable amount of wood used in rustic garden structures, such as summer-houses, out-door seats, trellises, porches, arbours, and the like. As a general rule, the less labour bestowed in preparing the wood the more satisfactory will be the result. The work of the axe and the saw should be as little seen as possible. It is, however by no means uncommon to see wood which, although used in its natural state, is entirely out of harmony with Nature through being used in the wrong way. The great principle to be observed is to so use it that the object for which it is employed be at once apparent, and the work itself useful and in harmony with what may be seen in Nature. Some people have a great notion as to the ornamental properties of old tree stumps or roots. In some cases they are quite admissible, and even desirable, but a great deal lies in the way they are used. I have occasionally noticed the roots of old trees turned entirely upside down on the borders of lawns, the surface where the tree was sawn away being in contact with the ground. The idea is utterly absurd, as such a thing would never occur in a natural forest. If, however, this same tree-root had been laid upon its side in the way in which it would remain if blown down in a gale, and the sawn surface buried in a bank or otherwise so concealed that the fact of its being severed from the trunk could not be seen, the impression, instead of being that of something incongruous, would be that the root was lying where it had fallen. The propagation of suitable plants in the soil between the roots could just as easily be carried out in this position as the other. I only mention this as an illustration. The same thing can be seen over and over again with other objects which, though proper in themselves, become ineffective and an eyesore through the want of a little thought in their arrangement. It is not, of course, possible to place everything in the position in which it grew, but when it is not it is better to make no attempt to do so; a bad imitation is always a palpable failure. In some cases it is best to leave the bark on the wood; in others it is better removed. The objections to the use of the wood with the bark upon it are that the bark has a tendency to harbour the damp, and consequently hasten the decay of the wood, and it also provides an asylum for vermin. On the other hand, when the bark is left intact it certainly has a more natural appearance. The smaller branches of the Oak is material which has always been much used for garden purposes, and from this the bark is in most cases removed for the sake of the product itself. It is probably better for the wood that it should be when it is formed into garden structures. The amount of heart-wood is relatively so small, that there is little but the sap-wood to be depended upon. Were the space, therefore, between the bark and the wood constantly full of moisture, the whole would soon become so rotted away as to be useless. It is for garden-seats and rough trellises that this Oak wood is mostly used, and the contorted way in which it grows adds to its value in this respect. The Yew is a capital wood for posts for garden structures, as it is durable and has a good appearance. For corner-posts of arbours or summer-houses there is scarcely anything better. It is not always, however, that it is to hand when wanted; when it cannot be obtained, the Scotch Fir is not a bad substitute. Both Scotch and Larch wood comes in well for trellises and screens, and when the work has to be finished in straight lines it has the advantage of growing in a more convenient form for using than the Oak. When it is intended to cover the erections with Ivy or any other kind of climbing plant, rougher or less durable material may sometimes be pressed into service. I do not much like the idea of Elm and Ash for such work, but sometimes small Ash poles may be used. In thinning in shrubberies or ornamental ground such woods as the Laburnum and many others of a similar class have to be cut away. Discretion, of course, must be exercised in these cases as to what may or may not be properly used. In some cases Maple, and even Elder, may be made to answer where it is difficult to obtain better. Woods such as the Beech, which damp will rapidly decay, it would be more profitable to leave to their more legitimate use. D.

REMARKABLE GROWTH OF SPRUCES.

There is an interesting account of the growth of some remarkable trees in Dallally Den by "J. F." (p. 570, June 19). He also writes about a peculiar growth of a Spruce, which had taken the form of an upright stem, as also throwing out fresh roots from the prostrate stem at 14 feet from the ground.

In visiting woods in various parts of Scotland, I have observed many such trees in all stages of growth similar to the one "J. F." describes. The most remarkable tree I have seen is one growing on an old turf wall at Muirward Wood, Perthshire. The original stem having been blown down, the root remained intact, and maintained the growth and circulation of the sap, which continued with more or less activity, according to the quantity of roots left to support it. Those branches which were most upright then took the form of suckers, and some ultimately attained gigantic proportions; one or two even grew as large as the parent stem, while the remaining branches either became much spread and flattened, or ultimately died down altogether. The probable explanation of this occurrence is this: when the original tree stem became embedded in the ground it gave rise to the formation of roots, which as they increased in development, ultimately supported the newly-formed stem, giving it a great stimulus, which would not be attained were the stem only depending upon the original roots. This newly-formed stem and its new roots became, therefore, independent of any assistance from the parent roots, and, were it considered necessary to cut away the original stem on each side of the young stem, the original tree would live on as formerly.

Such trees as these are often to be found in the primæval forests, and have led travellers and explorers to greatly exaggerate the age of some of our remarkable Coniferæ, which have been found, as they described, with a young tree growing over the prostrate stem of an old one; whereas, by careful observation it might have been found to be exactly the same as I have described. Again, I have observed in cases where trees have been torn up by storms in Scotland of late years, more especially in glens, dells, and hillsides, that where *débris* and other rubbish has fallen on the stems, roots of considerable size have been formed at all parts of the stem, which have led me to believe that roots could be produced on any part of stem or branch, provided they are brought in contact with soil favourable to their development. Along the coast side in Aberdeenshire, where some young plantations were formed some years ago, the Larch became partly covered by blown sand, on its removal, it was found that all the branches had taken root.

Here, in this moist and favourable climate, I find that the Larch, Spruce, Beech, and some other trees, which are covered round the stems by a rank growth of herbage, has in a great many instances developed roots from latent buds, which have taken root in the ground at various distances of from 18 inches to 30 inches on the stem, especially in glens and such like places.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE FRUIT CROP.

WE are enabled, thanks to our correspondents, to publish this week returns concerning the state of the fruit crop from nearly every county in England. From these it will be seen that on the whole Apples are not so plentiful as early in the season they were expected to be. The blossom, though abundant, did not set well, and now the fruit keeps dropping very much. Apples are, therefore, a thin crop. Pears, though not over plentiful, are better, and promise to be good in quality. Plums in most districts are a heavy crop; so heavy indeed in places, that the branches have to be propped up to keep them from breaking. Cherries, too, have been abundant, but small. Bush fruits, especially Gooseberries, have been good and plentiful. Concerning the Strawberry, to which special attention has been directed, much useful information, both as to varieties and culture, has been furnished. The best early kind, generally speaking, seems to be Vicomtesse Héricart de Thury, and the best late sorts, Oxonian, Elton, and Frogmore Late Pine. As to culture, most of our correspondents agree that no plantation ought to be allowed to stand more than three years. After that the fruit begins to deteriorate, both in size and quality. The ground for the new plantation should be well manured and trenched, and planted either with plants that have been forced, or with prepared runners obtained from fruitful parents. Few new kinds seem to be grown, with the exception of Pauline, which is said to be ten days earlier than any other sort. The wood Strawberry, red and white, from thin soils on limestone rock is reported to be finer this year than usual, and to be liked as a breakfast fruit, as are also the red and white alpines. The following, from Mr. Coleman on fruit prospects in Herefordshire, will, we are sure, be read with interest:—

In nine seasons out of ten fruit growers have occasion to lament the effect of a killing spring frost which decimates the crops, and not unfrequently overlook the fact that there are other conditions equally fatal. This year we have not had a sharp blossom-destroying frost since the earliest Apricots commenced unfolding their flowers, and yet we learn from all parts of the country some fruits, notably Apples, are extremely partial. In this there is nothing very remarkable, as the past, which may well be termed the great aphis year, was perhaps as unfavourable to the formation and perfect maturation of the flower buds as one can imagine. Apples in this part of a great Apple district were a heavy crop, and quite sufficient to prevent the trees from bearing two years in succession, but this was not the only drawback; a long drought set in, and insect pests literally destroyed the foliage. Rain at last came and many trees pushed a late growth which did not ripen. A long trying winter and a cold sunless spring followed; the foliage shot ahead of the flowers, a sure sign that the latter were imperfectly formed and badly ripened, and the last feather was laid on by torrents of rain which turned our valleys into seas when the bulk of the trees were in full blossom. All the trees, fortunately, have not suffered, as we find some that were heavily mulched in gardens and others in well-managed orchards carrying fair crops of fruit. These, it is true, are very backward, are thinning themselves severely; the hot dry month just terminated came upon them at a critical time, and it is now questionable if the finest autumn will carry choice sorts to maturity. The outcry that we shall not have many Apples comes round as regularly as St. Swithin's Day, but with one solitary exception during a period extending over more than a quarter of a century our Herefordshire orchards have turned out better than the prophets predicted. This year in some places will prove no exception to the rule, but the trees generally look starved, out of health, and the reverse of promising. Our best fruited trees include Keswick Codlin, Lord Suffield, Echlinville, Stirling Castle, Blenheim Orange, Golden Winter Pearmain, the old Herefordshire Pearmain (two constant bearers), Claygate Pearmain, Sturmer Pippin, the Quoinings, and an excellent culinary Apple raised at Eastnor called Moss's Seedling. Worcester Pearmain, Irish Peach, and Kerry Pippin also look fairly promising. Cox's and Ribston Pippins are a light crop.

PEARS, as a rule, look more healthy than Apples, and all the trees which produced flowers are carrying fair average crops. A few have required thinning; others which bore heavily last year are barren or, like the standards, too backward if they stand to be worth storing. Pitmaston Duchess, of which we have a number of trees on walls, Williams' Bon Chrétien, Beurré d'Amanlis, and Marie Louise are bearing good crops, and have made considerable progress since the hot days gave place to gentle showers. The following have required much thinning: Marie Louise d'Uccle, Beurré Clairgeau, Knight's Monarch, Josephine de Malines, Beurré Rance, the old Crassane, Belle de Noël, and Louise Bonne of Jersey.

OF PLUMS their name is legion, and, notwithstanding the fact that the trees last year were literally devoured by aphides, they are still perfectly clean, but decidedly late. Green Gages and the old Golden Drop seem to vie with each other in the crops they are carrying, and as nearly all the other varieties succeed where these do not fail, your readers may gather that Plums in the west midlands will be too plentiful for the grower if they ripen. In the Avon and Pershore districts the thousands of trees of Victoria and the commoner Egg Plum are already weighed down with fruit. The thinning of such vast quantities is, of course, out of the question; consequently the quality, which must be poor, will be compensated for by quantity.

CHERRIES in orchards and gardens set, or apparently set, an abundance of fruit, but, owing to the cold, wet state of the ground and the unfavourable weather which prevailed up to midsummer, they have thinned a great deal, and those which have stood are small, deficient in pulp and juice, and sour or flavourless. May Duke and Elton, two varieties which do so well here, are this year not more than half their usual size. Bigarreau Napoleon, one of our hardiest and best Cherries, although very late, is the only variety which promises to come up to the full standard; whilst Black Eagle and some other less luscious kinds are positively neglected by birds.

BUSH FRUITS of all kinds are clean, plentiful, and good; indeed, much finer than usual. We deferred thinning the wood during the continuance of the dry weather, and the warmth and shade favoured the swelling of the fruit. The wood of some of the trees will now be thinned to let in sun and air, but the bulk of our Currants being required late in the season, checks, followed by loss of suddenly-exposed foliage, are avoided.

RASPBERRIES at one time looked hard and unkind, and all the strength of the stools appeared to be running into young canes. The quarters in our own garden were well mulched and hosed quite up to the colouring, and fine fruit is now plentiful. Peaches and Nectarines on south and west walls set an enormous quantity of fruit, and, unlike other kinds, the latter, now thinned down to a Peach to every square yard of foliage, is swelling well. The trees have made excellent growth, are quite free from blister, and, with one solitary exception, fly has not been found upon them. In this cold valley, not considered favourable to the culture of Peaches, I check my trees at the root every year early in October, and give the shortened roots a small quantity of fresh loam corrected with lime rubble. Early in January they are loosened from the walls and nailed in, not tied, just before the blossoms open. I cannot very well enumerate any special varieties, all my trees having required thinning. I ought to say all my borders are heavily hosed as soon as the fruit is set; they are then dressed with old lime rubble and mulched with fresh stable litter.

FIGS in this part of the country may be pronounced a failure. Well protected trees still hold a few fruits, but they do not look promising.

NUTS were at one time considered a failure, but the rains of the past week have brought forward a fair half crop of Cobs and Filberts, and I believe the common wood Nuts are equally plentiful.

NOTES FROM FRANCE.

SORBUS DOMESTICA.—A writer in the journal of the French National Horticultural Society directs attention to the numerous large-fruited varieties of this tree, the generality of which seem scarcely known to planters. In some parts of France, notably in the neighbourhood of Bordeaux and Toulouse, the berries have a marketable value, and are sold from October till January, either half ripe or in that semi-decayed condition to which the Medlar comes before we consider it eatable. It is in the last-mentioned state that the berries are most often eaten. Two varieties, much superior to all others in cultivation, are strongly recommended, both on account of their ornamental appearance and the quality of their fruits, one of which is named after M. Dufresne, in whose estate at Bordeaux it has been discovered; the other was also found growing spontaneously in woods belonging to M. Lafitte at Agen. The first has large pyriform fruits of a carmine-yellow, produced in large bunches, and excellent as soon as they commence to mellow; the other has very large berries, the colour of which is at first pale yellow, changing to bright rose when fully ripe. Grafts of these two kinds can be obtained on remitting the amount of postage to M. Glady, Pont du Cosse, près Agen. The Service is so distinct in growth as to be worthy of more attention than it now gets, its only defect being its slow growth; but to those who can afford to wait the value of the wood makes up for the length of time necessary to bring it to maturity. It is much sought after, on account of its hardness, for the manufacture of cabinet-makers' tools and for other purposes. It commands even a higher price than Oak. The bark is in request for the transformation of wine into vinegar, and the berries have considerable medicinal qualities.

DOUBLE-FLOWERED CYCLAMENS.—It is not uncommon to see Cyclamens with supplementary petals, although I think that they are much more rarely to be found in the large-flowered strains than in the older ones, which were in general cultivation a few years ago. I have at various times raised plants bearing flowers of this description, but I do not remember to have seen one like those recently figured in the *Revue Horticole*. The illustration in question might easily be taken as representing some double form of Narcissus, the ordinary petals being increased in number and more or less twisted, whilst the stamens are converted into petaloid segments, these being also much contorted. The flowers have, therefore, a confused appearance, but the manner in which the petals twist imparts a quaint, informal, and altogether novel character to them. I am inclined to think that in time we shall obtain a race of double-flowered Cyclamens having considerable decorative value. In the case of the varieties raised by me the duplication consisted in the production of a double row of petals, one being rather smaller than the other. These double-flowered kinds were all whites. I never observed any tendency to doubling in the coloured varieties, but M. Bruant, of Poitiers, with whom the

double-flowered forms originated asserts that duplicature is not confined to the white kinds only. It is stated in reference to these double Cyclamens that they are most agreeably and strongly perfumed, the odour much resembling that of Orange flowers.

BEGONIA ARTHUR MALLET.—This new hybrid Begonia, as represented by a coloured plate in the *Revue Horticole*, is a most attractive variety, unique in colour, and will undoubtedly become very popular. It has something of the habit of B. metallica, the leaves being of the same shape and apparently about the same size, but the colour is violet-rose with a strongly defined, almost black, venation. The coloration is not, however, uniform over the whole surface of the foliage, but shades off imperceptibly here and there into much lighter tints, which produce a most pleasing effect. The flowers are disposed in umbels, the buds being of a deep vinous red, the exterior of the petals being carmine-rose, whilst interiorly they are of a pale flesh colour, thus affording a charming contrast of colour. This Begonia was obtained by M. Lionnet, gardener to M. Arthur Mallet, of Jouy-en-Josas, by crossing B. subpeltata with B. Eldorado. From the same sowing another fine kind has been obtained, which has been named Noémi Mallet.

EARLY YELLOW WALLFLOWERS. A variety of Wallflower having pure yellow flowers is much grown by market gardeners in the neighbourhood of Montreuil, Bagnolet, and Romainville. It comes into bloom by the beginning of November, and in mild seasons continues to bloom on through the winter. I am not aware whether this Wallflower is known in this country, but I should say not, as its culture appears in France to be confined to the districts mentioned. Its only defect would seem to be a tenderness of constitution, which places it at the mercy of hard winters, but it would probably answer the purpose of those who grow hardy flowers for market in this country, as when autumn frosts cut off tender flowers there is often a dearth of bloom from November onwards. A good breadth of Wallflowers well in bloom at that time would presumably find a ready sale in Covent Garden.

TRICOLOR BEECH.—Messrs. Transon, of Orleans, possess a Beech which came as a seedling in their nursery, and to which they have given the cumbrous name of Fagus sylvatica latifolia purpurea tricolor. It is a variety of the common purple Beech, but the leaves are bordered with bright rose striped with white. It is said to have a very ornamental appearance. J. C.

Byfleet.

NOTES OF THE WEEK.

Gunnera manicata.—A grand specimen of this noble plant is growing here, the largest leaves of which measure 7 feet 3 inches across, on stalks from 5 feet to 6 feet long. It is carrying immense spikes of fruit nearly 4 feet high. This is truly a noble plant for a sub-tropical garden; it is easily grown from seed or increased by division of the crowns, and it requires only a deep rich soil with plenty of moisture to grow in, and a little dried Bracken to protect the crowns in severe winters.—W. SANGUIN.

Nymphæa stellata variety.—Under this name there is now flowering among the tropical Water Lilies at Kew one of the most remarkable Nymphæas we have ever seen. The number of flowers one usually sees open at one time on a plant of Nymphæa is from two to six, the latter number being considered exceptional, though sometimes found on N. zanzibarensis when well managed. Curiously enough, this free-flowered plant was sent to Kew as N. zanzibarensis. It has foliage as in N. stellata, the common blue Water Lily, and the flowers rise in great numbers from the centre of the plant; they have stalks 18 inches long, and they stand up erect a foot or more above the water. The calyx lobes are 1½ inches wide by 3 inches long, green above, green and pale blue below, and they recurve back to the stalk; the petals are 3 inches long and three-fourths of an inch wide, the tips cucullate, and they number about twenty in each flower, their colour being a clear lavender-blue. Diameter of flower, 6 inches. The stamens form a corona 3 inches across, the filaments being bright yellow, as also are the stigma rays; the anthers are pale blue. On Friday last there were no fewer than twenty-three flowers open on one plant of this kind, and it is rarely that less than eighteen flowers are found open upon it. Whatever grounds there are for the opinion that this Nymphæa is botanically only a form of N. stellata, it must be evident from our description that it possesses characters which horticulturally place it far above any other blue Nymphæa, not even excepting N. zanzibarensis, of which grand Nymphæa several plants are now in flower at Kew. We should like to see this free-flowering Water Lily introduced into all gardens where an aquarium for indoor plants exists.

Amaryllis Akermanni.—Mr. Burbidge has sent us from the Trinity College Botanic Garden, Dublin, a fine four-flowered spike of this showy Amaryllis. It was cut from a plant in an open border, near a hot-house wall with a southern aspect. In this place Mr. Burbidge says it is perfectly hardy, and has been undisturbed for the past ten years or more. The flowers are large and funnel-shaped, and of an intensely deep scarlet-crimson colour. Such a brilliant flower must have a fine effect in the open border.

Carnations without sticks.—Stress is laid in last week's GARDEN on the importance of raising a race of border Carnations which shall support their flowers without the help of sticks. I send you two stems—cut to their extreme base to show their full length—of a Clove Carnation, of which I have now over 200 plants in full bloom, all the produce of two little bits sent me three years ago from a Worcestershire cottage garden. This Carnation is large-flowered, good in colour, most fragrant, and blooms abundantly until frost sets in. But its most delightful characteristic is that it carries its flowers on short stems as stiff as iron wire, which no combination of wind and rain ever bends or breaks. The Grass is almost as glaucous as a Sea Thistle, and altogether I consider this Carnation one of my most valuable possessions.—G. H. ENGLEHEART, *Appleshaw, Andover.*

*** With this, Mr. Engleheart sends flower-stems of a beautiful Carnation, which may be called an improved Clove. The above note describes it so well, that there is no need for further comment. The value of a Carnation with stems rigid enough to hold themselves erect without support cannot be overrated.—ED.

Trichinium Manglesi.—A more liberal treatment than was once considered essential to the welfare of this plant has resulted in the discovery that, under cultivation at all events, this native of the dry sandy deserts of Australia delights in what market growers call fat treatment. We have it stated that in its native haunts this plant is leafless when in flower, but with us it retains its leaves till the flowers have all faded. On asking what was the secret of the management of Trichinium as grown at Kew, we learned that it was simply cow manure!—the soil employed for it at Kew being loam two parts, cow manure one part, with a good sprinkling of sand. The plants are potted early in spring and placed in a sunny frame, where they get plenty of air on favourable days and are freely watered. After the flowers wither, which usually takes place in October, the plants are shaken out of the old soil and repotted in a fresh mixture, and at the same time numbers of the thick roots are cut into lengths of about an inch and pricked into pans of very sandy soil; from these a batch of young plants is obtained. That the treatment adopted for this plant at Kew is right is proved by results which may be seen in two large pans, each bearing about thirty fine flower-heads, and standing in the Cape house there.

The Swamp Magnolia (M. glauca).—Among the smaller growing Magnolias there are none to surpass this in beauty and fragrance of flower, and as it flowers at this season, it is the more valuable. The Swamp Magnolia, as this is called, frequently throws up several stems from the base, and forms a good-sized shrub, while at others it is of a low tree-like habit. The leaves generally have a silvery under-surface, but in this latter respect individuals vary to a certain extent, as they also do in the retention of the foliage, some being almost evergreen, while others are quite deciduous. This latter character will, of course, also be influenced by the situation in which they are grown. The flowering season is spread over a considerable period, while the ivory-white coloured blossoms are deliciously fragrant, especially during sunshine. Another point worthy of note is the fact that, owing to the comparatively low stature of this Magnolia (and even then it flowers freely in a, for it, small state), the blooms are brought more pointedly under notice than is the case with the large strong-growing kinds. The Laurel Magnolia, as it is called, is a native of a considerable tract of country in the United States, preferring damp swampy spots, which circumstance should be borne in mind when planting it in this country, though here it does well in a cool, fairly moist part of the lawn, where the soil is certainly by no means swampy.

Carnation shows.—We are reminded by the Rev. F. D. Horner that the annual show of the northern division of the National Carnation and Picotee Society will be held in the Royal Botanic Gardens, Manchester, on Saturday, Aug. 14. The schedule is much the same as that of the southern division, except that the competitors in the classes are defined. Thus the first two classes are open to all, the next two "to growers of 500 pairs or less," and the last two classes are for six Carnations and six Picotees for growers of 250 pairs or less. This, we think, a good arrangement, as it places large and small growers on an equal footing. We have also received from Mr. Dodwell a schedule of the exhibition of the Carnation and Picotee Union, which is to be held in Mr. Dodwell's garden at Stanley Road, Oxford, on Aug. 3. The competition will include all the sections of Carnations and Picotees, and good prizes are offered in the various classes.

The Zenobias.—These belong to what are collectively called American plants, among which there are few more beautiful or more elegant in growth. They are summer flowering deciduous shrubs, forming dense bushes with neat foliage, and bear a profusion of white Lily-of-the-Valley-like flowers. The blooms are larger than those of most of the Andromedas, and very agreeably scented. A considerable amount of variation exists among different individuals of the Zenobia or Andromeda, as it is often called; but by far the most distinct is the variety pulverulenta (the Andromeda dealbata of Liodley), in which the foliage is covered with a beautiful silvery glaucous bloom, while the flowers are rather larger than the form generally met with. These Zenobias, like most of their class, do best in leaf soil and in rather a moist situation, for if too dry the fine hair-like roots soon suffer. The dense mass of delicate fibres common to most of this Order allows the plants to be moved at almost any season without injury, if kept well watered after the operation, and consequently this Zenobia may be lifted in the spring, and when potted, it can be flowered under glass if needed. The variety pulverulenta is the best for this purpose, as the foliage is quite as distinct as in the open ground, and its peculiar hue renders it a very conspicuous feature.

Mixed climbers.—How strikingly effective are some combinations of climbing plants, the shoots of which have been allowed to intermix with those of other plants. Near here may be seen a magnificent mass of the golden-leaved Honeysuckle over which a plant of Clematis Jackmanni has spread in all directions. The masses of soft golden shoots set off the deep purple blossoms of the Clematis to excellent advantage. We have also a wall covered with Irish Ivy, amongst which a white clustered Rose has been trained and then allowed to grow as it likes. A third example is a fence covered with such a wealth of white Jessamine, that it loads the air with its fragrance. At its base are some self-sown Nasturtiums, which have spread out into a broad mass, and are now covered with gorgeous blossoms, while stray flowering shoots have run up the fence, and contrast strikingly with the white Jessamine. Endless other mixtures might be enumerated, all beautiful and well worth imitation. Who, for instance, with any appreciation of the beautiful could allow bare walls to

exist when, by planting a few well-selected climbers, they could be rendered so much more ornamental?—J. G. H.

ORCHIDS.

DECEPTIVE GROWTH IN ORCHIDS.

No class of plants that require to be grown under glass are so deservedly popular as Orchids, and it is more than likely that the ranks of their admirers will keep on increasing. For a long time after the introduction of many of the representative species there were several reasons which caused many who admired them to hesitate before undertaking their cultivation. The high price which nearly all the kinds that were worth growing commanded was in itself a serious matter; and to this might be added the uncertainty that existed as to their growing after large sums had been spent in procuring them. And though with many people there is a fascination attached to anything that is uncertain, still, when plants that had cost as many pounds as they now realise shillings, were found to die out in quantity, as they usually did where the disease known as spot set in, it was no wonder that many of those who had essayed the cultivation of Orchids were induced to give them up. The first cost of any article has naturally much to do with the price at which it can be sold, and in times past importing Orchids was an expensive and a risky proceeding. Little was known of the countries where most of the best species exist by those who went out to procure them, whilst there was a like absence of knowledge as to the right seasons for collecting them: the best modes of packing had to be learnt, carriage cost much more, and was often very much slower than it now is. All this tended to increase the value of the plants when they came through the ordinary channels, and if anyone depended upon friends who happened to reside in countries where the plants were indigenous to procure them, it was often found to be a very unsatisfactory way of getting them, as more frequently than not the kinds sent, if they came alive to hand, were worthless. Now all this is changed, and the greater number of the favourite kinds reach this country with so comparatively little injury that quantities are able to produce flowers from the first growths they make under the altered conditions of their existence, and in a few years acquire strength and vigour equal to that which they show in their native wilds, and, what is of still more importance, keep on in a condition little, if any, behind that in which they exist naturally. It is to this latter, as much as to the reduction in price, that the extension in the cultivation of Orchids is owing.

When the nature and general character of Orchids, especially the epiphytal species, are taken into account there is little to wonder at in its taking more time before the essentials to their successful cultivation were mastered than in the case of other plants; that is, before growers knew how to treat them, so as to not only have them in a condition that was satisfactory to the eye for the time being, but that would enable them to keep on in a healthy thriving state for an indefinite period, such as the character of their growth naturally permits of their doing. For it does not require more than an ordinary acquaintance with plant life to see that Nature has made especial provision in Orchids for their continued existence. In the bulbous species the old back bulbs die after a lapse of more or less time, but the growth in advance of them suffers in no way by their death, each year seeing young bulbs formed and matured, which keep on renewing the tenure of life in the plants differently to that of others. In the bulbless species the natural provision for their existence is equally apparent; the lower part of the stems, after the leaves and the roots they produced are decayed, die gradually upwards, but the stem in advance above is quite independent of the dead portion below, being able to keep on thriving and extending in a way that removes the limits of their existence beyond that of the generality of other plants. But though the character of growth natural to Orchids, coupled with their tenacity of life, is such as is calculated to give them a prolonged existence, still, in common with other plants, if the treatment they receive is such as to cause the formation of soft spongy growth, disease is certain to follow, although, from the comparatively slower rate of the growth natural to them, they are longer before they show any ill effects. Even after the cultivation of Orchids had extended considerably beyond that which existed, say, thirty years back, the treatment necessary to keep up a continued healthy condition was so far from being understood that their doing well might often be set down as much to accident as to any definite knowledge of what they required. This was seen by what was not an unusual occurrence, *i.e.*, in one set of houses a grower was able for a lengthened time to keep his plants in a faultless state, whilst with a change of houses he failed with plants similar in kind, though the difference in the construction or position of the two sets of houses was no greater than would admit of anyone with a knowledge of the treatment the plants required, such as is now possessed by any average cultivator, to so far adapt his practice as to enable him to succeed.

The mistake usually committed was to look upon the big leaves that were produced in the half-darkened, all but airless houses, with a steaming over heated atmosphere, as the sort of growth to be aimed at. Under such treatment strong, sturdy plants that had before been well managed would generally make immense leaves for a few years, beguiling the growers into the belief that it would be lasting. But the day of reckoning was seldom long in coming, as the condition described was all but invariably the precursor of disease, the effect of which was that the soft, coddled plants melted away, their backward movement usually taking less time than had been occupied in making the deceptive growth that had prepared them for disease. At one time or other a good many cases of this kind have come under my notice, one in particular, which I may mention: A good many years back, when the ordinary varieties of Phalænopsis were much scarcer and dearer than they now are, I saw a plant of P. amabilis sold at an auction sale in one of the large provincial towns. It was a strong plant, with unusually thick leaves, five in number; the price it fetched was eight guineas. It was bought to go to a leading collection in the south of England, which two years after was brought to the hammer in London. I saw the plant there, and it still consisted of five leaves, but of a different character from those it bore when I first made its acquaintance. The largest leaf was over 15 inches long, and the next 13 inches; in fact, it was the biggest single growth of P. amabilis I have seen. The price it was knocked down at was twenty-seven guineas—not a bad return for two years' attention and house room. The buyer, however, had some misgivings after making his purchase that the growth was not of a character such as to admit of the plant keeping on with, and he offered to exchange it with one of the nurserymen for a much smaller plant of the same species, but the offer was declined. Two years after I saw what remained of this grand looking, but deceitfully grown, plant; it consisted of one leaf about 7 inches long, badly spotted, and another forming that also showed disease, of which, in the course of another year, the plant died. Like untold numbers of Orchids that have been subjected to wrong treatment by growing them with not half enough light in an over-heated, stagnant atmosphere, it succumbed through over-excitement, the growth resulting from which often for a time leads to the impression that all was going well until the impression was dispelled by disease attacking the soft, spongy leaves. Such mistakes in the treatment of Orchids are much less frequent than they used to be, yet instances are still not wanting where the plants, either through unskilful treatment, like that already instanced, or by being grown in unsuitable houses, or both combined, go on for a time making growth that is so far deceptive, that their condition is deemed satisfactory, until all at once there is a break down, disease making its appearance. Only recently I saw a case of this kind. Some four years since several new houses were built with a view to being occupied by a collection of these plants. No expense was spared in the construction; in fact, if the outlay had been less the plants might have fared better. As it was, the houses were built 3 feet or 4 feet higher than they should have been, and a still greater mistake was made in placing them close to a number of big trees that interfered much with the light. In due course the plants—an extensive collection in good condition—were placed in their new quarters, where the bulbs made were longer, and the leaves much larger than the plants had produced before; this went on for two or three seasons, when spot in its worst form attacked the collection.

When I saw them, with the exception of the cool kinds and such of the warmer species as had been hung up near the roof, they were in a state that made it painful to look upon them. As will be easily understood, the kinds that require little heat had not suffered in the way that the different species that need a higher temperature had, on account of their growth being made under less exciting conditions, and through the greater amount of air given them. The cause of failure in this case was directly traceable to the unsuitable character of the houses and the dark position in which they were placed, either of which alone would have been much against the plants making the right kind of growth to render them able to keep in a healthy condition. But the two adverse influences combined were such as would have enabled anyone possessed of sufficient knowledge of the nature and requirements of Orchids to have told beforehand what would happen. It is not so pleasant to mention failures, like those named, as it is to speak of instances where successes have been attained. But the causes that bring about such failures are the rocks on which Orchid culture is often wrecked, and it may be well now and then to give a note of warning to those who, with little experience, undertake to grow them, of the causes through which failure is most likely to come. Orchids, with few exceptions, require abundance of light, and to attempt to grow them in house that are darkened by trees or buildings is the height of folly. In the case of houses that are too high, and where consequently the plants are too far away from the glass, there is no safe way of proceeding, except by being content with slower progress than is attainable in low, suitable houses. When Orchids are grown in houses that afford less light than the plants require, more air should be given than is necessary where there is plenty of light. This will to some extent make up for the deficiency. But, as a natural consequence, an extra amount of air means slower growth, yet under conditions of insufficient light any attempt at hurrying in a high temperature is tolerably sure to end in failure. T. B.

MARKET GARDEN NOTES.

Market gardeners are now busy gathering and marketing both fruits and vegetables, clearing off exhausted crops, and getting others planted or sown. We have lately had copious rains: therefore the soil is in first-rate condition for cropping. Potatoes have made grand progress since rain fell. Premature ripening need not now be apprehended, and at present the tubers are quite free from disease. Warm dry weather is, however, now needed for this crop. Digging and marketing early sorts go on briskly; the sooner they can be cleared now the better will the second crop be.

Peas and Broad Beans are clean and good, but not very heavy crops. Early and second early sorts are those most in favour, as they can be got off in time for Turnips or Broccoli. Late sorts seldom pay; they occupy the ground too late in the season to allow other crops to be sown with advantage after them. Runner and dwarf Beans are just coming into use. In open fields runners are nearly all grown without stakes, and very prolific they are treated in this way. The rains have come most opportunely, as, if dry at the root, the bloom falls off without setting. Dwarf or French Beans are already plentiful, and no sorts appear to be more popular for the main crop than Canadian Wonder, and Osborn's for the earliest. The last is a very dwarf, early, and prolific variety, and just as good in the open field as under pot culture.

Cabbages are now being cut in quantity, and still realise fairly good prices. Growers for market do not, as a rule, let the stumps stop in the soil to produce a crop of useful greens for winter, as is done in private gardens; on the contrary, they clear the crop right off, plough the land, and put in another crop

directly. Main crop Cabbages are now being sown. Early York, Early Rainham, Battersea, or Fulham and Enfield Market are the sorts most largely grown, and better crops of Cabbages than those grown under open field culture it would be impossible to find.

Turnips are plentiful and good; a moist season and rapid growth make them mild flavoured. Sowing for winter goes on briskly; white-fleshed sorts are those most in favour; they succeed well after Peas and Beans without disturbing the soil much.

Broccoli, Kale, and indeed all kinds of the Brassica tribe are being planted in quantity. The scarcity last winter, and the high prices obtained this spring, make growers anxious to get out a full supply. Autumn Giant Cauliflower is planted largely in this locality; the early crop of it is already growing freely, and by planting in succession this fine Cauliflower can be had for a long season. Brussels Sprouts are also put out early, for the longer and stouter the stalks the heavier is the crop. Scotch Kale and late and mid-season Broccoli are planted until quite late; for if a mild winter follows it is surprising how well late-planted crops succeed; the soil being light and well drained, they keep growing with scarcely a check from start to finish.

Onions, consisting of large kinds transplanted in spring from autumn-sown crops, are now first-rate in quality, and there is such a constant demand for good Onions, that the quantity grown in the aggregate is very large. Sowings are now being made of the White Spanish for drawing green during winter and spring, and large quantities of these mild-flavoured Onions are used in this way. The main sowing for transplanting will be made shortly. The Giant Rocca and Tripoli varieties are most in favour, as they make very large bulbs and do not run to seed prematurely so readily as some of the smaller kinds.

Radishes are largely sown about this date for winter use. The China Rose and Black Spanish are the kinds liked by market growers.

Vegetable Marrows and Ridge Cucumbers are now growing freely, although the early part of the season was unfavourable for them. The Bush Vegetable Marrow is by far the best this season, quantities of it being fit to cut before the fruits of any of the other kinds are even formed. The Long Ridge Cucumbers are now running freely over the beds; they meet with a ready sale towards the end of the season, when the supply of Telegraph and other frame sorts is exhausted.

Parsley is sown largely about this date for a winter supply, and sheltered spots are selected for it. The seed is sown in drills about 1 foot apart.

Lettuces and Endive for winter salading are now being sown. The old Brown Cos, Grand Admiral, Cabbage Lettuce, and green curled Endive are the sorts for market.

Bush fruits are plentiful and of good quality. Red, White, and Black Currants are very fine and clean. As regards Black Currants, it may safely be said that since Black Naples and Baldwin have become leading market sorts the berries are nearly double the size they used to be. The great drawback to Black Currants as a market crop is that they must be gathered as soon as ripe, or the finest berries drop off. The Red and White varieties hang well, and therefore realise higher prices, as they need not be forced on the market. Gooseberries are a medium crop; Golden Drop is a great favourite as an early dessert kind, Warrington and other rough reds being the best for a late supply. Raspberries are plentiful, the rain having come just in time to save the crop; that on the young growths will now swell up, and it is generally more valuable than the first few gatherings.

Apples are a thin crop and continue to drop very much; the best are on dwarf bush trees. Pears are a good crop, and more evenly distributed over the whole of the trees than last year; although late, they look like swelling off to a good size. Plums are by no means a regular crop; indeed, taken collectively, the crop of fruit this season does not promise to be up to the average. The Strawberry crop has been very disappointing in character—in fact, as regards season, one of the shortest we have had for years.

Gosport. J. Groom.

WARREN HOUSE, COOMBE WOOD.

Were we asked to name a few of the gardens within ten miles of Charing Cross which exemplify the best styles of pure English garden landscape, and also possess most interest in the way of trees and shrubs, we should have no hesitation in including in the list the garden at Warren House, Lord Wolverton's suburban residence. It stands conspicuous even among the crowd of beautiful gardens that are to be found around that delicious strip of woodland known as Coombe Wood. It contains more commendable features and fewer blemishes in design than other gardens we have seen in its neighbourhood; while as regard the trees and shrubs which it contains, it is perhaps unique. This arises from the fact that some years ago a portion of its grounds belonged to the late Mr. James Veitch, about the time when his son and other collectors were exploring Japan, California, and other countries in search of trees and shrubs sufficiently hardy to stand our English climate. This place, it appears, was made the trial ground for these new introductions, the consequence being that a host of the original trees then planted have remained undisturbed up to the present day. Need we say, therefore, that many of them are matchless specimens. There may be seen here towering trees of such Conifers as Cupressus Lawsoniana, two of which are over 50 feet high; a Thuja Lobbi higher still, and fully 23 yards round, looking more like a gigantic mass of Fern or Lycopod than a coniferous tree. Associated with these are lofty Wellingtonias, Silver Firs, Deodars, and Atlas Cedars, one of which is the glaucous variety, probably the finest specimen in the country. It is an extremely handsome tree, which in the sunlight looks not unlike a pyramid of frosted silver. It appears to have suffered at one time from overcrowding, but now it forms a conspicuous object on the lawn in view of the principal windows of the house. To a lover of Conifers this tree alone is worth going a long journey to see. Of smaller things in the way of trees and shrubs there are charming specimens of the Japanese Maple, so elegant in foliage and so rich in colour. They are losing their brilliancy at the present time, but the examples of sanguineum and others have been objects of great beauty—in fact, the most attractive feature of the lawn. Then there are great bushes 6 feet high or more of that beautiful Chilian shrub, Eucryphia pinnatifolia, which in the course of a week or so will be in bloom. It has large blossoms like those of the common St. John's-wort, but pure white. Near it is a standard Wistaria, not a common object, which when in bloom has a striking effect viewed from the house against a background of evergreen growth. Among other conspicuous shrubs one notices just now is Berberis Darwini, of which there are great spreading bushes loaded with bluish-purple Currant-like fruits. The otherwise flowerless shrubberies are lit up now with Spiræas and the bright yellow Bush Broom (Spartium junceum), which has branches like a Rush, wreathed with large Pea flowers of the brightest yellow. The Bamboos and Pampas Grasses also contribute not a little to the beauty of this garden. Of Bambusa Metake, now proved to be the hardiest of all and most suitable for our climate, there are huge clumps several feet high, and one might say yards through. The largest Bamboos are in proximity to the great Lawson Cypresses and Thuja Lobbi, and these, together with the Pampas Grasses and Ferns, make a garden picture which it would be difficult to surpass. Why Conifers, Bamboos, Grasses and Ferns succeed so well in this spot it is not difficult to understand. They are planted in or near a little rill of water which is constantly running, as an overflow from a pool in the higher ground, and this is sufficient to keep the ground always moist; in fact, the soil close to the Bamboos, Grasses, and Ferns is quite spongy. Although no attempt has been made to mention all the out-of-the-common trees and shrubs, enough has been said to show that the garden has been richly planted.

The mansion, like most others in the neighbourhood, stands in a very good position. It is built just on the outskirts of Coombe Wood, which is overlooked from the front of the house, while beyond the wood the view extends across Wimbledon Common right away to the Crystal Palace at Sydenham, whose towers are plainly seen. In the other direction lies a beautifully wooded country, while behind, but a few yards distant, is the great Richmond Park. The house, which is modern and built with red brick, associates well with the surroundings.

From the front of the house the lawn falls away in a gentle slope—here running into long vistas to the distant background, there receding into darkened nooks among the intricacies of the shrubberies and plantations—creating that play of light and shade which is the distinguishing characteristic of an artistically designed garden. Polished and unpolished portions of the grounds here meet in striking contrast. Groups of great trees, remnants of the old Coombe Wood, mix with Gold and Silver Hollies and trimly clipped Golden Yews, which at this season are about the only things that light up the garden with colour. Beyond the Japanese garden is another stretch of woodland, left to Nature, except that the paths are kept mown. Here one sees the beauty of the Silver Birch to perfection, also of the Holly and other native growth. The cunningly-designed path through this part leads to a point where one comes upon a full view of the polished garden, with the house in the distance; in fact, just the point from which the illustration on the opposite page was taken. Two plots close to the house are reserved for the only display of colour. These are not elaborate in design, but massive and simple. Gnarled Oaks, elegant seedling Birches, and a host of other native trees and shrubs are left to themselves, and rising, as they do, from a carpet of Bracken and Bramble, their wild aspect is the more noticeable. From this point, the walk that encircles the place leads to what is called the Japanese garden, but the term is inappropriate now, because, besides Japanese vegetation, there are ornamental trees and shrubs from other regions; in fact, more from California than elsewhere. The view from the high ground in the Japanese garden is very fine, as it extends right away to Wimbledon Common, with a richly planted garden as a foreground, and the beautiful valley in the mid-distance. A large pool in this part is densely crowded with shrubs and plants—in fact, left to Nature, and these contrast strongly with the pyramidal Hollies, the effect being in harmony with the house and the rest of the garden. The plant and fruit houses as well as the kitchen garden are on a scale proportionate to the importance of the place, and the whole is maintained in a high state of keeping by Mr. Woodgate, the gardener. W. G.

SHORT NOTES.—VARIOUS.

Pansies (*J. S.*).—Very pretty blooms, varied in colour and, as you remark, delightfully fragrant.

Gilbert's Champion Broccoli.—I can conscientiously say a good word for this Broccoli; it produces fine large white heads and its flavour is excellent, and this being planting time, it might be tried with advantage.—J. C. C.

Spiræa palmata.—This, growing in a very damp corner of the rock garden at Kew, is more intensely red than any I ever saw. When grown in borders like S. japonica it is often very pale in colour, and as I was assured that the Kew plant was only of the ordinary type, I can only attribute its extra bright colour to its semi-aquatic position.—J. Muir.

Fruit Garden.

GOOD STRAWBERRIES.

Your request that fruit growers generally in different parts of the country will forward notes on varieties and culture for publication in The Garden is a step in the right direction, taken not a whit too soon. Already many useful remarks have appeared in print, and more, no doubt, will follow, that is, if growers who make a specialty of the Strawberry will kindly give their experience of the new or little-known varieties which they have tested and approve of, or that have been found wanting. If we enter a score of private gardens, we do not find more than half that number of varieties grown, and yet more must have been tested and discarded by men capable of forming an opinion as to whether they were likely to displace old and well-tried favourites. The lists of Strawberries, like those of all other fruits, have become far too long and require reducing. One, by no means the largest I have seen, now before me contains over sixty varieties, but, judging from experience and the few names which have already appeared, a small percentage only of these are grown, and yet nurserymen are expected to pay high rents for their ground and keep all these varieties true to name. By all means let us have lists of the best kinds for flavour, for bearing, for coming in early, and for keeping up a supply until the season is over. Then, in order to benefit the trade and enable them to give us a better article for less money, a list of varieties which have been tried and found wanting should be published. This outcome no private individual or society can secure, as we find many kinds doing well in one part of the country and failures in others, but by getting up an election of sorts their general adaptability to certain districts could be settled by experience. Take, for instance, the British Queen variety, which perhaps ninety out of every hundred gardeners have grown or tried to grow, and if it is found that the majority of good cultivators in any particular district have left it out of their lists, we may conclude that experiments should precede extensive planting. Take yet another delicious old variety, Sir Charles Napier, at one time and possibly now a favourite with southern growers for the London market. But why is such a bright fresh kind so seldom met with throughout the kingdom? Simply because in cold heavy soils it is not only an unfruitful variety, it positively shrinks away and dies. Seasons, again, as well as soils have great influence over the Strawberry, and not unfrequently the effect of certain climatal conditions—say in two districts, the one good, the other inferior—is the reverse of what might be expected. A remarkable instance of this kind this season is now within my own knowledge. A late variety called Oxonian, sent out by the late Mr. Turner, has long been a great favourite in Worcestershire. At Madresfield Court, and along the warm red land east of the Malverns, the crop usually so good is a failure; on the Herefordshire side of the hills it is the best I have seen for a number of years. Promiscuous information from the few persons who rush into print will do some good, but to settle the matter thoroughly and reduce our bulky lists to decent proportions, I would suggest the distribution of simple forms to be filled up and returned by the leading growers in every county.

Strawberries degenerating.—A correspondent inquires if Strawberries degenerate, and goes on to say he has been obliged to give up the growth of several of the leading varieties after a short period of four or five years. If grown on the three years' system, it is hardly possible that they can have become tired of the soil; he must, therefore, set down his failure to some other cause—possibly the bad seasons which have prevailed for some years. Strawberry plants are so easily propagated, and many growers depend too much upon their own gardens for their annual supply of runners; whereas, were they to work upon the exchange principle, they would find that the same variety might be grown for any number of years. When Strawberry beds become infested with mildew they should be chopped up and burned. No one on any account should be allowed to have a runner from them, neither should the pickers be permitted to carry the fungus into clean beds in other parts of the garden. Dryness at the root is the main cause of mildew, and old beds are more subject to it than young ones; but by making new plantations on fresh ground every year and destroying an equal breadth of the old when the plants have borne three crops, this pest—one of the principal causes of degeneration—can be partially, if not entirely, stamped out. I have adopted the exchange principle and the three years' system for a great number of years, and so marked is the growth of introduced stock, that one can tell to a row where the plants terminate. Exchange alone, it is hardly necessary to say, is only one factor in the sum. I make a point of trenching my Strawberry ground when it is dry and warm early in the summer; grow summer Lettuces upon it in seed drills 2 feet 6 inches apart and plant in August, giving each Strawberry plant half a cubic foot of heavy calcareous loam, rammed as firm as rammers can make it. Mulching and watering play a very important part, and the Dutch hoe is the only implement used for destroying weeds.

Lawn view at Warren House, Coombe Wood, Surrey. Engraved for The Garden from a photograph by Miss Antrobus.

Varieties.—Our heaviest-bearing early Strawberry is Vicomtesse Héricart de Thury; the next La Grosse Sucrée, closely followed by Crimson Queen. These produce immense crops, and the plants are always free from mildew. Sir J. Paxton produces heavy crops of handsome fruit, slightly acid in cold seasons, but it has a good constitution, is well adapted for the main midseason crop, and the fruit travels well. President is a grand Strawberry for home use, and produces enormous crops of fine fruit when planted 3 feet apart every way.

For late use I find the old Elton a very profitable variety, and the best for preserving. Oxonian is a large, rather coarse Strawberry, but an immense cropper; it does well on north borders, and pays well. Moreover, it is a variety which will stand longer than any other before it shows signs of declining vigour. British Queen, Dr. Hogg, Loxford Hall Seedling, and Frogmore Late Pine stand first for flavour. La Constante, Lucas, Marguerite, Mr. Radclyffe, and Carolina superba are good Strawberries. Souvenir de Kieff and James Veitch I have given up; they are good for the punnet, but too coarse for our use.—W. Coleman, *Eastnor Castle, Ledbury.*

Strawberries in the North.

The north of England suffered as much from drought as the south and south-western counties, and Strawberries were much crippled in consequence. A friend has supplied me with a few facts concerning the different varieties cultivated there, and it appears that Vicomtesse Héricart de Thury is one of the best for all purposes; while on light soils Black Prince, if not allowed to remain after the second year, is still a profitable variety. In many gardens President is a total failure, going all to leaf, and in five places out of six Elton Pine behaves much in the same manner; but Frogmore Late Pine promises to be more profitable, though even this is not spoken very highly of. Among several new sorts tried at Aldin Grange, Durham, Loxford Hall Seedling promises to do well; and John

Powell, a sort in the way of Keen's Seedling, but more prolific, is also liked. Empress Eugénie, a rather coarse sort, and, as a rule, not highly flavoured, also finds favour with some of the Durham cultivators. Sir Joseph Paxton there, as elsewhere, is very popular. It was shown remarkably well at the late Newcastle show. Duke of Edinburgh is a great favourite with a market grower, who considers it the most profitable sort in cultivation. It is a vigorous grower, very prolific, and the fruit large, richly coloured, firm, and fairly good in quality. This sort ought to eventually become very popular among north country growers, and especially where Strawberries are cultivated principally for the markets. —W. I.

Strawberries in peat and sand.

WOULD you give me some advice as to making a new Strawberry bed? What sorts would you recommend for general planting—not late sorts. This house is about one mile from Ascot Heath, and the soil is very poor—a mixture of peat and sand, and, consequently, requiring much water, which is rather scarce in dry weather.—G. H. M.

*** If your ground lies high and dry, and the addition of correctives is likely to elevate the bed too much, wheel off a quantity of the worst, either from the surface or lower spit, and trench two good spades deep. Make the surface fairly level and apply a heavy dressing of rotten manure from the cowsheds or piggeries. Thoroughly incorporate this with the soil, working it well down to the bottom, and ram the lower spit as the second turning over is proceeded with. This will give a sound sustaining base for the lower roots, but something more is needed. You must have marl, or, lacking this, clay will be the next best substitute. Of one of these obtain a sufficient quantity to surface the bed to the depth of 4 inches or 6 inches: if dry and pulverised, so much the better; if otherwise, spread it roughly and loosely, and then leave it until the weather has gone through it. On a dry day, beat and pound the lumps until they are completely reduced, and fork it in without disturbing the lower stratum of peat and manure, already as solid as rammers can make it. When the finely-broken marl and surface spit, already containing a good quantity of manure, are thoroughly mixed, again ram until the whole mass is as solid as an old pasture; make the surface perfectly level, and the bed will be ready for planting. If the manures named cannot be obtained, rich manure from the farmyard will do; but that from pigs and cows being cool, solid, and rich will suit a peaty soil best. It is hardly necessary to say, the land should be clean and free from roots and weeds, and preparatory operations should be carried on in dry weather.

PLANTING.—August is the best time to plant, but rather than hurry the work, drying and breaking the marl into fine particles especially, planting may be delayed until September. Should this be the case, and the young plants are likely to become pot-bound in 3-inch pots, turn them out into a nursery bed and give them a good soaking of water. Here they will make fresh roots, and lift with good balls whenever they are wanted. When the plants and beds are ready set out the rows 2 feet 6 inches apart each way with small pegs, and draw shallow drills from peg to peg crosswise; then reverse the line and drill in the opposite direction. This will throw the whole of the ground into squares, the intersecting points being the stations. Having decided upon the number of rows of each variety, each row to run from north to south if practicable, lift the plants with good balls and let them in with a trowel, one at each angle, make the soil very firm about them and wash it home with a good supply of water. If, on the other hand, the bed can be got ready in reasonable time and the plants have been kept in pots, let them be thoroughly soaked before they are turned out, loosen the matted roots with the fingers and ram firmly with a potting stick, leaving half an inch of soil above the tops of the balls when all is finished. When planting is finished mulch well with short manure to draw out surface roots, as well as to prevent the soil from parting away from the balls, and keep the plants supplied with water until autumn rains render this attention no longer necessary. Peaty beds prepared in this way with marl and manure and made as firm as a board will grow good fruit of all the leading kinds, including British Queen, for three or four years, when they should be broken up, and the ground, for other crops, will never forget the preparation. A few rows of young plants should be put out every year when the labour will become light, and an equal number of the old can be destroyed without reducing the breadth under cultivation.

WINTER AND SPRING MANAGEMENT.—The beds from the time they are planted must be kept free from weeds, but no harm will be done by allowing the plants to throw out runners. This, during the remainder of the season, can be accomplished by hand-weeding or very shallow scuffling, but on no account from first to last must the roots be mutilated by digging or forking. When growth ceases, cut off all the runners, repeat the ramming, add more mulching, and the plants will be safe for the winter. Early in the spring, as soon as severe frosts are over, all deaths must be made good from the reserve, every plant must be again firmly rammed, as many of them will have been disturbed by frost lifting the soil, and a slight dressing of soot, avoiding the crowns, will do them no harm in March. When growth sets in, water being scarce, a heavy mulch of fresh, but well-worked, stable manure will keep the roots cool and moist, and the straw, washed clean and sweet, will form the best of all mediums for the ripe fruit to rest upon. Good plants put out in August give the finest fruit the first year, and the greatest quantity in the two years following.

VARIETIES.—These are now so numerous, and vary so much not only in quality and flavour in different parts of the country, but also in their positive refusal to produce fertile flowers under certain conditions and treatment, that one is inclined to say, Look round, make inquiry, and ascertain what kinds do best in the neighbourhood. But this matter of growing Strawberries in a manufactured compost in a peat district is slightly exceptional, and some kinds may prove a success where in cold heavy districts they are a comparative failure. The mode of preparation being expensive, I should say, do not try experiments with doubtful varieties, but plant Vicomtesse Héricart de Thury and La Grosse Sucrée for the earliest fruit; Comte de Paris, Sir Charles Napier, President, Sir J. Paxton, Crimson Queen, Carolina superba (a good, but neglected Strawberry), Mr. Radclyffe, and British Queen. The last may or may not succeed, but so decidedly is it the queen of Strawberries, that it is worthy of the most attentive cultivation. Heavy soil and plenty of mulching are the great factors in its culture, and if, in addition to the marl, a spadeful of good loam can be given to each plant at the time of planting, this variety in two senses will prove grateful.—W. COLEMAN, *Eastnor Castle, Ledbury.*

Little-known Strawberries.

I HAVE recently had an opportunity of forming an opinion concerning the merits of several sorts of Strawberries not in general cultivation, though not new. Of these, one of the largest is Kitley's Goliath, but in this case size is its principal recommendation. It is grown in the neighbourhood of Bath for market, and is found to be a very profitable late sort. Its fruits vary considerably in form, but, as a rule, they are thick and wedge-shaped; the seeds are deeply imbedded in the surface, the colour of which is bright red, and the flavour somewhat poor and flat. It is a strong grower, and on firm good ground crops heavily. The Countess, one of Dr. Roden's seedlings, is a very distinct variety. It is vigorous and prolific, and produces large, very flat fruits of a deep red colour. Its seeds are very thick and prominent; consequently it has the merit of being a good traveller. The fruits of it that I tasted were firm, but somewhat too acid to be pleasant; at any rate, I much prefer either Sir J. Paxton or President to it. Souvenir de Kieff is a fine handsome sort, good for either market or exhibition, and the flavour is brisk and pleasant. It is a vigorous grower, and on deeply trenched or rich loose ground it is apt to form too much foliage; on the whole, however, I am pleased with it. Loxford Hall is more generally cultivated than either of the foregoing, and may be termed a really good late Strawberry. This season, owing to the dryness of the ground, the flavour is naturally more acid than usual, but it is much superior to Oxonian, or Eleanor, as it is often called, especially as regards flavour, and it is quite as late as that variety.—W. I.

HEDGEROW FRUITS.

THERE will to all appearance be an abundance of hedge fruit this season. With regard to some kinds, the Blackberry, for instance, it is too early to speak, but in the case of others the fruit has been so far formed as to afford a pretty good indication of the crop. Of Hazel nuts there is a large quantity. There are a few hedge Sloes. For several years past this crop has almost entirely failed. This season there was reason to have expected more fruit than we really have, as it will be remembered that the extraordinarily sharp weather in the early part of March kept the Blackthorn from coming into blossom so early as usual. Of haws there is an abundance. The blossom of the Hawthorn was very abundant, and it now looks as if almost every blossom had set.

The Elder has not long passed flowering, but with trees which come into bloom so late in the season there is not much doubt of a crop, unless something very abnormal takes place. The Elder bushes have been a wonderful picture this season. There has been a great profusion of Dog Roses, so there seems every prospect of large numbers of hips. Out of all this immense bulk of fruit there seems to be very few sorts which may really be called edible. Practically, the Nuts and the Blackberries are about the only ones. It is true that hedge fruits have quite a legitimate use in providing winter supplies for the birds, yet it does appear strange with so many hundreds and probably thousands of miles of hedges that little or no attempt is made to turn them to account for fruit production. Farmers would not then require to devote all their farms to raising jam, as has been advocated by a high authority, but could obtain it from their hedgerows. Seriously, in many places there seems no reason why the Gooseberry bush, for instance, should not be employed instead of the Hawthorn. It is spiny enough in all conscience, and if kept cut in proper form would make quite as dense a hedge as the other. There is obviously no end of fruit trees which could be grown in hedges, but the number of dwarf trees or bushes which would be suitable to make up the fence itself does not seem to be so many. The Gooseberry is certainly one, and a valuable one, as it is just as easy to raise young Gooseberry bushes as young Hawthorns. I do not mean by this that we want hundreds of miles of Gooseberry hedges, but enough could be established to supply families with this useful fruit all the year round, as by means of preserving and bottling it can be made to last from one season until the next. Currant trees alone would be hardly suitable, but mixed with the Gooseberry there seems no reason why they should not be occasionally adopted in hedges. There are, no doubt, many drawbacks to such a plan of fruit raising, especially that of its liability to be stolen, but in many cases a little discretion in the choice of positions would materially lessen this danger.

D.

Pruning Gooseberry bushes.—I am pleased to find attention drawn to this subject, as I am convinced that Gooseberries get, as a rule, too much pruning. When severely thinned the loss of even a few buds by birds makes a serious gap in the crop; whereas, if left tolerably thick, loss in that way is scarcely felt. I recently visited a garden in which a grand crop of Gooseberries was

hanging, and the gardener assured me that he had never pruned the trees thus furnished with fruit for years, and they never failed to produce good crops. His plan was to plant young bushes, and let them grow without any pruning until they began to show symptoms of failing, when they were done away with and a fresh lot planted. Although it may not be desirable to dispense with pruning altogether in the case of Gooseberries, I feel sure that if only shoots that grow down on the ground or that cross each other are removed, much better results would be obtained than we now get. Ground on which Gooseberries grow should never be dug deep enough to interfere with the roots; it should simply be kept free from weeds in summer and lightly forked over in winter just enough to bury the old top-dressing of manure that is put on annually. The firm soil checks undue luxuriance and promotes fertility. —James Groom, *Gosport.*

NOTES.

White Poppies.—The big red Poppies of the Papaver orientale section are so well known and so highly appreciated by gardeners, that I am quite willing to leave them to their care, with this added caution, viz., keep only the very best forms and dig out all the bad ones, otherwise, supposing you wish to rear seedlings, all your seed is likely to be spoiled by pollen from the bad flowers. How comes it that the true great-flowered and great-fruited P. somniferum is so rarely seen in gardens? Even in botanical gardens a spurious smaller form of P. somniferum is often grown under the specific name. Quite recently Dr. Mahaffy, the Greek historian, made a little tour up the Nile to Thebes and Luxor, and he kindly brought me seeds of a white Poppy which has recently bloomed here six weeks after the seeds were sown. Mr. Baker tells me it is the P. setigerum of De Candolle, and in all probability the wild plant from which the Opium Poppy originated. A similar Poppy was grown by the people of the Swiss lake dwellings, and it is now grown for oil in the south of Europe. It has hairy flower-stems and a six-rayed deflexed stigma. The true Opium Poppy, with pure white flowers of satin-like texture nearly 6 inches across and almost as beautiful as those of Romneya Coulteri, has ten to thirteen rays to the stigma, and the common garden or spurious Opium Poppy has rays varying from eight to ten as a rule. The true Opium Poppy, again, is very distinct in its fruit, each being about the size and shape of a King of the Pippins Apple, and there are rarely more than from one to three flowers on each plant. It is, as I fancy, the most stately and effective of all the white Poppies.

Fruit from abroad.—The Australian fruits in the Colonial Exhibition will open our eyes a little as to the possibility of preserving and carrying fruit for long distances—in fact, from one side of the world to the other. In Singapore, for example, there are the finest of tropical fruits in abundance, such as Bananas, Mangoes, Durian, Langsat, Duku, Litchi, and Mangosteen, and yet when I was there a few years ago there was quite a furore because an Australian boat had arrived with a cargo of Apples on board. I had never eaten an Australian Apple before, and enjoyed their freshness and flavour alike as eaten beneath a tropical sun. There are a good many fortunes in the foreign fruit trade, and I often wonder why our preserved fruit manufacturers are so lethargic in the matter. You see Pine-apples by the bullock cart-load lying about in Singapore and other Eastern ports, but it is only quite recently that they have reached our markets in a canned state. Surely it is possible to preserve Mangoes and Mangosteen, even if it be not possible to carry them fresh to our shores. Fortunately, we can eat Oranges all the year round, and all who have eaten Mangoes in India will regret that they cannot be imported to our markets. The day is not far distant when the Chinese will send us all sorts of tropical fruits in syrup, just as they send Kumquats and Ginger now, and those who deal in the last named preserves might do a little by stirring up the Chinese traders in the matter.

Lotus and Papyrus.—The Lotus of the Nile seems to have been Nymphæa Lotus, a rosy Water Lily, the flowers of which were used in the funeral wreaths of the ancient Egyptians. It is a fragrant blossom, varying from white to deep rose, but the soft blue flowers of N. stellata and N. cærulea were also used in these appendages of burial. Nelumbium is the flower of Buddha, and is highly esteemed to this day as a sacred flower by both Indians and Chinese. If ever the Nelumbium existed in Egypt, it was most probably as a cultivated plant, and when introduced it was doubtless accompanied by traditions which soon led to its becoming popular, even if it did not, as some believe, supplant the native Lotus, or Nymphæa, as a sacred flower. The Egyptians had attained to such a state of culture, luxury, and wealth, however, that, no doubt, they were able to grow, appreciate, and utilise any introductions which came into their hands. All history, sacred as well as secular, points to Egypt as having been the garden of the world in its day. Plenty reigned there. Even the Israelites, who had been slaves in the land, regretted the flesh-pots of Egypt, the Leeks and the Cucumbers, when journeying through the desert. Another question is that of the Papyrus, which is rare as a native of Egypt now-a-days, and was, doubtless, cultivated in the delta when it was used for literary purposes. These two plants, the Lotus and the Papyrus, may stand as types of Egyptian civilisation, the one for the luxury, and the other for the culture of a wonderful people. Both are most beautiful, and worthy of our gardens of to-day.

Blue Shore Grass.—Wherever there is a demand for indoor arrangements of flowers and distinct foliage, this Shore Grass becomes very useful. It may either be used in its fresh state as newly cut from the plants, or dried for use during winter when elegant grassy foliage is scarce in the open-air garden. Arrangements of bronzy Spanish Irises and leaves of this Grass are very beautiful and distinct, giving harmony of form and contrast in colour; and no other leaves I know arrange so well with the bulbous Iris as do these and those of Typha angustifolia. Blue Shore Grass is the popular name of a wild Grass, known botanically as Elymus arenarius, a Grass as useful as it is beautiful, being scarcely surpassed by any other vegetation in the fixing and binding of shifting sands on the shore. The bluish grey hue of this Grass is so distinct, that a good clump of it on the lawn becomes a very attractive object. When planted, plenty of coarse sea sand should be mixed with the soil, in order to facilitate the production of luxuriant growth. A good deep pot or vase arranged with scarlet Gladioli and leaves of this Elymus is a beautiful combination.

Shade trees on the lawn.—Our climate is never quite so tempting as is that of Paris for open-air life; still there are many of our summer and autumn days when life out of doors is most enjoyable, and all that one desires is a leafy screen between our heads and the sun. Shade trees on the lawn just yield the protection needed, and their presence is worth ensuring wherever they do not already exist. Among other trees suitable for this purpose I have noted the Hawthorn, Weeping Ash, Horse Chestnut, Lime, which is, however, apt to be a little disagreeable when in flower. The Walnut is one of the best of all shade trees for a lawn, but slow in growth. One of the quickest of all in growth and most certain of growing in a shapely tent-like manner is the Weeping Elm, and the Weeping Beech is another excellent tree, and one well suited to limestone soils. Sometimes a little grove of five or six trees may be planted, and in this way a shady spot is quickly and certainly secured, or one may boldly form a pergola or shed of rough timber and cover it with Ivy, Clematis, Vines, Virginian or other creepers so as to ensure its becoming a thing of beauty as well as a useful adjunct to the house on fine days, especially during the time of Roses in the garden.

Violas.—The whole Viola family is a beautiful one, and that they may, every one of them, be grown well in a cottage garden is an additional advantage in every way. We have but few other flowers of summer that give us more pleasure than do these velvet-hued Violas of many kinds. From white through yellow and blue to a deep rich purple we have all shades. They show best as massed together, and during a hot and dry season like the present, we find the advantage of puddling, or lining, the beds in which they are planted with plenty of fresh cow manure. Apart from the extreme freshness and beauty of Violas, as seen growing—and a mass of V. cornuta alba now before me as I write is most lovely—their flowers are also valuable for cutting. Our plan is to cut all the sorts and colours separately. About three leafy shoots are first gathered, and to these we add about a dozen good, fresh, newly-opened flowers and buds, and the whole is loosely tied with a bit of bast, or with Crocus leaves. The same rule is observed with Roses, Carnations, Pinks, and other flowers, each being bunched separately and cut with long stalks, and, so far as possible, arranged with their own foliage.

English plant names.—The question is not of either alone, but of both Latin and English combined. Whilst convinced that Latin names have a cosmopolitan distribution and meaning to the educated people of the entire world, yet we must not forget the every-day wants of those who know no Latin and less of Greek. English names may be quite as scientific, that is to say as definitely descriptive as Latin ones, and this is what they should really be, and not merely popular or fancy names. A name that is popular to-day becomes unintelligible to-morrow, but this is not so if a name be framed from the backbone of our language. Latin names are and will be used by scientific men, and rightly so, but when a plant has a plain English name as well as a Latin one, every one of the millions who speak English has a double chance of knowing all that a Latin name can convey to the scholar. In a word, the only perfect system of plant-naming is, or will be, a dual system in which the so-called scientific and the so-called popular demands shall be fairly supplied. How very rarely is Latin used in speaking of forest trees, or of fruits or of vegetables, or of the Corn or the cattle on a thousand hills. In a word, nearly everything really useful to man has an English name already, be it bird, beast, stone, or plant, if we except the garden flowers, and no good reason has been yet shown why the principle of dual naming should not be systematically applied to them. A noted trade grower told me only yesterday that he should adopt good English names for all his plants, adding that they sold better when so named. Here is a philosophy which he who runs may read.

July or Gilly flowers.—In John Rea's "Flora," third impression, published in 1702,

there is a catalogue of three hundred and sixty varieties of Caryophyllus hortensis or July flowers, most of which he tells us were reared from seeds by the Dutch florists, and brought over from Holland, Flanders, and other parts of the Netherlands every year. Rea further says that "many varieties are yearly brought over to London and there sold at mean rates to gardeners, who sell them again to others who delight in flowers commonly at twelve pence a layer." Now-a-days all this is altered, the very finest of Pinks and Carnations being raised from seed in England, and in many cases from home-saved seeds. In Rea's time this was not possible if what he says be true. "Good July flowers are so aptly gained from seeds in the Netherlands," he says, but he adds, "yet they are not so with us, for if the seeds which some years we gain from good Dutch flowers be sown, transplanted, and handled with all possible care and diligence, yet most of the plants will bring but single flowers, and if any chance to prove double they are either much broken, small, or meanly coloured, and of little esteem." Rea places the July flower next to the Rose in his estimation, and I think he is right, for good Carnations and Cloves are nearly perfect as garden blossoms. The intricate instructions for pot culture and the preparation of soils read curiously to us to-day when our finest flowers are grown in the open air, and a packet of seed suffices to stock many a good garden with these fragrant flowers.

The watering-pot.—All the world over, where any attempt is made at gardening, there you find the watering-pot in some form or other. In Egypt a bag of skin does duty for it, the water being squirted through a narrow hose-like portion. The old earthenware water-pot is now rather rare in France, but is often shown in the Salon pictures of flowers and plants. In Borneo a hollow bamboo does duty as a water-pot, and there are different appliances elsewhere, but for persistent use of this appliance the Chinese are especially noted. A Chinaman seems to employ every spare moment in watering his garden. Early and late, rain or fine, it makes no matter—there he is at work with the water-pot; and it is rather amusing to see him stolidly pouring water about among his vegetables during a downpour of tropical rain. One fact is in his favour, for, wherever the Chinese take to growing vegetables, they beat all comers, and generally monopolise the trade. This season, in particular, we have been driven to the use of the water-pot more than usual. In watering permanent plants our plan is to scrape away the dry soil before watering and to replace it afterwards, so that it to a great extent prevents evaporation, and also caking on the surface. In transplanting during hot weather we also are very particular to water the plants well a day or so before they are moved as well as afterwards. When well watered before digging, we find it easy to transplant nearly anything without any injury whatever.

Canna Ehemanni.—This tall and stately crimson-blossomed species is generally considered to be a variety of C. iridiflora, and is so striking in habit and showy when in blossom, that it deserves a place wherever stove plants are grown. It is of vigorous habit, and attains a height of 6 feet or 8 feet in a hot temperature with plenty of moisture. By dividing a large plant and growing the pieces in various temperatures, it may be had in blossom nearly all the year round. It is most vigorous in a compost of fibrous loam broken into pieces as big as one's fist, and to this a little manure from an old hotbed may be added, or, as I think, a better plan is to pot the plant in pure loam, and then to give an occasional dose of liquid manure after the young roots have taken possession of the soil. Another free-blooming kind, C. floribunda, a smaller habited plant with erect spikes of crimson flowers, does well under the same treatment, and is one of the floriferous kinds. Even when not in bloom the above are so fresh and their leaves so shapely and ornamental that they are never unsightly, and therefore well worth a place wherever stove plants are grown.

Campanula lactiflora.—A tall-growing Bellflower introduced fifty years ago or more from Siberia, and even now not so well known in gardens as it deserves to be, seeing that it forms a spreading mass of stems 6 feet or 7 feet in height, each stem bearing a mass of flowers at its apex, and each flower being 1 inch in diameter and of a delicate tint between milk-white (hence its specific name) and pale sky-blue. It is quite readily propagated either from division of the roots in spring, or by seeds sown as soon as ripe in open-air beds. Its season of flowering makes it especially valuable, since its comes into bloom just after the Canterbury Bells are over, and before the Chimney Campanulas (C. pyramidalis), white and blue, begin to flower. Among other good Bellflowers now blooming, two of the best are varieties of C. Tymonsi, which somewhat resemble C. carpatica, but have darker coloured flowers. After all, is there anything in the whole group much more beautiful than the common "Blue Bells of Scotland" (C. rotundifolia) and its forms? Making a pilgrimage to Abbotsford last autumn, I saw hedge banks lined with this bonny flower of Burns.

Aciphylla squarrosa.—This is one of the Wild Spaniards of the settlers in New Zealand, a plant which at first sight reminds one of a slender-leaved Yucca, but which is really a divergent member of the Umbelliferæ. It has divided leaves, each division being linear, and tipped with a red-black pointed spine. As these spine-tipped leaves radiate in all directions from the ground level to the zenith, and are pretty thickly disposed, it follows that the plant itself is of the most exclusive or touch-me-not description. It is abundant on the declivities surrounding Mount Cook, growing in gullies and depressions among the stones. Seeds of it were sent to Edinburgh some few years ago, and from these plants were raised at Trinity Lodge, at the Botanic Gardens, and elsewhere. We have here a plant nearly a yard in diameter, which flowers freely every year, but produces no seeds, but seeds from the Edinburgh Botanic Gardens grow freely, and a nice little batch of seedlings are very welcome. If not actually dioecious, the plant shows an inclination in that direction, for while some individuals seed freely, others refuse to do so. Either as a distinct-habited plant for rockwork, or on the Grass, it well deserves a place in the garden.

Lavender.—Sweet Lavender is not quite so highly valued to-day as in times past, yet there are even yet many places where bunches of its flower-heads, neatly tied up in muslin bags, find their way into the wardrobes and linen chests of many old country houses. Even as an evergreen bush on the lawn, Lavender is well worth culture, and a bunch of Cabbage Roses or Carnations, with a few sprays of Lavender added, form a posy fit for a queen's boudoir. There is a little secret as to the cutting of Lavender flowers, and that is, never allow the flowers to open before they are cut, but reap them off as soon as ever the flower-buds show colour, since if left later much of the delicate essential oil will evaporate, or have become absorbed by the blossoming. The old herb gatherers of former times were most careful to gather their simples before flowering time, and the point is worth attention in the garden where everything, whether fruit, vegetables, or flowers, should be gathered a day too soon rather than a day too late. There are several varieties of Lavender, the best being that grown at Mitcham, in Surrey, for distillation, and where, at night more especially, the air is redolent with perfume from the fields or from the working still. Where is now the old white-flowered Lavender, figured by Besler in 1612, and which no doubt even yet exists here and there as a curiosity?

Gentiana gelida.—Formerly we used to call this pretty free-blooming plant G. septemfida, but the above now appears to be its generally accepted name in gardens. It is, as I believe, the best of all the summer-blooming kinds. Its deep sky-blue flowers are borne in dense trusses, or umbels, on leafy stems about 1 foot in height. They are very lovely, and have a dainty bit of finely-cut fringe in the sinus between the corolla lobes, which adds quite a unique finish to the flowers. It has grown here on a dry rockery having a southern exposure for at least seven or eight years with no protection other than a Wilsonian zinc collar as a safeguard from slugs and small snails, which esteem it a delicacy just as its succulent young shoots appear above ground in spring. After flowering it seeds freely, and if the sawdust-like seeds be sown at once after ripening in an open-air bed of peaty soil, they germinate freely the following March or April, and soon become strong, healthy little plants, fit for transplanting to the positions which they are destined to occupy.

Veronica.

Flower Garden.

NOTES ON HARDY PLANTS.

Campanula carpatica and its varieties.—What more beautiful or more effective dwarf plants could be named than these? Take merely the better defined forms of them, beginning with the type, then the purple turbinata, and after that the G. F. Wilson variety. If the bells or cups range for size in the order given, the fine purple colour is intensified in just the opposite order. Carpatica lasts for weeks in beauty, turbinata scarcely for a less period, and were the useless seed picked off, strong plants would do even better. As regards the Wilson variety, when I thought it had done flowering, the plants were severely divided and potted in grit and perfectly decomposed leaf-mould, and not only has vigorous growth begun, but flowers are coming afresh. These showy and enduring flowered plants are what may be safely recommended to be grown in not merely odd patches, but in quantity. Then there is the white strain, which runs out as far as turbinata, as well as some white, softly tinted with purple, varieties, but I have not yet seen this shade in other than the typical form, in which, however, it is common enough.

Carex riparia albo-marginata. — Notwithstanding the fact that variegated Grasses and other plants are often objected to for indoor use in a cut state, this Sedge, I think, should form an exception. Cut with a bit of root attached to it, so that the blades are kept in the position as grown, I know of nothing handsomer. When associated with the bright Iceland Poppies nothing more is required for a small vase. Many, I know, would shudder at the idea of having a Carex in the garden, but it is more easily kept within bounds than some things which most of us grow. It gives less trouble, for instance, than Forget-me-not, and when grown clear away from trees it may be found quite as useful as the little favourite just named.

Polemonium confertum is admitted to be one of the handsomest species of the genus to which it belongs; still, I fear there is not much interest taken in it, doubtless because it is not known. Every lover of alpines should, however, make its acquaintance, and for that there is no better time than now, for if

plants of it are not well established they are liable to be killed in winter, though perfectly hardy. If planted now it will make strong growth, and this is the only safe season (so far as I have proved from an experience of it for six or seven years) when it can be safely divided. In a very few days offsets become thriving plants.

Campanula Allioni with double flowers may not be uncommon, but I must say the double flowers do not equal the normal ones in beauty. On the same plant were one or two double bells last year, but this year these double bells are more perfect, that is, one bell within the other. I see no signs of more than one inner one.

Lathyrus rotundifolius.—How does it happen that this plant is so scarce? Surely a moderate sized climber cannot come amiss, especially when it produces flowers of good colour and substance for at least two months, as this so-called scarlet Pea does. If this Pea were tried fairly and given some twiggy sticks about 4 feet high to support it, I am sure no one could object to it—the colour is so clear and for picking, either as single flowers or as longish sprays, it is excellent. After several years' trial of L. polymorphus, I now give it up, for it is killed off every winter, even if mild. If anyone has succeeded with it in the open garden, it would be interesting to know under what conditions.

Sedum hirsutum is a gem. It much resembles a minute Sempervivum; its hairy, almost globular, rosettes are pleasingly placed around the parent on stolons of moderate length. Although the reddish flower-stems are not more than 3 inches or 4 inches high, they carry clusters of white starry flowers, which are large for the size of the plant. From the manner in which the black anthers rest on the petals for most of their time, they give effect to the flowers and attract notice. I have not tested this plant in a fully exposed situation—only where it has been safe from rain and snow; but it stood 16° of frost without injury when dry both top and bottom.

Dianthus cinnabarinus.—This is the most distinct alpine Pink with which I am acquainted, and, coming into flower as it does late, it is all the more desirable. If the flowers are small—three-quarters of an inch across—they are striking, being cinnamon-red in colour, and borne singly on stems from 6 inches to 9 inches long. A good sized piece of this Pink would, indeed, be a fine feature in a garden. I take it to be hardy, but I keep it in a cold frame during winter.

Milla longipes.—I have proved this to be a hardy bulb and a free bloomer. Its stiff scapes are from 9 inches to 12 inches long, and carry very handsome white star-shaped flowers, which underneath are of a rich ruddy-brown colour. They strike one at once as being of an unusual type. In my specimen, however, the leaves have quite disappeared, and, as in the case of other Millas, the flowers without foliage look a little forlorn; still, everyone must be pleased with them.

Polygonum capitatum.—This is a very small species—small in all its parts and prostrate in habit. Its little somewhat cordate leaves are grey with down, as are also the zig-zag and brittle-knotted stems. The flowers are not showy at all, and still they form the main feature of what must be termed a pretty little plant. They are of a delicate flesh colour, about the size of a marble, and quite as round; they are held above the flattened herbage on short, erect stems an inch or more in height. It grows freely, and every short lateral is terminated by a head of bloom. A good sized piece of it must have a unique effect. I have not yet fully tested its hardiness, but under dryish conditions it has withstood 16° of frost.

Achillea umbellata.—It is a pleasure to speak of the good properties of this well-known dwarf and silvery Yarrow. On a few stones in a corner fully exposed to the fiercest sunshine, and overhung with Clematis and Honeysuckle, a plant of this Yarrow has kept in capital form for not less than five years. Not only is the position dry and sunny in summer, but owing to the climbers overhead dew is prevented from falling. The fact is, this neat little plant enjoys dryness, and we should do well to take advantage of that circumstance more than we do, for we often find such positions as it could fill quite bare of vegetation.

Gentiana ornata.—This is again in profuse blossom; how it revels in moisture and warm sunny weather! Not only is this shown by the manner in which the buds quickly develop, but also by the way in which the stems root where they touch the soil. As soon as these roots get well hold, the shoots branch afresh, and every growth is terminated by a bud. During our short warm season this species should not be an hour without moisure, especially if flowers are desired. If rooted offshoots are wanted, less water may do, and shorter-jointed stems will be the result.

Erodium Reichardi.—What a pretty little alpine this is! and, as it thrives well under treatment of the most ordinary kind, it is surprising that it is so rarely seen. It is very dwarf, merely forming a mat of herbage on the surface, and its flesh-tinted white flowers scarcely rise above the ground. Though a stemless plant, there is no difficulty at all in dividing it. It is only needful to bare the crown and cut downwards half an inch, allowing each growth a portion of thick Liquorice-like root, which may be split, if need be, to its extremest point almost, and thus becoming more equally divided than could be done by any knife. The same process may be carried out with E. hymenodes and E. macradenum. In all cases, however, this should be done in the summer time, when these split tap roots may have plenty of time and a good chance to become furnished with new feeding fibres.

Woodville, Kirkstall.

In the garden at Warren House. Wellingtonias, Lawson's Cypresses, Pampas Grasses and Bamboos. (See p. 92.)

White Lilies.—These have been common everywhere of late. Here in Wales they may be seen in all sized gardens, and about ten days ago they were the best flowers in the London markets. They are growing abundantly in all the parks, and the florists use them largely for indoor decoration. The variety is the old L. candidum, and I would like to ask those who find it so useful if it would not be a great advantage to grow some other good varieties of Lilies in large quantities for such purposes. In several notable decorations I saw blooms of L. Harrisi, and in each instance the effect was better than that produced by the white ones. In such a grand and extensive family as the Lilies it is to be regretted that public favour should run on one variety alone, and that the most common one.—J. M.

Statice Suwarowi.—This is perhaps the best annual introduced for many years. At the Bristol summer show held on July 14 many excellent collections of annuals and perennials were exhibited, and this Statice, although only shown in one instance, was conspicuous amongst them all. Two or three days later I saw a small group of it in pots in the Cape house at Kew and another batch in the rock garden, and in both cases the plants were remarkably healthy, finely grown, and wonderfully attractive. The graceful spikes of soft rose-coloured flowers are well adapted for all kinds of floral decoration. It merits universal culture.—J. Muir, *Margam.*

Stipa pennata.—The Feather Grass is one of the most elegant of the ornamental Grasses. Its light feathery plumes, as they wave to and fro in the summer breeze, have an extremely pleasing appearance. This is not exactly a plant for isolation; it looks best in association with other things, and wherever hardy flowers are grown in borders

this Grass should find a place, both on account of its graceful habit and the admirable contrast it affords to other things. The easiest way to get good clumps of it is to sow the seeds where they can grow on undisturbed. If the ground is well stirred and a little manure worked in, some good clumps will be formed the first year, which will bloom well the following season. The seeds of Stipa pennata are hard and slow in germinating. I have known them to lie three months in the ground and then come up. For this reason many do not succeed in raising this Grass, giving up the seeds as bad before they have time to come up.—J. C. B.

WORK DONE IN WEEK ENDING JULY 27.

July 21 and 22.

Fine; completed Pine potting, and the re-arrangement of the plants in pits; unrooted suckers will be kept rather close, the walls and beds syringed morning and evening, but no water will be applied directly to the plants till roots have begun to work in the soil. First successions are arranged in two separate pits, Smooth Cayennes by themselves; and all other varieties, mainly Queens, occupy another pit. Smooths require shade, and this is the reason we endeavour to keep them apart from others that are impatient of shade, and require more copious watering than do Smooths. The border heat ranges from 80° to 90°, and the top heat is regulated by the weather; 70° at night, even in the hottest weather, we consider ample; and air is given by night when the temperature is likely to be higher than this. A medium condition of moisture is assured by syringing beds, walls, and floors night and morning; and twice each week clear manure water is used for syringing. Much the same treatment is given to fruiters, the only difference being that a rather drier state of the atmosphere is preferred as the fruit approaches maturity, but dryness at the root we at no time allow. Other work in the houses has been potting Euphorbias and Poinsettias, planting out succession lots of Melons, and keeping the growth of Cucumbers and Melons pinched back. Planted out late Broccoli and Purple-sprouting Broccoli after Peas. Firm ground best suits all the Cabbage tribe; therefore, we never dig, but simply clean the ground, draw drills, and plant 2 feet apart for the largest Broccoli. Planted out Leeks and staked Tomatoes on south borders, the fruit of which is already ripening. Trimming up woodland walks by switching away the projecting growths of Rhododendrons, Laurels, Bracken, Nettles, &c. Specimen trees in the lines of these walks we take pains to protect from damage by cutting back the underwood and rubbish somewhat severely.

July 23 and 24.

Showers on both evenings, with wind on the first date, near akin to that we get in March, and which has added to our other labours that of fresh staking and tying Dahlias, Castor-oils, large Fuchsias, and sundry other flower garden plants, as well as the clearing up of sticks and leaves that have blown and drifted in every direction. Luckily, we have got our kitchen garden work well forward, and can, therefore, devote our whole time to the ornamental department; then there is a quantity of hedge and shrub cutting, walks weeding and rolling, besides the pegging down and pinching of plants in flower-beds that since the rain have grown away most vigorously. Pinched into form, to preserve the true outlines of flower-bed designs, Gold Feather Pyrethrum, variegated Mesembryanthemum, variegated Alyssum, Gnaphalium lanatum, Coleus, Iresine, &c. We still keep the flowers picked off all plants that are required to be at their best from the middle of August and onwards. Pinched Figs and picked off a quantity of fruit, the crop being far too heavy if the fruit is to be large, which we much prefer to numbers. The first crop of ripe fruit being now cleared, syringing twice a day is now resumed, and the house closed early with sun-heat, to run up the temperature to 90° or 95°; then but little fire-heat is required; the trees have had a good soaking of manure water and the border a fresh mulching of long stable litter. Stopping laterals on Vines. Madresfield Court has not this season cracked nearly so much as previously, as, besides keeping the border and atmosphere on the dry side, we have bored a hole with a small gimlet right through the wood, about 4 inches behind the bunch. This matter was discussed in some of the papers last year, and the hints then given on this matter may have been of service to others besides myself. We have a house containing this variety and Gros Maroc only, and from present appearance, which is all that can be desired, the two kinds are well adapted for growing together. Gave all houses a general clean up.

July 26 and 27.

More showers on both dates, but not so heavy or continuous as to hinder our work. Continued trimming up woodland walks and drives, and the clipping into form groundwork plants in flower beds, and cut the Grass verges and upright (Herniaria glabra) edgings to the same. Cut all bad blossoms off Roses, pulled up and rubbed off Brier suckers and shoots, and partially cut back the longest shoots of the Hybrid Perpetual class. The Tea and Noisette section has lots of buds still to open, and therefore the shoots of these have been left intact. All the Roses have suffered from the heat and drought, but the injury is only temporary, as by a continuation for but a very short time longer of these beautiful showers there will be a good autumnal display of flowers. Of work in the houses there is still an overplus, Strawberry potting for forcing and Chrysanthemum stopping and tying being now to the fore. Arranged flowering plants in orangery, and also refurnished vases and baskets in mansion with similar plants. Hants.

FRUITS UNDER GLASS.

Peaches.

By this time a great number of early Peach houses will have yielded their crop of fruit, and steps must at once be taken, not only for cleansing, but also for preserving the foliage until the wood is ripe. Although nearly all Peach forcers run in pretty much the same groove up to the ripening period, perhaps no tree is made subject to more diverse modes of treatment during the remainder of the season, and yet the one great aim is the ripening of a set of shoots which will produce fruit another year. Years ago when disbudding was not so freely indulged in as it is now, the great fault was the laying in of too much of the summer growth. This practice, it is needless to say, gives an infinite amount of labour, and the result is unsatisfactory, as it is simply impossible for several shoots to develop their foliage and ripen up properly where there is only room for one. This, then, the thinning out of old shoots from which the fruit has been gathered is the first operation; indeed, if anyone were to ask me to define the best time to commence successful Peach forcing, I should say the day after the last fruit of the current year is gathered. On that day I would cut out every shoot not wanted for another year, and tie in those retained at least 6 inches apart all over the trellis. The foliage should be well washed late in the evening in fine weather, and the roots as regularly watered as if the trees were carrying crops of fruit. If old trees showed signs of weakness, moderate mulching and copious watering with liquid would form an important part of their bill of fare, while young ones inclined to grossness would be deprived of their surface covering and kept, not dry, but slightly on the dry side upon temperance principles. Air in abundance must be given, and all the movable lights worked upwards and downwards to give the foliage the benefit of refreshing rain in showery weather; but I would not sanction the cut-and-dry system of stripping the trees, no matter what the weather, so long as a leaf remained upon them; neither would I switch with a birch broom to get rid of the bright golden leaves before their time. Every leaf should fall naturally. Then, if the lights required repairing and painting, I would strip for a month in October. By this time, if not a little before, all root-pruning, lifting, and top-dressing, the materials having been previously prepared, should be taken in hand. Good heavy calcareous loam, fit for Melons, Strawberries or Roses, five parts, old lime rubble one part, and a dash of soot to kill worms in a dry state, but innocent of animal manure, would form the compost, and of this each tree should have as much as it would be likely to fill with roots the following year. By using the compost dry it can be firmly rammed, as Peaches always make the best short-jointed growth, and do not so readily become dry in a solid resisting medium. A moderate watering to wash the fine particles of soil home to the young roots, and a thorough watering a fortnight later, would then keep them steadily progressing, and as steadily filling and feeding the buds up to the time of starting. Peaches on open walls rarely drop their flower-buds, no matter how wet the winter; if they do, it is a sure sign that the drainage is imperfect or the wood is only half ripened. Why, then, do we so constantly hear of forced trees casting them? Simply because they are allowed to carry too much wood, and the roots are kept too dry through the resting period.

Succession houses in which the fruit is now ripening require precisely the same treatment after it is gathered; but stripping is not necessary provided the foliage is kept clean and the internal roots are well supplied with water. Indeed, it frequently happens in cold wet autumns that early closing, with dry sun-heat, becomes absolutely necessary to the perfect ripening of the wood and flower-buds.

Late houses furnished with trees whose roots have the run of external borders speak as plainly as trees can speak by making fresh healthy rapid strides after heavy falls of rain, a fair proof that water, both to the foliage and roots when the latter are inside, is one of the most important elements. The artificial mode of training large trees on trellises with every leaf and shoot within a few inches of the glass, and fully exposed to the sun, is very trying in hot weather, and causes a constant and rapid drain upon the roots to which homœopathic supplies of water are useless; but when, in addition to the foliage, they are carrying full crops of fruit, water in great abundance and of a stimulating nature is the only element which can keep the trees in health and prevent the fruit from prematurely ripening. Let all borders, then, be they inside or out, receive heavy mulchings of manure, and flood at short intervals until the water filters freely through the drainage. Syringe backwards and forwards twice a day, using water free from lime, but tinged with soot from a bag resting at the bottom of the soft-water tank; provided the trees are not too heavily cropped, there will be no possibility of the existence of spider. If not already done, raise the best of the drooping or hanging fruit to the influence of the sun, support them with pieces of lath placed crosswise over the trellis, and pinch the points out of all young shoots, which will be cut out after the Peaches are gathered.

Gathering, packing, and keeping Peaches.—Early morning, when the fruit is cool and quite dry, is the best time to gather Peaches. If to travel, they should be under rather than quite ripe, and the greatest care should be observed in handling. When all the Peaches are required for home use the finest flavour is secured by allowing them to rest on the trees until they begin to soften, then, with a pad of wadding in the left hand and a pair of strong Grape scissors in the right, they can be detached without subjecting them to the slightest pressure. If each Peach is laid on a square of silver paper and placed in a well padded, flat-bottomed basket, the latter can be carried to a dry, airy fruit room to remain undisturbed until the fruit is perfectly ripe and fit for use. London fruiterers always prefer having the fruit sent in before it begins to soften; if well coloured and quite hard they do not object, as it then travels free from spot or blemish, and can be hastened or retarded to suit their demand throughout the season. When gathered for market the Peaches are folded in squares of silver paper and tightly packed in dry well-beaten Moss, soft paper shavings, or wadding.

The first, where it can be obtained, is the cheapest and best. The second, if soft, answers fairly well, but wadding, particularly that which is glazed, becomes moist, hard, and objectionable. Bran at one time was much used, but it has a tendency to sink in bulk on the journey, when the Peaches become loose and arrive in a bruised or worthless condition. Boxes made of half-inch deal, 4 inches to 4½ inches in depth and of uniform size, but not over large, answer best: 24 inches by 14 inches is a suitable size for twenty to twenty-four fine fruit; three of these, if necessary, can be well corded together. When all the Peaches are folded, prepare the boxes by lining the ends and sides with cap paper, allowing the half of each sheet to hang over the sides for turning over the top. When all is finished, place a good layer of Moss evenly over the bottom, till the right hand end, and commence packing at the left hand corner. Shake a little Moss across the lower end and place the first fruit; keep it in its place with the left hand and follow with more Moss and fruit, never withdrawing the hand until the first row of four is finished. Then form a division with more Moss, and proceed until the box is full. Each Peach will then be resting on a soft nest of Moss nearly an inch from the bottom, and the same distance apart, with room for a good layer of packing on the surface. The Moss being very light and elastic, some little judgment will be needed in placing the finishing layer, as safety in transit depends upon the degree of tightness secured by pressing down the lid. Having turned over the half-sheets of paper, press down the lid, nail lightly, cord tightly, and advise the salesman to meet consignments at the railway terminus.

Pot Vines.

Growers who still depend upon pot Vines for their earliest crop of Grapes will not need telling the canes should now be fit for free exposure to the elements by day if not forward enough for turning out of the house to finish off against a south wall. Nurserymen and many private growers pressed for house space, not unfrequently against their better judgment, turn their most forward canes out far too soon, when the roots receive a violent check and the foliage gets battered about by wind and rain long before one or the other has properly performed its office. When this penny-wise-and-pound-foolish system is attempted in cold wet seasons, disappointment or partial failure frequently follows. The loss of a few pot Vines and their crop from a commercial point of view is not much, but under other aspects the gardener's failure with Vines which he has not himself grown is often attended by most serious consequences. Let all those who would succeed with their pot Vines strain, not one, but many points to keep them under glass until the wood and roots are thoroughly ripe and the foliage begins to change colour. Then, the house being wanted for other purposes, they may be removed and made secure with shreds and nails against south or west walls. If he must buy his Vines, let him see them growing and choose early from a stock which has had the benefit of light and air as well as heat, as canes suddenly removed from bottom heat and ripened out of doors cannot be depended upon.

Younger canes as well as recently planted Vines now making growth must still be encouraged by means of good syringing, mulching, and watering, with plenty of heat and air to fill up and ripen the lower buds. The growing season will, of course, continue for some time yet, but when the canes begin to turn to a bright nut-brown, the lower laterals may be taken out where the main leaves remain fresh and capable of filling up and feeding the buds, while the laterals above the point at which the canes have been stopped will require more freedom of growth to keep the sap in motion and prevent the base buds from breaking. It is no unusual thing to see these laterals rambling all over the upper part of the trellis in the wildest confusion, often blocking the ventilators and forming fine breeding centres for red spider; but this leave-alone principle may be carried too far, as growths and foliage which cannot have full exposure to light are of little use. Moderate stopping and regular tying should therefore be practised, and when the upper wires are covered gradual reducing will cause the canes to thicken rapidly without endangering the base buds.

Planting canes.—If these are still in bottom-heat the pots should now be gradually raised until the bottoms rest upon the surface of the bed, where they will require more water for a time; but having the benefit of sun and air, the roots will be less active and the young rods will soon begin to ripen; 6 feet to 8 feet in length being quite sufficient for ordinary planting Vines, the most forward should be pinched at this point, and weaker canes intended for cutting back to one or two eyes during the winter may be stopped at 3 feet to 5 feet. If at all crowded, a portion of the most forward may be drawn out and placed on the borders in light airy houses where the foliage can be kept near the glass and fully exposed to the sun. In order to prevent a sudden check and keep the roots evenly moist, the pots being small, they may with advantage be covered up with old leaves or litter, and the foliage must be regularly syringed to keep it fresh and free from spider.

Indoor Garden.

Night-blooming Cacti.

(Echinocereus Eyresi.)

The attention of Cactus lovers should be called to this easily-grown and interesting species. An old plant here bloomed on the evening of the 8th, opening simultaneously a coronet of five trumpet-shaped blossoms of the purest white, each 8 inches in length. It is impossible to describe the extraordinary loveliness and purity of these blossoms, whose only demerit is their evanescence. The plant is one of the ribbed Melon-shaped species, and belongs to the night-flowering section. It takes up but little room in a greenhouse or ordinary window, and needs but little care, beyond that of being placed in a sunny position, and kept moderately well supplied with warm water during summer. In winter, any dry corner safe from frost will suit it, water being entirely withheld, or nearly so, from October to March. Small plants, which are apt to cluster about the base of the parent, should be removed, or flowering will be considerably retarded. These should be potted in single pots, and shifted into larger ones, as they require it. Ordinary potting soil with a liberal admixture of coarse sand answers well for all Cacti; if a proportion of broken charcoal can be added, so much the better; but efficient drainage is of almost more importance than soil. It takes some time for a young plant to reach the blooming size. When, however, it has attained that point, I have never, under the above treatment, known it fail to produce its blossoms annually—sometimes, indeed, several times during the year. The development of the flower-bud is curious. It appears first in the form of a small, shaggy, brown knob, which remains stationary apparently for many weeks. Suddenly in examining the plant one becomes conscious that increased activity is taking place in these small excrescences, and in a week or ten days, according to atmospheric conditions, they reach, as before stated, a length of fully 8 inches in a mature plant. The rapidity of the growth of the flower tube during the last two days before opening is very remarkable and interesting. The full perfection only lasts, at the longest, for less than twenty-four hours, but during that time the flowers are marvels of beauty, which must be seen to be realised. The plant here alluded to is at least ten years old; how much more I cannot undertake to say. It inhabits an 8-inch pot, is 17 inches in circumference, and will, in all probability, bloom once or twice during the season. A small plant sent to a friend in July, 1884, opened its first bloom during the present month (July, 1886). It will be seen that though E. Eyresi may not be showy enough to please the million, it is essentially an object of interest to true plant lovers.

Wernolau, S. Wales. K. L. Davidson.

Abutilon vitifolium album.—I shall be happy to send a few seeds of this shrub, so far as they will go, to anyone who would like to have them. My plant is about 11 feet high, and was covered with flowers throughout the month of June, and appears to be quite hardy against a wall. I take this opportunity to acknowledge the receipt of a plant of the lilac vitifolium sent to me by an unknown friend last year; if this should meet his eye, I beg to say that it will give me much pleasure to return the compliment by sending him a young plant of the white variety.—J. H. Archer-Hind, *Coombefishacre House, Newton Abbot.*

Tuberous Begonias from seed. — These popular flowers, both single and double, are readily raised from seed, and I may add that they are of nearly all shades of colour. We have now amongst them clear whites, yellows, pinks, and crimsons. Last season I procured a large packet of double Begonia seed about this date. I sowed it at once in light sandy soil, and as soon as the young plants were large enough I potted them off into very small pots; they were set on the top shelf of a warm house, and before winter set in they had made nice little bulbs. They were then dried off and packed in ashes in a large box, where they remained until they began to show signs of growing in spring. Then they were repotted into 4-inch pots, and they are now coming into bloom, quite half of them being doubles and the other half good singles of various colours, and the freedom with which they flower makes them most welcome. A rich light soil suits them perfectly, but they are not difficult to deal with in this respect; even if planted out in the flower garden in any fairly good flower-bed soil they grow with surprising vigour. But few flowers show more marked improvement in every way than these Begonias have done during these past few years. A good strain of seedlings even may be relied on to surpass what were considered to be at one time the very best named sorts. -J. G. H.

The Moon Creeper (Ipomæa Bona-nox).—This chaste and beautiful climber is occasionally met with, but its property of flowering at night no doubt interferes with its more extended cultivation. It is a tender annual, and does well in a low span-roofed stove-house, where it can run along the roof. The flowers open soon after dusk, and are in the fulness of their beauty in the dead of the night, and they continue expanded till nearly noon the next day. There is such an exquisite delicacy about the shining whiteness of the flowers, that it is a matter for wonder it is not more generally cultivated, its night-flowering property notwithstanding. There is no difficulty in obtaining seed, and they should be raised in a moist brisk heat in April, grown on quickly, and potted into a large pot to flower, or be planted out in a small pit or any convenient place, and trained along a wire or any such support under the ridge of a span-roofed house, or in any suitable place.—R. D.

Calla æthiopica planted out.—We always plant out our entire stock of this Calla after it has done flowering. The plan which we adopt is to shake out the plants, and separate them all into single crowns; even small suckers, if planted out in June in good soil will make fine flowering plants by October, and anyone having pots crowded with bulbs of various sizes will do well to divide them at once. They will make but little progress if left to compete with strong bulbs. Those planted out in June are now shedding their old leaves and pushing up sturdy spikes of fresh foliage from their crowns. Callas are plants of the easiest culture; all they need is good rich soil and plenty of water, and they will make fine plants for lifting in October. We put one crown in a 6-inch pot, and three in 7-inch and 8-inch ones, using plenty of manure in the soil, and they always produce very large as well as numerous spathes of the purest white. As decorative plants few are so generally useful. The foliage being so ornamental, they can be made serviceable even when

not in flower for conservatory decoration. There can be little doubt that by this way of treating Callas finer spathes are produced than by the old plan of leaving the plants in pots all the season. In lifting them we take steel forks and raise the soil carefully, so as to get all the roots we can. When potted they are set in a cool shaded position, and kept syringed overhead until the leaves will bear full exposure without flagging. They are kept in a cool house during winter, and introduced to gentle heat according to the time at which they are required to be in flower. Manure water is given freely when the flower spathes are being pushed up, as the size and substance of the flowers depend upon liberal feeding. —J. G., *Hants.*

TREES AND SHRUBS.

TOP-DRESSING RHODODENDRONS.

I HAVE been told of an instance where the annual mulching of Rhododendron beds with the short Grass from the lawn sufficed to change a flowerless into a floriferous condition. There is no doubt that the Rhododendron, like many other hardy shrubs and plants, suffers from the neatness which it is considered necessary to observe. The old foliage is cleared away as it falls, and Nature's way of keeping up the fertility of the soil is not compensated for by a top-dressing of any kind. When Rhododendrons are planted in a depth of good peat, or in suitable loam, they do not so much feel the need of nourishment in this way; but where, as is frequently the case, these advantages exist in a modified degree only, the growth in the course of several years after planting becomes too stunted to admit of the formation of good flower-buds. I lately saw some Rhododendron beds which had come into this condition; the plants were healthy, but wanting evidently in vigour, and consequently gave scarcely any bloom. They were growing in prepared soil, but it was easy to see that the roots had long since taken possession of the whole of the compost. Looking among the branches, which were rather bare at bottom, I could see a clean, even surface, from which the rain must run off away to the side when once it becomes dry. Had the leaves which dropped been allowed to remain they would have served to return to the soil what the plants took from it, and would, moreover, have preserved the surface in such a porous, open condition as to allow of the free entry of the rain. There are many soils, including those of a poor, sandy nature, where Rhododendrons will make plenty of roots, but which require the addition of some form of nourishment. Mulching with short Grass or leaves will in a great measure do this, as it is not nitrogenous food that these Evergreens require, but rather decayed vegetable matter. Mulching, too, will sustain and promote freedom of growth by helping to retain moisture, and it should be remembered that Rhododendrons are moisture-loving subjects; they really require a large amount of water when in full growth.

J. C. B.

Eucryphia pinnatifolia.—This beautiful Chilian shrub is at the present time in flower, and there being but few other trees or shrubs in bloom it is the more conspicuous. It is a rather slow-growing deciduous bush, with pinnate leaves and flowers that bear a good deal of resemblance to those of a Hypericum, except that they are pure white in colour. The blooms are from 2½ inches to 3 inches in diameter, composed of four large petals, and a dense cluster of stamens just as in the St. John's-wort. When the flowers first expand the reddish coloured anthers are very conspicuous, and scarcely less so after a day or two when they become bright yellow. It has proved perfectly hardy in Messrs. Veitch's Coombe Wood Nursery, near Kingston, in Surrey. I was much struck recently at seeing it successfully grown in a pot and employed for decorative purposes, the treatment accorded it being to plunge the pot in the open ground till the flowers were on the point of expanding, when the plant was removed under glass. It was potted in an ordinary mixture of loam, peat, and sand, while when grown out of doors it does not seem very fastidious as to soil, provided it does not get too hot and dry. This shrub was first distributed by Messrs. Veitch a few years ago, but it is still very rare, no doubt owing to the fact that it grows rather slowly, and also that it cannot be increased to any great extent. Propagation may be effected by means of cuttings, but those that strike are usually so few that such a mode of increase is not to be relied on. Layering is the method generally employed for the purpose, but this can scarcely be carried out in the case of small plants.—T.

Fine Poplars.—In order to form an adequate idea of the grandeur of the black Italian Poplar (Populus monilifera), which is so much planted at the present time, such fine specimens as those at Syon, near Brentford, need to be seen. They are considerably above 100 feet in height, and have a stem girth of about 15 feet. Their massive forked limbs tower above those of the surrounding trees very majestically, and the huge bole, with its rugged bark, riven and torn by age, has an extremely picturesque appearance. A Lombardy Poplar, upwards of 130 feet high, rears it head above its fellows, and breaks the sky-line of the round-headed trees with fine effect. The true black English Poplar (P. nigra), not often seen planted as an ornamental tree, is represented by some grand specimens. It is a tall, quick-growing tree, which readily assumes a somewhat pyramidal form, with triangular, tapering leaves, and is a capital tree for growing in wet places, such as in water-meadows, by the borders of streams, lakes, &c. Of P. heterophylla, P. alba, and other Poplars there are equally remarkable specimens.—W. G.

Englemann's Spruce (Abies Englemanni).—According to Professor Sargent, this tree forms a shapely, tapering spire, from 60 feet to 80 feet high, with a trunk slender for its height, and which is covered with a thin, scaly, reddish-grey bark. In general appearance A. Englemanni resembles the Black Spruce of Eastern America, for which it was mistaken by all botanical travellers in the Rocky Mountains until Dr. Parry detected its specific distinctions, and dedicated it to the distinguished botanist whose name it bears. Of its merits as an ornamental tree, its resemblance to one of the common trees of the East will probably work against its general popularity, while its alpine character, and consequent habit of starting to grow in very early spring, will render it unfit for cultivation save in the extreme Northern States. In St. Petersburg A. Englemanni succeeds perfectly, in spite of the extreme cold of the Russian winters, and as heretofore the only Conifers available for planting in Northern Russia have been the Scotch Pine and the Siberian Spruce, its general introduction there is considered of the greatest value and importance. By far the most valuable of the Colorado Spruces, as a timber tree, and the equal in this respect to the Black Spruce, it is not improbable that Englemann's Spruce will some day form an important element in the formation of artificial forests in Northern Europe. It is the most alpine in character of the Colorado Spruces, forming in the Southern Rocky Mountains vast forests above 8000 feet, and reaching even 11,500 feet above the sea-level.

SHORT NOTES.—TREES AND SHRUBS.

Pinus austriaca for seaside.—The Black Austrian Pine is an excellent sea-coast tree, and the rich massive foliage preserves its somewhat sombre, but healthy green in all situations. If should be planted in masses, as when isolated as a specimen, or standing singly among deciduous trees, it is rather apt to be overturned by storms, because the roots are rather spreading than descending, and the head of the tree becomes very heavy and branching.

Variations in Coniferæ.—It is only when Conifers of the same variety are grouped together that one is able to fully appreciate the variety of form and colour that exists amongst them. The different gradations between young and old foliage is remarkable, a fact fully exemplified in Cupressus Lawsoniana and its varieties.—J.

GARDEN FLORA.

PLATE 555.

THE HIMALAYAN ANDROSACES.

(WITH A COLOURED FIGURE OF A. LANUGINOSA.*)

NEXT to Primroses the Androsaces interest cultivators of hardy plants perhaps more than any other class of alpines. They are, especially the European kinds, found in alpine regions, close to the snow line; and although part of the year covered with snow, they are ever ready to shoot into flower directly it melts. Such species as A. glacialis, A. helvetica, and others somewhat puzzle the grower as to how to establish them satisfactorily; indeed, unless great care is exercised they can hardly be kept alive for any length of time. Fortunately, those from the Himalayas are all comparatively easy to grow, and they flower so abundantly and are so pretty, that plant lovers, even with limited accomodation, would do well to have at least a few of them in their gardens. The early period at which they flower is another inducement, succeeding as they do the Primroses, and continuing in bloom during a time when other kinds of flowers are not over-plentiful. To be successful with them, they must be kept dry in winter; the majority of them being more or less shaggy, they naturally hold moisture, and if the drainage be at all defective they will not succeed. They may be propagated either by means of runners, cuttings, or seeds, which in dry seasons they ripen freely. Seventeen distinct species and many varieties are enumerated as being natives of India, and three of them, viz., septentrionalis, villosa, and Chamæjasme, are also represented in Europe. The following are all that have been as yet introduced :—

A. CHAMÆJASME.—This well known garden plant has a very wide distribution. It is found plentifully in Western Tibet, Barjila, and Karakorum, at elevations of from 12,000 to 15,000 feet above sea level. It also extends to Arctic Russia, Central and North Asia, Arctic America, and is found plentifully, travellers tell us, in the European Alps; indeed, it is from the last named source that the plants now cultivated in gardens are derived. When well grown, as we have seen it on a shady rockery, it has a charming appearance when covered with its pretty pink and white flowers. It requires a good porous soil, well mixed with old lime rubbish, and during spring and summer it must be well attended to with water. It is easily propagated by division, but as this is always risky in the case of an established plant, seeds had better be resorted to. It forms nice light green tufted masses, the central rosettes in which are generally twice as large as the outside ones; the flower-stem seldom reaches more than a few inches in height, and the flowers are less than half an inch in diameter. They are at first white, but afterwards change to pink, or even rose, and generally have yellow, but often reddish, rings round the eye. The flowers appear in May and continue until July and even August. Two interesting varieties belonging to this species are found in the Himalayas; one called uniflora has one or two flowers on a stem, and densely tufted leaves, the other called coronata has shorter and narrower leaves, and a corolla with a prominent ring round the eye.

A. GERANIFOLIA.—This is a new species belonging to the stoloniferous section; the stolons, which are said to be a foot long, are very slender; the leaves are from 1 inch to 2 inches broad, and the flower-stem from 6 inches to nearly a foot in height. It is apparently a really good garden plant, and one which is likely to prove quite hardy, being found in damp woods at Lachen at 9000 feet and 10,000 feet elevation.

* Drawn in Messrs. Paul's nursery, Broxbourne, in September of last year.

ANDROSACE LANUGINOSA

A. Hookeriana.—This is also a comparatively new species, having been introduced to our gardens only a short time ago. As far as we can at present judge, it is likely to prove an acquisition, and seeing that it reaches an elevation of from 12,000 feet to 14,000 feet in Lachen, little doubt as to its hardiness need be entertained. It belongs to the stoloniferous set, and forms rigid rosettes of flat, blunt-tipped leaves, shiny above, and with few or no hairs on the margin. The flower-stem, which is about 3 inches high, supports a loose umbel of pretty pink flowers of considerable size.

A. lanuginosa.—A good idea of the general appearance of this plant may be gleaned from the accompanying plate. It is perhaps the oldest Himalayan Androsace in cultivation. Seeds of it were sent to the Trinity College Gardens, Dublin, by Dr. Royle about fifty years ago, and plants raised from them flowered in the open border in August, 1842. Since then it has been cultivated largely in our gardens, both from seeds ripened in this country and from fresh importations from India. It is perfectly hardy, but, like most Androsaces, very liable to damp off in the winter unless special attention is given to guard against this calamity. In some gardens, and especially in those of Sir W. Bowman at Joldwynds, it grows as freely as a weed, covering large areas on dry sunny banks, and making a magnificent show during the late summer and early autumn months. Where the soil is heavy we mix with it plenty of lime rubbish, raising small mounds and planting on the top of them. This species is readily distinguished from all others by its long leafy stolon-like branches and by having small scattered rosettes. Its leaves are lanceolate, and the whole plant is covered with long silky hairs. The branches, although stolon-like, never root, as in sarmentosa. A variety called oculata has a distinct purple ring round the eye, and when well grown is very effective. It ripens seeds freely, and may be propagated in that way, but it also strikes freely from cuttings, and we find this the quickest mode of raising a stock of it. It is found on the Western Himalayas, from Kumaon to Kashmir, at 10,000 feet elevation.

A. rotundifolia.—In our gardens may be found various forms of this plant, none of which are equal to a poor Herb Robert, *i.e.*, if we except their large and singular calices, which quite eclipse the flowers. We are told, however, that the corolla is usually much larger than the calyx in some of the forms—a treat in store for us when the best of them shall have been introduced.

A. sarmentosa.—This seems to be the most variable of all the Himalayan Androsaces, resembling, in the form most commonly cultivated in gardens, villosa on the one hand, and differing in the variety called foliosa on the other, from any other Androsace, although there seems to be a gradation from the variety Watkinsi, through grandifolia, and primuloides to foliosa. The line between sarmentosa, villosa, and some forms of Chamæjasme is, we believe, very difficult to define when in a dry state, and especially if we take the Himalayan forms of the two last-named species, but in the garden the difference is wide, and may be detected at a glance. The great difficulty with sarmentosa is to keep it through the winter, as even in situations where it has grown and flowered well through the summer months it will go off in winter, *i.e.*, if it should be at all damp. In naturally well-drained soils it may be planted on the flat ground; but if otherwise, the more perpendicular the position chosen for it the greater will be the success, and if under a projecting rock or ledge so much the better; the soil should be light and gritty and the position exposed and sunny. No difficulty will be experienced in propagating this plant; all the stolons form little rosettes at the nodes, and if these be simply pegged down, either on the ground or in small 2½-inch pots, they will emit roots and be ready to cut away from the parent plant in a few weeks. It forms tufts which, if left undisturbed, will cover a wide area; the rosettes are silky-haired, the stolons leafless, and unless pegged down near the parent plant become in time unsightly. It grows 6 inches or more in height, and carries a round head of handsome rosy purple flowers, with a distinct yellowish eye, raised a little above the corolla.

The following varieties have, we believe, no precise limits, viz.: A. Watkinsi, a form with no stolons. Its leaves are an inch long, lance-shaped, and almost sessile on the stems. Grandifolia also has no stolons. It is stout in habit, and the leaves are very large, often measuring an inch across, and narrowed into long or short stalks. It is found at Tungu, at 14,000 feet elevation. A. primuloides resembles the variety Watkinsi, but generally has stolons and more slender flower-stems. A. foliosa, introduced a few years ago by the late Mr. I. Anderson-Henry, has a fine sturdy habit and no stolons; its leaves are an inch in diameter, and the flower-heads, which rise well above the foliage, consist of pretty rosy-purple flowers, larger than in sarmentosa. It is perfectly hardy, and is readily propagated by means of cuttings.

A. sempervivoides.—This is a charming little species, which we have only once seen. Its leaves are densely packed in small rosettes, from which grow the stoloniferous branches, forming, as in sarmentosa, an easy means by which it may be increased. The flower-stem is solitary, and the flowers small and darker than in the above-named species. It is a native of Western Tibet, Scinde valley, and Kashmir. It is probably hardy, but requires a somewhat shady position.

A. villosa.—The form of this plant which inhabits the Himalayas is widely different from the one which we see in the Alps, and which is the form commonly cultivated in gardens. The Indian one is densely hairy or villose; the leaves are arranged in larger globose rosettes; the flowers, too, are larger and fewer in a head. They are purple, and have a pronounced conical swelling round the mouth. It has stolons, closely beset with small rosettes resembling sarmentosa on a small scale, and, as in that species, rooting when pegged down. This plant generally is more easily managed than most of the other Androsaces, a sunny position on a gentle slope suiting it admirably. It requires copious waterings during summer, but care at the same time should be taken to see that the drainage is perfect. It flowers in May, June, and often in July. It is found in the Western Himalayas, in the drier regions from Kumaon to Kashmir, W. Tibet, Affghanistan, Caucasian Alps, Asia Minor, and elsewhere.

D. K.

The divining rod.—I cannot tell "Veronica" wherein lies the power of either the stick or the man, nor does the man Mullens himself pretend to explain the mystery. He is a plain, unpretending, working-man, and has no theories on the subject, but uses the gift which he undoubtedly possesses for practical purposes, and in that sphere has confounded all the experts and others who have tried him. I do not doubt myself that he would even consent to "Veronica's" conditions that in the event of his failing to discover water "the stick might be made to react on him in some other way;" but being accustomed to such proposals, he generally attaches the reasonable proviso that the "stick" be applied to the other party should his operations with the twig be successful. If "Veronica's" irresponsible monitor agrees to this performance at a public seance, I should be pleased to assist in arranging the preliminaries. To "Veronica's" other question, "Is the power possessed by other people?" Mullens tells me it is possessed in some degree by many people, and there are several professionals in Somersetshire besides himself. He has a family, but he is the only member of it who can "work the twig," a circumstance which he much regrets. Those who wish for further information about the man should apply for his testimonials and vouchers, of which he has a volume from gentlemen of position and education in all parts of the country—some of whom acknowledge having saved thousands of pounds by employing him, and who are willing to back up their testimonials still further if needful. —S. W.

Fruit Crops.

SOUTHERN DIVISION.

Claremont, Esher.—Peaches and Nectarines are exceptionably heavy crops in the gardens here and the trees healthy and vigorous; they had the usual covering of fish-netting (triple thickness) whilst in bloom and the weather being at that time cold and stormy, the covering was not removed until the fruit had reached a considerable size. If sufficient of this netting had been on hand, I fancy Plums and Pears would have been equally good; as it is, they are very thin, and in the case of Pears partial. The advantage of different aspects for choice varieties is this year noticeable; the crop is best on a north-east wall, where the bloom was later. Apricots are a complete failure; my experience agrees with that of many others, *i.e.*, that the bloom buds rotted without expanding. Of Cherries, both dessert and Morello, we have very fair crops. Apples are thin, and the foliage in many cases almost destroyed by maggot. Wall trees have been very free this season from insect pests, especially the Cherry and Plum fly, of which we have seen but little. Small fruits of all kinds are plentiful, and extra quantities will doubtless be required for preserving, to compensate in a measure for the loss of the Apple crop. Gooseberries as dessert fruits increase in favour year by year, and wire-trained trees are in great request. I would particularly recommend this system to all who have not given it a trial for many reasons, viz, great variety can be grown in little space, and the season may be thereby prolonged: the fruit is kept clean, and can be easily netted: the picker is able to do his work quickly; and the yearly crop from this restrictive system is very heavy. We throw a net over some Warringtons, planted under a north wall, and by this means make our Gooseberry season last some two or three weeks after all other fruit is removed from the trellis. In order to secure a long season for Red and White Currants, they are planted on south-east and north-west walls, as well as in open quarters. As to Strawberries, fruits have been plentiful, but the season short.—E. Burrell.

Deepdene, Dorking.—The fruit crops in this neighbourhood are not quite satisfactory, though of some things, such as Currants and Gooseberries, we have abundance. The Apple crop is not what was expected; many trees have a sprinkling on them, but scarce any are bearing a full crop. Pears are thin, except Pitmaston Duchess and Marie Louise, which are laden both on walls and pyramids; Apricots are thin; Peaches and Nectarines a moderate crop; Plums of all kinds are a very heavy crop; Cherries are a fine crop and good in quality; Gooseberries and Currants are bearing very heavy crops, and the fruit is clean. The Strawberry crop is very much under average; our favourite kinds for flavour are British Queen and Vicomtesse Héricart de Thury; our best croppers are probably Sir Charles Napier and Sir Joseph Paxton, and our best early sorts Vicomtesse Héricart de Thury and Keen's Seedling. Black Prince we cannot grow on account of its liability to mildew. Sir C. Napier and Frogmore Late Pine are the best late sorts. The most certain plan by which to insure regular crops is to plant out the old forced plants, grow them for two seasons, and then destroy them. Our favourite Strawberries for forcing are Vicomtesse Héricart de Thury, Sir C. Napier, and a few British Queens.—J. Burnett.

Leonardslee, Horsham.—Apples in this district are under the average. On some few of our bush and pyramid trees, such as Warner's King, Cox's Orange Pippin, Keswick Codlin, Lady Henniker, Lord Suffield, we have average crops. Pears with me are an average crop, but in this district they are under the average. Plums are fair crops all round; Cherries a very large crop in this district;

Morellos also very good. All kinds of small fruits are large crops and good. Strawberries are abundant. Kentish Filberts are a large crop and very fine. Of Walnuts we have a few; they are under the average. Apple orchards on this estate I find will yield scarcely a third of a crop. As to Strawberries, the following is a list of the kinds which I grow, and all are good, viz.: Keen's Seedling, Alice Maud, Sir C. Napier; these I grow in pots for forcing in the order just named, and also largely out of doors. Vicomtesse Héricart de Thury is an excellent bearer and good all-round Strawberry. Alpha is delicious, and one of the best for forcing. British Queen, Empress Eugénie, James Veitch, President, Sir J. Paxton, and Kitley's Goliath ripen in the order in which their names stand. Eleanor is the latest of all; it has been in grand form during these last three days ending July 22—which is good for this southern part of the kingdom. The best plan by which to secure good and regular crops is not to let the beds stand over the third year. We plant 2 feet apart every way, and get plenty of fruit. By the end of the season I daresay I shall have taken 350 quarts; in some seasons I have taken 400 quarts.—Sidney Ford.

Longford Castle, Salisbury.—Apples and Pears are not so good as they promised to be. The frosts which we had early in May, followed by a low temperature and east winds for several weeks at a stretch reduced the number of blossoms and embryo fruit to a considerable extent. However, there will still be fairly good crops of both kinds in this district. Apricots, Peaches, and Nectarines are also fairly good, and Plums are more plentiful than I have known them to be for a great number of years. Bush fruit of all kinds are most abundant, and Strawberries, though not so heavy a crop as last year, have been pretty plentiful and good. The varieties grown here are Vicomtesse Héricart de Thury, Keen's Seedling, La Grosse Sucrée, Sir Charles Napier, Sir Joseph Paxton, President, James Veitch, and British Queen for early and general crops, and Elton Pine and Oxonian for late crops, on a north border. I should not like to say which of the above-named varieties is the best flavoured, but James Veitch—the largest—is the worst. We also grow a small breadth of Hautbois and alpines—the former more on account of its rarity and peculiar flavour than for its usefulness, and the latter by reason of its yielding a supply of pleasantly flavoured fruits for months after every other variety has ceased to bear. The best way in which to secure good and regular crops is to plant a given number of forced and properly hardened-off plants every year as early in the spring as possible, laying on a good mulching of short manure between the rows and the plants afterwards, and annually destroying a like number of the three-year-old plants after the fruit has been gathered. The Strawberry delights in a stiff loamy soil.—H. W. Ward.

Goodwood, Chichester.—Fruits in general in this locality are good average crops, with the exception of Apples and Strawberries, which are much under the average. We find the most useful Strawberries to be Pauline, a good early kind for general cropping; Vicomtesse Héricart de Thury, Sir Charles Napier, Keen's Seedling, Dr. Moore, James Veitch, and Elton Pine, the last a good late sort. Such kinds as Dr. Hogg and British Queen, although excellent, do not succeed well on our light soil. The main way by which good crops of Strawberries may be got is deep trenching, well manuring, and planting out plants which have been forced. These rarely fail to produce good crops.—F. Rutland.

Basing Park, Alton.—Apples here are a good crop and the trees are looking well. The kinds that bear best are Keswick Codlin, Irish Peach, Lord Suffield, King of the Pippins, Kerry Pippin, Striped Juneating, Boston Russet, Blenheim Orange, Cox's Orange Pippin, Margil, Worcester Pearmain, Northern Greening, and Dumelow's Seedling. Of Pears we have the heaviest crop that I remember for many years, and the trees are very healthy. The following kinds do well here, viz., Williams' Bon Chrétien, Citron des Carmes, Louise Bonne of Jersey, Glou Morceau, Marie Louise, Marie Louise d'Uccle, Winter Nelis, Passe Colmar, Seckel, Van Mons Leon Leclerc, Alexandre Lambre, Duchesse d'Angoulême, Beurré de Capiaumont, B. Bosc, B. Diel, B. Rance, Knight's Monarch, and Catillac. Plums are a good crop, and the trees are clean and healthy. The best kinds here are Orleans, Pond's Seedling, Diamond, Coe's Golden Drop, Jefferson, Magnum Bonum, Washington, and Green Gages, early and late. Damsons, too, are a first-rate crop, and the trees clean. Of Peaches and Nectarines we have good crops, and the trees look well. Apricots are quite a failure. Of Gooseberries we have a very heavy crop, and also of Currants of all kinds. Raspberries are good in every way; Nuts also good. Strawberries are all but a failure; the late winter injured them very much, and the hot, dry weather which we have had completely ruined them. The kinds which usually do well here are Black Prince, Vicomtesse Héricart de Thury, Keen's Seedling, President, and Sir Charles Napier. These all force well, and are good early kinds for the open ground. Later sorts are British Queen, Dr. Hogg, Eclipse, and James Veitch. The latest of all are Frogmore Late Pine and Elton Pine. Where good plants are ready or well rooted, runners can be had: the sooner they are planted now the better, but I prefer using plants that have been forced, which always yield good crops the first year after planting. Before planting I always have the ground well manured and trenched, and plant in rows 3 feet apart and 18 inches asunder in the rows. The soil round the plants is made quite firm and kept watered till the plants have got well established. If the weather happens to be dry when the Strawberries are in bloom I give them a good soaking with manure water: then I mulch with litter, which keeps the fruit clean. I find it best to make new plantations about every four or five years, as after that time the fruit gets small and the plants require a change of ground, more particularly the class to which the British Queen and Dr. Hogg belong; much, however, depends on the character of the soil. At Elmham Hall, Norfolk, a bed of Keen's Seedling Strawberries was, I remember, over twenty years old, and always bore good crops of fine fruit, but that was on a good rich stiff yellow clay, or rather loam.

Early Potatoes are excellent, both in quality and quantity, and as yet quite free from disease. They will soon be ready to take up; the late kinds, too, are looking well—never better.—Wm. Smythe.

Wycombe Abbey.—In this district crops of Apricots, Apples, and Strawberries are somewhat below the average, but all other fruits are good average crops. As to Strawberries, I consider Vicomtesse Héricart de Thury one of the most useful kinds in cultivation and the best of all for early forcing; under fair ordinary treatment it is a safe setter, and when ripe at an advanced season its quality, in my opinion, is superior to that of any other kind; if we except the old Grove End Scarlet, too, which may have a slight advantage over it in point of colour, it is unsurpassed for preserving, and, moreover, its earliness in a natural way and its hardy constitution make it a most desirable variety. As a successor Keen's Seedling is pre-eminently good in every respect, and this variety is succeeded by President, Sir Joseph Paxton, and Sir Charles Napier; James Veitch we grow on account of its large size; next in order comes Oxonian, and last of all the old, but still highly esteemed, Elton Pine. The foregoing sorts constitute the collection grown here as being best suited for our requirements. New varieties also find a place until such time as their merits are ascertained, after which they are either retained or discarded.

Potatoes look remarkably well, and as yet there is no appearance of disease either on the haulm or in the tubers. The early crop, though not over-abundant, is excellent as regards quality. As to late crops, the yield will doubtless in dry positions be under the average.—G. T. Miles.

Beechwood, New Forest.—Of Pears we have the heaviest crop in open borders on pyramids and dwarf bushes that we have had during these last twelve years; that on walls is not so heavy, last year's crop being above the average. Apples are the lightest crop we have had here for several years; in a few sheltered spots may be seen a fair sprinking. Plums are a good crop, except Damsons, which are a failure in this locality. Of Cherries we grow May Duke and the Morello; the former is above the average, the latter below it. Gooseberries are a very light crop—the lightest in my remembrance. Currants—Black, Red, and White—are heavy crops, and the fruit large and good. Raspberries good and up to the average. Mulberries and Nuts are good, and of Cranberries we have abundance. Strawberries have been good, but of short duration, owing to the drought. I have grown several varieties here, but have discarded them for President and Eclipse; the former does well in this soil and bears large, handsome, well-flavoured fruit. It is also a good forcer. Eclipse is a good bearer, but the fruit is not so large as that of President. It is, however, good in flavour. We manure heavily and remove the runners three times; then we slightly fork between the rows and put on the manure, which is washed down by the winter rains to the roots. If they show signs of failing we renew our plantations every five years.—T. Clarke.

Trelissick, Truro.—Apples in this neighbourhood are a complete failure; with the exception of Hawthornden, scarcely a fruit is to be seen in many of our best orchards. As to the variety just named, I have not found a tree on which there was not a moderate crop of fruit. The failure of the crop is generally attributed to a terrific hail storm which visited us on the last day of March. But that I suspect is not the true cause, for Pears do not appear to have suffered in the least, though their buds were in a much more forward state than those of Apples. In this locality Pears will be quite an average crop. Peaches and Nectarines where unprotected are splendid crops; as to Apricots, we never expect to get any, though we keep a tree or two for old acquaintance sake. Plums in a large orchard house near here will be scarce—not nearly half a crop. Plums and Cherries on sheltered walls are pretty good. An enormous Brown Turkey Fig tree here, probably one of the largest in England, is bearing a grand crop, and if the weather for ripening should be favourable, we will have several bushes of fine Figs. All bush fruits have been very good, with the exception of Gooseberries, the buds of which were ruined by bullfinches in winter. As to Strawberries, early in the season they promised to be an unusually heavy crop, but the scorching hot weather that set in in the middle of June withered up the plants as well as the fruit. In many plantations where there was no mulching numbers of plants were entirely killed. I always mulch heavily and early with long stable manure, which prevents evaporation and protects the plants from the scorching sun. The ammonia contained in the litter being washed down by the rains proves to be a useful stimulant, and when washed clean it protects the fruit when ripe from contact with the soil. Strawberry plantations thus treated yield more than double the produce they otherwise would do. I have tried numbers of varieties, but my greatest favourite for a main crop is Sir C. Napier. It is a grand fruit, a prodigious cropper, and travels well; for forcing, too, I find nothing to equal it. Some of your correspondents speak of it as being wanting in flavour, an opinion with which I cannot agree, *i.e.*, as grown and ripened here. In Derbyshire we used to grow magnificent crops of British Queen and Elton Pine, both of which I have tried, but had to discard them as failures. I now grow Black Prince, an indispensable sort for first early, and Sir C. Napier for our main crop. I also grow James Veitch, Keen's Seedling, Dr. Hogg, President, and Vicomtesse Héricart de Thury, but not one of them is nearly so satisfactory with me as Sir C. Napier. With regard to cultivation, I can

add nothing to the admirable instructions already given by Mr. Coleman, which, if carefully carried out, will produce grand Strawberries the first season after planting. I invariably destroy a small patch every year, and plant a fresh piece to replace it, the best results being generally obtained the second year after planting.—William Sangwin.

Wildernesse, near Sevenoaks. — Peaches and Nectarines here are fairly good crops, but Apricots are under the average; although covered with double netting, 10° of frost on the 1st of May did much injury. Cherries are a good average crop, especially Morellos. Those grown on standards in Cherry orchards have been most abundant. Plums are fairly good, especially the Victoria and Orleans. Pears are nearly a failure, with the exception of Napoleon, Passe Celmar, and Duchesse d'Angoulême, on which there is a little fruit. Of Apples the crop here is the smallest known for several years past. The only kinds bearing a moderate crop are Cox's Orange Pippin, Sturmer Pippin, and Duchesse d'Oldenburg on espaliers, and Dutch Mignonne, King Pippin, and Wellington in the form of standards. Black Currants are under the average, while White and Red sorts are good crops. Raspberries are plentiful, but small, owing to want of rain. Gooseberries are a heavy crop and very fine, notably Lancashire Lad, Warrington, Whitesmith, Crown Bob, Jolly Tar, Sportsman, Jolly Farmer, and Roaring Lion. Strawberries are a good crop, but not so fine as last year, in consequence of the excessive heat which prevailed during the swelling period. The sorts grown here are, for earliest on a south border, Vicomtesse Héricart de Thury and La Grosse Sucrée. Main crop kinds consist of President, Sir Joseph Paxton, and James Veitch. Loxford Hall Seedling is planted on a north border in order to prolong the Strawberry season. My plan for securing good and regular crops is to plant a new bed each year; the ground is deeply dug and well manured; we never allow a bed to be more than three or four years old. Strawberry growers for market in this neighbourhood have experienced heavy losses this year; although watering was resorted to during the hot weather which we have had, the yield is many tons below what it should have been. The sort grown is principally Sir Joseph Paxton. Walnuts and Cobnuts are much under the average.—Thomas Carlton.

Bayham Abbey, Lamberhurst.—We cannot say that this is a fruitful season. Although Apples flowered well, they are not bearing full crops. Pears, too, are not a general crop. Peaches are pretty good. Cherries are an average crop. Plums a very heavy crop. Bush fruit good. Gooseberries, Red Currants, and Raspberries are indeed heavy crops. Black Currants are very fine—never better; the rains which we had in spring just suited them. Strawberries with us have been very good—better than for these last three years, although generally about here they have been but half a crop. The varieties which we grow are Black Prince, Keen's Seedling, President, Sir Joseph Paxton, and Elton Pine; also a few of the Bicton Pine for variety. Our latest Strawberry is Helen Gloede. The largest varieties, such as James Veitch, Dr. Hogg, and British Queen, do not set well here; therefore I have discarded them. I consider three years to be as long as a Strawberry bed should stand. The best position I can find for Strawberries is on a border with a west aspect under an east wall. Our borders are 15 feet wide, and we plant six rows in that width. The wall protects the plants from the east wind, and prevents the sun from shining upon the young flowers early in the morning, and by the time it gets round to the bed any little frost there is is gone; this is, indeed, the best position for all early crops.—W. Johnstone.

Mereworth Castle, Maidstone. — In this neighbourhood generally Apples are very scarce, many of the trees having been crippled in the early part of the season. With us, however, Blenheim Orange, Ribston, King of the Pippins, Cox's Orange Pippin, Summer Golden Pippin, Lord Suffield, Lord Derby, Hawthornden, Manks Codlin, Beauty of Kent, and Winter Quoining are all carrying excellent crops. As to Pears on espaliers and pyramids, the following sorts are heavily cropped, viz., Gratioli of Jersey, Conseiller de la Cour, Beurré Diel, Autumn Nelis, Alexander Lambert, Doyenné d'Ete, Huyshe's Victoria, Madame Treyve, Emile d'Heyst, Beurré de l'Assomption, and Williams' Bon Chrétien. Apricots are thin, with the exception of Moorpark. Peaches are more plentiful than they were last year, and the trees are making much better growth. Our best are Hale's Early, Early York, Noblesse, Grosse Mignonne, Bellegarde, Nectarine Peach, and Barrington. Of Nectarines, Elruge, Downton, Pitmaston Orange, and Humboldt are doing best. Plums, including Damsons, are very plentiful, and Cherries are exceptionally good. The same may also be said of Raspberries, Red and Black Currants, and Gooseberries. Nuts are very scarce, and Strawberries much below an average crop. The varieties that succeed with us are Vicomtesse Héricart de Thury, Sir Joseph Paxton, President, and Sir C. Napier. The latter we grow extensively for forcing as well as for outdoor crops. The best plan, we find, is to layer in 3-inch pots and to plant in well-trenched ground, ramming the soil firmly round each plant, and mulching heavily with good rotten farmyard manure.—H. Markham.

Pierrepont, Farnham, Surrey.—Apples here are a heavy crop. Pears, Peaches, and Nectarines good crops. Plums, Cherries, Raspberries, and Currants very heavy crops. Gooseberries a failure here, the buds having been taken by birds in winter, but in several places where unmolested they are a very heavy crop. Apricots are a failure. Strawberries a very heavy crop. The varieties grown are: Vicomtesse Héricart de Thury is an early and heavy cropper, and with us it continues fruiting till the end of the season, but after a few pickings the fruit becomes small; being good in colour, it is, however, useful for preserving. President suits our soil well and continues in bearing a long time; its fruit also swells to a very large size. Sir Joseph Paxton attains a good size, but does not continue in bearing so long as President. Sir Charles Napier is a very heavy cropper, and in a moderately moist season swells its fruit to a good size; it is one of the finest-looking Strawberries we grow, and with us it is better flavoured than when grown on a heavy, cold soil, but in a dry season its fruits are small, hard, and seedy, and unless there is plenty of water at command, I would not recommend it to be grown extensively, as on light soil it suffers more from drought than any variety with which I am acquainted. Dr. Hogg is the best flavoured Strawberry we grow, but it is rather a shy bearer. This and Eleanor are late kinds. The latter is nearly equal to Dr. Hogg in flavour, and it is a much better cropper, but even when ripe the tips of fruit are a little green. The following I have planted for trial, viz., James Veitch, Marguerite, Loxford Hall Seedling, Duke of Edinburgh, and Frogmore Late Pine. Our soil is very light and sandy on a gravelly subsoil, and it would be almost impossible to grow Strawberries satisfactorily without heavy mulchings of manure and abundance of water when the fruit is swelling. I plant fresh beds every two years with plants that have been forced the spring previous, and by so doing and giving a good annual top-dressing of manure and plenty of water we invariably get excellent crops. The principal fruit trees here, I may add, are planted in prepared soil carted from a distance, the poor sandy staple being taken away. I attribute the exceptionally heavy crops of all kinds of fruit this season to the hot summer of 1885, which so thoroughly ripened the wood.—J. Turner.

Leigham Court, Streatham.—Apples in this district are a very poor crop; there was a fine show of blossom and a fairly good set of fruit, but a continuation of east winds after the setting period completely destroyed the crop on many trees. Sorts which are bearing a partial crop are Blenheim Pippin, Lemon Pippin, Echlinville, Alfriston, New Hawthornden, and Ribston Pippin. Pears have fared better, having made a move before the cold winds which affected the Apples so seriously had set in. Some sorts are thin, but the following are carrying good crops, viz., Easter Beurré, Marie Louise, Seckel, Forelle, Fondante d'Automne, Louise Bonne, Beurré d'Amanlis, and Knight's Monarch. Plums on walls are scarce, but on standards there is a fair crop. Damsons are a good crop and promise to be good in quality. Cherries, with the exception of Morellos, which are a full crop, are never good here. Apricots are a failure. Peaches and Nectarines are nearly a full crop; there was an unusually good set of fruit, but it was much thinned by the cold east winds. The trees have, however, made good growth and are free from insects. All bush fruits are bearing very heavy crops, which are clean and good in quality; Currants are extra good. As a rule, Strawberries are an uncertain crop with us, and this year they have been unusually poor. Most varieties I have tried fail to fruit after two years. Vicomtesse Héricart de Thury is the best I have tried on our cold clay subsoil, and for the future will be depended on for the first crop, and also for preserving. Keen's Seedling is fine in flavour, but it is a poor cropper, and soon grows blind; therefore, it will be discarded. Sir Joseph Paxton is a poor cropper, and has little to recommend it in the way of flavour; so this too will be discarded. Eleanor produces large, well-flavoured fruit, and will be grown to succeed Vicomtesse Héricart de Thury. Sir C. Napier does fairly well for a later crop. In order to secure good and regular crops of Strawberries on this soil, I prefer layering good strong runners in pots and planting them out in well prepared ground as early as possible, fruiting them for two years only. For forcing, we prefer Vicomtesse Héricart de Thury.—E. Butts.

Pendell Court, Bletchingley.—Fruit crops here are in most cases deficient. Apples, Pears, and Apricots are poor crops, but Cherries and Plums, especially the latter, are better than usual; as are also the various small fruits, including Strawberries, which have been very much benefited by the recent rains, before which some sorts, such as Sir Charles Napier, were showing signs of succumbing to the drought with us. This variety is one of the best as regards flavour, and it is a first-rate cropper. As our soil is rather light, we obtain the best results by planting annually. Indeed, with very few exceptions (Vicomtesse Héricart de Thury and alpines), this mode of culture is the most satisfactory with us. In order, however, to succeed with annual plantations it is necessary to have strong, well-rooted plants, and to plant them early, say towards the end of August or beginning of September. This gives time for the plants to make good crowns and to become thoroughly established before winter. As soon as the crop is gathered we layer the runners in small pots, well plunging the latter so as to prevent them from becoming too dry or being upset, giving, at the same time, a good soaking of water, and keeping them watered until they are planted in their fruiting quarters, which is usually about the time just mentioned. We do not find it profitable to grow too many varieties; we therefore confine ourselves chiefly to Vicomtesse Héricart de Thury, Sir Charles Napier, Sir Joseph Paxton, President, Elton, and Frogmore Late Pine.—Frank Ross.

Hackwood Park, Basingstoke. — Apples hereabouts are much under the average—not more than half a crop. The sorts carrying the best crops are Lord Suffield, Warner's King, Keswick Codlin, Deux Ans, Irish Peach, Cockle, and Sturmer and Ribston Pippins. Pears are very thin; the best are Marie Louise, Josephine de Malines, Chaumontel, Pitmaston Duchess, Huyshe's Victoria, and Catillac. Apricots are quite a failure, and Cherries are much under the average. Peaches and Nectarines are average crops. Plums are good, the best being Victoria, Early Orleans, Belgian Purple, Jefferson, Magnum Bonum, and

Brahy's Green Gage. Raspberries, Gooseberries, and Red, White, and Black Currants are much above the average. Strawberries here have been an exceptionally good crop, but in many places in the neighbourhood they have been a complete failure. The sorts that do best with us are Vicomtesse Héricart de Thury, La Grosse Sucrée, President, Sir J. Paxton, and Sir C. Napier. I have tried Dr. Hogg and James Veitch, but they do not succeed, although they do well in places near here. Of Filberts we have very few.—W. Bowerman.

Eaglehurst, Fawley.—Both Apple and Pear crops in this neighbourhood are very thin, and the trees are again much affected with blight and have a mysterious burned appearance, for which I cannot account in any way. Of Apricots we have half a crop; Alsace, Kaisha, and the Royal Apricot are doing best. A few branches have died off, but this evil is not so prevalent this year as last. As to Cherries, our trees are mostly all young ones; the varieties bearing best are old Bigarreau, Black Tartarian, White Heart, Governor Wood, and Morello. The trees are clean and healthy. Gooseberries and Red and Black Currants are heavy crops and good in quality; Raspberries are the same. Peaches and Nectarines on walls are good crops; they were protected while in bloom with double netting. Plums are a very partial crop; some trees are loaded, while others have none on them. The varieties bearing best are Victoria (a kind which seldom if ever fails), Early Prolific, Kirke's, Pond's Seedling, and Jefferson. Strawberries bloomed well, but just as the fruit was setting the plants were suddenly attacked with "spot," and owing to dry weather setting in early in June, very few fruits came to maturity—not a quarter of a crop. I have tried most of the leading varieties, but find the sorts that do best on our dry light soil to be Sir J. Paxton, Sir C. Napier, Bicton Pine, and Eleanor. I make a fresh plantation on well trenched ground every year, using either forced plants or runners specially layered for the purpose; an equal amount of plants is destroyed every year, the plants left having an average duration of three years. They are heavily mulched early in the winter, and this mulching is lightly forked in about the roots in spring. By this system we rarely fail to get fine crops; this season's crop is the worst which we have had for these last eight years.—W. Watson.

Arundel Castle.—Apples here are very thin. Pears, on the contrary, are heavy crops both on walls and on standards, especially on such sorts as Jargonelle, Williams' Bon Chrétien, Eyewood, Marie Louise, Conseiller de la Cour, Glou Morceau, and Winter Nelis. Plums are abundant, especially Victoria, Green Gage, Coe's Golden Drop, Kirke's, and Jefferson. Cherries, except Morellos, which are good, are light crops. Peaches are under the average. Apricots so abundant, that we had to thin severely. Figs are under the average. Raspberries abundant, and the fruit is very fine. Bush fruits plentiful. Filberts and Walnuts under the average. Strawberries, too, are under the average—in some cases in this district a total failure. The following varieties do well here, viz., Vicomtesse Héricart de Thury, La Grosse Sucrée, Sir Joseph Paxton, Sir Charles Napier, Empress Eugénie, and Dr. Moreau; the latter we prize highly for mid-season forcing, being an excellent cropper; its greatest disadvantage is its colour, which is not at all good.—E. Burberry.

Coolhurst, Horsham.—Apples and Pears are generally light crops this year. Plums are under the average. Cherries are a fair crop. Raspberries, Currants, Gooseberries, and Strawberries heavy crops, and all good in quality. The Strawberries grown here are Garibaldi, which is a heavy cropper and good in flavour; Sir Joseph Paxton, a very good cropper, and the fruit is large and good in flavour; Empress Eugénie, fruit very large and of the best quality; President, a good cropper and very good in flavour (these two last we find to do exceedingly well under glass). Myatt's Eleanor is the latest we have; its fruit is very large, but its flavour is only second-rate. We think it of great importance to have all Strawberries properly cleared of runners and weeds; the soil between the rows are hoed and raked immediately the crops have been gathered—treatment under which the crowns get well ripened in autumn, and are in the best possible condition for producing good crops the following season. Young plantations we mulch with some light material, such as old hotbed manure; in September we keep all flowers picked off them the first season after planting, and thus we are able to secure heavy crops and fruit of the best quality. After having tried almost everything we have seen recommended for keeping the fruit clean, we find nothing to equal clean Wheat straw; a very light sprinkling serves the purpose, and it is easily put on, and slugs do not seem to harbour amongst it.—David Kemp.

Cothelstone, Taunton.—Apples in orchards are a variable crop hereabouts. In some cases the fruit is very thin, in others a fair crop; garden crops are more regular. With us the following are bearing well: viz., Ribston Pippin, Cox's Orange Pippin, Cox's Pomona, Braddick's Nonpareil, Northern Greening, Lord Suffield, New Hawthornden, Emperor Alexander, and Winter Peach. Pears are a very regular crop; ours are chiefly on walls; out of more than thirty varieties none are quite barren. The most fruitful are Josephine de Malines, Brockworth Park, Marie Louise, Winter Nelis, Huyshe's Victoria, General Todleben, Beurré Diel, Althorp Crassane, Comte de Paris, and Williams' Bon Chrétien. Plums are a fair crop; Green Gage, Golden Gage, Gauthier's Green Gage, Victoria, Coe's Golden Drop, and Magnum Bonum are our best bearers this year. Moorpark Apricots are a fair crop, and the Musch-Musch is heavily laden with fruit. Of Peaches not many are grown on open walls here, but the few trees we have are bearing well and are quite healthy. The sorts are Noblesse, Barrington, and Bellegarde. Morello Cherries are plentiful. Strawberries have been a fair average crop, and the fruit has been very fine, but quickly over from want of rain. Bush fruits of all kinds are plentiful. Damsons are a full crop in many places. Walnuts a partial crop.—J. C. Clarke.

Mount Edgecumbe, Plymouth.—Apples here are a failure; Pears are an average crop, and of Cherries we have abundance. Plums, Raspberries, Gooseberries, and Currants are also plentiful; Strawberries are more than an average crop. The sorts grown here generally are: Alice Maude, for an early crop; President, Sir Joseph Paxton, Sir Charles Napier, and Nimrod, the last for a late crop, and very prolific it is.—G. Brighton.

WESTERN DIVISION.

Holme Lacy, Hereford.—Fruit crops this year are very irregular; Apples, which at one time looked like being a failure, have turned out to be a good average crop. Pears are rather under the average, but the fruit promises to be good. Apricots and Peaches are under the average. Bush fruits are over the average. The Strawberry crop in this neighbourhood has been late and below the average in quantity. There was a profuse bloom in spring and promise of an abundant yield, but for some reason the flowers went blind. The best Strawberry here for flavour and productiveness is President; Sir J. Paxton, Keen's Seedling, and British Queen also do well. For an early crop Black Prince is very useful. For a late Strawberry Elton Pine is a good one, and this year Eleanor is on trial here and promises well. In order to secure good and regular crops, Strawberry plants ought not to be left on the ground after the third season, as after that time the fruit gets small. If runners are taken early and planted in good time in well-manured soil (which, if light, will be all the better for a quantity of strong loam being worked into it), they will bear good dessert fruit the following season, and for two seasons afterwards they will produce good fruit, both in quality and quantity, both for dessert and preserving.—Chas. Denning.

Garnstone, Weobly.—In this quarter Apples are a very poor crop; the most productive are Lord Suffield and Stirling Castle. Cider fruit in this part will be very scarce. Pears are under the average. Of Plums we have a very good crop. Apricots are under the average. Cherries are a good crop, and the same may be said of Gooseberries, Currants, and Raspberries. Strawberries are also a good crop. The following succeed well here, viz., President and Sir Joseph Paxton; Oxonian is a first-rate Strawberry for a late crop.—M. Biggs.

Wythenshawe, Cheshire.—Apple and Pear crops in the gardens here and throughout the neighbourhood are much below the average. There was a scarcity of bloom; many trees failed to produce a single flower; others blossomed and set their fruit abundantly, but it afterwards dropped off prematurely. Many trees, too, which were quite covered with flowers have scarcely a fruit left on them. The following varieties of Apples are bearing fairly good crops, viz., Lord Suffield, Stirling Castle, Old and New Hawthornden, Lewis's Incomparable, Keswick Codlin, Tower of Glamis, Northern Greening, Cellini, Yorkshire Greening, Kerry Pippin, Ribston Pippin, King of the Pippins, Adams' Pearmain, Golden Reinette, and Sturmer Pippin. The following pyramid and standard Pear trees are carrying moderate crops, viz., Beurré d'Amanlis, Autumn Crassane, Louise Bonne of Jersey, Comte de Lamy, Catillac, Bellissime d'Hiver, Délices d'Hardenpont, and Green Chisel. Of wall Pear trees, both cordon and horizontal trained, the following are bearing the best crops, viz., Williams' Bon Chrétien, Marie Louise, Autumn and Winter Nelis, Louis Bonne of Jersey, Van Mons Léon Leclerc, Marie Louise d'Uccle, Fondante d'Automne, Beurré Diel, Triomphe de Jodoigne, Autumn Bergamot, and Glou Morceau. Cherries on walls are bearing excellent crops. Gooseberries I have never known to be so plentiful; market growers say that large quantities of them are not worth the labour of gathering, as they cannot be sold. Black and Red Currants are also bearing very heavy crops. Plums on walls and bush trees are a light crop. Damsons are also a light crop, as they generally are in this garden, but on the higher and more exposed parts of the district there are very heavy crops of them. Strawberries are good with the exception of those grown on Moss land. The fruit is, however, smaller than usual, a circumstance which may be attributed to want of rain, the total amount of rainfall for the month of June being only 1·57 in., while the average for the same month in the last five years is 3·24 in.—W. Neild.

Crewe Hall, Cheshire.—Fruit crops are of rather a mixed character in this district. In some places, Apples and Pears are an average, and even an abundant crop; in others, the trees are bearing scarcely any fruit, and, on the whole, both Apples and Pears are below the average. Plums and Cherries are plentiful, and Damsons, which are largely grown in this county, are bearing heavier crops than they have done for many years. Apricots are under the average, but Peaches, Nectarines, and Nuts are rather above it. Small fruits are very plentiful, but Strawberries in some places are scarcely up to the average. The principal kinds grown here are Keen's Seedling and Sir Harry, for early forcing and for outdoors; President, Sir Joseph Paxton, and a local kind called Barnes's Seedling, and Helena Gloede for a late crop. These ripen in the order in which I have named them. British Queen does not succeed well here, and although Dr. Hogg grows and bears better and has a fine flavour, it does not bear so abundantly or force as well as President or Sir Joseph Paxton. In order to secure good crops, we find it best to plant afresh every third or fourth year on good, strong land, if possible, manured and made firm; afterwards we keep the plants clear of runners and weeds, mulch them

well with manure in the autumn, and when the fruit is set give the plants one or two good soakings of water; the latter materially assists the swelling of the fruit and keeps the plants in a healthy state of growth.—W. Whitaker.

Tatton Park, Knutsford.—Gooseberries and Red Currants are heavy crops; Black Currants light. Morello Cherries are a good crop. Apples, consisting of Keswick Codlin, Cellini, and Lord Suffield, are bearing very heavy crops on pyramids and bushes, and these kinds are sure bearers here. On Ribston Pippin and Irish Peach there are fair crops. Late Apples are thin. Pears are a fair average crop. Of Plums very few are grown here. Damsons, which are grown extensively in the neighbourhood, are good crops. Peaches and Nectarines on outside walls are thin. Strawberries are a very heavy crop, and the fruit good. For forcing we use Keen's Seedling, Sir Harry, and President; Sir Harry especially carries great crops of finely-flavoured fruit. We also grow a few of Sir Charles Napier, but this year they did not do so well as Sir Harry and President. Outside we grow a few Keen's Seedling, which are very fine in flavour, but do not carry a heavy crop. Sir Harry and President are our main-crop sorts, and Sir Charles Napier we use for coming in a little later. These are all very fine this year, and are three kinds that can be depended upon for outside culture. Helena Gloede does well on a late border, and gives us a good supply of fine fruit when the above kinds are over. I find the best plan to be to plant out the old plants after they have been forced; we then get a very heavy crop the following year. We plant a quarter and destroy an old one every year, letting them bear three heavy crops before destroying them. I have seen Sir Joseph Paxton very fine outside this year in Cheshire.—Joshua Atkins.

Alderley Park, Chelford, Cheshire.—Apples here are very scarce; Pears are a moderate crop; Cherries plentiful. Of Plums, including Damsons, there are enormous crops. Currants and Gooseberries, too, are very good crops. Peaches and Nectarines out of doors are a failure, but inside very good. We cannot get the wood properly ripened out of doors in the autumn to ensure anything like a crop. The Strawberry crop in this district has been in all ways very satisfactory. The sorts on which I chiefly depend are Black Prince, British Queen, President, and Vicomtesse Héricart de Thury. Black Prince has produced an enormous crop of very fine fruit this season. British Queen and President suit this district well, though President has suffered during the late winter more than any other variety. Late sorts, such as Sir C. Napier and Elton Pine, do not do very well, though of the former we have some fine fruit. James Veitch seems also to suit this part well. In order to secure a good crop every year where there is plenty of room to work Strawberry beds, I find there is no plan that suits this district better than the following: About the end of June or the first week in July, or as soon as ever the first runners can be secured, I have a bed of rotten manure, an old Mushroom bed, spread out about 3 inches thick on a good solid bottom either of gravel or ashes trodden firmly. On the top we spread from 2 inches to 3 inches of good loam, then, with runners just commencing to root, we plant on the surface 4 inches apart each way. If the weather be hot, shading will be necessary for a few days, after which they can be exposed to the sun. Always keep the small runners cut off, and by the end of August the ground to be planted should have a moderate coat of manure (and dug so as to bury it well), and firmed by walking over it as one would walk over an Onion bed. With a trowel cut out the plants from the bed, and they will take all the soil and manure clean away with them; plant them in rows 2 feet apart, and 18 inches asunder in the row. I find a heavier crop can be ensured in this way than by keeping old beds, thereby dispensing with the labour of digging and mulching, as all they require is clean straw spread under them as soon as they begin to bloom.—A. J. Oxford.

EASTERN DIVISION.

Great Gearies, Ilford.—Apples here are considerably under the average as regards quantity, but in quality the fruit will be good, as the trees are in excellent health. Some varieties are loaded with fruits, notably Hawthornden and Cellini; Golden Noble also is bearing a fair crop. A considerable quantity of fruit dropped off during the dry, hot weather. Of Apricots, we have but a poor crop, and the trees have suffered much from branch-dying. Cherries are a good crop and excellent in quality; usually the trees have suffered much by this time from aphides, but this year are clear. Peaches and Nectarines are also quite up to the average, but where the trees are in dry places the growth is poor, and aphides have attacked them. Pears are a good crop, and the quality in some cases promises to be good; in others the fruit seems to have been injured by frosts in the early stages of its growth. Plums are a most abundant crop, and we never had the trees so free from blight as they are this year. Strawberries are the worst crop we have ever had, but the quality is fairly good. The best kinds for flavour, bearing, and distinctness are Keen's Seedling, President, Sir J. Paxton, British Queen, Frogmore Late Pine, and Loxford Hall Seedling; no Strawberries beat these either for exhibition or other purposes. As a culinary Strawberry, Sir Charles Napier may be preferred; of early kinds the best are Pauline, planted on an early border, and Black Prince; and of late kinds, we prefer Frogmore Late Pine and Loxford Hall Seedling to all other sorts. James Veitch and Unser Fritz I consider the best foreign Strawberries. The best plan by which good and regular crops may be secured is to prepare a piece of ground in July by trenching and manuring it well, to layer the runners as soon as possible in pots, and to plant them out the first week in August, taking care that they do not suffer from want of water. Do this every year, and good crops of the best quality will be the result. Small fruits of all kinds are up to the average and the quality good, Gooseberries especially so.—J. Douglas.

Kimberley Park, Wymondham.—Peaches and Nectarines here are abundant. Of Apricots we have about half a crop. Apples and Pears are, generally speaking, poor crops. Plums are abundant. Cherries a good crop. Nuts a poor crop. Walnuts a good crop. Gooseberries, Raspberries, and Red, White, and Black Currants abundant. Figs, too, are a good crop. Strawberries are plentiful. For general work, bearing, and flavour we like the following: President is excellent; Garibaldi is a heavy cropper and comes in earlier than President; Loxford Hall Seedling does well with me and comes in nicely when President is getting over. Auguste Nicaise also produces capital fruit; I have had them 2¼ ounces in weight. I also grow Duc de Malakoff, a very large kind, but subject to mildew. Sir C. Napier is a good cropper, and Keen's Seedling is good in flavour, but a bad traveller when packed. James Veitch and Sir Joseph Paxton are shy bearers, and British Queen refuses to grow with us. The first three varieties are to be relied upon in every way, and never fail to yield good fruit.—Wm. Wainwright.

Bloxholm Hall, Lincoln.—Fruit crops in this neighbourhood are far from being promising. Apples and Pears, although blossom was plentiful, are very poor crops, and the same remark applies to Cherries. Plums are a good crop, as are also Gooseberries and Currants of all kinds. Raspberries are a fair crop, but the dry weather has burned them up very much. Nuts are very poor. Strawberries are a fair crop, but very much burned up, owing to the dry hot weather which we had in June and in the beginning of July; only where they have been well watered and mulched can a good crop be found. Our main-crop early Strawberry is Vicomtesse Héricart de Thury; taking it all-in-all, it is the most useful and profitable Strawberry grown either for forcing or for open ground culture; it is certainly not the best flavoured, but on all other points it is excellent. President is another all-round Strawberry either for forcing or for open ground culture. It has a hardy and strong constitution, and the same may be said of Sir Joseph Paxton, a mid-season variety. Our best late kind is Loxford Hall Seedling, a most useful Strawberry, and one which thrives best on good deep soil. British Queen and Dr. Hogg are excellent, but although they do well with us in pots, they do not get on very well in the open ground. We have tried several of the new varieties, but the above, as far as we know, are the most useful and profitable for our soil.—David Lumsden.

Sandringham.—Of Apples we have very few indeed, and the leaves are very much curled. Pears are half a crop, and that on some sorts only, such as Beurré Diel, Easter Beurré, Duchesse d'Angoulême, Beurré Rance, Knight's Monarch, and Louise Bonne of Jersey. Plums are an average crop on walls; standards poor. Peaches and Nectarines good. Apricots poor. Bush fruits good, especially Currants and Raspberries. Gooseberries not so good. Strawberries good; the sorts which I find to do best here are Sir J. Paxton, President, Vicomtesse Héricart de Thury, and Premier. Morello Cherries were almost killed in May by cold winds, which lasted from the 23rd of May to the middle of June. We are very much exposed to the north-east. All vegetable crops are now looking well.—Charles Penny.

Gunton Park, Norwich.—Apricots are thin here, and the trees have suffered much from loss of branches. Plums of all well-known kinds are bearing heavy crops—even sorts known to be shy bearers. Of Cherries, consisting of Bigarreau, Elton, Black Eagle, Black Tartarian, and Bigarreau Napoleon, there are fine crops on walls, but they had to be well watered during the drought to prevent them from falling. Peaches and Nectarines on walls have not set by any means heavy crops. The flowers were poor and thin, the wet autumn not having ripened the wood perfectly. Apples are very thin in orchards; the trees looked very bad during the drought, and the leaves were much eaten by insects. Apples on bush trees in the kitchen garden here are looking well, and are bearing good crops. Pears are an average crop—nowhere very heavy; a few kinds required a little thinning, viz., Doyenné du Comice, Winter Nelis, Fondante d'Automne, Glou Morceau, and Marie Louise d'Uccle. Other well-known kinds are carrying just sufficient to be good. Gooseberries and Currants are plentiful, and the bushes very free from canker, for which the best preventive is gas-lime sprinkled under the bushes in spring. If the ground is stirred first it kills the grub. Strawberries are one of the finest crops on record, the bloom having escaped the spring frosts, and the weather being fine and dry the plants set a prodigious crop of well-shaped fruit. The best flavoured kinds at the present late period are Unser Fritz and British Queen. Amateur, John Powell, Sir C. Napier, and Dr. Hogg are still bearing, but they are not so good in flavour as the first two mentioned. Nuts are a thin crop.—Wm. Allan.

MIDLAND DIVISION.

Trent Park, Barnet.—The fruit crop in this district is fairly good. Pears are, I think, quite up to the average. Apples, although they set very well, have dropped off since, owing, no doubt, to the excessively hot weather which we have lately experienced. Cherries are plentiful both on walls and standards. Raspberries are abundant, but I believe in some places they are not quite up to the average. Strawberries seem to have surpassed all previous crops of that fruit. I have been picking from British Queen (a sort which seems to do better here than any other) the largest fruit I ever saw, and no doubt after the rains which we have had, should warm weather again set in, late fruits will be equally large. President has done fairly well, and has ripened some good fruit. Currants and Gooseberries are very plentiful everywhere, and I think wall fruit may be said to be an average crop.—Edward Baxter.

Bayfordbury, Hertford.—Our fruit crop here this season is not so good as last year. Apples and Pears are a very uneven crop; where the trees are most sheltered from north and east winds there is quite half a crop, but where exposed the fruit is very thin indeed. Gooseberries and Currants are excellent. Raspberries have much improved since rain came. Plums, generally speaking, are a good crop. With regard to Strawberries, we have not any of the new kinds here. We grow mostly Vicomtesse Héricart de Thury for forcing, and also as a main crop. President succeeds it, and these do well with us. I generally select a piece of good open ground for Strawberries. I have it well prepared by trenching if necessary, and well manured ready to receive the forced plants as they are taken from the houses, and these I find often give us some good fruit late in the same season. We generally mulch our Strawberries in winter with manure, and we invariably have excellent crops. We also grow British Queen on a late border, and it does well, but this season it has been much too hot and dry for it, even though watered occasionally. I seldom let one crop of Strawberries remain on the same ground more than two or three years; I find that they do best on fresh well-prepared ground. The finest crop of Strawberries I ever grew, both as to quantity and quality, was grown on a piece of old pasture taken in to enlarge the garden.—John Gibbs.

Moor Park, Rickmansworth.—Apples here are very scarce, and the trees much injured by caterpillar; where protected by trees or walls from cold winds the crops are better. Lord Suffield, Wellington, Cox's Orange Pippin and Prince Albert are amongst the most certain cropping sorts grown here. Of Apricots we have a very fair crop, especially under Rendle's protectors. Our Pears are light, but the fruit is clean and the trees very healthy. Cherries are a good crop. Bush fruits are very abundant, but Gooseberry caterpillar is quite a plague; some trees laden with fruit are entirely defoliated. Raspberries are unusually plentiful and very fine. Plums in all situations are good crops. Strawberries are a less crop than I have known them to be for these past eight or nine years. James Veitch, President, and Sir J. Paxton withstood the drought better than most others I grow, but all kinds have improved since the rain which fell on the 11th inst. I am now gathering very fine fruit of Oxonian, a very good late sort, and one which deserves more extended culture than has hitherto been given it. The varieties that do well here are Vicomtesse Héricart de Thury, Keen's Seedling, James Veitch, President, Dr. Hogg, Elton Pine and Oxonian. Pioneer and La Grosse Sucrée are early, but not quite good enough in flavour. I plant a batch of runners and forced plants every year, and never let a bed remain after the third year. The alpine, Royal Hautbois and Quatre Saisons I grow; the latter is very fruitful.—J. C. Mundell.

Hatfield House, Herts.—The fruit crop here this year is only a medium one. Small fruits, with the exception of Strawberries, are particularly good. Plums, Cherries, Peaches, Nectarines and Pears are average crops; Apricots and Apples are under the average. Many Apples are falling off. When cut open they appear as though the bloom had not been properly formed; the trees, too, look weakly, and the foliage was much damaged by caterpillars in May; caterpillars were also at that time very numerous on Pear trees, the fruit of which they very much damaged. Our crop of Strawberries has been much under the average this year, both in quantity and quality; the hot, dry weather of last summer, I think, weakened the plants, and the frost on the 30th of April and 1st of May this year killed the fruit and best blooms, and, moreover, the weather was too dry and hot while the fruit was swelling. My principal varieties out of doors are Vicomtesse Héricart de Thury, President, and Sir Charles Napier; the first two are good in every way. Sir Charles has not such a good constitution as the others, but the fruit is large and firm and travels well. For the earliest crops I grow Black Prince, and for the latest Elton Pine. Last year I planted for trial a row of the new Strawberry, King of the Earlies, by the side of Black Prince. The plants were similar, and they were all planted at the same time. The King was ripe fully a week before Black Prince. I, therefore, intend to plant a large bed of the King this year. I plant on deeply trenched and heavily-manured ground 2 feet plant from plant in the rows, which are 3 feet asunder. I plant both old forced plants and young ones, and both do equally well. I do not take any fruit from the young plants the first year, all their strength being required to produce runners for pots. As a rule, they do well the following two years. I plant about a third of my stock every year, and destroy a similar quantity, a system which answers well. Vicomtesse Héricart de Thury bears a greater number of seasons than any other variety with which I am acquainted.—G. Norman.

Panshanger, Herts.—Most of the fruit crops in this district are below the average, though from the magnificent bloom which we had in the spring and the lateness of the season, we anticipated much better results. Owing to the prevalence of north-east winds and low temperature much of the Apple blossom never set, and the late excessive heat and drought have much deteriorated some otherwise promising crops. Apples are therefore much below the average; some trees may be seen bearing a fair crop, but they are few and far between. Pears are also under the average. Cherries are an average crop, but small, with the exception of Morellos, which are good. Plums are over the average, but owing to the late drought much of the fruit is now falling. Apricots are much under the average; Peaches and Nectarines are bearing good crops, and the trees are making excellent growth. Gooseberries, Currants, and Raspberries are abundant; Raspberries small, but good. Strawberries much below the average and small; much of the fruit, owing to the heat, dried up on the plants. The varieties which I find to be most useful and productive on our light gravelly soil are Pauline for first early, Keen's Seedling, Premier, Vicomtesse Héricart de Thury, President, British Queen, Dr. Hogg, and Frogmore Late Pine. Pauline was ten days earlier than any of the kinds just named, but that is its only recommendation.—R. Ruffett.

Clumber, Worksop.—Hardy fruits here and in this neighbourhood, with the exception of Apples, Pears, and Apricots, are fair average crops. Apples bloomed profusely, but the prospect of a good crop was destroyed by continuous cold wet weather, that prevented fertilisation. The kinds having most fruit are Radford Beauty, King of the Pippins, Red Astrachan, Fearn's Pippin, Manks Codlin, Syke House Pippin, Sleeping Beauty, Dutch Mignonne, Lord Suffield, Maltster, Kirke's Fame, and Tower of Glamis. Pears suffered from the same cause as Apples, and are consequently thin. Jargonelle, Williams' Bon Chrétien, Zéphirin Grégoire, Grosse Calebasse, Easter Beurré, Huyshe's Prince of Wales, Winter Nelis, Louise Bonne of Jersey, General Tedleben, and Beurré Giffard are bearing most fruits. Peaches on walls set well, but the foliage suffered severely from blister, and the fruit generally is small. Apricots are almost a failure. Plums are a very heavy crop. Cherries, both Morello and sweet, are good crops; so, too, are Currants, Gooseberries, Raspberries, and Nuts. Of Strawberries, such kinds as do well on our light sandy soil are abundant. Vicomtesse Héricart de Thury we mainly depend upon. It is one of the best-flavoured and heaviest croppers amongst Strawberries, and a most excellent variety for light sandy soils. Our course of treatment is as follows: a plantation is made every year in September, consisting of runners layered in pots for the purpose. The plants are planted in rows, 2½ feet apart and 18 inches asunder in the rows. From this plantation, which is not allowed to fruit the following season, we take runners for forcing, and after that every alternate plant in the rows is removed, leaving a distance of about 3 feet from plant to plant. By this plan we get strong early runners for forcing, and a heavy crop of fruit the second year after planting. The plants are not allowed to remain a third year, but are cleared off and the ground get ready for winter Spinach. Early-forced plants of Vicomtesse planted early in June in a warm south border give us a plentiful supply of fruit after the general crop is gathered, and continues bearing until cut off by frost.—M. Gleeson.

Osberton Hall, Notts.—The Apple crop in this district is nearly a failure. Pears, too, are a poor crop. Plums are a fairly good crop, and the trees have been very free from green fly. Peaches and Nectarines on open walls are good crops—the best, indeed, we have had for some years; the trees also are clean and healthy. Apricots are about half a crop; the bloom buds were greatly injured by the severe frost which we had in March. Gooseberries and Currants are heavy crops, and the fruits are very fine—the best which we have had for some years. Strawberries are a very good crop, and the fruit is large and fine in flavour; the sorts grown here are Keen's Seedling, La Grosse Sucrée, James Veitch and British Queen; the last is exceptionally fine, our light soil seeming to suit that variety well. For late use we depend upon Elton Pine and Frogmore Late Pine. Cherries are a good crop, with the exception of Morellos, which are not quite so heavy as usual.—S. A. Woods.

Thoresby Park, Ollerton.—Fruit crops here are not so promising now as when the trees were in bloom. Owing to the long, cold, dry, sunless weather and piercing winds the bloom did not set well, and quantities that did set have dropped off. Apples, Apricots, and Pears will be light crops here, at least in the case of some sorts. Plums are a fair crop, and Cherries are a good average crop. Small fruits are very fine, Currants, both Red and Black, being plentiful, and also Raspberries. Strawberries, too, are a heavy crop, and the fruit large and fine. We still keep to Keen's Seedling as our best both for forcing and outdoor. In flavour it comes next to British Queen; then comes President, which is always good. Under the following treatment we have always good crops: As soon as all the fruit is gathered we clear off all runners, hoe and rake the ground clean, and keep it clean until, say, end of October; then we give a good dressing of rotten manure, spread all around the plants and between the lines; in spring, just as the plants begin to grow, we give a good dressing of long litter from the stables. If the weather should be dry when they begin to throw up their flower spikes we give a good watering, and sometimes a dusting of any sort of manure we may have at hand before water is given, of which they get plenty. I find Oxonian to be our best late Strawberry.—A. Henderson.

Welbeck.—Apricots here are an average crop; Apples a very poor crop. The trees flowered profusely, but set very little fruit, and the foliage all through June had an unhealthy appearance. Pears generally are not a good crop. Williams' Bon Chrétien, Louise Bonne of Jersey, Marie Louise, Bezi Mai, and a few others planted on the south side of an arcade running east and west, are bearing good crops. Peaches and Nectarines are good average crops. Of Cherries, Morellos are good; others poor. Plums are a heavy crop, so much so as to oblige us to thin severely. Bush fruits are plentiful. Nuts very thin. Strawberries are neither plentiful nor fine. The weather during the time when they were in flower was harsh and cold. Vicomtesse Héricart de Thury, Keen's Seedling, Sir Joseph Paxton, and Dr. Hogg are most to be depended on, and the first-named most of all. We grow more than an acre of Strawberries, and plant a considerable space every season, chiefly with plants which have been forced. Before planting we manure heavily, and trench two spits deep. Such plantations usually stand about four years, and, as a rule, do well. As soon as the fruit is set we mulch with rough litter or Grass.—Richard Carr.

Kingston Hall, South Notts.—The rainfall in May was exceptionally heavy. June was very cold, and a cold June is certain failure in the case of Strawberries—at least on heavy soils. So far as I have been able to ascertain, this failure has been general in this neighbourhood, our own crop being very light compared with that of former years. We renew our plantations every three years, or nearly so. We have tried three modes of procedure, viz., 1st, plants after being forced; 2nd, plants layered in small pots, and planted out as soon as ready; and, 3rd, putting runners in nursery beds all winter and planting them out in spring, and this is, I think, the best plan. We always make it a point to keep our fruiting plants as clear of runners as time and labour will permit. In autumn the plants have a good cutting in and clearing: then they get a good mulching with stable litter, which also serves as a dressing to keep the fruit clean. We never fork amongst the plants (this, however, we should do in the case of all kinds of fruits, provided we had an unlimited supply of half-rotted manure at our disposal). Our varieties are Vicomtesse Héricart de Thury, Sir Charles Napier, Lucas, James Veitch, and Elton Pine. Of these we prefer the two first for ordinary seasons; but this year I must admit that James Veitch stands first as the best cropper. Lucas is a fine Strawberry, being with us good in flavour and a fine cropper, but a bad traveller. Raspberries are a very heavy crop, as are also Black Currants. Red Currants are a medium crop. Gooseberries are a fair crop. Morello Cherries also a fair crop. Pears on trees not heavily laden last year are good. Apples are thin on most trees. Damsons here are also rather a thin crop. Other Plums plentiful in the district. Altogether, if the autumn proves fine we have what may be termed a medium fruit crop.—J. W. Bayne.

Belvoir Castle, Grantham.—The complete failure of the Apple crop in this district was not the result of any single frost, but of a long period of chilling winds and cold, dull weather after the first flush of sap. The check sustained by the trees caused the bloom to fall, produced mildew on the foliage, and assisted the ravages of insects. Some few very vigorous young trees bore up against the trials of the early ungenial season. Stirling Castle and Lord Suffield amongst the number, and these are bearing fair crops. Pears suffered in the same way, the trees that failed to bear last year producing more fruit than those heavily cropped last year. The Plum crop is too abundant, necessitating thinning. There is but a moderate crop of Apricots. Peaches are bearing well and are healthy. Cherries moderately good. The crop of Gooseberries is exceedingly large; Currants, both Red and Black, are equally abundant. Raspberries are small and the canes affected by drought. The Strawberry crop is by no means large, and the fruit has been injured by dry weather. French Strawberries seem better able to resist heat and drought than English raised sorts; thus Grosse Sucrée proved the best early sort we grow; Keen's Seedling followed very closely, and maintains its position as an excellent fruit both for forcing and general cultivation. Alice Maud is growing into favour, both on account of quality and its packing properties; Sir J. Paxton and President follow and afford a main crop, succeeded by Vicomtesse Héricart de Thury, a heavy bearer, but a little acid. British Queen still maintains its pre-eminence in size, quality, and its habit of producing even and regular crops; Frogmore Late Pine is our latest sort, and well grown is invaluable, being a heavy cropper and of a deep rich colour. Pauline is on our trial ground as an early sort; James Veitch does not succeed with us; Auguste Nicaise is a large fruit, but not of high quality; it forces well. We employ forced plants generally to make fresh borders, and find it best to use manure liberally.—W. Ingram.

Waresley Park, St. Neots.—Fruit crops in this district, with the exception of bush fruits, are below the average. Apples and Pears are very scarce indeed. Plums are a fair crop Apricots rather thin, but large. Cherries abundant. Peaches and Nectarines good and trees healthy. Red, White, and Black Currants and Gooseberries abundant, and of first-rate quality. Raspberries and Strawberries promise to be good crops, but owing to the dry weather which we have had they are small, but of good quality. Vicomtesse Héricart de Thury, President, and British Queen I find to be sufficient both for inside and open-air culture. Filberts are scarce, but Walnuts are plentiful.—Robert Carter.

Kimbolton Castle, Hunts.—Strawberries in this district are almost a failure, though with us they are excellent, owing solely to our having given them fresh mulchings and copious waterings when the dry hot weather set in immediately after the 21st of June. The kinds which I find best suited to this cold clayey subsoil are British Queen, Dr. Hogg, Sir Charles Napier, and President, and yet they are the four best varieties grown. Keen's Seedling was almost a failure, the blooms seeming to perish beneath the continuous cold rains which occurred in the early part of June. Apples also suffered from the same cause, and the leaves are now falling off as if scalded. Of Apricots, Pears, Plums, Cherries, Gooseberries, Currants, Filberts (scarlet and white) we have great abundance. As to the latter, I never before saw such a profusion. In order to secure good and heavy crops of Strawberries, I always open a trench the same as for Celery and manure well, then fill in and plant with plants that have been forced. By these means I get a far heavier crop the following season than I could possibly obtain from plants prepared outdoors.—Thos. Cowburn.

Ramsey Abbey, Hunts.—Apricots here are thin, but the trees are healthy. The paucity of fruit I attribute to drought and scarcity of water last summer. Peaches and Nectarines are good; Plums and Cherries abundant; Apples about half a crop; Pears fairly good; Grapes on walls plentiful, but late—will require a fine autumn to enable them to ripen; Figs are a good crop; bush fruits and Raspberries very abundant; Nuts thin. As regards Strawberries, young beds have done well. One old bed that was condemned last year, but afterwards reprieved, has not been so good. On our soil the second year is usually the best, and on no consideration should beds of Strawberries be allowed to stand more than three years. The best kinds as regards flavour are British Queen and President, and they also bear well. Vicomtesse Héricart de Thury does well here as a second early. Black Prince and the Captain succeed well also. The best late kinds with us are Sir C. Napier and Elton Pine. The White Pine is liked here, and it bears well; it also forces well. The best way to insure good crops is to plant either a half or a third of the space occupied annually, according as we adopt the two or three years' system, to plant on good land firmly, to give plenty of room in proportion to the development of the particular variety growing, to mulch heavily, and to water freely up till the time when the fruit begins to ripen. The alpine with us is much thought of. It is sent in for breakfast every morning, and when the plants are well fed the fruit attains a good size.—E. Hobday.

Glossop Hall, High Peak of Derbyshire.—This is perhaps one of the worst fruit districts in England. There is an old saying here that we get nine months of winter and three months of bad weather, which is, so far as my experience goes, not far from correct. Apples and Pears, when their blossoms escape destruction by late spring frosts, rarely attain size enough to be of any use, with the exception of Lord Suffield, Keswick, and Manks Codlins, and these are only a very poor crop this season. Of dessert Pears we have none, all the bloom being destroyed by heavy rains and frost. Plums and Cherries also suffered from the same cause. Currants and Gooseberries are much under the average. Raspberries and Strawberries are about an average crop, but very late up to this date (July 23). We have not gathered a single Strawberry outside. President, Vicomtesse Héricart de Thury, Sir Joseph Paxton, and the old Hautbois were the only varieties in cultivation when I took charge here in the spring of 1885; to these I have added James Veitch, Keen's Seedling, Eleanor, and British Queen. In addition to a cold, wet climate, we have a wretchedly poor gravelly soil, and, worst of all, smoke from the cotton factories' and other chimneys. On soil of the nature of our own it is not wise to allow Strawberry beds to stand more than three years, as by that time the plants get quite exhausted. In the new beds we have made we have—by way of an attempt to improve both crop and quality—put about 4 inches of good stiff clay in the bottom of the trenches, and we have great hopes of this method being successful, assisted by liberal top-dressings of manure in autumn.—B. Ashton.

Westonbirt, Tetbury.—Apples here are an average crop; Pears good, especially early varieties. Winter Nelis on a west wall, has not failed during these last six years. Of Plums we have an excellent crop. Cherries are an average crop, but small. Peaches and Nectarines average crops; trees very much blistered, but making strong lateral growth. Apricots are under the average, but fine in quality. Of Figs we have an average crop. Small fruits are excellent, especially Gooseberries, many of the trees breaking down under their load. Nuts are plentiful, but late. Strawberries are good: the first fruits were very large, and rain came just in time to swell for the second crop, which was plentiful, but the fruit small in size. I find only three varieties to do well with me, viz., Keen's Seedling, Sir Joseph Paxton, and President. I have tried Dr. Hogg and British Queen; the former does not ripen well, and the latter does not make strong crowns. I force Keen's Seedling as my earliest, and it produces moderate-sized fruit. It is also the earliest out-of-doors and best for preserving. Sir Joseph Paxton I find to be early and goodfor forcing; it has a good constitution, and is not particular as to soil. It also packs and travels well. President I find to possess the same good qualities, but it is quite a fortnight later. Our soil is not good for Strawberries, but the varieties just named do well with us. I plant out my latest forced plants in well manured soil, and these bear and last well for three years.—A. Chapman.

Hopton Hall, Wirksworth.—Apples in this district had a good show of blossom, but scarcely any fruit has set. I have one remarkable pyramid tree, viz., the Irish Peach Apple, that I left unpruned in 1884, and last year I was rewarded by clusters of threes at end of every branch, and very fine fruit; it was a pretty sight to see the fruit hanging on the long slender branches. This year I am again rewarded with pairs, instead of triples, and a good crop. It appears likely to be the only tree that will ripen any fruit. Pears never come to anything here except in very fine seasons, but old Brown Beurré is carrying a good crop. Plums, such as Coe's Golden Drop, Early Prolific, Dove Bank, Victoria, Goliath, and Purple Gage on walls, are bearing full crops, but the last named never comes to perfection. On pyramids, Victoria, Oulin's Golden, and Guthrie's Late Green are good crops, but the two latter never ripen properly; Victoria and Orleans do best, but the Orleans has failed this year. Damsons opened their blossoms late, and were looked upon as a safe crop, but, alas! they have failed. Cherries on walls are good; our varieties are Early Duke, Early Guigne, Elton, Downton (this here succeds Elton), Black Eagle, Morello, and Late Duke. Cherries and Plums do well on the limestone here, but they require a wall to ripen them. Raspberries are good, but rather small. Black Currants are a good crop, and very fine and clean. Red Currants are also very fine; a row of old standards, with large heads, are heavily laden and clean. White Currants are likewise good and clean. Gooseberries are a heavy crop, especially on young standards which had very little pruning. Strawberries are heavy crops: most varieties that have been tried do well here, though on a shallow soil. I could dig on to the limestone at less than a foot from the surface, on which there is a bed of

President showing a fine crop, and we have no means of watering such crops. I keep the ground well covered with foliage by thicker planting than what some would recommend, and I mulch well in autumn with rather littery manure; this washes clean and preserves the fruit from grit. I gathered my first dish of Vicomtesse Héricart de Thury on 12th of July, and I have been gathering the Wood Strawberry from the 28th of June; of this we supply a quart daily for breakfast. This wild Strawberry is finer this year than I have ever before known it to be. It grows by the acre on the limestone rocks here. Vicomtesse Héricart de Thury stands first on our list for a general crop, and forcing and preserving; President is our main crop kind, and for forcing I select the forced plants every year that produce the finest fruit, and plant them out; Oscar does well, and produces fine high coloured showy fruit; it also forces well, but this season 53 per cent. went blind; Black Prince is allowed to ramble about at will; this never fails us; Auguste Nicaise bears freely and is distinct in colour; Marguerite is large and a good cropper; Comte de Zans throws up its fruit well above the foliage, but does not stand wet well; of Eleanor we have a fine crop; it makes a showy late dish, though very acid. With British Queen we get on very badly; it never produces a crop here; it used to do well in Shropshire and Staffordshire on the red sandstone formation.

Potatoes look remarkably well in this district. —George Bolas.

Waddesdon, Aylesbury.—Apricots here are a failure. Plums very good. Cherries an average crop; Peaches and Nectarines the same. Apples are under the average. Pears an average crop and good. Bush fruits are very good. Strawberries under the average. Raspberries very good; of Nuts we have none. Generally speaking, our soil does not suit Strawberries well; it is a very heavy black clay with a great quantity of iron in it. Dr. Hogg does as well as any with us; Vicomtesse Héricart de Thury crops well, and is good in constitution. Lucas is a favourite with us, so is Helena Gloede and Sir Joseph Paxton, but President is the Strawberry upon which we rely for a general crop. Sir Charles Napier does fairly well with us; and James Veitch, Loxford Hall Seedling, Oxonian, and the Red Alpine do well late.—Absalom Bradshaw.

Chatsworth, Chesterfield.—The Apple crop here is a capricious one. Early varieties are a good crop, including Codlins, but later varieties are scarce, and the trees which bore heavily last year have scarcely any on them this season. The reason for this must be, I think, the unripe condition in which the wood was left last winter after the almost unprecedentedly dull and cold autumn which we had. Pears are a fair crop. Plums an average one, and Cherries the same. So, too, are also Gooseberries, Raspberries, and Currants, excepting Black ones, which are light. Strawberries are under the average, and I find a greater percentage of blind plants than I ever remember before, especially in our plantations, and also in those formed with young runner plants. On the other hand, in quarters plentiful last year with plants which had been forced we have no blind ones, and these, in my opinion, always give the best return.—O. Thomas.

Shipley Hall, Derby.—There was an abundance of blossom on all kinds of fruit trees here and in this neighbourhood last spring, but the unfavourable weather in March and April, and a very wet, cold May, have in general had an unfavourable effect on our fruit crops. Apples, Pears, and Plums are a spare crop; even that free-bearing Plum the Victoria is very thin. Of Damsons we have half a crop. Morello Cherries are also almost a failure. Of the choicer kinds of hardy fruits, viz., Peaches, Nectarines, Apricots, and Figs, none are grown here except under glass. Raspberries are excellent in every way. Gooseberries are also laden with well-swelled berries. Currants, Red, White, and Black, are fair crops. Of Strawberries our earliest and best cropper is Vicomtesse Héricart de Thury, but this season they are unusually small, owing to the protracted drought which occurred during June. President and British Queen suffered most through the winter and from late spring frosts, many plants being quite stripped of their foliage; consequently, the crop is very poor indeed. James Veitch is our heaviest and best cropper this season, and is a variety that always does well on our heavy soil, but its value is much discounted by the fact that its fruits are the first to decay in damp weather, especially the largest ones, even before they begin to colour. For late picking on a north border, I grow Helena Gloede and Loxford Hall Seedling; both varieties are swelling heavy crops, and will give us a good supply during August. My practice is to plant runners in August every year to take runners from the succeeding year for forcing. These I plant in rows 2 feet apart and 1 foot asunder in the rows. After the runners are taken, the following year I root out every other plant, leaving each plant 2 feet in which to grow and fruit for two years afterwards. By this method I add to and take from my plantations equally each year.—W. Elphinstone.

The Globe flower (Trollius europæus).

Stoneleigh Abbey, Kenilworth.—Apples on bush trees here are very good. Pears under the average, but good. Plums on walls an average crop. Apricots under the average. Cherries on walls average good. Peaches an average crop. Currants of all sorts good. Gooseberries and Raspberries the same. Sir Joseph Paxton is the favourite Strawberry here, and in this neighbourhood Keen's Seedling is a good one and much used for forcing, but it has not fruited outside well with me this season. Vicomtesse Héricart de Thury dies off very much, though a favourite sort with me. I have a few plants of King of the Earlies planted out, and I like it much; it is very early. Of Macmahon I have also a few planted out. It is excellent in flavour, but, I am afraid, not a good sort for packing, being rather soft. Eleanor suits our garden, and is much later than those just named. Plums and Damsons are very good in neighbouring parishes. Small fruits are good. Apples and Pears moderate.—T. Beddard.

Hewell Grange, Bromsgrove.—Owing to the lateness of the season, all fruit crops here are abundant, with the exception of standard Apples in the orchard, which are a complete failure, with the exception of Blenheim Orange and King of the Pippins. Those on the Paradise stock planted round the borders of the kitchen garden are carrying heavy crops. The varieties to which I refer are, dessert Apples: Irish Peach, Red Astrachan, Golden Pippin, Kerry Pippin, Red Quarrenden, Oslin, Duchess of Oldenburg, King of the Pippins, Cox's Orange Pippin, Ribston Pippin, Syke House Russet, Pitmaston, Nonpareil, Margil, Braddick's Nonpareil, Herefordshire Pearmain, Cockle Pippin, Ashmead's Kernel, Calville Blanche, Duke of Devonshire, Claygate Pearmain, and Sturmer Pippin. Kitchen Apples: Nonsuch, Lord Suffield, Pott's Seedling, Echlinville, Stirling Castle, Beauty of Kent, Cellini, Cox's Pomona, Blenheim Orange, Gloria Mundi, Small's Admirable, Mère de Ménage, Waltham Abbey Seedling, Winter Hawthornden, Yorkshire Greening, Alfriston, Nelson's Glory, Tower of Glamis, Ware-

ham Russet, Warner's King, Golden Noble, Dumelow's Seedling, Bedfordshire Foundling, New Northern Greening, and Winter Peach. Of Pears we have heavy crops of Marie Louise, Jargonelle, Beurré d'Amanlis, Durondeau, Marie Louise d'Uccle, Napoleon, Glou Morceau, Winter Nelis, and Knight's Monarch. Those carrying moderate crops are Doyenné d'Eté, Doyenné du Comice, Pitmaston Duchess, Duchesse d'Angoulême, Brockworth Park, Dana's Hovey, Marie Benoist, Emile d'Heyst, Beurré Bosc, Beurré de l'Assomption, Chaumontel, Bergamotte d'Esperen, and Josephine de Malines. Pyramids are again carrying heavy crops. Currants, Raspberries, and Gooseberries are excellent, and entirely free from blight. Figs are also a grand crop. Cherries, too, are very abundant, both dessert sorts and Morellos, and they are free from black fly, although the weather has been dry. Plums on walls are heavily cropped; also standards, which will require to be supported, their branches being completely borne down with the weight of fruit. Damsons are likewise an excellent crop. Nuts also promise to yield well. Peaches, Nectarines, and Apricots are always a failure here, owing to the exposed position of this garden; therefore, few trees of these are grown outdoors. Strawberries are a very good crop; the sorts upon which I depend for a continuous supply are Vicomtesse Héricart de Thury and Sir J. Paxton, planted on south and west borders and in open quarters. Oxonian, Elton Pine, and Frogmore Late Pine are planted on east borders. I find Sir J. Paxton to be the best of all for packing for travelling. Its fruit is of fine appearance and excellent in flavour. The sorts just named carry me over a long period. In the case of those on borders, I am unable to change the ground on which they grow, but I renew a portion of them annually. The third year as soon as the fruit is gathered, I mow down the tops of those to be destroyed with a scythe; give a heavy dressing of manure and bastard-trench the ground; then I make it firm, and plant with rooted runners from pots. Of course those on open quarters can be changed about more than those in borders. By this mode of cultivation I always obtain excellent crops, and they can withstand a long period of dry weather without sustaining any serious effects. —Edward Ward.

NATURALISING GLOBE FLOWERS.

Naturalising garden flowers is a phase of culture happily becoming popular, and among the host of vigorous, yet showy, flowers fitted for the purpose, none are better than the Globe flowers. These have long been cultivated in gardens, and the variety amongst them now to be had, both in size of flower and shade of colour, will satisfy the tastes of all. The flowers of the European species herewith illustrated are clear yellow, while there is every shade between this and the deep orange of T. japonicus. All are strong growers able to hold their own with rampant growing perennials. The ground for Globe flowers simply requires to be broken up, and a little manure added if necessary to give them a start. At a friend's place the other day I was much struck with the quantities of Marsh Marigold which I saw growing by the side of a small lake, the effect of which was charming; it does not necessarily require water to grow in, although it will thrive all the better if the ground in which it is placed is a little damp. Epilobium angustifolium and the variety album, stately growing plants, have also a grand appearance growing in a semi-wild state, and if left for a few years undisturbed, they gain in strength in a wonderful way. K.

QUESTION.

5512.—**Anemone culture**—I am at fault as to the management of Anemones. Some of my friends say, leave them undisturbed in the ground, simply giving them a coating of manure. Others say, take them up in the autumn and keep them in a dry cool place until the spring. Both parties say that if the treatment contrary to their special views is carried out they, will be a failure, and between the two I am in a fog. I may say that I planted some in April last, and have had a grand lot of blooms of both single and double. I presume the treatment given for Anemones is applicable to Ranunculuses. If any successful grower will kindly give me any information on the subject, should be obliged.—W. Snowell.

SOCIETIES.

ROYAL HORTICULTURAL.

July 27.

The annual show of the Carnation Society was on this occasion associated with the usual fortnightly meeting, so that there was a large and varied exhibition, which also included a competitive show of vegetables for special prizes, and a capital display of orchard-house fruit trees from Sawbridgeworth. The plants and flowers submitted to the committee were fewer than usual, though some possessed exceptional interest. First-class certificates were awarded to the following:—

Cattleya gigas, Hill's variety.—A truly magnificent variety, and only comparable in the size of the flower and beauty of colouring to the C. gigas Hardyana, shown here some time since. Mr. Hill's plant is supposed to be a natural cross between C. Dowiana aurea and C. gigas, and as these two Cattleyas grow wild in the same district, and in fact together, the supposition is probably correct. To describe it one must imagine a very large flower of C. gigas, with broader sepals and petals than ordinary, the latter firm enough to hold themselves rigid. Their colour is a deep purple-rose, tessellated or chequered like the sepals of Vanda cærulea. The lip, the most gorgeous part, is quite 3 inches across, of an intensely deep magenta in the lower part, and adorned in the upper part with pale yellow, fading off to straw colour in the throat. The exquisitely frilled margin of the lip also adds much to its beauty. It would not be too much to pronounce it the noblest and most splendid Cattleya ever seen in this country. The fortunate possessor of it is Mr. Hill, of Arnott Hill, Nottingham, by whose gardener, Mr. Davenport, it was shown in fine condition.

Odontoglossum stellioerum Ernesti.—A variety of what has hitherto been looked upon as only a third-rate Orchid, and the present plant, shown by Mr. R. J. Measures, of Cambridge Lodge, Camberwell, is by far the finest form yet seen. The flowers are much larger than those of the type; the sepals are pale green, heavily spotted with dark brown. The labellum is three-fourths of an inch broad, and has a terminal lobe of pale claret colour, the upper half being pure white. The flowers are borne in the usual racemose way.

Rhododendron Rajah.—Another addition to the new race of greenhouse or Javanese Rhododendrons, characterised by having double flowers. This new variety is one of a batch of seedlings, produced from the same seed vessel, and which include a double white, a double yellow, and a double pink variety. The flowers of the Rajah are very double, and produced in massive trusses accompanied by luxuriant foliage. The colour of the flowers is a warm apricot yellow, flushed with red. It is a very beautiful plant, and one that will be sure to become popular. Shown by the raisers, Messrs. Veitch, Royal Exotic Nursery, Chelsea.

Matricaria inodora fl.-pl. grandiflora.—An improved variety of a well-known and popular hardy flower. The blossoms of the new variety are not only much larger than those of the ordinary form, but when fully developed are pure white, whereas in the original they are always greenish in the centre. The plant is dwarf, not more than a foot high, compact, and extremely floriferous. It will prove a useful border flower for cutting. Shown by Mr. T. S. Ware, Hale Farm Nursery, Tottenham.

Todea grandipinnula.—A supposed hybrid between T. Fraseri and T. hymenophylloides. It partakes of the characters of both of these lovely filmy Ferns, the fronds being broad, finely cut, and very pellucid. Shown by Messrs. Veitch.

Carnation Terra Cotta.—A new sort of a peculiar colour, a kind of buff-yellow, mottled with purplish hues of various shades. The flower as regards size, shape, and substance is the perfection of a first-rate Carnation. Exhibited by Mr. J. Douglas, Great Gearies, Ilford.

Among other exhibits worthy of note were two spikes of that superb Orchid, Lælia elegans Turneri, from Mr. Lee's garden, Downside, Leatherhead. One of these bore eleven flowers; the other nine; and these were cut from one plant, which bore other spikes also. It is seldom one sees such extraordinary examples as these, and Mr. Woodford, Mr. Lee's gardener, was deservedly awarded a cultural commendation. The colour of the flowers of this variety is claret-purple on the sepals and petals, the lips being a brilliant magenta. Messrs. Veitch showed a plant of Anthurium Bakeri, whose chief beauty lies in the bright red berries with which the long slender spadix is beset. It is interesting, but few would consider it very beautiful. The same firm also showed a new Caladium named Charlemagne. It has large transparent red leaves, having prominent veins of bright crimson. Mr. Jannech, of Dersingham, showed a new variety of the native Maiden-hair Fern under the name of Adiantum Capillus-veneris grande (Moore). It seems to have much more robust fronds than the type, and it is altogether of larger growth. It is, we consider, a very beautiful Fern, and being hardy, will be invaluable for growing in cool houses. Mr. Bealby, Roehampton, received a cultural commendation for a fine specimen of a double yellow tuberous Begonia named Louis d'Or, one of the best of the colour we have seen. The flowers are large, very double, and of a clear sulphur yellow. Mr. Owen, Maidenhead, also made a showy display with Begonias, which included some good sorts, and three struck us as being particularly good. These were named Queen of England, a large double salmon-coloured flower; Colindia, scarlet; and Marchioness of Lorne, a large single sort of a bright cherry-rose colour, and extremely floriferous. Mr. May, Dyson's Lane Nursery, Edmonton, showed a group of plants of his new Fern, Pteris cretica H. B. May, which has variegated fronds like the albo-lineata variety, but elegantly tasselled. Mr. Noble, of Sunningdale Nursery, showed some new unnamed sorts of Clematis Jackmanni, and also a wreath of the white Jackmanni, a very lovely variety. Mr. R. Dean again showed plants of his double Stocks, one named Mauve Beauty being extremely pretty.

Cut Roses from Messrs. Paul, of Waltham Cross and Messrs. Paul, of Cheshunt, made quite an exhibition in themselves, and were much appreciated; and scarcely less so the large gatherings of hardy flowers from Mr. Ware, of Tottenham, Messrs. Barr, of Covent Garden, and Messrs. Paul from their Brexbourne Nursery. All three collections were good, but they did not differ much as regards the material of which they were composed. Lilies were prominent in all, and Mr. Ware's group was especially noteworthy for the stately spikes of such noble Lilies as L. longiflorum, pardalinum, Humboldti, testaceum and candidum; while Messrs. Paul had some fine specimens of that darkest of all Lilies, the Dalmatian form of L. Martagon, known as L. dalmaticum. The Eryngiums, or Sea Hollies, in the Tottenham collection were also a noteworthy feature, there being large masses, two or three yards square in fact of E. giganteum, whose spring flower-heads looked more like electrotyped silver than real flowers, and also of E. amethystinum, which is, perhaps, the best of all, because it is brightest; the flower-heads and also the stems shine like burnished steel. The Iceland Poppies both in Mr. Ware's group and also in that from Messrs. Barr were charming, for nothing could well surpass in beauty the glowing hues of these cup like flowers, bright orange scarlet and lemon-yellow, and also snow-white. There were a host of interesting and beautiful bulbous plants to be seen in Messrs. Barr's group, while the numbers of first-rate hardy flowers were as numerous and well-grown as they have been on previous occasions, although there are still not a few weeds among the so-called border flowers which should not be exhibited.

The Carnation Show.

Without doubt flaked and bizarre Carnations and the edged Picotees are very beautiful, but it is an unfortunate fact that all the most noticeable blooms shown were grown under glass; thus these are seen under auspices very diverse from those grown as ordinary border plants. That the greater size and exceeding refinement found in these exhibition flowers repay for the additional trouble taken in their cultivation there can be little doubt. Still, it is well all who have admired these in their stands and paper-

collars, after they have passed through the hands of the dresser, should understand that blooms as presented in the interesting collections shown by Messrs. Veitch, Mr. T. S. Ware, and Messrs. Hooper are just what open-air culture produces, and not those delicately-refined blooms. Shown in the competitive classes, one thing was exceedingly noticeable in the competitions, and it was one to be regretted. It was that only two exhibitors, Messrs. C. Turner, of Slough, and Douglas, of Ilford, succeed in producing first-class flowers, all the rest being but very third-rate. As a result, when the blooms of these growers are seen, all further interest in the competitions pass away. Were these removed the show would be inferior indeed, but being present they did but emphasise the wide difference there is between high-class and mediocre culture.

Show Carnations.—The class for twenty-four blooms brought five collections, in which Messrs. Turner and Douglas were, of course, invincible. Amongst the best blooms staged were Rob Roy, James Douglas, Miss E. Wemyss, Mr. H. Cannell, A. K. Mayor, Matador, Corisande, Tim Rittorn, Diana, and Felicity. Mr. Turner's blooms were exceptionally fine, and those of Mr. Douglas hardly less so. In the class for twelve blooms, open only to amateurs, Mr. Douglas was first with superb flowers, whilst the Ipswich grower who followed was in fairly good form. Amongst the good blooms shown were Sarah Payne, John Hunt, Arthur Medhurst, Thalia, and Squire Walker. That there were no less than a dozen lots of six blooms staged shows that many small fanciers have entered the lists, the best of these being Mr. Phillips, of Earley. Exceedingly fine was the competition in the single bloom classes, some twenty blooms probably being shown in each. As these give the various flowers in their sections, they present, perhaps, most interest. *Scarlet bizarres* came first, Robert Lord being placed first and second; Arthur Medhurst, third; Master Stanley, fourth; and George, fifth. In *crimson bizarres*, Duc d'Aumale was first; Rifleman, second; Merryweather and Master Bob, third and fourth. In *pink bizarres*, Sarah Payne came first and second; Unexpected (Douglas), third; Squire Llewellyn, fourth. *Purple flakes* produced, first, Mayor of Nottingham, then Squire Meynell; Sarah Payne here sported to a flake; Sporting Lad and Major Gane in this order. *Scarlet flakes* were represented by Matador, Hy. Cannell, Sportsman, Figaro, and a seedling. In *rose flakes*, Rob Roy, almost scarlet, was first and second; Tim Robbin, third: Diana, fourth; and Thalia, fifth.

Picotees.—So good were the two collections of two dozen blooms staged that the judges placed them equal first, although to the ordinary observer the blooms shown by Mr. Turner seemed the best, and certainly the finest. Amongst those specially good were J. B. Royal, Her Majesty, Princess of Wales, Brunette, Miss A. Chancellor, and Constance, heavy edges; and Liddingston's Favourite, Mrs. Payne, Orlando, Clara Penson, Juliette, and Mrs. Gorton, light edges. There were nine boxes of twelve blooms; Mr. Douglas being here to the fore with some lovely flowers. Specially good were Alice, light purple edge; Mrs. Payne, light rose; Her Majesty, light purple; Favourite, light rose; John Smith, heavy crimson; Muriel, heavy purple; and Constance, heavy rose. There were thirteen lots of six blooms staged, fairly clean, pleasing flowers from amateurs. Singles were in great quantity, and came as follows: Of *heavy edged reds* were Henry, first and second; Prince of Wales, third and fifth; and Mrs. Dodwell, fourth. *Purples* were represented by Muriel, first and second; Miss A. Chancellor, third; Zerlina, fourth and fifth. *Roses* found the best in Mrs. Payne, first, second, third, and fifth; and Edith Dombrain, fourth. Of *light edges* the best reds were Mrs. Gorton, first and second; and Mrs. Williamson, third and fourth. Of *purples*, Juliette came first and second; Her Majesty, third; Nymph, fourth; and Pride of Leyton, fifth. Finally, of *roses*, Liddingston's Favourite took all the prizes. A class for *yellow grounds* gave Agnes Chandler and Prince of Orange as best blooms. *Self and fancy Carnations*, seemed to attract attention because of their greater variations of colour and markings, and even here the two premier exhibitors took the chief prizes. Very beautiful were Rob Roy, Sybil, Dan Godfrey, and Mary Morris, rose selfs; Magog, purple self; W. P. Milner, and the Governor, white; Edith, yellow; and of edged flaked flowers, Prince of Orange and Guardsman were excellent. There were five lots of these and eleven of six blooms, a very good class. *Yellow ground Picotees* had a special class for twelve blooms, Mr. Douglas having, in Annie Douglas and other renowned seedlings, some singularly beautiful flowers, and Mr. Turner in Prince of Orange, Princess Beatrice, Janira, Thomas Pye and others was hardly less meritorious. The prizes for nine pot plants, eight Carnations and Picotees, fell to Messrs. Douglas and Turner, the flowers being shown in deference to public opinion, without the absurd paper collars, once so favoured. Mr. Turner also staged a collection of plants, amongst which that fine Clove Souvenir de la Malmaison was finely flowered. First-class certificates were awarded by the judges to Picotee Pollie Brazil, shown by Mr. Anstiss, having a heavy purple edge. Also to Annie Douglas, yellow ground, heavily varied with rose; shown by Mr. Douglas, and to Messrs. Veitch and Sons, for dark crimson self Carnation, General Stewart, very fine and free. The *premier Carnation* in the show was Rob Roy, scarlet flake, from Mr. Turner's twenty-four stand, and the same exhibitor had the *premier Picotee* in Mrs. Payne, in his stand of twenty-four blooms.

Other displays of Carnations were made by Mr. T. S. Ware, who showed in boxes about 100 bunches, each of from seven to nine blooms in sorts, set up with foliage or grass. The effect was admirable, and excited great attention. The sorts comprised of whites W. P. Milner, Mrs. Fawcett, Ghost, and Comte de Chambord, whites; Mrs. Donaldson, Rose Perfection, and Mary Morris, roses; Pride of Penshurst, Florence, and Mrs. Davey, yellows; Holman Hunt, Guiding Star, Victorine, and Coroner, scarlets; Old Clove and General Stewart, crimsons; Cara Roma and Beauty of Foxhall, purples; and of Picotees and fancies, Triumphans, Meyerbeer, Sailor Gordon, Lady Armstrong, Endymion, and Sir B. Seymour were all good. Messrs. Veitch & Sons showed about 300 flowers in the usual way in boxes, and in wondrous variety. A lovely kind was Countess of Ellesmere, white ground, heavily speckled with reddish-purple. Also fine were General Stewart, Royal Purple, Pride of Penshurst, Field Marshal, Magnum Bonum, Constance, Brilliant, Miss Marianne North, &c. Messrs. Hooper, of Covent Garden, had a good collection of self and fancy flowers. Mr. H. G. Smyth, Drury Lane, showed H. G. Smyth, a crimson Clove, rather rough in petal, and Mr. H. Cannell, Swanley, had Pride of Penshurst, the best of the yellow selfs.

Certificated varieties.—The following three new sorts were awarded first-class certificates: Carnation General Stewart, a Clove variety with large deep crimson flowers, from Messrs. Veitch; Picotee Annie Douglas, a yellow ground flower with rose-pink edged petals, from Mr. Douglas; and Picotee Pollie Brazil, a heavy purple edged flower, perfect in size and form, shown by Mr. Anstiss, who was also awarded a first prize as a seedling.

Fruit committee.—There were a few seedling Melons and other exhibits placed before the committee, but they were passed over. Undoubtedly the most interesting exhibit in the fruit way was a collection of fruit trees in pots and gathered fruits sent by Mr. T. Rivers, of Sawbridgeworth. Specially must the Cherries, which were so superbly finished and coloured, have tempted sorely the thousands of persons who gazed upon them during the day. Of trees in pots, specially attractive was an 8-feet high Black Hawk Cherry laden with intensely black fruit. Bigarreau Gros Cœuret made a fine standard heavily fruited, and other kinds in smaller trees were full of fruit. Gordoni and Nectarine Peaches were finely fruited, and Grand Duke and Monarch Plums, each carrying about twenty-five fruits just colouring, were fine samples. Some Pears were fruiting admirably also. Of dishes of fruits very fine samples of Sea Eagle and Nectarine Peaches were presented; also some Early Louise, a smaller-fruited sort. Cherries were grandly represented by such black kinds as Early Rivers, which had been ripe a month; Geante de Hedelfingen, which would hang for a month longer if needed; Turkey Black Heart, Late Black, and Bedford Prolific, &c.; and of lighter hued kinds Emperor Francois, Bigarreau Monstreuse de Mezel, Bigarreau Napoleon, and Ludwig's Bigarreau. A silver medal was deservedly awarded to this fine exhibit.

Special Prizes for Vegetables.

Messrs. Carter, of High Holborn, offered prizes for twelve pods of their Leviathan Bean, eight dishes being entered. Generally, the samples were rather browned and hardly up to the usual standard, the best coming from Amersham and Penn, both in Bucks; they were about 10 inches in length, and each contained seven beans—rather few for such pods. Five collections of Lettuces were placed in competition, the sorts required being Giant White Cos, Longstander, one of the erect French curled sorts; and All the Year Round, white Cabbage kind. The first and last generally were good, but the curled kind was poor, lacking heart. For the best three specimens of Carter's Heartwell Cabbage shown it would seem as if the class permitted a wide latitude, as the fine samples which Mr. Osman took first place with might have passed for Imperial or any other good old kind. Unless vegetables claimed to be seedsmen's specialities have some very distinguishing characteristics, it is evident that offering prizes for them may lead to curious results.

Messrs. Sutton, of Reading, offered prizes for their First Crop Cauliflower, but for a kind bearing such a designation the end of July is very late, as first-crop kinds should be in a month earlier. Five lots were shown, every one of which, for all one could tell, might have been Early London, the best, very neat sample, 7 inches over, coming from Mr. Beckett, of Penn, and the next best came from Esher. Prizes for six dishes of Peas were to include Duke of Albany, a long green pointed pod, much like Telegraph, but rather darker, and Sutton's Satisfaction, a pale green blunt-shaped pod, something after the British Queen form; seven collections were staged, nearly all very fine indeed, the best coming from Boston, the Messrs. Marriott, father and son, taking first and second prizes, with fine samples. It was noticeable that on both these collections the labels were in the same handwriting. Naturally, such a fact calls for explanation. Of other kinds shown were Triumph, Progress, Telegraph, Telephone, Stratagem, Reading Giant, Pride of the Market, and Progress. There were nine lots of Cabbages staged in the class for Lettuces All Heart and Little Gem, the kinds varying in character decidedly in some of the collections. Oddly enough, the best came from a place long associated in name with the Cabbage, Enfield, the samples being fresh and solid. Only two lots of Messrs. Webb's Chancellor Pea were staged for prizes offered by that firm.

A list of awards is given in our advertising columns.

New Peas certificated.—At a meeting of the fruit and vegetable committee held at Chiswick recently, the collection of Peas growing in the garden was examined, and first-class certificates awarded to the following: *Fame* (Eckford).—A green wrinkled Marrow, with large deep green well-filled pods; height 5 feet. *Empress* (Eckford).—White wrinkled Marrow, well filled large broad pods, vigorous grower; height 5 feet. *Seedling No.* 16 (Wildsmith).—White wrinkled Marrow, very long pods, strong grower, good cropper; height 4 feet. *President Garfield* (Veitch).—White wrinkled, large well-filled pods, heavy cropper; height 3½ feet. *Seedling unnamed* (Sharpe).—A dwarf wrinkled blue Marrow.

Names of plants.—*W. R.*—1, Heuchera Richardsoni 2, out of flower, but apparently a Hydrophyllum; 3, Ligularia macrophylla; 4, Geranium pratense; 5, Psoralea orbicularis.—*J. Poyntz.*—Apparently Cymbidium ensifolium, but we cannot be certain without seeing the leaves, which, in this species, are distinct. The Gongora seems to be G. portentosa, and the bulbous plant is Crinum ornatum.—*E. C.*—Bougainvillea glabra.—*E. F. C.*—1, Senecio Jacobæa; 2, Scabiosa arvensis; 3, Hypericum hirsutum; 4, Gymnadenia conopsea.—*Fasque.*—1, Syringa persica; 2, S. Emodi; 3, Deutzia scabra. Please send others again; larger specimens.—*A. K.*—Balsamita grandiflora.—*T. M. B. O.*—We do not know the Pea, but it was much withered.

WOODS & FORESTS.

THINNING PLANTATIONS.

I have just been looking over some notes, taken at different times on this subject, and relating to forest trees of all kinds, and the following facts appear to be constant: 1st, that unthinned plantations—no matter how thickly planted at the outset—do produce a crop of good trees, although many of the weaklings are crushed out in the struggle; 2nd, that a greater number of trees are produced to the acre than are produced in plantations thinned artificially; 3rd, that the trees are invariably straighter and cleaner than pruned trees are; and 4th, that the cost of culture is almost nil, comparatively. One need not object to thinning, but it should only be resorted to to clear out such trees as have become smothered by the others and about to succumb before they become useless. It is a great mistake to suppose that timber trees should be left so thin in the young stage that the extremities of their bottom branches should only meet and no more; if only the top is left free it is sufficient. Treated thus, the lower branches decay at an early age, leaving no trace or wounds behind them such as are left from pruned snags or branches broken off after they have attained a large size. We could show fine Larches, perhaps eighty years of age, with probably about as many feet in them that have never been permitted more development than a small top, and which have no trace of branches on their trunks, which are clean and straight. Other trees behave in exactly the same way under similar circumstances. Another matter bearing on this subject is the fact that all trees grow fastest and straightest in ravines from the same causes, and the more we see the more we are convinced that it is in every case better to plant precipitous ravines and sides of valleys than bleak hillsides and tops, which, except under the most favourable conditions of climate, produce stunted trees.

This question of planting, thinning, and culture lies at the foundation of arboriculture in this country, for, unless we can compete with foreign importation, we shall have to give up the contest. The *Standard*, writing a few days ago on the report of the Parliamentary Committee on Forestry, takes a practical view of the subject, and the view which those who will have to spend the money will probably take also. The writer of the article in question says—

Trees, all must agree, exercise a beneficial influence on the climate. That they impart a peculiar beauty to the landscape is equally undeniable. But most of the witnesses admit that it requires the long-enduring faith of Mr. Mackenzie to plant a woodland which cannot be cut under forty or fifty years, and which even then may have to compete at losing rates with the cheaper produce of the primæval woods of America, Russia, Scandinavia, or the colonies. It has been estimated that there are some 2,000,000 of acres in Ireland capable of being advantageously planted, and that of the 41,000 square miles of waste land in Great Britain, about one-half is available for forests. This, however, means that the present generation must plant without the hope of reaping; and in any case the dearness of the soil and the higher cost of labour in these islands compared with most other countries would render the profits to be earned from this investment extremely problematical. In the first place, making no allowance for the value of the ground, on the plea that the young growth might be used for game coverts or other purposes, the lost interest of the money expended in planting 20,000 square miles, accumulating for forty or fifty years, must be added to the principal, and distributed over every acre of timber ready for the market at the end of the period. This will, of course, add very appreciably to the cost of the trees. Then the care with which such an area of tender timber must be looked after during a lifetime necessitates the payment of foresters and other guardians; so that, even allowing that the price of deals will be higher in 1926 than they are in 1886, it is open to doubt how far it will be possible for the English artificially-grown timber crop to compete on equal terms with that either cultivated in the wild lands of the New World, or hewn from the still untouched forests which cost man nothing to plant or to maintain.

Forest experts from India, writers of theoretical works on forestry, and teachers who regard the subject purely from the academic point of view are, no doubt, shocked at the apathy displayed as to arboriculture. But the landowner, who has to make his books balance, is apt to prove a very Gallio when trees are advocated as the salvation of the British farmer.

The *Standard*, in an editorial apparently written by one conversant with the matter, does not think a special school of forestry in England likely or necessary, and that it could only be established at a cost out of proportion to its value. The main thing to bear in mind, however, is the fact that landowners are averse to laying out money on woods without some prospect of return, and it is therefore desirable to show how the cost of culture can be lessened, and one way of doing this is, in my opinion, to plant more extensively suitable trees in suitable places, and spend less on culture in the period between planting and felling. It does not cost very much to plant ground thickly with young trees, and vast tracts are now planted by contract at a small sum per acre. Those who have timber of mature age should send all to the market that can be spared without denuding their estates and should plant in proportion, and in this way they can have an interest in planting for their heirs, whoever they may be.

Yorkshireman.

THE STAG'S-HORN SUMACH.

(RHUS TYPHINA.)

This distinct and highly ornamental shrub is of tree-like growth, and is especially suitable for planting as a single specimen or among lower growing shrubs. Besides being ornamental, it is a useful one, according to a pamphlet by H. B. Small on the forest products of Canada. It appears that the Sumach is of considerable economic value. In Mr. Small's pamphlet he states that "the Sumach (Rhus typhina) is not a tree, but only a shrub with wood orange-coloured, aromatic, and brittle. It grows on dry, rocky, gravelly knolls and in barren spots where nothing else flourishes."

The principal uses of Sumach are for colouring and tanning, the latter more especially for light-coloured leather. It is also used in dyeing and calico printing, as it yields with different mordants a great variety of tints. The collection and preparation of the leaves have assumed large proportions in Virginia and the middle States, especially since the close of the civil war. So abundant is the Sumach, that there is no need of its cultivation. It is largely imported from Sicily, but there is no reason why our own growth should not be used with the same results, the more so as the American Sumach contains 15 to 20 per cent. more tannin than Sicilian.

The necessary buildings, machinery, and appurtenances for preparing annually 400 tons would cost, perhaps, £2000. The following directions for gathering will be found to embrace all the essentials necessary. Sumach should not be gathered before the leaf is properly matured, which is generally about the middle of July, from which time it may be gathered till the first frost. It may be wilted in the sun, but must be cured under cover, and not allowed to be burnt by the sun or to get wet, or to be placed in such large quantities as to heat in curing, either of which destroys its strength and colour, and renders it worthless. It is better to cure it upon an open floor in order to let the air pass underneath. It should be gathered four weeks before it is ready for market, as not only the leaf must be perfectly dry, but the stem also. All the sap must be dried out, and it should never be delivered in damp weather, as it naturally draws the dampness of the atmosphere, and cannot be repacked till thoroughly dried out. The leaves must be of the same bright green colour when cured as when taken from the bush and must not be dark or smell musty. If any other kind of leaves or sand or dirt are found among it, it will be injured as a commercial commodity. No portion of the stalk or any berries should be left in it. The leaf is what is wanted, but to facilitate the gathering, the little twigs upon which the leaves grow should be cut off, all of which will be marketable when cured according to the above directions. Stripping off the leaves is apt to kill the stalk; therefore, in order to ensure a better crop the next season, it is best to cut down the old stalk, and the roots will spring up better than ever.

A.

CULTURE OF OSIERS FOR PROFIT.

With a steady demand at fair prices Osiers for basket-making forms a very good speculation, and so long as baskets are made, there will ever be a demand. Good sorts, such as the Golden, Brown Spaniard, Sussex New Kind, and other favourite kinds of English growth will always realise a good price, and after paying rent, labour, and a share of the cost of laying down, there remains a very fair profit on all suitable land. Say the first cost of laying down is £30, and the beds only to last ten years—as a matter of fact they last from fifteen to thirty years—and the cost of rent and labour is another £6 per year, or say a total of £10 per year for ten years, it must be a very poor crop, indeed, that will not give a net profit of £10 per year. Even if only eighty bolts per acre are produced, these at 5s. per bolt would produce £20, and I have known this quantity obtained off half an acre. At the same time it must be borne in mind that only good kinds must be grown, and these must be kinds that are well known in the basket-making trade, and the rods should be sorted into at least three sizes, small, middle, and great. Rods that are crooked in growth, or brittle, or what are termed "buz" topped, *i.e.*, bushy, are not those which produce good prices, and therefore the aim should be to have the very best that can be produced. It is useless to grow a quality of rod that is so brittle that it snaps off every time the basket maker bends it, as such stuff will not pay because the market is flooded with it, and it can be had at almost any price; neither do unsorted rods pay, because plenty of that class of produce can be had from abroad, where both land and labour is much cheaper than in England. To get the best return, the best materials only should be produced, and these, of course, require some care in both cultivation and selection. To grow brittle stuff for the charcoal-makers—Willow charcoal is used in the manufacture of gunpowder—is also a poor speculation, as the price to be obtained for rods of five or six years' growth is very small, and more particularly so if it has to be carted for any great distance, as this has to be taken into consideration by the purchaser, who naturally gives less for material which carries a deal of subsidiary expenses than for that which is free from them.

Preparation of the Soil.

This is of great importance in this work, and unless it is done well profit will be out of the question. The first thing necessary is to trench the soil to a depth of about 18 inches, removing all Couch Grass, Docks, Dandelions, and similar destructive weeds. Care should also be taken to remove every piece of wild Convolvulus, commonly called Bindweed, as this

causes a great deal of trouble where present. After the whole of the ground is trenched, it should be well harrowed over, and a crop of Potatoes, Cabbage, or other summer plant should be taken where possible. I prefer Potatoes, as the ground can be cleaned of Couch Grass, Bindweed, &c., during the time the Potatoes are growing, and if the whole of the ground is forked over when digging the Potatoes it will be ready for the sets. To have a good start the soil should be in a sweet and sound condition, and as a rule this is best done by taking off a crop before planting with Osiers. On land where this cannot be done, it should be broken to the full depth, and if possible be kept clean for a year, or it may be planted at once, but for a really good start nothing beats getting the ground into good tilth. In many places it is the custom to trench and plant as the work proceeds, and in most cases this is a matter of good policy owing to the state of the soil, as where it is very wet it would get very much consolidated if it was much trampled on, and as planting should be done between the end of October and the end of March, unless the season is very backward, the state of the soil is a matter of serious moment. The wetter the soil, the later should the planting be done, and on eyots on rivers subject to floods the trenching should be put off till rather late, so that the washing away of the earth may be prevented.

Sets or cuttings should be from 15 inches to 18 inches long, and should be made from well ripened rods of one year's growth, the straightest and best being selected for the purpose. The 18 inches or so at the top of the rod is rarely of use for planting and should be cast aside, and in making the rest into cuttings care should be taken that there are three or four prominent buds on the top end if possible, as such cuttings make the best growth. The sets should always be made from from what are technically termed "great," or "small great," rods, and should be straight if such can possibly be managed.

Planting.

The sets should be planted at the depth of a foot or more, according to their length, leaving about 3 inches or 4 inches above the surface of the soil, which will form the stools from which the rods grow in future years. For the greatest convenience in the after cultivation of the ground, the cuttings should be planted in straight rows, and if these can be arranged to run from north to south so much the better, as then each side of the stool will produce rods of equal quality. The rows should be from 2 feet to 3 feet asunder according to the soil, as on very rich loams less distance is needed than on poor sandy soils of a hungry nature, but as a general rule 30 inches is a good distance generally. The sets should be from 15 inches to 18 inches apart in the rows, for the same reason, as on rich soils, if too wide apart, the rods will be too large and bushy, while if too close together on poor soils, they will be too small to be of much market value. The number of sets required to plant an acre of ground varies from 20,000 to 24,000, and the price varies from 10s. to 12s. per thousand. The sorts which the basket-maker technically terms "trustworthy" are those to be chosen for profitable cultivation, and where good tough sorts are locally grown, the sets can be had from the local growers. A good basket-rod is one that will work without breaking, and which will, when green, twist from end to end without snapping off. Good kinds are the Golden, Brown Spaniard, White Osier, Plum, Long-skinned, and Sussex New Kind, as they are called by basket-makers, and for these when sorted there is always a ready sale. Where the Golden grows well it is very profitable, as the small rods, which are of but little value in other kinds, are largely used by market gardeners for bunching purposes. By using the sets from the best sorts, the most profitable results are to be obtained; indeed, a judicious selection of novelties is one of the first considerations in Osier growing.

After Cultivation.

This consists chiefly in keeping the rods and ground clean, and to do this both hoeing and hand weeding will have to be done, and particularly where Bindweed is in the soil. For the first year, when but little growth is made by the sets, keeping the surface well hoed to destroy annual weeds is of great importance, as there is then great facility for the work, and if hoed over with ordinary turnip hoes half a dozen times, the expense will not be lost, for the simple reason that by preventing the weeds from seeding, future crops will be greatly diminished, if not quite prevented. Hand weeding around the sets must be persisted in where Bindweed or other climbing weeds exist, as these spoil the rods when allowed to run up them, besides causing a deal of extra trouble and expense in cleaning the rods for sale. After the first year, the Osier grounds should be hoed over twice or thrice with proper eyot or bean hoes, before the young growth gets so forward as to render the use of the hoe injurious, and all climbing weeds should be broken off each time of hoeing. During June and July they should be broken off several times by hand, but it is not often safe to get about amongst the young growth after July, as the tops of the shoots would be broken about greatly by doing so, and the crop much lessened in value thereby. Where profit is the end in view, the slovenly and unwise practice of planting on Grass land without cleaning and trenching should never on any account be adopted, for Osier grounds should always be kept clean, otherwise the result will be disastrous in a very short time, and instead of the plantation lasting for a period of from fifteen to thirty years, it will not survive in profitable condition above five or six years, and even then the produce will not be of first-class quality. Like all other crops, Osiers require care and attention, and although periodical digging is not necessary, yet hoeing and weeding is, and should never be neglected.

Cutting the Rods.

This is an operation which must be carried out while the plants are thoroughly dormant, but not during frost, or the cut parts will die back. This work is best done with a proper rod hook —a kind of miniature sickle—and it must be kept sharp. The first cutting after the sets are put in needs to be done in an intelligent manner, and while cutting closely, just enough buds should be left to form a good stool, say a couple on the base of each rod, or what, perhaps, is better, the rods should be cut to within three-quarters of an inch of the old wood. This leaves a good growth the next year, when the rods should be cut in close, because stout long rods pay best, and these cannot be got if too many shoots are started from a stool; and while at all times a number of small rods must be expected, it is desirable that a good percentage of large rods be produced. Cutting is done by piecework at so much per score bolts, and some supervision is generally needed to ensure that proper work is done. Rods which are to be whitened should be left until as late as possible, and although such a practice rather injures the next year's crop, they may be left until the buds begin to swell. After cutting the rods which are to remain in their original state, they should be placed on faggots, leaning against rails, the bands having previously been loosened, and here they should remain until thoroughly dry. When dry they should be sorted into either three or four sizes, and either stacked or sold, as is most convenient. If stacked while green or wet the rods will get "mow burnt," or heated, which renders them brittle, a state which makes them useless for any purpose, and causes a dead loss. White rods are not cut until late, and are then loosely tied together and placed in pits containing about 6 inches in depth of water until the bark will slip off well, when they are drawn through a brake and hand-cleaned, washing in running water to clean off any stain. They are then laid on hurdles or rough frames to dry, and sorted and tied in bolts. White rods fetch about double the price of brown ones, but they do not yield a greater profit to the acre when a series of years are taken into consideration.

Bolting.

This operation is done by taking a number of rods and laying them on twisted Osiers, keeping the butts all one way and level, then drawing them tightly together with a rope and two levers, fastening off the withes while the rods are held by the rope, only wresting the butts. Great care, however, must be taken not to pull the rope tight enough to break or cripple the rods, and the rope should pass round just under the bottom band, which should be 14 inches from the end of the butts. A bolt of rods English measure, if unsorted, should be 42 inches, and if sorted, 40 inches round the bottom band, both brown and white being the same measure. For sorting and bolting it is desirable to have someone for a day or two to instruct the men employed, as "an ounce of practice is worth a pound of theory" in this part of the business, and although simple enough to those who know how, both sorting and bolting is difficult at first to those who do not understand the matter. W. J. M.

NATIONAL FOREST SCHOOL IN IRELAND.

In an able article in the *Irish Farm*, Mr. Dick, of Phœnix Park, strongly advocates the establishment of a school of forestry in Ireland. In the course of his article, he says :—

Ireland can clearly furnish the most eligible site for a national forest school. There is not a site in England or Scotland to compare with that we have already indicated, and if a section of upland country is desirable it will be found adjoining in Westmeath. It is already acknowledged to be a national want. We are behind France, Germany, and even Russia in this respect. Such a national undertaking would be remunerative in the best sense. It would pioneer the permanent reafforestation of the country, thereby ultimately introducing industries dependent on a supply of timber; the reclamation of bog lands would progress piecemeal on which there is an inexhaustable accumulation of nourishment for the growth of timber, a forest school would be the exponent of this capability. It is marvellous that no government ever bethought itself to undertake the reclamation of the bogs of Ireland as a national scheme of improvement, or as an investment of capital, or as a matter of expediency for the utilisation of the vast army of the unemployed in the country. Russia is at this moment reclaiming a bog much larger than all Ireland at an enormous cost in money and engineering skill under circumstances infinitely more formidable than would be the case in the instance of any single acre in Ireland. There is vastly more hope of a satisfactory return for the outlay in the temperate climate of Ireland than in the alternate torrid and frigid climate of Pinsk.

Gates in plantations.—Probably through some fault in my writing on the subject, I am made to say (p. 86) that where there is a public footway through a wood or plantation, gates should always be used. It is obvious, from what is stated further on, that this is just the reverse of what I intended, as in such places when possible they should be avoided. For private entrances or private paths I should certainly recommend gates, which may be unlocked when the necessity arises.—D. J. Y.

No. 768. SATURDAY, Aug. 7, 1886. Vol. XXX.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FERNS.

TASSELLED AND CRESTED FERNS.

NOTWITHSTANDING the statement made by "G." in THE GARDEN (p. 85), we have no good reason to think that British Ferns are more prone to become tasselled and crested than exotic species. I was years ago familiar with the Fern flora of extensive tracts in North Britain, and since then I have collected in the United States and extensively in Jamaica, and I am enabled to state that I found abnormal forms more common in the Tropics than elsewhere. Both at home and abroad I found "forked fronds, tasselled fronds, depauperated fronds, miniature fronds, and gigantic fronds" of certain species; but in the Tropics at least they were not considered representative, and therefore, as a rule, received only a passing glance. It was perhaps wrong to so treat these abnormalities; but it must be said by way of excuse that, with regard to them, botanists and plant collectors have a very bad example set them by Dame Nature herself. We are amazed at her productiveness as regard such forms, as well as her seeming want of maternal interest in their welfare, for the majority of them speedily "go to the wall." I am, however, acquainted with a few favoured exceptions which are severally colonised and spreading from their centres of origin. A form of Blechnum occidentale with the terminal pinnæ repeatedly forked, forming a crest, grows on a bank near to the Government Cinchona plantation in Jamaica. There are, or were two years ago, many plants of it. A variety of Asplenium cultrifolium, the terminal pinnæ of which are pinnatifid, is met with in rather extensive colonies in the same island. In Wisconsin, U.S., about twenty-five miles north of the capital and near the river of that name, I discovered, two years ago, an extensive colony of Cystopteris bulbifera, characterised by having all the pinnæ of the fronds terminally tasselled. I have before me a frond of Nephrolepis exaltata, collected in Jamaica by a friend, which is remarkable in being distinctly bipinnate, but in a peculiar manner. The pinnæ are simple or sub-entire, as in the type, for from 1 inch to 2 inches from the rachis, when by degrees they become compound or bipinnate, extending from 2 inches to 4 inches on either side of the rachis. The pinnules are from six lines to eight lines long. I may here remark that the fronds of the Jamaica Nephrolepis, especially those of N. exaltata, have what may be called a biannual growth or extension of the rachis. In the abnormal specimen before me the second growth referred to seems to have departed from the usual vertical direction and followed a lateral or horizontal course, appearing in an excess of vegetative vigour at the extremities of the pinnæ. My friend who discovered this variety informed me that there was quite a large clump of it. I also discovered in Jamaica a remarkable plant of the large and handsome Hemitelia horrida, the long segments of which formed crosses in a more or less regular manner on the rachis and costa, somewhat in the way of Athyrium Filix-fœmina vars. Fieldiæ and Victoriæ. It will doubtless interest "G." to know that the Ferns of the East Indies are not less sportive than those of the West and of Britain. In the preface to "The Ferns of Derbyshire," the editor—who made Fern abnormities a special study—gives the following quotation from a letter upon the "Flora of the East Indies," by the Rev. John Barton: "Some of the wild Ferns of Indian hill ranges vary exceedingly, quite as much as the female Fern or the Hart's-tongue at home. Some species of Microlepia, for example, Lastrea Filix-mas, and another species akin to L. dilatata and spinulosa exhibit all manner of varieties. I noticed that in damp warm spots there was a tendency to such irregularities of form, and I imagine this would be the case all over the world." GEO. SYME.

FRUIT GARDEN.

IMPORTING AMERICAN APPLES.

THE following letter addressed by Messrs. J. W. Draper & Son, of Covent Garden, to exporters of American Apples may prove interesting to our readers, and we have to thank Messrs. Draper for a copy of it: "This year may be regarded as the commencement of a new era in the import trade. The exhibitions that now take place annually in London have done much to foster competition between this country and America, but the latest, and perhaps the most successful, of the series—the Indian and Colonial—has given the greatest prominence to matters horticultural. The British colonies are well represented in every department, but in none more so than in the fruit trade. Hitherto the Orange growers of Florida and the Brazils have year by year endeavoured to obtain a footing alongside the Valencia, St. Michael, and other European shippers; but to-day they find fresh competitors from Natal, the Cape, and Australia—the latter we consider likely to be anything but an insignificant rival. In addition to tropical fruits, such as Bananas, Mangoes, &c., there is also every prospect of regular shipments of Grapes and Apples from the Antipodes. 'Will this,' ask some, 'affect the American Apple trade?' We answer, Not in the slightest degree. America enjoys indisputably the reputation of being the best Apple-producing country; for quality, variety and weight she stands unequalled, and, whatever may be on the market, American Apples can always command a sale.

"It has been our custom to issue periodically tabular reports regarding the Apple crops in England, France, Germany, Belgium, Holland, &c., in order that our consignors might in some degree be guided as to the prospects for shipments from the United States and Canada. This season offers fairer inducements to extended operations than perhaps any of its predecessors, as the crops in England, France, Germany, and in the Low Countries are unusually light; while those grown in Italy, Spain, and Portugal do not influence the market, their quality being altogether of an inferior character. American shippers, therefore, need not hesitate to export largely; they have the field to themselves, and, provided the fruit reaches its destination in sound condition, there can be no doubt of a fair result. Of course, in these days of keen competition much depends on the style of packing, uniformity of quality, &c., and for this reason, we think it well to repeat our old instructions concerning these matters, feeling convinced that too much attention cannot be given to them.

"KINDS.—Best sorts, such as Newtowns, Baldwins, Russets, &c., are always in demand, and if properly selected and well put up, will almost invariably meet with a good market. Each cask should have legibly stencilled thereon the name of the Apple, thus, 'Newtown,' 'Northern Spy,' &c.; this saves much trouble on arrival, and facilitates the handling of the goods at our auction sales.

"BRANDING.—One mark should be adopted and adhered to, as by this means a reputation is established. Buyers know in time whether or not they can depend upon the packer, and will purchase or reject according to the position such and such a shipper holds in their estimation. It is for this reason greatly to a packer's interest to deal fairly, and so win the confidence of the purchaser. Once fairly known, his brand will be eagerly sought after.

"PACKING.—Apples should be packed tightly, so as to prevent damage from oscillation in transit. Casks should be filled from the bottom, so that when the head is opened a flat surface is presented. The fruit should also be evenly sorted and uniform in size and quality throughout—as fine at the bottom and middle as on the top. The following remarks, made by a New York house on this point some two seasons ago, are pithy and well worth attention: 'In regard to packing, there is much room for improvement, and faults in this respect are not entirely confined to State packers. A large part of the receipts, especially during the last two seasons, have been "stuffed," the middle of the barrels containing inferior, trashy fruits, topped off with a few layers of good Apples. Buyers soon find this out, and the poor Apples bring no more than they are worth. The stock should be closely graded, the primes and seconds being packed separately and plainly marked. Only one variety should be packed in a barrel, and the kind and grade neatly stencilled on the head. The top layer should show, on opening the barrel, a fair average of the quality throughout the package. Brands packed in this manner will very soon acquire a reputation which will amply repay packers for their care and honesty.'

"ROUTE.—This is a question of the utmost importance, and although a London house, we must say that the Liverpool route is by far the best. Shipments made from New York, Boston, Philadelphia, Montreal, or any other ports to Liverpool at a through rate to London reach us in a minimum of time, and therefore in better condition than would otherwise be the case, while the direct London route is subject to delay, and an additional objection presents itself in the shape of heavy wharf and lighterage expenses; indeed, so great is the difference in these respects, that while 3d. per cask may be fairly reckoned as covering all extras (excepting, of course, cost of cablegrams and auctioneers' commission) beyond the original charge for freight and primage for goods *viâ* Liverpool, the London dock and wharf expenses, with cartage, &c., amount to something like 10d. a cask.

"As a rule the late shipments, more especially if the Apples are of a keeping character, are the most profitable. The demand for the earlier sorts is not so steady; prices fluctuate considerably, and the tone of the market is often capricious; yet, as the European crop this year is a comparatively light one, we think first shipments from the States and Canada will meet with good results."

Apple-tree caterpillars.—During early summer many gardens in Kensington were infested with swarms of small, black or very dark-coloured caterpillars, which cleared every atom of green off the Apple trees, often leaving skeletons of leaves standing; they never touched other foliage, even when mingled with that of the Apple. After some time they spun long threads, of unusual strength and thickness, on which they clustered and swung, sometimes dropping to the ground. Finally, they enveloped the stems and larger branches with web, under which, especially in the crannies, the cocoons lay like grains of rice. The moth is small and white, with minute black spots. Can you tell me its name?—M.

*** The caterpillars which infested your Apple tree are those of the small ermine moth (Hyponomeuta padellus), a very common insect, but it seems to have been unusually abundant this year. The best thing you can do now is to cut or pull the webs containing the cocoons out of the trees, and to burn or bury them. This should be done at once, or the moths will be leaving the cocoons. Next year if the tree is again attacked, shaking the branches will cause many of the caterpillars to fall to the ground

which should be previously spread with quicklime, or they may be killed with the back of a spade. Any which remain suspended in the air may be caught with a birch broom or a bunch of thorny twigs fastened to a long stick.—G. S. S.

GOOD STRAWBERRIES.

In order to secure good and regular crops of Strawberries we adopt the following practice, which has for a number of years proved entirely satisfactory. The soil of the kitchen gardens here is of a heavy retentive character, and if worked when wet it sets about as hard as sun-dried bricks. Land intended to be cropped with Strawberries is in the previous autumn deeply trenched, and cast into ridges 2 feet wide. It is liberally manured, and as the work proceeds a little fresh soil is brought to the surface. When trenching is completed the land is allowed to remain undisturbed until spring, when it is cropped with early Peas, for which, owing to the effects of exposure to frost and rain, it is in good condition. After the Pea crop is finished the haulm and stakes are cleared off; the land is then made ready—by means of levelling, hoeing, and raking—to receive the Strawberries, which are planted from 2 feet 6 inches to 3 feet apart, according to the variety. If the ground is dry it should be well watered, and a mulching of manure applied to it in order to retain moisture. Where it is not convenient nor desirable to sow Peas or early Potatoes for the preceding crop, French Beans may be substituted, and by exercising a little forethought in arranging the distances at which the rows should be sown, they do not interfere much with the growth of the Strawberry plants. The ground is frequently gone over, and all runners not required are removed, and also weeds, either by hand-weeding or by hoeing; but with this exception the ground is not disturbed from the time when the Strawberries are planted until they are chipped off after the third year. Each autumn a dressing of good manure is applied, and in spring a covering of manure as it comes from the stables with the droppings shaken out of it is put on sufficiently early to allow of its becoming thoroughly cleansed before it is needed to prevent the fruit from coming in contact with the earth and decaying manure. For outdoor plantations we layer the runners either in small pots or on pieces of loam, and a stone is placed on each which serves the twofold purpose of securing the plant and retaining moisture for its sustenance. We consider that the extra labour involved by this method is counterbalanced by the increased yield of fruit the first year. We take all runners required off the young plants that produce flowers and fruit, and destroy any that do not flower. Rather than grow many varieties, some of which might be worthless, we prefer to trust to a few sorts of proved merit and suitability to the character of the soil and atmosphere. They are Black Prince, of which we still grow a few on a warm border to succeed the latest batch of plants in pots. The fruit of this variety is small, and the plants are very liable to mildew; therefore, if it was not for its early ripening we should discard it altogether. Vicomtesse Héricart de Thury is eight or ten days later than the preceding; it invariably bears a heavy crop of medium sized fruit of good colour and fine flavour. If I were limited to one variety for all purposes, this is the one that I would grow in preference to all others. Is there any difference between Vicomtesse Héricart de Thury and Stirling Castle? I am told they are one and the same variety; if so, I should much prefer the latter name. President is a good and regular bearer, and the fruit, which is large and handsome, is fine both in flavour and colour. Sir Joseph Paxton is a free bearer, coming into use a few days later; its fruit is large, firm, and finely flavoured. Elton Pine is our latest variety; it is a good cropper, and the fruit large and of good colour and flavour.

A considerable portion of the land in this neighbourhood under Strawberry cultivation for market purposes is reclaimed Moss land, and on this the crop this year is a partial failure, the yield being about half the usual quantity. On the higher ground, which is of a heavy loamy character, the crop is quite up to the average. In both cases there were considerable numbers of plants which failed to flower. Owing to scarcity of rain during the swelling period, the fruit is smaller than usual, but that is compensated for by its enhanced flavour and colour. Bostock is universally grown by market gardeners in this district, as is also Myatt's Prolific, a coarse-looking variety which does not ripen well up to the point. These two varieties are grown in great quantities, the former for preserving, and the latter for dessert. Their chief merits are fruitfulness and firmness of flesh; consequently they do not suffer so much injury from carriage as do softer sorts. Sir Joseph Paxton and Elton Pine are also extensively grown for dessert.—W. Neild, *Wythenshawe, Cheshire.*

—— I have been much interested in this discussion. The remarks of Mr. Douglas (p. 597) are especially noteworthy, and coincide exactly with my own ideas and experience thereto. Of late I have not had much to do with Strawberries, for dwellers in London or the suburbs have in very few cases sufficient space to attempt the culture of this delicious fruit, and are obliged to content themselves with a few plants in pots. But years ago, when living in the country (Worcestershire), we used to grow Strawberries in considerable quantities and with great success. Our favourite varieties were exactly those mentioned by Mr. Douglas as those he would prefer to any others, viz., British Queen, Keen's Seedling, and Black Prince, the first being admired for its size and delicious flavour, the second for its productiveness, and the third for its earliness, free-bearing qualities, and also on account of the rich sweetness of its fruit. As regards the much-abused British Queen, we never had any particular trouble with it, and, beyond its being not quite so good a cropper as Keen's Seedling, we had no fault to find with it. The first place in which I remember it was a garden sloping southwards, of which the soil was a poor and very stony loam on gravel; very little manure was used, but all of the three varieties I have mentioned flourished wonderfully. Fresh beds were made every third year, beyond which we found the old plants did not pay for their room and trouble. A good-sized bed of Black Prince was a grand success; I have never seen since such a crop as that afforded us. Though not large, this is a grand Strawberry, and not half enough cultivated. The next place had a good sound loam on a clay subsoil, and here the fruit did better still, and we had very heavy crops. Another garden, only a few miles away, consisted of a rich loam on a clayey subsoil. This was far away from any town, and here both the Queen and Keen's Seedling literally grew wild. The beds often stood for five or six years, no manure was ever used, and the plants were sometimes allowed to become a mass of runners, yet they bore profusely most delicious fruit year after year. One point we found very important, which was to make and keep the beds as hard as possible. They were never forked up, and I remember that, as boys, we were encouraged to run over the beds as much as we liked, so long as we did not eat all the fruit. All that was ever put on the beds was a layer of fresh clean tan just before fruiting time, to keep the berries clean, and this was cleared off soon after the crop was gathered. Some gardeners about us used to complain that they could not grow Strawberries; but in every case it was pretty plain that they either did not care to succeed, or else coddled their plants too much. Some of the finest Strawberry grounds in Kent consist of comparatively poor and very stony loam, sometimes sandy, and often of a coarse marly character, and in some places this lies on the chalk—such material as no private gardener would think of planting Strawberries in: yet most profitable crops are obtained from it, and by rough-and-ready methods too. I believe that a great mistake is often made in overmanuring Strawberries. A moderate quantity should, of course, be worked in when forming fresh beds, particularly if the soil is naturally poor, or has been exhausted by previous over-cropping; but where the plants can be put out in a good sound maiden or other loam of moderate richness a very small quantity of manure, and this of a well decayed or sweetened character, will be sufficient, and indeed better than a heavy dressing. The Strawberry is naturally a strong-rooting plant, and when in a healthy growing state is sure to possess itself of whatever nourishment the soil may happen to contain.—B. C. R.

MARKET GARDEN FRUITS.

Whilst some growers of Apples think it is useless to grow many kinds, and consequently rely upon just a few for their crops, there is always the chance that they may now and then get blank seasons, and when such is the case considerable loss as well as much inconvenience results. Now this year generally we have a very light Apple crop. It is only here and there there is much fruit, and kinds grown largely are as thin as the rest. The chief exception is Lord Suffield, but even this is generally thin. I grow but just a tree or two of many kinds, and as a result seem always to have a few fruits in bad seasons and a fair crop in good ones. Thus this year that steadfast old kind, Waltham Abbey Seedling, in my mind the most constant bearing Apple we have, has a good crop, and the fruits will be of good size. The tree, which is large enough to carry a good crop of some six or seven bushels, has during the past ten years never been without some, more or less. I class it as the cottager's Apple *par excellence*, as it is not only such a free and constant fruiter, but the Apples are excellent cookers and keep well. Then Lord Suffield is fruiting well with me, so also are Kentish Filbasket, Tower of Glamis (these two yield good crops), Alfriston also very fair and Margil a good crop. Many other kinds, such as Golden Noble, Warner's King, Late Winter Pearmain, Stamford Pippin, &c., have a sprinkling. All the trees are on free stocks. Thus it is useful to have some kinds that are not commonly grown, especially in a year when Apples generally are scarce. Turning to Pears, all of which are on free stocks with one exception, I have a heavy crop of Swan's Egg, not a first-rate Pear by any means, but better than none. Nouveau Poiteau, a really fine and melting Pear and one of the handsomest and best of natural standards on the free stock is fruiting well; so also is Huyshe's Victoria and that free grower, Beurré d'Amanlis. Alexandre Lambre, almost broke down last year with fruit, is still carrying a nice lot, and is one of the very best kinds we have for bush trees. Winter Bergamot is also fruiting very well. Williams' Bon Chrétien has a thin crop. For the first time after a lapse of some ten years I am getting such a heavy crop upon bush Marie Louise double worked on Quince stocks, that I am compelled to give support to all the branches. Whether due to soil or other cause I cannot say, but with me double-worked Marie Louise has always proved far too robust, making growth equal to what is made by trees on free stocks. It is odd to find so much strength on Quince stocks in a variety never too robust, because on each Quince stock there are some 6 inches of stem of a rank-growing kind for the sap to pass through. Promising as this crop is, I dread the autumn days when the tomtits will play havoc with the stem ends of the Pears. Farleigh Prolific Damson on standard trees in open fields is a tremendous crop, the trees being literally torn to pieces already with the great weight of fruit.

Bedfont. A. D.

American Strawberry culture.—According to a daily paper, Strawberry culture is extending in Ohio, where it appears to be very successful. Before planting, two crops that can be hoed so as to exterminate weeds are grown, and then 100 to 160 loads of good farmyard manure are ploughed in. The plants are grown upon ridges, and they are allowed to remain till they are injured by the white grub, the only enemy of the Strawberry that does much damage in Ohio. From 100 to 140 bushels per acre of Strawberries are produced, and they are sent to Chicago for sale. Pickers are paid at the rate of 2s. a bushel, and at this price they earn from 4s. to 12s. a day.

Early Gooseberries.—Will any of the readers of The Garden who do not look with lofty contempt on this best of British fruits kindly tell me the names of the best early kinds, and about how much they are earlier than the commonly grown sorts—if they have taken notice of the difference?—J. J.

KITCHEN GARDEN.

BROAD BEANS.

All of the Longpod, as well as Windsor Beans are ordinarily termed Broad Beans; hence it is generally understood that in employing the above appellation the whole of the family, from the dwarf Fan Cluster to the huge podded Leviathan, is alluded to. The pods of the former are perhaps 3 inches in length; those of the latter sometimes reach 18 inches. During the present summer I have been enjoying a small trial of Broad Beans, not of varieties of my own selection, but kinds sent me from various sources. I have them on some rather stiff clay, which suits Beans well, but this season, as on most soils, they have suffered somewhat from heat and drought. In spite of this drawback, however, I have never seen Broad Beans so clean and free from black dolphin as they are this season, whilst growth generally has been good. The drought seems to have appreciably affected the setting of the bloom, and the resulting crop is thinner than is desirable, and the pods are hardly so large as would have been the case had we had more rain. Still, a very reliable test has been obtained as to the relative merits of each sort. First as to the Broad Windsors, I have Harlington Windser, which is one of the best, Carter's Improved Windsor and Taylor's Windsor. The first two seem to be practically identical and are both first-rate strains, but the production of three-seeded pods is not at all regular in either case; something is, however, due to the season; hence it is not fair to assume that a lack of the three-seeded pods is the average characteristic of the strains. Taylor's Windsor is less prolific, and the pods are not so large. The Windsors have a marked stiffness of stem, and it would be well if all other kinds had the same property. The Seville, Aquadulce, or Leviathan is just as wanting in stem-rigidity as the other has it in abundance, for when the pods get large the plants fall in all directions. I had some stocks of own saved Seville, also some from Messrs. Carter, and also some of their Leviathan. Just a little this latter seemed the best strain, but it yields no finer pods than their own Seville stock, which does not differ from mine or Leviathan. Generally the finest pods are found singly or in pairs on stems, no one plant producing many of these. In all cases, however, some plants produce shorter pods in greater profusion. These furnish capital household Beans, and early. Probably it is the rule to select all the largest pods and dub them Leviathan or Giant, whilst the smaller pods make up the ordinary Seville stock. No doubt one of the best tests of the relative productiveness of Beans is the seed produce after it is ripe. A capital strain is Carter's Selected Mammoth Longpod, but I take it to be a good form of Johnson's Wonderful, or as sometimes known as Mackie's Monarch. It is a prolific and fairly stout kind, the pods of good length and full. It is much better than the Dutch Longpod, which is the ordinary Longpod of commerce. Last year I selected from the Seville a distinct looking, stiff, erect-growing plant, which bore Beans of a broader and more abrupt-ended form than that kind usually produces. The produce this year is found to be stouter plants than those of the Seville and a better crop of Beans, which seem to come, as it were, almost intermediate between the Windsor and Mammoth Longpod. I think it is a genuine seed sport from the Seville, but hope to give it a wider trial next year. A. D.

Tomatoes at Harefield Grove.—This year there are 28,000 Tomato plants growing at Harefield Grove. The largest house devoted to their culture is 700 feet in length and 18 feet in width. They are planted out in rows the whole length of the house, about 18 inches being between each row, and the growths are tied to slim twine fences put up for their support. The house in question, as I saw it a fortnight or so ago, was a grand sight. Large fruits are not the aim, but multitudes of medium-sized fruits were freely produced. King Humbert is the principal variety grown; it is oval in form, medium in size, deep red, and clustered. Harefield Golden Gem is another one extensively grown here; it is bright yellow in colour, very smooth, from half a pound to one pound in weight, a very heavy cropper, and of first-rate quality. It is a hybrid raised at Harefield, and when better known cannot fail to be a favourite. The whole of the Tomato plants are growing in moderately rich soil well mulched, and in training they are restricted to one or two stems. The points are frequently pinched off the leading shoots; the plants are never allowed to bear a heavy crop of leaves, treatment which is certainly the means of producing most satisfactory crops of fruit.—J. Muir, *Margam*.

LATE TURNIPS.

From this date to the middle of August is a good time to sow late Turnips. They make a useful crop to succeed early Potatoes without much expense as regards preparation. If the ground be made level with the rake, the drills may be drawn and the seeds sown immediately, and after the recent rains the seeds will find a moist bed and germinate quickly. In a dry time I always soak the drills with water, using liquid manure when it is plentiful. This may not be necessary on all soils, but a little encouragement in the beginning, either in the shape of liquid manure, a sprinkling of superphosphate, or some other artificial, enables the plant to rush through its difficulties and makes a crop certain. This crop will be expected to stand through the autumn, and be used after Christmas and onwards till March and later; and the plants should be thinned out well, to ensure a dwarf, hardy habit. If the plants are left thickly on the ground, the leaf-stalks are drawn up weakly, and when the severe weather comes they form little or no protection. From 12 inches to 15 inches apart will not be too much space to allow each plant, and the leaf-stalks, being short and robust, lie close over the bulbs and protect them from a moderate frost. Of course, before very sharp weather sets in (and there are always some indications of its approach) the largest of the bulbs should be pulled up, and either potted or protected in some other way, but a very considerable number will still be left on the land. The best varieties for present sowing are Veitch's Red Globe, Orange Jelly, and Chirk Castle Black Stone. These are very hardy, and are less affected by the weather than most of the white-skinned kinds. E. Hobday.

Potatoes.—It is worthy of note that, although we have had much rain of late and unsettled weather, we have so far no evidence of disease in the Potato, although it is now a month later than the date at which this very destructive epidemic usually presents itself. Generally, the first early kinds are ripening off, all others are tubering rapidly, and growth of late kinds is vigorous and healthy. At present there is every probability that we shall have a heavy Potato crop; indeed, prices are already low, so rapidly is the market being supplied. In this extreme market-growing district, Beauty of Hebron has quite superseded the old Ashleaf and Early Rose for general cultivation. It gives a good turn out by the middle of July, and the ground thus rapidly cleared is at once filled with Coleworts or sown with white Turnips. It is worthy of remark that Beauty of Hebron on Middlesex soil is very dry and floury, and is much appreciated. A white Beauty of Hebron named Duke of Albany is, I find, rather earlier, as on a breadth growing beside the Beauty the haulm of the Duke is distinctly riper, whilst that of the other remains green. Probably, when better known, it will largely take the place of the pink-coated Beauty. Whilst the larger area for late kinds is still devoted to Magnum Bonum, Chancellor is becoming a popular kind, as it is a grand field Potato; and Prime Minister bids fair to take the place of the Regents, as it is such a heavy cropper. The comparative disappearance of the disease is a matter for congratulation, and it is to be hoped that if not quite extinct in this country, it may speedily be so.—A. D.

TOMATOES ON OPEN WALLS.

The present has thus far been a by no means favourable season for Tomatoes on open walls, for, with the exception of a short spell of warm sunshine in July, the weather has been dull and cold, so that such sun-loving plants as the Tomato have not advanced at anything like the pace they do when brilliant weather prevails; still, notwithstanding these drawbacks, many cultivators will doubtless secure good crops if favourable weather sets in. The most common error in regard to open-air Tomato culture is that of starting too late. The seed is not sown soon enough for the plants to mature a crop in the course of our short summers. The consequence is that when early frosts set in green fruits in various stages are all that will be obtained. The only way in which to get really good crops on open walls is to sow in March, pot off singly as soon as the young plants are fit to handle, and grow them on in a warm house or pit, keeping them as near the glass as possible. As soon as they are well established in 4-inch pots give them plenty of air, and by the end of April or early in May they may with safety be planted at the foot of a sunny wall, to which the shoots should be kept securely fastened. Cut away all side growths, and as soon as sufficient fruit is set for a crop stop the growing point and keep all superfluous growths stopped in close. If the weather is dry, water freely, and give them occasionally either manure water or guano. In short, keep the roots moist and the tops dry, and plenty of well-ripened Tomatoes will be the result. Those that fail to ripen we take up, stems and all, trim off the foliage, and hang them up in a warm house where they never fail to ripen. J. G. H.

NOTES OF THE WEEK.

Oncidium Lanceanum.—Mr. Law-Schofield, of New Hall Hey, Rawtenstall, sends us a flower of a very brightly coloured form of this beautiful old Orchid. One of his plants, he says, is carrying two spikes, one with eleven and the other with eight flowers.

Lilium auratum.—As illustrating the unusual vigour of Lilium auratum this season in Mr. G. F. Wilson's wood garden at Weybridge, he has sent us a grand specimen between 6 feet and 7 feet in height, and clothed with leaves over a foot long and 1½ inches broad. The flowers, too, of which there are seven on one stem, are unusually large and fine.

Pelargonium ardens.—No other Pelargonium equals this in colour—a maroon-crimson flushed with scarlet; but the flowers are small and not produced in large clusters. If hybridists could only produce a variety with the colour of P. ardens and with larger flowers, they would be well repaid. Some finely-bloomed plants of this Pelargonium may be seen at the present time in the Cape house at Kew in company with a host of other beautiful species but little known in a general way.

Montbretia crocosmæflora.—This is one of the hybrids raised by M. Lemoine, of Nancy, between the old Tritonia (Crocosma) aurea and Montbretia Pottsi. The flowers are intermediate in size between those of the parents and of much the same colour as M. Pottsi, but perhaps a little brighter. It produces its flowers on tall branching spikes, which are showy at this season. The New Plant and Bulb Company send us some good specimens of it from their Colchester nursery, where it is a favourite.

A new plant label.—Samples of a new patent clip label for flower-pots have been submitted to us for opinion by Mr. H. W. Bennett, Chandos Street, Strand. They are made of strips of zinc about half an inch in width, and are folded in such a way as to fit neatly over the rim of the pot, and hence are unobtrusive. There is sufficient spring in the folds of the metal to take a firm grip of the pot rim, but to prevent the label from being knocked off the two ends dip into the soil inside. The name of the plant is

written with indelible ink in the usual way. The chief merits of this new label seem to us to be its neatness, simplicity, cheapness and durability. Usually a plant label is so large and unsightly, that one cannot see the plant for the label. We could wish that the inventor had in some way so prepared the zinc that it would not coat itself with the white powdery blotches one so often sees on zinc labels; some kind of varnish may answer the purpose. These labels are made in two sizes to fit the different sizes of pots.

Ornithogalum thyrsoides.—A spike of this handsome bulb comes from Mr. Bartholomew, presumably cut from a plant in the open air. This species has tall spikes on which the flowers are borne in a crowded cluster at the top. Each bloom is as large as a shilling and white, except a faint tinge of greenish brown at the base. This species therefore differs a good deal from O. arabicum, which may be at once distinguished by the very dark centre.

Spigelia marilandica.—This showy perennial is not often seen; indeed, it may be called a little-known plant. It is now in bloom, and the flowers being crimson outside and yellow within, a mass of it is showy. The flowers are tubular, about 1½ inches long, produced in terminal clusters. The plant grows about a foot high, or even 18 inches in spots suitable for it, such as a moist and partially shaded peat border. We saw it the other day in the Coombe Wood Nursery, where it has been some time in bloom.

Acis autumnalis.—This delicate little bulbous plant, which is also called Leucojum autumnale, is so seldom sent to us, that we fear it is but little known. Mr. Kingsmill, of Eastcott, Pinner, has sent us some specimens of it during the week, which show what a lovely little plant it is. The stems are slender, about 6 inches high, of a ruddy tinge, and terminated by three small bell-like flowers drooping from slender stalks. The blossom is quite white except at the base, which is stained with claret colour. Mr. Kingsmill does not say under what conditions he grows it, but we fear it is not quite hardy, and moreover requires attention. It is a native of Spain and Portugal, and is also found in the Mediterranean islands.

Cyrtanthus Macowani.—This is a really beautiful bulbous plant, which was introduced from South Africa about fifteen years ago. It is the brightest coloured of all the species of Cyrtanthus yet introduced, the flowers being brilliant orange-scarlet. They are about 1½ in. long, much curved in a downward direction, and produced in clusters of about a dozen on stems a foot or so in height. It is indeed not a botanical curiosity, but a plant worth growing, and if grown in quantity would be valuable at this season for the greenhouse. Mr. Kingsmill sent us a flower-stem of it well furnished with finely developed flowers.

A pretty aquatic.—Mr. Bartholomew sends us flowers of Melanthium junceum, which he has grown successfully as a water plant, treatment which seems to suit it, as the specimen sent is finer than any we have before seen of this plant. It is, we believe, a native of the Cape; therefore, not quite hardy, though we have seen it grown out of doors protected during winter. It has tall Rush-like stems, out of which the flower-spike protrudes nearly at the top. The flowers resemble those of an Ixia in size and shape. They are pale mauve with a beautiful carmine-purple centre. It would be appreciated by those who are fond of interesting plants.

Flowers from Edge Hall.—I enclose flowers of the following plants: Chrysanthemum (Leucanthemum) maximum of De Candolle, a Pyrenean plant of great merit, for which the coarser C. latifolium (syn., lacustre), a native of Naples and Portugal, generally does duty in nurseries. Chrysogonum virginianum (Gray), a dwarf five-rayed N. America Composite, of neat habit and flowering the whole season. Polemonium cæruleum var. piliferum (see Bot. Reg., vol. xv., tab. 1303) This is generally sold in nurseries under the erroneous name of P. Richardsoni, a totally distinct plant (see Bot. Mag., tab. 2800). This was certificated by the floral committee of the Royal Horticultural Society under the name of Richardsoni. Flowers of the very variable Anthemis tinctoria, which produces the greatest mass of flower (a globe 4 feet high and wide) of any plant I have. Flowers of Papaver Hookeri, a plant producing even a greater variety of colour and form than the garden forms of P. Rhœas.—C. Wolley Dod.

Anthurium Andreanum.—It may be interesting to know that this plant stands well in a cool temperature during the summer months. We have had two plants of it in our flowering Orchid house all this summer. This has had no fire heat since the end of May, yet the plants have made growth and produced fresh flowers since that time. The leaves are not so strong as would be made in a stove, but they are quite healthy and the flowers are very brilliant. The fine colour and the length of time during which they will last in good condition make this and the old A. Scherzerianum of the greatest value in the summer decoration of plant houses.—W. Holah, *Rollcaf.*

From Colchester Dr. Wallace sends a gathering of some pretty bulbous plants, among them being Lapeyrousia corymbosa, with small violet-purple flowers, Babiana tubiflora, Ixia viridiflora and monodelpha, and the beautiful new Vallota magnifica, of which we wrote in high praise recently. As regards Iris juncea, sent to us lately, Dr. Wallace says: "We have no difficulty here with it on our light dry soils; planted in or out in winter, it never fails to flower and to produce three to four flowers on a spike. Sunshine and good drainage on a light soil will ensure flowering."

Double Balsams.—The flowering season in the case of Balsams is now at its height, and several samples of good "strains" have reached us from different growers, those from Messrs. Carter, High Holborn, and Mr. R. Dean, Ealing, being the finest. If the flowers sent are fair samples of the strain, it is an uncommonly good one, for the blooms are almost as large and quite as double as those of Camellias and well varied in colour. There are snow-whites, delicate roses, purples and crimsons, while some are curiously flaked and spotted. There are few showier greenhouse plants at this season than well-grown double Balsams.

A hardy Gladiolus.—We have received from the Rev. J. G. Flint, of Bellingham, Northumberland, some flower-spikes of a very beautiful Gladiolus which seems to us to be identical with that named insignis, one of the ramosus section. Judging from what Mr. Flint says in his letter, this must be quite a hardy plant, even so far north as Northumberland. He says, "To my knowledge it has been grown for the last thirty years in the open ground in the counties of Durham and Northumberland without being lifted in the autumn, and without any protection in winter; therefore it must be perfectly hardy. At Ushaw College, Durham, where I got it from, tufts of it in strong clay soil retained their green leaves all through the winter." The flowers are as large as those of the gandavensis group and of a bright cherry-red, blotched with purple on the three lower divisions. The hardiness of this Gladiolus is a great point in its favour.

Hypericum reptans.—All the shrubby species of St. John's-wort are beautiful and worth culture, but no praises I could string together would express the grace and dainty habit of this creeping beauty as seen at its best, growing like a waterfall over stones. It has bright red stems, very slender and a foot in length or more; they are clothed with small, pale green leaves, and each thread-like branchlet is tipped with a shining yellow conical bud, or with a single flower like the flower of a tiny single Rose, but of a clear yellow colour. It is propagated by cuttings, or old plants may be layered and afterwards divided. It succeeds best planted out in the rock garden so that its slender stems can hang down over a boulder, and if planted a little above the eye level so much the better. When well established it forms dense mat-like cushions, and bears its flowers in great profusion. There are several other dwarf species, such as H. Coris, H. ægyptiacum, H. empetrifolium, and others, all pretty when well grown and easily reproduced from cuttings, but none to my mind are so graceful and effective as is H. reptans. Among larger bushy kinds, H. oblongifolium, H. patulum, and H. nepalense are all good and showy, and having about the same degree of hardihood as have the New Zealand Veronicas of the V. Andersoni section.—F. W. B.

AN AUSTRIAN GARDEN.

We have to thank Mr. Otto Forster, who has so frequently contributed to The Garden notes on alpine and other hardy plants, for a beautiful series of photographs taken in his garden at Lehenhof, Scheibbs. Two of these, showing the interior of plant houses, we publish this week, and both show, we think, charming arrangement, forming a striking contrast to the usual style followed in this country. Mr. Forster evidently aims at making his plant houses harmonise with the picturesque surroundings of his open-air garden. A friend who has visited the garden was delighted with it, and writes as follows concerning it:—

"From Vienna the railroad runs through a lovely tract of country, the "Wiener Wald," to the station Poechlarn, whence a branch line runs along the shores of the Erlaf to Scheibbs, a large village, in the immediate neighbourhood of which is situated the residence of Mr. Forster, around which the landscape is most picturesque. The mansion, which was erected by one of the Austrian nobles to accommodate large hunting parties and to serve as a summer residence, is situated at the best chosen spot in the valley, commanding a beautiful view of the Austrian snow-clad Alps. Mr. Forster has considerably improved the place; everything in and about it indicates the refined taste of its present possessor. There is a large range of glasshouses specially adapted for plant culture. The largest house is a winter garden in two divisions, the space between the warmer and cooler parts being a sort of rockery tastefully planted with appropriate plants, which produce a very good effect. Orchids are cultivated to some extent, and the place is famous for Rhododendrons and their hybrids, of which some very fine forms have been raised here. In the park-like garden, which is kept in excellent order, some parts are devoted to the naturalisation of Primroses and alpine plants. Primula cashmeriana grows plentifully on some sloping ground, and for the cultivation of other alpines advantage has been taken of a natural rockery, on which some very rare specimens may be found growing in the greatest luxuriance. A large collection of European and foreign Primroses may also be seen here, as well as multitudes of herbaceous and greenhouse plants."

Alstrœmerias.—In your notice of my Alstrœmeria (p. 66 you speak of it as Alstrœmeria pelegrina. I think this is wrong, though several books have it so. It is an error crept in, and the proper word is peregrina. Herbert (Amaryll., p. 91) puts it "peregrina–pelegrina"—the first being correct.—A Rawson, *Windermere.*

Whortleberries.—These are unusually plentiful this season. Vast quantities of them are sent by rail from the south-western counties to all parts. I have known as many as twenty-one tons to be sent from one railway station in one year; but this season I think the quantity will surpass even that amount.—J. C. C.

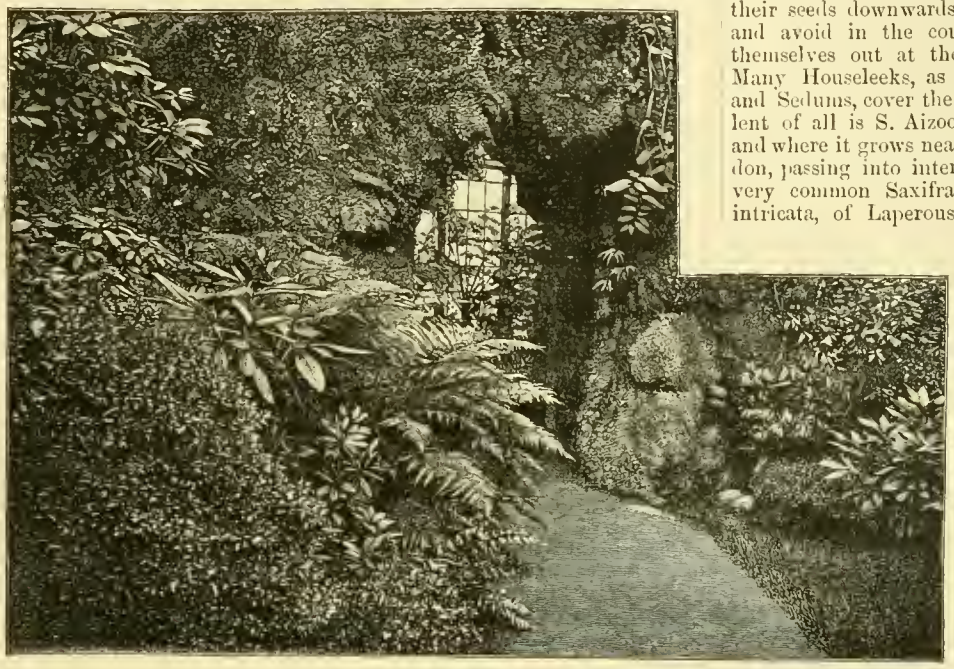
Flower Garden.

SPRING FLOWERS IN THE PYRENEES.

The Pyrenees, as a native home of garden flowers, are second only to the Alps in importance. It would be tedious to enumerate all the uncommon plants seen in a hasty visit to the chief watering-places of these mountains, but I propose to mention a few of the more interesting flowers as I saw them growing at the end of spring in this year near one or two of the better-known centres to which tourists resort. It is a pleasure to recall the delightful drives and walks, of which I made no notes at the time, except in memory; and some of those who know the flowers only as garden plants may like to learn how they grow in Nature.

St. Sauveur les Bains stands in the most beautiful as well as the most flowery of those magnificent roads constructed during the Second Empire to connect the chief watering-places of the Pyrenees, and called Routes Thermales. A branch railway from Lourdes runs up a beautiful mountain valley to Pierrefitte, which is the terminus for four important towns, Cauterets, Luz, Barèges, and St. Sauveur. The first of these places is surrounded by the grandest mountain scenery in its immediate neighbourhood, but for accessible flowery roads, St. Sauveur is the best station. The road from Pierrefitte runs along a narrow valley, with a large Gave or torrent roaring at the foot of precipices below it sometimes as much as 200 feet. Where the steep rocks and forests afford room the land is cleared into meadows for hay and pasture, artificially irrigated by diverting some of the many streams which fall down the mountain sides. Some of these meadows are on such a steep slope, ending in a deep precipice, that haymaking cannot be conducted without some risk. The hay is all carried out on the backs of the peasants, chiefly the women, who seem to do all the hardest work. At the end of May these meadows are as gay as gardens; they continue at intervals all the way to Gavarnie, where the carriage road ends, about twenty miles from Pierrefitte and twelve from St. Sauveur. At the time we saw them the gayest flowers of all were those of a large field Scabious, perhaps S. arvensis, but larger, brighter, and far more varied in colour than we see that flower in England, being different shades of blue, pink, and clear deep rose. I was not sure of the species, and did not bring specimens. Orchises are abundant, especially in the wetter parts, mostly varieties of O. maculata passing into the rich purple forms of O. latifolia. O. ustulata was there also of large size, the flower-heads being sometimes 3 inches long. Amongst many meadow plants familiar to us in England were others new in appearance. None was more striking than a tall light blue Phyteuma, raising a pyramidal spike of flower above the Grass. Its name is P. betonicæfolium. I have never seen its cultivation tried, and it would probably prove a failure. The Columbines formed another conspicuous feature, covering in some places several yards square. They were uniform in colour, of the rich deep blue of the large-flowered typical Aquilegia vulgaris.

Gedre is a village about half way between St. Sauveur and Gavarnie, and when the road has passed this the Grass in the meadows is shorter and the flowers brighter in colour. Daffodils were over, but the leaves showed how abundant they had been. In some spots Hyacinthus amethystinus coloured whole fields, so as to be visible at a distance of half a mile. Scilla verna and S. Lilio-hyacinthus are abundant. Forget-me-nots, with flowers of an intense blue I never saw in England, belonged, I suppose, to Myosotis alpestris, and were very common. The thickets were full of Dog Roses of different varieties, and R. pyrenaica was coming into flower. The white flowers of Amelanchier vulgaris made a great show. I must not forget the large-flowered and low-growing Ranunculus Gouani, which, near Gavarnie, nearly supplanted the commoner forms of Buttercup.



View in winter garden at Lehenhof, Scheibbs, Austria.

The streams attract special moisture-loving plants. Where they fall over steep rocks, the Ferns, belonging often to kinds rare in Britain, are very luxuriant; but where they run through the meadows they are edged by such plants as Thalictrum aquilegifolium, both the common and the purple-flowered form, which was plentiful close to the hotel at St. Sauveur. Cardamine latifolia, a sort of Watercress with rose-coloured flowers, was growing quite in the water; whilst on the drier banks, St. Bernard's Lily (Anthericum Liliago) and Ononis rotundifolia varied the colours. Anthyllis Vulneraria was extremely abundant, but all with pink flowers; I could not see one of the normal yellow in the Pyrenees.

I have not yet spoken of alpines proper, which, of course, are in great quantities amongst the rocks. It is quite delightful to see beautiful collections of them on high ledges of the precipices close to the road, which can be reached neither by ladders from below nor by ropes from above, and which must for ever defy plant gatherers. There is Ramonlia, pyrenaica abundant everywhere along this route which delights to nestle under a moist, overhanging ledge, just out of the sun; the plant is turned either downwards or sideways, but seldom looking straight up to the sky. But the most beautiful plant of all I saw here is the exclusively Pyrenean Saxifraga longifolia, which grows on the perpendicular faces of the highest precipices, the rosette being always turned horizontally, and the flower-spike growing always at right angles to the face of the rock. The first I saw were when looking down from that grand bridge, the Pont Napoleon, which spans the wide Gave at St. Sauveur, at a height of more than 200 feet above the water. It is a character of this Saxifrage that it nearly always grows in a single large rosette, which at the age of four or five years flowers and dies, and is reproduced from seed. As I saw the beautiful flower-spikes of pure white, and nearly a yard long, projected from the precipice, a botanical puzzle occurred to me. How do these plants, which must always shed their seeds downwards, maintain their altitude, and avoid in the course of centuries running themselves out at the bottom of the valley? Many Houseleeks, as well as other Saxifrages and Sedums, cover the stones. The most prevalent of all is S. Aizoon, a very variable plant, and where it grows near S. longifolia or S. Cotyledon, passing into intermediate forms. Another very common Saxifrage I made out to be S. intricata, of Laperouse. The various London Prides are too familiar to attract notice, but occur here everywhere.

Amongst the rocky slopes near and beyond Gavarnie 5000 feet above the sea level alpines become more prevalent. There were large masses in flower of Rhododendron ferrugineum. The moist rocks are in many places covered with Primula viscosa, growing as I can never make it grow in cultivation, its roots clinging to the moist stones like Ivy.

Teucrium pyrenaicum is still more plentiful, but of this we can imitate the growth in our gardens. In the soil amongst the stones Primula elatior—our Bardfield Oxlip—grows everywhere at high elevations. I noticed, too, large breadths of Horminum pyrenaicum, a plant with little to recommend it.

Primula farinosa fringes the stony little rills, and Gentiana acaulis and verna are everywhere where conditions are suitable, the former common near the road in many places. On the ledges of the higher rocks Alchemilla alpina, Lychnis pyrenaica—a plant I have never seen tried in gardens—Linaria alpina, Dryas, Saxifraga oppositifolia, are all of them represented, together with many similar mountain kinds.

Besides the flowers already mentioned as growing by the roadside were many others, varied in character according as the banks are constantly wet with the drippings from a long upward slope, or dry from a break in the continuity, as was generally the case on the lower side of the road. Here were masses of Cerastium, probably alpi-

num, Helianthemum polifolium, canum, and vulgare; Lamium longiflorum, a very prevalent weed in the Pyrenees, ornamental neither as it grows there, nor in gardens, where its introduction has proved a failure; large-flowered Mulleins of the biennial class such as I never saw in England. One tiny plant which grew out of crevices on the dry stones especially attracted my notice, forming close-growing silvery masses of crowded flowers. It was Paronychia capitata, a plant which has hitherto been all leaves on my rockery, but it should evidently be grown quite without soil. I must not omit Erinus alpinus, which is everywhere, though the white variety is scarce. On the wet banks of every roadside the most beautiful flower was the great Butterwort, Pinguicula grandiflora. The abundance of this was often such that I have seen at least a hundred flowers in the space of a square yard. Another plant, less universal in its distribution, but always growing from under dripping ledges and covering surfaces of wet rock, was Hypericum nummularium, its habit affording a lesson to those who try to grow it on a flat, dry surface of soil.

I noticed only one Androsace in the Pyrenees; this was common in many places at high elevations, but most abundant on bare stony ground above Gavarnie; it bears a profusion of white flowers with a purple centre, and is exceedingly pretty, though not easy of cultivation. It is certainly the A. villosa of Linnæus, but is of entirely different habit and appearance from a Himalayan plant of the same name, which I find easy to cultivate. If I am told on authority that the two plants are botanically the same, I am not going to dispute it, because I write as a gardener. In similar situations to those occupied by this Androsace I observed dwarf forms of Veronica, Teucrium, Vicia pyrenaica, a plant of dwarf growth and richly coloured flowers in its own mountains, merits which it loses entirely in cultivation; Jasione humilis, Globularia nana, Hieracium villosum, the latter not nearly so fine as it becomes in cultivation, by which some alpines are decidedly improved. I have not a flower in my garden which gets more admiration from good judges than this. I find, however, on reference to the "Botany" of Grenier and Godron, that the true H. villosum is not found in the Pyrenees, but is represented by H. pyrenaicum, a closely allied form. I hope to be allowed to speak another time of other flowers which I saw about Luchon.

C. Wolley Dod.

Roses and Gladioli.—One of the best arrangements which we have at the present time by which cut flowers can be supplied in quantity is Roses of the Perpetual type planted in rows 5 feet apart, with a single row of Gladioli between them. By Perpetual Roses, I mean a selection of kinds that really do keep on flowering more or less during the entire season, *i.e.*, like Gloire de Dijon, and others that can be had in abundance out of doors from June to October, and with but very moderate appliances in the way of glass for nearly the year round. It is very disappointing to plant Roses simply because they are classed as Perpetuals, and to find that they have nothing of a perpetual character about them but the name. By means of rigid selection, however, one may get sorts that really are perpetual. The Gladiolus is certainly one of the grandest of hardy flowers, and cutting the spikes, so long as one does not cut the leaves, rather benefits the bulbs than otherwise, as the entire strength of the plant then goes to perfecting the bulbs. We keep our Gladiolus roots in the ground the whole year round, and when lifted for dividing and replanting, we do so with as little delay as possible, as drying the bulbs by exposure is of very doubtful benefit; and I am thoroughly satisfied with the results thus far obtained by my plan, as under it the bulbs not only increase rapidly, but the flower-spikes push out two or three good side spikes nearly equal in strength and beauty to the central one.—J. G. H.

THE LOST HELLEBORE FOUND.

Helleborus lividus has for nearly a generation been a lost plant—lost not only to gardeners, but even to botanists, so that its identity was denied. The two published drawings of it in the *Botanical Magazine* and Sweet's "Flower Garden" were considered apocryphal, and the name itself was given to another Hellebore because of a fancied resemblance to the original plate. The name of H. lividus thus became attached to another Hellebore altogether, viz., H. corsicus or trifolius. All this is to be found fully set forth in Vol. XXVIII. of The Garden (pp. 28, 528, 608, and 645). At page 28 I gave a summary of the discussion which had been commenced in the previous volume, and which had been continued by Mr. Archer-Hind and myself. This article concluded with the expression of a hope that botanists who might be visiting the shores of the Mediterranean would try to solve the puzzle by finding H. lividus, the lost Hellebore. It was also stated that Mr. Baker, of Kew, thought it most probable that it might be found in the Balearic Islands.

In this discussion it was shown that plate 72 of vol. ii. of the *Botanical Magazine* undoubtedly represented a plant that formerly abounded in English gardens. That a second portrait of the same plant was published many years later in Sweet's "Flower Garden" (vol. v., p. 190), and that it had been described both by Aiton and Don as a beautiful garden plant. Mr. Archer-Hind and Mr. Burbidge afterwards published evidence of its still more recent existence in English gardens. The record, however, was all that remained, and the plant itself was not to be found.

In pursuance of the search for the lost Hellebore, I forwarded strips fully describing it, and giving particulars of the discussion, to many European botanists, and to some I sent tracings of the plates above referred to. By the kindness of friends the island of Corsica was thoroughly searched for it, and my friend Mr. Schloss, of Bowdon, spent two months in the Riviera searching every likely locality and inquiring about it from all the botanists whom he met. This was the most likely locality, because the specimen of H. lividus in the Forsyth Herbarium at Kew was labelled Nice, and it was thought probable that it might again be found in the neighbourhood. Mr. Schloss was, however, unable to find it. Particulars were also sent to the Balearic Islands.

Mr. Baker, of Kew, wrote me on the 23rd ult. that a dried specimen of H. lividus had been sent to Kew, and that this Balearic Hellebore agreed capitally with *Botanical Magazine*, t. 72. It had been found in Majorca, and occurred on the banks of rivulets and rocky places on the Sierra de Toller in calcareous soil at 130 feet to 3250 feet above sea level. He identified it as the Helleborus lividus of Aiton. Here, then, is the lost Hellebore re-found; and we may hope in due time to obtain living plants of it again for English gardens. Wm. Brockbank.

Brockhurst, Didsbury, July 24.

Gentiana gelida and G. septemfida.—"Veronica" remarks (page 96) that G. gelida has become the accepted name in gardens for G. septemfida. It may be so, but if so, more's the pity, as plants ought to be called in gardens by their right names. Gentiana septemfida (Pallas) and G. gelida (Bieberstein) are both natives of the Caucasus, but differ from one another in the following particulars. The name septemfida, which means seven-cleft, refers to the scales which separate the divisions of the corolla, and are fringed generally with seven divisions in the former species. In G. gelida these scales are entire, or at most two-cleft. In the second place, the colour of the corolla in G. gelida is pale yellow (ochroleuca) not blue. G. gelida, as far as we know, has never been in cultivation in England.—C. W. Dod.

NOTES ON HARDY PLANTS.

Campanula pelviformis.—Few Bellflowers show themselves off to better advantage than this one. It grows about a foot in height, and is neither top-heavy nor does it suffer its handsome saucer-shaped flowers to be beaten down by rain. Those who are unacquainted with it would perhaps be a little surprised at the length of time during which it continues to develop its soft grey-blue flowers. Wherever the more rare and attractive alpines are cultivated this is surely entitled to a place. As regards its treatment, it practically wants none; the most ordinary soil and positions do for it. Anyhow, it will thrive under the same conditions as the common carpatica, and it is even more readily increased by division.

Gymnothrix latifolia.—This is one of the handsomest broad-leaved and deep green Grasses we have tried. It may be planted in beds, borders, shrubberies, or as isolated specimens in summer, and if it has some rich and light material to root in it will soon grow large and imposing, though seldom more than 4 feet high. Let no one leave his whole stock out of doors to be frost-bitten if it is intended to keep it, for as sure as the frost nips it it will die, though it is spoken of it as being hardy. The best way to deal with this Grass is to lift it and pot it when frosts threaten. So long as the leaves keep green the plants may be employed for decoration indoors; when they turn yellow, dry off and place the pots on their sides, secure from frosts, until spring, when the plants may be started gently, and as soon as the bulky crowns sprout it will be better to divide the clumps, pot and grow the pieces close to the glass until April or May, and then plant them out again.

Papaver pilosum.—This has medium sized orange-red flowers. Seen growing many would not care for it, the pilose and rough stems and leaves are so hispid to the touch, and not of the most desirable hue, but the well branched flower-stems are a feature in this Poppy, and they serve to render the flowers less formal than straight, long stalks would. This Poppy is very hardy; it will grow in almost any kind of soil, and forms a big bush like specimen in two years, from which great quantities of bloom may be cut for a long season. The late period to which it continues flowering renders it valuable, and if the seed-heads are regularly picked off the results are very satisfactory.

Nierembergia rivularis.—If those who covet this charming little plant could only see some of its roots they would not be surprised that it is not easy to establish. The small runners, just under the surface, depend on roots of a very different kind which go a good depth down. The latter are as thick as strong packing twine, very strong, and remain alive, feeding the plants, for seven or eight years. It is some of this class of root that should be got up when it is sought to further increase it. The White Cup, as this plant is called, is a water-side plant, but we have grown it successfully for years in a sunny raised bed. The soil is, however, both deep and well worked, or rather it was deeply worked some years ago for Asparagus. A deep well-worked soil, with plenty of manure dug into it, is a good substitute for the damp positions said to be needful for moisture-loving subjects.

Veronica crispa.—If this handsome wrinkled Speedwell never bore a flower it would be worth a place in collections, consisting of the rarer and more beautiful hardy plants. It is apt to go off, not from any want of power to resist cold, but from being placed among tall growing plants which deprive it of sunshine. It likes an isolated sunny situation, where it can send up its straight stems charmingly furnished with leaves which shine with an almost metallic lustre. It does well in stiff clay, but plenty of light and as much sunshine as possible are indispensable.

Saxifraga aizoides.—This is a much more useful plant for the rock garden than hundreds of plants often seen there; native though it be, can a more pleasing yellow-flowered Saxifrage than this be

found either for midsummer or earlier use? When I speak of aizoides, of course I include the pretty dark-flowered variety called autumnalis. These remain in good form for several weeks. Let no one debar himself of the pleasure of big masses of these because he has no damp places in his garden corresponding with the watery habitats of the wildlings; they will grow beautifully under the ordinary conditions of a well-made bit of rockwork or in ordinary beds.

Spiræa palmata.—This is generally seen in an unsatisfactory condition in open borders. In, perhaps, nine cases out of every ten the cause may be put down to either planting too late or in positions too dry. I believe that in most gardens a suitable place may be found or made for it with very little trouble, and if that is the case, there is no reason why this plant should not be freely and well grown. The difficulty seems to be to find a moist and cool rooting place for it, but let it be put, say, an inch or two lower than the surrounding ground, where surface water, after a heavy shower, would run to, and it will succeed. If the soil is thin or porous, it should be removed to the depth of 18 inches, and a close-grained sand substituted; this, if top-dressed during the growing season, will induce this Spiræa to produce fine flowers and foliage. It is hardly necessary to say that sand put in a hole into which water can run in rainy weather will keep as cool and moist as a bog, while, if we want a warm bed for forcing or rooting purposes, we could scarcely employ better material during summer if formed into a raised bed in full sunshine. If, therefore, by such simple means we can accommodate this moisture-loving plant, we ought to do so, and the roots cannot be set too soon after the tops have turned yellow. On this point there is a little difference between roots that are to grow out of doors and those intended for pot culture.

Potentilla lupinoides.—I fell in love with this plant at first from seeing it in autumn in its rich leaf hues—bright yellow and red on a smooth glistening surface, and the small leaves withal of a handsome shape. The plant is a neat creeper, forming itself into a dense mass of stems and leaves, among which, in July and August, the large and bright yellow Rose-like blossoms nestle; the deeper orange-yellow anthers are conspicuous in the cup-formed flowers, and contrast charmingly with the now dark green and deeply-cut leaves. So far as I know it is not in general use, but for the rock garden it should be noted as "a good thing." It appears that this Pyrenean species is variable in the colour of its flowers.

Anemone rivularis —As a plant or flower with fairly good all-round qualities this may be mentioned. It is perhaps the only generally known Anemone that blooms in July and August, and we are so far indebted to it for keeping our thoughts fixed on its family which is always so gay in spring. Where well-established roots of this happen to stand near A. alpina and sulphurea the Windflowers are not likely to be forgotten even in midsummer, for the immense seed heads of the kinds just named greatly enhance the effect of the pretty, if somewhat small, flowers of the River Windflower. Its starry white flowers not only withstand wet weather, but, unlike the big Japan Anemone, they keep open no matter how dull, and if there is no sunshine for several days together the anthers may be seen to be furnished on the newly-opened buds with sky-blue pollen. No other Anemone gives cultivators less trouble. It is easily established in almost any sort of soil, and it soon makes a fair show of bloom.

Gypsophila paniculata.—This in many gardens seems to soon run its course, often ending its days in four or five years; by that time the woody stools may have become as stout as a man's fist with roots of corresponding thickness, but they suddenly decay after perhaps a most prolific crop of useful little flowers. Those therefore who desire to keep their gardens furnished with this plant, the flowers of which are valuable for picking, should see that young specimens are coming on to form a succession. It would not, indeed, be amiss to plant one every year, as until the second and sometimes the third year they do not produce much bloom. It thrives best in light soil.

Polygonum sphærocephalum.—This is the same plant about which I wrote under the name of P. affine. I understand it has recently been renamed at Kew; ugly as the new name sounds, it is a good descriptive one. It is doubtless a plant for the future for the following reasons: Its flowers are lasting as well as brilliant, and they are produced in succession: then it ripens seed—always an important matter where it is desired to have plenty of a certain plant. The roots in this case are knobs or tubers, which, so far as I can at present see, do not yield offsets. I have already gathered and sown ripe seeds, which show a tendency to sprout almost as freely as those of P. viviparum. J. W.

NOTES.

The garden after rain.—One of the fairest and most satisfying of all things is, to my mind, a good garden in late summer or early autumn time as seen in the sunshine that follows rain. Gone the dust, and gone the thirsty dryness of the leafage, and instead there are exuberant freshness and elasticity in every bud or leaf, and in every uprising stem. The last of the white Lilies glisten among tall blue Larkspurs, and Jackman's Clematis hangs its wreaths of royal purple amongst the gold-leaved Ivy on the walls. There are the most delicious whiffs of fragrance as you walk among the flowers, Carnations, Roses, and Stocks, and from the sweet-smelling leafy things, such as Musk, Rosemary, and Lavender, or from Sweet Brier and Thyme. Last, but not least, the rain has given freedom to cuttings and seedlings of many beautiful things. All through the dry, dusty weather these were huddled together like children forbidden to play. But now they are safely planted out and growing in health and vigour every day. This warm, showery weather is also the best for propagating nearly all kinds of hardy plants from slips or cuttings under handlights in the open air. So, too, between the showers one may dig and transplant Daffodils, Squills, and the hundred and one hardy bulbs now at rest, but which, after these soft warm rains of August, will soon begin to root and grow. The single Dahlias and the white Japan Anemone are opening their flowers; some of the earliest of the Chrysanthemums are in bloom, and yesterday I caught the first twitter of the robin's song, all of which are sure signs that fruity autumn is with us once again.

A sweet posy.—Take two Moss Rose-buds half open, a spray of Rosemary, and half-a-dozen of the flower-heads of Lavender, to which add a cluster or two of Mignonette, three old Clove Carnations, a small bunch of white Jasmine, and a few leaves of the sweet-scented Verbena (Aloysia citriodora). If to the above you add a half-opened old Provence or Cabbage Rose so much the better, and the result will be a sweet posy that a duchess might like to have near her, and which, if tastefully put together, will delight the eyes as well as the nose. This sort of sweet posy was far more common in the days of our great grandmothers than now. You will notice how careful the late R. Caldecott was to give his sweetest of early eighteenth century maids a dainty little posy to sniff at as they cross their tiny feet and sit demurely in the fine old Chippendale chairs he must have liked, or he would not have drawn them so well. Well-made *pot-pourri* is delicious in winter, but during summer time every room in every house which has a garden ought to be full of fresh flower fragrance, leaving the mummied odours for the winter of our discontent. You must not for a moment fancy that the above recipe for a sweet posy is a bit of literary labour out of my own head, so to say. The truth is, I found it written inside the cover of an old herbal, and to-day I tested its efficiency, and having found it not wanting, I offer it to every Lady Corisande who reads The Garden.

Spiræa palmata alba.—Plants are like men, inasmuch as nothing tries their character and capabilities like time. When I first saw the above plant in bloom my verdict was one not at all likely to extend its distribution in any way, but I obtained a plant, and when it first bloomed here as a novelty nearly everyone said, "Ah! what a pity; that is Spiræa palmata spoiled, is it not?" This year, however, the plant has quite vindicated its character, and as now in bloom is a lovely thing. It is planted in a half shaded peat bed among Rhododendrons and other shrubs, and bears about a dozen of its pure white feathery sprays. It is by no means the first new introduction that has been "under a cloud." The Bornean Jasminum gracillimum had a narrow escape from total oblivion, and those who refused a certificate to Cypripedium Lawrenceanum can see it now in the best groups of Orchids at the best of exhibitions, but this white-blossomed Spiræa is really just at this season one of the most beautiful of hardy flowers, and as such, now well established and well grown, everyone admires it. It has at any rate proved to me that nothing but actual trial under favourable conditions can decide whether a plant is a good one or not. The position, soil, surroundings, and culture make all the difference with this feather-flowered Spiræa, as with many other things.

Aconitum variegatum.—The old purple Monkshood is a welcome flower early in the year, but there are now far more attractive kinds in blossom. A. japonicum is one of the best, and later in the year A. autumnale and its white variety will be masses of flowers 7 feet or 8 feet in height. Just now we have nothing in the genus finer than this A. variegatum, which is also known as A. bicolor in some gardens. Its hooded blossoms are borne on branched spikes 5 feet or 6 feet in height, each flower being half white and half pale blue or lilac. It is easily increased by division, and comes tolerably true from seeds sown as soon as they ripen, in which case they germinate during the following spring. A good group of this plant looks well as seen against a background of evergreen shrubs, and is robust enough to hold its own in open sunny positions, beside woodland walks or drives. Another species with panicles of pale yellow flowers, A. Lycoctonum, is also adapted for similar positions, and is quite distinct from its allies in general effect when in flower.

Lilium longiflorum.—This is one of the cheapest and most beautiful of all the Japanese Lilies, and should be grown in all gardens where white flowers of noble form are appreciated. In mild localities near the sea it is hardy, but, as a rule, the best results are obtained by pot culture in a cold frame. Its growth appears early in spring, and is very apt to be frost-bitten; but if the bulbs be grown in pots in a frame they are safe from harm, and flower beautifully if plunged out of doors in May or June. A pot so grown and plunged out among other things in a peat bed is now very pretty. It bears ten perfect flowers, a result never attained by unprotected clumps which are left outside with us all the year. In some few places I know this Lily really does beautifully outside in beds or borders, but, as a rule, pot culture will be found a preferable plan of growing it to anything like perfection. Five strong bulbs in an 8-inch pot make a show when they flower. On such a pot I have seen five stems, each bearing four or five of its great trumpet-shaped blooms. There are several varieties, of which eximium and Harrisii are perhaps the best, but the typical plant is much

cheaper. L. Harrisii may be forced quite readily for Easter decorations, and a pot of it in full flower at that festive season is a great prize.

Cuttings or slips.—When I was a boy nearly everything was increased from slips, and I am not sure that the more modern and now general practice of taking cuttings is more successful than the old plan of slipping off short axillary shoots with a heel instead of cutting them with a knife. If ever I feel the least doubtful as to which method is best, I try both ways, and after some little experience in this line, I find the balance in favour of the slips. Milky plants, such as Euphorbia jacquiniæflora, often fail as cuttings, but short growths stripped off grow well. Pinks, Carnations, Cloves, and mule Pinks, Onosma tauricum, small Veronicas, &c., we propagated quite successfully from slips planted under cap-glasses or handlights on a sandy border. Hollow-stalked Pansy cuttings generally fail to grow, but the same growths stipped off at the crown and inserted deeply in sandy soil grow quite freely. Of course, facilities for the rooting of cuttings are now greatly improved, yet for hardy plants more especially I believe we might return to the old-fashioned habit of planting slips of many things with advantage, and especially when cuttings have been tried and failed.

Gingerworts.—As a family these are very beautiful in leafage as well as in blossom, and the economic usage of their rhizomes is as yet in its infancy. The fleshy rootstocks of any kind of Alpinia, or Hedychium, or Kæmpferia would afford fairly good "ginger" if cured in syrup or candied on the Chinese plan; indeed, so far as proof goes, there is nothing to show that the genus Zingiber proper is ahead of other plants of the Order in aromatic and stimulating properties. When I was exploring in the Bornean forests, a few years ago, I found Scitaminaceous plants very common, and in pulling up the plants themselves I was very much impressed by their fat and aromatic rhizomes. The Bornean, or native, Ginger is made from an Alpinia with banded or zebra-marked leaves. Kæmpferia Galanga I found in plenty in one place only, a hot, swampy plain, the road through which was knee-deep in soft mud, roofed over with tall Sedges and Grasses, and when passing through these Grass-lined tunnels the mosquitoes neglected not their right to take toll from the passing traveller. Wherever an open, sunny mud flat was reached there the flat leaves of the Galanga covered the soil, or its pretty white and purple flowers were seen. The Chinese were settlers in North Borneo centuries ago. The largest mountain there is Kina Balu (*i.e.*, "Chinese Widow"); the largest river is Kina-batangan (or "Chinese rock-fringed stream"); and if ever the Chinese colonise that country again they will find Ginger roots awaiting them by the ton. I speak subject to correction, but I should say the fleshy rhizomes of any Hedychium or Alpinia would make good "ginger."

Colour and perfume.—Botany was in a state of chaos until the time of Linnæus, whose numerical arrangement of anthers and stigmas simplified the science into an order until then unknown. The natural system carried progress still further, but it is only quite recently that any attention has been paid to colour or to perfume as essential characters in the science of botany. You may read descriptions of plants by the dozen without getting the slightest information as to whether the flowers of the plants described are red or yellow or blue. In a word, colour has been to a great extent like the round 0 of our cricketing days; it has stood for nothing through decade after decade of classification. So, too, the perfume of flowers has been left to our Rimmels and Piesses, for it was held beneath the dignity of a botanist to tell us anything of these subtle things. Shakespeare, indeed, never forgot the main facts of Nature, and so he generally tells us that Roses are sweet and that Rue is bitter, but even yet colour and perfume are unknown quantities in the botany of to-day. The amateur gardeners are more exact, size and colour and perfume being essential points in their eyes. The absence of a yellow spot on the lip of a Coelogyne, or a few purple bars on the petals of an Odontoglossum may add fifty or a hundred guineas to the price of any individual plant. It may never be practicable to add the natural perfume to our coloured plates of flowers, but we may at least expect that some indication of their fragrance be conveyed in words.

Betonica alopecuros.—We have in this genus some very effective and free-growing garden plants. B. grandiflora forms a mass of red and purple flowers early in the year, and just now the species above named is very beautiful. It is known as the Foxtail Stachys, and is a plant a foot to 16 inches in height, and its erect leafy stems are each tipped spear-like with a conical cluster of flesh-pink or rosy-salmon flowers. Like all its allies, it is most readily increased by division in spring or in autumn—that is to say, either before or immediately after flowering. As seen here on a free, light and sandy soil both the above plants are very showy and well worth a place in even good gardens. Another good and distinct Labiate now flowering is Ajuga Brockbanki, a plant having clear blue spires rarely exceeding a foot in height and very pretty as seen at its best. In deep rich soil in a partly shaded place this plant is very attractive. The history of the plant is, as I believe, this: It appeared in Mr. Brockbank's garden at Didsbury, near Manchester, as a chance seedling, and was given by him to Mr. Smith when manager of the Newry Nursery, by whom it was named and sent out. As grown here it forms a solid sheet of blue, and is very beautiful as seen at its best in June or July.

Choretis (Hymenocallis) glauca.—This is not very common, but I consider it one of the very best of all the Bridal Lilies (Hymenocallis), all of which are as fragrant as they are fair. I have had bulbs of it for years; indeed, I started with three, and I should have had three now, but I gave one away, and it has been an annual pleasure to its owner. In a word, while the bulbs of this plant flower freely every season, they do not increase so fast as do some other species of this noble group. As seen in blossom, the plant is very shapely and effective. Five or six thick oblong leaves spread from the apex of the bulb, and from the centre appears a flattened scape a foot high or more, and the snow-white flowers radiate from the apex like a tiara or diadem. The leaves are of a pale glaucous shade of green, and not dark glossy green, as in H. macrostephana, nor are the flowers of H. glauca quite so large, but their purity of whiteness and delicious fragrance would be difficult to surpass. The old Pancratium fragrans is not equal to either of the above as a garden plant, and the narrow-leaved P. caribbæum is by comparison a weedy plant not worth pot room. Of course, all these Bridal Lilies are beautiful, but the best known to me are H. macrostephana and H. glauca. Among other bulbs in flower, Urceolina pendula is one of the prettiest, its elegantly-shaped dangling bells being generally admired.

Arundo conspicua.—Years ago a good pot of this New Zealand Grass used to be very ornamental in the Cactus house at Kew. At that time the plant was rare in Europe, but now it is largely cultivated as a hardy plant, and is just now very pretty as seen bearing aloft its silvery plumes each at the tip of a slender wand or stalk. It is earlier by six weeks, and, as I believe, much more graceful in habit than any form of Pampas Grass, and being of smaller growth it is also more suitable for small gardens. The great fault of the Pampas Grass is its lateness, so that in northern gardens its beauty is destroyed by wintry storms almost before it flowers. The Arundo is on this account worthy of a place, even if it be necessary to grow it in pots or tubs, so that it can be sheltered during the worst of winter weather. In most gardens, however, it will prove to be quite hardy, especially if planted on large banks or in dry positions amongst stones, so that it does not become water-logged during frosty weather. A few stones and a little coal ashes or sand will generally suffice to preserve it in exposed positions, and as seen at its best on the lawn, the plant is so graceful and effective, that no pains are too much if its presence be secured thereby. It is readily increased in the spring by division or from seed.

Calystegia pubescens.—I can generally manage to secure any plant that I wish to obtain, but, so far, this has beaten me entirely. The double-flowered variety is, I know, a weed in many gardens and grows well here, but I never saw nor heard of the single-flowered Calystegia pubescens. The common Kerria (Corchorus) japonica is another instance of a plant being common in a double state while the typical wild species is rare, but I have often met with the single form of it, and it is not uncommon in botanic gardens. Can anyone tell us of the single-flowered Calystegia pubescens? The double form is now very pretty, both as twisting about on the ground or as scrambling up bushy supports, its elegant growths being covered with axillary blossoms of a pale rose colour. It is easily naturalised at the foot of a low hedge of Privet or of Thorn, and as so grown forms a beautiful plant; or its roots may be planted at the foot of an Ivy wall on the Grass. In some places it rambles about so vigorously, that care should be taken in planting perennial Convolvuli of any kind. As a rule, they are safer and prettier isolated in beds on the Grass, where the scythe or the lawn-mower keeps their stolons within bounds.

Burbidgea nitida.—This orange-flowered Gingerwort is now flowering freely here potted in loam fibre on a well-drained bottom. We have two plants, and both are flowering on stems less than 12 inches in height. The individual flowers are rather fugitive, but as the buds open in succession this fault is not so great as it at first sight seems to be. Mr. Court once told me that it grew and flowered better in America than in English gardens, but we have had no difficulty with it, except that once we nearly lost it by its having been transferred to a close hot pit among some Nepenthes. When I first discovered the plant in Borneo it was growing on a dry hillside, its roots clasping the mossy boulders of sandstone and growing there in shady positions; its flowering stems were 20 inches to 30 inches high. Its rich orange-yellow flowers in spikes at the ends of the glossy-leaved stems are pretty, but growers always seem to have failed in its culture since the original plant bloomed at Chelsea seven or eight years ago. Our plants stand on a shelf facing the east, and so escape the mid-day sun. If the plants were potted in nodules of sandstone and fibrous loam in a pot drained as if for an Orchid, I fancy fewer failures would result. Its rhizomes are very aromatic, and quite scented the air, I remember, as I tore them off the rocks in Borneo, a country very

rich in Alpinias, Globbas, and other aromatic Gingerworts, many of which might be useful economically. VERONICA.

TREES AND SHRUBS.

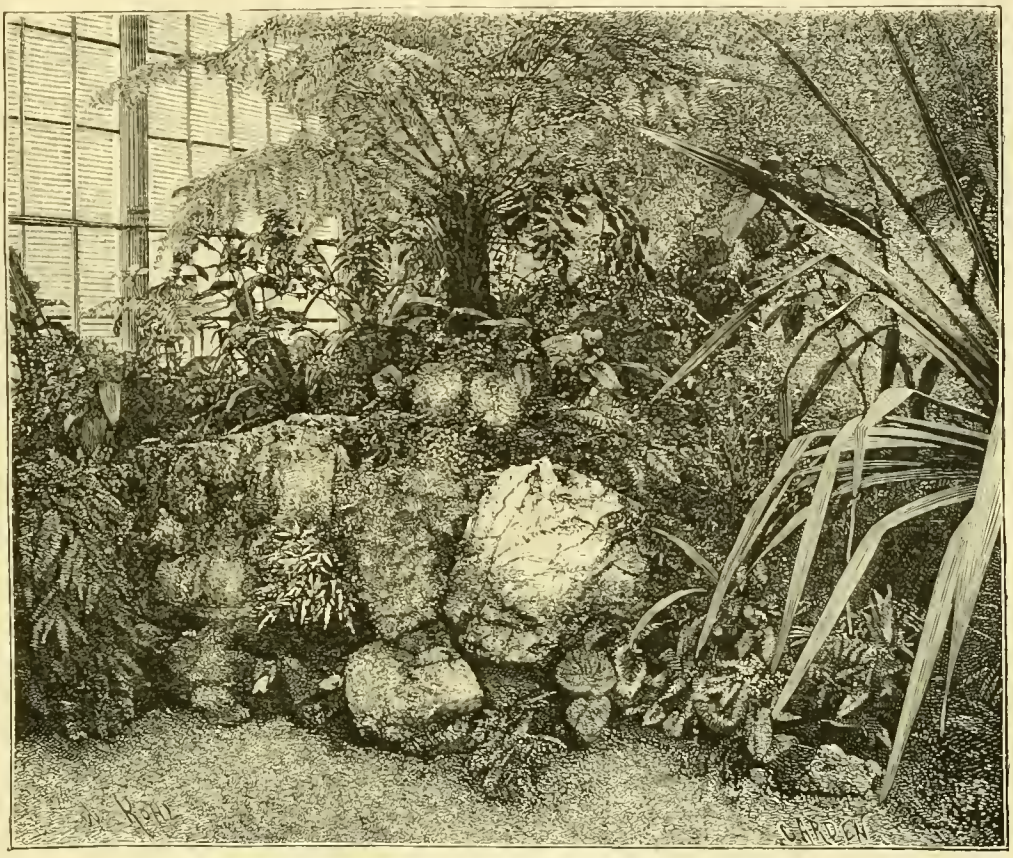
PLANTING STREET TREES.

DURING the past few years tree-planting in provincial towns has been carried out extensively, doubtless in imitation of the good effect produced on the Thames Embankment and other spacious thoroughfares in the metropolis, as well as in Continental towns. Street tree-planting, like most other new fashions, appears likely to be overdone, as already we find them being planted in thoroughfares where before there was barely space for the traffic. The guards necessary for protecting the stems are a great inconvenience to pedestrians, and the tops, if allowed to spread out in anything like a natural way, soon block up the house windows. To obviate this the most barbarous mode of pruning is often adopted — in fact, the trees look like the hideous pollards one often sees in country lanes and hedgerows. Whenever the town authorities undertake to provide trees for beautifying the streets, they should be certain that the positions assigned to them will allow of their growing to a reasonable size without the need of annual shearing, or there can be little doubt that such discredit will be cast on a really good undertaking, that before long we shall find street trees looked on as a positive nuisance, and they will be swept off root and branch. There appears to be little variation as to the kinds of trees used, Poplars, Limes, Sycamores, or Planes being used to the exclusion of everything else. Doubtless they are good trees in positions where there is unlimited space, but surely trees of less spreading growth than these could be found for streets of limited width. Let us hope that before long those in charge of street trees may educate themselves on the subject of trees, and choose kinds that will enable them to put away the pruning-hook, and allow the trees to develop themselves as such beautiful objects should do.

Gosport. J. G.

Spiræa bullata.—This shrub is more suitable for a rockery than a shrubbery, for if it be allowed to contend with ordinary shrubs it becomes overgrown and quickly succumbs, while on a rockery it forms a dense little bush less than a foot high, with small neat foliage and flattened clusters of blossoms, crimson in the bud state, but a deep shade of carmine-pink when fully expanded. It is just now in flower, and a clump of it here at the base of the rockwork forms one of its most attractive features, while a further point in its favour is, that a succession of bloom is maintained for some time. This Spiræa is of comparatively recent introduction, and up to the present somewhat scarce, but as it wins favourable opinions from all, and is, besides, of ready increase, no doubt it will soon be met with much more frequently. This Spiræa is a native of Japan, and is also known under the name of S. crispifolia, from the curled character of its leaves.—T.

Æsculus parviflora.—Though one of the handsomest of all hardy shrubs, and one, too, which is in full beauty when few others are in bloom, this North American Chestnut is comparatively seldom seen in this country. It is, however, perfectly hardy, and only requires to be seen to secure a fuller recognition of its merits. As a rule it rarely attains the height mentioned by Loudon, viz., 10 feet to 15 feet, and is perhaps best treated as a dwarfer subject, a number of the stems being cut away every year. A constant succession of strong shoots is thus secured, and these bear much finer flowers than those produced by older branches. Loudon sums up the good qualities of this species as follows: "The shoots are slender, spreading, and rooting at the joints where they happen to rest on the soil, with ascending extremities. The tree comes into flower about a month or six weeks later than the other Æsculaceæ and continues flowering, in the case of large plants on moist soil, for three months or longer, forming one of the greatest floral ornaments of the shrubbery, at a season when very few trees or shrubs are in flower. The fruit, which is small, seldom ripens in England, but in America it is said to be eaten boiled or roasted; and M. Poiteau, accordingly, has included this species of Pavia in his list of fruit trees." It has red leaf-stalks, glossy dark green leaves, and long paniculate racemes of white flowers, the long white filaments of which, surmounted by the red anthers, impart to them a fine fringed appearance. In various books, &c., this is found under the names of Pavia macrostachya, Æsculus macrostachya, Pavia edulis, &c. It delights in a moist situation or near water, and thrives well in a strong clay soil.—N.



Rocky fernery in the garden at Lehenhof, Scheibbs, Austria. (See p. 116.)

Potentilla fruticosa.—This pretty little flowering shrub forms a much-branched bush growing a yard or more high, with small leaves and bright golden blossoms nearly an inch in diameter. It will grow in dry sandy soils, and if not too dry will flower throughout the latter part of the summer; indeed, I have had it bloom from July till October, and this season it promises to do the same. This Potentilla is found wild in some parts of England, but, generally speaking, in a wild state it does not attain the dimensions reached when under cultivation.—A.

Double-flowered Brambles.—Though most Brambles are far more fitted for the wild garden or woodland, there are two or three kinds well worthy of a place even among the most select shrubs. The pink double-flowered form of the common Bramble is one of these, and most beautiful it is where allowed to ramble at will; but if no place exists in which this can be allowed, it may be kept to a bush shape by tying to some stakes, and occasionally shortening in an unusually strong shoot. In this way it will be now a mass of flowers, which, in addition to other attractive features, are of a most pleasing shade of pink. The closely packed prettily quilled petals suggest the name of bellidiflorus, which it is sometimes called, as well as R. pomponius flore-plena. Under whichever name it may be called this Bramble is very ornamental, while in spite of two or three names being given for double pink-flowered Brambles, as far as my experience goes they are all the same. The double white is altogether different from the last named, the petals being much broader and the blooms but semi-double. Being borne in clusters, they remind one somewhat of the Aimée Vibert Rose; indeed there is a much greater resemblance between these two in the shape of the flowers than is the case with the pink and white Brambles. This kind may be treated in the same way as the pink form, and, like it, is now in full flower. Another pretty double Bramble is R. rosæfolius, a small upright growing kind that flowers during the autumn and winter months, but it is of so tender and delicate a constitution, that it is only seen to advantage when treated as a greenhouse plant. To increase the hardy kinds of Brambles the best way is to layer the tips of the growing shoots, which will quickly root and soon form plants.—H. P.

Olearia Haasti.—It is only within the last few years that this Australian shrub has had attention directed to it from its valuable late summer-flowering qualities. Already it has become popular, and deservedly so, for it possesses many desirable qualities. It has proved itself to be perfectly hardy, at all events in the southern part of England, and where in a thriving condition few shrubs are more attractive at the present time,

for even in the case of small specimens they are so densely covered with good-sized clusters of small star-shaped pure white blossoms, as to present quite a mass of that tint, while even when out of bloom the neat evergreen foliage and compact habit of the plant render it valuable without taking into account the flowering qualities. When the clusters of blossoms are cut just as they commence to expand and placed in water, they remain a very long time without withering—more so indeed than most shrubs at this season. It is not difficult of increase by cuttings of half-ripened wood, put in sandy soil and kept under a close handlight or bell-glass till rooted, when they should be potted off and kept for a short time in pots before they are planted out. This shrub is also known as Eurybia parviflora, and is interesting from being one of the few composite plants of a shrubby nature hardy in this country.—Alpha.

THE WINTER IN YORKSHIRE.

Now that Mid-summer Day is past it may not be amiss to note the effects of the unusually prolonged winter of 1885-86 on the more or less tender trees and shrubs which we grow here, including, perhaps, an unusually large number of Coniferæ. I may say that our elevation is about 400—450 feet above the sea, and that the plants spoken of are all fully established, many of the Coniferæ, however, being seedlings raised here. I congratulate myself that the only real loss which we sustained was in the three plants Chamæcyparis sphæroidea variegata, Coronilla glauca, Desfontainea spinosa. The first of these was grown in an open, but sheltered, situation near a running stream; the two latter were planted against the house, with a south-west exposure. Until the end of June I thought that Desmodium penduliflorum and Aloysia citriodora (Verbena triphylla) in similar situations had shared the fate of the Coronilla and Desfontainea, but I find that this is not the case, as they are both throwing up strong shoots from the ground.

Of plants injured, but not killed, it seems strange to say that old plants of Rhododendron ponticum and Aucuba japonica, both of which are assumed to be very hardy, fared worse than most other things, whilst the numerous hybrid Rhododendrons, including some very choice ones of the Castle Kennedy strain, remain unhurt. Biota orientalis in a border near the house, with a south exposure and a wall behind it at 3 feet distance, was killed. In open places, the side exposed to the sun was destroyed, whilst plants in other situations escaped entirely, showing clearly that the damage was caused by the action of the sun during frost, which is, I find here, one of the greatest evils with which we have to contend.

The following, amongst others, escaped unhurt, viz., Abies Alcoquiana, Albertiana, Engelmanni, polita, and Smithiana; Athrotaxis selaginoides, Biota pendula, Cedrus atlantica and Deodara, Cephalotaxus Fortunei, Cryptomeria japonica and elegans, Cupressus Lawsoniana (many forms), nutkaensis, sempervirens, macrocarpa, and Lambertiana; Fitzroya patagonica, Olearia Haasti, Picea amabilis, baborensis, cephalonica, concolor, firma, magnifica, Pinsapo, sachalinensis, Veitchi, Webbiana, &c.; Pinus insignis, koraiensis, excelsa, and Pinea; Retinosporas of many kinds, plain and variegated; Salisburia adiantifolia, Sciadopitys verticillata, Sequoia sempervirens and argentea, Thujopsis and Thujas (many), and Torreya myristica.

These have all successfully resisted the inclement season: Cistus cyprius (ladaniferus) and the Rose Lamarque have for a fortnight contended as to which could be the most beautiful against the wall of the house, on which the hardier Roses are now a mass of bloom, having succeeded the Wistaria and various varieties of early-flowering Clematis. Lonicera sempervirens is covered with its scarlet tubes; whilst the brilliant Tropæolum speciosum scrambles up for many feet amidst the bright leaves of Chimonanthus fragrans, which, although 8 feet high, has not yet flowered with me. Hydrangea paniculata and Clematis Jackmanni give fine promise for the autumn; and Eccremocarpus scaber, killed to the ground during the winter, is trying, and I think with probable success, to reach the top of the house. In a sheltered corner Elæagnus argentea and aurea, two or three variegated Euonymi, and Azara microphylla are luxuriant. Bambusa Metake made shoots 7 feet in length last year, which the winter has curtailed to about 3 feet, and it is now pushing vigorously. During the spring the various Narcissi were as fine in their way as the Roses now are, and the alpines, including many Androsaces, Saxifrages, Haberlea, Wulfenia, Ramondia, &c., were never more flourishing.

The above will show that, despite the supposed disadvantages of a rainy and cold climate, the culture of a varied assemblage of plants may be successful in North-west Yorkshire. R. Milne-Redhead.

Ilden Clough, Clitheroe.

White Indigofera.—This is a white form of Indigofera floribunda, and though the pale blossoms are not so showy as the rosy purple ones of the type, yet it affords a good addition to summer-flowering shrubs. Unfortunately, these Indigoferas cannot be regarded as thoroughly hardy, for they are much injured during severe winters, unless protected by a wall or in some other manner. A good way when grown against a wall is to secure the branches thereto, and after the space is covered the plant or plants may be allowed to grow at will, and the slender drooping branches have a very pleasing appearance when treated in this way. An allied species, I. Gerardiana, with deep rosy pink blossoms, is another desirable kind, and may be often successfully treated as an outdoor shrub, for if cut back it quickly recovers and flowers most profusely even in a small state. These Indigoferas may also be grown successfully in pots; indeed, I was much struck with some plants of this white variety the other day in Messrs. Veitch's nursery at Coombe Wood, grown in comparatively small pots, and being laden with their pure white blossoms were most attractive. Some bushes against an open-air wall are also covered with bloom.—T.

Spanish Broom (Spartium junceum).—When the flowering season of most of the different kinds of Broom is past this one is at its best, and a goodly show it makes at the present time, as the curious Rush-like branches are crowded with large rich golden-coloured blossoms, and unless the weather be unusually dry, the specimens of it will continue to bloom for a considerable period. At the same time it will resist drought better than most other shrubs, as the roots take a direct downward direction, and are therefore less susceptible to its influence than in the case of shrubs that root near the surface. As the Spanish Broom will thus hold its own amongst most other shrubs with which it may be associated, it is useful for planting in a mixed border, and may be employed with advantage where a screen or belt of Evergreens is planted to shut out any unsightly object from view, as in the case of shrubs 5 ft. or 6 ft. high the Spartium will tower above them and give a goodly show of its beautiful golden blossom. It is a native of Spain, Portugal, and the south of France, and, according to Loudon, was introduced so long ago as 1548. Seed is readily produced, from which plants can be raised in almost any quantity. Loudon mentions a variety (flore-plena) regarding which questions have been asked from time to time, and having had the pleasure of seeing a specimen in full bloom, I may mention that the flowers are really semi-double, but the plant is less showy than the single form.—Alpha.

SHORT NOTES.—TREES AND SHRUBS.

Thujopsis dolabrata.—The chief defect of this handsome Conifer at present seems to be its slow growth, but in Japan it grows to be a tree which is described as of great beauty.—G.

Berberis coccinna is a charming little Himalayan Barberry, with small neat foliage, light green above and silvery white beneath. The pale yellow flowers appear in July and August, when scarcely any other species is to be found in bloom. It is a distinct and handsome dwarf growing Evergreen, and is most at home in the rockery or in the front of the shrubbery border.—N.

Pinus excelsa.—This Pine, the nurserymen say, is rarely asked for; but if planted and treated as recommended, it will prove an ornament to the pinetum or shrubbery, its long light-coloured leaves contrasting admirably with the foliage of the generality of the dark-leaved Pines. P. excelsa, when left to itself, has rather a sprawling habit of growth, the branches in most cases being widespread, to the detriment of the leading shoot. Trees of P. excelsa have been branch-pruned here, more or less, for the last twenty-five years. Such plants so treated have now assumed the habit of P. Cembra.—M.

The scarlet Oak.—Most planters who grow this fine American Oak are thoroughly aware of the beauty of its large leaves during the summer, and the brilliant autumnal colour they assume before being shed. It grows, too, in almost any soil, and soon forms a distinct and handsome tree. The beautiful tints of the second growth are also a recommendation; in the arboretum at Kew and in other places trees of this species are now very conspicuous, the bronzy red of the young shoots and leaves forming a striking contrast to the older foliage.—N.

WORK DONE IN WEEK ENDING AUGUST 3.

July 28 to August 3.

Having been too busy to make any but the most fragmentary notes, and these most irregularly, this week's account of "work done" is made from mental recollection only. Except an hour's rain in the early morning of August 2, the weather has been fine throughout, so that there has been no interruption on that score. Fruit gathering for preserving—Raspberries, Currants, and Gooseberries—we have completed, and a few trees of each have been netted over to preserve them for future use. Cleared off old plots of Strawberries, and after drawing drills between the rows, planted out at 2 feet apart Purple Sprouting Broccoli, Cottager's and Ragged Jack Kales, three of the best and hardiest types of winter greens that can be had; made the last sowing of Turnips, also of Peas and French Beans. Dug up early Potatoes; they are a remarkably heavy crop, and free from disease; this ground will now be utilised for a late crop of Cauliflowers—Early London and Walcheren; Autumn Giant is longer in coming to maturity, else that variety would be the best to plant. Our last batch of this kind was planted out a fortnight ago. Flower gardening now takes up the bulk of our time, there being always some tying up of plants to be done, not to mention the immensity of pinching and picking over of beds to keep all in neat order, the designs true in their outlines, and the edgings of beds and walks regularly cut, for without such neatness the arrangements, however good, do not afford that amount of pleasure that all have a right to anticipate from a flower garden. Cleared and weeded among-st Ferns and rockwork. The few Phormiums, Bamboos, Ferulas, and Eucalypti that we have about this garden are by far the most charming hardy plants to use as sub-tropicals, and associate well with such annual types as Castor-oi's, Solanums, Chilian Beet, variegated Maize, and Hemp. Lobelias, Calceolarias, Violas, and Verbenas flower so persistently in the early summer, that to keep them in a flowering state the summer through it is necessary that they be regularly kept free of seed pods and be well supplied with water. Lobelias we cut partially over twice or thrice during the season, and this conduces to the production of new shoots from the bottom, and also ensures a bushy habit of growth by causing the plants to make side shoots from the main stem, and consequently we get a succession of flowers. The self-same treatment is applicable to Verbenas, and should be practised if there be any danger of the plants flowering to death. Picked bad flowers and seeds off all plants in vases, and watered them with manure water. This is needful at least once a week, unless the vases, which is very rarely the case, are extra large, and consequently the soil does not get so quickly exhausted. Work about the houses has not been very varied; it has consisted of Strawberry potting, and also of the potting of sundry odds and ends of plants; pinching Vine laterals and tying Peaches and Nec-

tarines to trellis. Staked bush-formed Chrysanthemums, and pinched side shoots off plants that are grown for the production of large flowers. Got out fruiting Pines from pit, and put them in cool house to retard them till required. Watered inside borders of several houses; also Pines; and tidied up the beds by putting a slight covering of Cocoa fibre over the leaves. HANTS.

HARDY FRUITS.

CROPS of fruit on wall trees generally are fairly good; Peaches and Plums super-excellent, and Pears will be more plentiful than we at one time anticipated. Moreover, trees of all kinds are remarkably clean, but the fruit is decidedly late; indeed, some of our finest varieties of Pears are so far behind, that it is questionable if the brightest autumn will finish them properly. With this disappointing prospect before us, it will not do to lay down our oars and drift with the stream, as such a course would be sure to lead us into breakers. What then must we do? Why, look round and see what can be done to help the trees forward and hasten the swelling of the fruit. Cleanliness and moisture at the root are decidedly in our favour; all we now want is sun heat and warm nights; the rest is in our own hands, for we can keep all growths thin and closely nailed into the walls to give them the full benefit of every reflected ray, and we can pinch every lateral and sublateral where their presence is likely to rob the fruit or produce too much shade. To this end, then, let every Peach tree have two dressings where in forward seasons it might do with one; pinch the points out of shoots which will not be wanted after the fruit is gathered, and let every leaf and shoot retained for next year's fruit-bearing have free exposure to light, air and sunshine. Keep the foliage clear of spider by washing it once or twice a week with pure water; if warm, so much the better; and protect the surface roots from drought by mulching the 4-foot way with fresh stable litter. As growth advances and the fruit begins to colour turn the leaves aside, but do not cut them off, as some advise, for much as this practice may check the vigour of the tree and hasten maturity, the time gained is purchased by the sacrifice of size and flavour. Apricots require similar treatment, not so much on account of the fruit as the wood and spurs, as we often see trees in favourable situations ripening their fruit under the most primitive method of summer management; but these favourable spots are exceptional, and for this reason the treatment under which they thrive is by no means applicable to nine-tenths of the trees grown throughout the kingdom. Let pinching, training and mulching then be regularly performed, and on no account allow the roots to feel the want of water, for much as Peaches enjoy an abundance of this element, the Apricot in a well-drained border is capable of taking more. It is neither wise nor necessary to water during the time the fruit is hanging in a ripening condition, as well managed borders are watered and mulched before that stage is reached, but copious washings with the hose again become necessary after the fruit is gathered. Here a word as to mulching may not be out of place. All admit that the mulching of south wall borders is a great help to the trees as well as the fruit; but enthusiasts do not always exercise a wise discretion in the selection of suitable materials. When hardy fruit trees show unmistakable signs of weakness from poverty, rich, solid manure is the proper material, as it keeps the roots cool, and constant washing in soon changes the character of the growth and increases the size of the fruit. But Apricots and Peaches planted with the greatest care we are capable of bestowing always grow quite strong enough in the compost prepared for them, and become unfruitful and unmanageable when the growths are gross and root-lifting is neglected. Moreover, the roots as well as the shoots must have warmth to ripen them, otherwise bud-dropping, blister and gumming soon settle the account with the trees. Of two evils then it is best to choose the least by erring on the side of moderate growth of root and shoot, and getting them well ripened before winter sets in. Moisture, it is true, must be kept in the borders, otherwise the most valuable roots will suffer and the fruit will ripen prematurely; but this difficulty can be met by the use of stable litter, which, while preventing evaporation, will let in sun heat and air, and feeding where necessary can be supplied in the form of diluted liquid or artificial manure.

PEARS

must be kept closely pinched, and the leading shoots nailed or tied into the walls or trellises. Some kinds, notably Marie Louise, Louise Bonne of Jersey, the old Crassane, Pitmaston Duchess, and that excellent Pear Josephine de Malines, have set heavy crops and require much thinning. From these we have removed all the small and deformed fruit to favour the full development of those left, and trees on the Quince stock have been well mulched with half rotted manure, a material which the surface roots thoroughly enjoy. Many of these trees having been root-pruned or entirely removed in the autumn of 1884, aphis and drought prevented them from making much progress last year, but they took well to the new loam, thanks to a plentiful supply of water, and formed more flower buds than were needed for a crop. To these an extra supply of mulching has been applied, but a portion of it will be cast over the vegetable borders and forked in when the time arrives for letting warmth and drought into the soil in October.

RASPBERRIES AND CURRANTS

having made an immense growth of young and rather soft wood, the first should be well thinned down to five or six of the best canes, when the old ones are cut out and carefully tied with strips of matting to secure them from injury in wet and windy weather. The fine rains of the past fortnight having penetrated the quarters, the canes retained will become very strong, and the season being late, timely thinning to let in light and air is of more than ordinary importance. The Currants we thin out and shorten back to keep the trees within bounds, and let the sun into the spurs as soon as the fruit is gathered, while those upon which we wish it to hang for late use are slightly thinned, but not shortened, as we find a moderate quantity of foliage the best protection from sun and birds when other soft fruits become scarce. We do not, however, trust to foliage alone, as nothing short of stout herring netting will keep out those greedy marauders.

GOOSEBERRIES.

The heaviest crop we have had for some years has made very little wood; consequently the fruit is quite open to feathered foes now the fruit is ripe, but friends in the past, as immunity from insects is, no doubt, due to their vigilance through the early part of the season. To circumvent these and prevent them from taking more than their well-merited share, we transfer the nets from Raspberries to the Gooseberry quarters, and elevate them sufficiently to allow the pickers to pass underneath them. The worst pests we have to contend with are wasps; although abundant in the spring, they have not yet put in an appearance, and at the present time the weather, unfortunately for the crops, is against them. Nottingham or some other light small-meshed netting is the best protecting material, and this should be applied to trees or bushes before the wasps attack the fruit.

STRAWBERRIES

from which the crops have been gathered should forthwith be divested of runners, sticks, and ties to let in light and air. Old beds intended to stand another year, after being cleared of weeds and loose straw, will well repay another mulching with good rotten manure or fresh heavy loam to draw out new and feed existing surface roots. Where the land is light and unfavourable to the Strawberry, there should be a steady and constant gathering of suitable materials throughout the season for this purpose. Roadside parings, old Melon soil enriched with liquid, old lime rubble, anything, including marl, that is fresh, rich, and heavy, together with a fair quantity of soot, can be got together in an out-of-the-way place in every garden, and if turned over occasionally, it will be found invaluable for top-dressing or planting. If new beds have to be made, and the ground is vacant, no time should be lost in getting it properly prepared and planted. So much having recently been written, every reader of THE GARDEN now knows the Strawberry requires deep, rich, heavy soil, firm planting, plenty of room, and good mulching.

THE ORCHARD.

Now is the time to look through the plantations, and continue notes on the health, vigour, and general good or bad qualities of the trees. If too thick on the ground the least promising trees should now be marked for cutting down to let in light and air, as overcrowding is one of our greatest failings. The great difficulty we have to contend with in old orchards is the immense number of trees without names; but this can be got over by attaching numbers and entering them in a book, together with notes, until the varieties, if good, can be determined. If the autumn examination proves them to be bad, the sooner they are grafted or cut down and reduced to ashes for top-dressing the better. Apples this year are partial, and many trees are not in a condition for testing by their fruit; but work of this kind cannot be taken in hand and completed in one season. All that is wanted is a system of close observation; time and attention to the removal or improvement of that which is bad and the encouragement of the good will soon tell on the appearance and value of our most neglected orchards. Since my report was written I have examined a great number of small holdings on the fringe of the Hereford and Worcester plantations, and find my remarks that the crops will turn out better than was at one time anticipated more than realised. The best orchards are those which have been well grazed by stock or get an annual top-dressing. The lightest and poorest crops are on large farms where this system is only partially carried out or altogether neglected. In the first the trees will return a handsome profit; in the second the yield will be small and disappointing. Autumn and winter are no doubt the best seasons for draining and general overhauling, but the present is not an inopportune time for top-dressing. If the trees are carrying heavy crops, artificial or animal manures will improve the quality of the fruit and most likely insure a good set next year; if they are fruitless, a step in the right direction cannot be taken too soon.

Newly grafted trees should be examined, and the strongest of the young growths secured to sticks to prevent them from being blown out by the wind. This point secured, the less they are interfered with the better, as wild growth from the stems of large trees keeps the sap in motion and very often prevents them from going wrong in dry seasons. Notch cleft-grafting is the best system for mature stocks, as there are neither ties nor ligatures to look after; consequently the clay need not be disturbed at a critical time. Young stocks, on the other hand, on which the scions are growing and swelling fast should be examined, and the ligatures cut to favour free expansion at the union. The clay need not be removed, although the trees will do equally well without it. A few training sticks inserted in the ground, to which the young growths can be tied, will save many of the best from destruction in gusty weather. Young trees, like the old ones, we allow to make all the growth they throw out the first season, and only shorten back the second. We also frequently introduce three grafts where ultimately there will be left but one, as every leaf and twig the first year gives life to the closely-headed stocks, while the superfluous wood makes the best of scions for future use.

BUDDING.

We frequently are told that the finest of the old sorts of Apples are dying out, and so great is the prejudice on the part of native grafters, that they positively refuse to put on the scions. Grafts from old stunted trees no doubt make weak growth; the second generation is stronger, and the third is still better; but three removes take time, and as buds can always be obtained, the best way to resuscitate old sorts is by inserting them on the Paradise stock, the which, if healthy, will produce the best of wood for grafting on the free stock. One instance I will give. My grafter refused to put in grafts of an old favourite, the true Flanders Pippin. Unwilling to jeopardise his skill, I gave way. Buds were inserted on the Paradise, and next season he will have clean wood the thickness of one's forefinger and set with flower-buds, with which he will go away rejoicing. The budding of Apples in August

is very simple, and although I do not wish to tread on the nurseryman's heels, private growers who cannot buy any particular old sort true should certainly adopt this mode of helping themselves out of a difficulty. W. Coleman.

Eastnor Castle.

Indoor Garden.

POT CULTURE *v.* PLANTING OUT.

Experience has proved that there are a few greenhouse plants, and also some of the occupants of the stove and intermediate house, that succeed better planted out than in pots. For instance, some strong growing climbers, whose roots will not bear disturbance or breakage, do better in a bed of well prepared soil than in pots, as if kept in the latter they quickly exhaust the soil to such an extent, that it becomes difficult to keep up the requisite vigour in a way that will admit of sufficient shoot extension to afford the desired amount of bloom. Camellias, also, when they have attained considerable size, and where it is desirable they should fill as much space as possible, usually make more progress when planted out than when their roots are more restricted. Old plants of these, when they have got into a stunted condition, recover more quickly when turned out than they generally do if kept in pots. Stove climbers, as a rule, are much less impatient of having their roots disturbed by the removal of the old effete soil than are the kinds that thrive in a lower temperature, yet in the case of such things as Allamandas, the strong growing Thunbergias, and a few others of like character, it is sometimes found advantageous to plant them out, provided the space allowed is not so much as to induce them to make an undue amount of top-growth, for when this occurs the result is that the climbers shut out the light from whatever plants occupy the body of the house underneath in a way that reduces them to a state in which they are useless, unless the knife is used to an extent that is objectionable in several ways. It is scarcely necessary to say that the size and character of the house have much to do with the way in which the plants to be grown should be managed.

In structures as large as the Chatsworth conservatory, or the Palm house at Kew, planting out admits of being carried to an extent that is out of the question in smaller structures, and where there is room it is desirable that large growing plants should be treated in a manner that will allow them to show as much as may be of their natural character in the way that kinds that attain a large size are enabled to do when their roots are not restricted. But a common mistake now made is in turning plants out in beds in houses that, from their insufficient size, are wholly unsuited to this system of cultivation. This error is oftenest seen in Fern houses and in conservatories of limited size; in the former where a more or less attempt is made at growing the plants in the natural style and amongst artificial rockwork, planting out is right, provided the kinds selected are moderate in size and suitable for the house. Yet as often as otherwise some of the large tree species are planted out where, through the unconfined run their roots have, in a few years the heads grow to a size that is not only out of all proportion to the structure that contains them, but also causes them to smother all others that are overhung by them. The same thing occurs in conservatories where Palms and Tree Ferns are turned out in beds where they quickly reach a size such as compels their being removed, which, in the case of Palms, means destruction, as the plants rarely do any good after the loss of roots unavoidable on taking them up after being planted out. And as regards Tree Ferns, they so far dislike the loss of roots consequent on removal, that they are some time before they get over it. The fact is, that when plants of the character named are turned out in unsuitable places a mistake is made like that which is often committed in tree planting in pleasure grounds, where it seems as if there was an absence of any thought that the plants would grow larger.

If a house of the character under notice should be occupied by some half-dozen plants alone, planting out would be the right course to take. But the object which it is most desirable to attain is to get as much variety as possible by adopting a course of cultivation that will give accommodation to as large a number of plants as can be kept in a thriving state. This, fortunately, can be done with the plants grown in pots, tubs, or boxes by the plunging of which in beds a natural appearance is secured, with the advantage that whilst the growth of the plants is thus necessarily restricted, they can be kept for a long time in a healthy condition, such as will admit of their showing sufficient of their natural habit to satisfy reasonable requirements.

During late years some attempts have been made to plant out permanently various kinds of flowering stove and greenhouse plants in addition to such as have been already spoken of—Gardenias, Eucharises, Roses, &c. The advantages claimed are, that labour is saved in watering, and that the plants make more growth. Something may be set down to the former, as the roots will not dry up so quickly in a bed as they will where confined in pots. As to a greater amount of growth being obtainable where the roots are not confined, this is deceptive, for, though the plants so circumstanced may individually under ordinary cultivation make more growth than when in pots, still the house in which they are grown can only hold so much, and so, supposing that they grow larger individually, fewer would fill it. As to the quantity and quality of the flowers produced, which are ordinarily the chief considerations in the matter, plants in pots occupying a given space when they get right treatment will yield as fine flowers, and quite as many of them, if not more, than when planted out. For the longer, more straggling growth that always is made where plants have an unrestricted root-run does not admit of as large a number of flowers being forthcoming within the same space.

It may be urged that on account of some of the plants that are subjected to planting out getting larger than they often do when in pots, something would be saved through fewer being required to fill a house. But the kinds generally so used are so easily increased, that nothing worth naming can be reckoned on that head. All that can be set down in favour of planting out *versus* pot culture is the saving of time in watering, and against this there are two objections which much outweigh the gain thus claimed. The first is, that there can be little control brought to bear on the time of flowering of the plants so managed; they are fixtures; nothing can be done in the way of moving a portion of the stock of any particular kind, either when it is desirable to bring them on into bloom or to retard them; all necessarily have to come on together. This is inconvenient enough when a house is filled with one thing, such as Tea Roses, for instance, but it is worse when the turned-out plants, as they often are in private gardens, are in a house with various other things that need to be either brought on or kept back in a way opposite to that which the turned-out plants happen to require, the result being that the flowers either come in when not required, or are not existent when wanted, or do not open in the right quantity to give the needful succession. The second objection is the difficulty that exists in dealing with insects, which are inseparable from plants that are in a fixed position under glass; in the case of any that are subject to the attacks of scale or mealy bug, the labour of cleaning them and the waste of any kind of insecticide that is used, are very much more than where the plants individually can be moved and placed in the best position for ridding them of the pests with which they may happen to be affected.

It might be supposed that if the planting-out system answered anywhere, it would be with the leading market growers, who, from the quantities they cultivate of the various things they take in hand, often have a number of houses occupied by the same kind of plant, concerning which they would find it to their advantage to adopt the practice. Yet all that I have known who have tried the proceeding have given it up, finding that any apparent gain attached to planting out was overbalanced by the drawbacks that I have pointed out. T. B.

Garden Flora.

PLATE 556.

LILIUM LONGIFLORUM.

(WITH A PLATE OF L. LONGIFLORUM HARRISII.*)

Of L. longiflorum several varieties exist in gardens, but amongst them Harrisii has had by far the greatest share of attention paid to it. This variety is also known as the Bermuda Lily, a name under which a fine spike bearing five flowers was shown at South Kensington by Mr. G. F. Wilson in June, 1883. It is thought to be superior to the ordinary longiflorum in regard to the following points: first, its precocity when forced, blooming as it does in January; secondly, its being more floriferous, large-sized bulbs yielding five and even eight blossoms; thirdly, its prolificacy as regards reproduction, single scales making flowering bulbs in one year, and small bulblets of the size of Peas flowering the first year after being potted. Mr. Hovey, with whom this Lily is a great favourite, has always strongly advocated its claims; when it flowered at Kew, and was decided by Mr. Baker to be the same as eximium, he wrote thus respecting it: "I have had some 500 plants of Harrisii in flower for over six months; potted in October, they began to flower in February, and I could cut to-day (July 24) twenty-five lovely flowers from the same plant that flowered at Easter, when I had a magnificent show, and disposed of quantities of plants 3 feet high, some with two stems and some with only one each, being furnished with from three to five flowers, though the bulbs were very small. No eximium ever did this, besides which it is very much larger, being nearly twice as large as longiflorum." Our supply of L. Harrisii seems to have been from two sources, firstly from Bermuda, and secondly from the United States. The Bermuda bulbs are mostly much larger than any of longiflorum which we are accustomed to see; they produce a stem from 3 feet to 6 feet high, crowned with from three to eight of such blossoms as are here depicted. If treated as a greenhouse plant this Lily blooms during the latter part of June and in July, and soon after flowering, that is before the stems are dead, two or three shorter ones are pushed up from the bulb, and these generally bear one or two blossoms each. In this way a succession of flowers is often kept up till Christmas; indeed, at that time we had several flowers of this fine Lily in full beauty, as well as two or three late blooms of L. neilgherrense. The American bulbs are, as a rule, much smaller than those from Bermuda, but in proportion to their strength they are quite as prolific as regards the production of a second crop of stems, though being weak many of them do not flower. Harrisii differs from L. longiflorum in having narrower leaves more scattered on the stem, and in the flowers being less reflexed than those of the typical kind, while a side-by-side comparison of plants of equal strength of eximium and Harrisii when in flower would lead most people to decide that they were the same; but eximium, as grown in this country or imported from Japan, does not yield a second crop of flowers as freely as Harrisii, though it does so to a certain

* Drawn in Mr. Kendall's garden, Cornwall Lodge, Kingston Hill, July 10, 1885.

LILIUM LONGIFLORUM HARRISII

extent. These characteristics belonging to Harrisii may, however, disappear after a few years' cultivation in this country, but at present it is certainly the best of the longiflorum class.

L. longiflorum itself has long been known in this country, having been introduced from Japan early during the present century. Its name is now, however, a misnomer, its flowers being surpassed in length by those of L. neilgherrense, philippinense, and Wallichianum. Amongst other more prominent varieties of L. longiflorum, besides those just mentioned, may be named Takesima, the principal distinctive feature of which is the purplish tinge that exists in the exterior of the blossoms, especially when in the bud state. In the variety albo-marginatum the leaves are clearly edged with white, but the flowers are the same as in the ordinary form, but are sometimes rather more satiny in texture. A very distinct variety of L. longiflorum is formosanum, introduced from the island of Formosa. This possesses several features so well marked as to almost, if not quite, entitle it to rank as a distinct species. It has more the character of L. philippinense than that

Bulbs of Lilium longiflorum.

of longiflorum, being a slender-habited plant with narrow leaves, but the flowers, instead of being very long, as in L. philippinense, are shorter and rather more widely expanded than in the other varieties of L longiflorum. They are pure white within, but tinged with purple on the outside. Another name which frequently crops up in catalogues is Wilsoni; but as usually grown I fail to see any difference between this and eximium.

The culture of L. longiflorum and its varieties is comparatively easy; while many Lilies are difficult to deal with, these can be not only grown and flowered well, but increased to almost any extent. If planted out of doors the most suitable soil for them is a good, open, sandy loam, in a well-drained, but, at the same time, not dry spot. The bulbs should be at least 6 inches below the surface, and if the soil is at all holding, a good plan is to surround them with sand. In common with all other Lilies, these are most effective when arranged in bold masses or clumps, instead of being dotted singly here and there. To the outdoor culture of these Lilies a couple of objections might be raised, viz., should the weather prove showery, the yellow pollen stains the spotless purity of the blooms, and, moreover, in showery weather the tube splits, and the flowers present a ragged appearance.

As L. longiflorum and its varieties readily submit to pot culture, great numbers are grown in that way. The bulbs should be potted as soon as received in a good open loamy soil with which a little well decayed manure has been incorporated. They may then be placed in a spot sheltered from very heavy rains (if in a frame plenty of air must be given them) till signs of growth make their appearance above ground. If required to bloom early, the most forward may be then shifted into a warmer structure—say, a good light house in which the winter temperature ranges from 50° to 60°. Treated in this way the first lot will bloom in March, and by introducing occasional batches, a succession of blooms may be had till they open on plants out of doors. The long-tubed forms, either eximium or Harrisii, are much more amenable to forcing than those of the ordinary type. The sized pots in which they should be placed will depend upon the purposes for which they are required; for a good-sized single bulb a pot 5 inches in diameter will be needed, while three bulbs in a 6-inch pot form useful little specimens, but, if required, large pots can be filled with a number of bulbs, and thus form large clumps. The relative sizes of pots refer, of course, to ordinary bulbs, and not to the very large bulbs of L. Harrisii, that are imported from Bermuda, some of which will fill a pot a foot in diameter with roots. Thorough drainage is as great a necessity in pot-culture as in the open ground; the roots must not on any account be allowed to become dry; when well drained, copious supplies of water can be given without danger. When the buds begin to swell, weak liquid manure will be of service. The greatest enemies of these Lilies are aphides, which increase most rapidly, and not only injure the foliage, but cause the buds to become deformed, so much, indeed, that unless checked, very few flowers will open properly. Fumigation, or dipping in tobacco water, will kill these pests. L. longiflorum and its varieties can be quickly increased to an almost unlimited extent; when growing freely not only does the principal bulb often separate into two or three, but minor offsets are also produced, and the buried portion of the stem is generally thickly studded with small bulbils, that rapidly increase in size when detached from the parent plant, and soon become strong enough to flower. Another way, and one that has been largely followed in the case of Harrisii, is to strip off some of the outside scales, an operation that can be done without injuring the bulb in any way. These scales should then be laid in pans of light sandy soil, and just covered with the compost. If placed in a warmish structure they will form small bulbs by spring, when they have still a season's growth before them till autumn sets in. The smaller scales may be planted entire, and the larger ones separated in the middle without any ill effects.

H. P.

THE EDGE HALL ROCK GARDEN.

In my opinion there is no gardening like hardy plant gardening, and especially like that on rockwork and mounds. I have just returned from a visit to a well known garden in Cheshire where rockwork gardening is admirably carried out. Pressing home work keeps me from many pleasant and instructive visits, but being obliged to go to the neighbourhood of Liverpool, and having my son with me, I could not resist the pleasure of a few days at Edge Hall. Much had been done since my last visit, and the rockwork, with its varieties of stone, is wonderfully successful, and shows what energy, perseverance and study, assisted by an excellent library, will do in a climate colder and damper than that of our home counties. Many of the plants, some of them difficult ones, grow in such vigour, that it shows that the climate suits them, but sheltering rock and judicious lightening of soil make others grow which prefer warmer and drier situations. Campanulas have always been favourites with Mr. Wolley Dod. Some of the rarer ones were simply masses of bloom. A favourite plant of my old friend Mr. Atkins, of Painswick (Onosma tauricum), had grown more luxuriantly than I ever before saw it. Arnebia echioides showed itself thoroughly at home, as did many of the rare Saxifrages. I will not attempt to enumerate the different plants which are in great numbers and many of them rare. I was much interested to find that Mr. Dod, by his broken granite, had arrived at results which we have been attaining by different means, but on the same principle. In his garden beds Lilium pardalinum in all its varieties and L. testaceum were very fine and in great vigour, and in a rough cold Lily house L. Parryi, L. Humboldti, L. Washingtonianum and L. dalmaticum were as fine as I have ever seen them under any treatment. People often speak of gardening as a pleasant amusement; it is, of course, a pleasant occupation, but, carried out as it is at Edge Hall, it is a study, and as much a science as any of the other more recognised sciences. In conclusion, I would advise anyone with plants, especially alpines, which they cannot master to send some to the Rev. C. Wolley Dod, Edge Hall, Malpas, Cheshire, and I shall be surprised if he does not discover how to make them grow. G. F. Wilson.

Heatherbank, Weybridge.

MARKET GARDENING IN MIDDLESEX.

The dripping weather which we are now having is decidedly favourable to market gardening operations. The chief market gardens in my neighbourhood have a light and rather stony soil, from which water passes away freely, and thus it is soon workable. In a large plantation of standard Victoria Plums, planted about six or seven years ago, the crop is a very small one; it does not average more than ten or twelve fruits on a tree. Last year the trees bore enormously, their branches being borne down to the ground by the weight of the fruit that was upon them. This spring there was abundance of blossom, but, owing to the heavy crops last year and partly, perhaps, to the drought of last year and the inclement spring of this, there is little fruit. The trees are, however, making grand growth, which indeed fruit trees everywhere are doing, and they appear to be wonderfully free from blight. Trees bearing a light crop this year appear to be very thickly furnished with fruiting spurs for next season. Raspberries grow between the lines of Victoria Plums, and, being moist at the roots, they produce excellent crops, which are now being gathered for preserving. Close at hand is a piece of Early Dwarf Erfurt Cauliflower for seed purposes; it is in full bloom, and the plants are singularly clean and free from blight. Nothing else belonging to the Brassica tribe is in flower near it for miles round; therefore no fear of injurious fertilisation need be apprehended. The plants were put out very early in spring in patches of three under hand-lights, and, being in a warm sheltered spot, they did remarkably well despite the trying spring weather to which they have been subjected. This year for the first time, according to my own observation, Leek seed was drilled in the open ground. Hitherto it has been the practice to raise the plants in a seed-bed in a cold frame and transplant. Last year but few of the Leeks comparatively that were transplanted matured well; it was hot and dry when they were put out and scarcely any rain fell, the result being that the Leek crop almost failed, because so little growth was made. The Leeks sown in the open are now very strong plants, and in another month or so will be large enough to market. It was necessary to thin out some of the plants, and such thinnings were used to fill up vacancies in the sown lines in which there were gaps. A great many young plants sown in the ordinary way have just been put out, and the showery weather is enabling them to get a good start. Leek culture appears to be extending in this part of the county.

Tomato growing is extending wonderfully in the open air in this district. One grower has nearly three acres on light, stony land, and no crop could look better.

The sort mainly grown appears to be an early and free-bearing variety of the ordinary Large Red type. A good mulching of long manure, as brought from London, has been placed between the rows, and now the workmen are going over the plants and pinching out the laterals, so that the fruit—in the case of the earliest plants half developed—may have the full benefit of sun and air. The plants are about 2 feet or so in height, and have two and three main stems. If the weather proves favourable there will be a heavy crop, and it is said to be a good paying one.

The ground cleared of spring Coleworts was, some six or seven weeks ago, planted with Brussels Sprouts, and the plants have already acquired considerable size. A large space of ground on which scarlet, purple, and white Ten-week Stocks for bunching for market grew has been planted with Coleworts, which will be marketed in autumn. Spring Cabbages are already above the soil in the seed beds, and they appear to be unusually free from fly. Large breadths of Turnips have just been sown for autumn. Runner Beans are now good. They were late in starting into growth, but having done so are now growing freely. Here it is the practice to sow clumps, each consisting of three beans; then three sticks are placed, one to each plant, and tied together at the top. They are from 4 feet to 4½ feet high, and thus supported beans are produced in abundance. The sort selected is the Painted Lady, chosen no doubt on account of its earliness. By the side of them are lines of dwarf Negro French Bean, a universal favourite with market gardeners. There are gaps in the lines showing that weather and slugs had at one time checked their growth, but the plants having been earthed up within the last week or so are now doing well.

Vegetable Marrows are doing well this season. Last year it was difficult to get anything like growth into the plants put out in the ordinary way, owing to the drought; now they are growing with great freedom and bearing large crops. A good selection from the long white Marrow appears to be the favourite kind here. Some of the market gardeners who have plenty of frame room raise plants of Vegetable Marrow in early spring, and plant them out in the frames, covering them up carefully at night, and giving adequate protection in frosty weather. These plants furnish an early supply under glass; then, as soon as the weather admits of its being done, the lights are removed, and the extending shoots are allowed to overflow the sides of the frame, and spread themselves over a large space. In this way a good supply of Marrows is got into market early, when prices are remunerative. A good surface mulching of long manure is always given to Vegetable Marrows, and this tends to keep the surface soil cool and moist, and prevents the fruit from becoming splashed through rain.

The Beet crop looks wonderfully well. The sort grown is what is known as the Covent Garden, or Pine-apple Beet, a handsome dark variety. The Dell's Crimson-leaved type is too small for market work, though so rich in colour. Ugly shaped roots of Beet, not good enough for market, are manufactured into dog food. The summer crops of late spring-sown Fulham White Cos Lettuce will soon be ready to pull. Ground occupied by early-sown plants will be planted with Coleworts and Cabbage for spring, and successive crops of White Cos Lettuce are now being dibbled out. R. D.

Adiantum rubellum.—Most Ferns are remarkable for their fresh greenness, but several of the Maiden-hair kinds are delicately tinted with dark rose or rosy purple. A. rubellum is one of the most ornamental in this respect, its delicate fronds being richly tinted with a roseate hue, which is all the more apparent when contrasted with other forms of the Capillus-veneris section to which it belongs. The plant is dwarf and compact in habit, and its elegantly tinted fronds, which are produced in abundance, vary from 6 inches to 8 inches in length. It is a native of Peru, and to Messrs. Veitch & Sons, of the Royal Exotic Nursery, Chelsea, we are indebted for its introduction to our collections. It grows well in a cool fernery, or anywhere where there is a very moderate temperature. Its culture is as easy as that of other Maiden-hair Ferns; it should be treated to fresh fibrous peat and sand, together with a moderately humid atmosphere and a liberal supply of moisture at the root when growing.—N. B.

Fruit Crops.

SUPPLEMENTARY ENGLISH REPORTS.

Tortworth Court, Falfield.—Fruits hereabouts this season are most abundant. Peaches and Nectarines are over the average, and good. Apricots are very good. Apples quite an average crop, and promising to be good. Pears and Plums also most abundant. Cherries are over the average, and good bush fruits of all kinds are excellent. Raspberries a full crop and good. Quinces, Medlars, Cob Nuts, Filberts, and Walnuts quite average crops. Strawberries, owing to the exceedingly hot dry weather, have not been so satisfactory as usual. We find Vicomtesse Héricart de Thury and Keen's Seedling to be our earliest and best. These, with President, Sir Joseph Paxton, James Veitch, and Oxonian, are the best for this district.—Thomas Shingles.

Luton Hoo, South Beds.—Apples are abundant on some trees, while on others the crop is light. Most kinds of Apples succeed well in this district. Our crop will be over the average. Apricots do not succeed well here; they are very liable to canker, especially the finer sorts. Cherries are a good crop, but small, on account of the dry weather. Currants of all sorts are abundant. Figs are promising and in good health. Gooseberries are a wonderful crop, weighting the shoots to the ground. Nectarines are a fair crop, as are also Peaches, but the leaves of the trees are much blistered, owing to the prevailing cold weather which in their earlier stages they encountered. Plums of all sorts, excepting Damsons, are a very heavy crop. Pears are under average on walls, but good on pyramids. Raspberries are a good crop, but very small. Strawberries are under the average, many of the plants being blind. Our standard sorts are Sir Joseph Paxton and President, the fruit of the latter being large and well flavoured; it is our favourite variety. My system of culture is to make a new plantation every year, consisting of plants that have been forced, and to destroy the old ones. This I find to be better than keeping plants two years on the same ground.—Wm. M. Baillie.

Bulstrode, Bucks.—Apples here, and in most gardens in this district, are rather thin. Plums, too, are under the average, but in some places they are a full crop, both on walls and standards. Pears are rather under the average. Of Nuts we have not half a crop, and of Walnuts none. Peaches and Nectarines are fair crops, but Apricots are very scarce. Morello Cherries here are an average crop; other kinds abundant. Gooseberries and Black, White, and Red Currants are full crops. Although Strawberries flowered well, they are a very poor crop, owing to the cold winds and rain which we had from the 10th to the 17th of last month. In some gardens they are, however, an average crop.—W. Waters.

Castle Gardens, Warwick.—With the exception of Apricots, all fruit trees here are carrying excellent crops. Apples and Pears are above the average; Peaches, Nectarines, and Figs a fair average. Of Cherries and Plums we have very heavy crops; old people say there never was so heavy a crop of Plums in this district before. All small fruits, with the exception of Strawberries, are plentiful and good. Strawberries suffered much from cold winds when in bloom and from drought when swelling, causing the crop to be light and the fruit to be indifferent in quality. I find the following varieties to suit this district best for crop and quality, especially the first three named, viz., Vicomtesse Héricart de Thury, President, Sir Joseph Paxton, James Veitch, British Queen, and Oxonian. For regular supplies of good fruit I find it best to make a fresh plantation every season by taking runners as soon as possible, and planting them in a bed of good soil; then removing to their fruiting quarters when they have made roots enough to lift with good balls of soil. After the third or fourth crop of fruit is gathered all plantations are destroyed. —A. D. Christie.

Wroxton Abbey, Banbury.—The fruit crops in this garden and neighbourhood are, on the whole, under the average. Apricots are very much under it. Of early Apples we have a few, but late ones are quite a failure. Peaches are an average crop. Plums are very heavy crops. Bush fruits we also have in abundance, Raspberries being laden with very fine fruit. Our Strawberry crop is very much under the average. The British Queen is our best flavoured variety; Dr. Hogg comes next. Sir Joseph Paxton does best in this district, and it is also my best kind for forcing. Vicomtesse Héricart de Thury does well here, and so also does President. Black Prince is our earliest variety. Keen's Seedling is the best for early forcing.—Thomas Doherty.

Shardeloes, Amersham.—Peaches here are a very good crop, and the trees clean and healthy. Apricots do not do well here, and on the few trees which we have there is scarcely any fruit. Plums are abundant both on walls and standards; we find Victoria to be the most useful and a sure bearer. Coe's Golden Drop is a valuable late Plum, and of this we have a fine crop, and the trees are clean and healthy. Pears are a very thin crop, and so are Apples. Gooseberries, Currants, and Raspberries are abundant and very fine, especially Black Currants and Gooseberries, which are wonderful crops. Figs are very good crops. Cherries are a fine crop in orchards, and our Morellos on north walls are excellent, and there is scarcely a black fly on them. Of Strawberries we have had a good crop. We cultivate only a few varieties. We find Vicomtesse Héricart de Thury the best for forcing and early work outside. In addition to this we grow British Queen, Sir Charles Napier, Bicton Pine (white), Filbert Pine (very good), Duc de Magenta, Frogmore Late Pine (a very valuable late Strawberry), President, and Dr. Hogg. We never keep the plants more than two years. We plant a yard apart from row to row, and 18 inches plant from plant, and never dig between them. We mulch well late in the autumn, and place a good lot of long litter between the rows after the fruit is set, which serves to keep it clean and the ground moist. Unless the weather is exceptionally dry, we scarcely ever water.—Thos. Bailey.

Harewood House, Leeds.—Apples here are nearly a failure. What fruit we have are on young trees, consisting of such varieties as Stirling Castle, Echlinville, Lord Suffield, and Warner's King. Pears are quite a failure. Cherries plentiful and good. Plums a light crop. Apricots scarce and very poor. Peaches outside are good crops, but late. Gooseberries, Currants, and Raspberries are heavy crops. Strawberries plentiful, large, and of good quality. The varieties grown here are James Veitch, President, British Queen, and Loxford Hall Seedling.—James Fowler.

Wortley, Sheffield.—Everything is about a month late this season. Crops generally are fair; small fruits abundant. As to Strawberries, Vicomtesse Héricart de Thury is one of the most constant and reliable ever tried in this district, and is a favourite. Both here and in other gardens such sorts as the old and generally prolific Keen's Seedling go barren. Black Prince is good, and that and the first named are also the best forcers. British Queen and allied varieties do little good, but James Veitch promises well. La Grosse Sucrée soon becomes gross and abortive. I have tried most of the popular kinds.—J. Simpson.

Studley Royal, Ripon.—Of Strawberries, Vicomtesse Héricart de Thury, Keen's Seedling, and Sir J. Paxton are all good croppers. James Veitch is large, but rather coarse. Sir C. Napier,

President, Dr. Hogg, and British Queen are our best as regards flavour. Elton Pine is still one of the latest. These, we find, give us regular and constant crops. We take forced plants for making fresh plantations every year, planting on well-manured ground, and destroying a corresponding portion annually. The crop this year is very good, but our strong ground is favourable to Strawberries. Bush fruits are plentiful, though the Currant crop was somewhat injured by the cold winds which prevailed during late spring and early summer. Raspberries seem to have suffered from the dry weather. Plums are a failure so far as our garden is concerned, but I hear of heavy crops occurring in some places. Apricots are plentiful, but the trees have suffered much during these last few years. Ours have been planted twenty-five years, and are going off in the usual way—part of a tree at a time. During twenty years they have only failed once to carry good crops; and I may add that they have never been covered in spring for nearly that length of time. Pears with us are a very light crop indeed. Apples are very partial, and, as a whole, a light crop; the cold winds and frost late in spring withered up all the blooms, which seemed to be weak this year. Peaches we grow principally under glass, but what few trees we have out of doors have fair crops on them. Nuts are a very light crop.—John Clark.

Ribston Hall, Wetherby.—The fruit crop here this season is under the average, with the exception of small fruits. Apricots and Plums are under the average. Of Cherries we have a good crop. Peaches and Nectarines, Apples, Strawberries, and Nuts are all under the average. Small fruits, such as Currants, Gooseberries, and Raspberries, are good crops in this neighbourhood. Strawberries can be bought for 3d. per quart, and Gooseberries for 4d. and 5d. per stone of 14 lbs. Cherries, Currants, and Raspberries are equally cheap. The very best Strawberry for forcing and outside culture here is Empress Eugénie. I grow eight or ten other sorts. Sir Harry, Garibaldi, and Ne Plus Ultra are sorts that do well with us in ordinary seasons. I fruit my plants for three years, and in order to keep up a succession, I plant six rows every year, and cut up six rows that have fruited three years.—Thomas Jones.

Duncombe Park, Helmsley.—Apples, Apricots, and Pears are almost a failure. Morello Cherries and Plums, especially the Victoria, are plentiful. Currants of all sorts are a good average, and Gooseberries a very heavy crop indeed. Strawberries have done fairly well, considering the protracted drought which occurred between the time of setting and ripening. Among the following varieties—James Veitch, President, Keen's Seedling, and Ne Plus Ultra—Vicomtesse Héricart de Thury is decidedly the best as an all-round Strawberry, *i.e.*, taking into account quantity, size, colour, and flavour. Keen's Seedling is our earliest variety; Black Prince is too susceptible of mildew for our tenacious soil and low lying situation. President we like for flavour, Vicomtesse Héricart de Thury for a cropper; Keen's Seedling for early work, and Elton Pine as our standard late kind. Bothwell Bank Prolific promises to be a heavy cropper; it is of good size, but deficient in colour, and as regards flavour not equal to President. Prince of Wales is so acid, that I have determined to consign it to the rubbish heap this autumn. In order to secure good crops on our strong loam, plantations are made on ground previously that has been cropped with Broccoli; it gets an ordinary manuring when it is dug previous to planting in August, and a good mulching of stable yard manure before the plants come into bloom; thus treated, and well supplied with water should drought set in, they yield heavy yields for seven or eight years.—J. Riddell.

Stricklandgate, Kendal.—Apples here are under the average; Keswick Codlin, Lord Suffield, Manks Codlin, and other Apples of the Codlin section are bearing good average crops, but all other varieties with but few exceptions are a complete failure. Pears are a fair average crop; the best sorts are Marie Louise, Althorp Crassane, Beurré Diel, Beurré d'Amanlis and Winter Nelis. Plums are an average; Victorias are over the average; Damsons are a good average. Cherries are over the average; May Duke is the principal sort grown. Peaches and Nectarines are average crops. Apricots are very little grown. Gooseberries are over the average. Raspberries, average. Currants, Red and White average; Black under the average. Strawberries are good average crops: the best for flavour and bearing are John Powell and President; the best district varieties are Vicomtesse Héricart de Thury, Sir Harry, John Powell, President, Sir Joseph Paxton and Keen's Seedling; the best early kind (excluding Black Prince, which being small is little grown) is Vicomtesse Héricart de Thury: the best late varieties are Elton Pine and Myatt's Eleanor; other varieties grown to some extent are Rivers' Eliza, Cockscomb, Duke of Edinburgh, Sir Chas. Napier and J. Veitch. The best plan to secure good and regular crops we find to be to renew the plantations every fourth year and by planting the following varieties we have always obtained most satisfactory results, viz., Vicomtesse Héricart de Thury, Keen's Seedling, John Powell, President and Myatt's Eleanor; the variety grown more than any other in this locality is undoubtedly John Powell, the fruit of which is large and well coloured, and being a very heavy cropper it is being more extensively planted yearly. Nuts are an average crop. Fruit prospects in this district were much blighted by a snowstorm which occurred on May 12. The wind blew with such violence, that many fruit trees were denuded of both blossom and foliage, and the snow laid from 6 ft. to 9 ft. deep in some of the valleys. Many shrubs which had stood the previous trying winter succumbed to the effects of this storm.

Potatoes.—Early varieties are a very light crop, owing to want of rain to swell the tubers. Late varieties look well; as yet there is no sign of disease. A considerable breadth of Potato in the low lands at the mouth of Morecombe Bay were cut down to the ground by frost on July 16.—Robert Craig.

Waterdale, St. Helens.—In this neighbourhood the fruit crops are variable, according as the situation is sheltered or exposed. Pears are a fair crop all round, and the same may be said of Apples, with the exception of Lord Suffield, Keswick, and Hawthornden, on which the fruit is very thin. Cherries are very good. Plums fair, and Damsons an immense crop, and the same may be said of Gooseberries. Currants of all sorts are good. Raspberries a fair crop, Fastolf being the best cropper and good in flavour. Strawberries are only a light crop; Black Prince has been the best for quantity. Vicomtesse Héricart de Thury is good. President is the best for evenness of fruit and cropping; it also bears carriage well. Sir Joseph Paxton is fine as regards fruit, but only moderate in quantity. British Queen is still the best, but on our deep, cold, clay subsoil it is not so fruitful as I have had it on deep light soil under the following treatment. My plan was to trench the ground 2 feet deep; in each trench to put two layers of rotten manure, cow manure being best, and when the plot was all trenched to give a good coating of clay dust, treading it as hard as possible. The plants were put in 2 feet apart each way. The chief point was to select the runners from good fruiting plants. A system which I always found to answer well was to select the quantity of forced plants which I required when in fruit, marking them by putting a peg in each pot; when all the fruit was gathered I removed them to a frame, and gave them a good drenching with the garden engine every day for a week or so. This cleansed the foliage, and then the plants were gradually hardened off for planting out. Before planting out I remove the crocks from the bottom, and with a wooden peg loosen the outside of the ball to liberate the roots, pressing the soil solid round them, and if they show any bloom buds in the autumn I pinch them out, which strengthens the plants for the following season. In spring the bloom buds will show early, but pinch them off as they show themselves in order to encourage runners, which, if pegged down as they grow, will be ready for planting out by the time the early Potato ground is vacant. Any runners the young plants may make in the autumn must be pinched off as they appear. The following spring most of the young plants will show a good truss of bloom or more, and produce some fine fruit. Remove all the runners as they appear. I never dig among Strawberries, but as soon as the crop is gathered I remove all the runners and a few of the outside leaves. I then give a good coat of clay dust and half rotten manure, which the rain carries down to the roots, leaving the litter on the surface to protect the fruit from being soiled. At the end of the third season I trench them down and make a new plantation every year. I found this system to answer best, both as regards quantity and quality. Anyone not forcing plants may select from the open ground by placing a peg to the most fruitful plants and removing the runners from the others to prevent them from getting mixed. This may seem a good deal of extra labour, but in order to get the British Queen to crop well it must have liberal treatment, which also suits all sorts. The clay dust is made by keeping a regular supply of lumps about the boilers to dry. On wet days it is broken up, run through a fine sieve, and then placed in a dry shed ready for use when wanted. It is thirty-two years this season since I first used clay dust and a light boggy soil for pot Strawberries, and the result was so satisfactory that I have used it more or less ever since in the case of many pot plants besides Strawberries, and with equal success.—James Smith.

Lowther Castle, Penrith.—Of Apricots we have a very few indeed. Plums on walls, such as Victoria, Denniston's Superb, Impératrice, Prince Englebert, Magnum Bonum, and Golden Drop, are an average crop; standards and bushes in the open are a failure, as are also Damsons. Apples, with the exception of a few varieties, are very scarce. The sorts that are carrying the best crops this season are Keswick Codlin, Stirling Castle, Tower of Glamis, and Echlinville. Gooseberries and Red, White, and Black Currants are good crops, also Raspberries and May Duke Cherries; Morellos are under the average. Strawberries when in bloom gave promise of being a full crop, but owing to the hot, dry weather which prevailed for some time after they were set, most of the later fruits were destroyed, thus leaving us with not half a crop. Nor is the fruit so fine as in former years; our best sorts this season are Garibaldi, President, and Duke of Edinburgh; these are carrying an average crop of fairly good fruit. Our mode of culture is as follows: The strongest and best runners are layered in 5½-inch pots, and when established are planted on good prepared ground at 2 feet 6 inches row from row, and 2 feet plant from plant. We give them a good top-dressing of half rotten manure as soon as the fruit is gathered, and again early in the following spring; no digging or forking amongst them is allowed from the time they are planted to the doing away with the plantation, which takes place after the fourth year of fruiting.—Frederick Clarke.

Worsley, Manchester.—Our orchard crops generally are deficient, especially Apples, of which the mid-season and late keeping varieties are, as a rule, a complete failure; early varieties are a fair crop, and promise to be of good quality. Pears are very thin and irregular; stone fruits are better than usual, though on our soil (border of Chat Moss) they are never a great success. Gooseberries and Currants are excellent crops, though in some quarters aphides have completely destroyed the growing shoots. Strawberries have been abundant and good, perhaps a little under size, but excellent in colour and flavour. No variety is so generally appreciated as Vicomtesse Héricart de Thury. It is an abundant and constant bearer, bright in colour, handsome in shape, brisk and rich in flavour, and equally suited either for dessert or preserving. I have yet to discover a Strawberry combining so many good qualities,

or one that will adapt itself so well to either light or heavy soil. La Grosse Sucrée is also a favourite here, especially for forcing outside; its tendency to bloom early, however, often subjects it to spring frosts. President is likewise an excellent variety, our great objection to it being that either forced or grown outside it is liable to decay with the slightest damp. For late varieties, British Queen and James Veitch suit us best. We have Helena Gloede on trial, and it promises to be good. I have recently tried Pauline, but I find it to be so uncertain a fruiter, that it must be abandoned. Bothwell Bank I consider a good variety of President, hardly so dark in colour, and generally better shaped; in other respects it is identical. We get best results from planting forced plants, our soil being generally light; we, as a rule, destroy the plantation after the third crop has been gathered; all runners are kept carefully cut off, and the soil is superficially picked up in spring, and mulching with good manure is given just before the bloom shows itself.—W. B. Upjohn.

Seaham Hall, Sunderland.—Gooseberries and Currants, Red and Black, and Raspberries are abundant here. Apples of almost all sorts are a failure, owing to the cold winds we had in spring. Lord Suffield and the New Hawthornden have a few on them. Pears are also scarce; only a few are to be seen on the Jargonelle. Of Strawberries, the most suitable kinds that are grown in this locality are the Black Prince for furnishing early fruit, and President and Ruby are good useful sorts either for forcing or for general use. Comte de Zans is another favourite; this is a sure cropper, and good for forcing. High culture is the secret of success, nourishment having been furnished at the time of flowering and colouring. In this locality several kinds do not fruit well; they have a tendency to grow to leaf instead of flowering. British Queen and Alice Maude are doubtful sorts to plant extensively without a trial in a small way.

Potatoes look well, and the crops in general look well after the late rains. No disease has been noticed in Potatoes up to this date (July 23). —R. Draper.

Knowsley, Prescot.—In this garden Apples and Pears will be less plentiful than usual, especially late sorts. Apricots are a good and promising crop. Peaches are plentiful and promise well, the trees having kept clean and healthy. Cherries are not perhaps quite so equal all through; nevertheless they are good, one of the best being Governor Wood. Plums promised well at first, but seem likely now to disappoint, although I never saw the trees look better. Gooseberries, Currants, and Raspberries are carrying heavy crops, and now that they have got the much-needed rain they seem likely to finish well, but late. Our Strawberries were mulched early in the season, and to this may perhaps be attributed their success in spite of adverse weather. They are later than usual, but plentiful, and of good size and quality. Our indoor crop of Strawberries is of more importance to us than those from the open ground, and therefore we grow chiefly such sorts as succeed best in pots under glass, almost the only exceptions being the Grove End Scarlet and the alpines, which are indispensable. We take our runners from the plantation made last year and fruit from the two-year-old plants, which are then destroyed. Our best sorts include Keen's Seedling, Duc de Malakoff, Sir J. Paxton, President, Sir C. Napier, and Conseiller de la Cour.—F. Harrison.

Shawdon Hall.—The fruit crop in Northumberland is, on the whole, light. Apples blossomed late, and it was hoped that the crop was safe, but the low temperature in June and cold nights prevented the blossom from being properly fertilised, and the result has been that the greater portion of the fruit has fallen off. In many places the foliage of the trees has been affected by caterpillars. Altogether, the Apple crop in this district, under the most favourable circumstances, will be unsatisfactory. The same may be generally said of wall fruits. Apricots are a light crop; so are Pears in all gardens not sheltered from the east. Cherries are not grown extensively in this district; where they are, the fruit is small and the trees affected by fly. Bush fruit is in most places a fair average crop. Gooseberries, having escaped the late frosts, are good in quantity. Black Currants are less plentiful and small in size; so are Red Currants. Raspberries are likely to be a fine crop; they are so late this year, that they are only now (23rd of July) beginning to ripen. The Strawberry crop is the lightest that has been gathered for some years. Although the blossom was abundant, the rain came too late to swell the fruit; in some places the fruit-stalks are so short as hardly to raise the berries from the ground. Sir Joseph Paxton is largely grown, both for sale and in private gardens. The most useful kind for all purposes is Garibaldi; it is an excellent kind for preserving, and stands our moist climate better than any other sort. President possesses qualities very similar to Garibaldi, and succeeds it. Dr. Hogg is one of our best and richest flavoured Strawberries. In gardens on Tweedside it has an aroma that is seldom found in our choicest sorts. Where Marguerite is grown it has been found to be an acquisition. Perhaps no sort of fruit is so much influenced by soil as the Strawberry. This is so much the case, that the same sort will bear freely in one garden, while in another a short distance off it is all but barren. This is the case with Keen's Seedling; therefore it is only grown in a few places in this district. Black Prince will grow and bear in almost any soil; but it is seldom seen at its best when it is grown on the same ground more than two years. Marshal MacMahon is an exceedingly handsome fruit on the dessert table, but here the foliage becomes bloated and easily affected by such weather as we have had this season. During the whole of the month of June the thermometer fell here during the night to the freezing point. Altogether the spring and early summer of 1886 must be recorded as one of the coldest we have had for several years.—James Thomson.

Heckfield, Winchfield.—In this district fruit crops generally are by no means so good as the profusion of blossom led us at one time to expect. Apples are very thin; indeed, on a large proportion of the trees there are none. Apricots are all all but an entire failure, but the trees are in fine health and have not lost a solitary branch—a fact which puts an end to our theorising that branch-dying is caused by extremes of heat and cold, and by long-continued frost in particular. It would appear that over-fruitfulness may be the source of the mischief, not cold certainly, seeing that to this cause must be attributed the failure of the crop this year. With fruit buds the trees fairly bristled, but few unfolded; they dropped off as growth became active—alternate frost and thaw, for weeks continued, being the only possible cause of the failure. Pears, too, are a thin crop, all varieties, forms, and aspects sharing alike in this respect. The extra heavy crops of last year must to a great extent be credited with the present season's scarcity. Plums and Morello Cherries are good, the former a full crop—which was by no means the case last year. Peaches and Nectarines have never been finer nor heavier crops, nor the wood-growth more healthy, than this season. Our trees were well protected with canvas blinds, which can be let down and rolled up at pleasure—a decided advantage compared with fixed coverings, which, perforce, must be left on in all weathers. Currants and Gooseberries are extra good, and Strawberries would have been the same but for the roasting weather that set in just as ripening commenced, the result being a crop about half what it should have been. As to varieties, we have tried, and continue to try, most of the sorts sent out, but two kinds only do superlatively well, viz., Vicomtesse Héricart de Thury and President. We wish for none better, either as regards forcing or open-air growth, for dessert or preserving. In a word, quantity and quality were never more perfectly combined. Three years is the utmost limit we allow the plants to occupy the same ground, and, as a rule, only two. Our soil is a light, deep, sandy loam, which, if trenched deeply and heavily manured, suits Strawberries well. It would perhaps be better were it a little heavier or more clayey in texture; but we meet that requirement by rolling the ground before putting out the plants, and, in addition, they are well pounded into the soil, and never afterwards is it disturbed, except to hand-weed, till the plants are cleared off. Heavy manurial mulchings are given early in autumn, and this is added to in spring-time in the form of long stable litter, which, as it gets washed by heavy rains, also serves as a strawy covering to keep the fruit clean. —W. Wildsmith.

Strathfieldsaye, Mortimer.—I can report, I am glad to say, rather favourably of fruit crops here this season. Apples are quite a full crop, and the trees freer from insects than usual. Warner's King, Lord Suffield, Cox's Orange Pippin, Duchess of Oldenburg, and King of the Pippins are the most certain bearers on our cold clay. Pears are a fair crop both on walls and standards; Marie Louise, Williams' Bon Chrétien, and Doyenné du Comice are our very best varieties, and appear to suffer less from spring frosts than many others. Peaches are a fine crop. A rather remarkable circumstance in connection with them is that green fly and red spider have been less troublesome than I ever knew them to be. After trying many new varieties, I have found few equal to Royal George for mid-season and Walburton Admirable for late in the year. Apricots are thin, but Plums and Cherries plentiful. Small fruits, with the exception of Strawberries, are abundant; the latter suffered much when in bloom from frost.—J. Bell.

Conholt Park, Andover.—Fruit prospects in March and April this year were good, but the trees suffered from the cold frosty nights which we had in May and early in June. Apples are almost a failure. Apricots under the average. Pears average. Cherries on walls are plentiful and fine in quality. Plums are a good average crop; those we grow are Victoria, Washington, Orleans, Diamond, and Denbigh. All bush fruits are heavy crops, especially Gooseberries and Red Currants. Strawberries very seldom fail with us; Vicomtesse Héricart de Thury, Sir Charles Napier, Eclipse, President, and Elton Pine are our best varieties.—John Bisset.

Leigh Park, Havant.—The fruit crop generally hereabouts is fairly good, with the exception of Strawberries, which have not been worse for some years past, a circumstance to be regretted, for this neighbourhood generally sends heavy consignments of them for the London and other markets. The best sorts for open-air culture are Vicomtesse Héricart de Thury, Sir J. Paxton, Sir Charles Napier, President, and a local Strawberry called Kimberley, which is a good bearer, fine in flavour, and travels well. It also forces very well. Apples are fairly good, but partial, and the same remark applies to Pears. Peaches and Plums are very good. Small fruits are generally abundant, but very difficult to keep from birds, which being strictly preserved, and therefore plentiful, are hard on small fruits.—C. Penford.

Englefield, near Reading.—Apples here are about half a crop. Two or three kinds, such as Cox's Orange Pippin, old Keswick Codlin, Hawthornden, and Yorkshire Greening, are bearing good crops, but other well-known kinds are quite a failure. Pears, consisting of Williams' Bon Chrétien, Brockworth Park, Pitmaston Duchess, Marie Louise, Glou Morceau, Seckel, and other well-known good kinds are all bearing fair crops. Peaches, both indoors and out, are good. Plums the same. Morello Cherries are very good indeed; dessert kinds a fair crop. Currants very good. Gooseberries an average crop. Apricots about half a crop. Raspberries good. The Strawberry crop here this year has not been good, the well-known and highly-prized Sir Charles Napier being quite a failure. On the other hand, Sir Joseph Paxton has borne more than an average crop, and President and Pauline average crops. The four varieties just mentioned are the only ones

growing here. We used to grow Vicomtesse Héricart de Thury, but after growing it for two or three years with great success, it singularly enough died off to the extent of almost every other plant in a bed, also in pots. If we potted 1000 plants at the end of the autumn we might have 500 left. This year I am getting a stock of Duc de Malakoff for forcing next spring. It has been recommended to me as being a good all-round Strawberry both for pots and out of doors.—James Coombes.

Albury Park, Surrey.—Hardy fruits here, with the exception of Apricots and Strawberries, are all good average crops. Many sorts of Apples, indeed, are bearing very heavy crops. Peaches, Nectarines, and Plums of all kinds are also excellent. All fruit trees have been very free from blight and spider this season. Cherries have been good. As to all kinds of bush fruits, I never remember seeing them finer both as regards quality and quantity. We did not protect any trees on walls, but nevertheless we have fine crops. As regards Strawberries, the sharp white frosts and cold cutting east winds which we have had ruined the crop. Keen's Seedling, President, Sir J. Paxton, and Sir C. Napier do well here, and under good cultivation I consider there is no need of more kinds. Sorts that were grown twenty-nine years ago are as yet unbeaten, but in many gardens Strawberries are not too well treated. We might do worse than take a lesson from market growers in respect to this fruit. Nuts both in gardens and woods are abundant.

Potatoes and all other vegetable crops look well, and promise to yield an abundant supply.—W. C. Leach.

Killerton, Exeter.—Peaches and Nectarines set their fruit this year as thickly as Gooseberries, and had to be thinned down to what we considered to be a full crop; even the Walburton Admirable, which with me never bears well, is carrying a fair crop. The trees, too, are all clean and healthy, and in spring were free from curled leaves. I am gathering some highly coloured fruit of Early Beatrice from open walls. All our Peaches and Nectarines are on a south-east wall by east. Apricots are a fair crop generally; I am now gathering fine ripe fruit of St. Ambroise. Apples generally are scarce, both in gardens and orchards. Among the best are Lord Suffield, Cox's Pomona, Manks Codlin, Mère de Ménage, Golden Spire, Ross Nonpareil, and King of the Pippins. Pears, both pyramids and on walls, set very thickly, and although a great many fell off there is still a fine crop. Plums are scarce; Cherries very good, and the trees clean and healthy. Filberts are a moderate crop; Walnuts a good crop. Gooseberries, Black, Red, and White Currants, and Raspberries have been abundant and fine. Strawberries have been good; the bloom was unusually fine, but the plants were much affected by the drought. Our earliest sorts are Black Prince and Sabreur, next Sir Joseph Paxton, James Veitch, and Bicton White Pine; the latest are Crimson Queen, Elton Pine, and Nimrod. As to the last sort, its lateness and good appearance are its only recommendation. For new beds we layer in small pots and transplant as soon as ready into deeply trenched, well manured ground. We always grow a few beds of the white and red Alpine Strawberry, which give a good supply of fruit throughout August and September, when other sorts are over. I am also growing the Quatre Saisons, but have not yet sufficiently proved it. It is similar in appearance to the alpines, but I think not equal to them in flavour.—John Garland.

Sherborne Castle, Dorset.—With the exception of Strawberries and Raspberries, fruit crops in this neighbourhood are fairly good. Apples in the garden here are an excellent crop, but very partial in orchards. Pears vary a great deal, being spoiled to a great extent by the cold nights and east winds which we had in the end of May and beginning of June. Apricots in most places are very good, but with us the trees have suffered more than they have ever done before. In some instances as much as half and three parts have died away. Peaches and Nectarines outdoors and under glass are carrying very fair crops. Plums are abundant both on bush and trained trees. Morello Cherries are also a heavy crop; other varieties do not do well here. Of Gooseberries and Currants we have had too many, the market being glutted. Of Filberts there is a nice sprinkling; and the common Hazel Nuts in the woods are plentiful, but Walnuts are very thin. As to Strawberry culture, I adhere to the old plan of deep trenching, giving plenty of strong manure and a good dressing of soot. For a great number of years I have adopted and advocated the system of layering in turves. I peg one runner on a piece 3 inches square for forcing purposes, and three on pieces 6 inches square for open-air culture, well soaking the turves in liquid manure before using them. I have found this plan to answer admirably. We only grow four sorts, viz., Keen's Seedling, Vicomtesse Héricart de Thury, President, and Sir Charles Napier.—W. G. Pragnell.

Canford Manor, Wimborne.—Apricots here are under the average. Apples average, and good. Morello Cherries average. Nuts the same. Peaches and Nectarines average. Pears under the average. Small fruits average and good. The Strawberry crop in this part has suffered from drought. We depend on the following varieties for forcing, viz., for first crop Keen's Seedling, which we prefer to Vicomtesse Héricart de Thury, on account of the fruit being larger. Our second batch consists of La Grosse Sucrée, and for the main crop indoors we depend on President, Marguerite, and Sir J. Paxton. These carry us through till Keen's Seedling is ripe in the open air. The varieties that do best here for the open air are Keen's Seedling for early use and for preserving; then President, Marguerite, Pioneer, Aromatic, Sir Joseph Paxton, Sir Charles Napier, and Frogmore Late Pine. With good culture and under ordinary circumstances these yield us a good supply, but the outside crop this year suffered from want of rain after the fruit was set. Pioneer, rather a new variety, is rich in flavour, solid, and travels and keeps well. Aromatic is robust in habit and excellent in quality. In order to secure regular crops it is advisable to renew the plantations every three or four years, and by planting a batch of old forced plants in August in good ground well trenched and manured we can depend on a crop the first season after planting, and a good crop the second and third year. After that the fruit becomes small. We destroy a patch and plant one of equal size every year to keep our stock in good cropping order.—David Williams.

Down House, Blandford.—Apples here are very bad, with the exception of King of Pippins, Irish Peach, Striped Beaufin, Nonpareil, Cornish Gilliflower, and one or two other sorts. Of Pears, Marie Louise is bearing a heavy crop; others fair average crops. Apricots under a glass coping very good. Plums and Cherries very good. Gooseberries and all sorts of Currants are very heavy crops. Raspberries very good. Filberts and Medlars the same. Strawberries have been fairly good crops; the sorts mostly grown and best for flavour and general purposes are Vicomtesse Héricart de Thury, President, and Sir Joseph Paxton. The plan by which I get good results is planting those which have been moderately forced in spring in 6-inch pots. As soon as the fruit is gathered we harden off the plants at once, and plant them out on the first opportunity, say the latter end of May or early in June. The plants thus treated get well established before autumn, when they produce good crops the first season, while by planting runners one has to wait till the second season before any quantity of fruit is got from them. By doing away with a third of the old plants every season and planting the same quantity of young ones on fresh ground we invariably get good crops.—Thos. Denny.

Moreton, Dorchester.—Fruit crops in this district are, on the whole, fairly satisfactory. In some gardens the Apple crop is light, in others fairly good, though in all under the average. Of Apricots we have few; not many are grown in this district. Pears are good average crops. Of Peaches and Nectarines we have few on open walls, and here not a full crop even in an unheated orchard house. The temperature was very low when the trees were in bloom, and they did not set well. Plums on walls are very good crops. Cherries a good average crop. Raspberries, Gooseberries, and Currants abundant. Strawberries have also been good. The sorts most in favour in this district are Vicomtesse Héricart de Thury, President, and Sir C. Napier. Other kinds are grown, but the two former we find to be the most reliable in our light soil.—D. Uphill.

Strensham Court, Tewkesbury.—Plums and Damsons are extraordinary crops here. Peaches and Nectarines very good crop and clean. Apricots half a crop, fruit fine. Apples, a very good crop. Pears, not a crop on walls, but fair on standards. Filberts, very thin. Bush fruits very plentiful. Strawberries, both early kinds and late, good; intermediate kinds very unsatisfactory. Pauline is our earliest Strawberry, and one to be recommended for size, flavour, and colour. I gathered our first dish from a warm border on June 15 this year—five days before Black Prince. Oxonian has been a failure; British Queen not so good as usual, but still our best flavoured Strawberry. Of Keen's Seedling a good many plants did not flower; otherwise good. Sir C. Napier fairly good, but not large. Frogmore Late Pine I consider to be our best late Strawberry; we are now gathering from it. Last winter killed great numbers of the plants, which could not withstand the long-continued frosty weather and cutting winds. My system of growing Strawberries is to have the ground well trenched, and to put into it plenty of thoroughly good manure. I layer the plants in little pots, and keep them well watered till rooted; then I plant (after well treading the ground) in rows 2 feet 6 inches apart and 2 feet asunder in the rows. I manure well in autumn, and fork it into the ground. I also mulch with good half-rotten manure when the plants are coming into flower. We renew the beds every three years.—W. Evans.

Redleaf, Penshurst.—Apples this year are very variable. On some trees there is a heavy crop, while on others there are none. There was a wonderful show of blossom in spring, but late frosts, hot sun, and cutting winds were too much for a good deal of it. Among our best sorts this year are Wellington, Blenheim, Cellini (bearing a heavy crop), Bromley, a very useful cooking Apple; Waltham Abbey Seedling, a really good kitchen Apple, a good grower, attaining a large size, and handsome, almost a certain bearer, and very hardy; Royal Russet, Norfolk Beaufin, Lord Nelson and Lord Suffield—all standards in the orchard, and mostly old trees. Of dessert kinds we have Kerry Pippin, King Pippin, Golden Reinette, Golden Harvey, Winter Quoining, and a fair lot of Ribston Pippins. These are about the best this year. Bush trees on Grass are very poor, but in the kitchen garden a little better. Those bearing the best crops are Cox's Pomona, Cellini, Hawthornden, Worcester Pearmain, Lord Suffield, Beauty of Kent, Margil, Grenadier, Lord Derby, and Duchess of Gloucester. Other varieties are scarcely up to the mark. Our neighbours generally, and especially in low-lying parts, complain of very light crops of Apples. Pears are a thin crop. Williams' Bon Chrétien, Doyenné du Comice, Duchesse d'Aremberg, Baronne de Milo, Pitmaston Duchess, Knight's Monarch, Brockworth Park, Emile d'Heyst, and Comte de Lamy are our best on walls. On bush trees we have Beurré Hardy, Eyewood, bearing a heavy crop; Beurré Bachelier, Pitmaston Duchess, Bergamot d'Esperen, and Olivier de Serres, the last a really good Pear, which keeps well and is most delicious. Other sorts are very thin indeed. Apricots are a poor crop. The Peach variety is our best this season; some of the old trees have died back a great deal this year. Peaches and Nectarines are a fair crop. Early Louise, Early Grosse Mignonne, Noblesse, and one named Falcon have the most

fruit among Peaches; and Lord Napier and Violette Hâtive among Nectarines. Plums are a very large crop, and promise to be good both on walls and in the open. Our best are Early Rivers, Orleans, Yellow Impératrice, Emperor, Mitchelson's, Prince of Wales, Victoria, Pond's Seedling, and Blue Impératrice, the last an excellent Plum, which hangs on the tree until frost or wet spoils it. Green Gages are also good, old standards being loaded. Small fruits are most abundant, Gooseberries, in some instances, breaking down the trees. All our quarters were mulched in winter with about 4 inches of stable litter, and not dug in any way. By this plan we get fine fruit, clean healthy foliage, and strong wood; Black Currants are especially fine. This has not been by any means a Strawberry year in this district; ours were strong and vigorous, and showed flower well, but the long and extremely cold spring continuing until the fruits were nearly ready to colour caused the blossoms to set badly, and seemed to cripple the young fruit so much that the greater part of it did not attain the size that is so desirable to Strawberries. Then a sudden change to very dry, hot sunny weather seemed to induce premature maturity. Black Prince ripened on June 19; this was followed by President, Vicomtesse Héricart de Thury, La Grosse Sucrée, Sir J. Paxton, Sir C. Napier, and Loxford Hall Seedling; the last two were our best both in quality and flavour, and the only really good Strawberries we had, but they certainly had the advantage of being young plants, and of being on an excellent piece of ground. The fruit on the older beds were somewhat the earliest. The old Bath Scarlet we always grow for preserving, a purpose for which it is preferred to any other. This variety has been grown here for years on an easy plan and one which answers well. The runners are allowed to grow out on one side of the bed as far as they will go, the soil being made good for them to root in. These are left to fruit the next season, and a piece on the other side is chopped off with the spade, so as to keep the bed about 5 feet wide and easily reached over to gather the fruit; when the plants have got right out on fresh soil, the old soil is cropped for a season or two, and the process is repeated in a backward direction, and little or no trouble is involved in this plan, and we always have plenty of fruit. The variety being a very small one, the plants grow quite close and seem to like the treatment thus given them; we top-dress them with some fine rotten manure early in the spring, and that is all we do to them. For dessert fruit we trench 2 feet deep, manure freely with manure from the cow yard if possible, plant from 2 feet 6 inches to 3 feet apart—3 feet when we can spare the ground, mulch in spring, and do not dig between the rows at all. In this way in ordinary seasons we have good results; the beds are mostly cleared off after the third year. The last two seasons have taken more out of the Strawberry plants than double that number would have done if rain had fallen and had the weather been more suitable. Raspberries have borne a very heavy crop; the much-belauded Baumforth's Seedling has not turned out any better than the old Antwerp Red at present. Nuts—Cobs and Walnuts—are scarce. Cherries are a very fine crop; all good, especially the Bigarreau.—W. Holah.

Hall Place, Tonbridge.—The Apple crop here is a failure—at least as far as orchard trees are concerned. Pyramids and bushes in gardens are bearing about half a crop. As to Pears, the late spring frosts proved disastrous to not only bush trees, but also to pyramids, and the fruit is still dropping. They are somewhat better on walls. Peaches and Nectarines under glass copings are abundant. Apricots under the same condition are a full crop. Plums on walls are plentiful, also culinary sorts on standards, and the same may be said of Damsons. Sweet Cherries are about half a crop; Morellos a full crop. Gooseberries are very plentiful. Raspberries are a good crop. Black, Red, and White Currants average crops. Kentish Cobs and Filberts are thin, but Walnuts are plentiful. Quinces and Medlars are good crops, and Mulberries promise well. Strawberries here and for some distance round are very light crops—I may say the worst we have had at Hall Place for sixteen years. Some varieties hardly ever known to fail here, such as Keen's Seedling, Sir J. Paxton and Sir C. Napier, were destroyed before flowering, or when the flowers were just pushing. Later sorts, such as the Countess, Unser Fritz, and Loxford Hall Seedling were badly damaged by frost when in full flower. The above six sorts, with La Grosse Sucrée, we consider to be our very best as regards flavour, travelling, and cropping. We have tried many new sorts here, but very rarely do we find one superior to those just named. King of the Earlies and the Captain suffered so much from the late severe winter, that they are now in so weak a condition that I cannot say much about them. Should the flavour of the latter prove good, it will be a good addition to our better sorts of Strawberries. It is large and good looking, and seems to bear freely. Before planting we trench the ground deeply and manure well. In autumn we dress the surface heavily with well-rotted manure, and in spring with fresh stable litter. This we do each year, and never fork or dig between the rows. Our soil is rather retentive.—J. Berry.

Homewood, Chislehurst.—Apricots here are very scarce, many of the trees not bearing a single fruit; Breda, a small round sort, is doing best. It is rather dry-fleshed, but when ripe has an agreeable flavour. Apples are very thin, except a few free-bearing sorts—trees grown as espaliers in the kitchen garden. The trees in our principal orchard bore a grand crop of blossom, but when fully open caterpillars completely destroyed it, and the leaves, too, were quite disfigured; even now they are only just recovering, and scarcely a single Apple can be seen. We have another orchard in which the trees are bearing a fairly good crop, *i.e.*, such sorts as Early Harvest, Keswick Codlin, Cellini, Warner's King, London Pippin, and Bascombe's Surprise. This last is quite a local kind, a constant bearer, and its fruits keep till late in the spring. Tower of Glamis and Stirling Castle are also bearing heavy crops. Cherries are grown rather extensively in this district, and the crops in general have been abundant; our crop of Cherries growing here in the garden, both standards and trained trees, have borne very abundantly, but the fruit has not been quite so large as usual. The varieties which have bore the heaviest crops are May Duke, Bigarreau Napoleon, Elton, and Governor Wood. The Kentish has borne a very heavy crop, as has also the Morello. Currants are very plentiful and the berries extra large, more especially the Black Naples, which is bearing an extra heavy crop. Figs, upon a south wall, are a fair crop. Gooseberries are most abundant. Peaches and Nectarines, on a south wall, are thin, but the trees are healthy and making clean firm wood. Nuts are a very thin crop. Plums are bearing an average crop on walls, but not so good on pyramids or standards. Damsons are plentiful. Quinces are an average crop. Raspberries are very plentiful, and the fruit has improved in size considerably since we have had rain. Carter's Prolific, Prince of Wales, and Yellow Antwerp are our best sorts. Strawberries have partly been a failure with us, taking the whole crop and the different sorts grown into account. The best have been Vicomtesse Héricart de Thury, Sir Joseph Paxton, Keen's Seedling, and a medium crop of that useful variety, President. Hundreds of acres in this district are cropped with Strawberries, and, taking the whole, there has not been, on an average, much more than half a crop, but the late rains have improved the late crop considerably. Pears are an average crop upon trained trees on walls and espaliers, but only about a third of a crop upon pyramids and standards.—Wm. Christison.

Cobham Hall, Gravesend.—Apples are a failure hereabouts, except such sorts as Lord Suffield and Manks and Keswick Codlins. Pears, too, are a bad crop. Plums an average crop, Victoria and Gisborne being by far the best. Apricots bad. Peaches and Nectarines an average crop. Of bush fruits we have a good average. Filberts are a bad crop. Of Strawberries there has been on heavy soil a good average crop, and I have had the same on light gravelly soil, but I always use forced plants. In planting, I have trenches thrown out similar to those for Celery, 3 feet apart. These I fill with manure and plant out in May or June, and if we have some showers after planting to keep them growing, I generally have some fruit in the latter end of August. I never have any digging done between the rows, but mulch with old spent Mushroom bed manure. Our best sorts are Keen's Seedling, Sir J. Paxton, Sir C. Napier, Vicomtesse Héricart de Thury, President, and La Grosse Sucrée.—F. Deuxberry.

Papworth Hall, Cambridgeshire.—Apples here are quite a failure, and Pears are not half a crop. Plums on walls are abundant. Those on pyramids are rather thin. Cherries have not been at all plentiful on some trees, though a fair crop. Gooseberries have been abundant, likewise Black and Red Currants. White have not been quite so good. Strawberries with us and around this part have been abundant, but the dry weather came upon us soon after the blooming season and caused a great many fruits to shrivel up before it acquired its full size. The varieties which we grow are the following, viz., Keen's Seedling, always good both in flavour and size; Black Prince, good; Sir Joseph Paxton, always very good indeed; President, one of our very best varieties; James Veitch, fairly good; Eclipse, a useful variety; Frogmore Late Pine, very useful late variety and always good. We have tried British Queen, but on our cold clay it never came satisfactory. We make new beds every third year, using strong runners layered in 3 inch pots. We always prepare the ground well before planting. A grand variety, both for outdoors and also for late work in pots, is Atherton's No. 1, which, when better known, will be, I think, a favourite. There used to be a variety in cultivation some twenty-five years ago called Oscar. I recollect it was thought well of for some years after it was distributed. What has become of it?—Thos. Smith.

Hallingbury, Essex.—Our Strawberry crop this season is very poor indeed, being cut off when in bloom. The following sorts do well with me, viz., Keen's Seedling and Garibaldi for early crops; President, Sir J. Paxton, Sir C. Napier, and James Veitch for second early crops; and for late crops British Queen and Frogmore Pine. Pears and Apples are but light crops. They got cut very much by the cold east winds which we had; here and there on a tree well sheltered may be seen a fair crop, but they are few and far between. Plums, including Damsons, are very fair crops where sheltered, but, generally speaking, they are only average crops. Currants and Gooseberries are a good crop, but the fruit is rather small. Peaches, Nectarines, and Apricots are under the average. Although sheltered, the bloom was very small, and the fruit dropped when just set. Nuts are a good crop. Raspberries the same, but small from want of rain.—Edw. Spivey.

Aswarby Park, Sleaford.—Of Apples we have none; in the neighbourhood there are a few. Apricots are a poor crop. Cherries, a full crop. Currants, Red, White, and Black, excellent. Figs in the open air a full crop. Gooseberries abundant. Plums fairly good. Strawberries a heavy crop, and fine in quality. The varieties grown here are Early Marguerite, Keen's Seedling, Garibaldi, President, Duke of Edinburgh, British Queen, Dr. Hogg, and Loxford Hall Seedling. As regards cultivation, we trench deeply, manure heavily, and top-dress in October, to remain on the ground until the fruit is gathered. We then clear away all runners not required, slightly fork the old top-dressing into the ground, then top-dress with good manure, to remain on the surface until the fruit is gathered. I make new plantations every year in August, and from these, if the season is favourable, we in general gather our finest fruit.—Richard Nisbet.

Hardwicke House, Bury St. Edmunds.—With the very important exception of Apples and Pears, fruit of all sorts may be said to be plentiful in the open air, and even Apples are less scarce than Pears, and here and there fair crops of both may be found, but, on the whole, they are very far from being an average yield. Peaches, Nectarines, Apricots, Cherries, and, in many localities, Plums are a heavy crop, the latter being, as usual, somewhat capricious, and in some gardens plentiful on standards and few or none on walls. Bush fruits of all sorts are plentiful, and Raspberries an extraordinary crop. Nuts are also fairly plentiful, and Strawberries one of the best possible crops. Some of the early ones suffered considerably from the intense heat and drought, but the rains came in time to save and fully develop the later varieties. As already stated, we have largely reduced our number of varieties, only growing a very few in bulk, such as President, Keen's Seedling, Eleanor, and Frogmore Late Pine. We used, however, to grow a far larger collection, including Black Prince, Vicomtesse Héricart de Thury, Lord Napier, Sir Joseph Paxton, James Veitch, Sir Charles Napier, Bicton Pine, Lucas, Dr. Hogg, British Queen, Elton Pine, Admiral Dundas, Carolina superba, Cockscomb, &c. Some of these have been discarded, owing to the sorts or soil here not suiting them, and this has been notably the case with the British Queen and its near ally, Dr. Hogg. Others, again, such as Sir Joseph Paxton and James Veitch, did not yield such quantity as President. We are now trying several others, such as Baronne Brize, Gros Bonne, Countess, Duke of Athole, Constantine Tretiakoff, Pioneer, Jucunda, Lucas, &c., but on a scale that hardly warrants an emphatic opinion as yet, though most of them possess three good qualities—free growth, fertile habit, and good flavour. Such sorts as Pauline and Loxford Hall Seedling I have also seen remarkably good, though the former has to be longer on the ground than most sorts before it can be had in full bearing, and the latter has probably too much Queen blood to thrive alike well everywhere. Pauline is not only earlier, but larger and finer than Black Prince. King of the Earlies and Captain are also very early sorts and likely to supersede the Black Prince. The latter, however, is still one of the earliest, most prolific, and highest coloured of all Strawberries, and possesses in a high degree the merit of perpetual bearing, a merit now specially claimed for the new Strawberry Roi Henri. Without at all disparaging the merits of the latter, we have had Black Prince ripen one crop in March, a second in June, and a third in October. These were kept in pots all the while, and well fortified with liquid manure water. Perpetual bearing, or, to write more correctly, two or more crops a year from forced plants is more a matter of culture than of variety. Still, if Roi Henri or any other sort will yield a certain second, or even a third, crop in the open under ordinary treatment, that will be a large step forward in extending the Strawberry season, or making the supply continuous throughout the growing season. Will some grower of new white sorts kindly say if any are better than the Bicton Pine? A good white or lemon-coloured Strawberry is really a very desirable acquisition, as although red, crimson, or pink will probably always be the most popular colours for Strawberries, yet light-coloured fruit would give greater variety to the dessert, the great object being, however, to keep up the standard of quality to the very highest pitch. A good deal more may also yet be done to develop new flavours from the very excellent Hautbois, which is so distinct as to deserve to be reckoned almost as a new fruit. The taste for Hautbois, however, needs to be educated before the flavour can be appreciated; hence, to a great extent their unpopularity, though their frequent barrenness under cultivation has also greatly limited their cultivation. This, however, occasionally happens to the most fertile varieties. Among newer sorts now pressing to the front, several of them, such as Hundredfold and Belle de Bourg la Reine, are so much like Vicomtesse H. de Thury, that it seems doubtful if they are worth growing alongside or instead of it. Will someone who grows the Traveller say whether it deserves its name in the sense of being a good traveller—a quality by no means too common among Strawberries? This last is a point our fruiterers could provide valuable information upon by furnishing a list of sorts that, as a rule, arrive in best condition in their many consignments. Without going now into the different modes of cultivating the Strawberry, there is one point of much importance that needs further discussion, viz., the most fertile age of different varieties. In our rage for what may conveniently be designated baby plant fertility, we have probably lost as well as gained a good deal. At a time when few Strawberry plants are allowed to live more than three years it is rather startling to find Pauline sent out by its raisers with the statement that it is best the third year after planting. This suggests the query, whether the rush after mere fruitfulness of plants in Strawberry culture has not been carried too far for bulk and profit of crop. For mere size of individual fruits the young plants doubtless have it, but for gross weight, the experience of the past and also not a few modern cultivators seems to point in the direction of older plants. Within the memory of not a few of us, Strawberries were provided for among the semi-permanent crops of the garden. Now they are often treated as biennials, and, perhaps, more generally as triennials. Is the latter the natural limit of their profitable productive life? The present most useful discussion, which unavoidable circumstances have prevented me from taking part in earlier, affords a capital opportunity for re-opening the question of the effect of age on Strawberry plants and the bulk and flavour of their produce. That young plants yield fair sized fruit may be taken as proven. But many have doubts about the other points. Neither do I think that any hard-and-fast line about age can be applied to all the many varieties of Strawberry in cultivation; on the contrary, it is more than probable that almost every variety or family has its own distinctive age of maximum productiveness, and this being so, it is more than probable that not a few sorts are trenched in before this age is reached.—D. T. Fish.

Capesthorne, Chelford.—Fruit crops in the garden here and neighbourhood are on the whole satisfactory. Apples and Pears are slightly under the average. Cherries are abundant; small fruits are the same, and very fine. Peaches and Nectarines are very little grown out of doors in this part. Apricots are under the average. Plums abundant, especially Damsons: the latter are grown very extensively here, and the trees are literally laden with fruit and fine in quality. Strawberries are not grown here very largely, the soil being too light for them. The varieties which I grow are Keen's Seedling and President. To do Strawberries well they require to be grown on stiffish soil, deeply trenched and well manured, and the plantations need to be renewed every three or four years.—Alexander Dewar.

Cholmondeley Castle, Malpas.—Strawberries here are a good crop and fine in quality. Plums are a fair crop. Gooseberries very good. Currants an average crop and the fruit fine in quality. Morello Cherries are an average crop; sweet Cherries under the average. Peaches are a good crop. Raspberries the same, and the fruit is good. Apricots are a moderate crop. Pears a fair crop, and the fruit clean. Apples on pyramids in the garden good, but on standards in orchards under the average.—C. Flack.

Biddulph Grange, Congleton.—Fruit crops here are not so good as was expected; although we escaped the spring frosts, we did not escape the cold, cutting winds which followed. Peaches and Nectarines are very little grown out of doors here and seldom do any good, and this year is no exception. Of Apricots there are very few. Apples are under the average; the following sorts are the best here, viz., Lord Suffield, Hawthornden, Keswick Codlin, King Pippin, Ribston, Dumelow's Seedling, and Warner's King. Pears are under the average—more on walls than standards. Of Plums there are good crops of the following sorts: Victoria, Golden Drop, Kirke's, and Damsons, and the trees are freer from blight than I remember seeing them for some years. Bush fruits are plentiful, especially Gooseberries and Black Currants: Red and White Currants are much blighted. Raspberries are good. Strawberries partial. The sorts that have done best here this year are President, Sir Harry, and Elton Pine.—Robert Bass.

Abney Hall, Cheadle.—Apples and Pears are under the average here. Some Apples that have been good and regular bearers, such as Hawthornden and Prince Albert, have nothing on them this year. Cellini, however, is bearing a full crop, and so are Grenadier and Cox's Orange Pippin. The best of our wall Pears is Marie Louise this year. Beurré Clairgeau, Louise Bonne of Jersey, and Beurré d'Aremberg are the best amongst standards. Of Plums on walls we have very few, but on standards and Damsons they are very good. Gooseberries, Currants, and Raspberries are also good crops. Strawberries are next to a failure—the worst crop we have had for a dozen years. Is this owing to the wet autumn last year? From the end of August we had perpetual rain for weeks; therefore the crowns could not ripen. There was, however, a fair crop on a patch of Black Prince, upon which we never depend; although early and of good colour, the fruit is too small to be of much value. From what I can learn one of the best cropping kinds in this neighbourhood is Myatt's Prolific: it is, however, rather coarse. The best samples of fruit, however, that I have seen grown in this part have been that of President and Sir Joseph Paxton, two well-known kinds.—Robert Mackeller.

Brentry House, Westbury-on-Trym.—Plums here are very abundant; in fact, I never saw standard trees more heavily laden than they are this year, and I believe it to be generally so in the west of Gloucestershire. Pears, too, are very abundant, particularly the earlier sorts. Apples as a rule are a failure. With regard to small fruits, such as Gooseberries and Currants, the trees are literally covered with fruit. Strawberries as a rule have borne very heavily, but the berries have not been so large as I have seen them in former years. In my opinion Vicomtesse Héricart de Thury still stands pre-eminent as a preserving Strawberry and for very early forcing, with the exception, perhaps, of Princess of Prussia, which is a fortnight earlier and larger in the berry, but not nearly so well flavoured. For second and later sorts I find President, Sir J. Paxton, and Princess Alice to be the best. Alexandre de Kief is said to be a very fine Strawberry, but I have not had much experience in regard to it, although I have seen it wonderfully good at some exhibitions. Loxford Hall Seedling, however, stands first in this neighbourhood as a market Strawberry. It equals Dr. Hogg in flavour, but is not quite so large. It is a very heavy bearer and travels well. In order to secure good and regular crops the best plan is to plant out the forced Strawberries as soon as the fruit is gathered in a plot of ground ready to receive them. Let new plantations be made every third year. The soil should be well trenched and, of course, well manured, and if planted early a fair crop will be produced in the autumn of the same year, and fine crops the three following summers. Before planting the balls ought to be slightly shaken. Where forcing is not carried on to any great extent, the best plan would be to secure runners from the previous year's planting. Lay them in 3-inch pots, which should be plunged, and the runners should be kept in their place by putting a stone on them, which I prefer to pegging them, as it keeps the soil damper. The loam in which they are layered should be light and rich. As soon as the pots are filled with roots, say about the first week in July, plant them out in well-prepared ground 2 feet apart.—Frank Nichol.

Powderham Castle, Exeter.—Peaches and Nectarines here are average crops. Peach blister in many cases almost destroyed the trees; ours escaped with only a slight attack, which we kept pinched off as it appeared in order to prevent its spreading. Nectarines in our case seemed to be more blistered even than the Peach. Has this been found to be the case generally? Apples are under the average, but they promise to be very fine in consequence. Pears are generally a good crop, and everywhere look remarkably well. Plums are a heavy crop in some districts, and particularly free from aphides. Early Cherries did well; Morellos, which suffered at the stoning period, are not half a crop. Apricots are under the average, but very fine in quality. Bush fruits have been very good indeed, especially Raspberries. Strawberries commenced well, but the growth of mid-season crops was arrested by drought. Late varieties, too, were not able to set their bloom owing to the same cause; all were doubly mulched, but we suffer sadly from drought. Sir Joseph Paxton is our best kind for cropping, flavour, and packing—three good qualities. James Veitch we are discarding, and also Elton Pine. We have planted Sir J. Paxton on early borders for our first crop, and intend to plant the north or late borders with the same variety. It is the only one we use for forcing, so highly is it thought of here. Walnuts and Cobnuts are full crops. Medlars good.—David C. Powell.

Hornby Hall, Lancashire.—In this locality all sorts of Currants—Black, Red, and White—Gooseberries and Raspberries are generally very good crops. Apples are nearly a failure; of Pears we have a fourth of a crop. Damsons are a very fair crop in certain places, not so good in others. In respect to Strawberries, we had a good general crop. President is generally the favourite in this locality both for preserving and flavour; Elton Pine is considered to be the best late variety. In reference to culture, with newly trenched ground 2 feet deep and an ordinary quantity of manure, almost any soil will grow Strawberries; and I would recommend the three years' system, that is, planting every year, and digging down some every year.—James Young.

Cuerdon Hall, Preston.—Strawberries do very well here. Our soil is a brown loam on limestone. It is not a heavy soil. Keen's Seedling is our favourite for an early crop. We have a south border that has been planted more than twelve years, and yet every year we have good crops of early well-coloured fruit. It is manured every autumn, but never dug. British Queen bears well, but not so well as on heavy loam or marl. We grow regularly, besides the two sorts just named, President, Carolina Superba, Vicomtesse Héricart de Thury, James Veitch, Sir Joseph Paxton, Oxonian, Sir Harry, Duc de Malakoff, and several other sorts, including some lately introduced, but of which, without further trial, we cannot speak. We had abundance of bloom and a heavy crop of very fine Strawberries. We like Vicomtesse Héricart de Thury and President for forcing.—J. Roberts.

Enville Hall, Stourbridge.—In this district, as far as I can learn, Apples are under the average. They bloomed well, but set very badly, and many have since fallen. Pears are a good crop on walls, espaliers, and pyramids. Plums are a good average. Peaches under glass are very good, and also on walls protected by glass copings. Apricots, where protected by glass copings, are grand crops; previously to glass being used I scarcely ever had half a crop, but since their use I have not had a total failure. The coping projects about 2 feet and is a fixture, remaining on all the year round. Gooseberries, Currants, and Raspberries are abundant and fine. Strawberries are not a good crop, and small. The best kinds I find for this district are Keen's Seedling, President, La Grosse Sucrée, and British Queen. These are the only kinds grown here for main crops and for forcing. La Grosse Sucrée I consider to be one of the best for forcing as a variety to follow Keen's Seedling and President. British Queen I find to be invaluable as the last batch for forcing; in point of flavour it cannot be surpassed by any other kind.

Early Potatoes are a poor crop with us; second early and late kinds are looking very well, and promise to be good crops.—Geo. H. Green.

Thirkleby Park, Thirsk.—Apples with me, and as far as I can ascertain in this neighbourhood, are almost a failure; also Plums. Stone fruits, too, are much below the average, and will require a fine autumn to bring them to perfection. Bush fruits are plentiful with us and fine in quality. Strawberries are below the average, but what we have are large and fine in quality. The varieties which we grow are Keen's Seedling, James Veitch, President, and Dr. Hogg. Empress Eugénie also does well here.

Potatoes are a fair average crop and free from disease at present, but rather small.—H. Brunton.

Half-opened flower of the white Ramanas Rose (Rosa rugosa alba).

Gorhambury Park, St. Albans.—The Strawberry crop here has been a light one and of short duration. We have discarded all but three varieties, and these are Keen's Seedling, for early forcing and for planting in borders for jam-making; Sir C. Napier for second early forcing, and for main crop dessert fruit; and we grow President for late produce both indoors and out. In a good season these meet all my requirements, but this year has completely upset all rotation; there was no second bloom—all came in together—and the crop was soon over. Apricots are a light crop, but good in quality. Plums good, especially Gages. Cherries good. Peaches and Nectarines are a light crop, but good. Apples are below the average, but seem good in quality. Pears are a fairly good crop. Gooseberries and Currants good in every way. Of Nuts we have fair crops.—Joseph Thompson.

Danesbury, Welwyn.—Apples here are under the average and the trees are blighted, especially standards. Pears too are under the average; the best are Beurré Giffard, Brockworth Park, Alexandre Lambre, Beurré Diel, Josephine de Malines, Forelle, and Marie Louise. Of Plums we have heavy crops and good. Peaches too are good and the trees healthy. Apricots are an average crop. Cherries are over the average and good. Strawberries have been bad; the cold spring and long-continued dry weather afterwards injured them. Nuts are an average crop. Bush fruits very good, especially Raspberries and Gooseberries.—R. F. Sawford.

Royal Gardens, Frogmore.—In consequence of a long winter and late spring all fruit crops are much later than usual, but both trees and fruit are remarkably clean and healthy. Strawberries have suffered very much, and some of the plants have not produced any fruit. Sir Joseph Paxton, which usually bears heavy crops, is quite a failure this season. Apricots, Apples, Pears, Plums, and Strawberries are, on the whole, only average crops. Peaches, Nectarines, Cherries, Raspberries, and small fruits are particularly good. Our best Strawberries are La Grosse Sucrée, Keen's Seedling, Sir Joseph Paxton, and Vicomtesse Héricart de Thury for early crops. Of late kinds our best are Frogmore Late Pine, Elton Pine, and Unser Fritz.

Potatoes promise to be excellent, and no disease has as yet made its appearance.—Thomas Jones.

Bearwood, Wokingham.—Apples hereabouts are good. Pears thin. Peaches and Nectarines very good. Plums on walls are clean and bearing good crops. Apricots are under the average. Cherries good. All kinds of small fruits are good average crops, and the recent rains have done wonders in gardens generally. Strawberries have disappointed us this year; cold in the first instance and then drought injured them, and the fruits that did ripen were not of average quality. The sorts grown here for forcing are Keen's Seedling, President, Sir Charles Napier, and British Queen. The sorts just named I also rely on for our supply from the open. My plan has been for many years to plant out the forced ones and to make fresh beds every year. The sort on which I trust most is the British Queen. With me it surpasses every other variety, and this year it has given me more fruit than all other sorts put together. In some gardens it is, however, useless to plant it. Our kitchen garden soil is very stiff on a bed of clay, and very suitable for Strawberries. In planting I have the soil put up in ridges about 8 inches high, and plant singly in rows 2 feet apart each way. By this plan of planting, should the season be wet, the fruit has a better chance of ripening, and is not so apt to rot. In autumn the beds are top-dressed with old hotbed manure, and when they commence throwing up for bloom I put a slight covering of straw over the top-dressing to keep the fruit clean.

Early Potatoes of all kinds have been good and excellent crops, free from disease and good in flavour. Late ones, too, look strong and promising.—James Tegg.

Wotton, Aylesbury.—All sorts of Gooseberries and Currants are bearing heavy crops. Apples hereabouts are an average crop. Pears are under the average, except Williams' Bon Chrétien and Jargonelle, both of which are bearing fairly well. Apricots are under the average; our trees suffered a good deal last winter. Peaches are an average crop, and so are Figs on walls. Plums of all sorts are heavy crops. Strawberries here have been a full crop. The treatment which suits them best here is to plant every fourth year in August, to clear off all runners, and to top-dress with a mixture of rotten manure and loam. I never dig between the rows. The soil here is stony black loam, in a subsoil of yellow clay. The

orts which I grow for main crops are Vicomtesse Héricart de Thury, James Veitch, Keen's Seedling, and President. British Queen also does well.—James Smith.

Alton Towers, Stoke-on-Trent.—Apricots with us are plentiful and good. Peaches fairly good. Strawberries plentiful. Small fruits excellent. Apples plentiful and good, and so are Nuts. Bilberries are a great crop and fine. Pears are fairly good. The hot sunshine which we had some time ago suited this locality well, and the later rains have suited all growing crops. Plums and Cherries are producing heavy crops. All round here there are very large orchards.—Thomas H. Rabone.

Woburn, Beds.—The Apple crop in this neighbourhood is below the average, although when in bloom it promised to be the heaviest on record. Cherries are an average crop. Apricots showed but little bloom, and that very weak; consequently they are very scarce. Plums, including Damsons, are good average crops. Pears average, but they do not swell off vigorously. Currants and Gooseberries are abundant and clean. Raspberries fell off much from want of rain. All kinds of fruit trees are very free from insects. Strawberries suffered much from the long trying winter, and the frosts in May and the continuous cold nights in June prevented the bloom from setting; on the whole, therefore, they are the worst crop I have had for years. We keep to the old kinds. Black Prince for preserving; Keen's Seedling is still good for early work; whilst for general use President, Elton, and particularly Lucas are always grown. After trying various plans, we trust to the simple one of planting out a bed of forced plants on fresh ground every year. As soon as convenient after fruiting, we do away with the same number of plants that have stood about three seasons; by these means we have mostly had excellent crops of fruit.—Alexander McKay.

Madresfield Court, Malvern—With the exception of Apricots there are good average all-round crops of fruit in this neighbourhood, and the trees are looking healthy and clean. The earliest Strawberry here is Early Prolific, which is fit to gather on June 17. La Grosse Sucrée, Vicomtesse Héricart de Thury, and Pauline are a week later. Good one-year-old plants from the earliest runners are found fit to gather from sooner than older plants, and are altogether preferable to them, *i.e.*, if good, generous cultivation be given them. Pauline is an excellent Strawberry, and bids fair to rank high when better known. President is the best main crop kind, and, when the season is favourable, good in flavour. James Veitch is the best for size, and Oxonian for latest crops, although the latter has proved to be somewhat fickle with us this year for the first time. We get our best crop by planting out annually large beds of old forced plants, taking one crop from them and then destroying them, and planting Broccoli on the same ground with a crowbar. Of course, the beds are first well prepared by trenching and manuring.—William Crump.

Highclere Castle, Newbury.—Apples with us are a fair average crop. Pears the same, more especially on standard trees. Peaches and Apricots are poor. Plums are a very heavy crop. Gooseberries and Currants abundant, and Raspberries are also very good. Strawberries here have been abundant and good—quite up to, or above, the average. The sorts depended on for the main crop are Vicomtesse Héricart de Thury and President. The best late kind is Frogmore Late Pine. Other sorts grown here are Black Prince, La Grosse Sucrée, James Veitch, Helena Gloede, and Loxford Hall Seedling. I find it best to make two or three young beds every year. These are especially useful for furnishing a good crop of early runners the first season after planting. I also make a practice of planting the best of the forced plants, which are cropped two years in the open, and then cleared off in time for planting late Broccoli. Those planted from runner will crop three, or even four, years satisfactorily, but it is not advisable to retain them longer than three if the best results are looked for. The ground between the plants ought never to be dug, as the firmer the soil is the better the fruit, both in quantity and quality. I find a good mulching of rotten manure in autumn to be very beneficial.—William Pope.

Wynyard Park, Stockton-on-Tees.—Fruit crops here, generally speaking, are little, if any, below the usual average. Apples are an average crop and very good. The best are Devonshire Quarrenden, Keswick Codlin, Stirling Castle, Tower of Glamis, Hawthornden, Echlinville, Blenheim Orange, Sturmer Pippin, Pitmaston Nonpareil, Summer Golden Pippin, Court Pendu Plat, Cockle Pippin, and Margil. Pears are a moderate crop, but some sorts are good, especially Marie Louise, Napoleon, Williams' Bon Chrétien, and Easter Beurré. Plums, particularly Victorias on standard trees, are a first-rate crop, but fruit on wall trees is very thin. Apricots are a light crop. Morello Cherries are first-rate; numbers dropped in stoning, but enough are left to make a heavy crop. Strawberries are very fine and plentiful, particularly James Veitch and President, these two being far and away the best sorts for us here. With regard to bush fruits, all are very good and carrying heavy crops. Taking fruit trees generally, I have never seen them looking in better health or making better growth, which, I hope, augurs well for next season. Nor do I remember a season in which fruit trees have been cleaner or freer from blight.—H. E. Gribble.

Eden Hall, Penrith.—In this district fruit prospects are exceedingly poor, with the exception of bush fruits, which are good and plentiful. Most kinds showed abundance of bloom for a full crop; but the bitter winds which we had in May not only destroyed the bloom, but almost denuded the trees of foliage. Pears are a complete failure. Apples the same, with the exception of Lord Suffield, Irish Peach, and Ribston Pippin, which hardly ever fail here to produce a crop. Of Plums we have a few on Victoria and Green Gage. Of Apricots we have none; they never do well here. Cherries are very poor. Strawberries are a fair crop. Vicomtesse Héricart de Thury (the best for all purposes), President, and Sir Joseph Paxton do very well here. I find that the best results are obtained by forming plantations yearly from runners layered in pots as early in the season as possible. We plant in well-trenched ground and mulch heavily—a necessary operation, our soil being light.—T. R. Cuckney.

Alnwick Castle.—Last year fruit trees were heavily cropped, and the autumn was cold, with little sun; the wood, therefore, was imperfectly matured, and much of the fruits, even that of Apricots, did not ripen; some of them were on the trees in November. The natural result has been that many varieties of Apples, Peaches, and Pears were scantily bloomed, and what flowers did open have been unable to stand the cold winds which prevailed here through the spring. Of Apples, Lord Suffield is bearing a fair crop, but, generally speaking, Apples are scarce. Pears are much below the average, but the fruit promises to be good. Peaches on open walls are a light crop, with the exception of Royal George (always good), on which there is a fair crop. This is one of the best varieties in the north. Plums are an average crop. Victoria, Jefferson, Golden Gage, and Kirke's are among the best. May Duke Cherries are good; Morellos light. Gooseberries are a heavy crop, and other bush fruits are tolerably good. The Strawberry crop is under the average. We have had a cold, late spring, and the plants in many cases have small contracted leaves, and many have scarcely flowered; whilst others have done so abundantly, and are now yielding excellent fruit. The usual method of planting Strawberries in this neighbourhood is as follows: After deep trenching and heavily manuring we plant in rows 3 feet apart and 15 inches asunder in the row, and allow all runners to grow. These beds fruit the second year, and continue for several years, in favourable seasons, to produce great crops. After trial of a great number of varieties, those found fit to survive are Keen's Seedling (earliest), Garibaldi, Sir J. Paxton, President (this damps badly in wet weather), and McMahon. The last can be gathered to the 20th of August and is a great boon on that account; but we hope that some one will raise a Strawberry (a good one) to fruit into September. Sir J. Paxton and McMahon are the best of those just named. Strawberry plants should be made firm in the ground. We mulch with short manure, and cover it with new stable litter in April—it is soon washed clean with the rain; and about three weeks or so before ripening we dust the ground with a little guano (or use it in a liquid state), and give a heavy watering, the land being light, and the result is a fine crop of Strawberries. Many acres of Strawberries are grown about here for market. Where the runners are allowed to grow thickly, no mulching, of course, is needed.—George Harris.

Lambton Castle, Fence Houses.—Apples are a short crop with us. The bloom was abundant, but was destroyed by spring frosts, from which, as a rule, our garden suffers much, as it only lies a few feet above the sea level. Of Apricots we have none, repeated hard winters having killed the trees. Plums are short, and being late are not likely to be fine. Cherries are a moderate crop, but fairly good in quality. Of Peaches and Nectarines we have none out of doors. Bush fruits have done well, and Strawberries are plentiful and good. I find Keen's Seedling to do well. I discarded it a few years ago on account of its not fruiting, but after getting a fresh stock of runners it has again taken a favourable position, both as a fruiter out of doors and under glass. Duke of Edinburgh does well, and is a fine looking fruit for dessert or for the exhibition table. Eclipse forces well, and is also bearing a heavy crop outside; it proves to be a most useful Strawberry. I grow Black Prince, Captain, and King of the Earlies, the two latter in small quantities for trial. Of Vicomtesse H. de Thury we grow lots; it always fruits heavily, and answers admirably for preserving. We renew our plants every four years; the two last years we generally allow the runners to remain, and we never lose a crop. Gooseberry bushes are weighed down to the ground with fruit.—J. Hunter.

Chatsworth, near Chesterfield.—An error appears in the last few lines of my fruit report (p. 108) referring to Strawberries. What I intended to have said was, that "Strawberries are under the average, and I find a greater percentage of blind plants than I ever remember before, especially in our old plantations, and also in those formed with runner plants. On the other hand, in quarters planted last year with plants which had been forced we have no blind ones, and these, in my opinion, always give the best returns."—O. Thomas.

WHITE RAMANAS ROSE.

The half-opened flower of the white Ramanas Rose (Rosa rugosa) is so lovely, that we have been tempted to again illustrate it, so as to show the bloom in this stage. When fully expanded and showing the golden tassel of stamens, the flowers are beautiful indeed; but the half-opened state is to many even more charming. If cut as soon as the buds are upon the point of bursting, they will expand well in water and last longer than if cut when quite open. Everyone who knows this Rose will agree that it has no rival; even among the multitude of beautiful Roses which we now possess none have such luxuriant green foliage, and none are more beautiful in autumn when adorned with hips, which are unusually large and bright orange-red in colour. It is so well known now as a perfectly hardy shrub suitable for any open sunny spot, that no more need here be said about it.

EVILS OF OVERCROWDING.

The aphorism, "The man who causes two blades of Grass to grow where only one grew before is a public benefactor," is only true in a limited sense; for if the land had been previously well covered with herbage, the doubling of the produce might ruin the whole. In gardening, one of the greatest evils met with is overcrowding, or, as it may be otherwise termed, overcropping. The trees in the wood, the White Thorns forming our hedges, the Apple trees in the orchard, the Laurels and other things in the shrubbery, and annuals in borders are commonly planted too thickly to permit of their displaying themselves to the best advantage. Many fail in gardening from lack of resolution. They know very well that leaving too many bunches of Grapes on a Vine, or too many fruits on Peach trees, or too many Peas in a drill, will depreciate the value of the whole, and yet the excess is constantly permitted. If statistics could be given of the number of inferior crops of Grapes—say, for instance, that were due to overcropping—the magnitude of the evil would be at once seen. Judicious feeding in many instances mitigates the evils of overcropping considerably, but cannot eradicate them. Knowing how and when to give extra support to tree or plant in times of pressure furnishes us with the key as to our mode of procedure. A few weeks ago I noticed a bed of double Zinnias looking weakly and of inferior growth. I sprinkled the surface lightly over with Amie's manure, hoeing it in, and now they are as luxuriant as one need wish them to be, and the flowers large in size. Much more might be effected by means of artificial manures than is now done. I have found an application of phosphates to benefit stone fruits, and liquid manure from the farmyard or house sewage never comes amiss. On porous soil over-feeding need not be dreaded. A tree carrying a full crop of fruit now should be well fed either with liquid manure of home manufacture, or a sprinkling of artificial manure of some kind carried into the soil with a soaking of pond water. If we try to grow two plants of Broccoli or two Lettuces where only one grew before, the chances are we shall gain nothing by it; but Veitch's Autumn Cauliflower, when planted at wide intervals, grows to an immense size, and a Cauliflower a foot in diameter, even when firm, close, and of good colour, is too large for table, so I have found it advisable to plant these near together in order to obtain the small white heart desired, thus showing that there is no rule without an exception. On the other hand, Broccoli which are expected to stand the winter can hardly have too much space in moderation. Four feet for the largest kinds should not be exceeded. Few things suffer so much from overcrowding as spring-sown annuals. By reason of want of space they are often rushed up to blossom and bear seed, and become shabby without having reached proper development. E. Hobday.

Carnations at South Kensington.—Seldom indeed can fault be found with the reports of exhibitions given in The Garden; nor is there anything, perhaps to complain of now, as the matter to which I wish to direct attention may be a matter of opinion. It is as follows: At page 110 it is stated "that only two exhibitors, Messrs. C. Turner and Douglas, of Ilford, succeeded in producing first-class flowers, all the rest being but very third-rate." This is certainly not my opinion. Many exhibitors besides the two named exhibited first-class blooms, notably Mr. Hines, of Ipswich, and Mr. Lakin, of Oxford, in the class for twelve Carnations. Mr. Hines had the most even lot; but Mr. Lakin's collection contained a few superb blooms, and amongst them a fine specimen of C. B. Master Fred. In the collection of twelve Picotees, Mr. Lakin's was also very fine; while Mr. Rowan and Mr. Buxton likewise showed well. Mr. Huson Morris, of West Hayes, Kent, exhibited twelve very fine Picotees, especially a bloom of Liddington's Favourite. Mr. Henwood and Mr. Phillips, of Reading, and Mr. Anstiss, of Brill, exhibited well in the class for six blooms of Carnations and Picotees. All the above exhibitors showed much above the third class. I would decidedly place them in the first class. In the section for selfs and fancies, the amateurs' class was for twelve, not six blooms; and certainly the exhibits were anything but third rate. Mr. Aubery Spurling obtained the first prize with a superb lot of blooms, and they were the more creditable to him, because he does all the work himself after business hours. Indeed, there were no fewer than twenty-nine exhibitors, a large proportion of them being in the same position as Mr. Spurling; and after the efforts they have made and the excellent results obtained, it is, to say the least, somewhat discouraging to be told that their flowers were "very third-rate."—J. Douglas.

MUSHROOMS FOR AUTUMN AND WINTER.

This is the season at which one should commence preparations for autumn Mushroom beds. In ordinary positions and under common circumstances, it takes several days to collect and prepare the materials for making a good-sized bed. Day by day, if convenient, or at least at intervals of two or three days, the manure as it comes from the stables should be shaken over, and the droppings, including the shortest of the straw, should be wheeled into an open shed and there spread out to dry. A little fermentation may not be amiss, as it will assist in driving off the superabundant moisture more rapidly than could otherwise be effected, but it must not heat violently. If there is danger of the manure becoming too hot, a little loam may be mixed with it. A little loam is, I think, an advantage, as it helps to bind the whole together, and at the same time, if the manure should be a little too fresh, prevents overheating. As soon as materials sufficient for one bed have been collected, a second should be commenced; in fact, if a good supply of Mushrooms is required all through the winter, there should be no stay in the making of beds till the end of October. During the time the manure is lying in the shed frequent turning and mixing must take place, throwing the outsides of the heap into the middle, and *vice versâ*. This permits of the drying process being equal throughout the heap. Next to good spawn, the most important matter in Mushroom culture is making the beds firm and spawning at the right temperature. When a proportion of loam is used with the manure, the beds may be spawned very shortly after they are made up, as there is not much danger of over-heating.

At this season Mushrooms will succeed very well in the open air. More labour is required with open-air beds, but otherwise the result is usually a success; in fact, any person succeeding in growing Mushrooms in a house will succeed with them in the open air. The preparation of the materials is the same in both cases, and the construction of the beds is the same also. But the open-air beds should be of larger dimensions if possible, *i.e.*, the beds should be deeper and built up like a ridge, in order that the heat may be more steady and permanent. The beds may be spawned as soon as the heat declines below 80°. I have spawned beds at a higher temperature when the heat was declining, but unless one is quite sure about the condition of the material of the bed, it is better to wait till the temperature falls below 80°. If several beds are made between the middle of August and the middle of October there should be no difficulty about a supply of Mushrooms all winter. If the soiling of several of the last made beds be delayed for two or three weeks, it will extend the season of productiveness, as though the spawn will work freely through the beds, the Mushrooms will not push through till the soil is placed on if the operation be not delayed unreasonably. If the beds in the open air are kept dry and comfortable they will produce Mushrooms after those in the house have ceased to be productive.

The soil for covering the beds should be fresh loam of rather a sandy character, and should be laid on the surface of the beds from 1½ inches to 2 inches thick, and be made thoroughly firm by beating with the back of a spade. The finishing touch should be given after damping the surface over with a rosed water-pot, so as to make all firm and smooth. Thatched hurdles are good coverings for open-air beds, placed on each side so as to form a ridge. They throw off the water in a most effectual manner. In addition to the hurdles the beds should have a covering of dry litter. If the latter, next the bed, by any chance gets wet the spawn may run into it from the bed, and its productiveness be injured. Where many beds are made the expense of the spawn becomes a consideration, as it usually costs from 5s. to 6s. per bushel. Many good growers obtain their spawn by breaking up a part of a bed in bearing, and use the spawn found there for spawning other beds. This is a very good and a very economical plan. It usually takes a fortnight from the time the materials are collected till the bed is fit to make up, but in cases of emergency the beds may be made at once by adding more loam to the manure, blending all together, and making the bed as firm as possible. The bearing of Mushroom beds is very often injured by watering too freely. In the early stages of bearing very little water will be required, especially if a light covering of hay or litter be used to check evaporation. A light sprinkle with the rosed-pot or the syringe, to soften the hard surface and permit of the young Mushrooms forcing their way out, is all the attention needed for several weeks after bearing begins. When the produce falls off in quantity, a good watering may be given with advantage, using a little artificial manure in the water.

E. Hobday.

Chrysanthemum Madame Desgrange.—This is one of the very best of early white-flowered Chrysanthemums. It is much in advance of the small flowered early pompons, such as Model, that flower at the same date. We find the blooms most useful in a cut state, for although when they open they are creamy-white, they soon change to the clearest white, and last for a long time in water. We have grown a quantity of this variety, and a good proportion of the stock is now in full bloom, while others are only just showing bud, thus giving a long season of flowers for one variety. The early flowering ones are those that were left on the old stools when under glass, and that had made considerable progress before they were removed to their summer quarters. The later flowering ones, which are much the finest plants, are those struck from cuttings and grown on in the usual way, and I have no hesitation in saying that this beautiful variety can be had in flower for fully three months by utilising the earlier growths made under glass, and allowing them to grow without stopping for the earliest bloom, and depending on spring-struck cuttings to supply the main and late crop of flowers. This Chrysanthemum is especially valuable from the fact that the season at which it flowers is about the most difficult time of the whole year in which to get good white flowers in quantity, except by those who have plenty of glass structures. I feel sure that the large demands made on gardeners for white cut flowers will lead to this kind being very largely grown, and to its season being prolonged by various devices. I may also add that it makes most effective pot plants for indoor decoration, being dwarf and sturdy in habit, and requiring no stopping or pinching to induce it to form bushy specimens.—J. G., *Hants*.

Names of plants.—*E. F.*—Mormodes pardinum eburneum.—*T. Poyntz.*—Cymbidium aloifolium, Miltonia Regnelli, Cattleya crispa and Odontoglossum cordatum—all good varieties, particularly the latter, which is much deeper in colour than usual.—*C. H.*—1, Leycesteria formosa; 2, Hemerocallis fulva.—*W. M.*—Tulip Tree (Liriodendron Tulipifera).—*Norman*—White flowered climbers, Physianthus albens.—*A. K.*—Balsamita grandiflora.—*K. A. Spurrell.*—Lilium calcedonicum.—*Reader* (*Cork*).—1, Crataegus Crus-galli pyracanthifolia; 2, Bravoa geminiflora.—*W. Cash.*—1, Begonia weltonensis; 2, cannot name without better specimen with leaves; 3, Veronica decussata; 4, Phlebodium aureum.—*G. G.*—3, Leycesteria formosa. Others next week.

WOODS & FORESTS.

"YORKSHIREMAN'S" CORSICAN PINES.

Some of our writers on forestry, and more particularly "Glendye" and "J. F.," have criticised somewhat harshly the merits of the Corsican Pine as a timber tree suitable for planting extensively in this country. "Yorkshireman," on the other hand, has continually and consistently written in favour of it, asserting that it is the most suitable Pine to plant for the future. He drew his inference as to the merits of the tree from its behaviour on the bleak moorland districts in South Yorkshire. He has placed it before the Scotch Pine, and even the Larch, as a profitable timber tree; in short, he has come to the conclusion that it is the tree of the future for British plantations. To satisfy ourselves upon the subject we went the other day to see "Yorkshireman's" Corsicans about which he has written. He took us to several parts of the estate, high and low, sheltered and exposed, so that we had a good opportunity of judging for ourselves as to the character of his climate. In the lower parts it is pleasant enough, but the greater part of the estate lies high and exposed, and is as bleak as any spot in all Yorkshire; in fact, we could not see a very great area where "Yorkshireman" could coddle up his Corsican Pines, as "J. F." seems to allege. Added to this, the soil is not of the best, particularly in the high parts; there it is thin and stony, in fact overlying a stratum of hard rock—about as poor a spot as perhaps "J. F." could find in the Scotch highlands.

"Yorkshireman" first of all took us to the Corsicans in the home woods, which are sheltered a good deal and have fairly good soil. Here they were planted years ago with a mixed collection of other Conifers, Black Austrian and Scotch Pines included, and left to the mercy of numberless rabbits, which are, even at this season, audacious enough to bark Portugal Laurels with stems as big as a man's leg. Side by side you see the Corsican, the Austrian, and the Scotch Pines, and in every case the Corsican has the best of it for height and girth, but in spread of branches and density the Austrian is ahead of it. All were planted at the same time, in similar soil, and were of the same age. The Corsicans are now about 30 feet high, at a rough guess, and with larger boles than the Scotch, which are not much shorter. Moreover, the Corsicans have a clean length of bole without branch or knot. In the wood where these particular trees are growing there are numbers of others, and the same difference amongst the three kinds is perceptible in every part. We then went to the higher parts of the estate—to the moors, in fact, hundreds of feet above sea-level—where there are many acres of mixed plantations which were formed about fifteen years ago. The chief elements of the mixture are Scotch and Corsican Pines, Larch, and deciduous trees, such as Beech and Sycamore, the foliage of the latter being often lashed into shreds on this bleak spot. Of these only the Scotch and the Corsican Pines can be said to be really flourishing, and it did not need a trained eye to see which was the best of these two. One could single out the Corsicans at a distance, so much taller, bushier, and healthier they seemed than the Scotch, and coming closer to them one could see how much stouter and longer were the yearly growths, some being as much as 18 inches. Of course, they had a different aspect also, on account of twisted leaves and less bluish-grey hue. The Austrians in this part were bushy enough, too much so, for their dense mass of branch and foliage gives such a hold to the wind, that they are often blown out of the ground, as the soil is not very deep and often boggy. We saw enough on this hill to convince us that the Corsican Pine is better able to flourish than any other tree, and eventually clothe the hills with good timber; and we are sure that "Yorkshireman" would be glad to show the same plantations to "Glendye," "J. F.," or anyone else interested in the subject.

"Yorkshireman" seems to be quite aware of the defects of the tree which our writers have pointed out. No one is more aware than he that it is a tree not to be handled in the nursery stage like the Scotch Pine. But he makes allowance for this, and his nursery stock shows that he is no more exempt from failure than other people in the matter of dealing with the juvenile Corsican. He can show you breadths of irrecoverable seedlings which had been planted just before a spell of bad weather. It is, indeed, a capricious tree to deal with when young, but this must be allowed for. The broad question is: Is it, or is it not, the best Pine to plant extensively with a view to ultimate profit from its timber? Somebody must try experiments, or where should we be? What if the Duke of Athole had not in the last century boldly planted the Larch when first introduced before anyone knew about its behaviour in this country? It was then presumably a tender tree, and is so now when in a young state; and, moreover, we had the native Pine whose timber was then thought to be scarcely surpassable. What would have happened had every planter waited till the Duke of Athole's trees were big enough for ship timber? The Corsican Pine is almost a parallel case. We have in it a tree which we know yields timber of excellent quality. It is of quick growth, even under adverse circumstances, and will presumably yield a quicker return than the Scotch Pine. At a time when many think that the Larch is deteriorating we should be only too pleased to avail ourselves of a substitute. In conclusion, we are quite satisfied that "Yorkshireman" has not over-estimated the value of the Corsican Pine, that he has described his plantations correctly, and that he has no motive for advancing the claims of the Pine other than a keen desire to further the interests of British forestry.

THE PROPOSED FORESTRY SCHOOL.

"Yorkshireman" (p. 111) quotes the *Standard* on the school of forestry question, and, notwithstanding what is said on the other side, the conclusion seems pretty general that the prospect of having such an establishment is rather a remote one. What, however, seems to be lost sight of is the fact that there are forest schools lying already at hand. Take any 10 square miles of average English country-side and turn it for the nonce into a field of investigation, and I am sure the student will find quite enough to interest and instruct him without any specially prepared site. In fact, I think the advantage is all the other way, and that a stretch of timbered country taken as it comes is a better ground for study than a place cut-and-dried for the purpose. In saying this, I do not dispute the utility of having sites for observations for special purposes, but, looking at the matter on its broadest footing, I certainly think there is too much made of having forests manufactured for purposes of instruction. A week or two ago I mooted the question of more closely studying the relations of trees and soils. This I conceive to be an important point in forestry, but it is certainly a thing which could as well be studied by taking a few miles of country wherever the learner happened to be as it could be at specially appointed stations. There is nothing special in the way in which the district from which I write is timbered, yet by taking a field of, say, 10 square miles from any suitable point, the young forester would get a variety of soils, aspects, elevations, and species of trees. As an outline of the course he could take with regard to trees and soils, I have mentioned that within the distance referred to we have chalk downs, slopes, and levels of greensand, the coral rag formation, and then the Oxford clay. There are, of course, others beside these in the neighbourhood, but these will serve to illustrate. To take the case of the Elm; upon the chalk it grows as upon all the rest of the soils I have spoken of, but to nothing like perfection. The soil, taken in connection with the elevated situation it occupies, does not seem suited to it. Immediately below this, however, both on the slope and on the level where the greensand commences, the Elm assumes quite another character in habit of growth, size, and quality. In fact, the best Elm I am acquainted with grows on this soil. Coming to the coral rag, we get Elm of fair dimensions and quality, but without the especial excellence of the last-named. On the clay it seems comparatively stunted in its growth and of indifferent quality. With the Oak the conditions are in many respects the reverse, as on the clay, although the process of production is a slow one, timber of the best quality is generally to be found. As a rule, the trees are not left to grow very large, and when trade is brisk the fellings are soon bought up. Where the best Elm grows, the Oak, though it often reaches a large size, cannot be depended upon for quality. In some cases the trees turn out sound enough; in others they are practically of little use. Even full information on these points will not be an absolute safeguard to the planter, but there can scarcely be a more important subject for careful study, and it is one which, as has been said, can be as well pursued in any place wherever the student may happen to be as upon any especially arranged ground. In addition to this, there are very few districts of the size I have indicated where there are not young plantations and woods of various ages which may be studied in connection with what appears to be the native growth. There is, of course, the fact of the lands and woods being private property, but, from my own experience, there are very few who would deny access to them at proper times for the purposes of study.

D. J. Yeo.

THE MOST PROFITABLE WILLOWS.

It is very difficult indeed, out of 282 varieties of the Salix or Willow family, says Mr. Hutchison in one of his excellent papers communicated to the Highland Society, to single out one or two of the most suitable and advantageous for general planting as timber trees; but at the same time, though there may appear 282 varieties, botanically speaking, these may be reduced to a very much smaller compass when they are treated of collectively as similar trees. In fact, they present frequently so few features of distinctive merit or difference, that the number might be very safely reduced to a much smaller list of distinctive individual trees worth growing for their timber in suitable soils and situations throughout Scotland. Indeed, after a careful analysis of all the species, it appears that the entire list of Willows, which may be regarded as claimants for popular favour as timber trees, may be simply reduced to four distinct varieties, viz., Salix alba (the White or Huntingdon Willow), Salix caprea (Goat Willow or Saugh tree), Salix Russelliana (Bedford Willow), and Salix fragilis (Red-wood Willow). Of these varieties, the first named, viz., the Huntingdon Willow (Salix alba), is probably, when unpruned and grown naturally in favourable circumstances, the handsomest and finest of all the Willows of really tree dimensions. It is, in truth, a most picturesque and beautiful tree, whether it be regarded for its general outline and habit, or for the peculiar and distinctive whitish appearance of the foliage, which, combined with its general light and elegant outline, contribute to render this one of the most favourite trees for planting

in such situations as conduce to its early and full development. Such situations are river banks in deep, damp alluvial soil in flat marshy ground, and upon those low-lying swampy situations so well known and common in Scotland, where few planters care to risk a general crop of timber trees. This Willow, which we deem worthy of far more universal cultivation in this country than has hitherto been attempted, has, like many other varieties of its tribe, the advantage of thriving very well indeed in rather poor soils, and in thin sandy stretches or on damp sub-soils. Certainly most trees will thrive better in deep rich loamy soils, with rather a damp sub-soil, than in a poor thin one; but the only point of importance to be observed now-a-days is, that the soil (whatever its nature may be) shall be well drained from stagnant water, and trees of magnitude, such as the White Willow, Grey Poplar, and other rapid-growing timber trees, will all benefit immediately. Thus in cold upland situations not only may the Grey Willow, but also the Bedford Willow (Salix Russelliana) be grown with profit and advantage. In any situation of soil, with damp bottom, the progress made by the Grey Willow is truly marvellous. The plants so situated soon attain considerable height, and rush up with clean straight boles when planted closely, and yield timber of no small value in a very few years. It has been observed that the annual increase in the timber of the Grey Poplar, in trees of about twenty years of age, is at the rate of about 2 cubic feet in certain situations—certainly no inconsiderable rent for the ground occupied by the tree—and this measurement has been verified in more than one place both in Scotland and England; and, in some soils, trees planted eighteen years ago have now attained, in strong clayey loam, fully 25 feet in altitude, and girth about 7 feet in circumference at 1 foot from the ground. The wood of the Salix alba is used for a variety of wright-work. It is peculiarly light, tough, and easily wrought, and is adapted for a great number of country purposes—such as cleading of carts and wagons, railway brakes, planking and joisting boards, and for many purposes in connection with millwright work; tool handles, hoops, copper-work, and basket-making. Indeed, there is no part of this tree, from its thick and heavy trunk to its youngest twig, but is adapted to some use. The bark of the Grey Willow abounds in tannin, but does not appear to be sufficiently appreciated, and is worthy of more notice in this country for the purposes of the tanner. In this respect it appears to be much more generally used on the Continent of Europe. The facility with which this tree is propagated, and rushes up into shape after being planted, is another recommendation to its future increased introduction. All that is requisite to commence a willowry or plantation of this tree is to insert into the soil cuttings made from one or two years' wood (about 2 feet long) to the depth, say, of 10 inches to 1 foot. Stobs made of this tree of greater thickness, say even up to 4 inches to 6 inches in diameter, succeed very well in damp sub-soils, and many fine large trees have been grown from them, although, upon the whole, and in a variety of soils and situations, trees grown from the smaller sizes are preferable. The next variety of Willow, well worthy of culture in this country, is

The Goat Willow (Salix caprea), commonly called the Saugh. Although it can hardly be said to acquire a great height and large dimensions, there are, nevertheless, examples throughout the country of immense size, considering the habits of the tree. It thrives in any soil or elevation, but will attain its highest height and dimensions in a dry, rich, deep, loamy soil, with a cool, if not dampish bottom. The wood of the Saugh is tough and elastic, having considerable lateral as well as longitudinal adhesion, and admits of a very fine polish. It is of considerable value for jobbing purposes; but the White Willow (Salix alba), in point of utility as a timber tree, beats this variety completely. The price which the Salix caprea will realise in a sale is about the same (according to district) as that of the Larch or Birch wood. It is very profitable as an undergrowth in many plantations, for in favourable seasons it will yield young shoots fully 5 feet in one year; and very suitable for the purposes of the crate-maker or basket manufacturer. The bark yields a large amount of tannin. Another member of the Willow family worthy of notice is the

Salix fragilis, or Red-wood Willow, a tree regarding whose utility there is considerable difference of opinion. On the one hand, its timber has been condemned by some arboriists as useless; and they have further asserted that the qualities usually ascribed to it are due to another species, with which they say it is confounded, viz., Salix Russelliana; while, upon the other hand, its suitability, on account of durability, lightness, and toughness for many purposes, whether local or for shipbuilding, for which it is well adapted, renders it worthy of more notice than it at present attracts in our plantations, where damp soil, with deep alluvial subsoil, foster its rapid growth. Its wood is likewise available and very suitable for constructive purposes, for houses, water-wheels, planking, &c., and, indeed, for all country work where a really good, clean, light, tough, elastic, and useful wood is required. One considerable drawback to this Willow is its liability to become dead in the top shoots, or "stag-headed;" and as this habit is of frequent occurrence, this variety is in much less repute than the Salix Russelliana or Salix alba as a timber tree of rapid growth. It will thrive best upon a stiff, damp, clayey soil with cold subsoil. The wood is, when cut, red in the heart, with a white margin, and upon being exposed to the influence of the air for a time, the whole assumes a reddish pink hue of agreeable appearance, and of a consistency easily wrought, and of a very useful texture for any domestic or rural purpose. The other species of Willow which has been mentioned as worthy of extended cultivation in this country is

The Russell or Bedford Willow.—Resembling as it does the Salix fragilis, already described, it is rather more graceful and elegant in its foliage and contour; and indeed, in the case of large and well-grown trees, the Salix Russelliana exhibits a far finer outline than any other of the congeners of this family. Its rapidity of growth is fully equal to that of the Salix alba, and far superior to that of the other members of the Willow tribe already described. Its timber is about equal to that of the Salix alba. While light, tough, elastic, and unlikely to crack or split, its timber is highly prized in the building of manufactories, and for flooring and such like purposes; for its non-combustive properties, coupled with its non-liability to shrink or crack, render it very useful in the building of many edifices—such as mills, manufactories, granaries, &c. It is also, like its other neighbours of the Willow and Saugh tribes, greatly used for cleading cart and wagon bottoms, making railway brakes, lining coal pits and stone or lime quarries, and for almost any purpose connected with rural economy. This Willow succeeds best in a deep moist soil of medium description, but is decidedly unsuited to situations where water is stagnant in the subsoil. It will also thrive and produce good timber upon cold clayey soil, if there be due regard to drainage of the till beneath. Upon the whole, the Salix Russelliana is very decidedly a tree to be extensively planted in conjunction with the Salix alba and Salix fragilis upon exposed uplands for timber purposes, and in such situations it will yield a quick and good return to the planter. It should be grown in masses, for in such circumstances it is far more profitable than when planted as a single specimen or hedgerow tree, or when mixed with others whose too rapid side-spreading growth may interfere with its head or stem.

SEASONABLE WORK.

During the present month, when but little special work demands the attention of the forester, every effort should be made to push forward the general work connected with the enclosure, drainage, and cultivation of land intended for new plantations. This is the more necessary upon heavy clayey soils, where winter work proves highly injurious to the prospects of a successful growth of young trees. Pitting for October planting should be done as early as possible in August. Ground intended to be planted the coming season may now receive attention whenever hands can be spared, by means of clearing, fencing, and cutting open ditches to drain wet places, and laying off surface water in low places. Young plantations that are becoming too thick and crowded should be thinned at once while hands generally can be better spared than later on when forest work is more varied and plentiful. Wherever much game is kept in the woodlands the work should be suspended after the middle of the month to allow the game to settle down quietly when driven in by harvest operations, and if the rides are at once mown and cleared, the woods may remain undisturbed until October. In point of convenience, too, where game is preserved, any covers thinned at this season can be left quiet and undisturbed until cover shooting takes place, which is more particularly necessary in the case of outlying plantations adjoining arable lands, for as soon as harvest commences game of all kinds is driven into the covers.

Hedgerow trees should be pruned where necessary as soon as the corn crops are cut and the removal of branches becomes possible. Too much hedgerow timber of low growth is one of the greatest impediments to high and profitable farming. Young hedges should be kept clean by means of hoeing, or, by what is still better, hand-weeding; older hedges may be kept clean enough by cutting the weeds off with a hook and spreading the litter over the roots of the hedges, unless in the case of Docks and Thistles, or other bad seeding weeds, which should be exterminated by rooting out and burning. See that watercourses, culverts, and pipe drains underneath rides and drives are well cleared out and put in proper order for carrying off a sudden flood of water. Clean and scour out open ditches and trenches and cut new ones, where Rushes and other aquatic weeds abound.

Unusual tree growths.—Trees of all kinds develop abnormal and peculiar growths, but the Larch does not often produce deformities—such at all events, until lately, has been my acquaintance of the tree. While wandering on the Garrol Hill, Fasque, in a wood of Larches I was attracted to a Larch by a somewhat strange swelling on its bole a few feet above the ground. Protuberances are not unusual on some trees, such as Alder, Birch, Beech, Elm, &c., but upon the Firs they are rarely seen. The tumour on this particular Larch is 11 in. by 10 in. by 6 in., so that it is quite a conspicuous object, and may be worth preservation one day when the tree is being felled. There are numerous small ulcerous swellings seated on the large burr or knot.—J. F.

No. 769. SATURDAY, Aug. 14, 1886. Vol. XXX.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSE GARDEN.

ROSES IN 1886.

THE dejected Rose-grower, who had carefully budded, released, sticked, and perhaps just secured with the first tie, what were to have provided him in the summer of 1886 with lovely maiden blooms, might, any time the first week in May, have exclaimed with Whittier,

Of all sad words of tongue or pen,
The saddest are these, "It might have been!"

All had been going on well. After a winter of rest, a strong, sturdy growth was deliberately proceeding, and affording every prospect of a glorious harvest, when suddenly Stage-manager Eastwind whistles, the sunny scene changes to winter with a rapidity that would do credit to a modern pantomime; only, the transformation is the wrong way, from the "Scene of rustic happiness" to "The maiden in distress." In fact, the thermometer having dropped down to some 12° or 15° below the freezing point, all the tender growing maidens were converted into cut-backs in the most relentless way. Not that the cut-backs got off much better; indeed, on the 1st of May they looked almost the worst of the lot; but then they had so much more material to go back upon than the newly-budded plants, that though they also had to do all their work over again, they recovered in time to throw up good flowers from behind the injured points. Just a few gardens that escaped the ordeal have shown what a season "it might have been," and probably finer flowers have not been seen than Mr. Haywood's thirty-six at Reigate and Mr. Pemberton's thirty-six at Bath; but otherwise the evidence of the visitation has been general. Of course, the displays most injuriously affected have been those of the trade-growers, who rely chiefly on maidens for their exhibition blooms; and, as a consequence, the Rose shows of 1886 cannot be regarded, on the whole, as otherwise than below the average in point of quality. However, if the shows have been less gorgeous than usual, the gardens have been more than usually interesting. In the first place, the checking of the growth of the plants by the late frost has greatly prolonged the flowering season. Many varieties which in the south of England are normally over within the first ten days of July are only now in perfection, so that the usual gap between the first and second flowering seems likely this year to be bridged over. Again opportunity has been afforded for noting the varieties that are most capable of resisting or recovering from such unseasonable attacks, and in this respect the Tea-scented varieties stand out to conspicuous advantage. Not as resisting, it is true; they all "sat down" with a meekness of submission, which, if not gratifying, was at least prompt and unanimous. But as soon as the cold wave that made them "duck" was passed, they got up again and succeeded in looking as if nothing had happened far better and sooner than the more unyielding Hybrid Perpetuals, that tried to stand up through it. The latter affected to go on growing as if there was nothing the matter, but the few that did succeed in producing some dreadful deformity of a flower only proved the hopelessness of the case, and they had to begin again from the bottom after having wasted the time in trying to pose as hardy plants. Even the summer Roses and some of the species were cut off, so that another peculiarity of the season was, that all the Roses—singles, Damasks, Gallicas, Mosses, Ayrshires, Teas, and Hybrid Perpetuals—were seen flowering simultaneously. Some of the more tender summer-flowering sorts never succeeded in producing any bloom at all, while the blossoms of others, though numerous, were nearly all imperfect. Of the former, Fortune's Yellow, which was giving splendid promise of a coming "shower of tawny gold," was a case in point, every flowering shoot being injured beyond recovery; and nearly all the other summer Roses, except the Provence and Mosses, were in the latter condition, flower after flower expanding, each more deformed than the last, being either quartered, or green-eyed, or in many cases having a second flower-bud growing up through the centre of the half-expanded blossom.

Among the Hybrid Perpetuals, the first to recover and get into flower was the popular and thoroughly dependable A. K. Williams, a little under-sized, perhaps, but bright and otherwise quite in character. The way in which this beautiful variety has come through the recent winter and spring, and afforded first-rate blooms throughout the season, ought to remove all doubt as to its claim to be considered as the best all-round Hybrid Perpetual—especially when grown on dwarf Brier stocks. It is generally the first to open and the last to succumb to October fogs. Its upright habit makes it exceedingly gay in the garden, and its flowers being nearly always perfect in form whatever their size, it is equally available for exhibition and general cut-flower work.

The next variety to make a display was Charles Lefebvre, on cut-backs—the maiden plants never recovered at all; and Madame Gabriel Luizet was a good third, producing myriads of flowers in the hope of gaining the verdict, but her usual perfect finish was terribly wanting.

The garden was now gay enough with bloom on the cut-back plants of every kind, though fully two-thirds of the flowers would not bear critical inspection; but the maidens remained ominously green, and, as if to make up for the absence of greenfly and mildew, Orange fungus, or red rust, made its appearance on the varieties that were budded on the Manetti. It is worthy of especial note that the plants on Brier cuttings or seedlings were, and have continued almost entirely, free from this unsightly fungus; while those on the Manetti in their neighbourhood have hardly in a single case escaped.

In fact, evidence is gradually accumulating from all sides in support of the contention that dwarf Brier (cutting or seedling) is the stock upon which all Roses ought to be worked. Of course, as Manetti stocks can be so easily made and budded, and so quickly form big saleable plants, they will die hard, for there is no denying the Manetti the merit of convenience, but that is about its only virtue. Plants worked on dwarf Briers give more perfect maiden blooms than those on Manetti, and, not beginning to grow so early, are less liable to injury from spring frosts; they are hardier, since, owing to the greater hardness and vigour of the Brier roots, they are better able to withstand extremes of drought and cold; they are longer lived; and while numerous varieties, including all the Tea-scented and Noisettes, require Brier, and will not succeed out of doors upon Manetti, no varieties are ever mentioned as succeeding upon Manetti which will not do equally well, or better, upon dwarf Brier.

It is probable that the rapid deterioration of plants worked on Manetti has been the cause of Roses being so often grown merely for cut flowers, instead of being boldly treated as decorative garden plants. To be effective in this way they should be massed in considerable groups of one variety, rather than indiscriminately mixed in ones and twos. A bed of a hundred dwarf trees makes a far more brilliant display when planted, say, in five varieties of distinct colours than if all, or most, of the plants are of different sorts. Care should be taken to select varieties of decided colour and sturdy habit that hold their blooms erect, and that are free and perpetual flowering. By way of an example, a bed to hold a hundred plants might be arranged in five irregular groups of twenty each of the following varieties: A. K. Williams, Hon. Edith Gifford (a valuable erect-growing white Tea of great freedom of bloom), Marquise de Castellane, Merveille de Lyon, and Charles Lefebvre. If a mass of bloom is considered preferable to more brilliant individual flowers, Noble's Queen of the Bedders is an admirable variety to grow. It will thrive in most soils, and is a free and continuous bloomer, throwing up a succession of large trusses of flowers of Charles Lefebvre colour, though wanting individually in refinement. Another beautiful light variety for similar purposes, and not liable to the last objection, is Nabonnand's seedling from La France—Cannes la Coquette. La France itself is a little too much inclined to be pendulous to be quite effective in the garden, and is also easily spoiled by wet; whereas Cannes la Coquette has a stiff upright habit, and owing to its thicker, more substantial petal, is not readily disfigured by rough weather, and its colour is almost exactly that of Lady Mary Fitzwilliam. For a Tea-scented variety to associate with the two foregoing, nothing prettier could be found than Madame Joseph Schwartz, whose great trusses of lovely white shell-petalled flowers, just washed with the tenderest rose, are held boldly up to the admiring gaze of every passer-by. This habit of holding its flowers erect is essential to the permanent popularity of any Rose as a garden plant. Many a good variety, such as Leopold Hausburg and Madame Emma Hall, have gone out of general cultivation because they produce no effect, through hanging their heads. Pendulous flowers are, of course, admissible in climbers where one may stand under the wall and look up into the inverted goblets; but varieties of the normal habit of growth available for making beds or bushes that are not able to hold up their heads on the plant, nor even when cut without the help of a wire, ought not to be encouraged.

It would seem desirable that raisers should pay a good deal more attention to the other points in a Rose's character instead of basing their estimate of a new variety solely upon the merit of its flowers. The flower is undoubtedly the most important part of a Rose, and new colours and more perfect forms are of the highest importance; but gain in this direction may be more than counterbalanced if the plant upon which it is to be displayed definitely refuses to grow, or carries its blooms in such hang-dog fashion as to be completely unornamental in the garden. There is another Hybrid Perpetual sent out last year following in the line of Claude Levet, Louis Doré, and such like; it may be distinct perhaps, but as the tallest plant in the row of maidens is about 9 inches high, it is certainly worthless, and there is no doubt that the reputation of raisers of such varieties would be greatly enhanced if they could bring themselves to refrain from sending them into commerce.

Perhaps this flooding of the market with worthless or consumptive hybrids may be partly owing to the want of sympathy on the part of the raiser with the objects of the subsequent

grower; and in that case the best plan would be for amateurs to raise seedlings themselves, and endeavour to find out by some consistent plan and method of proceeding how far it is possible to attain a definite end. That looking for one thing will result in the finding of something else is perhaps truer of raising seedlings than of many other undertakings, and no doubt the attempt to raise a race of Roses capable of resisting the insidious attacks of mildew would incidentally result in the production of some distinct variety which, if not mildew-proof, might otherwise be a great acquisition. If the avowed object be to raise seedlings that shall be exempt from mildew, the employment of any of the summer Roses, or any of their near relatives, as Madame Gabriel Luizet, should be studiously avoided, for the way in which the pest overwhelms the latter, and even to a greater extent the Gallicas, is hopeless. On the other hand, most of the North American species, as Rosa lucida, Rosa rubifolia, &c., seem always free from any disfigurement of foliage, and are of excellent constitution. It is satisfactory to see that the classes framed at the National Rose Society's exhibition, and since at Manchester and elsewhere, are helping to bring forward some unduly neglected favourites, including a good many of the single Roses, such as macrantha, the Austrian Briers, rubifolia, &c.; and now that the latter are beginning to obtain some share of recognition in our gardens, there will be a better chance of getting their good constitutional qualities combined with the substantial advantages of existing double Roses for the production of the "coming race" of Roses, which, rising superior to the chronic diseases of an effete old-world population, shall keep all gardens gay throughout the summer with blooms of every conceivable shade of colour in which blue is an unknown quantity. T. W. G.

ORCHIDS.

HARDY ORCHIDS.

Seven years ago, in a quiet, semi-shady corner of a little Welsh garden, aspect southern, a small bed was specially prepared for the reception of hardy Orchids, and the following report of both successes and failures with these pretty and interesting, but now, I am forced to add, rather capricious, subjects will, I know, prove of interest to more than one reader of The Garden.

The bed, a rectangle of fully 80 square feet of surface, was formed by removing nearly 2 feet in depth of the soil, placing a couple of inches of rough Anglesey gravel in the bottom, and levelling up with a half of pure and good woodland leaf-mould, a quarter of rough bog removed from a deep railway cutting, and a quarter of the originally taken out soil. Heights and hollows were next formed in the bed, for well I knew that the Marsh Orchis could never succeed on a dry hillock just as well as I knew that the Bee Ophrys was never intended for inhabiting a swamp. To remove the monotony of bare soil, a few limestone blocks, or stones, I should rather say, for blocks are not readily obtained just when one wants them, were inserted in half-natural, half-suitable positions, and against the sides of these such kinds as require calcareous situations were planted with a great amount of success. The bed being thus formed, all the Orchids in the immediate neighbourhood were transferred to it in a most careful manner, generally by the half-dozen, the strongest and best-marked flowers being always chosen. From time to time during the space of two years, whether by purchase or exchange, I succeeded in collecting together all our native species, with, perhaps, three exceptions, these being planted in soils and positions akin, as nearly as possible, to those in which they were found in a state of nature. Foreign species were more readily obtained—Messrs. Ware, Dammann and Co., and Ant. Roozen offering very tempting lists, and a couple of dozens of the reputed hardy and easily managed of these were likewise purchased and planted according to catalogue directions, until in all there were nearly 100 distinct kinds in the bed, the surface of which was carpeted with such low-growing subjects as Campanula hederacea, Anagallis tenella, Arenarias, and Saxifrages, this for the double purpose of imparting an ornamental appearance and keeping the soil cool and moist by preventing excessive evaporation.

Of all these a few have done remarkably well and increased both in size and number; a larger proportion have done but middling, while more than one-fourth have entirely disappeared, a good deal owing, no doubt, to my inability to procure strong uninjured specimens, at least more so than from any difficulty as regards their culture in our English soil and clime. Of those that have succeeded well and become established we will now in turn say a few words, but it may be well to state that they are not treated of or ranked according to merit, but rather in an indiscriminate manner.

Amongst the various species of Orchids, O. foliosa has done remarkably well planted in the dampest ground, and with no attention save an annual top-dressing of rich vegetable refuse. Spikes nearly 3 feet long, and bearing from 60 to 80 flowers each, are not exceptional; indeed at a short distance away the plants look like great, well-grown Foxgloves, the colour of the flowers—a pinky-purple—feigning that of the Digitalis in a very marked degree. Division of the roots and fresh planting should take place every third year, for as these increase rapidly and are of a large size, starvation, arising from poverty of the soil, is sure to come about, the results of which are but too well known to every cultivator, in small, dwindling, ill-flowered specimens. It needs plenty of water during the growing season so that the big, glossy green leaves may become fully developed, after which the flower will take care of itself. Our native O. pyramidalis is, in truth, a lovely plant, and of the easiest management, and might just now well grace any border with its pyramidal spikes of sweetly scented rosy flowers. Here it runs wild in a red calcareous-infected loam, and where the ground is thickly matted with the mountain Cudweed (Antennaria dioica). Of the brown Man Orchis (O. fusca), let everyone who has the chance procure a couple or three specimens and plant them in chalky loam, in sunshine or shade, and in a dampish situation, and during the spring months, about May, "they will charm the eye and gladden the heart" on more than one occasion with their quaintly conspicuously hooded flowers. About our two commonest species, O. mascula and O. maculata, I need hardly say a word, for every one knows their value in alpine gardening—at least if they do not they ought to do—but remember to plant in good-sized irregular-shaped masses of a dozen or more in each, for not till then is their true worth as garden plants found out and appreciated.

The fragrant Orchis, O. conopsea, is a choice and desirable plant, its pretty mauve flowers and delicious fragrance being special recommendations for its extended culture. To get it established requires neither much care nor circumspection. A white-flowered variety of this Orchid was sent to me from Ireland some time ago, and it is doing well. O. Morio is rather insignificant, but rich in colour, and not at all difficult to cultivate; while O. laxiflora, from Guernsey, increases at the rate of one, and sometimes two, new plants in the year. This latter is an ornamental species when well grown, the individual flowers, though rather loosely arranged, being bright and lasting.

By far the finest and most easily managed of the Continental species is O. undulatifolia, a charming plant, with variously-coloured, curiously-shaped, usually pink-spotted flowers, and large glaucous, wavy leaves. It has become quite established in various positions, and increases from year to year, the soil used being ordinary loam, with which a small quantity of old lime rubbish is incorporated. There is a spotted-leaved variety which is a great improvement on the normal plant, the flowers being more numerous, of larger size, and brighter in colour. O. sambucina, the Elder-scented, and O. Cupani have done middling, but if I could only lift the tubers in their native wilds myself, I feel confident they would do much better. All the Helleborines (Epipactis) grow like weeds when established, and several are highly ornamental. Our three native members of this family—E. latifolia, with its variously coloured flowers, E. palustris, with its pretty raceme of pinky white blooms and conspicuously crenated lip, and E. ovalis, that dwarf, purple-flowered, limestone-loving plant—all bloom freely year after year; while one out of two of the nearly allied Cephalantheras is likewise quite at home in a shady corner, where it is almost stifled with Saxifrages and Campanulas. The Musk Herminium (H. Monorchis) is a sweet little plant, whose scant wants—an elevated site and rough chalky loam—are readily enough complied with. As the tubers of this plant are formed at the ends of stout roots, and consequently at a considerable distance from the original stem, unusual care in transplanting must be attended to. On the sloping side of a limestone block the rare highland Orchid, Goodyera repens, blooms freely; while not a foot from it, but in damper soil, Liparis Loeselii, an interesting, though not very ornamental, plant, has regularly appeared and flowered well for five years past.

Thanks to Mr. Gumbleton, I can now boast of possessing healthy, well-flowered specimens of that rare and interesting Irish Orchid, Spiranthes Romanzoviana, a plant that has been found wild in no other part of Europe, its nearest stations being some of the cold, upland bogs of North America. The flowers are creamy white, Violet-scented, and arranged spirally in three rows.

With the three native species of Ophrys I cannot say that I have been very successful, although O. apifera has certainly flowered for several years in a satisfactory manner. Occasionally, however, it disappears for a season or two, and again reappears full of life and vigour—a peculiarity that is shared in by one or two other native Orchids, and which should make cultivators doubly careful about giving up for lost what in reality increases beneath ground to bloom above. The genus Cypripedium is well worthy of attention as garden plants, for some half dozen kinds are perfectly hardy, of the freest growth, and quaintly original in their conspicuous flowers. The well known and deservedly popular Mocassin flower (C. spectabile) is a grand plant when well flowered, and associates nicely with such peat-loving favourites as the Trilliums, Heaths, and plants of a like temperament. With C. parviflorum, the small yellow Lady's Slipper, have I, however, been most successful, not only as regards rate of increase, but quantity of bloom produced. A specimen of it with two eyes and good uninjured roots was planted in pure, coarse leaf mould and sharp river sand some five or six years ago, and this season it produced no fewer than sixteen flowers, and had fully twenty stems. By coarse leaf mould is meant such as is intermingled with pieces of half decayed wood and half decomposed leaves, for this I find, or rather have read, in that delightful book, "The Orchids of New England," is the most natural food for this handsome tribe of plants.

C. acaule I cannot manage, but C. pubescens appears regularly year by year, and is an interesting and pretty plant. That rare and pure flowered species—I refer to C. candidum—likewise does well and increases rapidly, which, sorry am I to say so, is not the case with C. arietinum nor C. macranthum.

I wish someone would send me good roots of either or both, for I quite believe that they are manageable enough; but the stumpy, emaciated specimens which one gets for 3s. 6d. were never meant for succeeding, but rather sold, as the flowers of a much-prized Continental Rose were,

with the eye removed, so that propagation was out of the question.

The English Lady's Slipper, C. Calceolus, puzzled me long enough, but now, thanks to those who kindly sent me eyes, roots and all, it is a treat to see it established in at least three positions, increasing in number and luxuriance, and blooming freely for these two years past.

Mr. Wood's sand recipe for "picking up" mutilated rooted specimens is good, but give plenty of water, as Orchids, above all things, cannot abide drought. There are two or three other North American Orchids, as well as the Cypripediums above referred to, that are worthy of more than a passing note, and, first, let me refer to Orchis spectabilis, for it is a bold, easy-habited plant with an amount of Yankee folk lore attached that is almost distressing, and with a fine dense spike of pinky flowers and a remarkably good constitution. Planted with Cypripediums from the same country it will do well, but try it in dry ground, as somebody did, and you will be disappointed and think the printed directions for cultivating the plant a little bit misleading. Last of all, a Chinese Orchid, Bletia hyacinthina, has done well in dampish peaty soil, where it produces its grassy foliage and spikes of handsome purplish flowers nearly as perfect as the generality of those offered for sale in the market-place at Canton. The genus Serapias has been neglected, for I should have said that three species at least, S. Lingua, S. neglecta, and S. cordifera, are satisfactory, and that is saying a great deal.

In conclusion, I may add that only such species as have done well are treated of above, and any person procuring good roots of these and giving them a fair trial will certainly be far from disappointed with the results.

A. D. Webster.

AUGUST FLOWERING ORCHIDS.

As the present month is considered to be the beginning of the dull season as regards Orchid bloom, every showy kind that flowers naturally now should be grown by those who like to see their houses lit up with bloom, and who like to cut Orchid flowers all the year round. These late-flowering kinds are generally thought to be more difficult to manage than those which naturally flower in early summer, when there is a surfeit of bloom of all sorts, but their value quite compensates for any extra trouble bestowed upon them. Appended is a list of those kinds which come into bloom in August and September, and perhaps earlier, and these also are supplemented by earlier kinds, such, for instance, as Odontoglossum crispum and Peseatorei, which linger on till autumn. The list is not exhaustive, and some of your readers may be able to add to it :—

Cattleya Leopoldi
Dowiana
aurea
Harrisoniæ
Gaskelliana
Eldorado
Schofieldiana
crispa
Lælia elegans præstata
Turneri
Mormodes luxatum
eburneum
Zygopetalum Gautieri
Oncidium Lanceanum
variegatum Rogersi
prætextum
Oncidium stelligerum
macranthum
aurosum
cultum
Miltonia Regneli
spectabilis
Odontoglossum caudatum
maculatum
Epidendrum vitellinum
majus
Acineta Humboldti
Galeandra Devoniana
Bueri
Stanhopea (various species)
Disa grandiflora

G.

Montbretia Pottsi.—A complaint was made by a correspondent about this time last year that he could not get this plant to flower, at which I expressed surprise, seeing that I never had any difficulty with it in that respect. We have just now a plant in a pot with four spikes of flowers and the individual blossoms are unusually large, yet this has been obtained with very little trouble. According to custom, at the end of last October we took off a quantity of side growths from a plant growing in a mixed border; five of these pieces were put round 6-inch pots in ordinary garden soil. All winter and up to the end of April the pots stood on the floor of a cool Peach house and were watered as often as the soil got dry. When brought out of doors in spring, all but the plant now in flower were planted out; that left was put into a 7-inch pot and left in the frame ground exposed to all weathers; the only attention which it has had consisted in giving it plenty of water when it required it. That this treatment has suited it is evident by the strong flower-spikes and large healthy leaves which it has produced. Our other plants are later in coming into flower, at which I am not surprised, as they suffered from want of root moisture, we having had no time to attend to them in that respect.—J. C. C.

Garden in the House.

ARRANGING CUT FLOWERS.

The art of arranging cut flowers does not seem to keep pace with the rapidly growing demand for flowers of all kinds. In the majority of decorations, bouquets, or in whatever they are employed far too many flowers are used, quantity seeming to be thought to make up for lack of arrangement. Even in establishments in which professional decorators are kept, I have frequently been surprised at the lack of originality shown as regards combination or arrangement, while in villa residences and even cottages one often finds exquisite taste displayed. To what excellent use is the common Ivy put by some, who, having but few flowers, are compelled to make the most of what they have; associated with a few common Ferns in hanging baskets, it lasts for months in ordinary windows or corridors. Such sprays, too, are useful in winter time for entwining over the handles of baskets containing cut flowers. Baskets, too, filled with fresh green Moss require only a fraction of the flowers usually considered necessary to fill either them or vases satisfactorily. There can be no doubt that overcrowding is the greatest of all evils in regard to cut-flower arrangement, and unless one has a firm base, such as sand covered with Moss, the flowers press too closely on each other. Unless every flower has room to stand out clear of its neighbours, the arrangement cannot possibly be perfect. Small vases, dishes, or baskets look most striking when filled with only one variety of flower. Even in mixed vases three colours are more effective than when more are introduced. The free use of foliage is one of the greatest safeguards against overcrowding, and, as a rule, nothing suits a flower so well as its own foliage. The old notion of garnishing everything with Maiden-hair Fern has happily to a great extent gone out of fashion. It is very transient and soon gives a worn-out look to the flowers which it is intended to enhance. Very large vases must have flowers and foliage in proportion. At the present time there is a wealth of such material in gardens, notably Gladioli, Lilies of the lancifolium type, Hollyhocks, and Dahlias. These look well in large vases if cut to suit them and dropped into them so as to stand clear of each other. If a good stiff branch of Butcher's Broom be first inserted each stem will then remain firm where placed, and for draping the edges of such vases long trailing sprays of common Periwinkle are very effective. In towns large stems of the common Bulrush are in great request for vases; they last a long time in good condition, a consideration by no means to be overlooked.

J. G. H.

Button-hole Carnations.—I should like to see the National Carnation Society establishing at its annual shows a class for button-hole Carnations. No doubt it will be said that all Carnations are suited for button-holes, but whilst it is obvious that flaked and bizarre flowers are too "bizarre" for such uses, these are the very flowers upon which the society bestows most encouragement. I prefer to class as button hole flowers those which do not produce big blooms, *i.e.*, sorts that have flowers not large enough for ordinary exhibition purposes. Specially pleasing for button-hole flowers are selections from the self, and even some edged flowers found in the French strain. Small, but full, flowers, distinct and pleasing in colour, need not be wanting in beauty or sweetness. It adds much to the merit of these kinds that they can be easily raised from seed, and that they also seed freely. None the less, many of them give plenty of grass for pipings or layers if need be. Still, with seed plentiful it is easier to save some and sow annually. Care in the selection may produce improvements in the flowers, but size of bloom should be less a desideratum than securing good form and substance and beautiful shades of colour. This strain will give plenty of flowers for the million. A class for button-hole Carnations or Picotees in bunches of six blooms, one variety in a bunch, would afford some scope for opinion as to what size of flower and hue of colour were best suited for the object in view.—A. D.

NOTES OF THE WEEK.

Lilium auratum.—Some thousands of this lovely Lily are now finely in flower in the Brooklane Nursery, Ormskirk; each stem bears from six to ten flowers, and amongst them are many of the crimson-banded variety. All of them have been raised from seed, and are growing in beds in the open air, where they improve both in strength and floriferousness every season. With me imported bulbs deteriorate after one or two seasons' growth, but home-grown ones improve.—J. Hathaway, *Latham House, Ormskirk.*

Primula Parryi.—As an ornamental plant, I am unable to make this Primula a success, but others may have done better. Two years ago I raised about fifty from Mr. W. Thompson's seed, and planted them out, as is my habit, under many different conditions. They seem happiest on a raised bed of moist peaty loam, facing the north-east and sheltered. The flower is purple, not much larger than that of a common Cowslip. The leaves are about 8 inches long, rather like an elongated Auricula leaf. The plant is a native of the Rocky Mountains.—C. Wolley Dod, *Edge Hall, Malpas.*

Hybrid Montbretias.—Mr. W. E. Gumbleton sends from Belgrove, Queenstown, specimens of three new varieties of Montbretia crocosmæflora, itself a hybrid between M. Pottsi and Tritonia aurea. All the three sorts differ from the original. One has very dark red flowers, and is named Etoile de Feu. Another, called Gerbe d'Or, is a pure yellow self, while the third is between the two others in colour, and is named Bouquet Fait. Mr. Gumbleton observes that they are all abundant bloomers and quite hardy with him during ordinary winters.

Montbretia Pottsi.—I see complaints made from time to time in The Garden about Montbretia Pottsi not flowering. I send you a few sprays of it, and also of the hybrid M. crocosmæflora. They bloom admirably with me, and yield a full crop of seed.—W. B. Hartland, *Cork.*

*** The specimens which Mr. Hartland sends are excellent, but we doubt if such good results could be obtained with this plant in a less favoured locality.—Ed.

The Formosa Lily.—The variety of Lilium longiflorum which is found wild in the island of Formosa is named formosanum, and a fine flowering specimen of it has been sent to us by Mr. Taylor Shier, from St. Martin's House, Colchester. It differs from the ordinary form of L. longiflorum in several respects. The flowers are slightly stained with purple on the outside, the foliage is longer, and the stems taller. It was introduced by Messrs. Veitch about seven years ago, through their collector, Mr. Maries, and an illustration of the first plant that flowered in this country will be found in The Garden, Vol. XVIII.

The daily papers and matters botanical.—An instance of the way in which newspapers educate their readers in matters botanical occurred in one of the leading London daily papers this week. It contained a long rigmarole relating to "an Orchid sale," written ostensibly by "an Orchid cultivator," but the way in which the writer blundered respecting little details clearly showed that he had been "coached," and that he did not possess great knowledge of his subject. The queer way in which he mixes up "professional and amateur cultivators" is amusing, and scarcely less so his ideas respecting genera. Another reporter writes as follows respect-

ng the tuberous Begonias shown at South Kensington on Tuesday last: "Ten years ago this bloom was a small and insignificant field flower, upon which but little attention was bestowed, whilst now it is one of the garden pets, and its colours have become legion. Yesterday there were shown double flowers resembling Balsams; whilst there was a larger number of new varieties, amongst them a singular duplex!" Alluding to the beautiful Fuchsia triphylla shown from Chiswick, the same writer reports: "A new Fuchsia, more resembling Heather than the members of its own family, was a specialty." Now, when everybody is going to the moors, the writer may have had Heather on the brain, but the Fuchsia in question is no more like Heather than it is like a Cabbage.

Genista ætnensis.—This is one of the most elegant of all the Genistas, and forms a good sized shrub 9 feet or 10 feet high, a prominent feature of which is the elegantly drooping branchlets, and just now the bright golden blossoms impart another and a very attractive addition to its ornamental qualities. It is a native of the district around Mount Etna, from whence the name is derived; according to Loudon it was introduced in 1816, but it is even now quite a rare plant in gardens, though it is so ornamental and can be increased by means of seeds to an almost unlimited extent.—H. P.

National Dahlia show.—Mr. Moore, the honorary secretary to this attractive exhibition, which takes place at the Crystal Palace on September 3 and 4, asks for space to remind growers and exhibitors of this interesting autumnal flower show that the Turner Memorial Prize (silver cup, value £10, for twelve show and six fancy Dahlias) will be open for further competition at the ensuing show, and to say that he will gladly furnish the prize schedule to any person who may apply for it. Entries for the show should be sent to him (at the Botanic Garden, Chelsea, S.W.) on or before August 27.

Lilies and shelter.—Mr. G. F. Wilson made some very interesting statements the other day in The Garden about Lily growing. I can quite agree as to what he says as to the beneficial effects of shelter, especially during the early stages of growth. I had many Lilies planted in various positions through the garden, but those grown in the Rhododendron beds have been much the finest, and I now send you a few samples, including L. Martagon var. dalmaticum (with forty-one flowers on a stem, 7 feet high), L. pardalinum, L. testaceum, L. chalcedonicum, &c.—F. W. Moore, *Glasnevin, Dublin.*

*** The Lilies sent by Mr. Moore are indeed very fine, particularly the L. dalmaticum—one of the best specimens we have seen.—Ed.

Variegated Sophora.—This is a distinct-looking variety, having the leaves marked with creamy white, changing to pure white as the foliage matures. The variegation is not so clear and well defined as in some shrubs, but is effective at a little distance, when the variegated leaves give to a specimen the appearance of being laden with white blossoms. It is far less vigorous than the common green-leaved type, but like that will thrive in dry soils; indeed, grown in this way, the variegation is better defined than in a moister spot. As a single specimen there are few more effective shrubs than this at the present time. It is generally increased by grafting on seedlings of the common green-leaved form.—T.

A new annual Poppy (Papaver pavoninum).—I observe that you have received specimens of my new Poppy, Papaver pavoninum (Schrenk), but as I think it probable the flowers may have fallen to pieces in transit, I venture to send you a few branches, in the hope that the buds may expand in water and thus give you perfect flowers. I think it an interesting, or even a remarkable species. The foliage is decidedly less weedy than that of many annual species, and while the plant is young is even elegant in its pinnatifid lobings, reminding one of the genus Daucus. The singular horn-like appendages of the sepals are, so far as I know, peculiar to this species, and at any rate readily distinguished from all others at present in cultivation. The brilliant scarlet flowers with the deeply contrasted glossy black zone will, I hope, speak for themselves. The specimens sent are from plants which have been some little time in flower, and the blossoms are therefore by no means of maximum size, but rather below it.—W. Thompson, *Ipswich.*

Spiræa Lindleyana.—This Spiræa does not continue so long in bloom as some other species, yet it has such ornamental foliage and is so beautiful when in bloom, that it must rank among the most select shrubs. It forms a large bush 10 feet or 12 feet high, when grown in good free soil, and if in an open position will be as much in diameter. The long wand-like shoots that are pushed up from the base of the plant are now terminated by large feathery panicles of white blossoms, which in association with the light pinnate foliage cause this Spiræa to be so much admired. It is seen to the greatest advantage when planted by itself, for then it can show its full beauty, though it is able to hold its own when planted with other shrubs. This Spiræa is a native of the Himalayas, and is occasionally injured during exceptionally severe winters, but, as a rule, quickly recovers. It may be easily propagated by detaching rooted suckers, which can, as a rule, be done without difficulty.—T.

Ferns.

TASSELLED AND CRESTED FERNS.

I have been much interested in reading a reply to my notes on this subject which appeared in The Garden (p. 113); still, I do not think the writer has disproved my argument. My statement was that, according to my observations, British Ferns were more subject to variation from their normal forms than exotic species. I, moreover, believe that this variation has come about recently. Old British botanists were keen-eyed enough to discover a few abnormal forms, which they duly recorded, and it is only feasible to suppose that, had the varieties we now have been in existence in their day, they would have been noted. I am aware that many abnormal forms have been bred in gardens, but enormous quantities can be gathered wild any day in a good Fern locality. I have made Ferns one of my special studies for about thirty years, during which time I have collected an herbarium of nearly 2000 kinds. I have had working access to some of the largest Fern herbariums in the country, besides having the care of some of the largest collections in cultivation; therefore I approach the subject with some practical knowledge. I have large collections of Jamaica Ferns, and I possess specimens of a forked Blechnum from near the same spot mentioned by Mr. Syme; but the genus Blechnum, or Lomaria combined, has never yet produced the number of sports that our solitary species, L. Spicant, has done. Our British Ferns do not amount to more than about one in sixty compared with the exotic species; and whilst we have hundreds of named varieties of the former, I think one hundred would embrace all the known abnormal forms of the latter. It is quite probable that there are plenty more yet to be introduced; that they may have been passed over by the botanical collector is feasible enough; but as all trade collectors know that there are numerous admirers of these plants, and that they obtain a ready sale at home, they would be greatly to blame if they did not add to our knowledge of them and enrich their employers' Fern collections at the same time. Mr. Syme states that many Indian Ferns vary as much as our common Hart's-tongue, but I would certainly be glad to know what species of exotic Ferns with simple fronds so vary. I have looked through all known to me, but cannot find one; in a large series of Elaphoglossum I can find no abnormal forms. I certainly find the species running into each other in a way which large sets of any genus will always show, but the only crested simple-fronded exotic Ferns with which I am acquainted are Microsorium irioides, Asplenium palmatum, and Niphobolus Lingua. The inference which I draw from the great variation that occurs in our native Ferns is, that some climatic change is going on which influences these plants in a more rapid manner than plants in any other Order; if that be not so, to what can it be attributed? Would Mr. Syme kindly give us a list of the forked, tasselled, and crested forms of exotic Ferns with which he is acquainted? G.

THE BIRD'S-FOOT VIOLET.
(VIOLA PEDATA.)

Well named is this pretty American Violet, the shape of leaf-stalk and leaf strangely resembling a bird's foot and leg;—a pretty, interesting flower, with a look of some shy animal with ears thrown back. The flowers vary a good deal in different plants both in size and shade of colouring—usually a bright cheerful lilac. There is a white variety, and one that is deep purple and white. It thrives in cool peaty ground, but needs careful watching in winter, as the roots die entirely away, leaving only a little stocky stump, which is easily thrust out of the ground by frost.

Crinum giganteum var. concinnum.—This pretty dwarf growing and free-blooming Crinum is now blooming for the second time this year in my greenhouse on a bulb obtained last autumn from Mr. Bull, of Chelsea. Its flowers are pure white, and are borne in umbels of six to eight on a slight stem of only a foot in height, which is very low for a Crinum, the flower-stems of the other varieties now in flower here being C. Moorei, 2 feet 4 inches, and C. Powelli (in open border), exactly 4 feet high. The flowers themselves, though of good size, by no means deserve the name of giganteum, but have to bear it, as the plant is merely a low growing form of C. giganteum, figured in the 86th volume of *Botanical Magazine*, plate 5205, which is, though an exceedingly handsome, undoubtedly an extremely coarse-growing species, only suitable for the largest sized stoves, where it can be planted out, as in the Palm stove at Kew. Except under this treatment, which it would be possible for so very few to give it, it would doubtless be almost impossible to bloom it; while the variety whose name heads this note may be grown and bloomed successfully by any lover of these handsome plants who has an ordinary warm stove to grow it in. It seems to be an evergreen species; whereas most Crinums are deciduous.—W. E. Gumbleton.

Bedding plants in Hyde Park.—When taking a somewhat hasty survey, recently, of the flower-beds in Hyde Park by the side of Park Lane, I noticed two good bedding Lobelias: one is named Snowball, and, as its name implies, it produces white flowers. It is dwarf and compact in habit, and produces large, stout, well-formed flowers, without the slightest trace of blue on them. The other is Omen, clear bright lilac, a charming bedder, and novel in colour; both are used with excellent effect as edgings, and they should be made a note of by those of your readers who are interested in this style of gardening. One of the best of the zonal class of Pelargoniums for bedding purposes is Charles Schwind. In Hyde Park it is strikingly effective; the habit is vigorous, and yet compact, and it flowers with remarkable freedom; the trusses large and bold, and the flowers, individually, of a rich crimson colour. I was pleased to see Carnations, Picotees, Canterbury Bells, and Phlox Drummondi among other good old-fashioned plants, and used in combination with other subjects. Fuchsias and Begonias may be seen here in charming combination, and both make admirable bedding plants. Fuchsias are not nearly so much used in this way as they deserve to be. One very pretty combination bed consists of Phlox Drummondi and yellow Picotees mixed, carpeted with purple Violas and edged with the same; there is an outer circle of Coleus Verschaffelti, and also an outer edging of Poa trivialis variegata. Mixed Verbenas make pretty beds, and they are continuous as regards bloom, *i.e.*, if the decaying flower trusses are picked off. Another pretty bed was made up of the variegated Fuchsia Meteor and Lobelia cardinalis mixed together; round this were Coleus Verschaffelti and an outer edging of the golden Lysimachia Nummularia, or Creeping Jenny. Much useful information as to the adaptability of certain plants for bedding purposes might be picked up just now in Hyde Park.—R. D.

Trees and Shrubs.

MULCHING RHODODENDRONS.

I agree with "J. C. B." (p. 100) that a mulch on the surface of Rhododendron beds would be of great benefit to them. Some years ago when I had charge of a dry bank planted with choice varieties of Rhododendron we made it a practice early in August every year to cut a wagon-load of green Bracken and lay it down between the plants sufficiently thick to require treading, so that when completed it was from 4 inches to 6 inches in thickness. At first it withered a good deal, but there was always sufficient to afford a thick surface mulch. During winter it gradually decayed into a fine mould, on which the roots used to feed with marvellous avidity. Thus the plants were kept in excellent health and vigour. Anyone acquainted with the light and friable character of decayed Fern will readily understand that it is just the kind of material that the delicate surface roots of Rhododendrons would like, for their rootlets are so small that they are not able to grapple with any harsh or stubborn substance. I have had no experience with regard to short Grass as a mulch for Rhododendron beds, but if laid on thick enough where the soil is not very deep and naturally dry, I do not doubt that it would be of service. I should, however, prefer a thick layer of leaves, and where there is not a large space to deal with some large stones laid on the leaves would keep them from being blown about by wind. I have used half rotten manure as a mulch for Rhododendrons with very good results; in fact, I believe that anything that is capable of resisting the drying influence of the sun if laid on the surface is beneficial. Being much troubled with rabbits burrowing in the soil in the case of some plants standing singly on the lawn, I covered the surface with large flat stones, and in a year or two afterwards I found, on lifting the stones, that there was a perfect network of roots beneath them, while the spaces between the stones had no roots so near the surface. From this I am persuaded that in many dry places a surface layer of stones would be of great advantage where no other attention could be given. I have, however, greater faith in mulching material that will feed the roots and at the same time increase the depth of soil. I have practically tested this matter by laying on the surface a coating of soil, and I am convinced that when old plants have exhausted that below, they may be kept in health and induced to flower regularly by an annual application of suitable soil on the surface, *i.e.*, if laid out as far as the roots extend. There are, however, some cases in which neither mulchings nor surface dressings are sufficient to keep the plants in health. When the soil is not deep and of a light dry character, old plants not unfrequently suffer a good deal from the want of root moisture, even as early in the summer as July, and if not watered they either make but little growth, and consequently produce but few flowers, or else they die altogether. None but an observant cultivator can understand how much Rhododendrons suffer from want of root moisture. The inexperienced naturally think that because they resent the presence of too much moisture about their roots in winter, they are comparatively indifferent in regard to drought in summer. But that is not so, for few, if any, hardy plants sooner show their dislike to drought. Therefore, in order to be successful with them, root watering in some cases becomes a necessity, and it does not require a very keen eye to ascertain when it is necessary. If it is found that the leaves quickly flag under a bright sun, and that the young growth is weak and the leaves small, then it may be safely concluded that a good root watering is wanted. During my experience I have found that these plants suffer more in a dry autumn than at any other time; then, I suppose, there is a greater strain on the roots than at any other time, consequent on the formation of the flower-buds.

J. C. C.

AUTUMN-FLOWERING SHRUBS.

Though spring seems the natural time of blooming in the case of trees and shrubs, autumn is not altogether flowerless. One of the prettiest deciduous shrubs that blossom in August is the

Buckeye (Pavia macrostachya).—This is a miniature Horse Chestnut, but does not fruit—at least, I have not seen a fruiting specimen. It is easily propagated from suckers and layers, grows from 6 feet to 10 feet high, and makes a pretty lawn shrub.

The Bird's-foot Violet (Viola pedata). Engraved from a photograph for "The English Flower Garden."

Spanish Broom (Spartium junceum) is one of the showiest things in the shrubbery at this season. With us it has been in bloom some time, and will continue to be laden with its golden blossoms some time longer. It has a pretty effect among dark-leaved Evergreens.

Clematis Flammula is usually considered a wall plant, and it has a pretty effect climbing over a porch or festooning round the windows, but it is also a good thing to set against a pole, and not trained too closely, so that its flowering branches may be allowed a little motion. It has white flowers, which, though small, are pretty and sweet, their numbers compensating for lack of size.

Escallonia macrantha.—This is one of the brightest shrubs for a wall. It was thought a few years ago that it did not succeed except at the seaside, but it will grow here in the midlands, and thrives well on a wall, and in good soil in a sheltered situation it will succeed as a border or lawn shrub. It has pink flowers, which are borne in trusses at the ends of the young shoots of the same season's growth. The flowers are very persistent and very useful for cutting.

Althæa frutex (Hibiscus syriacus) is a very useful class of flowering shrubs, very showy at the present season. There is considerable variety amongst them, and some have variegated foliage. All are deciduous, and grew from 4 feet to 5 feet high.

Venetian Sumach (Rhus Cotinus).—Though not exactly an autumn flowering shrub, this season it will be in blossom with us up till the end of August. It is a handsome lawn shrub, and very striking now with its bright green leaves and large masses of crimson inflorescence.

Spiræa ariæfolia.—This is another August flowering shrub of exceptional merit, not half so common as it ought to be. In good soil it grows from 7 feet to 8 feet high, and when in blossom it has a very striking appearance. The flowers are white, and are borne in large drooping panicles. Spiræa bella is a useful late-flowering shrub of smaller dimensions than the preceding.

The hardy Fuchsias are among the most beautiful of hardy shrubs, and in sheltered situations they attain large dimensions. They must be sheltered from the wind, or the flowers will suffer.

Garrya elliptica is perhaps more a winter blooming plant than autumn, but the catkins appear in October in sheltered situations. I have on several occasions had this Garrya do well as a shrub in the open, but it is only seen at its best on a wall.

Hypericums (St. John's-worts).—These form a large family, and all bear yellow flowers. Many are dwarf and only suitable for rockwork, and some are of doubtful hardiness. H. calycinum (Rose of Sharon) is one of the best plants with which I am acquainted for furnishing bare places under trees or clothing dry banks where other plants will not grow.

Veronica Girdwoodiana and others of the same shrubby habit are very useful autumn-flowering plants, and are largely employed by seaside planters, especially on the south and west coasts. Very large bushes may be seen near the sea in South Devon.

Catalpa syringæfolia and C. Kæmpferi are striking-looking small trees at this season. They are among the latest trees to don their foliage, but they always attract attention. Though the flowers are not showy, they are pretty when looked into.

Among climbing plants the Passion-flower is one of the most beautiful at this season. It grows freely on a south wall, and is worth some pains in the preparation of the site at the beginning. A hard winter will sometimes injure it a good deal, but it is rarely killed outright. The young shoots should be frequently trained in the beginning of the season till the wall is covered, and then more freedom may be permitted. Jasminum nudiflorum is one of the very best late autumn and winter flowering shrubs. Though it likes the protection of a wall, it succeeds very well in a warm situation, and soon forms a dense mass. Perhaps the best autumn flowering shrub is the Rose Gloire de Dijon. Plant it in good soil against a pole or an arch in any position where the young wood need

not be rigorously cut back, and flowers will be produced in abundance till quite late in autumn. Large headed standards are very effective in the front of shrubbery borders, and also on the lawn on the leeward side of a bed of shrubs or some other shelter; it is not only an autumn bloomer, it is also one of the earliest Roses to flower in spring, and, after a little time to recuperate, it goes on through all the summer and autumn without any break, and, contrary to most other Roses, its late blooms are but little inferior to those produced in the first blush of the Rose season.

E. Hobday.

PLANTING ORNAMENTAL TREES.

Trees and shrubs on lawns should for the most part be disposed in an isolated manner; that is, in such a way that each individual plant may assume its natural shape and habit of growth. When trees and shrubs, however, in a pleasure ground attain a large size, they very frequently become more or less crowded, and therefore destroy the individuality which belongs to each. Therefore, as they advance in growth, they should either be cut in or thinned out, so as to fully develop the nobler individuals, and where possible to form groups. Half the trees planted, whether for ornament or for profit, are either disfigured or rendered comparatively valueless by having been originally planted too closely together, or by being allowed to remain too long without thinning; care should therefore be taken to place them in the first instance at a distance apart sufficient to permit them at a future day to display their individuality. The form and outline of trees and shrubs also vary very much according to the physical circumstances in which they are placed, such as soil, situation, and climate, and we only get the full grandeur of character which an individual tree is capable of expressing when, from its youth up, we save it from being weakened and deprived of light and food by other trees.

In planting trees and shrubs, the first point to be considered is the selection of such kinds as are known to flourish in the particular locality allotted to them and to thrive in the soil about to be operated upon; the next thing to be determined is the ultimate object in view, viz., whether you wish to create a permanent wood, or to plant merely as a means of reclaiming the land, or for shelter, or for ornament. In the formation of large masses of trees and shrubs, or when trees are introduced into ornamental plantations, they should be kept as much as possible in the background; great care should also be taken that all the taller-growing kinds are placed in the rear of the less vigorous and slow-growing ones; otherwise they will soon overgrow them, and eventually leave only branchless skeletons, such as we so frequently see disfiguring plantations around many country seats. Again, we often find on lawns groups of trees planted with the full intention on the part of the planter in the outset that the nurses should be wholly removed to allow such trees as are intended ultimately to adorn the grounds to assume their natural forms; but these nurses are, in nine cases out of ten, allowed to become robbers, excluding light and air from those trees which they were at first only intended to shelter.

The predilection which different trees and shrubs indicate for different soils may occasionally furnish hints to planters for the selection of species, and prevent that meagre, starved, and poverty-stricken appearance which too often manifests itself, notwithstanding that heavy expenses have been incurred; for trees and shrubs in a state of nature are all indicators of the character of the soil and subsoil where they grow. They also point out its aridity or moisture, a fact which should be kept in mind by the planter for his guidance in the selection of proper and suitable kinds for particular sites, for it is lamentable to see unsuitable trees so frequently planted by persons unacquainted with their nature and habits in places where they only exist; whereas, if suitable kinds had been selected and properly planted, a very different effect would have been produced. When the planter has only to consider what trees he should like to see growing around him, and not what the land is most suitable for, he can plant what he pleases, as some kind of trees appear to flourish, and really do so, in most soils for a few years; but after some ten or twenty years they become stunted and dwarfed, lose their foliage prematurely, and either actually die or survive only to present a melancholy spectacle.

G.

Loropetalon chinense.—This is especially interesting as being a member of that curious group of plants, the Wych Hazel family, of which the species of Hamamelis, the Sweet Gum (Liquidambar), and Parrotia persica are the most familiar examples. Loropetalon chinense is not unworthy of general cultivation from a purely garden point of view. It is a free-flowering shrub with the flowers, clustered in small heads, terminating the branches, the calyx being pale green, and the long linear petals pure white. When better known this shrub will probably become a favourite; quite small specimens flower freely. It was first introduced into this country a few years ago by Messrs. Veitch. It is a native of China, whence it was sent by Mr. Charles Maries.

The Ailanto (Ailantus glandulosa).—The Ailanto possesses a very different aspect in its ripe old age from the saplings of it often met with. The largest tree of it in the neighbourhood is at Syon; indeed, it is the largest among the many fine trees that exist of it in the country. The Syon tree, which was figured in Loudon's "Arboretum," is nearly 100 feet high, with a clean, erect bole, rising some 30 feet before it branches, and terminated by a huge hemispherical head of handsome foliage. Though a rapid-growing tree when young, it has taken many years for this specimen to attain such a large size, and now that it is fully developed there seems to be no variation in its character from year to year. It occasionally bears flowers, which are succeeded by small fruits. The flowers are produced in terminal erect clusters of a whitish green colour, and they exhale a disagreeable odour. This tree thrives in almost any soil, though that of a light, moist character suits it best. Few trees possess such an elegant foliage and graceful habit of growth as the Ailanto, which is also called the "Tree of Heaven."

Golden Elder.—The summer's sun served to intensify the depths of colouring in this golden-leaved shrub. Just now the exposed portion of the foliage is of a rich golden-yellow hue, and where associated with dark-leaved plants, this golden tint is heightened by contrast with the surroundings. This Elder possesses the great merit of not being in any way fastidious as to soil or situation, though it is seen to the greatest advantage in a fairly dry spot and thoroughly exposed to the full rays of the sun, for though it will not grow so rapidly as in a moister soil, yet the foliage is much brighter where the roots are moderately dry. Besides this, the golden-leaved Elder will grow very readily from cuttings taken when dormant and dibbled in some sheltered spot. Like all cuttings that are inserted in the open ground they need to be put in firmly, so as to be proof against severe weather and drying winds, which often cause havoc amongst cuttings that are not inserted deeply enough in the ground. —T.

Olearia Haasti.—I did not think very highly of this hardy shrub while our plants of it were small, but now they have grown into large bushes I begin to see that it is really attractive, and, what is more, a very useful plant. It is so neat and compact in growth, that it just suits the front line of a shrubbery border, needing no cutting back to keep it within bounds. The flowers are small, but numerous enough to make a large plant attractive; and what further enhances its value is the fact that it flowers in August when so few other hardy trees or shrubs are in bloom. The blossoms, too, are useful for many purposes in a cut state. It appears to be indifferent about soil; our plants of it are growing in ordinary garden soil, but I have an idea that peat would suit it better.—J. C. C.

Ceanothus azureus grandiflorus.—This is a grand plant for south or west walls in any of the southern or western counties, but it would probably prove too tender for the north. Here, in the west, on a wall facing the west, it hardly ever gets injured, and it grows in the most luxuriant manner. It commences to flower in July and continues in bloom for two months. I never prune it until the end of February, when a good many of the shoots which have flowered and some of the old ones are cut away, and young growth laid in to fill up the space.—J.

FLOWER GARDEN.

ALPINE FLOWERS IN THE PYRENEES.

No. II.

Bagneres de Luchon, in the department of the Haute Garonne, is a gay town of some 5000 inhabitants. A friend told me that he once suffered so much from the heat there in June, that he determined never to go to the Pyrenees again. We were there the second week in June, and we suffered more from rain and cold, and were very glad of a fire in the evening. Except to the south, in the direction of the Porte de Venasque, one of the chief mule passes into Spain during summer, where there are fine snow-capped mountains, the scenery from the town is not grand, but it is within easy reach of the wildest parts of the Pyrenees. It is the nearest town to the Malaletta, their highest point, in which the Garonne rises, and amongst whose rocks is one of the last strongholds of the ibex or bouquetin, the "wild goat" mentioned by Homer. Eagles and vultures are to be seen sailing about the sky near Luchon nearly every day, and bears, which in the Pyrenees are neither mythical nor formidable, descend to within a few miles of the town after wild Strawberries which abound there. We heard of two female peasants lately gathering wild Strawberries who were suddenly confronted with competitors for the spoil in the shape of a she bear and two cubs. It was doubtful whether man or beast was the more surprised. The cubs began to growl, but their dam gave both of them a box on the ears for their bad manners, and led them away. As for flowers, the neighbourhood of Luchon has the reputation, perhaps not undeserved, of being the most flowery part of the Pyrenees. We went the usual expeditions from the town, in spite of the weather, and I will try to remember what plants we noticed in each of them. The first trip was to the Vallée du Lys. In spite of the spelling the name suggests Lilies of the Valley, but we are told that Lys is an old word meaning water, and that the valley took its name from the number of cataracts, not from Lilies, there. However this may be, a Lily grows there in great profusion, and was just coming into flower towards the middle of June. It is the Lis de St. Bruno (Anthericum Liliastrum), a plant worthy of giving its name to a valley of which it is a characteristic feature. Still more conspicuous at the time when we were there were the Narcissus poeticus, abundant all round Luchon, but already past in the low meadows near the town, but higher up at an elevation of about 4000 feet it was quite at its best, and

whitened the ground over many acres. I looked about for varieties, but failed to detect any special character by which it could be referred to any of the varietal names given in catalogues, and concluded that it was N. poeticus pure and simple. Pulmonarias were abundant along the road, as also in the whole region of the Pyrenees, the character of the leaves varying greatly, some being spotless, some full of irregular white patches, others with well-defined round spots. They varied, too, from broad heart-shaped to narrow lanceolate, and I soon concluded that it was hopeless to attempt any division of the class founded upon the leaves. Besides the beautiful flowers of Scabious mentioned before, a new feature in the meadows here was the abundance of Astrantia major. A pure white Hesperis matronalis was also common, but I saw no purple forms of it. Geranium phæum also grew everywhere in the fields, the colour of the flower varying a good deal. Hepaticas were not so common by the roadside here as at Eaux Bonnes, but are generally distributed. Many of them have their leaves beautifully marbled, and I selected and brought away a few of the best in hopes that they may keep this character. I was struck everywhere by the one-crowned appearance of the Hepaticas, as if in their second year from seed. On the mountains, where they were still in flower, I did not find the colours mixed, but on one mountain they would be all white, on another all blue. I do not recollect to have seen any pink. Meconopsis cambrica is common in the Pyrenees. I observe that in Grenier's "French Flora" the colour of the flower is given as "jaune orangé," but I never saw it either in England or in France with orange flowers till I saw it covering a bank by the side of the road to the Vallée du Lys. I was too much struck by it to delay securing a plant or two, which was lucky, for when we returned every flower had been gathered by some rival admirers.

Another expedition from Luchon is to the Lac d'Oo. This, too, is famous for flowers; but especially so is a high valley called Val d'Esquierry, 2000 feet or 3000 feet above the village d'Oo, at which the carriage road ends. Botanists call this the garden of the Pyrenees, and, of course, I was most anxious to see it. The landlord of our hotel was quite enthusiastic in his description of the treat in store for me, enumerating a long catalogue of colours, and indicating with his hand, palm downwards, the height from the ground at which I was to expect to see each colour. I was afterwards told that he had never been to the famous valley, being by no means addicted to climbing mountains. During the first part of the drive from Luchon we saw hanging from the rocks by the roadside large masses of Saponaria ocymoides, varying much in the shade of colour of the flowers. This is a plant which I find it better to grow from cuttings than from seed. The best shades of colour are in this way preserved, and the plants are more flowery and less straggling. As we got near the end of the carriage road the meadows became more crowded with flowers known in England only in gardens. Besides such plants as Geranium pyrenaicum growing everywhere on the banks, the fields were full of a light purple Geranium—I think sylvaticum. Here, too, I noticed Meconopsis cambrica with orange flowers. Narcissus poeticus was also there, and so were some splendid Thistles, large and rich in colour. But the most remarkable part of the colouring in the meadows was produced by different shades of Viola cornuta carpeting the ground. We noticed this plant in many parts of the Pyrenees, but here especially. From the end of the road I started with a guide for the promised garden of the Val d'Esquierry. By the side of the steep and winding path I noticed Ramondia pyrenaica—the only place I saw it in the Luchon district. Other notable plants were a quantity of Anemone alpina of dwarf growth and very large flowers, covering a green knoll near a stream. A little beyond, Aster alpinus was in flower, of a bright colour which I can never get it to show in gardens. These, with the exception of a few Saxifrages and Daffodils of the variety nuticus, were about the last flowers I saw there. Promise of flowers there was in abundance. Aconites, I suppose Napellus, and also that form of A. Lycoctonum with the large leaves known as pyrenaicum, were just enough grown to recognise. The large white Asphodel, called by French botanists A. albus, but better known in gardens as A. ramosus, which grows everywhere in the Pyrenees, and the coarse shoots of Gentiana lutea were just showing. Further on the Daffodils were only just putting their noses through the yellow dead Grass, which the snow had hardly left and was again beginning to whiten, for the rain, which had been coming down in torrents ever since I left the carriage and had wet me through, had now changed to snow; still I went on in spite of the bitter cold, hoping that I should come to some hyperborean region where the flowers would be all bright; but my guide at last undeceived me, and convinced me that we were far too early, so we went down again, wiser and sadder, and I advise my friends who wish to see the Val d'Esquierry in its beauty not to visit it before July at the earliest. I have still one mountain walk to describe, a far more successful one, but it must be deferred till another week.

Edge Hall. C. Wolley Dod.

Group of alpine flowers.

The Layias, better known, perhaps, in gardens under the name of Calliglossa or Callichroa, are less frequently met with in gardens than they should be, considering the ease with which all of them may be grown. They are hardy Californian annuals which may be sown in the open border in March. They begin to flower in June, and in ordinary seasons continue in bloom until the end of August. Their flowers, which are extremely handsome and varied in colour, are very useful in a cut state, lasting in good condition, in vases, for a con-

siderable time after being cut. One of the best we have yet seen for this purpose is L. glandulosa, a kind which forms close tufts literally smothered with pretty white flowers: the others, such as L. elegans, L. Calliglossa, &c., have flowers shaded with yellow—some with distinct rings, and others with no well marked hue. They ripen seeds in abundance.—K.

NOTES ON HARDY PLANTS.

Erythræa diffusa.—This is one of the brightest of summer-flowering alpines, and yet one may go into a dozen gardens and not find it, a circumstance attributable possibly to there being something biennial in character about it. Anyhow, in some soils it never survives as a presentable specimen its first season, *i.e.*, if it flowers freely. I know that it can be perpetuated by root division, and, therefore, is not a biennial in the true sense of the term. On the contrary, that operation seems to increase its vigour when carried out seasonably. But perhaps the best method by which its masses of shining rosy-red flowers can be secured for our rockeries is to raise plants of it from seeds. The neat evergreen foliage on the prostrate stems, too, is worth something for winter decoration.

Thalictrum adiantifolium.—This, as its specific name implies, resembles a freely grown tuft of Maiden-hair Fern, and in this its beauty wholly consists, for the flowers are inconspicuous. During the rainy weather of the past fortnight specimens 9 inches or 10 inches high, and as much through, showed themselves off to advantage, the rain-drops clinging to the leaflets like so many crystals. It makes a pretty rock plant if grown apart from all else. It also makes a unique edging, but here again it should be planted sufficiently far apart to show off its pretty bush-like habit.

Saxifraga aquatica is a somewhat rare species as yet, and, in my opinion, will continue to be so so long as we try to grow it under unnatural conditions. It is not unlike S. Wallacei, but it is in every way much larger, especially the leaves, which are also softer, more spread out, and darker green. The flowers, which are clean, white, and fragrant, are freely produced in lax panicles. For several years I grew it on a raised bed in full sunshine in light soil, but deep and rich; there it grew so fast that we had to cut it back several times a year, and finally I had to remove it, owing to the trouble it gave close by a narrow walk. Since then it has been grown in a large 18-inch pot, half filled with manure, on the top of which were put a few inches of sandy loam; the pot has stood upwards of a year fully exposed to the sun and not plunged. I annually cut off all long stems after flowering, and put short cuttings made from them into old cocoa-nut fibre to root. The old plant makes fresh growth from the cut-back parts. From this it would appear that so-called aquatic species may be treated just like other Saxifrages. There are other plants which do quite as well in our climate without bogs as with them. The few that occur to me at the moment are S. peltata, the Pampas Grass, Iris Kæmpferi, some Primulas, and Bambusa Metake.

Stobæa purpurea.—This seems to be a desirable plant, its flowers being both curious and beautiful, and its leaves Thistle-like. Two things it seems to require, or, at least, to enjoy, viz., a loose, rubbly soil and a very sunny aspect. Its ample foliage never turns flabby in the fiercest sunshine or during the longest droughts. One or two plants of it seem quite happy on a disused rubble walk on which there is but an inch or two of soil.

Herbaceous plant cuttings.—Nearly all hardy herbaceous plants may be propagated by cuttings, but seeing that great numbers of them may be readily had by root division and seed, it is questionable if rearing cuttings is worth the trouble. That operation, however, has its value where plants do not divide easily or do not come true from seed. Cuttings when set should be half their length in the soil and half out, and taken slip-fashion from the parent plant, *i.e.*, with a heel. Very often short slips taken off close to the ground or main stems have rudimentary roots attached to them, and one may always add to the chances of success by taking the cuttings from the sunny side of the plant. In pricking them out, too, in beds or pots, all the leaves should face the strongest light; in other words, the under sides of the leaves of newly-inserted cuttings should not be exposed to the sun. Hardy plant cuttings should be rooted as early as possible, so as to get them well grown before winter sets in.

Swertia perennis.—This, according to my experience, is a decided moisture-loving plant, though it may be kept for years in an ordinary border. It is one of those curious subjects which must needs be grown well, or it will not flower. When in good form it is not likely to want admirers, dusky though its starry flowers are. The whole plant, indeed, is very dark in colour, and very different from the Gentians, to which it is nearly related. Owing to its colour and stature—2 feet high or more—its effect in bold patches is striking enough. Its habit is firm and erect, desirable properties in a plant intended for such springy and semi-wild places as it affects.

Polemonium confertum.—This dwarf, but excellent species refuses to grow in some kinds of soil, and therefore soil in which it will grow must be obtained for it. That it is hardy I have no doubt, having grown it so long. The first thing to do is to raise the soil 6 or more inches above the common level. Charge it with light material, such as grit, thoroughly decomposed stable or cow manure and leaves, and in this not only can the plant under notice be grown with success, but many other choice and difficult plants to manage. It likes to be exposed to full sunshine. I have just gathered seeds from a grand variety of Jacob's Ladder, which grows 3 feet or more in height. It is in every way larger than the native form; the flower-stems are less leafy, but the radical leaves are bold, long, and arching. It lasted several weeks in flower, though cramped in 4-inch pots. The seeds came from one of the Southern United States, and the plants raised from them have proved to be quite hardy.

Horminum pyrenaicum.—This is better than all the Ajugas, and if planted would prove far more serviceable than many would suppose; its thick, wrinkled leaves are pleasingly arranged in rosettes from 6 inches to 9 inches across; they are evergreen, and strongly remind one of those of well-grown Ramondias. It has a happy way of tightly holding itself between big stones, where it forms a pretty feature even when flowerless. Its short spikes of indigo-blue blossoms keep appearing in succession for a long time in summer and autumn. It is a plant which anybody may grow, and as it is not rampant or spreading, there can be no fear of its encroachment on other things. J. W.

Culture of Anemones.—Some advice in reference to this matter has recently been asked for in The Garden. In a light sandy soil with a good exposure and where the tubers can get thoroughly baked during the summer months, I do not think anything is gained by lifting and storing them. But, on the other hand, in a heavy clay or otherwise damp soil the stock may often be saved by lifting the tubers after the leaves have become brown, and laying them alongside a south wall or other convenient place where they can get plenty of sun to thoroughly bake and ripen them, planting them again as soon after that has taken place as possible. Another point which I think is not sufficiently attended to, especially in the case of bulbs or tubers that require a little care, is the fact that decaying matter in the soil is harmful where the drainage is in the least defective. Of course, bulbs as well as other plants require food, but other means will readily be found of giving it, such as top-dressings, liquid manure, &c. Nothing I find to be so injurious to the less vigorous class of bulbs as decaying leaves about them in winter, and that even where sand is present in large quantity. The leaves seem to act as a sponge, drawing and retaining all the moisture from the surrounding soil, a state of matters quite the reverse of what is desirable. Good growers of Narcissi prefer pure loam in which to plant their bulbs, and if this is found necessary in the case of Daffodils, it is much more so in that of many other bulbs, tubers, and corms which we grow in the open air.—K.

HARDY SUBSTITUTES FOR SUB-TROPICAL PLANTS.

Knotweed (Polygonum sachalinense).—How is it this once seen never-to-be-forgotten foliage plant is so seldom met with in country gardens? Hardy and as indestructible as the common Dock, it increases steadily, and forms a most picturesque group when planted in shrubberies, or, better still, on lawns, where it can be backed up and sheltered from high winds by Conifers or shrubs. Some years ago I obtained a small root and planted it well on a sloping bank where, backed by Abies canadensis and supported on either side by golden Yews, it now forms a clump 9 feet or 10 feet through and quite as many in height. The creeping roots travel silently and steadily along beneath the turf, and throw up their shoots, not thickly and crowded, but in the most irregular and natural manner imaginable; in some places two or three come together, in others single stems crop up where least expected, but just where they are wanted. Although such a rapid grower, and every cane is clothed with immense red-nerved leaves, it neither requires stick nor string, but sets wind and rain at defiance, and waves majestically over the green sward. Owners of gardens who do not or cannot afford the cost of wintering, coaxing, and hardening off sub-tropicals should not lose a day in getting this hardy herbaceous plant established in quiet nooks where its great height will not render it objectionable. Sub-tropicalists who place out of doors a host of tender plants for the sake of their foliage should plant it extensively, as its free and graceful bearing fits it for the most refined society throughout the summer, and its pleasing nankeen foliage renders it very conspicuous in the autumn after its shivering companions have been cut down by frost or removed to their winter quarters.

Plantain Lilies (Funkias).—In these days of retrenchment, time and money may be saved and our gardens may be made to look more natural by the use of these plants, which increase from year to year and defy the sharpest winters. Take, for instance, Funkia Sieboldi, one of the boldest and best; dig the plants up, divide them, replant in deep rich soil, and they will give a handsome account of themselves in the production of a profusion of cordate leaves of a whitish hue shot with rich purple which no tender sub-tropical plant can surpass and few can equal. Give them plenty of room, and let them expand into large natural masses in nooks and in front of clumps of Rhododendrons or golden Yew, and they will contrast or tone down with anything. But look out for shell snails, for if any exist in the garden they will surely find out the Funkias and speedily disfigure the young leaves when the plants have attained a foot or more in height, and afford safe shelter from the thrush, their inveterate enemy.

The Acanthus.—Of this family I would plant A. mollis, A. spinosus, and A. Candelabrum, not as single plants, but in great masses; not cramped up in herbaceous borders, but in front of shrubs on lawns, where in deep soil and quite open to the sun they would have room to develop their graceful, I may say their classical, foliage, and live for generations. It is generally supposed that these plants will not increase on heavy clay; be this as it may, they do well on heavy limestone marl, and A. mollis with me is now beginning to open its flowers. This clump more than twenty years planted is 6 feet or more in diameter, and has Funkia Sieboldi and Anemone Honorine Jobert equally large for its companions. A. Candelabrum grows well in moist loam, rather shaded by large deciduous trees, and forms beautiful groups through the autumn months. Being such a strong grower it tells well when placed, always on turf, a considerable distance away from the walks. Golden Yews and Hollies, the Retinosporas and Japanese Maples form fine settings for this intensely green variety, and a few pieces of

limestone lying about do not spoil the picture. The spine-leaved variety, more formidable than the others, is well worth a good station, and looks well in front of rockwork or shrubs having deep green leaves. Like the field Thistles, it is a faithful friend when once established in deep rich loam.

Bambusa Metake.—When first introduced I obtained a plant of this Japanese Bamboo and planted it on low moist soil, but it disappointed me. It grew, it is true, and flowered, and then disappeared for a time. Disappointed, another attempt was made—this time in front of a large Portugal Laurel on much higher and drier ground, sheltered from the north and east and fully open to the south. Here in company with the Acers, Quercus glabra, Ilex latifolia and Cunninghami, Aralia Sieboldi of twenty years' growth, Osmanthus ilicifolius and the beautiful Olearia Haasti, the Bamboo soon proved that I had been fortunate in my selection of a site in the Japanese garden. The soil, stiff loam resting on limestone, was broken up, dressed with burnt clay, and the wretched roots were transferred to their new home. This took place many years ago, and they have never been disturbed. They never flower, but send up hundreds of graceful shoots, and the roots, like those of the Knotweed, creep quickly along just beneath the turf. Anxious to lend a helping hand, once in two years I break up a broad strip of the turf a foot or two in width all round the margin of the bed, add plenty of burnt clay and leaf mould and my crescent shaped bed of Bambusa Metake is equal to anything I have yet seen in the way of sub-tropical plants.

Eastnor Castle, Ledbury. W. Coleman.

NOTES.

White Jasmine.—There is a fineness of make and a fragrance about a bush of white Jasmine that lifts it high, in our estimation, above many other shrubs in the garden. It is very pretty as a dense rounded bush on the lawn, or as trained on a sunny wall. At Straffau there is an old plant on a wall, with long branches trained fan-fashion, and the young growth is spurred back to the hard rods every year. This is a very old-fashioned way of growing the plant, and in some ways a very satisfactory one, since plenty of nice long flowering sprays are thus ensured for cutting, if such be required. In Besler's fine old work, "Hortus Eystettensis," there is a figure of the large-blossomed Jasmine, which has evidently been pruned back to the old stem in this way, and as Besler's work was published in 1612, we may fairly say the method is an old one in gardens. A simple cluster of common white Jasmine forms quite an uncommon posy of itself, dark and elegant in leafage, while around its snow-white flowers there lingers an odorous spiciness, rich and satisfying as any from Eastern seas. The large-flowered or Catalonian Jasmine is also worth a place, but it is not nearly so floriferous nor so neat in growth as the typical kind.

Agapanthus umbellatus.—Well grown this is a noble plant, not generally hardy and floriferous in the open air it may be, but well worthy of pot or tub culture, which enables one to give the plant shelter conveniently during the coldest portion of the year. There are several varieties, but none better than the old blue for outdoor culture near the sea. It enjoys a deep, warm sandy soil, and during dry weather it may with advantage be mulched with leaf mould or Cocoanut fibre. If pot culture be resorted to, there are several forms of this plant worth attention. There are a strong-growing white-flowered kind (albus), a dwart-habited, small-flowered blue (Mooreanus), a large-flowered variety with pale lilac-blue flowers (lilacinus), a tall, large-flowered blue (giganteus), and also a double-blossomed blue sent out a few years ago, but never very generally grown. Grown in tubs for plunging on the lawn these plants may be had anywhere, and but few other blue flowers can rival the typical A. umbellatus with thirty spikes on a plant. The white-blossomed kind is doubly useful either as a specimen in a cool greenhouse or for cut flowers. In mild sheltered localities, a bed of the typical blue forms a pretty picture during the autumnal months.

Common flowers.—In the garden nothing is common, using the word common in its right sense, and not as a synonym for plentiful or abundant, and yet there was a time when the words "hothouse flowers" were synonymous with choice blossoms, they in a way being thought of as representing the "Lords," while hardy flowers did duty for the "Commons." All this is now altered, and we find the best of people growing Roses, Carnations, Buttercups, Daisies, Lilies, and Pinks, as well as Orchids or other rare plants from tropical lands. Let us hope that fetish worship in the garden is over, and that no one class of plants will be valued to the exclusion of all others in any one garden worthy of the name. The question now-a-days is whether a flower is noble or elegant in form and good in colour or satisfying in perfume. Certainly we may grow Ferns, Palms, or Asparagus for their beautiful leafage or elegant stems; but, after all, it becomes a question of useful beauty or of beautiful use in the garden. That is the true test of all things, and we never need contrast the Orchid of the tropics with the Dryas or the Saxifrage of the arctic circle, each being equally lovely in its own way. The path of the gardener is broad enough, since the plants of the whole world are his to cultivate if he or his employer wills it so. But in the whole world we find no flowers that are "common," although many that are as numerous as sands on the shore.

The Dutchman's Pipe.—I do not wish to allude to the cloud-producing tendencies of our good friends, the bulb growers of Holland, but simply to draw attention to one of the very best of large-leaved climbing plants, viz., Aristolochia Sipho, a shrub which has for many years been well known under the above popular name. As summer foliage plants, apart altogether from their blossoming, I consider this Aristolochia from North America and the Chinese Wistaria two of the very best and most effective. A friend of mine who has definite opinions once made a dead set at the variegated Acer Negundo, characterising it as a plant one or two of which would suffice to spoil a good garden. There may be a "white-rag-on-a-bush" effect about the Acer, but for wealth of greenery and for variety from spring to autumn no one could well object to the Dutchman's Pipe, with its great heart-shaped foliage as seen scrambling up a tree trunk, or as hung in graceful garlands on a wall. We have here the Aristolochia just now most effective growing up a dead tree on the lawn, and a plant on a wall, so planted that its bold cordate foliage mixes and contrasts with that of the Wistaria, is much admired. Both these plants take time to become established, but afterwards they are very beautiful. The Wistaria acquires a light golden green tint of leafage in autumn, and then forms a delicious picture along with Clematis Jackmanni.

Coreopsis lanceolata.—Now and then I notice people object a little to golden-blossomed composites on account of their healthy vigour, which, being interpreted by the popular mind, is expressed by something like "coarseness of growth," or "a common sort of look, don't you think." But I have now in my mind's eye, and in the garden also, two kinds of Coreopsis, viz., C. lanceolata and C. tenuifolia, than which nothing can well be more elegant and "fine," using that word in its best sense. Both are, moreover, perennials, and I am particularly anxious to say this, for of late years more especially there seems to have arisen a growing dislike to annuals as a class, amongst amateur gardeners more especially. Perhaps it is that the word "perennial" seems to promise much peace of mind if once a plant is secured and planted; while "annual" seems ominous of constant seed-saving and seed-sowing from year to year. To return to my text, however, the two species of Coreopsis named above are so satisfactory in all ways, that they should at once be added to all collections where they are not already represented. They may be divided and replanted any wet day after they go out of bloom with advantage.

Helenium pumilum.—This is a really good garden plant, which I obtained years ago from Parker's then celebrated nursery of hardy plants at Tooting. Since then it has replaced the old tall-growing H. autumnale in many a garden besides our own. It is now in flower at 18 inches in height, a mass of deflected irregular florets, depending from the usual cushion-like disc. Like nearly all the other composites known to me, and they are more than a few, this plant is better for division and replanting every second year at the furthest, and so treated it is a most floriferous and useful thing. This constant, indeed almost annual, replanting in fresh deeply-dug soil is what is needed to ensure the full beauty of many, even if not most of our larger perennial composites. Manure makes them coarse and leafy, while annual replanting seems just the treatment they enjoy best. I see to-day (August 9) some fine flowers on Harpur Crewe's Doronicum excelsum, flowers as fine as the first which came in March last. Nearly all the Doronicums are persistent in their blooming, but this seems the freest and best of all in our soil.

Catananche cærulea.—This is an old garden plant, but is not even yet quite a plentiful thing. It is just now very pretty, each plant yielding quite a sheaf of its rustling flowers of a soft pale lilac or lavender-blue. We find it most useful and endurable for cutting, and a very ornamental perennial to boot, since on light sandy soils it does well year after year. The plant does not divide freely, nor do the seedlings like transplanting, except when very young, so that we now sow a few seeds on the borders where the plants are thinned out and left to establish themselves. A friend of mine who has a garden high up on a rocky hill overhanging the southern side of Dublin Bay told me years ago that nothing would grow there. I recommended her to plant nothing for a year or two, but to sow seeds of all sorts, especially of Cistus and Sun Roses, Linaria, Erinus, and hundreds of other alpine plants hardy in our climate. The only difficulty now is the weeding out of plants which many good gardeners would be glad to grow if they could do so. When seedlings establish themselves their tap-roots find congenial quarters, but in transplanting this provision of Nature is destroyed, and so on hot dry soils failure is courted and often obtained.

Campanula pyramidalis.—Gerard's "steeple milky Bellflower, both blew and white," is too often neglected in English gardens. Well grown in pots, as it used to be for indoor use years ago, it is a noble plant. In rich soils it attains a height of 7 feet or 8 feet, and as much in large pots if aided by liquid manure. When I was very young I remember gazing with something akin to awe at some fine pots of this plant grown by the thrifty blacksmith's wife in my native village. They used to stand in the cool and spacious bay

window of a low-beamed parlour facing the village street, and I have often seen travellers stay their horses to look at them when at their freshest and best, so lovely and uncommon did they appear. In the Royal Academy a few years ago there was a painting of a group of these tall Bellflowers arranged near the altar of some little church in Brittany. No words could express the cool, fresh heavenly blue of their flowers as caught by the painter's cunning. But better than any picture is the lovely reality of these flowers as seen on the borders in autumn, or as potted and grown on in a cool house or porch, where their flowers are untormented by wind or rain. The plants themselves are quite easily obtainable from seeds sown in spring, or from division of the roots at any time.

Helianthus rigidus.—Everyone who sees this plant in bloom here now seems fully persuaded that it is the very best of all the perennial Sunflowers. Be that as it may, it is a most useful plant, and one that should have a place in every garden. Its only fault is the freedom with which it takes possession of a bit of well-tilled ground. Just now its slender stems are topped with yellow Daisies 4 inches across, and each having a dark-tinted centre increases the effect, as also does the buds, which are of a blackish olive colour. It may be as well to say that this plant is also known in gardens as Harpalium rigidum. Last autumn Mr. Archer-Hind gave me a bit of a perennial Sunflower which he had received under the name of Helianthella uniflora. It is now in bloom, and while reminding one of Rudbeckia Newmanni seems an earlier and finer plant. The yellow ray florets are stout in texture and rich in colour, the disc or centre of the flower-head being brownish black. When well established it promises to be a noble plant, and well worthy of a place in all good gardens.

A white Bellflower.—One of the prettiest and freshest of all the Campanulas now in bloom is one I received years ago from the late Miss Hope, of Wardie Lodge, Edinburgh, under the name of C. Hosti alba. It is low growing and spreading, and is just now covered with its elegantly shaped bells of a snow-white colour. It is quite readily increased by division, and is, so far as I know, decidedly one of the most distinct and beautiful forms of the C. rotundifolia group. Another pretty little form from the Engadine has blue flowers peculiarly shortened and piquant in form, and I also notice a fine dark variety of Platycodon grandiflorum Mariesi in flower—a plant now fairly established, since we have had it three or four years, and every season the flowers are larger and better in tint. The most singular of all the Bellflowers just now flowering is that called Michauxia campanuloides. In this plant the bell becomes regularly slit into six or eight segments or more, and these segments reflex like those of a Cyclamen; indeed, there is quite a Passion-flower sort of aspect about these Michauxia flowers. The plant is 5 feet or 6 feet high, and bears a great panicle of white bl ssoms.

Veronica.

Salvia Horminum violacea.—As a bedding plant to withstand rain this Salvia is unapproached by any plant that I know used for summer bedding. It has withstood three weeks of dull and stormy weather; even though subjected to regular downpours, it is as bright at the end of them as at the beginning, while on Pelargoniums, Calceolarias, Petunias, and Verbenas every flower was spoilt. The purple bracts of this Salvia, which constitute its chief ornament seem so persistent that they are able to defy either wind or rain. To be successful with it as a bedding plant I find that a rather poor soil suits it better than a rich one. In good material it requires to be planted a foot apart each way, and it wants but little water, even in the driest of seasons, after it has once commenced to grow. It does better in a bed by itself than associated with other subjects. Being an annual, it can be readily raised from seeds, and if sown in a gentle heat in March the plants can be got of a suitable size for bedding out by the end of May.—J. C. C.

WORK DONE IN WEEK ENDING AUG. 10.

August 4 to 10.

The weather continues dry, and, for August, the small amount of sunshine is remarkable; under the circumstances, therefore, the latter, so far as gardens are concerned, is a decided advantage, for till rain falls in quantity, bright sunshine would have a deteriorating effect on fruit and vegetable crops, which at present are doing fairly well; water and mulch is the order of the day. Peas and runner Beans hold out much longer by a thick mulching than by repeated waterings. Celery, Tomatoes, and lately-planted winter greens are given water as frequently as time can be afforded for such work. Peaches, Nectarines, and Pears on walls are drenched with hose once a week. The latter are a far better crop than was anticipated, and we have had to thin such kinds as Beurré de Capiaumont, Knight's Monarch, Poire Ananas, Nouveau Poiteau, and Beurré Diel. Gathered the first Moorpark Apricots on the 6th, Early Orleans Plums on the same date, and Peach Early Louise on the 2nd. This last is not of first-rate quality, and we intend to replace it by that fine early variety Alexander, which indoors has ripened fully five weeks in advance of Bellegarde; and Hale's Early has ripened a month in advance of Early Grosse Mignonne and was quite as large, as well flavoured, and much finer in colour, being a bright red. With the good supplies of water that we have been able to give, flower-garden plants have thriven beyond expectation, and the whole may now be said to be at their best; combinations of foliage and flowers are our particular fancy. Large beds of one colour, no matter of what hue, have no charm for us; we must have greenery of some description as a setting for the flowers, and we get this by the free use of small standard plants, such as Retinosporas, Grevilleas, Draciænas, Abutilons, Fuchsias, &c. For the dividing lines in designs we always use foliage plants, our best types being Gnaphalium lanatum, variegated Japanese Honeysuckle, and variegated Thyme, of course pegged down till the ground is covered, and afterwards pinched. The best dwarf plants for the like purpose are the various types of Sedums, from the deep green of the variety Lydium to the creamy white of acre elegans variegatum. No edging plant that we have ever used is nearly so good as Herniaria glabra, and not the least of its merits is that very little labour is requisite to keep it in order. Tying up Dahlias, Marguerites, Castor-oils, and other tall growers has to be done once a week, and the seed-vessels we keep regularly picked off single Dahlias, else they would soon be flowerless. At the present time the most effective flowering plants are Violas Mrs. Grey (white) and Blue Bell, Purple King Verbena, yellow and white Marguerites, Ageratums, and Heliotropes, Fuchsias, Salpiglossis, Stocks, Lobelias, single Dahlias, and, lastly and least effective, Pelargoniums—pink and rose-tinted varieties being the colours to which preference is given. Work in houses and framing ground, though abundant, is of such a routine description as to require none but the merest record by way of memoranda for future reference—watering borders, keeping the laterals of Vines within reasonable bounds. On such varieties as Gros Colmar, Madresfield Court, and Mrs. Pince, that are now colouring rapidly, we allow the laterals to remain intact. Lady Downes and Alicante make such a quantity of wood that some of it must necessarily be cut away; still, we like to let the lateral growths of these varieties also have a wide berth. All white Grapes put on a more golden hue if sun can reach the fruit, so that the same degree of freedom in regard to lateral growth can hardly be extended to these, but we stop as little as possible till the "shanking" stage has passed, after which we expose the bunches to light by cutting out part of the laterals and by tying aside any of the large foliage that overshadows the bunches. Air is now left on all night, and warmth is still kept up in the pipes to keep the air buoyant; this is particularly necessary, for the Madresfields and Muscats, that have a predilection for cracking when the atmosphere of the house is in a damp and stagnant condition. Planted out another succession lot of Melons and made another sowing. This may be too late to do much good, but if the autumn be sunny the probabilities are we shall get a good crop of fruit that will help to save Pines when the greatest demand is made on us by way of dessert for the shooting season. Sowed Cucumbers and Tomatoes for winter use, and threw away the old plants of the latter that have been fruiting in pots for several months past; our present supplies are now being had from frames, and a few that were planted out very early in the open garden. Strawberry potting goes on daily, as does tying Chrysanthemums to their supports. Our first buds were taken on the 7th, the varieties being Thunbergi, Boule d'Or, Elaine, and Madame C. Audignier. Top-dressed old plants of winter-flowering Carnations and some Tea Roses that are flowering freely. Potted off another batch of Cinerarias and shifted Poinsettias into larger pots. Tuberous Begonias and Gloxinias now in full flower we shade and keep as cool as possible to prolong their beauty. The flowers we still keep picked off Pelargoniums that are being grown on in pots for winter flowering, and now that the pots are getting full of roots manure water is freely applied.

Hants.

FRUITS UNDER GLASS.

Cucumbers.

A moderate stock of young plants should now be kept constantly at hand for taking the places of Melons as they are cleared out of the compartments. It is not well to have too many of these or young Melon plants standing about, as they are so apt to get starved into a breeding colony; but, by sowing a few seeds at short intervals and throwing old ones away, a clean stock can always be kept at the cost of very little seed. Pits and frames, as I have before stated, are the best nursing places for summer and autumn use, as there the heat can be maintained by the aid of fermenting materials, and the plants—no unimportant matter in the preparation for winter—can be kept short-jointed and sturdy. Plants put out now will not require much fire-heat for some time to come, but the pipes should be in the house ready for use when nights become damp and cold, from September onwards, when a little gentle warmth, kept in by covering, will make all the difference between success and failure. If the first batch, as is often the case, is to be worked hard, say, till Christmas or January, when Melons again come in, the great care usually devoted to winter Cucumbers proper will not be necessary, as they will have passed away before the trying month of February comes in. Narrow pits in the house, filled with rough compost, longitudinal ridges or hills will therefore answer better than pots, especially if the roots can feel the influence of bottom heat from fermenting materials without getting into it. Light rich turf and old lime rubble will start and grow the plants well, but poor turf may require enriching at the outset. Rotten manure is the usual heal-all, but the less the better for winter use—that is, if stimulants, including soot, bone-dust, and good liquid, can be obtained; otherwise, dry, well-rotted cow manure rubbed to pieces or flaky leaf mould may be used. Hills at this time of year may be made one day and planted the next, and the greater their distance from the top-heat pipes the less the danger of spider when strong fires become necessary. Plants intended for fruiting through the spring I prefer keeping in pots, as the roots are so thoroughly under control, and the bottom heat can be regulated by the addition of fresh fermenting material without disturbing them. The soil for winter plants should be lighter than that recommended for summer culture, and the pots well crocked and placed upon pedestals to prevent them from sinking and strangling the plants.

Summer plants now in full bearing will take copious supplies of diluted liquid and good syringing to keep them clean and in health. Spider and mildew are the most troublesome pests when the plants become aged and enfeebled by heavy cropping; but these can

be kept in check by the use of sulphur, sulphur water, or sulphide of potassium, quarter of an ounce to a gallon of water. The best time to apply this remedy is late in the evening, when the house can be kept close; every part of the foliage above as well as below should be thoroughly bathed with the liquid, and well syringed with pure water early the following morning. If badly affected, the first dressing does not always act upon every part of the oldest leaves; a few of the worst should therefore be cut away the better to expose those retained, when the house being shaded syringing may be repeated every evening, always provided pure water is used early the following morning. Unlike many other insecticides, this preparation does no harm to the roots, although fatal to worms, which sometimes become very troublesome where animal manure is used as a summer mulching.

Melons.

Where late Melons are appreciated, and there is full command of top and bottom heat, strong plants of free early varieties, like Reading Hero, may still be put out in 12-inch pots with every chance of ripening their fruit in October. With hot-water pipes in near proximity to the bottoms of the pots, and a good body of fermenting leaves for giving off genial warmth and moisture, the plants will run quickly up to the setting stage, when it may be necessary to keep the valves constantly open. As soon as the fruit is set and swelling kindly, frequent renovation of the bed to reduce the necessity for constant firing is very important, as heat so obtained keeps the foliage fresh and clean without the aid of direct syringing. Late Melons should not be allowed to make more leaves and laterals than are absolutely necessary to the production and support of the crop; and the higher the fruit is kept, provided it does not protrude above the foliage, the better will be the flavour. Plants upon which the fruit is well advanced will now require plenty of air through the early part of the day, and atmospheric moisture can always be secured by the ordinary practice of damping the paths, walls, and beds without wetting the stems and foliage. At one time I always gave my plants a heavy syringing immediately after the houses were closed for the day, but this practice has been given up, and I now find the foliage keeps fresh and free from spider, and the quality of the fruit is greatly improved by giving the plants a vapour bath only. Animal manure I never use, the only addition to the loam being a little bone dust and old lime rubble, which make the vines short-jointed and fruitful, and diluted liquid is supplied to the roots when the fruit is swelling. To some a compost of this kind may appear expensive, but such is not really the case, as Melons require very little soil provided it is naturally rich and heavy.

Pits and Frames.

The weather, so far, has been fairly favourable to plants in pits, but the time is now at hand when the greatest care will be necessary. A low, damp, fluctuating atmosphere, and the gradual decline of bottom heat when the fruit is swelling and should be ripening, form conditions so thoroughly opposed to success, that no pains should be spared in the management of the lining not only in the spring, but throughout the season. To this end, alternate renovation once a week, even in the hottest weather, will always keep up the supply of heat and ammonia, when fresh air, the best of all preventives of canker, can be freely admitted. Sun being so necessary to flavour, the lights should be kept scrupulously clean, the tops of the mounds on which the plants are growing perfectly dry, not too thickly covered with foliage, and all surplus growths closely stopped to the first bud on the laterals. When watering becomes necessary, early on a fine afternoon when the lights can be thrown off for a short period is the best time to apply it, and then the supply, at a temperature of 90°, should be thorough. It is, of course, necessary to shut up as soon as the bed has been flooded, but in order to let out superabundant moisture, the lights through the night should be slightly tilted at the apex, when an extra mat hung over the back will break cold currents and prevent the top-heat from declining. A word as to ventilation. In the ordinary course we ventilate common pits and frames by tilting the lights at the back and letting out all the heat and moisture, to be replaced by a flood of cold air from the north. The mercury soon answers, and possibly sinks 10° in a few minutes, but what about the poor recently perspiring plants? They feel first and show the effect quickly by drooping and flagging, as it is termed, on a bright sunny morning, when watering or syringing are dangerous operations. Something, however, must be done, so the unscientific person—I will not say gardener—in a clumsy way sets about healing the wound he has so unwittingly made by shutting up and shading. Aided by a sharp north-east wind—no uncommon thing with us in summer—the grower makes rapid progress, and very soon finds his Egyptian subjects infested with vermin and ripening their foliage prematurely. A chink at the highest part of every frame is always necessary for the escape of heated or vitiated air; but the supply should be admitted at the front or south side, and in sufficient quantity to keep the pit or frame constantly full. By adopting this plan draughts will be avoided, as a large volume of heated air will pass through the front ventilators just as fast as the chink at the back allows the vitiated air to escape. When the top ventilation is in excess of the front, cold currents enter at the highest point, beat the vitiated air down, and the fresh air passes over it. The plants in such a medium, it is hardly necessary to say, do not thrive; but by providing a number of front ventilators, the nearer the surface of the bed the better, every leaf is kept in motion, and one of the great causes of canker in Melon stems is swept away and replaced with fresh life-sustaining air.

Orchard Houses.

Early trees that were potted as soon as the fruit was gathered will now be fit for removal to the open air, where they should be plunged or packed up into litter and regularly attended with water. If perfectly clean and free from spider, night dews and summer rains will most likely keep them healthy; but in the event of the weather becoming hot and dry, an occasional dash from the hose will sustain the foliage and feed the newly-formed flower-buds. If any of the later varieties which were in fruit when the first batch was potted have not been transferred to larger pots, no time should be lost in getting this work over. Space under glass being adequate, it is a good plan to return them to their quarters and keep them moist, rather close, and slightly shaded until the lateral leaves, by their crisp appearance, show that new root-action has set in. If the house is wanted for other purposes, they may then be removed to the open air, otherwise another month under glass will do them no harm. Older trees, which it may be desirable to replenish with fresh compost without increasing the size of the pots, will require more careful handling, as it will be necessary to disroot and pick out some of the old soil. The balls should then be soaked in water preparatory to repotting in new compost, which cannot be too dry, as it will be necessary to ram with the potting-stick until it is impossible for water to pass through the new without entering the old. Trees so treated flag a little at first, but shade from bright sun for a few days in a rather close house and frequent syringing will very soon bring them round, when shading must be discontinued and more air gradually admitted. Where early forced Peaches are planted out in raised borders the same rules apply, as trees having so much freedom cannot be kept in order when annual root pruning is neglected. Many plant on the level, but I prefer giving each large tree a raised station on good drainage, and enclosing its roots with a solid turf wall raised a foot or more above the floor-line. The advantages are an abundance of solar heat and air playing about the roots, their capacity to take more diluted liquid when the fruit is swelling, and last, but not least, the saving of time in forking down the old walls and replacing them with fresh turf mixed with old lime rubble. The secret of success consists in the annual performance of root pruning operations and getting them re-established before the leaves fall. Early houses in which the above system of planting-out is practised should be constructed with portable lights for running down in showery weather after the fruit is gathered. Cheap fixed roofs do very well for midseason and late culture, but where the fruit is forced to ripen in June and July there are times when full exposure of the trees is a decided advantage, if not an absolute necessity.

Midseason houses in which the fruit is now ripe or approaching that stage will require all the air that can be admitted, and water in sufficient quantity to keep the soil in a growing state. Mulching having done its work, fresh supplies will hardly be necessary, but a covering of some kind that will prevent the surface roots from drying out will save much trouble in watering, and prove a decided advantage to the trees. Where fine fruit is the first object there is nothing better than fresh stable litter slightly charged with ammonia, but when the orchard house is made an ornamental appendage to the dwelling, disagreeable smells are objectionable and must be avoided. Cocoa-nut fibre and Moss are good non-conductors, and may be used where they can be obtained at a cheap rate. When Peaches and Nectarines approach the ripening stage direct syringing must be discontinued, as some varieties, notably Lord Napier Nectarine, scald and become rusty; atmospheric moisture must be maintained by syringing the stems and walls, and damping the floor two or three times a day when the weather is fine. If Figs are grown in the warmest part of the house, the syringe will play a very important part in keeping down spider until the fruit is well advanced in its last swelling. Mulching and liberal watering until the most forward Figs begin to ripen will also be necessary, when the give-and-take principle must be observed, as fruit in various stages must be kept progressing. Cherries, ordinary Plums, and early Pears should be potted and treated as Peaches until new root action sets in, when they may be removed to the open air to make room for later kinds. The latter, including choice dessert Pears and Coe's Golden Drop Plum, being capable of standing any amount of solar heat with full ventilation, will, of course, remain under glass until the fruit and wood are ripe, when a dry, buoyant atmosphere will greatly enhance the flavour, and protection from birds will become necessary. If Strawberries are fruited on the shelves, the plants intended for another season will now be established in 5-inch to 7-inch pots and standing in an open part of the garden, where, properly attended with water and kept clear of weeds and runners, they will mature their crowns and roots by the end of October. The Strawberry question having been so thoroughly ventilated, readers of The Garden will experience no difficulty in making a selection for early or late forcing. Vicomtesse Héricart de Thury, President, and Crimson Queen are three good sorts, and where British Queen succeeds I would grow a quantity of plants for leading up to the crop from the open air.

Eastnor Castle, Ledbury. W. Coleman.

Kitchen Garden.

Notes on Peas.

Being desirous to test the merits of some of the dwarf-growing Peas side by side, I sowed a collection of eight different sorts on the 23rd of February last, on a border facing the east, under what I considered to be very favourable conditions. The only drawback was the soil being a little too rich; nevertheless, but few of them grew more than their normal height. A careful record was kept of their growth in every stage. M'Lean's Blue Peter has round pale green seeds, and grows 2 feet in height. It was in flower on June 11, and fit to gather on July 7; pods short, and an indifferent bearer. Turner's Emerald—seeds light green, wrinkled; in flower on June 11, and fit to gather on July 12. This sort bears a few long well-filled pods, but is not a desirable variety. Carter's Little Wonder—seeds pale green, large and wrinkled; in flower June 14, and fit to gather on July 17. This produces very long pods, each of which contained as many as nine large Peas; height 3 feet; an indifferent bearer. Bliss's American Wonder—seeds light green, wrinkled: in flower on June 1, and ready to gather on June 28, height 15 inches. This, in every respect, is the best of the collection. It is much the best bearer, and its growth is more regular than that of the above. M'Lean's Little Gem—seeds green, large,

and wrinkled; in flower on June 9, and ready to gather on July 13; a fairly good cropper; height 2 feet. Carter's Tom Thumb—seeds round, small, and light green, pods small and not sufficiently numerous to be profitable; height 2½ feet. Bijou—this has large, wrinkled, pale green seeds. In growth it is fairly vigorous and a moderate cropper; height 2 feet. Carter's Extra Early Premier—seeds green and wrinkled. About four days later than American Wonder. An excellent cropper, and altogether a very desirable Pea; height 2½ feet.

This trial, in my opinion, seems to show that many sorts of dwarf Peas are not wanted. I never looked upon them with any favour, and I shall hereafter do so with less, inasmuch as they are for the most part poor croppers; the fact is they have not bearing surface sufficient to produce a good crop. Out of the light sorts just named, only two are worth growing: these are American Wonder and Carter's Extra Early Premier; the first is decidedly the most prolific. For small gardens dwarf Peas may be useful, but where a regular succession has to be kept up, it is necessary to sow at least once a fortnight, each crop only yielding two gatherings.

Mildew.—Heat and drought are pretty well known to produce mildew in the case of Peas, and according to my experience all Peas are more or less liable to become mildewed. Some may, however, not be so seriously affected as others under the same conditions, and it would be useful to know their names. If I were asked to name two sorts that are not seriously affected by mildew, I should say they were Walker's Perpetual Bearer and Evolution. The last is comparatively a new Pea, and a good one too; it produces very large pods well filled with large Peas. Walker's Perpetual is not unworthy of its name, as it continues longer in bearing than any other sort with which I am acquainted when grown as a mid-season Pea. I have seen both these sorts but little affected, while all others have been white with the fungus. At the same time, I do not believe that any Pea enjoys perfect immunity from mildew in a season of prolonged drought, and the lighter and dryer the soil the more seriously are they affected. This naturally opens up the question of watering Peas, and in reference to this I may also say at once that I am not a believer in its efficacy. I have tried both plans, and have had as good crops without watering as with it; even during the present season I have put this matter thoroughly to the test. I watered and mulched some of our Peas heavily, but those on which we have spent so much additional labour are no better than others which have been neither watered nor mulched.

Selection of Peas.—Singular as it may appear, in point of earliness we have not gained anything during these last thirty years. Sangster's No. 1 has supplanted the old Early May as regards its name, but it is neither earlier nor better than that old sort. William the First has taken the place of Early Warwick as a second early, and I must admit that it is a decided gain as regards flavour. The old Auvergne, which used to be a standard favourite as a mid-season Pea, has not yet been beaten as regards cropping qualities and flavour. Its only fault was that it was small as regards both pod and Peas. Its place has been filled by Telephone and Stratagem, and certainly those who require Peas that will fill the basket as well as the vegetable dish can have them in either of these newer sorts, but they are no advance in flavour, and they certainly lose something in the time during which the respective sorts remain in bearing. It requires three sowings of these new Peas to two of Auvergne to keep up a succession. It is much against large-podded Peas that so few of them are produced, and that they so quickly go out of bearing. According to my experience, half of the space sown with Emperor of the Marrows or the Duchess of Edinburgh will yield as many Peas as either Telephone or Stratagem on double the amount of ground. As exhibition Peas the Duke of Albany and Evolution will, I believe, become popular. The first-named is perhaps the handsomer of the two. Its pods are well inflated, and when taken just at the right stage and opened, they exhibit such a fine display of Peas, that they are sure to arrest attention. Evolution I look upon as the most serviceable for the table, its eating qualities being excellent. In growing any of the new sorts of Peas for the first time it is not good policy to depend on them entirely for any particular crop. Many of them differ in the length of time at which they come into bearing. Soil also influences the crop somewhat; some will do better in one garden than in another. It is therefore well to grow them on a limited scale at first. J. C. C.

WINTER CUCUMBERS.

It seems to be generally admitted that Telegraph is the best variety of Cucumber for winter work, its free-bearing habit and short-jointed growth in the dark days eclipsing all other kinds. The seeds should be sown singly in small pots, about the third or fourth week in August, in fibry loam, lightened and enriched with old mellow manure. Robustness of habit is especially valuable in winter, and therefore the soil should not be too light. Plunge the pots in a frame near the glass where there is a little bottom heat, covering them with a sheet of brown paper till the seeds germinate. Afterwards uncover, and ventilate to ensure sturdiness of habit. More seeds should be planted than the number of plants required, as some may fail to grow, and others that germinate may be weaklings, and none but strong plants should be employed. The house in the meantime should be thoroughly cleansed, the paint washed with soap and water, the walls limewashed, and everything removed from the bed, so that there may be no harbour for woodlice or other insects. Whatever the arrangements may be for supplying bottom heat, it should be equal to a steady temperature of 75°.

Usually the bottom heat is supplied by hot water pipes, and it is an advantage if these are laid in a watertight tank, so that if necessary moisture may be given below the roots. The best arrangement is to lay the pipes in a cemented chamber and fill in with rubble, the rubble rising 6 inches or so above the pipes. On the rubble lay 6 inches of stable manure, or more if space permits. The best soil is a turfy loam not too heavy, and to every bushel of loam I like to add from one to two pounds of Amies' manure. This manure seems to furnish just the kind of stimulant Cucumbers require, and it is especially valuable in top-dressings applied when the plants are bearing freely. It is best not to hurry the plants with a high temperature at first, and they should not be planted too thickly, as overcrowding must weaken their growth. Four feet apart will not be too much to permit the side shoots to be tied out and give room for the foliage to develop properly.

Unless fruits are required early, it is best not to stop the main stems till the top of the house is nearly reached. The side shoots should be stopped one joint beyond the fruit, and this should be done as a system all through the existence of the plants, but leaving the leader unstopped for a considerable time does add immensely to the general strength of the plants, which will be of great service through the winter. The Telegraph is a free bearer, but only a light crop should be taken through the autumn if the plants are to bear well after Christmas. The soil should always be kept moist, as dryness at the roots will cause the foliage to suffer, and injured Cucumber leaves never recover, and it should be a point to retain the main leaves as long as possible. The atmosphere should be kept genial and moist. In most Cucumber houses there are troughs on the pipes, which are kept full of water, with liquid manure given occasionally, and in addition the floor can be damped and the walls syringed. Ventilation should be given in genial weather to keep the atmosphere fresh and pure, but the amount of ventilation must hinge in a great degree upon the construction of the house, and the best Cucumber houses are those which require the least ventilation, as in such houses there is not much fluctuation in the temperature. The night temperature should range from 65° to 70°, with a corresponding advance in the daytime with the sun's heat. It will be necessary to shade in bright weather through the autumn, but the lighter the shade the better, as shading always has a tendency to weaken.

When the plants are bearing freely liquid manure should be given, and there is great value in top-dressings, which should be light and frequently applied. A little fresh compost not only encourages the roots, but helps to keep the atmosphere pure and the foliage clean and healthy and free from insects, mildew, &c. A sharp look out must always be kept for insects destroying them as soon as their presence is first noticed, by a timely application of the usual remedies. All fruits should be cut as soon as they are large enough for use. A large number of fruits hanging at one time is a gratifying sight, but it has to be paid for in the after exhaustion of the plants.

E. Hobday.

Garden Flora.

PLATE 557.

PURPLE BOX-LEAVED MILKWORT.

(POLYGALA CHAMÆBUXUS PURPUREA.*)

The genus Polygala consists of a large number of more or less handsome flowering plants, ranging from the common Milkwort of our heaths and meadows to the bushy shrubs well known at exhibitions, which require the protection of a greenhouse in winter. A goodly number, however, both annual and perennial, natives of North America, are quite hardy in this country; a few of them would find a suitable home on the rockery, and, mixed with other things of an evergreen character, would help to make that part of our gardens attractive in winter as well as in summer. Seldom are our native representatives of this genus seen in gardens, a surprising fact, as few who have seen them growing amongst stubby Grass or peeping from under the cover of a Furze bush will dispute their claim to such a position. The difficulty lies in lifting them properly, an operation in which the roots generally get damaged, and failure is the result. This year we took the precaution to have a large sod of turf of a good depth lifted, and in this way have had a grand display of flowers. P. Chamæbuxus and its varieties, all of which are shrubby in habit, make excellent plants for the rockery; they flourish in almost any position, and, associated with such plants as Ericas, Lelums, Veronicas, &c., make very interesting groups of dwarf evergreen shrubs, which effectually clothe places that would otherwise be naked and unsightly during the winter season. These shrubs in the rockery are also useful as a protection to bulbs, even quite hardy ones, by warding off cutting winds, &c., and preventing the flowers from getting injured by them. Crocuses seem to thrive much better planted on the lee side of these small shrubs than elsewhere. Daffodils are always earlier, and even such tender bulbs as the Calochorti do exceedingly well under such conditions.

P. Chamæbuxus.—This elegant little evergreen shrub produces flowers from May until October, but most plentifully in May and June. It bears so little resemblance to other European species, that old botanists considered that it belonged to a different genus. Many varieties of it have been found growing wild, a few of which are in cultivation. Of these perhaps the best is that represented in the annexed plate. It has large yellow

Drawn at Munstead, Godalming, May 4, 1885.

POLYGALA CHAMÆBUXUS PURPUREA.

and deep magenta-purple flowers, and makes a truly magnificent show during early summer. P. Chamæbuxus and its varieties may be readily cultivated either in borders or on rockwork, but they like a position shaded from the mid-day sun. The soil should be rich sandy loam, mixed with lime rubbish or tufa stones. They may be propagated freely from cuttings, taken off now or a little later and placed in sand under a handlight. P. Chamæbuxus is a native of Austria, Germany, &c., and is said to have been cultivated in the Oxford garden as early as 1658.

P. PAUCIFOLIA.—This is another dwarf North American species. It makes a handsome little plant for the rock garden, growing as it does only from 3 inches to 4 inches in height; the stems, which are leafy—chiefly at the summit—rise from slender prostrate or underground shoots; the flowers are large for the size of the plant, being often about an inch long, rosy purple, rarely pure white. It likes shady places and peaty soil, and may be associated with such plants as Linnæa borealis and Vaccinium Vitis-idæa.

P. VULGARIS.—This is so well known, that we need only direct attention to it as a plant suited for the rockery. P. calcarea and amara, two nearly allied species, also natives, are likewise suitable plants for the same purpose. They are all easily grown on stones, which they over-hang, and on which they produce their flowers freely, some blue, others purple, pink, and white.

D. K.

FRUIT CROPS.

SCOTLAND.

Moredun, Midlothian.—Apples here are a very poor crop, Lord Suffield, Iris'h Codlin, and King of the Pippins being the best. Pears are also a very poor crop, and the same may be said of Plums. Apricots are about one-third of a crop. Peaches outside are poor. Gooseberries are fair average crops; in some places abundant. Black, Red, and White Currants, too, are plentiful, as are also Raspberries. Of Strawberries we have fair average crops, but fully two weeks later than usual. The best for bearing in this locality are James Veitch, Vicomtesse Héricart de Thury, President, Elton Pine, and the old Grove End Scarlet, which we use for preserving. As regards flavour, we consider Black Prince, Keen's Seedling, President, James Veitch, and Elton Pine the best. We have also tried King of the Earlies and The Captain, but must try them another season. The method which we have adopted for years in order to secure good crops is as follows: We trench deeply and manure liberally, incorporating it well with the soil. We prefer horse manure for heavy soils, and cow or pig manure for light ground. Trenching we begin as soon as we can get the previous crop off the ground; we expose as rough a surface as possible to the winter frosts. In March we give a good dusting of soot, fork over the surface, firm it with the feet, and rake smoothly. We then plant single plants in rows 30 inches apart and 18 inches asunder. Digging afterwards amongst the plants we do not recommend, but we keep them clean with the hoe. In the end of the year, *i.e.*, as soon as we have had sufficient frost to render the ground hard enough to carry a barrow, we give the plants a good mulching of rough manure, and of this, by the time they are in bloom, there is little left but the straw, which forms a clean bed for the fruit to rest upon. This system we have adopted for years, and find it to suit admirably. We always destroy the plants after they have borne their third crop.—JAS. SMITH.

Riccarton, Currie.—We have here but poor crops of Peaches, Apricots, Pears, and Apples. Plums, such as Coe's Golden Drop, Jefferson's, and Purple Orleans on a south aspect, are fair crops. Victoria on a west aspect is good, but the trees have suffered considerably from branch-dying. Small fruits are pretty fair on the whole. Strawberries are not quite so good as last year. Late frosts blackened the flowers on several occasions. Garibaldi is decidedly the best variety we have either as a forcer or for outdoor work, taking size, flavour, and colour into account. For flavour Garibaldi and Bothwell Bank are our best, and our best croppers are Garibaldi and James Veitch. Black Prince is our earliest variety, and Elton Pine and Bicton Pine our latest. The best plan by which to secure regular crops of good sized fruit is to plant annually a few rows of each variety in August, and trench down an equal number of the oldest rows. In making young plantations always have the rows to run north and south. Leave 2½ feet between each row and 16 inches plant from plant. Two rows of Onions for spring use may be sown between each row of Strawberries.—GEORGE BROADFOOT.

Tynninghame, East Lothian.—Bush fruits in this neighbourhood are a very good crop. Apples, Pears, and Plums are, as a rule, small crops. Apricots fairly good. Strawberries irregular; in some cases they are quite a failure, in others a crop, though a small one, while with us they are a very heavy crop. In the garden here Apricots are extra plentiful. Peaches the same. Plums a fair crop. Pears a small crop. Good cropping Apples, such as Warner's King, Stirling Castle, Echlinville, Tower of Glamis, Rymer, Lord Suffield, Mère de Ménage, Northern Greening, and Duchess of Oldenburg, as well as some free-bearing dessert kinds, are bearing good crops. Strawberries in this district were much damaged by late frosts, and subsequently a period of protracted drought emphasised the mischief. Our own beds were only slightly damaged by frost, and the drought has not done much harm, thanks to a deeply worked soil. I now grow only four sorts for our out-of-door supply. These are Grove End Scarlet for preserving, Vicomtesse Héricart de Thury, President, and Elton Pine. I have tried and discarded for various reasons Dr. Hogg, British Queen, Loxford Hall Seedling, and Pioneer (these do not ripen thoroughly), also Keen's Seedling, Unser Fritz, Lucas, Samuel Bradley, James Veitch, Prince of Wales, Duke of Edinburgh, Frogmore Prolific, La Grosse Sucrée, Helena Gloede, and several others, the names of which I do not call to mind. Keen's Seedling is largely grown in the locality, but Vicomtesse Héricart de Thury is equally good and a firmer fruit. Our system of culture varies somewhat, but, as a rule, we select strong-rooted runners as early in August as possible, lift them carefully with balls, and transfer them to the ground chosen, and, if possible, on a damp cloudy day. The best ground is that from which a second early crop of Potatoes has been lifted. It requires no preparation, and as we try to have the two crops, immediately preceding the Potatoes, to be Celery, the ground is in capital condition for the Strawberries. The sorts for preserving and some of the Vicomtesse are grown in 4-foot beds, in which they produce large crops for three seasons. President and Elton Pine are set out in single plants, in rows 3 feet apart and 2 feet plant from plant in the row. From three to four seasons is as long as Strawberries do well. We find a sprinkling of manure scattered over the plants in the beds in winter to be a great help in the way of promoting a strong fruitful growth. Between the rows of the young plants we grow Onions and Carrots; an old bed is each year stubbed up, the plants burned on the spot, and a fresh crop set out in their place without any preparation. A mulching of manure is applied to the new plantation.—R. P. BROTHERSTON.

Callendar Park, Stirling.—The soil in this locality varies very much. In some parts it is light, on a gravelly bottom; in others it is stiff, with a clayey bottom. Crops therefore vary accordingly, especially Strawberries. Here the only kinds that succeed well are Garibaldi, Elton Pine, General Macmahon, and Wizard of the North. All these kinds are excellent this season, the best we have had for eight years. Our earliest is Garibaldi. I have tried Black Prince and a host of others, but without success. We plant in rows 2 feet 6 inches wide and allow every other row to fill in, thus forming, the second year, beds which never fail. Our first gathering off a plot 26 yards by 26 yards, consisting of eleven-year-old plants of Garibaldi, was 420 lbs. This was on the 17th of July. On the 21st of the same month we gathered about half that quantity. Last year I dug down Strawberries over twenty years old, from which I have had fair crops, but latterly they showed signs of exhaustion. Our ground before planting is well manured; then nothing in the shape of manure is given, but the spaces between the beds are kept clean by means of the hoe. At Polmont, about 2½ miles from here, Mr. Scott grows largely and successfully for market on the plan just recorded, but he has to change the crop about every five or six years. His best kinds are Brown's Wonder, a grand cropper, but a little acid. Black Prince with him is good in crop and rich in flavour. Wizard of the North bears fair crops, but its flavour is not good. Elton Pine is the best late sort. Duke of Edinburgh bears good crops, but neither this nor the Elton Pine are high in flavour. Garibaldi is good both in crop and flavour. Of Sir Joseph Paxton we have a fair crop and good in flavour. It is the hardiest of all. Admiral Dundas bears good crops and the fruit is very large and fairly well flavoured. Plums in some cases are very heavy crops both on walls and standards; in others there is no crop at all; the best is Victoria. Pears are a fair crop. Apples very scarce; Nelson's Codlin is the best with us. Black Currants in some cases are fair crops, in others poor. Red and White Currants good; and Raspberries and Gooseberries are very good.—THOMAS BOYD.

Whittinghame, Prestonkirk.—Of Apricots we have very few. Peaches are a total failure. Plums and Pears are under the average. Cherries are an average crop, except Morellos, which are under the average. Apples, too, are under the average. Strawberries are under the average. Raspberries and Gooseberries are average crops. Currants are over the average. Nuts a failure. Of Strawberries the kinds grown here and considered to be the best for this district are Keen's Seedling, Elton Pine, Bothwell Bank Seedling, President, Dr. Livingstone, Garibaldi, Rifleman, and Duke of Edinburgh.—JOHN GARRETT.

Dalmeny Park, West Lothian.—Of Apricots we have a few. Peaches and Nectarines here are scarce. Dessert Plums are scarce; culinary ones a fair crop. Apples and Pears are also fair crops. Of bush fruits we have good crops. I only grow two sorts of Strawberries, viz., Keen's Seedling for early use and Elton Pine for late use. I trench the ground for Strawberries in autumn and plant in spring, pinching off all flowers and runners the following summer, and fruiting the plants for two years only.—JOHN MOYES.

Polmaise, near Stirling.—Large old Apple trees have very few fruit on them. On young trees there is a small crop; the best are Lord Suffield, Cardross Green, and Hawthornden. Pears on walls are also a small crop; Beurré Diel, Passe Colmar, Jargonelle, Moortowl Egg, and Beurré d'Aremberg are the best. Morello Cherries on a north-east wall are a very fine crop. Of Apricots we have very few. Plums on walls are fewer than usual and late. The best are Pond's Seedling, Victoria, Jefferson's, Green Gage, and White Magnum Bonum. We have ceased to grow Peaches out of doors, as they never repaid the trouble which their culture involved. Gooseberries are a very heavy crop. Raspberries plentiful, but small. Black, Red, and White Currants all excellent crops. Strawberries a moderate crop, but as a rule they do very well here, our soil being strong. I plant the runners in beds in autumn, on which they stand all winter. I ridge the ground intended to be planted (giving it a good dressing of old hotbed manure) in November, and before it is lightly dug over in spring I give it a good dressing of lime. The plants are put into it in March, in rows 3 feet apart in patches, each consisting of three plants, which are 2 feet asunder. I mulch with leaves in the summer, and they are dug in along with the runners at the

lack end of the year. I try to have the ground in good condition when planted, as I never give any manure afterwards. I take four or five crops off the plants and then destroy them. The varieties which I grow are President, Keen's Seedling, Vicomtesse Héricart de Thury, Frogmore Late Pine, and Elton Pine. As a first-rate Strawberry for table, President is the best, but it is easily damaged by wet. The Vicomtesse is a very fine cropper, and good for preserving. In a dry season it is subject to mildew. Frogmore Late Pine does moderately well; Elton does not succeed here; I am going to discard it. The best late Strawberry I have grown here is Wizard of the North, though a feeble grower.—W. W. Ritchie.

Alloa Park.—Apples here are this year under the average, and so also are Pears, Apricots, and Peaches. Cherries and Plums are very good, and small fruits, such as Gooseberries, Currants, and Strawberries, excellent. The varieties of Strawberries grown here and those that are most prolific are Dr. Hogg, Duke of Edinburgh, Elton Pine, Garibaldi, James Veitch (a grand variety), President, Sir Joseph Paxton, Stirling Castle, and Vicomtesse Héricart de Thury. We renew our Strawberries every third or fourth year: a plantation therefore is renewed every year.—Thos. Ormiston.

Blair Drummond.—Apples, Pears, and all wall fruits here are below the average. Small fruits, such as Gooseberries, Raspberries, and Currants, are abundant. Strawberries also are a heavy crop. For flavour the best here is the Duke of Edinburgh, although not so heavy a cropper as Garibaldi, which comes in a little earlier, but behind it in flavour. Next comes Sir Joseph Paxton, of which we have a remarkable fine crop of beautiful fruit, but rather worse in flavour than the Duke. President is not such a good cropper as Sir Joseph, but equally good in flavour. I have gathered fruit from it weighing 2 ozs. each. Then there is Bothwell Bank Prolific, rather an earlier variety and a fine cropper, but lacking colour and flavour; also Prolific Hautbois, the fruit of which is small and rather peculiar in flavour, but plentiful. Our latest sort is Elton Pine, of which we have a good crop of very fair fruit, and good in flavour if the weather is dry. There is another sort here, viz., Aromatic, which comes in before the Elton, but it is inclined to produce foliage rather than fruit, and its flavour is only second rate. As to culture, after lifting Potatoes we merely dig the ground and let it lie all winter in a rough state; then we rake it early in spring and plant with a trowel 2½ feet apart between the rows and 1 foot between the plants. After the fruit is gathered we cut away all runners from amongst the plants, and hoe and rake. We find digging very objectionable. Mulching is recommended by some, but we find by renewing the quarter every four or five years we get much better fruit than by applying too much manure and keeping the ground hard. Our soil is heavy loam on a sandy subsoil.—John King.

Balcarres, Colinsburgh.—Fruit crops in this district are very varied; they have been much injured by late frosts. Apples are very poor; the best (which bloomed early) are Aitkins' No. 2 and Irish Peach. Pears on east walls are pretty good; on other aspects we have none. Plums, with the exception of Victorias, are a failure. Cherries good, particularly Morellos. Of Apricots and Peaches we have very few. Small fruits are good and excellent in quality. Gooseberries are heavier than we have had them for years. Raspberries and Currants are also very good. Strawberries, too, are plentiful, but rather small. The sorts which I grow and find do the best on our strong soil are Keen's Seedling, Garibaldi, President and Marshal MacMahon; for late crops we grow Victoria and Elton Pine. We grow our Strawberries for the first two years in single rows, and after that allow two rows to form a bed. We find this system the best, as by it we get good and well flavoured fruit for five or six years. This plan has been much practised in this district of late years.—Edward Tate.

Castlemilk, Rutherglen, Lanark. — Our best Strawberries both for flavour and crop, according to my experience of thirty years' duration, are Black Prince, British Queen, and Dr. Hogg. James Veitch and President are excellent, but do not stand damp well. Elton Pine, Garibaldi, and Vicomtesse Héricart de Thury I find best for late crops. As to culture, in loose soil I neither manure nor dig before planting, which is done in autumn. I merely clear away our early Peas or Turnips, hoe and rake the ground, put in the plants, and I have never failed in having a fair crop. In some years it has been no uncommon thing for sixteen berries to weigh a pound. Here I have to dig, the ground being stiff, but I do not manure nor dig afterwards. I never grow the same plants more than three years on the same ground, and the result is large fruit and fine in flavour, and the plants do not make much foliage—a great advantage, as much foliage is detrimental both as regards fruit and flavour. Other crops in this district are fairly good. Early Cherries are poor, but late ones are abundant. Apples and Pears are a thin crop. Gooseberries with me are a heavy crop, but in some of the more exposed places they are nearly a failure. The same remarks apply to Black and Red Currants. Wall Plums, especially Victoria, are a good crop in most places. —Alex. Brewster.

Terregles, Dumfries.—Apples, with the exception of a few sorts, are a very thin crop in this district. Pears are also very thin. Plums on wall trees are a good average crop; standards not so good. Cherries are a small crop with the exception of Morellos, which are good. Currants, Gooseberries, and Raspberries are abundant. The Strawberry crop is the worst that has been known in this district for a number of years. We had a grand show of blossom, but the drought which we experienced in June prevented the fruit from swelling. In a neighbouring garden, in which the soil is heavy and the beds well mulched, there is the heaviest crop I have seen for years. The sorts that have proved the best with us for size, flavour, and good bearing are Garibaldi, Sir Joseph Paxton, and President; the best late kind is Elton Pine. In order to secure good and regular crops the beds should be renewed every three years and the plants given plenty of room. I plant in rows 2 feet 6 inches apart, leaving from 18 inches to 20 inches between the plants. I mulch the beds in winter or early spring with fresh stable litter, allowing it to remain on all the summer in order to keep the roots moist and the fruit clean. —Alex. Chalmers.

Castlecraig, Dolphinton, Peebles. — Our altitude is 850 feet above sea level; consequently everything is very late; only this morning (July 28) the thermometer registered 33°, and 36° at 6 a.m. Of Apricots and Peaches we have none grown outside. Of Apples we have almost none; Pears the same. Of Plums the Victoria is a fair crop; others a failure. Cherries rather under the average. Raspberries abundant. Gooseberries are above the average. Red and White Currants a heavy crop; Black Currants a medium one. Strawberries are an average crop. Keen's Seedling and President are the best flavoured. These, Black Prince and Garibaldi do best and crop the heaviest; Black Prince for first early, Keen's Seedling and Garibaldi for second early, President for main crop, and Elton Pine for late work. Sir J. Paxton and Marshal MacMahon have been on trial; many varieties have been tried here and discarded. We plant one-third every spring, and destroy a third every autumn; no digging between the rows is allowed, only cleaning and top dressing in autumn. Autumn planting does not answer here.—William Milne.

Galloway House, Wigtonshire.—Fruit crops in this district are below the average, especially where much exposed to east winds. Apples of the following, viz., Keswick Codlin, Cellini, Hawthornden, Galloway Pippin, Warner's King, Yorkshire Beauty and Blenheim Orange are good crops. Pears are about half a crop; the best are Jargonelle, Marie Louise, Beurre Diel, Swan's Egg, and Louise Bonne of Jersey. Of Cherries we have a very good crop. Apricots are a fair crop—better than for some years past. Peaches and Nectarines are very scarce, much of the wood being destroyed in winter, owing to unripeness. Plums are a heavy crop throughout; Victoria, Lawson's and Green Gages have required thinning. Currants, Raspberries, and Gooseberries are all good crops and the fruit very fine. Strawberries are below the average; early kinds were good, but the late sorts (Frogmore and Elton Pine) have failed to swell off their fruit. For early use we grow Black Prince on south borders. For main crops on open quarters Keen's Seedling, President, Vicomtesse Héricart de Thury and Sir Joseph Paxton have proved to be the best. Frogmore and Elton Pine we grow for late use. Bothwell Bank has been grown here for three seasons; it ripens about four days later than President, and in flavour, colour, and firmness of fruit it is inferior to that variety. To get fine fruit and regular crops, the plantations must be renewed every three or four years. We plant in well manured and deeply trenched soil, 2½ feet apart between the rows, and 2 feet plant from plant. —James Day.

Milne Graden, Coldstream.—Apples here are almost a total failure, owing, I believe, to the prevalence of wet and cold at flowering time preventing a free set of the fruit. Pears, too, are considerably short of a full crop. Amongst Plums, Gages are rather thin; Victorias and Magnum Bonums good crops. Peaches, where protected, are a full crop, and the trees healthy and free from aphides and curl. Apricots are a very light crop here generally. Gooseberries, Red and Black Currants and Raspberries are full crops. Of Cherries we have none. American Brambles promise well. Strawberries are a full crop in quantity on such kinds as James Veitch, President and Vicomtesse Héricart de Thury, but the fruit is inferior in size, owing to the drought which has prevailed here recently. Sir J. Paxton, Excelsior and Duke of Edinburgh have been very disappointing this year; they have grown most luxuriantly, and produced large healthy foliage, but scarcely any flowers. The plants, I may say, were completely denuded of leaves by the frost of the late severe winter, which I think must have damaged the crowns to such an extent as to make them abortive as regards fruit. British Queen is one of the best flavoured of Strawberries where it succeeds, as it does in a neighbouring market garden here, on a chalky soil. James Veitch is the heaviest bearer we have here, and seems to be less affected by drought than most of the other varieties. Vicomtesse H. de Thury is one of the earliest and best all-around Strawberries that can be grown, and one that is not so fastidious as to soil as many others. Wizard of the North is one of the best late sorts, some years yielding a supply of fruit well through September. Of foreign varieties, Triomphe de Paris is certainly an acquisition, and of recent introduction. It is a compact growing variety, and produces finely coloured fruit freely and well out from the foliage; the fruit is round, medium sized, and of good flavour. The best way in which to secure a continuous yearly supply of fine Strawberries is to make a new plantation every spring on ground that has been previously trenched, well manured, and trodden hard, planting in rows 2 feet apart, and leaving 16 inches between the plants. Mulch well in autumn, and stir the surface with the hoe in spring, instead of digging between the rows, as is usually done; keep the ground clean and the plants isolated, or free from one another, and, if other conditions are favourable, good crops will be the result.—James Graham.

Wishaw, Lanarkshire.—Apples and Plums here are under the average, but in other gardens on the Clyde they are full average crops. Bush fruits are average crops. Strawberries are above the average, especially the earlier varieties. Our best flavoured and main cropper in this district is Vicomtesse Héricart de Thury; the earlier varieties are Black Prince and Grove End Scarlet. For late use we grow Elton Pine and President. The

best way in which to secure a good regular crop is to manure heavily and turn the ground up to the winter frost before planting, our soil being very damp and heavy.—John Munro.

Blackadder, Chirnside, Berwickshire.—All small fruits hereabouts are good, especially Strawberries. The leading sorts for flavour are Dr. Hogg and British Queen. For early use we grow Keen's Seedling and Vicomtesse Héricart de Thury, and for late use Elton Pine, President, Sir C. Napier, and Eleanor. In order to secure good and regular crops, make young plantations on heavily manured soil. The Apple crop here is very poor. We had a fine show of blossom, but most of it dropped. Pears are a fair crop. Plums and Cherries very good. Of Apricots we have none.—F. Hacker.

Torwoodlee, Galashiels.—Of Pears here we have almost none, and Apples are not much better. Plums and Cherries are fair crops. Black Currants poor; Red a good crop, but the fruit is small. Gooseberries pretty good. Raspberries look well. Strawberries are very poor. The best early sorts are Dr. Hogg, President, and Keen's Seedling, but the colour of the latter is rather dark. Our late sorts are Sir Joseph Paxton and Elton Pine, also James Veitch, but the last is not very productive.—Thos. Shannan.

Munches, Dalbeattie, Kirkcudbrightshire.—Pears here are thin, and Apples a poor crop, with the exception of Lord Suffield. Cherries are a fine crop. Plums an average crop. Gooseberries average. Raspberries under the average. Black and Red Currants fine crops. Strawberries a fair crop. The kinds that do best here are Black Prince for early use, and the old Grove End Scarlet; the latter bears heavy crops, which we use for preserving. Garibaldi does well here, also Vicomtesse Héricart de Thury and President. All are on a clay soil, and they hardly ever fail to bear heavy crops.—John Jeffrey.

Kilkerran, Ayrshire.—Gooseberries, Currants, and Raspberries here are good crops. Apples a failure, except a few young trees, consisting of such varieties as Lord Suffield, Echlinville, Hawthornden, Small's Admirable, Ringer, and Pigsnout, which are bearing a few. Pears on standards are an entire failure, and almost the same on walls. Plums on walls are about half a crop, on standards about a third of a crop, and so late that they will not ripen. Of Peaches and Apricots we have none. Strawberries in this neighbourhood are very poor—with me not more than half the usual crop. The winter did not leave a leaf on them, and the spring and summer were dry and cold. The varieties which I find do best are, for early gathering, Black Prince, an abundant bearer and of first-rate quality; Garibaldi, also an abundant bearer, but only of second quality; for midseason we have Barnes' Seedling, President, Bothwell Bank Prolific, and Sir Charles Napier. Barnes' Seedling is very little known. It is a large cone-shaped fruit, of a pale red colour, and an enormous cropper, but only second-rate in quality. Bothwell Bank I consider the best both as regards cropping and flavour. For late use we have Wizard of the North, which is an abundant bearer, and Elton Pine, which does not bear very freely, but is of good quality. The mode of culture which I consider best for securing a good crop of large well-flavoured fruit is to trench the ground three spits deep, enriching between each spit with a layer of well rotted manure, and as soon as strong runners can be got in August to plant them in lines 3 feet apart, and 2½ feet asunder in the line, in clumps of three plants in a triangle 3 inches apart. This allows plenty of air and light to get to the fruit, and also leaves plenty of space for cleaning among plants and for gathering the fruit. Varieties such as Black Prince I plant in lines 2 feet apart and 15 inches asunder in the line. I keep down weeds with the hoe until the beginning of November, when I give a good mulching of rotten manure. This is allowed to lie on the ground all the year round, and is renewed every November. I never disturb the ground, except with the hoe, until the plantations show signs of exhaustion, which is after a lapse of three or four years; then they are trenched down. I consider digging between the rows to be a bad practice. In light soils I should make the ground firm before planting. If planted in August, as they should be, I allow them to bear fruit the first year; but if through want of ground or other causes they are not planted till March, they should not be allowed to bear fruit that season. To keep the fruit clean I use rough litter from the stables. I never dig among Raspberries either, but keep the ground covered with manure and keep weeds down with the hoe. Anyone who sees the difference which this treatment makes in the size of both canes and crops would never afterwards dig among them.—Geo. Gallaher.

Culzean, Ayrshire.—Fruit crops hereabouts are very bad, especially Apples and Pears, which are very scarce. Plums are about half a crop and the fruit very much rusted, owing to the cold weather which we had in June. Bush fruits are a medium crop. Black Currants a heavy crop. Strawberries about half a crop. Garibaldi and Duke of Edinburgh are our best sorts as regards bearing. King of the Earlies and The Captain, two new varieties, promise well for the future.—David Murray.

Castle Toward, Renfrew.—Here Strawberries, Gooseberries, Red Currants, and Plums are extra good crops this season. These fruits are now made a speciality of in this district, and many hundreds of acres are planted with them. The work of gathering the crops has commenced, and many tons of fruit have been already despatched by rail to Glasgow. Apples and Pears will compare well with crops of former years in low-lying orchards, but in the high levels the fruit trees got such a shaking from severe winds which we had in June, that a large crop cannot be looked for; such as there is, however, looks well, and is better than that of last year. I generally grow Vicomtesse Héricart de Thury Strawberry, Myatt's Seedling, Trollope's Victoria, and Keen's Seedling. The ground here is rather stiff for early crops, but we generally have fine late ones. The east winds in April and May keep every kind of crop back here.—Harry McLeod.

Dupplin Castle, Perth.—Apples hereabouts are a thin crop. Of Apricots we have scarcely any. Cherries are a thin crop, except Morellos, which are heavy. Pears are also scarce; Moorfowl Egg is carrying a good crop. Plums are thin also, except Victoria and Jefferson's, which are bearing average crops on young trees that were watered during the dry weather of last summer and autumn. Strawberries are the lightest crop I have ever known here, and the fruit is poor in quality, having suffered very much from drought. Elton Pine is the only sort bearing anything like an average crop. Raspberries are a heavy crop and good in quality. Gooseberries and Currants, especially Red ones, are bearing exceedingly heavy crops. Nuts are a fair crop, but so late that I fear they will not ripen.—John Browning.

Drummond Castle, Perth.—Of Peaches and Apricots we have none here this season. Apples, consisting of Stirling Castle and Lord Suffield, are bearing a sprinkling; others, none. Of Plums, with the exception of the Victoria, which is a fair crop, we have but few. Cherries, consisting of May Duke and Morello, are good crops, but late, owing to the dry weather which we have had for the last six weeks. Raspberries, Gooseberries, Currants, Black, White, and Red, are good crops, but want rain. Of Strawberries, the varieties that I grow, and which are mostly grown in this locality, are Garibaldi and Elton Pine, which usually produce good crops when not left too long in one place.—John Robb.

Abercairny, Crieff.—The fruit crop here is not so good as that of last season. Apples and Pears are under the average, and the same may be said of wall fruits, such as Apricots, Peaches, Plums, and Cherries. Standard Plums, however, are a good average crop. Bush fruits are up to the average, but deficient in size of berry. Strawberries are a good crop, and though somewhat smaller in berry than usual, the quality is all that can be desired. Garibaldi, for early and main crop either for in or outdoor, and Elton Pine for late use are the two standard varieties with us, as both do well in this district. In making new plantations my system is to lay down the ground in good condition, to trench and manure pretty heavily, and especially for Elton Pine. We plant 3 feet apart each way, and keep the plants singly in the rows. In autumn we clean the ground and mulch early in spring, and the return is seldom or never deficient.—James Brown.

Marchmont, Dunse.—Apples here are scarce and small in size. Pears very scarce. Apricots, where protected, good. Plums, about half a crop. Gooseberries in some gardens are a heavy crop in others a failure, the buds having been destroyed in spring by birds. Currants are a light crop and small. Strawberries are not half a crop and they are not ripening well. The sorts grown here are Black Prince, Doctor Hogg, Duke of Edinburgh, Keen's Seedling, President, and Sir Harry. They are grown in rows 3 feet apart and 18 inches asunder in the row. I renew them every four years. I trench the ground deeply, and put in a heavy dressing of farmyard manure in the bottom of the trench.—Peter Loney.

Scone Palace.—Owing to cold weather in the end of April and beginning of May, Apples, Pears, and Plums set badly, and, with one or two exceptions, are poor crops. Strawberries are a good crop, but owing to the long continued drought which we have had they are small in size. Other kinds of small fruits are abundant and very fine. The varieties of Strawberries that succeed best here are Garibaldi, Keen's Seedling, Sir Joseph Paxton, Duke of Edinburgh, Sir Charles Napier, Auguste Nicaise, and Elton Pine. The kinds grown for early crops are Garibaldi and Black Prince, and for later supplies Elton Pine. The soil here is a heavy retentive loam on a clayey subsoil, and produces excellent crops of Strawberries; if the quarters are annually top-dressed with rich manure, they continue to bear heavy crops for five or six years.—A. M'Kinnon.

Fingask Castle, Perthshire.—Apples hereabouts are a very thin crop. Apricots light. Pears the same. Plums almost a failure. Cherries very thin, except Morellos. Peaches outside a failure. Gooseberries abundant. Currants, Red, White, and Black, and Raspberries excellent crops. Of Strawberries we grow Grove End Scarlet for preserving. Oscar, a large fruit and good in flavour, does well here. Sir Harry is good, both as regards crop and quality. Dr. Hogg is a fine hardy fruit, and one which travels well. On a dry bank it has not done well this season, nor has Sir Joseph Paxton. These two have a peculiar musky flavour. Comte de Paris is a fine early Strawberry and good in flavour. This and Keen's Seedling are on a dry bank, and have suffered from drought. Elton Pine is our best late kind. White Bath Strawberry I have grown over fifty years; its fruit is large and white, but when quite ripe it is tinged with red. It makes a useful variety for table where several dishes are required. It does best away from other sorts; if mixed it gets overcrowded and killed.—Peter Loney.

Dunkeld, Perthshire.—The Strawberry crop here is in every way excellent. It came forward rather quickly, owing to the dry weather which prevailed here up to this date (July 23). Our best kinds both for crop and quality are Duke of Edinburgh, Elton Pine, Duke of Athole, President, and Keen's Seedling. Vicomtesse Héricart de Thury is early and fine in quality. Duke of Edinburgh is a second early, and in such a season as this extra fine in quality and very large. Duke of Athole is grand as regards quality and excellent for dessert, but it suffered in spring from the severity of the weather. Elton Pine, when true to name, is in every way without doubt the best late Strawberry in cultivation. Of Plums on walls we have an extra fine crop; on bush

trees a fairly good crop. Apples are a very poor crop, and Pears, too, are a very inferior crop. Of Peaches on walls we have very few. Apricots are also very poor crop. Cherries are fine in quality, but not a heavy crop. Gooseberries are a fairly good crop, but greatly damaged by gales which we had here about three weeks ago. Currants are not a heavy crop.—P. W. Fairgrieve.

Pitfour Castle.—Of Pears and Plums we have none here. Apples, with the exception of Lord Suffield, are about as bad. Of Apricots and Cherries we have fair crops. Currants, Gooseberries and Raspberries are abundant and very fine. Strawberries may be called the crop of the season. The sorts grown here are Black Prince, Vicomtesse Héricart de Thury, President, Sir J. Paxton, and Elton. I also think well of King of the Earlies and The Captain. My system of culture is as follows: I heavily manure and double dig the ground for them in autumn or winter, and defer planting till early in April. Early sorts are allowed 2½ feet between the rows, and the others 3 feet. There being no fruit the first season, the ground between the rows can be cropped with Lettuces, Spinach, &c. If, therefore, all has gone well there need be little fear of gathering a good crop next season. We usually have a period of dry weather in June during the flowering time, and therefore, when the fruit is fairly set, an abundant supply of water must be given. After the crop is gathered, I lose no time in clearing off the runners, decayed foliage, &c. I hold this part of the system to be of the utmost importance, the whole strength of the plant being then available for maturing the crowns for another season. Light hoeings are given as required, but no digging or forking. Before hard frosts set in a good dressing of stable manure is laid between the rows, and, thus treated, they furnish profitable returns for four or five years, Sir J. Paxton excepted, three years being its profitable limit here.—Alex. Forbes.

Skibo Castle, Sutherland.—Strawberries on two-year-old plantations are good crops here, but under the average on older plantations. Sir Harry, an old standard in this district, is our earliest. From this we gathered fruit this year on the 10th July, three days before Garibaldi, and five before President. Garibaldi, President, Elton Pine, and Myatt's Seedling come in in succession in the order named. Raspberries are a good crop. Gooseberries are extra heavy, and Red and Black Currants good. Cherries on walls have been good. Plums average crops. Pears and Apricots under the average. Apples, both on standards and bushes, are a very clean, good crop on young trees, but scarcely any on old ones.—John Urquhart.

Cullen House, Banff.—Apples and Pears here are almost a total failure, a circumstance to be expected after the abundant crop of last year and the very untoward autumn that we had for ripening the wood and maturing the fruit buds. Small fruits are very good, especially Black Currants. Gooseberries are a fair average crop. Plums of some sorts, such as Jefferson's, Victoria, Washington, and Golden Drop, are extra good; other kinds are only partial crops. Apricots, Peaches, and Nectarines are also only partial on open walls. Cherries the same. Strawberries promised to be good, but the weather was against them at the time of setting. Our earliest and best kinds are Black Prince, Garibaldi, and Beehive. These do well and bear good crops. Our soil is a cold, stiff, retentive loam, which suits Strawberries well. We do not dig amongst them in winter, but clean off the runners and then give them a good mulching with half-rotted manure, which is left on the ground all the following season, and which saves strawing in order to keep the fruit clean. We grow all our Strawberries on the single-plant principle, planted 18 inches apart in the rows and 3 feet between the rows. Of late Strawberries we grow the following, viz.: President, Keen's Seedling, Myatt's Eliza, Dr. Hogg, Duke of Edinburgh, and some others, all of which do equally well as the early sorts.—George Berry.

Cawdor Castle, Nairn.—Apricots, Peaches, Cherries, and Pears are all very poor crops, and Apples in all situations are the same. Bush fruits, viz., Gooseberries, Currants, and Raspberries, are all good. Strawberries are fairly good, but the fruit, especially that on old plants, is small. The sorts which I grow are Garibaldi for our earliest crop, President and Duke of Edinburgh for succession, and Elton Pine for late crops. The latter keeps bearing until October. Duke of Edinburgh is the most vigorous Strawberry I have grown. It is a good bearer, the colour is good, and it keeps bearing for a long time. The flavour is not first-rate, but it is nevertheless a useful variety. I trench the ground for Strawberries the year before I plant them, and give as much manure as I can afford; before planting I also dig in a good coating of manure, firm the ground, and never dig between the lines until they are trenched down; after bearing four or five crops, I find that fresh soil is always best.—James Maitland.

Haddo House, Aberdeenshire.—The fruit crop in this district is in most cases under the average. Apples and Pears are almost a complete failure; numbers of trees had no blossom on them, and the fruit set very thinly upon those which had. Plums, consisting of Victoria, Jefferson's, Coe's Golden Drop, and Orleans, are good crops; others sorts are thin. Cherries of all sorts are about half a crop. Among small fruits Raspberries are a large crop; Black and Red Currants and Gooseberries generally are rather poor crops; early Strawberries are a large crop, late sorts under the average. For this district I find the best early sorts to be Keen's Seedling and Rivers' Eliza for flavour and bearing; to succeed them Marshal McMahon is the best I have tried. For a late sort that known in this neighbourhood as Myatt's Seedling is the most suitable. A new variety, the Aberdeen Favourite, sent out by a local grower three years ago, is well spoken of, but it does not succeed here. In order to secure regular and good crops we plant a certain quantity every spring on well-manured ground, allow no fruit the first year to grow on them, and give a top-dressing of well-rotted manure and bone meal, lightly pointing them in between the rows in spring. We in general fruit them for four years, when they are trenched down and the ground cropped with different sorts of vegetables for three years at least before planting it again with Strawberries.—John Forrest.

Redcastle, Muir of Ord.—Owing to frosts in May, June, and July we have no crop of Apples or Pears here this year. Currants, Black and Red, are very poor. Gooseberries indifferent, Warringtons excepted. Raspberries are a very good crop. Of Plums we have none, except Victorias, which are a fair crop. Strawberries are very poor and not ripening well. We only grow four kinds, viz., Garibaldi, Sir Joseph Paxton, Elton Pine, and Frogmore Late Pine. The best flavoured is the Frogmore Late Pine, but it is a total failure this year. The best crops we have are those on Sir J. Paxton and Elton Pine, but both are a long way behind what they were last year.—Thos. Fraser.

Kinfauns Castle, Perth.—Of Strawberries we have not half a crop; indeed, some sorts did not flower at all, but in numbers of places in the neighbourhood there are excellent crops where they have fairly light soil. Our ground is very heavy and retentive. The kinds that do best with us are Garibaldi, President, Duke of Edinburgh, and Elton Pine; the last does best in our heavy soil. The Captain has not done very well with me, but it may do all that is claimed for it in more suitable quarters. King of the Earlies I have not fruited yet. In making new plantations we take the runners off now, and plant, not too closely, in nursery beds until spring, when the ground is thoroughly trenched and manured, and planted as soon as workable. We choose ground on which Strawberries have not grown for a number of years, and I think it is very advisable to have the plants from another locality, just as we change our Potato seed. By planting out the early forced plants we sometimes get a good late dish or two, but with us they do not pay for the trouble. If Strawberry beds are dug at all, it ought to be done early in the autumn, but I prefer to mulch them well with good rich compost. Apples with us are greatly under the average, and also Pears. Of Cherries we have average crops. Morellos indeed are very abundant. Plums are under the average. Peaches average. Apricots under the average. Gooseberries average. Currants of all sorts and Raspberries very heavy crops. The following Apples are fairly well cropped, viz., Stirling Castle, King of the Pippins, Lord Suffield, Tower of Glamis, and Keswick Codlin; these are the only sorts we have bearing anything like a crop. Jargonelle Pears on walls are an average crop.—D. Macdonald.

Jardine Hall, Lockerbie.—Fruit on the whole is much better here than last year. Apples and Pears are fair crops. Plums good. Cherries fair. No Apricots, Peaches, or Nectarines grown out of doors. Currants, Gooseberries, and Raspberries extra heavy crops, and fine in quality. Strawberries a fair crop, but would no doubt have been better if rain had come sooner. The best varieties grown here are Sir Joseph Paxton and Duke of Edinburgh, but as I have only been a short time here I cannot say much as to other kinds in this district. As regards culture, I consider that it is much better to spread manure between the rows and allow the rain to wash it in than to dig it in. It should be put on at the latest in November. It is also a good plan to spread fresh stable litter between the rows in spring or early summer; it assists the plants, and the straw remains to keep the fruit clean. There is a plan practised in this district which I have not seen elsewhere. When a plantation shows signs of exhaustion, instead of trenching it in, the old plants are lifted with good balls, and planted again in freshly prepared soil; they do very well, and I have seen very good crops this season gathered from plants thus treated. They should be moved as soon as the fruit is gathered, so as to allow the roots to get a good hold of the fresh soil before winter sets in.—Alexander Henderson.

Dunrobin Castle, Sutherlandshire.—Apples are very scarce here this year, and Pears are a very thin crop. Cherries average, or rather under the average. Black and Red Currants are average crops. Gooseberries average. Plums, especially on young trees, over the average. Strawberries of most kinds are average crops. A good patch of Garibaldi in the second year has come almost entirely blind, or where flowers have appeared they have not set. As this is the second or third season in which this failure has occurred, I shall discard it as worthless. Duke of Edinburgh on the same ground, under the same conditions and planted at same time, is bearing an excellent crop of large, finely coloured fruit. It is the largest Strawberry we have here. An enthusiastic amateur in the neighbourhood has a few rows of it bearing the finest and heaviest crop of fruit I have seen this season. Elton Pine is our mainstay for midseason and late work. Sir Harry, Marguerite, President, Oscar, and some of the newer sorts have only given medium results. The best way in which to secure good and regular crops is to grow the kinds which suit the soil and climate best. Young plantations should be made before old ones fail. In some gardens I have known plantations to last in excellent bearing for eight or ten years; in others from two to four. A dressing of red marly loam or meadow soil produces good results in old gardens.—D. Melville.

Glamis Castle, Forfarshire.—Fruit crops hereabouts are under the average, except small fruits, including Raspberries, Gooseberries, and all kinds of Currants, which are good. After trying most of the popular kinds of Strawberries, we find some of the old varieties to answer best. Keen's Seedling, Vicomtesse Héricart de Thury, Elton Pine, Grove End Scarlet for preserving are good sorts. Sir Joseph Paxton bears heavily, but

does not suit wet weather. We prepare the beds and plant out as soon as the runners are well rooted, *i.e.*, any time between the middle of August and the middle of September, thus giving them an opportunity to get well established before winter sets in. We give a heavy mulching of decayed manure to save them from frost and as a fertiliser. Our summer this year has been exceedingly cold and dry throughout, which accounts for the all but general failure.

Potatoes are a large crop, and what we have been using are excellent in quality. We see no signs of disease as yet, a circumstance doubtless attributable to the dryness of the season.—Geo. Johnston.

IRELAND.

Chief Secretary's Lodge, Dublin.—The Apple crop here is very light except in the case of a few varieties, such as Lord Suffield, Echlinville Seedling, Cellini, and Warner's King. Pears generally are a good average crop. Morello Cherries are a heavy crop, but of sweet ones we have very few. Apricots are light, and also Peaches, a circumstance not to be wondered at, considering that we had 7° of frost when they were in flower and unprotected. Plums are a very fine crop, Victoria, Coe's Golden Drop, Reine Claude de Bavay, Jefferson's, and Transparent Gage being all heavily cropped. Small bush fruits we have in abundance. Strawberries have not been so fine for the past five years as they are this season. The sorts which we grow are President, Sir J. Paxton, Oxonian, Vicomtesse Héricart de Thury, and Sir Harry. Of these the two first are the best flavoured. To secure good and regular crops it is essential to renew the plantations about every fifth year. We give a good dressing of well decomposed manure every autumn, and we find it a good plan in the spring, instead of forking in, to rake off any unsightly rubbish that remains, as in digging the most careful hand is sure to disturb some of the roots, a thing which Strawberries dislike. To preserve the fruit from the ravages of slugs, the best thing we find is tan spread between the rows, and if this is applied a month or so previous to the fruit ripening, there will be no unpleasant smell. Slugs have a particular dislike to it, and it does not adhere to the fruit in the same way as short Grass cut from the lawn does. Robt. McKenna.

Straffan House, Kildare.—Fruit crops in this neighbourhood are very much under the average. Apples, as a rule, are a total failure. Pears are fairly good. Plums thin. Apricots and Nuts none. Small fruits of all kinds very heavy crops and excellent in quality. Raspberries have suffered a little from drought. Strawberries were a heavy crop, but owing to the intense heat which prevailed when they were ripening they were quickly over. Our main crop kinds are Vicomtesse Héricart de Thury, President, Sir J. Paxton, and Loxford Hall Seedling, and if I were confined to two sorts it would be the Vicomtesse and Loxford Hall; the latter supplies a long-needed want, being both late and of good flavour. For all purposes I think the Vicomtesse the most useful Strawberry grown. We get fine crops of Strawberries by planting out all our forced plants and taking two crops from them. These never fail. If short of forced plants the best way is to layer runners early in 4-inch or 5-inch pots, and plant them out in August in well prepared ground. By this means a good crop is secured the first year. We never dig amongst our plants from the time of planting until destroyed, as forking among them with us means the loss of a crop. We mulch heavily with good manure in the end of March or early in April. The following are the names of Apples, Pears, and Plums that are bearing fairly well with us. Of Apples we have average crops on Lord Suffield, Yorkshire Greening, Cellini, Striped Beaufin, Tower of Glamis, Waltham Abbey Seedling, Echlinville, Blenheim Pippin, Fearn's Pippin, Holland Pippin, Kerry Pippin, Golden Pearmain, and Tibbet's Pearmain. The last is a grand kitchen Apple, and one which seems to be but little known. Of Pears we have good crops on Thompson's, Marie Louise, Louise Bonne of Jersey, Winter Nelis, Passe Colmar, Flemish Beauty, Beurré Rance, Knight's Monarch, and Glou Morceau. Of Plums our best crops are on Rivers' Green Gage, Washington, Victoria, Magnum Bonum (yellow), Prince of Wales, Orleans, Kirke's, and Transparent Gage.—F. Bedford.

Kilruddery, Co. Wicklow.—Apricots where protected are a good crop; Apples and Pears under the average, the bloom having been destroyed. Plums are a fair crop; Damsons abundant—the best crop that has been for years, and the same may be said of Cherries. Of Peaches and Nectarines we have none outside. Figs are a good crop, but will not ripen. Currants, Gooseberries, and Raspberries are an abundant crop. Of Strawberries we have a good average crop. There was plenty of bloom, but the fruit suffered from drought when swelling. The sorts grown here and which I find do the best are President, Bothwell Bank Prolific, and Vicomtesse Héricart de Thury, a good variety for preserving and early. The two first named are the best flavoured and the finest fruit for dessert.—W. Cooper.

Kilkea, Kildare.—Our Apple, Pear, Cherry, Raspberry, and Currant crops are very good this year, especially the two latter, which are exceptionally fine, both as regards quality and quantity. Plums, Peaches, Gooseberries, and Strawberries are below the average with us. Strawberries especially are very late, although they promised well during the flowering period, but the late spring frosts which we had at that time considerably damaged the bloom; in fact, from various inquiries which I have made I find the lateness and scarcity of this crop to be a general cause of complaint in this neighbourhood.—Isaac Milsom.

Charleville Forest, Tullamore.—Apples on old trees in orchards are almost a failure. Young trees in the kitchen garden quarters, both pyramids and bushes, are fairly well cropped. Ribston Pippins, some of which we have planted on a south wall and trained in the form of a single stem up to coping and around Apricot trees, bear fine fruit every year, though some of them canker at times. Blenheim Pippins are bearing a good crop; also Echlinville. All Apples bloomed well, but failed to set. Pears are a good average crop. Marie Louise, Louise Bonne of Jersey, Bon Chrétien, and Jargonelle are clean and healthy, and are bearing good crops on walls in various aspects. On pyramids in garden quarters such kinds as Brown Beurré, Urbaniste, Chaumontel, Bon Chrétien, Knight's Monarch, and other good sorts are bearing fairly good crops. Plums are a heavy crop; Green Gage, Jefferson's, Victoria, Magnum Bonum, and others are all well cropped and the trees are healthy. Damsons, too, are good. We cannot get Peaches to live more than three years on open walls. We have tried them several times in new soil under deep and shallow planting and in poor soil, but they will not succeed; they blister till every leaf is a wretched sight; under glass they do well. The same remarks are applicable to Nectarines, which, however, live longer on open walls than Peaches. Apricots are not an average crop, though there are some on all the trees—about eighteen of Moor Park—but not nearly as many as they should carry. The Orange variety is bearing a good crop. The Moor Park lose branches at times, an evil to which the Orange is not so liable. Cherries are an extra heavy crop, especially May Duke and Archduke, both of which do well here on west walls, and also as standards and pyramids. Bigarreaus and White Hearts have done better this year than I have seen them for years. They have made fine healthy wood, and free from that terrible enemy, the black fly. We have the same varieties on a north wall, on which they also do well. Filbert and Cob Nuts are good crops. Black Currants are a heavy crop and large in size. Red and White Currants, too, are equally heavy.

Potatoes promise well. Our early Ashleafs have been good, and also Myatt's. Champions are our winter crop, and they look well. We are finding an odd tuber diseased in our second early lot. We grow about a dozen sorts, round and long. Magnum Bonums are not cared for here, nor is the St. Patrick variety. The Grampian, a second early, is well suited for this soil. The American sorts are not approved of here, being generally soft.—J. Roberts.

Quartertown Park, Co. Cork.—The drought early in the summer was very severe, and caused a great many Apples to fall off, but there is yet a good crop. Pears, Plums, and Cherries are very scarce. Currants and Gooseberries plentiful, also Raspberries and Strawberries. The following are the sorts I find to be best with us, viz., British Queen, Carolina Superba, Dr. Hogg, Keen's Seedling, and, last, Elton, which I am now gathering.—B. Perryman.

Blarney Castle, Cork.—I have four varieties of Strawberries in the garden here, viz., Frogmore, President, Sir C. Napier, and Whittaker's Seedling; all have done remarkably well with me. I prefer Sir C. Napier to the others for a general crop; it has given me every satisfaction for the last five years. I have forced President for these last three years, and it has done well. As regards Strawberries in light ground, owing to the dry season many became blind. Our outdoor Peaches have not done very well this season, and Apples will not be a heavy crop; high winds and rain injured them very much. As for Grapes, we have had a very heavy crop.—T. J. Marney.

Fota Island, Cork.—Fruit crops in this district are very precarious; in some gardens there is a full crop of some kinds; in others none. Apples are a very light crop, but the trees are healthy. Pears are a moderate crop. Gooseberries in some gardens are a very full crop; in others light. Cherries are under the average and not very large, but good in flavour. Peaches and Nectarines are full crops in places; in others there are none. Nuts are a light crop. Black and Red Currants full crops and very fine. Raspberries good in some gardens. Strawberries in some places have been a good crop; in others there are hardly any. In this garden the crop is the lightest we have had for years. Keen's Seedling we still cling to for forcing; it is a certain cropper and fairly good in flavour. It is good for a general early crop out of doors. Marshal MacMahon is, however, our greatest favourite; it is compact in growth and the leaf-stalks are short; therefore many more can be grown upon the same area than most other kinds; it is a wonderful cropper. To show how we value it here, we have layered 1100 of it, and only about 500 each of other kinds. Sir Joseph Paxton comes next in favour, but owing to plants of it growing to a large size it wants much room. Its fruit is large, good in colour and firm, and it is a heavy cropper. President is also a favourite; it is firm and excellent in flavour, it has a good constitution, and bears well. Garibaldi, perhaps, stands next as a heavy cropper. We find the above the most reliable for general work together with any good late kind to prolong the season a little.—W. Osborne.

Glasslough, Co. Monaghan.—Apples here are below the average on pruned trees, and far below the average in orchards. Pears are a very light crop both on walls and standards. Hardy stewing kinds with me are the most prolific, namely, Catillac and St. Germain. Plums are almost a failure; the best are Rivers' Early Favourite, Jefferson's, and Green Gages. Morello Cherries are not good this season, though usually very fine. Dukes are very good, but rather small. Gooseberries good, but not equal to other seasons' crops. Red and White Currants not up to the average in quality. Raspberries the same. Black Currants are a very heavy crop; and of Strawberries the best kinds proved here during the last seven years are Keen's Seedling, Prince of Wales, Sir Charles Napier, Loxford Hall, and Old Scarlet Pine. Medium and late-season sorts do best here, as the garden lies open to the full east. The best way in which to secure good crops in the cold

north of Ireland, I find, is to make fresh plantations every three or four years. Select good quarters for them, and manure well and trench deeply; also raise or procure strong early runners, and plant early so as to get them established before the autumn rains and winter sets in. President grows well in this district. La Constante quite failed with me after repeated trials.—W. Swanborough.

Carton, Maynooth.—Strawberries showed an extraordinary quantity of fine bloom, but, with the exception of a two-year-old plot, they have not given the results anticipated, a circumstance which I attribute to the long spell of hot, dry weather which we have had. The two-year-old plot in question, consisting of Black Prince, Bothwell Bank Prolific, James Veitch, President, and Vicomtesse Héricart de Thury, has been very fine. James Veitch enjoyed the tropical heat, and gave us magnificent dessert fruit, especially the Vicomtesse. President, too, produced large fruit, but of bad colour—more brown than red. Black Prince gave us fruit a week in advance of the others. Gooseberries, Currants, and Raspberries are plentiful and good. Of Apples, Eehlinville and Keswick Codlin are bearing in profusion; others a light crop. Pears on walls are an average crop; also Plums. Apricots light. Cherries, early kinds fairly good; Morellos abundant.—E. Knowldin.

Baronscourt, Newtown Stewart.—The Apple crop here is very light; the trees had plenty of bloom on them, but it set badly. Pears are much better than last year; indeed, in this country they do very badly as a rule; this is the best year I have seen for eight years. Plums are a very heavy crop, especially the Victorias. Strawberries are a grand crop, and the flower-stems are far longer than ever I can remember to have seen them. Our best cropper is Vicomtesse Héricart de Thury, next President, and our best flavoured variety is Dr. Hogg; altogether, our soil is too light for very large fruit, but the quantity produced is enormous. There are no Peaches, Nectarines, or Apricots grown in this neighbourhood out of doors. We have very fine crops of Pears grown in a lean-to house with a movable roof. The roof is taken off when all danger from frost is past, and put on in the autumn when it is useful for sheltering Chrysanthemums.—A. Dickson.

Markree Gardens, Collooney, Co. Sligo.—Apples here are a good average crop. Pears on walls average. Of Plums we have very few, and these only Victoria. Of Apricots and Peaches we have none out of doors. Gooseberries, Red Currants, and Raspberries are very abundant. Black Currants are a quarter of a crop on account of birds. Strawberries are also, owing to frost, about a quarter of a crop. Keen's Seedling (our earliest variety) suffered most from the frost, but this is the first season in which it has failed. Helena Gloede (our latest variety) has stood well, and we hope to continue gathering from it for some time yet. This is a first-class Strawberry and a strong grower and free fruiter. The only other variety I grow is Vicomtesse Héricart de Thury; this does fairly well with me, but not as well as I have seen do in the midland counties of England. Those three varieties I find can be most relied on in this district. My system of culture is to plant on well-trenched and heavily-manured ground towards the end of July or as soon as runners are ready; sometimes we layer in pots and plant later, which is certainly the best way if time can be afforded for it. All we do afterwards is to keep the plantation clean and free from runners and weeds, and give a good annual dressing of manure, working some short portions in about the collars of the plants.—J. McPhail.

Castlewellan, Co. Down.—In this district the fruit crop is very unsatisfactory. Of Apples and Pears we have scarcely any; even such reliable sorts of Apples as Lord Suffield, Cellini, Keswick Codlin, Blenheim Orange, and Warner's King are very light crops. The trees flowered badly, and while they were in bloom we experienced a severe snowstorm. Knight's Monarch is the only Pear carrying an average crop, other varieties having very few fruits. Plums and Cherries are not half a crop. Strawberries, Raspberries, Gooseberries, and Black and Red Currants are carrying full crops of very fine fruit.—T. Ryan.

Glenart Castle, Arklow.—Of Apricots we have none, and of Peaches and Nectarines (outdoors) very few. Plums on walls are fair crops. Pears and Apples light. Cherries good, especially Morellos. Small fruits very good. Strawberries excellent; the sorts grown here are President, Sir Joseph Paxton, James Veitch, and Frogmore Late Pine. The two first and last are the best flavoured, but James Veitch is very large and a continuous cropper. These varieties ripen in the order named. I prepare my ground for Strawberries by digging two spits deep, giving plenty of manure, and then using plants that had been fruited in pots, planting them 3 feet by 2 feet apart. I mulch in spring with littery manure.—R. Willmet.

Birr Castle, Parsonstown, King's County.—Apples are almost a failure in this locality, with the exception of a few hardy kinds, and I see that they are daily dropping off the trees. Pears are only a middling crop and late, and small Plums and Cherries are both good. Nuts are a fair average crop. Peaches and Nectarines will not do here in the open air. Bush fruits are abundant. Strawberries are the worst crop that I have known for many years, and very small and poor. The plants showed an abundance of blossom, but failed to set or swell, the weather being unfavourable in May and the early part of June. The kinds which I find to succeed best are President, Vicomtesse Héricart de Thury, Black Prince, and Keen's Seedling. Oxonian also does remarkably well: it is a hardy, robust variety and a sure bearer, but the fruit is very soft and poor in colour and flavour. I have tried several of the British Queen class, but they cannot be relied upon for a crop. Frogmore Late Pine does fairly well as a late kind.—T. J. Hart.

Kylemore Castle, Co. Galway.—The fruit crop in the gardens here and in this district is on the whole very good. Apples on well-known free-bearing varieties are a heavy crop, and the fruit clean and well shaped. Pears a thin crop. Apricots, Peaches, Nectarines, and Figs are never very profitable crops out of doors in this dull, wet climate, but we have fine crops of them under glass. There is a great quantity of Plums, but the fruit is small in size compared with that of past years. Cherries, Raspberries, Gooseberries, and Currants are heavy crops, and the fruit in every respect good. Strawberries are an average crop; we find the best for general use to be Keen's Seedling, Duke of Edinburgh, Sir Joseph Paxton, Vicomtesse Héricart de Thury, and British Queen. James Veitch bears very heavy crops, but is deficient in flavour in our wet climate.

Potatoes generally are looking very well, and as yet no traces of disease have made their appearance; field crops are very vigorous, and promise to yield well this year.—John M'Kinnon.

Elm Park, Limerick.—We have a fair crop of fruit this season, but not equal to that of last year, especially Gooseberries and Red Currants. Plums and Cherries are good crops. Peaches and Apricots fair crops. Pears good. Of Apples in orchards there are no more than half a crop. Strawberries are a good crop, but late, and not so large in size as last year. The varieties which I grow for our main crop are President, the best for size, flavour, and productiveness, Eleanor, and Frogmore Late Pine: these three are the best for a general crop. We plant in rich well prepared ground 2½ feet apart each way, and lay on a heavy dressing of manure in spring, treatment by means of which we get very heavy crops of fine fruit. By keeping the runners cleared off in autumn, a plantation will continue in bearing for three years. —Thos. Conway.

Shanes Castle, Antrim.—Fruit crops in this neighbourhood are, as a rule, very light this season, though in a few localities small fruits are abundant, particularly Gooseberries. Strawberries are a miserable failure; we have about an acre of them, and from the whole have only gathered some 125 quarts, being about a quarter of the usual crop. The kinds grown here are Keen's Seedling, Vicomtesse Héricart de Thury, President, Duke of Athole, Trollope's Victoria, and Elton Pine, all of which do well in general. This season Duke of Athole has produced the best crop, but it is only fit for market, being deficient both in colour and flavour, and I intend substituting for it James Veitch. Apples on espaliers in the kitchen garden are carrying good crops, particularly King of the Pippins; on standard trees there are very few; indeed one could count more trees than Apples. Of Apricots we have none. Figs are a good crop, but late, and unless favoured with a warm autumn they will not come to much. Peaches are fairly good on young trees on a north wall. Cherries are a good crop, particularly May Duke and Morellos. Of Filberts and Walnuts we have none.—Charles Warwick.

Bellarena, Londonderry.—The Apple crop here and in this neighbourhood is very poor. The Pear crop middling. Cherries on walls good. Plums very good. Currants good. Gooseberries, Raspberries, and Strawberries all good. The only variety we find to yield a satisfactory crop, after trying many, is President; British Queen, Dr. Hogg, and Mr. Radclyffe are too tender for this part of Ireland.—W. Hubbard.

The Park, North Wexford.—Apples hereabouts are a complete failure; when in bloom we had a gale that not only destroyed the Apple crop, but scarcely left a leaf on the Beech trees. The following varieties of Apples, even in the worst of seasons, always bear a heavy crop here, viz.: Devonshire Quarrenden, Lord Suffield, and Cellini. Pears are a very thin crop, especially on walls. Cherries are carrying very fair crops this season. Plums are heavily laden with us; they set almost as thickly as Gooseberries, but we can only grow them on walls; standards do not succeed. Peaches out of doors set very well, but the trees suffered very much owing to the backwardness of the season, and it is questionable if they will finish well. Bush fruits are all heavily laden, Gooseberries especially so. Strawberries I find to vary according to soil and situation; here British Queen is far beyond any other both as regards quantity and quality. A point in which it differs from nearly every other is that the longer it has been planted the more prolific it becomes. Here it has been on the same ground for five years, and this season the crop has been something enormous. In one garden near here it has been planted thirteen years, and still it bears very heavy crops. The soil is rich sandy loam resting on pure sand. Ours is a loamy soil resting on marl. Before we plant we trench about 24 inches deep, putting a heavy layer of manure at the bottom. We then point in a little hotbed manure on the surface, and put out our plants as soon as we can procure them in lines 3 feet apart and 2 feet from plant to plant. As soon as the crop is gathered one man goes before with a knife and trims off all the foliage which is lying down around the plant, just leaving those leaves which are standing upright. The ground is then hoed over with a Dutch hoe, so as to clear off all runners and weeds. We then get manure from the early-made hotbeds, spread it between the rows, not forgetting to give a good coat of it, and that is the entire treatment which our plants receive until they come into good bearing, which is not for two years. We cut off all runners. Afterwards the following varieties bear so heavily that we have no trouble with runners, viz., British Queen, Black Prince, and Elton Pine. We have grown a very large number of varieties, but those are the only ones worth growing here. Strange to say, none do worse with us than President and Garibaldi.—T. Scott.

Tynan Abbey, Armagh.—Many are disappointed with their fruit crops this year. We had a grand display of bloom on Apples and Pears, but if we were to examine the trees to-day we

would not find more than a dozen of fruit on a large tree. Plums are the same, and all owing to the cold frosty nights which we had in May and June. I have had a very good crop of May Duke Cherries. I have many other sorts, but none to compare with May Duke. As to Strawberries, I do not go in for many sorts, as some do not turn out productive in our light soil. I have British Queen, Trollope's Victoria, President, and the Wizard of the North; they come in in succession as I have named them, and the flavour is good, but Trollope's Victoria produces fruit so very large that it is not so productive as British Queen or President. The Wizard of the North I would highly recommend to all who wish for a good sure cropper. It is late, has a sightly, firm berry, and is good in flavour. I commenced to gather its fruit in the beginning of July, and it continued in bearing till the end of August, and if the weather keeps favourable, I can have fruit from it in September. I find three and four-year-old plants to be most productive. By manuring well and pointing it lightly into the bed, I seldom fail to get good crops. Gooseberries and Currants are abundant, but, owing to the cold, sunless weather which we have had, they are flavourless.—W. H. Baker.

Belvedere House, Mullingar.—Apricots here are under the average, but they are not much grown. Plums are also under the average. Cherries average. Apples and Pears under the average. Small fruits abundant and good. Strawberries an average crop. The chief varieties grown in this neighbourhood are President, Sir Joseph Paxton, and Keen's Seedling. I have found it a good plan in making a new plantation to plant in firm ground, viz., the Onion quarter, that had been trenched deeply and well manured the previous autumn. I have the young plants ready, and plant as soon as that crop can be removed.—James Bayliss.

Bantry House, Bantry.—The Apple, Pear, and Plum crops here this year are very light. We had a very severe storm about the second week of May which literally blew the blossom off the trees in heaps, and what was left blackened and fell off. There are hardly any Apples in this neighbourhood. Bush fruits are, however, very good, Gooseberries, Currants, and Raspberries being unusually heavy. Strawberries were a fair crop, but late. Vicomtesse Héricart de Thury is the best cropper with us, but we do not grow many kinds. —Robert Brennan.

Castle Upton, Antrim.—Fruit crops here are variable, but on the whole under the average. I attribute partial failure to the drought of last year. Trees on well-drained ground have suffered most; we watered as much as we could find time to do last year, but could not give enough, the result being a want of plumping up of embryo buds, too plainly indicated by the wholesale dropping of the young fruits. Codlin Apples are bearing a fair crop, Pippin or dessert sorts fewer; that always sure cropper, King of the Pippins, has failed this season for the first time for many years—not only one tree, or in one position, but both young and old trees on east and west walls, and in the form of bushes in the open. With the exception of Hessle as a bush, which is carrying a full crop, Pear trees are only producing a sprinkling of fruit. Plums are better, but by no means a full crop. Gages are bearing much the best; the Victoria so well known to be a sure fruiter is only bearing a very few this year. Cherries on walls were partial crops; on two walls (both south) we had a good crop on one, on the other a poor crop; nearly all dropped; of Morellos we have half a crop. Bush fruits, with the exception of Raspberries, are fairly good; the latter from some cause unknown to me failed to grow well either as regards cane for the ensuing, or fruit for this year, although treated with a little extra care. Black Currants with us are half a crop, but very fine. A few miles from here, I understand there are extra heavy crops; other sorts of Currants, too, are very good. Gooseberries—everybody's fruit—are best cropped of all. Peaches, Nectarines, or Apricots do not succeed here; our position lies low, and the soil, naturally heavy, rests on a great depth of limestone. We are fairly protected with woods at a respectful distance; our great enemy is damp, on account of our low position, and frost nips with greater intensity; we had 5° on last Wednesday (28th July).—G. Kevan.

Bangor Castle, Belfast.—I cannot give a very flattering report of our fruit crop in this part of the country this year. No doubt our small fruits, such as Gooseberries, Currants, Raspberries, and Cherries, are quite up to the average; but Apples, Pears, and Plums are but a light crop, and at least a month late. The only Strawberries we grow are Comte de Paris, President, Elton Pine, and Duke of Edinburgh. I have tried many other kinds, but found none so serviceable, nor any that suited our climate better. In preparing the ground for beds, I trench three spades deep and manure with good cattleshed manure, mixed well with each spadeful, and before planting work in a little short manure on the surface. After planting, we never disturb the plants by digging about them. In November all the runners are cut off, and afterwards a good heavy dressing of strong manure is given, and this remains on the top of the ground till the following fruit season, when it serves for a protection to the fruits, as it keeps them from coming in contact with the earth. This treatment is continued each November, and under it I have had good berries every year for five or six years in succession from the same bed.—Robt. Fisher.

Shelton Abbey, Arklow.—Apples here are a very light crop; on large trees we have scarcely any, if I except Royal Russet, which is bearing well. Low cordons are also all bearing good crops, but bush trees are not so regular. One of the latter, Domino, is a most abundant and regular bearer, the branches every year bending to the ground under the weight of the fruit. As an early kitchen Apple I know of none that can compare with it as a profitable market fruit. Pears are a very thin crop; on walls we have few, with a few exceptions. Our best cropping ones this year are Pitmaston Duchess, Easter Beurré, Doyenné du Comice, Williams' Bon Chrétien, Bergamotte d'Esperen, and Beurré Diel. On pyramids we have scarcely any, though all were covered with bloom. Peaches and Nectarines we do not grow out of doors. Of Figs, Brown Turkey we have fine crops. Of Apricots we have but very few. Cherries are a fair average crop, but Plums are much under the average; the best, as usual, is the Victoria. Nuts are a failure this year. All small fruits are good crops, though the last fruits of Strawberries suffered somewhat from drought. The sorts grown here are Vicomtesse Héricart de Thury, President, James Veitch, Sir Joseph Paxton, and Frogmore Late Pine. For the main crop I rely upon President, which I consider much the best.—C. Tyler.

Castle Forbes, Newtown Forbes, Longford.—Apples in this neighbourhood are about half a crop. Plums a very heavy crop. Pears a good crop; standards better than last season. Peaches, indoor, good; none grown out of doors about here. Bush fruits very good. Gooseberries and Black Currants very fine, and so are Blackberries. Strawberries have been good, but the cold rains for the past two weeks have cut their season short. I generally have a heavy crop. I can gather basketfuls of berries each 1 oz. weight. My mode of culture is somewhat novel; after the ground has been well dug and manured, I open a trench as if for Celery. I then take freshly dug sods from an old clean pasture and place them along in a row in the trench, then close in the soil on them 4 inches or 5 inches deep, making it firm and smooth; then plant at 2 feet 3 inches apart every way. They get no more digging of any kind for five or six years, when they are destroyed. Cut straw is laid between the rows in May, first well shaking it, or you will have a crop of Oats. The varieties which I grow are President, a very fine cropper; Garibaldi, good for preserving; Sir J. Paxton, an excellent kind, the fruit of which is firm and large, but not so good in flavour as President. Keen's Seedling I grow for a first crop, and Princess Helena for late use: the last is a fine large-fruited variety, but unless the weather is fine it damps off; Doctor Hogg I find to be too delicate for us, but still it bears some fine berries. Our soil is a stiff, cold, heavy clay, resting on a hard, red subsoil.—J. Rafferty.

Ballywalter Park, Down.—The Strawberry is rather capricious; the variety that does best in our garden may prove quite a failure in another. A few years ago I grew several new and little-known sorts, and though some were good, all points considered, none seemed likely to supersede old and well-tried kinds. Marshal McMahon is one that deserves to be better known than it appears to be; it is of dwarf, but robust habit, produces good crops of fair sized fruit, and to my taste has a very pleasant flavour. Varieties that I noted for flavour were Doctor Hogg, Unser Fritz, Marguerite, and Mr. Radcliffe. I have never since seen British Queen do so well as it did about twenty years ago on heavy soil in the north-west of Middlesex, though a few years later it began to fail in the same gardens; that clay will not always ensure success I have since proved. Where it does well, I like Keen's Seedling for an early variety, either for forcing or for outdoors, but in some places, though it grows luxuriantly, it produces only a few small fruit; in that case I would substitute Vicomtesse Héricart de Thury with President for a main crop, and Elton Pine for a late sort; not, however, to the exclusion of all others; but as three varieties that may generally be relied on to produce a good supply of fruit for all purposes. I never allow the ground occupied by Strawberry plants to be dug, even lightly. After the crop is gathered, all weeds, runners, and the oldest leaves are removed, and a good dressing of rotten manure is put on, or, failing this, a sprinkling of soot or artificial manure; this I believe to be the best time to feed the plants, *i.e.*, when they are forming the crowns that are to produce next year's crop. In March the ground is covered with fresh stable litter, which serves as a mulching, helps to keep down weeds, and by the time the fruit begins to ripen it is washed and bleached, and is the best material that can be used to keep the fruit clean. Strong-growing varieties are often planted too closely; the rows should be 3 feet apart. Of course, where the soil will only sustain the plants one or two years, this would be waste of space, but on strong soils, with good treatment, the same plants will continue to produce good crops for several years; and if not allowed sufficient space the rows meet, and in wet seasons much of the fruit rots, while in fine summers it is not well coloured. For forcing my plants are prepared as follows: After the summer cleaning, a batch of late runners is produced, and as soon as these begin to emit roots they are taken off and planted about 3 inches apart in beds of fine soil. In May the following year they are lifted and potted in 6-inch pots and treated in the usual manner. By this plan the best results are obtained with the least amount of labour, as we save all the labour of layering and attending to the layered runners at a very busy season.—W. Crane.

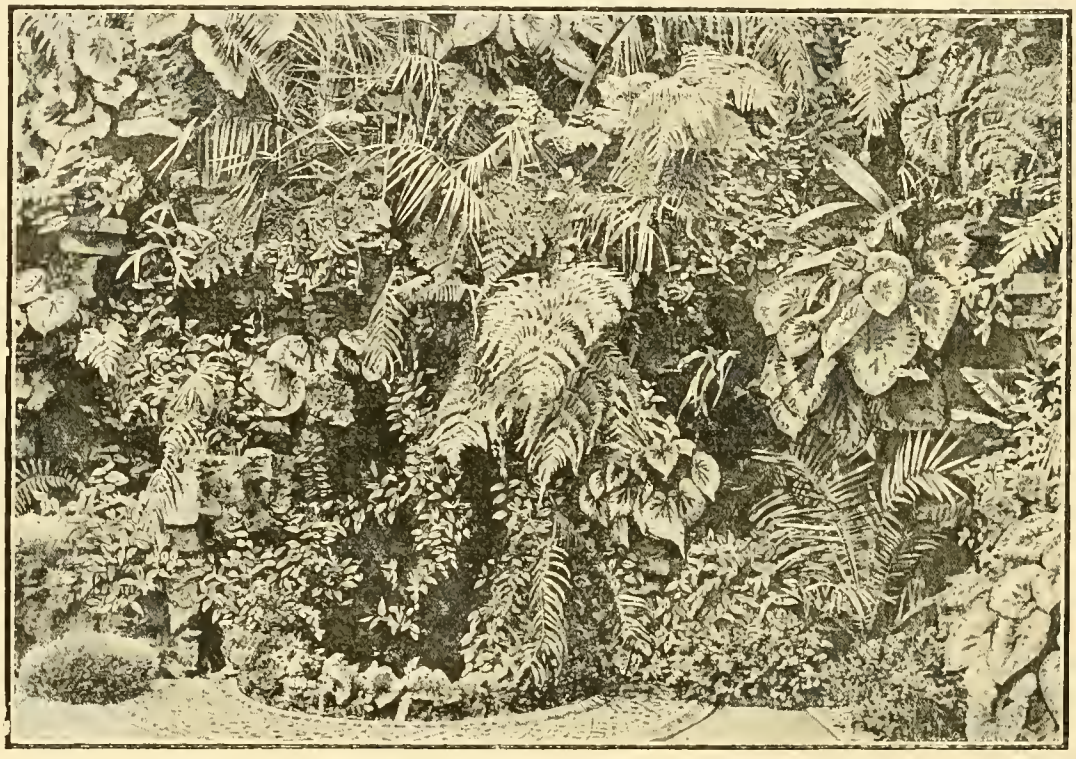
Woodstock, Kilkenny.—Apples, Pears, and Plums hereabouts are very thin crops. Amongst Apples, Lord Suffield, Stirling Castle, Small's Admirable, and Echlinville are the only sorts bearing an average crop. Of Pears, Louise Bonne of Jersey, Marie Louise, Williams' Bon Chrétien, Jargonelle, and Beurré d'Amanlis are carrying average crops on walls, but almost none on standards. Victoria Plums are a fair crop; all others very much under the average. Cherries, Gooseberries, Currants, and all small fruits are abundant and good in quality. The Strawberry crop was also very good, but of short duration, owing to the lateness of the season and the excessive heat which we experienced during the latter part of June and beginning of July. The sorts which we find to do best on our light soil are Vicomtesse

Héricart de Thury, President, and Loxford Hall Seedling.—William Gray.

Dromoland, Clare.—Apples here are an average crop. Currants I have never seen so fine as this year. Pears and Plums are good average crops. Raspberries a very heavy crop and fruit good. Gooseberries are a very light crop. Of Peaches and Apricots outside we have almost none. I am generally very successful with Strawberries, but this year they were not so good as usual, owing to dry weather setting in just as they were in flower and continuing until the crop was ripe. The soil here is heavy loam on limestone rock. I mulch with manure in spring, and dig it in August after the crop is gathered. For preserving we prefer Black Prince to any other. President and Sir J. Paxton are very fine here. Marshal MacMahon is a fine Strawberry; it produces but few runners, but it does not stand drought.—W. Wilson.

Doneraile, Cork.—Wall fruits of all kinds are scarce here, owing to the very late frosts which we had in May. We had 14° in the second week of that month. Apples are very scarce, but small fruits are plentiful and good. Strawberries were very good, and a very fair crop. Marshal McMahon is the kind most cultivated hereabouts. It is a good cropper, and very good as regards flavour and appearance. I cannot say much for other kinds.—W. H. Swanborough.

Castle Coole, Enniskillen.—For these four years past we have had Strawberries in abundance. Our mode of treatment is as follows: As soon as the fruit is gathered, we cut away all runners and all the bottom foliage. This admits plenty of sun and air to mature the crowns. We then just prick over the surface with a fork about an inch deep, and apply a good top-dressing of short stable manure, mixed with bog mould, just as it comes from the horse-boxes. In spring we run a hoe through them, and the bog mould, being still on the top, makes a good protection for the fruit instead of straw or any other material. Our soil is stiff, so the bog mould keeps it open. The best sorts for this district, both for flavour and good bearing, are the following, viz., Marguerite, Vicomtesse Héricart de Thury, Keen's Seedling, James Veitch, President Delacour, Helena Gloede, Loxford Hall Seedling, and Elton Pine. Of Plums we have good average crops. Peaches, Nectarines, and Apricots under the average. Pears and Apples the same. All small fruits are average crops.—George Cliffe.



Fernery at Canon Bridges' garden Beddington, Surrey.

WALES.

Cardiff Castle, Cardiff.—Apples in this district are only a medium crop. The trees are clean and healthy, and what fruit we have is swelling freely. The following varieties are bearing good crops, viz., Lord Suffield, Lord Derby, Echlinville Seedling, Cellini, Keswick Codlin, Wellington, Hawthornden, Cox's Orange Pippin, Blenheim Orange, Gloucester, Golden Pearmain, and Irish Peach. Pears are a heavy crop, both on walls, pyramids, and standards. Indeed, we have not had so good a crop for these last thirteen years. Most of the pyramidal trees have to be propped up to keep the branches from being broken by the weight of fruit. The following, amongst others, are loaded both on walls and pyramids, viz., Jargonelle, Duchesse d'Angoulême, Pitmaston Duchess, Williams' Bon Chrétien, Beurré d'Amanlis, Beurré Clairgeau, Beurré Magnifica, Beurré Bosc, Glou Morceau, Easter Beurré, Ne Plus Meuris, Bergamotte d'Esperen, Winter Nelis, Marie Louise, Knight's Monarch, General Todleben, and Beurré Diel. Peaches are an average crop. Plums and Cherries medium. Grapes on the castle walls here and in the vineyard at Castle Coch are good. Strawberries are a poor crop. They promised well, but the continued dry weather injured the plants, and the fruits dried up before ripening. Raspberries and Black Currants are plentiful. Gooseberries and Red and White Currants are a failure.—A. Pettigrew.

Margam Park, South Wales.—Apples with us are an average crop: Keswick Codlin, Lord Suffield, Hawthornden, King of the Pippins, Winter Quoining, and Stirling Castle are the most prolific. Pears are not so good as last year, but may be called an average crop. Marie Louise, Brockworth Park, Beurré Clairgeau, Jargonelle, Louise Bonne of Jersey, Beurré d'Amanlis, Doyenné d'Ete, and Winter Nelis are the leading kinds this season. Plums, especially Kirke's and Victoria, are heavy crops. Cherries are abundant, May Duke and Morello being the best. Apricots are thin. Currants, Gooseberries, and Raspberries have been more abundant than they have been for two or three years. Some of the newer Black Currants and Raspberries are great improvements on the old sorts. Peaches and Nectarines are very plentiful. All fruit trees are unusually free in growth and clear of insects; we did not experience the cold east winds this year which generally blight the foliage about the time when the fruit is forming. On the whole, fruit crops may be said to be up to the average in this district.—J. Muir.

Cyfarthfa Castle, Merthyr Tydvil.—On open walls we seldom get a crop of fruit here. Plums and Pears even in a good season do not ripen to perfection. We have only Plums, Cherries, and Pears on walls. Plums are very scarce, Cherries dropped in stoning, and Pears are by no means plentiful. Strawberries are over the average. The following do best here, viz., Keen's Seedling, James Veitch, President, and Vicomtesse Héricart de Thury. I find the best plan in order to get good fruit and crops is to plant out forced plants in good rich ground as early as possible after the fruit is gathered.—G. B. Jones.

Powis Castle, Welshpool.—Apricots and Plums here are light crops. May Duke Cherries are very good crops; Morellos scarce. Peaches and Nectarines very poor, but the trees are clean. Apples and Pears are under the average. Bush fruits plentiful and good and very clean. Strawberries are a grand crop and good in flavour. We only grow two sorts, Vicomtesse Héricart de Thury and James Veitch. The first we use for early work, and James Veitch for the last crop. We plant a fresh piece with Strawberries every year, and after the third season dig them up. Strawberries like a change into good holding soil. We plant 3 feet apart, and never disturb the roots afterwards. We mulch with good rotten stable manure about November, and over that in spring, just before the plants come into bloom, we put a little clean straw.—William Lee.

Wynnstay, Denbighshire.—The Apple crop here promised at one time to be a heavy one, but it has been since greatly thinned. Nevertheless, we shall have nearly an average crop. Pears are somewhat thin on standards, but fairly good on walls; they also suffered from cold and wet. Apricots are very middling, very late and medium in size. Peaches are fair, but Nectarines very thin. Figs are a good crop, but unless the autumn is very favourable few will ripen. Red and Black Currants are heavy crops. Gooseberries are a fair crop. Raspberries are a good crop. Sweet Cherries are fairly good as to quantity, but dry and cracked. Morellos are a good crop, and should we have more moisture soon will be of fairly good quality. Plums are a heavy crop on standards, but thin on walls. Damsons are a good crop. Quinces are a failure, although at one time most promising. Walnuts almost a failure, the catkins being all killed before the female flowers were open, and the same remark applies to other Nuts. Strawberry crops, generally speaking, are fairly good. Old beds were all but killed off,

Beds of a few years' standing are bearing good crops. Last year's plantations are very middling as to crop and very late. All varieties on this cold substratum of sandstone over the coal beds deteriorate very much in quality, size, and flavour, although they crop plentifully for many years, except Keen's Seedling, President, Wizard of the North, and La Grosse Sucrée, which grow rank and stop bearing. Sir Harry bears until it dies out. Carolina Superba and British Queen are only satisfactory for about two seasons the second or third year after planting. Vicomtesse Héricart de Thury does not last long in the soil. Dr. Hogg is inferior. Elton Pine is one of our most constant varieties. For our cold soil and for a permanent bed nothing is better than a good dressing of crushed bones and stable manure slightly forked in The surface we mulch with litter in early spring to prevent the ground from cracking and caking. I have grown some of the varieties named on calcareous soil at Llangedwyn for twenty years, and they have not shown the slightest deterioration, especially Keen's Seedling, British Queen, and an old but excellent variety called Grove End Scarlet. This is beautifully red in colour, pleasantly acid, and delicate in flavour. It is also more self-protecting from birds than any other sort. It has very little care. Let all who like a faultless pot of Strawberry jam try this variety.—P. Middleton.

Penllergare, Swansea.—Of Pears, Apples, and Plums we have here very few. Peaches and Nectarines are bearing good crops, and the trees are perfectly healthy and free from all blight. Cherries are good. Gooseberries abundant and very fine. Of Raspberries we have plenty, also of Black, Red, and White Currants. Strawberries are excellent, and the fruit very fine. We grow many varieties, but the sorts that do best here are President, Black Prince, and a late variety which we call Nimrod; of new varieties we have The Captain and King of the Earlies, which I think will be satisfactory. My practice is to plant Strawberries about the end of July in ground well manured and trenched. In the case of established beds, after the fruit is gathered I cut away all runners and clean the beds; in the autumn I give them a good dressing of rotten manure and slightly fork it in. The following spring the dead leaves are cut off with a knife, and through the summer the beds are kept free from weeds. By simply attending to their wants in that way the plants keep in a bearing state for six or seven years.—Charles Warmington.

Dynevor Castle, Carmarthen.—All fruit crops are late with us this year. Apples are about half a crop; the trees looked promising when coming into flower, but the blossoms failed to set. Our best crops are on dwarf trees. Pears are abundant both on standards and dwarfs in most gardens. Plums are a light crop. Peaches and Nectarines are good. Gooseberries in some places are abundant; in others scarce. Currants—Black and Red—and Raspberries good. Strawberries were late, and owing to the setting in of dry, hot weather at the end of June and beginning of July they were a very light crop. I find such old sorts as Alice Maud, Myatt's Eleanor, Sir J. Paxton to suit us best. For late crops Elton is still one of the best. The newer kinds tried here are James Veitch, Dr. Hogg, Aromatic, President, Sabreur; these do well in this damp climate.

Potatoes are looking well and promise to be a heavy crop; as yet they show no signs of disease.—J. Ticehurst.

Penrhos, Holyhead.—The best kinds of Strawberries which we have here both for flavour and bearing are Pauline, Vicomtesse H. de Thury, Keen's Seedling, President, and Frogmore Late Pine. Of these the crop is excellent in spite of the dry season and a shallow soil, in some cases not more than 18 inches above the rock. I attribute our success to early mulching with good stable manure before they came into bloom, which prevents them ever becoming dry at the roots. Our method of culture is to plant a fresh piece every year on well-manured ground, and to trench them down after the fourth year. Our best early kind is Pauline, and the best late Frogmore Late Pine. Apples are a very thin crop, except Lord Suffield and Keswick Codlin, which are bearing fairly good crops. Pears on such kinds as Jargonelle, Louise Bonne of Jersey, Marie Louise, Beurré Bosc, and Duchesse d'Angoulême are fairly good. All late-keeping kinds are very thin. Plums are a good crop, especially the Victoria. Green Gage and Coe's Golden Drop are partial crops; other sorts quite a failure. Peaches and Nectarines are fine even crops right through, but all are under glass. Apricots are not grown here. May Duke Cherries are a very fair crop, as are also Bigarreaus and Morellos. Currants, Raspberries, and Gooseberries are abundant.—F. W. Everett.

Plas Gwyn, Pentraeth, Anglesea.—The Strawberry crop here has been excellent; I grow Sir Charles Napier and Keen's Seedling. The former is very fine, good in flavour, a moderate cropper, and rather earlier than Keen's, which here crops heavily. Raspberries have done very well, but other bush fruits are very poor.—J. Williams.

GUERNSEY.

Somerset Terrace.—We grow very few Strawberries here. The sorts which we do grow are Sir Harry, British Queen, and Frogmore Late Pine. The crop generally in the island has been light under the average. The fruits set thinly, no doubt owing to the wet cold weather which we had when the plants were in bloom. Gooseberries in some places are thin; in others heavy; on the whole they are about an average crop. Raspberries and Currants are heavy crops. Of Apricots scarcely any are grown in this island. Plums, too, are not much grown here. Peaches and Nectarines we grow chiefly under glass. The only sort grown here outside is the Diamond Peach, which bears good crops every year. It is protected by a glass coping in spring, which we take away when the fruit is safe from frost. In the houses we grow very good crops of fine fruit, both of Peaches and Nectarines, chiefly in pots; in fact, we get the best fruit from trees in pots. The sorts are, of Peaches, Dr. Hogg, Dagmar, Falcon, Princess of Wales, Nectarine Peach, and Lady Palmerston. Of Nectarines we grow Lord Napier, Stanwick Elruge, Pine-apple, Rivers' Orange, and Victoria. Pears with us, such as Doyenné du Comice, Chaumontel, Beurré Superfin, Pitmaston Duchess, Winter Nelis, and Josephine de Malines, are good crops. Other sorts are rather thin. Both Apples and Pears, I should say, are about average crops.

Potatoes have been very good, but late. The disease has made its appearance since the late rains set in, and I am afraid it will be injurious to the late sorts. We had a very dull, cold month of February, followed by a late cold spring, which affected our crops generally, and our season this year is quite three weeks later than usual.—E. Peters.

CONSERVATORY AT BEDDINGTON.

A good example of a tastefully planted conservatory exists in Canon Bridges' garden at Beddington, and one that is worthy of imitation. The conservatory adjoins the mansion—in fact, is a kind of wide corridor, with the walls adorned in the manner shown in the illustration, which has been reproduced from a photograph. The centre of the house is paved and unobstructed by borders, and the planting is confined to the margin. The back wall is faced with rocks so placed as to allow of a good amount of soil for the plants to grow in the crevices and on the ledges. There is a great variety of plants, but the most conspicuous are the fine-leaved Begonias of the Rex type, which grow in the most luxuriant way, forming large masses of rich leaf-colouring. Greenhouse Ferns and a host of trailing plants thrive equally well, while the pool below, which is supplied artificially by a miniature waterfall, affords a place for water-loving plants. As a relief to the foliage there are groups of bright flowering plants, which are changed according to the season. The old-fashioned plan of pots and stages in conservatories is fast becoming a thing of the past, and nothing can more effectually further their entire banishment than contrasting them with such beautiful arrangements as that just described.

Societies.

ROYAL HORTICULTURAL.

August 10.

The show on Tuesday was chiefly remarkable for the large display of florists' flowers, such as Gladioli, Hollyhocks, China Asters, Begonias, Zinnias, and Roses, which together made a bright exhibition. A large number of the exhibits were certificated, but were chiefly florists' flowers. First-class certificates were awarded to the following:—

Fuchsia triphylla.—A beautiful species and quite different from all others in cultivation. It is dwarf and bushy, with the leaves generally arranged in threes on the branches; hence the specific name. The flowers are about an inch long, bright scarlet, produced plentifully in loose clusters terminating almost every shoot. It is a beautiful plant, and one we hope will be distributed widely. Mr. Barron showed a capital plant of it from the society's garden at Chiswick.

Miltonia spectabilis bicolor.—An extremely pretty variety, differing from the original chiefly in the colour of the flowers, the lips of which are half pure white, the rest bright carmine-magenta, while the sepals also are white. Shown by Mr. W. Bull.

Chrysanthemum Mrs. Burrell.—A new early flowering variety, probably the finest that has been raised. It is somewhat similar to the sort Madame Desgrange, now so popular, but its flowers are much larger and more freely produced. The colour is yellow in the centre, fading to a straw colour towards the tips of the florets. It will without doubt prove a valuable plant. Exhibited by Mr. G. Miles, Victoria Nursery, Dyke Road, Brighton.

Begonia Imperial.—A tuberous variety having very large semi-double flowers, Rose-in-hose as it were. The petals are thick and rounded, and of a brilliant carmine-crimson flushed with a purplish hue. Shown by Mr. R. Owen, Maidenhead Nurseries.

Dianthus chinensis Black Prince.—A variety of Indian Pink with flowers of a very deep crimson—in fact, almost black. The plant is dwarf and floriferous. Shown by the raisers, MM. Andrieux-Vilmorin, of Paris.

Aster, dark rose scarlet.—A China Aster with medium sized blooms of a deep reddish crimson. The plant is dwarf, compact, and flowers profusely. From M. Ernest Benary, Erfurt.

Picotee Duchess.—A beautiful sort, flowers large, petals broad, pure white, heavily edged with deep rose. Shown by the raiser, Mr. C. Turner, Slough.

Gladioli Lord Salisbury, colour brilliant carmine flaked and blotched with crimson. Sir M. Hicks-Beach, rose-pink, flaked with carmine. Clarence, deep purplish crimson, flaked with a plum-purple or almost a black tint. Sir Cunliffe Owen, pale salmon flushed with sulphur-yellow, lower petal wholly pale yellow. All these were shown by Messrs. Kelway, of Langport, and, as may be imagined, were perfect in every point, the spikes being massive, the flowers large and faultless in substance and form.

Hollyhock Rivival.—Flower large and full, and of a buff yellow colour. Shown by Mr. A. Chater, Cambridge.

Hollyhocks Shirley Hibberd and Prince of Wales.—The first a rich rosy crimson colour, the second a deep rosy salmon. Both large and full flowers. Shown by the raiser, Mr. Blundell, West Dulwich.

Picotees Annie Douglas and Almira.—Both yellow ground sorts, with large, full, and perfectly shaped flowers. The former is flaked with pink, the

latter flaked and edged with a rosy salmon. Both shown by Mr. Douglas, Great Gearies, Ilford.

Hollyhocks Crimson Queen and Primrose Gem.—Both with large flowers perfect in form, the former of a deep red-crimson, the latter a pale yellow. Shown by Messrs. Webb and Brand, Saffron Walden.

Zinnias, dwarf striped.—A new strain having flowers variously coloured, some half one colour half another, others striped, flaked, and spotted. Such strange diversity of colour is quite novel among Zinnias, and the strain, which was exhibited by MM. Vilmorin, of Paris, will without doubt be appreciated here.

Dahlia Squire Gammie.—A large-flowered, single variety, deep crimson, flushed with a darker colour towards the centre. From Mr. T. S. Ware.

Adiantum cuneatum Phillipsi.—A form of the common Maiden hair Fern, having more delicately-cut fronds. A very graceful plant. Exhibited by the raiser, Mr. Phillips.

Among other plants exhibited were the following. From Mr. Bull came a fine basketful of plants of the brilliantly flowered new Balsam, Impatiens Hawkeri, which was again shown in good condition; also good plants of Cienkowskia Kirki and of the rare Cattleya Schofieldiana. This has flowers some 5 inches across the sepals, deep olive-green, heavily spotted with brown, the lip magenta streaked with white. Mr. R. J. Measures showed a variety of Cypripedium Lawrenceanum with the dorsal sepal heavily flushed with plum-purple, and a Trichopilia, named luteo-purpurea, evidently an intermediate between T. coccinea and T. tortilis. He also showed a plant with four flowers of the true Cattleya velutina, a small-flowered species having greenish yellow sepals and a rosy-tinted lip with a golden yellow blotch. Messrs. Low, of Clapton, sent some admirably flowered plants of the brilliant, but now rarely seen, Beaufortia splendens, an Australian shrub having its scarlet flowers arranged in a bottle-brush-like manner. Messrs. Krelage, of Haarlam, sent some new seedling varieties of hybrid Gladioli of the Lemoinei race; and Mr. Barron showed, from Chiswick, a Carnation with bright crimson flowers, called Chiswick Red. Messrs. Carter, High Holborn, showed samples of their Camellia-flowered double Balsams and single Petunias of various colours, and curiously marbled and striped. A large number of Hollyhock seedlings was shown chiefly by Messrs. Webb and Brand, of Saffron Walden; Mr. Chater, of Cambridge; and Mr. Blundell, all of whom seen to have succeeded in raising some first-rate seedling sorts, which would compare with those seen years ago, when the late Mr. Chater was the leading Hollyhock grower.

The most brilliant display was made by Messrs. Kelway, who had no fewer than 200 spikes of Gladioli, the cream of the immense collection they grow in their nursery at Langport. The collection contained spikes of the finest old sorts, besides numerous new seedlings, four of which were certificated. The best of the others were those named Lord Halsbury, Lady Salisbury, Abantes Demerata, Duke of Grafton, vivid scarlet, Lord Randolph Churchill, and Countess Onslow. A silver-gilt medal was deservedly awarded to Messrs. Kelway. Messrs. W. Paul and Sons, Waltham Cross, also took a silver gilt medal for a large display of cut Roses, numbers of which were shown in large masses of one kind, the following sorts shown in this way being very conspicuous: Etendard de Jeanne d'Arc, Mme. de Watteville (both superb new kinds), Perle d'Or, Homère, and Niphetos. Messrs. Paul, of Cheshunt, likewise had a very fine display of Roses, as fine as were shown in July, a large number of the leading kinds being included in it. Besides this there was a very fine collection of hardy flowers in the Cheshunt exhibit, consisting of a selection of the finest August flowering plants, such as Helianthus multiflorus maximus, Harpalium rigidum, Coreopsis grandiflora, Campanulas, herbaceous Phloxes in every variety, Pentstemons, Lilies, &c. For this fine group and the Roses Messrs. Paul took a silver-gilt medal. Messrs. Vilmorin, of Paris, showed an extensive collection of various kinds of flowers, chief among which were Camellia-flowered Balsams, large, very double, and diverse in colour; Zinnias, the dwarf pompon sorts, which grow only about 6 inches high, besides the singular striped strain which was certificated. They also showed a beautiful strain of single fringed Petunias, double-flowered Gaillardias of various shades of pellow and red, and Liliputian China Asters, which grow but 6 inches to 9 inches high. A silver medal was awarded to Messrs. Vilmorin, and likewise to Mr. Ware, Tottenham, for a large gathering of hardy flowers, consisting for the most part of Lilies, Iceland Poppies, August flowering Composites, and a huge sheaf of that beautiful Cape plant, Sparaxis pulcherrima, so seldom seen grown and flowered so finely as Mr. Ware showed it. Mr. R. J. Measures, of Cambridge Lodge, Camberwell, took a silver medal for a prettily arranged group of flowering Orchids, consisting of several plants of the comparatively small number of kinds that flower at this season, among which the following were noteworthy: Cattleya Regnelli, Barlingtonia candida gigantea, with much larger flowers than usual, Oncidium prætextum, Dendrochilum filiforme, Angræcum articulatum, Aerides virens superbum, and a very fine specimen of Aerides odoratum, carrying no fewer than two dozen spikes, and particularly remarkable on account of its having been grown without fire-heat in summer, and in a house with 50° night temperature during winter. The New Plant and Bulb Company, Colchester, took a bronze medal for a gathering of Lilium auratum flowers in variety and for spikes of hybrid Gladioli. Messrs. Cannell, of Swanley, exhibited their beautiful new bedding Lobelia, Fascination or Blue King, a very dwarf variety, producing an abundance of deep blue flowers with white centres. They also had plants of a handsome Fuchsia, named Rose of Castile Improved, besides a gathering of single and double Begonia, the latter, all named sorts, being extremely fine, one, named Goliath, being about the largest bloom we have seen.

There was also on this occasion a competitive show of various classes of plants, including Fuchsias, China Asters, Begonias, and Gloxinias. None of the classes were numerously represented, and by far the most remarkable was a magnificent group of tuberous Begonias, exhibited in the open class by Messrs. Laing, of Forest Hill. This group consisted of about 150 plants, the majority being very large, with flowered specimens of the finest sorts in cultivation, besides a host of new seedlings flowering for the first time this season. The class for nine Begonias, from amateurs, was far better represented than in former years, and it seems as if amateurs have overcome the difficulties of growing specimen Begonias. A very fine group was shown for the first prize by Mr. Newell, Fairlawn, Wimbledon Common, and the second and third groups were very creditable. Some of the specimen Fuchsias were good, but the Gloxinias were comparatively poor; as were also the China Asters, which would have been beaten at many a small country show.

Special prizes were offered by Messrs. Webb, of Wordsley, Stourbridge, for the best collections of vegetables of not less than eight kinds. There were three competitors, but Mr. Waite, of Glenhurst, Esher, who won the first prize, quite out-distanced his rivals, both in the extent and quality of his collection, which consisted of some two dozen dishes. The best of these were Pen-y-byd and Moore's Cream Marrows, Telephone and Stratagem Peas, Carter's Perfection Tomato, Sutton's King Cauliflower, Leviathan Bean, New Intermediate Carrot, Snowdrop Potato, and Anglo White Spanish Onions. Some excellent dishes were shown in the other two collections. Prizes were offered for fruits of Webb's new Melon Beauty of Wordsley, a handsome green-fleshed netted variety, but only one brace of fruits was shown, and these were over-ripe, so no award was made.

Fruit.—A cultural commendation was accorded to Mr. Condle, Springfield, Ulverstone, for a dish of Royal George Peach from a four-year-old tree, and a dish of Noblesse Peach from a tree twenty-four years old. In both cases the fruits were very fine. Messrs. Bunyard, Old Nurseries, Maidstone, exhibited fruits of three early Apples, viz., the Gladstone, a small high-coloured fruit, said to be the earliest and best Apple; Red Juneating, also a first-rate sort; and the new early American Apple called Tetrofsky, a small pale-coloured fruit, said to be of excellent flavour.

A list of awards is given in our advertising columns.

A FEW GOOD OLD PLANTS.

The following old-fashioned greenhouse plants are at the present time so conspicuous that a word of praise of them may not be out of place. The great merit belonging to these old favourites is, that they are easy to manage, and never fail to yield a good display of bloom at their appointed season, and the appliances necessary to insure their perfect development are of the simplest kind; anyone with a greenhouse, or even glass-covered pit, may have them in the highest perfection. Agapanthus umbellatus is now in fine condition; its strong spikes, crowned with lovely blue flowers, make a grand show either in the conservatory or verandah, and as a vase plant few excel it. Good strong pots that will resist the pressure of its powerful roots are indispensable, and I find a good sound loam to be the best soil for it. If potted well at first, it will last without interference for years if well supplied with water and a little liquid manure from May until October. Hæmanthus coccineus forms a good companion to the preceding, and the same cultural treatment suits it exactly. Its brilliant heads of scarlet flowers with yellow stamens are very effective. Eucomis punctata succeeds well associated with the above, but flowers a little later. Its mottled stems and foliage are very pretty, and the large spikes of flowers, although not brilliantly coloured, emit an agreeable perfume, and last in good condition for a great length of time. Altogether it is a desirable plant for a cool greenhouse. Crassula coccinea is another brilliant old favourite, able to hold its own with any of the new comers. Cuttings of it strike freely at this time of year. Oleanders, with their lovely heads of double pink blossoms, are just now most conspicuous. They frequently drop their buds—a circumstance mainly owing to lack of food, or being allowed to get dry at the root. A good stiff loam and plenty of water during the growing season seldom fail to cause them to yield abundance of bloom. Funkia Sieboldi, with its beautiful foliage and pure white fragrant flowers, is another of the easiest of plants to grow, and one that gives unfailing satisfaction. Hydrangeas, both pink and blue, are grand old plants. The blue is obtained by mixing with the soil iron filings or watering with alum water. Then there is the newer white-flowered variety, called Thomas Hogg. This is very floriferous, and most useful in many ways. And last, but not least, we have the feathery-flowered H. paniculata, that, if cut down like a Pelargonium, makes a beautiful bushy plant. The Lance-leaved Lilies, too, make grand greenhouse plants. The best time to repot them is in the autumn, just after the stems die down. Shake them out, arrange the bulbs in equal sizes, and use a compost consisting of turfy loam, rotten manure, and sharp sand. Put about five bulbs in a 10 inch pot, and only fill the pots three parts full at the first, so as to allow for top-dressing when the stem-roots appear. Be careful not to over-water and look out sharply for fly. A plant with twenty or thirty expanded blooms on it is a grand sight. J. G.

Hants.

Adiantum pedatum (*E. F.*).—This is certainly a hardy Fern, and may be exhibited as such.

WOODS & FORESTS.

PINES FOR PROFITABLE PLANTING.*

When "J. F." is challenged to defend his assertion that the Corsican and Austrian Pines "will not compare in a single useful quality with the Scotch Pine," in the face of examples I offer to show him growing under both favourable and unfavourable conditions, such as he specifies, not to speak of the favourable testimony of all save himself who know the tree, he replies by launching into a defence of the Scotch Pine, and ignores the information I offer him. He assiduously endeavours to make the question of value of the Corsican Pine a matter of my experience alone, shutting his eyes resolutely the while to what evidence I can furnish. There are none so blind as those who won't see, and "J. F.'s" condemnation of the tree in question, I have good reason to know, does not exert much influence with planters, with whom the Corsican and Austrian Pines are now most popular. He appears to have failed to grow the Corsican Pine, and concludes everyone else must have done the same; but he is wrong, and the sooner he relearns his lesson the better. That the Corsican, Austrian, and Scotch Pines will always grow alike under all conditions I have not asserted, but what I have already stated is true, and can be proved, and if "J. F." will go where I can send him, he will be compelled to acknowledge as much. The latest testimony to the qualities of the Corsican Pine is from a paper read before the Scottish Arboricultural Society, and copied last week into the *Timber Trades Journal*, from which I clip the following paragraph relating to the tree's behaviour on the Welsh coast at Penrhyn Castle, where it has been so extensively planted. Referring to the quality of the Corsican Fir timber, the writer says:—

"Regarding the quality of home-grown wood of Pinus Laricio, it would, as I have before stated, be premature to speak with any amount of certainty, as few trees have attained a size at which the wood could be considered mature. We have, however, cut up several of the largest trees here, and used the timber for various purposes on the estate with very satisfactory results. When sawn into boards, the wood resembles somewhat the red deal of commerce; it is, however, more brittle, extremely resinous, tough, weighty, and the concentric rings firmly packed. It works smoothly and easily, and is likewise susceptible of a fine polish. A series of experiments with the timber are at present being carried out on this estate, such as for fencing posts, gates, boxes, &c.; but sufficient time has not yet elapsed since the commencement of these experiments for us to form a correct idea of the real value of the wood as grown in this country; so far, however, the results are in every way satisfactory."

In regard to positions in which the same tree thrives, he adds:—

"For planting in exposed situations, or within the influence of the sea, this Pine is excelled by none with which I am acquainted. Along the outskirts of several plantations that are fully exposed to the south-west, from which point our west winds blow, the Corsican is far superior to the Scots Fir, and about equal in value with the Austrian Pine as a screen or shelter tree. Where the Scots Fir becomes weather-beaten, and, as it were, shrinking or bending from the blast, the Laricio stands boldly out, seeming as if to defy both wind and storm, and rearing its head far above any of the surrounding trees. This is very noticeable in several clumps and strips of trees planted nearly half a century ago in the park here for shelter and effect. Again, near the seacoast this Pine grows with a vigour excelled by few, and seems quite at home even within the direct influence of the salt spray; and for this reason, as well as its ornamental appearance, has been extensively used in the formation of our seaside plantations. On the mountain side between Llandegai and Aber, at altitudes ranging from 300 ft. to 500 ft. above sea-level, where, upwards of thirty years ago, several extensive plantations were formed, Pinus Laricio, although used in very limited numbers, may be seen above any of the other trees planted at the same time, and boldly facing the south-western blasts, which at times sweep along the hill-sides with terrific fury."

So much for the seacoast. I have at times furnished similar testimony as regards the behaviour of the tree compared with the Scotch Fir on the most exposed inland situations in the north of England, where no other Conifer except the Austrian will thrive, and where some will not even live. Let "J. F." furnish like testimony to the contrary or disprove the facts furnished, or, on the other hand, let him be silent until he has learned more about the subject. Yorkshireman.

* The above was written before the remarks of the editor in last week's Garden appeared.

PLANTING RECORDS FOR FORESTERS.

The value of keeping a record of all plantings carried out by the forester on an estate is not, I am sure, fully recognised. To young foresters especially such a record would be a great guide to future plantings. Information which can be gleaned from books or journals must necessarily be of a general character, and cannot be made to apply with any degree of certainty to individual places. Records of successes or failures kept in a special "tree book" upon an estate would, however, be of the greatest possible worth. Failures upon particular spots, if recorded at the time they occur, would be as instructive as any portion of the work, as, lacking the knowledge of such attempts, the existing generation may repeat the mistakes of the preceding one. It is most likely, indeed, that the accounts of failures would be of more value than the accounts of successes, as these would generally be left to speak for themselves, whilst the traces of the failures would have disappeared if there was no record left behind. There is no doubt that there are very many foresters now living who possess a large fund of information of this kind with regard to the localities in which they have spent many years, but which, in the absence of a "tree" or "planting book," will be lost to posterity. There are places, I know, where the plan is being carried out, and a century hence the experience of the present generation will be referred to and become a guide for their operations. As such things as these are very often overlooked from the fact of their being merely every-day occurrences, the suggestion may direct attention to it. There are very few proprietors, one would suppose, who would not be willing to provide a special book for such a purpose; and there are very few foresters who would not gladly record their experiences for the benefit of their successors.

Y.

Sowing Grass in woods. Where it is intended to lay down with Grass any land cleared of trees, this should now receive a thorough cultivation and cleaning, and afterwards be dressed with lime. Towards the end of August roll down the land and make the surface as firm as possible, sow a proper mixture of about 40 lb. of seeds per acre, and lightly brush them in, taking care that none of them are too deeply buried.—W.

Insects and Conifers.—During August a sharp look-out should be kept on Coniters for insects and their larvæ. This is about the time when they begin their work of destruction, and, what is most provoking, the leading shoots are most liable to be attacked, thus destroying the season's growth, and throwing the symmetry of the tree out of balance for perhaps two or three years; some trees, indeed, never regain a proper leader.—W.

Fencing against cattle.—Gates, stiles, and all kinds of fences bounding plantations ought to be made perfectly secure against cattle. Those fences adjoining grazing lands should have special attention during hot weather, for cattle when driven by insects quickly find out weak places in hedges, and when one breaks through the whole herd or flock will surely follow, and, of course, can in a very short time do an immense amount of injury to young trees or underwood; and, besides, when once cattle get into a habit of trespassing into covers it is no easy matter to fence them out.—W.

MACHINERY AND HOME-GROWN TIMBER.

The final report of the Royal Commission on Trade Depression, to which attention is just now being directed, seems to emphasise the views of those who hold that one of the best ways to improve the position of the British timber market is to cheapen the manufacture on the spot. There are many points in the report—of which, however, I have only seen a summary—which bear considerably, though indirectly, upon the question as it affects us. One important deduction certainly is—though it has been known before—that there is no lack of consumption. The trouble is that, either by more enterprise, cheaper labour, or some similar cause, the home grower is driven out of his own market. There are very many other things of which this is true besides timber, but this is the one with which we are now concerned. The fact seems to be accepted in a general sort of way, and yet no effort is made to meet it.

As has been over and over again urged, there is one condition which, try as he may, the foreign producer cannot remove and that is distance and freight. To lessen this inconvenience to his competitor, the home producer cannot go a better way to work than continue many points of the present system. To gain anything from the advantage of production contiguous to the market, there must be a departure from the beaten track, and this can be done in more than one direction. A larger use of the home-grown produce, instead of purchasing foreign, is one, and perhaps the first; a curtailment of the amount of labour in carting about the raw material unnecessarily is another. To anyone who has had the slightest experience of the way in which the English trade is usually carried on it is painfully clear that a vast quantity of effort is continually wasted in hauling new timber from one point of the compass to another to be manufactured. It is, indeed, often carried on to such an extent, that it is a standing cause for wonder how the buyer is able to pay the producer anything at all for his timber. It may be argued that this is a thing which concerns the merchant alone, but with this position I cannot agree, as it is perfectly obvious that the price paid for the new produce will be in proportion to the price obtainable for the furnished product and the intermediate expenses. These expenses can and will be materially reduced by the application of suitable machinery to manufacture the material where it grows. That this is not more generally done at present is not perhaps altogether the fault of the merchant. It must be admitted that from some points of view a portable saw-mill and the area surrounding it are not altogether the tidiest spots it is possible to conceive, yet there is often a kind of false delicacy about landowners, especially if the fall of timber is at all within reach of the house, about permitting the cutting up of wood upon their place. When this is the case, the buyer is often driven to cart the unsawn wood for several miles to a fixed mill at a comparatively heavy outlay, and perhaps in the operation pass a station from which the sawn product could have been despatched if it had been manufactured on the spot. This is a thing of very frequent occurrence, and, as a consequence, the seller does not get so much for his timber, by the extra cost of cartage, which is a serious difference, and is money thrown away. The matter is one which, of course, everyone who has timber to sell must decide for himself, but to the ordinary observer there seems no

reason why there should be more objection to a portable saw-mill than to an ordinary threshing-machine. The assumption is that it shows financial weakness to be cutting up the timber upon a place—at any rate it is difficult to suppose any other reason—but such an idea should have no weight, as it would be just as reasonable to argue upon the same lines that a crop of corn should not be threshed because there would be an appearance of wanting to realise it. This may be to some extent a side issue, but it is one which is certainly part of the question.

By encouraging the manufacture of the wood upon the spot where it grows, the producer would, where he possesses no machinery of his own, reap another indirect advantage, viz., that of an opportunity of getting what timber he might want for his own uses cut up by skilled hands. These points may individually appear to be of small importance, but collectively they have considerable bearing on the issue. There is all the difference in the way in which a tide sets, and so it is with the production and disposal of home-grown timber. If the tendency is an earnest endeavour to improve an indifferent position, the attempt cannot be entirely unsuccessful, but if we are to drift listlessly on, matters, instead of becoming better, must gradually become more and more unsatisfactory as we are further and further pressed by the ubiquitous foreigner. J. N. B.

UNTHINNED PLANTATIONS.

My conviction is that if we could only come at the facts that could be recorded, the question of most practices connected with forestry could soon be settled. There is no dearth of experience or of facts, but a dearth of testimony. English foresters seem extremely reluctant about telling anything. This was my feeling the other day when travelling by rail through certain well-wooded estates which it appeared to me could furnish excellent information on several disputed points if only those in charge would kindly tell us their experience, for it is presumed that some foresters and planters read The Garden and Woods and Forests. When passing a station, about half way between York and Scarborough, where a considerable quantity of timber was piled, I was struck by some examples of Larch poles in a lot. I should say they averaged 80 feet in length, 6 inches quarter girth, more or less, and were as straight and even as any Norway poles I ever saw. They had clearly been grown in a crowded plantation of no great age, a fact which caused me to take note of the extensive woods near the railway in the neighbourhood as we went along. A fellow traveller said the woods belonged to the Castle Howard estate near Malton, a favourite resort of the tourist. They consisted principally of Larch, Spruce, Ash, and Oak, all apparently in excellent condition; but what took my attention most, both going and returning, was what one would call the crowded condition of the plantations, the length and straightness of the trunks, and the thoroughly healthy condition of the tops. All the plantations seemed to be crowded, and in one case a small wood of Larch and Spruce did not appear to have ever been thinned at all. So dense were the trees, that one traveller remarked, "Why, it is almost dark under those trees!" The plantations were close to the railway, and could easily be seen. I wonder if those who have the charge of these plantations could kindly supplement this note with some further information on the subject. Yorkshireman.

QUESTION.

Age at which Lime trees flower.—At what age does the Lime tree usually first flower? It is a matter which I have never specially noticed, and this season I have no young Limes of known age within reach. Would any reader who has young Limes in flower be good enough to state their age? —Tilia.

THE WILLOW AS A TIMBER TREE.

The Willow has never received fair treatment as a forest tree, simply because it will bear more ill-usage than any other tree. Few people have ever seen a Willow plantation in its prime, say after having been forty years planted and properly cared for; those who have seen such a plantation will not readily forget its beauty any more than the owner can forget its profit. The Willow, when in perfection, is "a thing of beauty;" and those who have possessed well-grown specimens of it have seldom cared to have them cut down until decay had set in, and the Willow soon decays after reaching maturity. To speak in trading phraseology, it is a tree which brings a quick return for invested capital.

Lowe, in his survey of the county of Nottingham, states that so very valuable are Willows as plantation trees, that at eight years' growth they yield in poles a net profit of £214 per acre, and in two years more he states that they would probably have yielded £300 per acre. In page 1520 of Loudon's "Arboretum Britannicum" it is stated that a cutting planted by Mr. Brown, of Hetherset, Norfolk, became in ten years a tree of 35 feet in height and 5 feet in girth; and in the same work a tree is mentioned at Audley End, Essex, of twenty years' growth, which was 53 feet high and 7 feet 6 inches in girth. I myself saw six trees felled in 1869, near Southwell, Notts, which, after thirty-eight years' growth, unitedly yielded 232 feet of measureable timber, which sold on the spot for 1s. 2d. per foot; and the six trees did not occupy more than 18 square yards of land.

To grow Willow trees in perfection they must be planted closely, say 3 feet apart each way, or 4840 to the acre would not be too close for the first eight or nine years, when they might be thinned out to half that number. The thinnings would find a ready sale for general farm purposes. At the end of sixteen or twenty years they might be reduced to 1210 trees, or 6 feet apart each way, which would generally afford ample space for their full development. The time to fell such a plantation must depend very much upon circumstances. No unvarying rule can be laid down, but it is better to cut too early than to allow them to stand too long; for, as before stated, when the Willow has reached its best it speedily decays. Its duration may be said to range from thirty to fifty years; but whenever dead branches begin to show themselves there should be no delay in cutting down. In felling Willows do not think of leaving a few selected trees in the hope of obtaining larger timber, for after having been so crowded and then suddenly exposed they would almost invariably perish. If heavier timber is desired, plant more openly at the first.

I will now endeavour to arrive at an approximate value of an acre of such timber at its prime, say after having been planted forty years. There is plenty of evidence to show that it is not an uncommon thing for a Willow tree at thirty years of age to yield 45 feet of measureable timber or at the rate of 1½ cubic feet per annum. The experiments of the Duke of Bedford and others prove this to be the case. I will not, however, reckon upon such great results, and will further assume that 110 trees out of our 1210 are worthless, being a much greater margin than would be probable, and that in forty years we only produced one-third of the above, or half a foot instead of 1½ feet per annum. We shall then have 1100 trees, containing an average of 20 cubic feet each, or 22,000 feet, worth, at the lowest computation, 1s. per foot, or £1100, the produce of an acre of such wood in forty years, leaving the two thinnings to cover the cost of labour, which would be more than sufficient for that purpose. This is no fanciful calculation, but one fully borne out by the experiments of men whose words cannot be doubted. It cannot, however, be too often repeated that the Willow will not arrive at perfection in swampy, undrained land. Willows grow freely on the slopes or tops of exposed hills; indeed, there are few situations in which they will not grow, but in no place so badly as in water-logged land. For timber trees the Salix fragilis, or some of its kindred varieties, of which there are not fewer than twenty or thirty under cultivation, should only be employed, some of the lately introduced varieties being not only vigorous growers, but extremely beautiful. It must also be borne in mind that all Willows grow more vigorously from cuttings than from rooted plants, and therefore rooted plants only should be employed when immediate effect is desired.

It may be asked, to what use is Willow timber put when grown, and where would a market be found for it? There is no wood in greater demand than sound Willow; it is light, smooth, soft, tough, will take a good polish, and does not easily burn. It will bear more pounding and hard knocks without splinter or injury than any known wood, and hence it is used for cricket-bats, and, whenever it can be obtained, for the floats of paddle steamers, "strouds" of water-wheels, brake-blocks for luggage and coal trucks, the sides and bottoms of carts and barrows, where wear and tear are greatest. To the wood turner it is almost invaluable, and were it grown as timber and obtainable, it would be used for very many purposes to which foreign timber is now applied, and that, too, with considerable advantage both to producer and consumer.

Withy.

PLANTING TREES ON POOR SOILS.

It has now become the rule to advocate planting trees on all waste ground worthless for any other purpose. There are grave doubts whether such advice as this is not dangerous. It must be admitted that trees of large size and of the best quality often grow in places the most unlikely, and on soils which would have been of very little use for agriculture, but it is an utter fallacy to argue from this that trees will be sure to grow well in such places, or that there is a reasonable prospect of their doing so. There apparently is a general belief that there are few trees which will thrive in boggy and undrained soils, and that subsoils which have run together so as to form a pan are equally unsuited. At this point information ceases. It must not, however, be blamed to this circumstance entirely that there are so many plantations in existence which are doing badly. The fact rather is, that the planter generally has to do his best with very unpromising sites, and, what is more, is often restricted in his choice of trees. It often happens that there is no choice of site, as surrounding conditions control it. In such instances, if the work is given to an experienced planter, as much latitude as possible should be allowed in the selection of trees. In other cases there may be the opportunity of choosing between various positions. When this is so it may not be the best policy to relegate the plantation to the worst soil in order to save the other sites for another use. Indeed, when there is a disinclination to surrender land which has a certain known value, it is quite an open question whether it would not be advisable to abandon the project of planting altogether rather than be driven upon what would be likely to turn out an unsuitable soil. D. J. Yeo.

Abies Alcoquiana.—This proves to be one of the most beautiful of coniferous trees. The purple buds on the new growth look like blossoms. It is hardy as a rock, and seems so far free from insect troubles. In Japan it forms a noble tree from 90 feet to 100 feet in height.

GOOD STRAWBERRIES.

Vicomtesse Hericart de Thury.

THE most remarkable thing in your fruit reports this year is the generally favourable estimate given of the popular variety generally known under the name of Vicomtesse Héricart de Thury, for I believe it is grown under at least one or two other names. I know of no Strawberry that has been generally grown and known these last twenty-five or thirty years that has ever been so popular. The Strawberry is one of those plants that is much affected by the soil in which it grows—of which more hereafter—but all soils seem to suit the Vicomtesse equally well. Heavy or light, clayey or sandy, deep or shallow, it never refuses to grow and bear more or less abundantly. It is not of a very gross habit, but it possesses a wonderful vitality, and to that more than anything else I think its fertility is due. It forces wonderfully well—never misses a crop—and if the forced plants are shorn over in June and planted out they will bear a fine crop all through the autumn and prodigiously the next two years following. The fruit, too, is of fair size and good flavour. Speaking of soils, both my neighbours here and myself find that some varieties do not bear freely, or at all, that are most prolific elsewhere. What the cause may be I cannot say, for the texture of the soil is not apparently different from that in which the same varieties do remarkably well elsewhere. At one time there was no more popular variety for growing and forcing than Keen's Seedling. In the Lothians of Scotland it used to be matchless—never failing even under indifferent culture—but in this part of Yorkshire plants procured from Scotch stock and from other sources grew amazingly, ripened well, but would not fruit, and after repeated trials had to be discarded, and I do not think a single plant of it has been grown here or in any of the large gardens in the neighbourhood for that reason for many years. Pot plants of Keen's that I grew myself in Scotland and brought here with me in the pots forced remarkably well and bore fine crops, but plants propagated from these and other fertile stocks, after having been a year in the soil here, failed both in pots and planted out. A good many years ago I stated these facts in a contemporary, and was taken to task by the late Mr. Cramb, of Tortworth, for my statements. A particular friend of his being my neighbour, however, in a well-known place, Mr. Cramb came to see him once, and came over here, and we showed him such incontestable evidence of the fact in more gardens than one, that he afterwards wrote to the same paper acknowledging the correctness of my observations. This peculiar effect of the soil on varieties of Strawberries has always been a puzzle to me, for the same thing is observed in other sorts, only not so much as in Keen's Seedling. Black Prince, on the other hand, a sort which at one time I did not admire and did not grow, does just as well as Vicomtesse Héricart de Thury, and is a fail-me-never in pots. The mildew which frightens gardeners from growing it in many places gives us no trouble, as it yields to one syringing with sulphur-water, applied just when the fruit is set or setting. This year we have gathered the twenty-second annual forced crop of it without a break or failure in all these years, the plants having all been propagated in direct succession from the first stock. Under good culture the fruit from pot plants is nearly as large as Keen's and always plentiful.

As a dessert variety for general use and late forcing, I have never yet tasted a Strawberry to equal the British Queen when well grown and fairly well ripened, for it seldom gets red quite to the point. In the light rich loams of the Lothians it used to do very well outdoors and beat all others for late forcing, the crops always being good and constant. The only fault it had was its liability to red spider, which ruined the foliage if not checked in time, but otherwise it was all that could be desired. Here, like the Keen's Seedling, it does not grow at all well.—J. S. W.

Strawberries at Bristol.

At the excellent exhibition held in the Zoological Gardens, Clifton, on July 14, Strawberries were extensively shown. In many instances President and Sir Joseph Paxton are almost the only kinds staged, but varieties were more numerous at Bristol; indeed, the two kinds named were not conspicuous. There were many dishes of British Queen, Loxford Hall Seedling, Countess, and Souvenir de Kieff. These varieties won the first prize in the class for four dishes. Loxford Hall Seedling is of the same type as the British Queen, but, as seen here, was densely furnished with small seeds; Countess was of good size, highly coloured, but not first-rate in flavour; Souvenir de Kieff was extremely large and deeply coloured. In appearance this was the finest of the four sorts named, but in flavour the worst. In the single dishes, as in the preceding class, competition was keen, and a fine lot of fruit was staged. Here Sir J. Paxton was first, Goliath second, and Countess third. Goliath is a very large, thick fruit, highly coloured and showy, but if ever Strawberries come to be judged by flavour it will never be heard of. British Queen was shown in several instances, but the fruits were so poor in form, that they could not be placed in the prize list. James Veitch was well shown, but poor in colour; indeed, I very rarely see this variety of the same colour throughout.—J. MUIR, *Maryam.*

Strawberries of fifty years ago.

On looking over the recently published reports of this year's fruit crops in THE GARDEN, I have been struck with the fact that the Keen's Seedling Strawberry, which was the leading sort both for forcing and general crops say fifty years ago, still holds its own in many establishments; but where is the little Roseberry that used to come in as a first crop some few days before the Keen's, and which was also grown specially for preserving on account of its rich colour (for it was well coloured throughout)? It was conical in shape and small in size, but most prolific. Again, where is the Hautbois (a species, I believe, of alpine Strawberry), the musky flavour of which was so distinct from that of other kinds? Is its absence owing to the fact not being generally known that plants of this kind bear fruitful and sterile blossoms—in other words, have the male and female organs on separate plants? As the male plants are the strongest, unless they are thinned out they overrun the weaker, and thus the cultivator becomes disappointed at not reaping a crop of fruit. Some thirty years ago I procured this variety from Mr. Myatt, of Deptford.—H. HOWLETT.

Newly-rooted Strawberries.

No new Strawberry plants can be secured until the runners are formed in June or July. In some seasons runners are emitted much earlier than others, but, as a rule, they are of a good size and well rooted by the first week in August. Those who force Strawberries in pots always try to have runners rooted as soon as possible, and quantities of them are layered in small pots or in pieces of turf. In each of these cases the runners should be allowed to root well in the new soil before any attempt is made to cut them away and set them agoing on their own account. When severed from the old plants too soon some of the most tender young rootlets are apt to be checked or perish, and the young plants do not grow away so freely and luxuriantly as they do when the pots or turves are a mass of roots. Indeed, the main secret in succeeding with pot Strawberries during the early stage of their growth is, as I have said, to see that the runners are thoroughly well rooted before they are taken from the old plants. I do not approve of potting them on the day on which they are cut off, as, no matter how well they may be rooted, they generally flag a little for a few days after being separated, and this is quite enough for the young plants to bear without being submitted to the additional trial of being re-potted. As soon as the young plants in pots are cut off they should be placed in a somewhat shady spot, and here they should remain for a week or so until they have overcome the slight check arising from separation from the old plant. As soon as they are off, and until they are repotted, they should be liberally watered with liquid manure; and as this will induce a great many young rootlets to break out, they will be in excellent order to place in larger sized pots. In potting these on small squares of turf care should be taken to see that the turves are not broken or the roots disturbed, and as soon as potted they should be heavily watered and shaded from bright sunshine until they have begun to root into the new soil and are able to bear exposure without flagging. Last year, and for some years past, we have rooted quantities of our pot Strawberries in turves, and by the autumn when fully grown, or in spring when in fruit, they could not be picked out from these which had been rooted in pots. I am therefore inclined to think that the one system of layering is as good as the other. There are, however, very many growers who do not force Strawberries, or have any means of layering them for any purpose. Growers of this class generally allow their runners to root into the soil between the rows, and as soon as they are sufficiently rooted lift them and form new plantations with them. This is a good way in which to secure young plants, especially if the runners are well attended to. Runners intended for planting should never be shaded overhead with superfluous foliage. Only the strongest and best rooted should be selected, and in digging them up a ball of soil should always be secured with the roots. Many are in the habit of lifting them from the old beds and planting them direct in the new quarters, but much better results may be obtained by lifting them from the old plantation and planting them in a nursery bed for a few weeks; then they can be transferred to their permanent quarters. This nursery bed should be very rich, in order to induce the formation of abundance of roots as well as harden the plants, and as they will lift with excellent balls of soil they may be transplanted a second time if need be without ever feeling the change. During the time when they are in the nursery bed they should be watered frequently with liquid manure should the weather be dry, and if planted there now they will be ready for the main plantation early in September, which is a very good time to plant Strawberries.—J. MUIR, *Maryam, Port Talbot.*

Cold district Strawberries.

When I came to this place, which is high, cold, and bleak, seven years ago, I got 600 Strawberry plants for pot culture, all good tried kinds, with the exception of Duc de Malakoff. After fruiting them I planted them out of doors, but the very first winter satisfied me as to which varieties I should grow. All the long foot-stalked kinds were good for nothing: Keen's Seedling even did not answer: Duc de Malakoff and Black Prince were the only two which I selected for further trial. I have tried some other varieties since, but without success. Malakoff is a good setter; its fruit is not large, but it colours well. I am not fond of pale fruit for table. I have grown 500 plants of it in pots each year since, and afterwards planted them out of doors as early in the year as I could. I plant out every year a certain portion and annually destroy a similar piece. Duc de Malakoff is certainly the best all-round Strawberry for a cold district, and anyone who gives it a fair trial will, I think, be satisfied with it. Every year I have to buy fresh plants for

pots; runners cannot be got early enough to ensure a crop in pots. If planted in September they would be nearly all lost by the spring time. This year our crops outside have been but moderately good; the foliage suffered severely early in the year, and about a month ago it was again injured.—Aaron Bird, *High Crompton, Shaw, Lancashire.*

Two good Strawberries.

Allow me to say a word or two in favour of two varieties of Strawberry. One, King of the Earlies, raised by Mr. Laxton, is pretty widely known. It is an excellent fruit and quite deserves its name. It is good in shape and flavour, and a fruit that tends to prolong the Strawberry season at one end is nearly as serviceable as one that would lengthen it at the other. I should also imagine that it would be good for forcing. The other is a variety I came across at Helston. There was a very fine dish of Strawberries exhibited at the Rose show, and which was afterwards brought to the luncheon given by Mr. Gall to the judges and exhibitors. It was eagerly partaken of and pronounced by all, amongst whom was Mr. Laxton, to be excellent. It proved to be a seedling, the result of a cross between Dr. Hogg and President, partaking of the good qualities of both parents. It is stated that it is very vigorous in growth, hardy in constitution, and forces well. It has, therefore, been called All Round. Whether it deserves all that has been said of it, I know not, but its parentage would justify me in believing that it does. All I can speak of it is what I know of the fruit; it is handsome in appearance, firm in texture, and excellent in flavour.—Delta.

OVER-CROPPED VINES.

Few readers of The Garden would have far to go to find a house of over-cropped Grape Vines, and it is surprising what an extraordinary weight of well-finished fruit experienced cultivators may cut from a house of Vines; but if the inexperienced attempt to do the same, they are very liable to fail the first season as far as the quality of the crops is concerned, while the chances are the following season there will be a great falling off in both the number and size of the bunches produced. When the Vines are well "built up"—that is to say, have not been overworked in their young days, and have a well-formed border, plenty of moisture at the roots at all times, besides liquid manure and surface dressings of manure, special or otherwise—they will do almost anything in reason. We can point to two good examples of superior culture, viz, Longleat and Cardiff Castle. In the former case the Vines are wonderfully strong, and as they are well fed at the roots they are quite capable of perfecting extra heavy crops; indeed, if not heavily weighted, they would become too gross. At the present time they are bearing grand crops, the Muscat of Alexandria being exceptionally fine. In some parts of the large house devoted to that invaluable Grape, nearly every lateral on a rod is carrying a heavy bunch varying from 2 lbs. to 6 lbs. in weight, the berries being very large. We are not at all sure that Mr. Pratt is not working them too hard, but then, as before stated, they were cropped very lightly in their younger days, and with such stems and roots may now, when about fifteen years old, stand the strain. The Black Hamburghs are also heavily cropped; but as these are finishing grandly, the berries being large, and little or no shanking being apparent, it cannot be said they are overdone. In the late house, which is devoted entirely to black sorts, Alicante promises to be as fine as ever, and that in spite of heavy crops both last season and this. Lady Downes have hitherto been somewhat unsatisfactory, and they are now being more heavily cropped to correct grossness. Instead of one bunch to nearly every lateral, two are left, and such a crop ought to check superfluous vigour. Great judgment has to be exercised in cropping Mrs. Pince, or it is certain to fail in colour, and unless we are much deceived the Longleat examples are likely to be some of the best ever seen of it. At Cardiff Castle the Vines are much younger, or probably about five years old, but when we saw them last season we were obliged to confess they were carrying the best and most even crops we had ever seen. The sorts grown principally are Black Hamburgh and Foster's Seedling for early use, and Alicante for the late supplies, and these are grown on the single rod system; whereas those at Longleat are on the extension, four Vines filling each large division. At Cardiff each rod is about 16 feet in length, and when we saw them they were carrying about twenty-five large bunches, or say not less than 50 lb. weight of fruit. We ventured to prophesy evil concerning them, but as it happens, instead of the crops being inferior this season, they are really better than usual in every respect. In this case also the borders are inside, and there is no stint of water and plenty of the best of manures.

Over-cropped Vines, however, are much more plentiful than they ought to be, and very few ought to attempt to follow the examples just alluded to, for the simple reason that it frequently ends in disastrous failure. No general rules can be laid down, so much depending upon circumstances. When the roots are confined to the inside of the house and are neglected, not receiving half enough water and manure, one or at the most two heavy crops in succession are enough to completely ruin the Vines. Large borders are not required, especially in ordinary lean-to houses, but these should not be trampled down, and generally neglected, as is too often the case when amateurs do their own work. It is not yet too late to partially remedy a defect in the treatment of such borders. First, the surface should be forked over, then a liberal supply of soft water be given, followed, if possible, by a good lot of diluted farmyard liquid manure. Then if a mulching of short manure, faced over with the strawy portion of it, is given, this will encourage the roots and preserve the moisture. It must not be thought that no further attention is necessary; on the contrary, the border should be examined at least once a week, and whenever approaching dryness ought to receive more water, or water and liquid manure. In the autumn an attempt should be made in many instances to formalise a border, and for our part we always prefer a boundary wall, especially when the house is also utilised for plant growing. We have seen capital crops of Grapes annually produced on Vines rooting in a narrow border, or about 4 ft. wide; but, it should be added, they were as carefully attended to as pot plants. When the roots are anywhere and nowhere—that is to say, nobody knows exactly where they are—they get very little in the shape of food other than they can forage, and that is not much, unless they happen to come across a drain from a cesspool. Many, perhaps much the largest majority of Vines, are rooting in outside borders, and more often than not the principal portion of the roots have left the border formed for them, and have rambled yards away, neither walls nor gravel walks serving to confine them. When this is the case the Vines do not often suffer from want of water, but more frequently they are too deeply rooted, and very few subsoils are suitable for them. They make but little fibre, and Vines with fibreless roots are liable to form soft growth, and are much addicted to shanking, anything like a heavy crop being out of the question. If we left a great number of bunches, half of the berries would shank; and the greatest judgment is required to be exercised in the matter of thinning both the berries and bunches. The remedy is either lifting and shortening the roots, relaying them in a formalised border, or a new border and new Vines, the latter being the most expensive, though preferred by many. At the same time it is surprising what good Grapes may be grown on Vines with their roots principally in a bad medium. The greatest judgment is required in the matter of cropping, the Vines being capable of perfecting a certain number of bunches, and no more, as all extra assistance is denied them; whereas those with over-cropped Vines with roots under control can give extra manurial help to them. Badly-rooted Vines also do not force safely, and they must be brought on very slowly, especially at the colouring period, or those that should be black will be nearer red in colour, and the so-called white Grapes will be green.

As we have previously hinted, the number of bunches to be left on each rod or Vine must, or should, depend upon the health and vigour of each In very many instances the sole end and aim would appear to be the securing of as many bunches as possible, and if two show on each lateral so much the better, the consequence being none really presentable. One Vine in a small mixed plant-house and vinery in the nearest garden to us was last season allowed to perfect as many bunches as it would, or about 150 in all; whereas fifty bunches would have been ample, as well as of greater value in the end. This was at the rectory, while the doctor's Vines were treated still worse, as these, besides being allowed to bear as many bunches as they would were also denuded of much of their foliage in order to encourage them to ripen their crops. When we saw them, there were nearly as many bunches as leaves. Both growers were warned that they were ruining their Vines, but nothing we could say induced those in charge to cut off many bunches, and this season they are not there to remove. These are two examples out of the many that could be given. In some instances the gardeners are to blame, and in many more the employers are responsible, or ought to be held responsible, for the results of this reprehensible over-cropping. If Grape growers looked farther ahead than they usually do, we should hear of fewer premature breakdowns, and, instead of the Vines being worn out when about ten years old, they would then be at their best. There is yet time to lighten the extra heavy crops on many overworked Vines, and the knife should be set to work at once. The Vines being in fairly good health, with well-developed foliage, and supposing they are properly assisted at the roots, a bunch may be left on every second lateral at the most; but if weakly and the foliage small, the number of bunches may with advantage be still further reduced. It sometimes happens that the true character of the crop is not apparent till the berries have coloured somewhat, and even at that advanced stage, much good may be done by the timely removal of a few bunches. This may seem a wasteful proceeding, but we have known instances where the removal of a few bunches has completely saved the remainder of the crop, rendering what would have been poorly coloured equal to taking prizes at the Crystal Palace and other shows. After all, any cut away need not be wasted, as green or partially ripened Grapes can be made into most excellent wine, and those removed before being far advanced after the thinning of the berries are much liked in tarts. In the case of young Vines, those perhaps producing large bunches, one bunch to every third lateral is ample, and these will finish well without impairing the health of the Vines. Exception may be made in favour of those producing small bunches, notably Lady Downes, and these may be left rather more thickly, while the luxuriant and rather shy-bearing Gros Maroc may usually be allowed to perfect as many bunches as are developed. Golden Queen is also a very vigorous variety, and on this we leave more bunches, or one to every second lateral. It is not, however, those in charge of such Grapes as these that are the greatest blunderers as regards over-cropping, but rather the proprietors of small gardens with only one or two vineries. Let us, therefore, hope that some at least will profit by the warning we have attempted to convey.—W. I. M., in *Field.*

SHORT NOTES.—FRUIT.

Arrested growth in Pears.—Can you tell me the cause of a large Marie Louise Pear having a good number of fruit like the enclosed upon it? It is an old tree on a south wall; it has always borne well hitherto, and has a fair crop of good fruit on it this year also.—Subscriber.

*** We cannot explain the cause of the local arrest of growth in certain fruits of your Marie Louise. Possibly it is owing to the age of the tree, or the small fruits were possibly affected by the continued hot weather in early summer, the more vigorous fruits escaping. The arrest has not been caused by attacks of fungi or insects.—G. W. S.

QUESTIONS.

5513.—**Coltsfoot.**—Can anyone tell me how I can destroy or prevent the growth of this weed?—T M.

5514.—**Soil for Primroses.**—Will any reader of The Garden kindly say what is the most suitable soil in which to plant Primroses in order to maintain their lovely primrose colour?—Derby.

NOTES OF THE WEEK.

Edelweiss.—I send you a flower-head of Edelweiss cut from a plant two years old, being raised from seed in July, 1884. Last year it produced one flower-head, and this year four similar to the one sent, but all have lost their colour very much owing to the late heavy rains that we have had.—Wm. Duncan, *Hampsfield, Grange-over Sands.*

. A very fine head quite 5 inches across, borne on a stem 9 inches high. It is as fine a specimen as we have seen cultivated.—Ed.

Out-of-door Begonias.—I send you a few blooms of tuberous Begonias gathered from plants growing out of doors, the seed of which was sown in January of this year. The flowers, I think, show what capital plants these Begonias are when properly managed. No weather affects them adversely, either extreme of wet or dry.—E. Molyneux, *Seamore Park, Bishop's Waltham.*

Very fine blooms some 4 inches across, of good shape, and brilliant in colour.—Ed.

August-blooming Orchids.—Seeing in The Garden (p. 138) a list of August-blooming Orchids, and a request therein contained to add to it, perhaps you will allow me to do so. Such lists may be useful to beginners, and therefore worth recording. The kinds which we have now in bloom are Lælia Schilleriana, Epidendrum prismatocarpum, Oncidium Jonesianum, Miltonia virginalis and Morrelliana, Odontoglossum odoratum and Lindleyanum, Mesospinidium vulcanicum, and Thunia alba.—De B. Crawshay.

Begonias at Reading.—Thousands of Begonias of various sizes from seed sown so recently as February last may now be seen at Messrs. Sutton's. Many are in 7-inch pots, dwarf, compact, and sturdy, and blooming in profusion. The crimsons are gloriously brilliant. The soft rose hues are delicate in the extreme, and the apricots, the creams, and the pure whites are all grand in their way. Some, too, have white centres with heavily shaded edges: indeed, there seems to be no limit to the range of colours which exist amongst these Begonias. In short, sights so beautiful should not be allowed to pass without being seen.—A. D.

Fruits in Western New York.—The following note in reference to this subject we extract from a private letter from Mr. Barry, of the nurseries at Rochester, New York: "We flatter ourselves that we have here, in Western New York, the finest Apple district in America, some of our counties producing from £100,000 to £200,000 worth a year; but this year, owing to a severe attack of aphis on the foliage, the crop is a failure. Pears are looking well. Peaches fair. We have already gathered and sold Waterloo, Alexander, Saunders, Dyer's June, Rivers', Louise, &c. Our Rivers' Peach was superb, but it does not sell well in our markets, owing to its pale colour."

Victoria regia.—The queen of Water Lilies is now in the height of her beauty, large cupped leaves like table-tops, and magnificent pure white, deliciously scented blossoms being developed rapidly at this season. The Kew specimen has been flowering for about a month, and should bright weather set in, there will be almost another three months of bloom. Most of us are too familiar with this prodigious plant to care much about it, and if familiarity has not bred contempt, it has perhaps brought its companion, indifference, to half close our eyes to the charms of this giant Water Lily. But there are thousands to whom Victoria regia comes as a great and wonderful delight, for we have heard something of their astonishment as they walked into the Victoria house at Kew, and beheld for the first time the plant which previously had probably been heard of only as a myth, or a figure in an "Arabian Nights'" story. The regularity with which the flowers expand, the transformation that takes place after the first day from pure white to rose-red, or white with broad streaks of that colour, the powerful Pine apple-like odour which seems to come in clouds from a newly opened flower, these are a few of the points of interest that belong to Her Majesty's Lily. Perhaps the most astounding point of all is that of the age of the plant, it seeming incredible to non-professional people that so gigantic a plant should have grown from a seed sown about three months ago.

Anemopægma racemosum.—Attention has already been called to the beauty of this stove climbing plant under its more common name of Bignonia Chamberlayni, a representation of the flowers having been given in The Garden of last year (Vol. XXVIII., p. 431); it may now be seen finely in bloom in the Palm house at Kew, where a large specimen is trained against the roof in a sunny position, and bears dozens of many-flowered pendent racemes. Grown in this way the beauty of the flowers is displayed much better than when the plant is trained on a balloon trellis or against an upright pillar, as the flowers hang naturally downwards, just as Lapagerias do. Being a robust grower and soon covering a large space, this plant is not easily kept in health in a small house, but where there is plenty of roof-space it is one of the most useful and easiest to manage. A barrowful or two of rich loamy soil about its roots, plenty of water at all seasons except midwinter, and pruning only immediately after the flowers fade are the chief requirements of this handsome Brazilian climber. The flowers are tubular, 2 inches long, and have spreading segments coloured primrose-yellow. As many as 16 flowers are produced in a single raceme, the racemes being axillary and borne abundantly on the ripened shoots.

Dichorisandra thyrsiflora is an old, and therefore neglected, stove plant, but yet a long way superior to many newer and more favoured kinds. To grow it well, the treatment must be as generous as for Cannas, viz., large pots, a rich loamy soil—rich, that is, in good manure—and liberal supplies of water daily. It forms large fleshy tubers like those of the Yam, and pushes up numerous thick succulent stems, clothed with large, lanceolate-shining green leaves, and at the top an erect spike or thyrse of purple-blue flowers, strong stems producing spikes 9 inches long and about 3 inches through. These flowers last for several months, and in large stoves or warm conservatories they have a most beautiful effect, as may be seen in the Palm house at Kew, where over a dozen large pot specimens are distributed about the house. The stems all perish in the autumn, so that during winter the roots may be turned out of the pots and stored under a stage till spring, when they should be shaken out of the old soil, repotted, and placed in a warm moist house to grow. Any number of plants may be obtained by simply dividing the plants in spring. We commend this truly beautiful plant to all gardens in which its requirements can be met.

Ornamental Gourds as stove climbers.—Almost the whole of the roof space in the Water Lily house at Kew is devoted to a select collection of these plants, and they are just now bearing numerous fruits, some of enormous size and quaintness of form, others brilliantly and fantastically coloured, whilst others are remarkable in the structure revealed, as in the case of the Luffas, by the decay of the rind or shell, or as in the Momordicas, by the bursting and twisting back of the divisions of the fruit. It would be difficult to find any collection of plants more attractive to the thousands who daily visit Kew than these Gourds are, and after seeing them there one wonders how such striking and often highly ornamental plants are passed over by growers of stove plants. Most of them grow and fruit as freely as Cucumbers under precisely the same conditions in which Cucumbers delight, and they may be raised from seeds in spring and grown into fruiting plants in a very short time. The Water Lily house at Kew is rendered specially attractive by these plants, and by the Allamandas, Hedychiums, Cannas, and last, but not least, the beautiful Water Lilies, all of which are now flowering freely. In our opinion the appearance of this house just now is better than anything we have seen at Kew for a long time.

The Exacums at Kew are still beautiful, notwithstanding that it is over three months since we noted their being in flower. Of course, E. macranthum is so far the best of the kinds seen in cultivation, though we learn that there are several others which are even better than this, and of which Kew possesses young plants. Now that we have secured a place for this plant in gardens, it ought not to be allowed to disappear again, for we have no stove plant that could fill its place; indeed, the only rival we can think of is Lisianthus Russellianus, which, however, is almost hopeless as a garden plant on account of its wretched constitution. E. affine, the pretty little species from Socotra, if not the equal of the Ceylon Gentian, as E. macranthum is called, is still a worthy little annual, but one wants to see a group of it before one can properly appreciate its beauty. If some of the nurserymen into whose hands E. macranthum has fallen can only succeed in making it produce seeds, then the difficulty of preserving it is solved, but even if they fail to do this cuttings put in at the proper time always answer the same purpose at Kew, and in Ceylon and India the plant is as common as Chicory is with us, so that seeds ought to be easily procured from thence.

Aristolochia elegans.—The plate of this plant recently published in The Garden was made from specimens imported by Mr. Bull from Rio, and, curiously enough, about the same time as Mr. Bull obtained his plants it was also sent to Kew by a Brazilian botanist, who claimed to have introduced it from the interior into Rio, where it at once became a popular garden plant. So beautiful and easily grown a climber, and one which has the pleasing characteristic of not possessing a disgusting odour so general in plants of this genus, is almost certain to take a foremost place among garden plants here. It is easily grown too, wanting only warm greenhouse treatment, plenty of moisture, a light rich soil, and a balloon trellis to grow upon, or it may be trained along wires in small houses. The shell-like form and rich markings of the flowers are exceptionally choice. Melastoma, or black-mouthed, was the name proposed for it by its discoverer, and the black velvety centre of the flower is surrounded by a delicate reticulation of the same colour on a yellowish ground. One of the Kew plants is now in bloom, and is apparently a larger flowered form than that possessed by Mr. Bull.

Clematis coccinea.—We have seen varieties of this plant which were so poor both in colour and size of flower, as to injure the reputation of what is in its best form one of the most distinct and beautiful of all hardy climbers. One of the very best varieties both in respect of colour and growth is now in flower against a sunny wall at Kew. Possibly the favourable position in which it is growing has something to do with the excellence of the flowers—full sunshine all day, its roots in a rich, well-drained border, and its shoots clinging to a few Pea sticks (nailed against the wall this plant is robbed of half its charms) being no doubt what this Clematis likes. The leaves are perfect, a good healthy dark green, and the flowers over 1 inch long and coloured a rich blood-red, the yellow edges of the four slightly recurved segments showing like what we call the facings in a soldier's uniform. A dozen strong roots of this Clematis planted in a warm sunny border, and the shoots allowed to twine about a few stout Pea sticks, would form a beautiful specimen; and if one were fortunate enough to obtain a dozen or so of so fine a variety as this one at Kew, the picture they would represent when in full flower would be exceptionally attractive. We suspect that this graceful and pretty climber has lost caste in some good gardens through being represented by inferior varieties.

Dipladenia Harrisi — From Mr. Latham, curator of the Botanic Gardens, Birmingham, we have received a beautiful flowering branch of this rare Dipladenia, rare, we imagine, because of its seldom flowering under cultivation, although we have met with the plant growing along rafters or up pillars in stoves, its large, bright green leaves being in themselves attractive. Mr. Latham has, however, succeeded in flowering his plant, and so strikingly handsome and distinct are the flowers he sends us, that if this species could be bloomed as freely as the other garden kinds, it would surely take a prominent position among stove climbers. D. Harrisi was introduced by Messrs. Veitch, and flowered by them in September, 1854. Purdie, the collector, who found it in Trinidad, says: "This fine plant is not surpassed by any one of its congeners, whether we consider the size, and beauty, and fragrance of its flowers of metallic lustre, or its entire habit." We have better Dipladenias now, perhaps, than Purdie knew, but, without making comparisons, D. Harrisi claims attention as a rich yellow-flowered species, the blooms being like those of Allamanda Hendersoni in size and form, and, in addition to their yellow colour, they are blotched and striped with red. They are produced

on the ends of the shoots in crowded axillary racemes, the shoots being vigorous, smooth, and twining, and the foliage 1 foot or more long, by about 5 inches wide. It requires a stove temperature, but we should be glad to get details as to treatment from Mr. Latham. It may be added that although known generally as a Dipladenia, this species belongs really to the genus Odontadenia, of which eighteen kinds are known, all showy flowered, and all natives of South America and the West Indies. The difference between these two genera resides in the curiously toothed stigmatic cup of the Odontadenia.

Ferns.

FERNS AND THEIR VARIETIES.

Having paid a good deal of attention to Ferns—British and exotic—for many years, perhaps I may be allowed to say a word in connection with the controversy now going on in The Garden relating to them. Before Moore published his "Nature-printed Ferns," folio and 8vo, now about thirty years ago, few varieties of Ferns were known to exist. The publication of these works created an interest in them, and led many to devote their leisure to searching for and cultivating them. A little later Lowe's well known "British Ferns and their Varieties" appeared, and more recently still the valuable series of folio nature-printed plates, with descriptive notes, by Colonel Jones, of Clifton, an enthusiastic and accurate observer. The names of Fern admirers published in these works show the amount of interest taken in the subject. Without these publications the vast majority of collectors would have remained unknown to each other. The intercourse thereby created of course tended much to increase the taste for these plants. For many years past I have been collecting all the works on Ferns that I could hear of, but I can find no reference to any similar work, or even pamphlet, in any foreign country whatever. If such exist I shall be glad to hear of them. Professional collectors, too, were stimulated by the high prices occasionally given for new sorts. I was informed that as much as £80 was paid for a single plant (the whole stock) of a crested variety of Polystichum when the rage for Ferns was at its height.

Were the subject taken up in any other country, I do not see why similar results should not be obtained. A Wollaston, a Jones, a Lowe, or a Barnes would, I am sure, be equally successful in the discovery of varieties abroad as they have been in this country. The finding of varieties worth cultivating is not so easy a matter as "G." seems to imagine. He says "enormous quantities can be gathered wild any day in a good Fern locality." One of our best Fern hunters in England told me that if he found three good sorts in a day's hunt, he considered himself fortunate. No doubt many varieties have been found wild from first to last, but that is the result of many years' work by a large number of collectors. Many of the hardy varieties in cultivation have had a garden origin, as "G." says, but varieties of tender Ferns have also been garden-bred, though necessarily to a much more limited extent. The varieties of Adiantum cuneatum and Capillus-veneris may be quoted as examples of tendency to sport.

Several years ago, when on a visit to Pau and Biarritz, I found, under unfavourable circumstances, as many varieties as I ever found in the same space of time in this country. From New Zealand a living plant of crested Lomaria alpina was sent me some time ago, and my correspondent there speaks of other varieties of Ferns which he possesses. This was in reply to my inquiry as to varieties, he previously having paid them no attention. I have also crested Woodwardia from the Azores, a curious form of Polypodium vulgare from British Columbia, several varieties from the Cape of Good Hope, besides a stray one occasionally from other quarters. "G." draws his inferences from herbarium specimens only; Mr. Syme, on the other hand, from actual observation in their native habitats. To "G.'s" theory of "climatic change" going on in this country, and thus accounting for abnormalities, I attach no importance. The Nephrolepis exaltata referred to be Mr. Syme is probably the same as I received a fragment of, some years ago, from a private garden in the Azores, as it was said to be originally from Jamaica. Being a lovely variety, I tried in vain to get a living plant; and it would be a boon to cultivators could it be procured from Jamaica.

The conclusion at which I arrive as to the paucity of exotic varieties in our herbaria is simply from the want of interest taken in them abroad; Mr. Syme's experience goes to prove this. Perhaps other collectors who have had the opportunity and an eye to varieties will give us the result of their observations. P. Neill Fraser.

Murrayfield, Edinburgh.

TASSELLED AND CRESTED FERNS.

In reply to "G." (p. 140), allow me to say that I never doubted the existence under cultivation in Britain of many more abnormal forms of British than of foreign Ferns. I merely doubted, and still doubt, the correctness of the statement that British Ferns in habitat are more prone to vary than exotic species. I have already named and partly described several abnormal forms, of a well established character, of exotic species which "G." has not yet seen. By thus particularly naming these, and by general references to numerous other forms of a less fixed and, consequently, of a less interesting character which I had seen abroad, I had hoped to show, first, that at least so many existed outside of Britain and altogether unknown to "G.," and, secondly, to account in some measure for the almost complete absence of specimens of such and similar abnormities from the State and other large herbaria in Britain accessible to "G." I have to mention in this connection one or two other Fern abnormities of decided character which it was my fortune to discover in a small tropical area, but before doing so I must ask "G." to consider that the forms specially and generally referred to in my last paper, with one or two exceptions, were discovered and brought to light, so to speak, by one collector. It cannot for a second be credited that I am the only Fern gatherer among thousands in the wide tropical world who has discovered abnormities of the kind referred to. I would suggest that "G." should enquire of such collectors as Nock, of Ceylon, and Jenman, of Demerara, who have made excellent use of their eyes, if they in their extensive Fern hunting in the Tropics have not come across many Fern abnormities. Their herbaria may not contain any, and if so, I prefer to believe that it is because, like me, they have not considered such to be of much botanical interest. In this we may be greatly to blame, and to make amends, personally, I am prepared to introduce and furnish "G." with living plants of all the varieties I have named, and others not yet mentioned, on condition that he agrees to meet the cost. "G." says "Mr. Syme states that many Indian Ferns vary as much as our common Hart's-tongue," but that is not strictly correct; I never made such a statement. The only crested, simple-fronded exotic Ferns known to "G." are Microsorium irioides, Asplenium palmatum, and Niphobolus Lingua. I should have mentioned in my last paper that I discovered in Jamaica a large growth of Acrostichum latifolium, every frond of which was broadly crested. I detached about a dozen pieces, which I afterwards established in pots, and, if my memory serves me rightly, one or two were subsequently despatched to Kew, where they may now be. Some were distributed among cultivators in Jamaica, and the balance I left in the botanic garden there. I also found on a tree in the mountains there several plants of A. squamosum, with the majority of their fronds shortly forked. Forked fronds of other species of Acrostichum and of Tænitis and Antrophyum, also of several of the simple-leaved species of Polypodium, were frequently met with. To me this forking of simple-leaved Ferns seemed in a sense much more natural than the sporting in the same way on the part of highly decompound species. It may be remarked that some of the species of Stag's-horn and Filmy Ferns represent as regards their fronds initial development from the simple to the compound, and may be compared morphologically with the less normal crested and simply forked variations above referred to, as well as with similar familiar forms of our Hart's-tongue.

I am asked to supply a list of the forked, tasselled, and crested forms of exotic Ferns with which I am acquainted. This, I regret to say, I am not at present prepared to do, my more immediate purpose and desire being to furnish a list of such forms as are altogether unknown to "G." This list comprises one more form which I had overlooked. It was a most regularly-tasselled plant of either Nephrolepis acuta or N. exaltata. Taking this list for what it represents, I may be allowed to suggest that were the hundreds of enthusiastic Fern collectors in the tropical field to supply "G." with lists of the Fern abnormities which they have seen, the sum total would perhaps greatly change and widen his views.

A not less interesting list would be one enumerating all the forked, tasselled, and crested forms of British species known to have been found in habitat only, in contradistinction to those raised under cultivation. Possessed of such a list, others besides "G." might be prompted to speculate, and even generalise, on the causes which lead up to abnormal variation in Ferns, as well as on the disproportionate amount of such variation, if, as has been stated by "G.," it exists in the case of British as against exotic species. Geo. Syme.

VIEW IN THE PALM HOUSE AT LEHENHOF.

This is a view of Mr. Otto Forster's very interesting garden at Lehenhof, alluded to in M. Max Leichtlin's note in The Garden (p. 116). We have not seen the place ourselves, but from the views sent by Mr. Forster we cannot help being interested in it, and in the natural and artistic disposition of its contents.

Bracken, or Brake Fern.—Abundant as is this Fern on heath and moor, yet its beauty is so great and its habit of growth so distinct, that it may often find a genial welcome in the garden. Now and then a house is built on a breezy hill, and if the Brake is allowed to live on here and there, among the Gorse and Heather, the result gained is often better than that obtained by the "choke-muddle" planting of the kind but too usual around a new house. Besides, while it is easy to leave a good breadth or two of Bracken where it exists naturally, it is not so easy to introduce it where it does not already exist, or to replace it where it has once become destroyed. The best plan of introducing Brake Fern to the garden is to dig up whole sods of loam or peat wherever this Fern grows, and to bury them and the rhizomes they contain like a floor wherever you want the Fern to grow. Any other plan of transplanting is sure to be more or less of a failure. Travellers are often surprised to meet with this native Fern abroad nearly everywhere, for it is distributed widely in both hemispheres. It forms a favourite cover for the tiger in the Malayan Peninsula, for the bear of the north of Europe and Asia, and for the pheasants of Northern India and China, just as it does for the dappled deer in our own parks at home. I saw it luxuriant on the tops of mountains in Johore, while lower down, some species of Gleichenia, closely resembling it in habit, seemed to supply its place. A peat-bed of Brake Fern, Heaths, and Lilies intervening is a pretty sight just now.—F. W. B.

Indoor Garden.

PLANTS FOR WINTER FLOWERING.

Those desirous of having a good supply of flowers during the dark days of winter must now endeavour to have their stock of plants for that purpose in as forward a condition as possible, as upon making the most of the hours of sunshine depends the amount of success that will attend their efforts when artificial heat has to be resorted to. There is no lack of plants that either flower naturally during winter, or that may be induced to do so by careful management. Amongst the most reliable we have yet tried may be mentioned the following, viz.: Abutilons—these are most floriferous in character; in fact, they will flower without intermission the year round; but those for winter we divest of all blooms about this date, give a shift into a size larger pot, or some top-dressing, and then they start away with renewed vigour. We find none to equal Boule de Neige, but in order to give a little variety in the way of colour, we grow Thompsoni and a few other mixed coloured ones. Bouvardias are indispensable; we grow cuttings of them on during the summer, and after the bloom is cut off they are dried off like Fuchsias, and in spring are introduced into gentle heat, and as soon as fairly started the old soil is shaken away from them. They are then repotted and replaced in warmth until well rooted, when they are transferred to cold frames and finally fully exposed. These make finer bushes than plants grown on from cuttings in one year. They do well in a temperature of about 55°, which is a safe medium for the majority of winter-flowering plants. Arum Lilies for winter or spring are planted out now in a partially shaded position; next month they are lifted and the most forward amongst them are placed in heat to get the flower-spathes expanded by Christmas. Tree Carnations are amongst the best winter flowers for button-hole bouquets that can be grown. Spring-struck plants are now in 5-inch pots, standing on a coal-ash bed fully exposed to sunshine. Thus treated they produce a long succession of flowers. A good sound loam and a little leaf-soil and sharp sand suit them as far as soil is concerned. Chrysanthemums are every year becoming more popular; for the mid-winter supply the latest flowering sorts should be grown, such as Ethel, Meg Merrilies, &c. They must be kept out of doors as long as the weather will permit, and, when placed under glass, a cool orchard house is the best place for them. Eupatoriums are of the easiest culture, and flower most profusely in a heat of 50°. We have some planted out and others in 6-inch and 7-inch pots, and by introducing a few into heat from a cold house at intervals of a fortnight, we get a succession of their white feathery bloom from October to March, when they are cut down close and kept cool and rather dry for a short period. Pelargoniums of the zonal kinds rank amongst the brightest of winter flowers; our stock for the season is now in 6-inch pots in an open sunny position; all blooms are kept pinched off them until September, when they are set on shelves near the glass. Under this treatment any free-flowering kind of the Vesuvius type does well. Roman Hyacinths are being potted or put thickly in boxes for supplying cut flowers. Any rich light soil suits them. We cover the pots or boxes with ashes until they begin to grow, when they are transferred to heat as wanted. Primulas, both single and double, are now in frames set on a coal-ash bed; they will be transferred to stages in the greenhouse next month. The old double white is still one of the best for button-hole bouquets, and the single varieties are most useful for indoor decoration. Careful watering is necessary, and the blooms should not be picked off until next month. Our Tea Roses are now being repotted and set in a sunny position out of doors. They soon start into growth, and when placed under glass produce grand buds for several weeks. Of whites, Niphetos is one of the best. Violets now claim a good deal of attention. The late rains have started them freely into growth, and the single kinds in beds now cover the ground with fine large foliage. Double-flowered kinds for frame or pot culture require the runners to be cut off frequently and the soil surface-stirred to keep down weeds. Red spider is the worst enemy Violets have, but a free use of the watering-pot will keep it in check. Miscellaneous subjects for winter include Helleborus niger and similar plants that, although hardy, are grateful for the shelter which glass affords their delicate flowers, and if we would have fine ones in quantity, now is the time to promote a healthy growth of the foliage, for on the maturation of that depends the quantity of flowers which we will get.

RAISING TUBEROUS BEGONIA SEEDS.

When I first began raising seedling Begonias, I used to sow the seed early in spring and bring on the young plants in heat, but as I required a good number for bedding purposes, I found that they occupied a good deal of room at a time when space under glass was valuable, and that induced me to alter my plans. I now sow the seed as soon as it is ripe, a plan which I find answers best. I save my own seeds and watch for the first ripening pods, so as to secure them before the pods burst, and scatter the seeds. On plants brought on in a warm greenhouse in spring the seed is generally ripe early in August, and, if sown at once, I find it to vegetate much sooner than when kept to the following spring. I fill a rather large pan with fine sandy soil and well water it before sowing; I then sow the seed and cover it with silver sand. A square of glass is put over the pan, which is then taken to a warm house, where it is shaded from bright sunshine. In about ten days the seedlings appear, and the glass is then removed, and the pan brought out so as to give them more light. Watering to keep the soil moist is, of course, done with great care, which is all the attention they require. About the middle of October the pan is taken to the stove, in which there is more warmth. By this time the plants will be growing nicely, and the additional warmth keeps them growing until about the end of the year, when the leaves begin to get yellow, and the plants go to rest. Water is then withheld, and the pans placed out of the way of drip on the floor of a cool house, where they remain all winter. It is useless attempting to hurry the little bulbs into growth in spring; they will rest their own time, even if subjected to a high temperature. I therefore allow them to remain undisturbed until early in May in a cold frame. A bed of soil is made up to receive them. As the roots must be well nourished the soil should be fairly rich, and they do not object to a little well-rotted manure placed 3 inches under the surface, but fresh manure is fatal to these Begonias; altogether there should not be less than 4 inches of soil and manure. I turn out the pan of soil into a closely-meshed sieve; then, by means of rubbing, the earth is separated from the bulbs, which are left free and clean in the sieve. The bulbs are then sorted into two sizes, the largest generally being about the size of a Hazel nut. These are planted 6 inches apart each way, and the small ones 4 inches. The crown of the bulb is kept about half an inch under the surface; no water is given them until they begin

to show their young leaves; the lights are of course put on the frame, and attention to air-giving is also a part of the details of management. Careful watering is a very important matter, for if the soil is kept too moist the roots will make but slow progress. As the young growth gains strength more air must be admitted, and in bright weather a little shading is desirable to prevent the soil from being quickly dried up. In a general way the lights may be removed altogether from the strongest plants about the middle of July, and from the others a fortnight later, as they gain strength faster by being fully exposed to the air than they do when drawn up under glass. There are two advantages belonging to planting them in a bed of soil. The first is less trouble as regards management, and the other is that much larger bulbs are obtained than when confined to pots. The plants soon commence to flower after they start into growth, and as the blooms expand, we mark such as we think suitable for any particular purpose. For bedding I prefer those with short sturdy growth that have red or crimson flowers, and I select those as much as possible that have erect flowers; those, however, with drooping blooms are not to be despised, for they flower with greater freedom than the others. If the lights are left off during autumn, the plants will go to rest in their own way; but not until all the stems have died down should the bulbs be taken up. We keep our bulbs for bedding in a cool shed where frost cannot reach them. A heated structure is fatal to them. With regard to treatment in spring for bedding, I could not wish for better results than have been obtained by planting the bulbs in a bed of good soil in a cold frame early in April, and transferring them to the beds at the end of May. At first we give them no water in the frame, and no air is admitted until the leaves appear, when both air and moisture are given, the amount of air being increased as the season advances. During the last fortnight the lights are drawn off during the day altogether. At night they are covered with mats to protect the young growth from frost. At bedding-out time we lift them with a fork, place them on a hand-barrow, and carry them to the bed in which they are to be planted. Begonias thus treated feel their removal but little, and are generally in full flower before Pelargoniums put out at the same time, and when in blossom they stand wind and rain better than the majority of summer bedders. J. C. C.

Malpighia coccifera.—This is a stove plant which bears at this season of the year a profusion of singular, but pretty flowers. They are blush in colour and emit a pleasant odour. The leaves are small, neat, and firm, and bear on their margins small bristles, which in some species have the power of stinging, as in M. urens, the Barbadoes Cherry. It has no objection to being placed in dark corners beneath other plants; in short, it is one of those plants which can be pushed aside when it has finished flowering until it requires to be placed in a more prominent position. It thrives well in equal parts of loam and peat with some good sharp sand for drainage.—W. H.

SHORT NOTES—INDOOR.

Impatiens Hawkeri.—Judging this new plant by the specimen which I saw the other day at South Kensington, I do not hesitate to predict that it will prove as valuable as it is beautiful. It far surpasses in brilliancy that of the now well known I. Sultani.—G.

The blue Throat-wort (Trachelium cæruleum).—This was shown the other day at Southampton as a pot plant in grand condition by Mr. Molyneux. It is well deserving attention as an autumn flowering plant.—W. H. G.

Didiscus cæruleus (Trachymene cærulea) is an annual not worth growing as a border plant, as it always has a shabby look when planted out, but for pots it is altogether the other way. The flowers are light blue, a colour somewhat rare amongst umbelliferous plants, and its native country is Australia. The seeds should be sown in gentle heat in February, and as soon as ready to handle the young plants should be pricked off into 6-inch pots, about six or eight in a pot, in a compost of loam, leaf-mould, and sand. As soon as frost is over place them in a cool frame, where they can remain until wanted.—W. H.

Centaureas from seed.—When Centaureas are about to be stored for the winter, it is a good plan to select such as are most straggling for seeding purposes; when employed in this way they should be divested of all rough base leaves, and also of all lateral shoots, retaining only the principal growths and such as are likely to bloom next year. To bloom Centaureas, however, and to induce them to ripen seeds are two very different things: therefore, to accomplish the latter object, every endeavour should be made to cause them to bloom early. In spring, plant them out as soon as they can be safely trusted out of doors, and carefully prevent the growth of fresh side shoots. Thus treated, they soon get into bloom, and also produce seeds, which should be gathered when ripe, kept dry for a week or two, and then rubbed out of the heads and held in readiness for sowing. If sown in September in pots or pans filled with light sandy soil, placed in a moderately warm house or pit, and covered over with a pane of glass or a bell glass, they will soon vegetate, and may then be pricked off into other pots or pans of light soil, and be left without the use of special glass coverings. After being pricked off, they should be kept throughout the winter quite close to the glass on a shelf in an intermediate house or warm greenhouse, where by spring time they will have formed fine plants, which should be potted off separately in 3-inch pots. In this way, and by placing them for a month or six weeks in an open frame before planting them out, excellent plants may be obtained for bedding purposes. It is not absolutely necessary that the seed should be sown in autumn; it may be sown any time before the end of March, but spring-sown plants, owing to being forced so much in heat, are not so hardy as those raised in autumn. The lateral shoots taken off Centaureas, to be kept for seed, should be struck as cuttings, selecting the hardest and most slender ones, and discarding such as are soft and succulent, which would be almost sure to damp off.—W.

ROSE GARDEN.

THE ROSE SEASON.

This was late this year, short, and, on the whole, not up to the average. A roseless June must absolutely result in a late season; but why Roses that hardly bloomed till the second week in July should mostly have bloomed out before the end of that month is by no means so obvious. And no doubt there have been, there are, many exceptions to this brevity of blooming, and the fortunate possessors of these will rush into print to contest our statement. Well, the more such protests the better, for they prove that the season was longer in some quarters than in others, and that the heavy rains and gleaming sunshine had failed to bring on and drive out the Roses with a rush everywhere. And then no one expects the winners of cups and of valuable prizes *ad libitum* to agree to our moderate estimate of the Rose season. And yet not a few victories were the easier won this season owing to the under average character of not a few of the Roses grown. I do not say that none of the champion prize takers reached their usual standard of superlative excellence. A few, perhaps as many as could be numbered on the fingers of one hand, did; but beyond these—I hope I may write it without offence—we plunge into mediocrity, and this not in one or two places, but in many places and many counties, from South Kensington downwards. In some cases the high estate of the Teas did a good deal to redeem the under average condition of the Perpetuals; but, on the whole, the average Rose harvest, so far as it has gone, like the coming harvest of Apples and Pears, was decidedly under average. As to the causes of this, I attribute it mainly to the incessant worrying of long-continued cold and drought throughout the spring. These little goes of frost which abounded throughout the winter, and ran almost through the spring, often do far more permanent injury to vegetable life and products than one or several old-fashioned seasonable frosts of far greater severity.

In this case they seemed to undermine the strength of the Roses without inflicting any apparent injury, and hence the majority broke weakly as well as late; and, contrary to very general experience, as the growth became more rapid, it failed to pick up lost or delayed vigour. Associated with this tendency to weakness there was an almost entire absence of aphides and insect pests. Rejoicing in this immunity, not a few of us expected that this set-off would more than compensate for the weak start and continued weakness. But it did not, though no doubt it greatly helped the Roses to produce the harvest of beauty and sweetness they have yielded us. Doubtless this almost complete immunity from insect pests would have proved of more benefit had it not been for abnormally early attacks of red rust. Absolutely this debilitating and disastrous pest was not much earlier than usual, but, relatively to the condition of the Roses, it was much earlier, and it was also more virulent. During the whole of my experience I never heard so much of the Orange fungus on Roses as this season. Complaints of its prevalence and applications for cures poured in from all directions. Persistent hand-picking of the infected leaves and the burning of the same by fire seem the only possible means of checking its ravages in its active state in summer, and it must be confessed that the remedy is nearly as bad as the disease, for defoliated Roses are almost as pitiable spectacles, and as impotent for the discharge of their vital functions, as those reddened deep with this rust-like fungus. Fortunately, the second growths are not seldom free from this pest, and thus the Roses recoup their vital force in the autumn. Mildew has been abnormally prevalent as well as the red rust, and in some places these two coloured fungi have threatened between them to make an end of the Roses. As a rule, Tea Roses are less attacked by mildew than others. But this season such smooth-leaved and vigorous growing Teas as the Gloire de Dijon have suffered as much from mildew as the roughest foliaged Perpetual or other Roses. The mildew also clings to our Roses later than usual this season. As a rule it is often drowned off them in the autumn, but at present it shows few symptoms of losing its hold or giving place to clean foliage, and unless this welcome change takes place soon, I fear the autumnal bloom will hardly be up to the average either in quantity or quality. But from these rather sombre views of the character of the Rose season and its effects we gladly turn to note a few of the Roses of the season. First and foremost among those alike in order of time and of merit must be placed Lady Mary Fitzwilliam. This has now taken rank as one of our most useful and popular Roses. Her Majesty has hardly been seen in good form throughout the season. But this is hardly to be wondered at when the recent date of its distribution in this country is taken into account, and possibly next year it may take the popular rank that its early reputation entitles it to. Princess of Wales has appeared in good form on several occasions; and Merveille de Lyon has on more than one occasion taken a first place, not only as the finest white Rose, but the best Rose in the show. This will doubtless prove welcome news to not a few who have hoped much from this Rose and have hitherto reaped a sort of semi-double disappointment. Marie Van Houtte, Etoile de Lyon, La Boule d'Or, Comtesse de Nadaillac, Madame Watteville, and Niphetos have also been specially conspicuous among Teas; Baroness Rothschild, Charles Lefebvre, Alfred Colomb, Etienne Levet, Marie Baumann, Ulrich Brunner, Violette Bouyer, Reynolds Hole, Mdme. Gabriel Luizet were among the finest Perpetuals. Like Merveille de Lyon, Mdme. Lacharme appeared among the finest white Roses of the season this year; while Edith Giffard and Jean Pernet also hold high places of honour among the whites. D. T. F.

White Rosa rugosa.—Wherever the ordinary form of this Rose grows well, the white variety should also find a place. Its large, single satiny

white blooms contrast well with those of the type, and both are equally floriferous. They bloom continuously throughout the summer months, and in autumn produce large showy fruits. The white variety is still comparatively scarce, and in the case of a few specimens of it, purchased by a friend, they had been budded on some strong-growing stock—not on the typical form—a mode of increase certainly not to be commended, as the suckers which spring up are a continual source of trouble; while in the case of a plant on its own roots, the shoots that push up from the base tend to increase the effectiveness of the specimen. In a general way, both kinds can be easily layered, and as roots are readily produced, this plan offers the most convenient method of increasing them. The common form can also be grown from seeds, but whether or not the white variety will come true in this way I cannot say, for though we have raised some they are not large enough to flower. In depth of colouring the ordinary form varies considerably, some being of a much deeper tint than that of others; indeed, there is a variety called rubra that is very deep red.—H. P.

AUTUMN ROSES.

Hybrid Perpetuals promise to bloom well this autumn; the heavy rainfalls which we have had came just in time to start them into a second growth, which in some cases is already pushing forth flower-buds. Specially noticeable in this respect are Ulrich Brunner, Beauty of Waltham, Bessie Johnson, Captain Christy, and Maurice Bernardin, while such well known Perpetuals as A. K. Williams, Boule de Neige, Charles Lefebvre, and La France have not yet been without flowers this season. La France may certainly be styled the queen of Perpetuals, for whether grown as a standard or as a dwarf bush it is a most continuous bloomer, and when on its own roots I think it is better than when on any other stock. I have another old Rose on its own roots, viz., Madame Victor Verdier, which has often surprised me by producing almost continuously during summer abundance of flowers. This is a very dark-coloured Rose in the way of Prince Camille de Rohan, but a rich satiny shade overlies the petals to a greater degree than in any other variety. Singular to say, when budded on the Manetti I could not get this Rose to make anything but the very poorest growth. I also find that many other autumn flowering Perpetuals bloom more freely on their own roots than on any stock, and as the present is a good time to ascertain which are the most continuous bloomers, it is just the time to set about striking them from cuttings. Two or three handlights or cloches are all the appliances required; mix up some sand with the soil on a border facing the east or west, and in this insert the cuttings, which should be made of the hardest portions of this season's growth. Let them be from 7 inches to 8 inches long, and bury half their length in the ground, in which they should stand 4 inches apart. Put them in very firmly, and when the space is filled give a good watering; then put on the lights and leave them to take care of themselves, except it be to see that the soil does not get too dry. In very severe weather an old mat or some other protection should be put over the lights, which about the end of May may be taken away, leaving the young plants exposed to all weathers. By the autumn they will be well rooted, and may be planted wherever they are wanted. All the cuttings may not grow, but a fair proportion will do so.

Roses will be greatly benefited by having a little attention now. The points of the shoots which flowered should be removed, and the suckers rising from such as are budded on the Manetti should be searched for and cut off below the surface. It is also a good plan at this season to loosen the surface soil over the roots. This is especially necessary in the case of heavy soils that are liable to crack. It is best done with a light fork, as it is only necessary to go about 2 inches deep. Loosening the surface in this way allows moisture to get down to the roots; whereas when hard and smooth an ordinary shower scarcely penetrates it. Only in dry soils is there much mildew on Roses at the present time, but wherever there is any, remedial measures should be resorted to at once; the leaves should be dusted with sulphur, and the roots should receive some stimulating liquid to induce the formation of new growth. Good liquid from the farmyard is doubtless the best, but house sewage will answer the purpose, and if there is nothing else, liquid guano is better than nothing at all. This may be used at the rate of an ounce of guano to a gallon of water, and each tree should receive two gallons of it weekly. Should the weather be dry during September, all Roses will be benefited by liberal supplies of water at the roots, and clear water should never be used if house sewage or farmyard liquid is to be had. Briers budded a few weeks ago should now receive attention; any growth which they may have made since the buds were inserted should now be cut back. The ties on all the most forward buds may now be loosened, but not wholly removed, and any buds that may have started into growth should be supported with a stick. Young buds are easily blown off if not made secure in this way. J. C. C.

WINTER BUTTON HOLE ROSES.

The following remarks refer specially to the production of Tea-scented Roses during the autumn and winter months to supply blooms for button holes, for it is not so well known as it should be that this section of Roses is more suitable than any other for furnishing flowers late in the year. In the first place, it is essential that suitable varieties be chosen, and these may consist of the following, viz., Devoniensis, creamy white; Catherine Mermet, rose; Elise Sauvage, pale yellow; Isabella Sprunt, white with pale yellow centre; Madame Falcot, apricot colour; Madame Lambard, bronzy red; Marie van Houtte, yellowish white; Safrano, fawn colour; David Pradel, rose; and Niphetos, white. The next point of importance to understand is the fact that, in order to furnish a good number of Roses continuously, rather large plants are necessary, as small ones only produce a limited number of blooms, and then go out of flower. The sized plants I have in view should occupy 12-inch or 16-inch pots, and, if well treated, will yield a large number of flowers at a time when Roses are scarce. If the varieties have to be provided, I would rather start with young ones than old exhausted examples that have been indifferently managed. If one could begin at once with plants in 6-inch pots that have several branches and require more root-room, one might in a year or two build up thrifty specimens. Such plants as those just alluded to should be shifted at once into 8-inch pots, choosing for compost a good fibrous loam and a moderate quantity of coarse sand. If the loam is inclined to be heavy, use one-third peat for the purpose of keeping the soil open. It is important to provide thorough drainage, but it should not be so bulky as to occupy much room in the pot. After the plants are potted let them have the shelter of a cold pit or frame, in order that they may be shaded from bright sunshine for the first ten days. After that the lights may be removed. The plants may be transferred from this pit to a cool, airy house early in September, and, except to keep them regularly supplied with water, they will not require any further attention. In all probability most of them will furnish a few flowers during the autumn. If blooms open in the cool house, well and good; but the first season they must not be subjected to any extra heat in order to cause them to open their flowers, for the plants must rest during winter preparatory to making strong growth in spring. They must have plenty of light and air in winter, and be kept from severe frosts. In the following spring a light, airy position must be found for them in a greenhouse temperature. They must not be pruned, unless it be to shorten back to half their length any long, strong shoots. If pruned like Hybrid Perpetuals, they will be many years before they attain a good size.

Assuming that they have been managed according to the directions just given, and that a dozen plants have been prepared, a third of that number should be introduced into a house heated to about 8° higher than the temperature of an ordinary greenhouse in the middle of October; and if the others are introduced in equal numbers into the same structure at intervals of a month, a continuous supply of flowers may be obtained all winter. In future years a slight increase in the temperature during December and January may be required, but that is a point which each grower must decide according to circumstances. According to my experience, the most important part is the summer management; they must have a good rest, and they must not be disturbed at the roots during the summer or autumn. If they want larger pots or top-dressing, it should be done early in May, so that the roots may have plenty of time to get established in the new soil before they are turned out of doors. As to resting, they must be taken out of the house about the middle of June, and the best place for them during summer is a warm, sunny border facing the south. They must stand on a hard bottom, for both the roots and the branches require the fullest exposure. Any flower-buds they may have on them must be picked off, and only just enough water should be given to keep the roots right. If the latter are kept quiet, the cultivator may hope to see the young growth hardened up to the colour of mahogany in the autumn, and then he may rest satisfied that it is in a proper condition for flowering in winter. As autumn approaches they will start into growth again at their own time, and, if desired, all of them will be bristling with flower-buds early in October; but such plants as are to be reserved to flower late should have all the most prominent buds removed, and be left out of doors until the middle of November, *i.e.*, if there is no frost to injure them. The others should be taken under cover earlier. With regard to soil and potting, I have already described the kind of compost most suitable for Tea Roses in pots; but, as to repotting, I can only say the cultivator must to some extent use his own judgment. As the object is to get large plants, they will want more root room for the first three years than they will after that time. As soon as they have filled the 8-inch pots with roots, they may be shifted into 10-inch ones; but as soon as they get into 12-inch ones, or others of larger sizes, the roots will not require anything done to them except a rich surface-dressing, say once in two years. When it is considered necessary to give them a change of soil, that should be done in May. About two-thirds of the old material should be removed from the roots, and the new compost must be firmly rammed round the old ball. They will not require top-dressing the same year in which they have been repotted—only in subsequent years, when nothing has been done to them. In order to give them a substantial top-dressing, 2 inches of the old soil should be taken off the ball, and its place supplied with a mixture of half loam and half well-rotted hotbed manure, well rammed down on the old soil. With respect to pruning, they will not want much of that until they get as large as they are required to be; then they may have the old flowering branches cut back a little every year; but, as I have said, until they get large plants, only the long and strong shoots should be shortened back; and as regards training, they will want an occasional stake for support, but the less contortions to which branches are subjected the better.

C. J.

Netley Fort, Hamble.—Here may be found some giant Arbutuses, which thrive admirably by the sea; these and other notable specimens growing here have been carefully preserved and encouraged to display their proportions to the greatest advantage. On the lawn in the vicinity of the mansion are gay carpet and other beds, but the object aimed at throughout the grounds generally is to produce a rich and varied wild garden, only as much labour being bestowed upon it as will show everything in as natural a state as possible. Lilies will soon be a prominent feature here, and also Olearia Haasti, which seems to be a good seaside plant. Handsome specimens of Cedrus atlantica may be found here. Besides the pleasure grounds there is a walled-in kitchen garden, the central borders of which are devoted to good herbaceous plants, Roses, &c., the produce of which is used in the form of cut bloom.—W. H. G.

Kitchen Garden.

STAKING BEANS AND PEAS.

Much unnecessary trouble is often gone to in this direction; at any rate, such is my impression, and experience confirms it. I will not go so far as to say that half of the Beans and Peas grown in gardens would do equally well without staking, but I am fully convinced that a large proportion would succeed without that attention. I am not now speaking of what are recognised as dwarf varieties, but of such as grow to an average height when staked. A good deal depends on whether the season is wet or dry, and especially the situation and character of the land upon which the crop is grown. Here both soil and subsoil are comparatively porous; therefore they do not long retain moisture and the situation is high. The conclusion I have come to is, shortly, that for the earlier Peas, which may be expected to grow, say, a yard in height, it is decidedly best to use stakes, but that for the later crops, except such as grow to a great height, their use is unnecessary. In early spring, when the soil is cold and moist, it is perfectly reasonable that the young plants will grow to greater perfection when supported and, to some extent, sheltered by stakes, but as the season advances they do equally well without any attempt at staking. A day or two since I had occasion to be amongst some Peas which were grown without stakes, and they were certainly more fruitful than others growing in a similar situation, but held up to bleach by sun and wind. With a succulent vegetable like a Pea I take it this bleaching and drying process is just the thing to avoid, and it can be avoided by allowing the crop to mature under the protection of its foliage and in proximity to the soil. The same thing applies to runner Beans. Each year I stake a portion and leave a portion to grow on without stakes, and with no attention except occasionally pinching back the runners. Last season I was especially successful in this treatment, and although it is too early this year to speak positively, present comparison is greatly in favour of Beans without stakes.

So far as I am personally concerned, except for the earliest planting of Peas, I should not hesitate to plant as many of either vegetable as was likely to be required, and grow them on without the aid of stakes. There is a greater secret in their production than stakes. These we can successfully dispense with, but manure to enrich the soil we cannot. When stakes are used, Hazel is probably the best wood for the purpose—at any rate it is the most popular. There is no need, however, to be confined to this. The wood from hedges of several years' growth will often make good staking wood. I do not mean White or Black Thorn, or spiny woods of that class, as they would be very objectionable to handle, but such as Wych Elm, Maple, and other thornless woods which are frequently found in hedges. The wood should, of course, always be cut when the leaves are off, as to use stakes with the dead foliage upon them is both awkward and untidy. This can be overcome by cutting off the small branches upon which the leaves grow, but it is never satisfactory. D.

Late crops of Scarlet Runners.—We find it a good plan to sow a late crop of Scarlet Runners about the beginning of June, and if nearer the middle than the beginning of the month, so much the better. This crop we find comes in admirably when that sown early is on the wane; and this late sowing also produces larger and more tender Beans than the produce of plants which have become exhausted through long bearing. In our case the early crop gets so much injured in autumn by rough winds, owing to the heaviness of the growth on the top of the stakes, that it is frequently useless; but that sown later, owing to its not being so top-heavy, escapes serious injury. If I had to deal with a poor soil, and not overburdened with manure, I should always prepare trenches for Scarlet Runners the same as for Celery; and what manure I could spare I would put in the bottom of the trench. By adopting this plan, the plants would get the whole benefit of the manure, and in dry weather, if water is poured into the trench, but little of it would run to waste. No kitchen garden crop pays better for watering than Scarlet Runners. Those who plant runners in ordinary drills should, after they have watered them, put a thick layer of half-rotten manure over the roots on each side of the row. This can be drawn aside when more water is given.—J. C. C.

SOWING SPRING CAULIFLOWERS.

Where there is no glass, Cauliflower seeds should be sown between the 20th and the 30th of August. A date intermediate between the two just named suits us here very well, but seasons vary, and of local conditions and circumstances note should also be taken. When sown too early, if the winter should turn out mild, many of the plants will button prematurely and be useless. I should, therefore, recommend waiting a day or two rather than sow too early. Sow thinly in drills, and transplant to the south side of a thick hedge as soon as the plants are large enough to handle safely. A stout Thorn or Yew hedge is better than a wall as regards protection, as it shelters without forcing the plants in any way. Plants growing at the foot of a south wall may, in cold, bright weather in winter be injured by the refraction of the sun's warmth from the wall, but the temperature at the foot of a hedge would be steady and as genial as the case required, especially when sheltered by a few Fern fronds or evergreen branches. The alternate thawing and freezing of young plants at the foot of a south wall often has an injurious effect.

Those who have a glazed frame or two to spare may delay sowing till the middle of September, and there will then be little danger of their bolting. The plants, too, when large enough to handle may be transplanted into other frames to pass the winter, and be planted on a south border in March. The warmth of the south border when steady and progressive in early spring is of real help in forwarding early crops.

Where artificial heat can be had regular and moderate from Christmas onwards, there is no particular occasion to sow Cauliflower seeds before the new year. I have sown them in frames in a night temperature of from 50° to 60°, pricked them off when large enough to handle singly into small pots, grown them on shelves near the glass, and planted them out in March and April, according to the character of the season and the means of shelter available, and have cut Cauliflowers from the forced plants before those sown in August in the old way were ready. The trouble, too, is but little when there is space under glass. The space occupied by 500 or 1000 little pots is not much.

E. Hobday.

Tomato Wonder of Italy.—In The Garden (p. 51) is published the result of the Tomato trials made at the Ohio Experimental Station, at the end of which the compiler states that "the Tomato Wonder of Italy" (introduced by our firm) "is small and worthless." As far as mere size is concerned, we agree with him, the fruit being pear-shaped and from 2 inches to 2½ inches long. We, however, disagree entirely with him as to its being worthless. On the contrary, it is not only not worthless, but highly valuable. Were it not valuable, hundreds of acres in the environs of Naples, for which a high rent is paid, would not be annually cropped with it. In fact, Wonder of Italy is one of the most productive of Tomatoes, an average crop of it being about 35 tons per acre [?] It must therefore, we think, be admitted that a variety producing such crops cannot be quite worthless. Either it has not been tried fairly or the variety has not been true to name. Its fruit is all one mass of flesh with but few seeds, a circumstance which makes it valuable for conserves. This Tomato is very early, and does not suffer from those diseases to which other varieties are subject. It is also dwarf. It is true that, owing to its belonging to the small-fruited class, it is not so good as some others for table use, but for conserves it is, as we have said, excellent.—Dammann & Co., *Naples*.

VEGETABLES AND THE SEASON.

In March and April vegetables were very backward and most unpromising, but they progressed wonderfully in June and July, and of late I have seen more really good vegetables exhibited than I ever remember having seen before at this season. Carrots, Turnips, Potatoes, and roots generally are unusually fine, and Cauliflowers, Cabbages, and other greens are luxuriant and abundant. Onions were very late in beginning to bulb, but they have done wonders since they began, and spring-sown bulbs 12 inches in circumference are now plentiful. As to autumn-sown Onions, I never saw them finer. A dozen bulbs shown from here, to which a first prize was awarded at Cardiff last week, weighed 16 lbs., and they were solid and well formed. There were many complaints in the early summer months respecting the deficiency of vegetables, but there is no lack of them now, and they promise to be unusually plentiful throughout the autumn.

I cannot remember the time when, in the middle of August, there were no instances of Potato disease, but as yet I have not seen a diseased Potato. Crops of this esculent are very good indeed, the tubers being abundant, large in size, and fine in quality. Wet weather might bring disease amongst the late crops, but early ones are now out of danger, and the sooner they are dug up and harvested now the better. When matured they are not apt to become diseased if left in the ground, but, at the same time, they are better under protection; we are therefore pushing on with the storing of our crops as fast as the weather will allow us.

Runner Beans are always preferred to the dwarf varieties, and as soon as they can be obtained the demand for such sorts as Canadian Wonder ceases. But runners are now producing pods in such quantities, that it is almost impossible to use them as fast as they become ready, especially where no marketing is done, and if the old pods are allowed to remain on them after they become too old for use, they will soon cause the young ones to cease forming. Nothing brings Beans to a standstill quicker than this, and therefore whenever a long succession of tender young pods is desired from one row or a small space, the pods should all be gathered as soon as they become fit for use. It would be better to gather and throw them away than allow them to remain and terminate the pod-bearing properties of the plants. We often hear of Kidney Beans being very prolific for a time and then suddenly becoming unfruitful; the cause of this may easily be found in the clusters of overgrown fruit seen on the plants. A short time ago a row of our Sweet Peas ceased flowering when the plants were covered with seed-pods. These were all gathered and the plants are again in full flower, and this is what happens in the case of all Beans and Peas which are allowed to carry quantities of matured pods. Where late rows of Kidney Beans are grown these will keep up a supply during September and October; but where the August-bearing plants are expected to produce tender young pods during the months named, do not on any account allow old pods to remain on them.

Yellow Turnips are greater favourites in the north than in the south, but they have much to recommend them everywhere; they are very hardy, they succeed well sown late, and bulb freely in October and November. They bear severe weather better than any of the white ones, and they are always tender and well flavoured. Their colour is the only point that is supposed to be against them, and that is nothing. We have known some cooks to refuse all Turnips but white-fleshed ones; others, on

the contrary, were always pleased to have yellow ones, especially in winter, and I would advise all who desire to have a good supply of Turnips from October until April to at once sow a large quarter of the Orange Jelly variety. There is now plenty of vacant ground from which Potatoes and other crops have been recently removed, and a portion of such ground may very profitably be devoted to yellow Turnips.

Margam, Port Talbot. J. Muir.

The Celery fly.—There seems to be no cure for this troublesome pest beyond the somewhat drastic one of stamping it out by destroying the crop, or, at least, seriously injuring it by picking off and burning the leaves containing the maggot. I think, however, that its appearance may be prevented if taken in time and the plants are dressed with something to make them distasteful to it, but to be effectual it should be applied before the eggs are laid. Syringing the rows with soapsuds and dusting the plants afterwards with soot will generally keep the fly at a distance, especially if repeated once or twice during the time when it is depositing its eggs. Then a solution of Gishurst compound may be used instead of soapsuds, and tobacco powder instead of soot as alternative treatment. In neither case is the expense or trouble very great, and all the ingredients have some manurial value. The eggs are laid by puncturing the leaves, which, as the grubs grow, appear to be blistered, and when the grubs have attained full size they descend to the earth, where they remain in the chrysalis state till the following spring. They then are transformed into the perfect insect. Being encased within the folds of the leaf, there seems to be no means of getting at them with either washes or powders, but if the plants are made distasteful in the way suggested, the eggs will not be deposited. —E. Hobday.

Dwarf French Beans.—One of the finest and most prolific of dwarf Beans is the Long-podded Negro. So much has been said from time to time in favour of Canadian Wonder, and it has become so popular for show purposes, that it has largely ousted other kinds; still if cultivators will get a true stock of the Long-podded Negro and grow it, they will not be in a hurry henceforth to grow Canadian Wonder. The growth of Negro is robust, and the pods are long, straight, and handsome, and produced in great profusion. In dwarf Beans we want something more than show pods; we want flavour, tenderness, and, not least, prolificacy, and these will be found in the Long-podded Negro. I notice that in one seed list this kind is termed "Monster, Long-podded." The first appellation is both superfluous and misleading, as there is nothing of the monster whatever about even the finest dwarf French Beans, and such terms are misapplied. We have quite a score of kinds of dwarf Beans under name, but after all the differences among them are but slight. Three or four kinds will suffice for any garden. Some one kind gets more favoured for forcing than others, but so much depends upon the facility with which the blooms set in heat, that ofttimes success or failure is more due to treatment than to sorts. One good all-round kind very often answers well in all cases.—A. D.

SHORT NOTES.—KITCHEN.

Wilson's Royal Ashtop Potato.—I have for six weeks past been lifting what may be justly termed the prince of all Ashtop Potatoes, and this day I felt curious to know the turn-out per acre. I find, by careful measurement, it amounts to 9 tons, 5 cwt. 3 lbs. I am growing a few true old Ashtop, which is said to be better in quality. It need be, as the turn-out is ridiculously small compared with that of the one under notice. I have sent you a few as a sample.—R. Gilbert, *Burghley.*

*** The Potatoes sent by Mr. Gilbert were a very good and even sample, and the flavour—the only thing, we think, of much importance—was excellent—an old-fashioned kind of flavour, if anybody will understand what we mean by that. —Ed.

VEGETABLE MARROWS.

The Vegetable Marrow classes at exhibitions show that no one kind is favoured more than another, as is the case with most other vegetables. At a recent show at which I was engaged as judge I found twenty-two pairs of Marrows in one class, and of these no two seemed to be exactly of the same kind. Again, if we turn to the exhibitions of garden produce from the best private gardens, long, short, round, or Custard Marrows are invariably presented, but with this difference, that only white kinds are shown, whilst cottagers have just as much regard for green or mottled kinds as for white ones. Very probably, all other things being equal, it will be found that white kinds get the preference, but that is purely a matter of fancy, as when cooked it would be difficult to discover in what respect green-skinned kinds differed from white ones. Some kinds are more prolific than others; in one respect that may be so; the smaller fruited kinds produce more than large fruited ones, but in the end the balance of actual bulk is about the same. Of course, if the fruits of the longer or larger kinds be cut whilst small, the relief given to the plants favours more abundant fertility, but the best test of any plant's productive powers is found in leaving all its produce to mature fully, and then weighing the whole at the end of the season. In the market gardens the long white is preferred, and if somewhat ribbed all the better. Still, a nice green specimen or two is not objected to, as these produce variety and give some acceptable colour to the greengrocer's window. Cut whilst the skins are tender, Marrows soon become battered and disfigured. There are few directions in which reform is more needful in connection with market garden produce than our method of packing and getting it fresh and uninjured to the consumer. Some little divergence of opinion exists amongst good vegetable judges as to the proper size or age for prize Marrows. They may be too big in some cases, but if the skin is quite tender and the fruits even and handsome, it seems unfair that small fruits should be put before larger ones. It is a common rule to allow something for size in the case of cottagers' products, for these show by their exhibits that they think quantity to be of considerable merit. When, however, such kinds as Moore's Cream or the round Pen-y-byd are presented, of course size is out of the question, and here it is really one of quality and flavour. Marrows have become very popular; they are widely grown, and they prove valuable aids to the gardener during the summer months. A. D.

Late Peas.—Rows of Ne Plus Ultra sown on May the 20th are now (August the 14th) 7 feet high; the pods at the bottom are fit to gather, and higher up are younger pods and blossoms innumerable. This Pea, in my opinion, has no superior during this month and September. British Queen sown on June the 4th is now in blossom, and will carry us on as long as the weather is warm enough to cause the pods to fill. Duke of Albany sown on June the 4th is well loaded with beautiful green pods, the earliest of which are now fit to gather. This is a very handsome podded variety, and the pods are very deep green in colour. Huntingdonian, the best of the Champion of England section, sown in the middle of April, is producing a very profuse second blossom that will result in a very useful crop, though the pods will be smaller than those of the first crop. The late rains have been beneficial to Peas and Cauliflowers, but Potatoes and the grain crop want sunshine.—E. Hobday.

Loasa lateritia.—During summer this thrives well in the open. The seeds should be sown as soon as gathered in the autumn, and kept in an intermediate house throughout the winter, when some of the young plants may be transferred to larger pots for greenhouse decoration. Those to be kept under glass should have some slight support given them. They require to be cautiously handled, as the bristles, which are copious, secrete an acrid fluid, and inflict a peculiar sensation when touched with bare hands. Loasa bispida bears yellow flowers and has a more erect habit. It grows to the height of about 1½ feet.—W. H.

Trees and Shrubs.

SLOW *v.* FAST-GROWING CONIFERS.

It is stated in The Garden (p. 122) that the chief demerit in Thujopsis dolabrata is its slow growth. This statement is news to me, as I have always looked upon this superb Conifer as a gem of the first water, alike useful in the pinetum, the flower garden, as a screen or hedge tree, and last, but not least, as a lawn specimen in the villa garden. Moreover, it is as hardy as a common Oak, bears pruning to any extent, and is by no means fastidious as to soil, provided it is not waterlogged. The situation, however, which suits it best, at least with me, is on the side or near the foot of a slope where moisture is always present, and the soil, a strong calcareous loam, is not easily affected by drought. In a situation of this description, although the tree grows slowly at first, it makes good progress when fairly established, as the following particulars will show. My first tree was planted out in stiff loam resting on limestone in 1867. It has not been disturbed or protected, has withstood 34° of frost, and now measures 18 feet in height and 9 feet in diameter close to the turf. The tree, as is its habit, for the first few years threw out side leaders, but these were regularly shortened whenever they appeared, and it is now a dense cone as handsome as the finest Lycopod ever grown.

If "G." requires fast-growing Conifers, the great American continent, independently of Japan, leaves him no lack of choice, as he has the Pines and Piceas, the Abies and Wellingtonias to select from, and, be his garden large or small, I shall be taken by surprise if he asserts that he has not found more than one suitable spot for Thujopsis dolabrata. If the landscape planter takes in acres or scores of acres, his arboreal picture will be incomplete without this, and most likely the variegated form, an equally good grower, worked in with Bamboos and Japanese Maples. If the flower gardener wishes to break away from the everlasting flats of bedding plants, let him introduce good sized trees of Thujopsis, 2 feet, 3 feet, or 4 feet apart, and fill in with flowering plants. If perchance he has a sloping bank or a group of rockwork, what so graceful and refreshing as the dwarf compact Thujopsis dolabrata læte virens? If the villa gardener wishes to get away from his cockneyism, let him eschew the Californian giants, and spare his friends' nerves by planting comparatively slow-growing Conifers of which I will name a dozen.

The hatchet-leaved Thujopsis is one, Thuja elegantissima is another. The Plum-fruited Yew (Prumnopitys elegans) comes next, and although a native of Chili, it is quite hardy, and contrasts well with the greenish bronze of the first and the rich gold of the second. Cryptomeria elegans, bright green in summer and rich plum colour in winter, must not be omitted, and Abies orientalis may be its companion, but not too near the house, as either of these will attain 20 feet in good loam in as many years. Then to tone down the colour, the soft, lovely grey Abies Hookeriana or Pattoniana, A. Tsuga and A. T. nana may be introduced with telling effect. These Abies make delightful lawn specimens, and ought to be in every collection or selection, be the garden large or small, but, judging from the fact that they are seldom met with, we may assume that they are not known, otherwise Wellingtonias within 20 yards of the hall door would not be so frequently seen as they are swamping the villa grounds. If the planter wishes to shut out a neighbour, the kitchen garden, or buildings, and true Pines are to be represented, P. Cembra may be introduced with telling effect, and by way of adding the finishing touches of graceful form and bright colour to the foreground, the Retinosporas are indispensable. These may be had in green and grey, in gold and silver, but, unfortunately, they are not quite at home on all soils. With me they did not succeed on our cold calcareous loam, but by excavating and forming stations with lighter soil from the igneous

rock formation to which a little ordinary peat was added, they have settled down into satisfactory growth in the most exposed situations.
Eastnor Castle, Ledbury. W. Coleman.

VARIETIES OF HEATHER.

Most of our hardy Heaths are represented by several well-marked varieties, but the most prolific in this respect is the common Ling or Heather (Erica vulgaris), some of the forms of which differ widely from each other and from the type. A selection of the most prominent among the several varieties would include the following: dumosa rubra, a low, dense, but upright-habited kind, with slender spikes of deep coloured blossoms; alba minor, in habit like the preceding, but with pure white blossoms. In rigida alba the flowers are also white, but the plant is more spreading and the spikes of bloom larger. In pubescens alba the foliage is covered with a hoary pubescence, which stamps it as a distinct and peculiar kind. Another white-flowered variety is Searlei, a fine bold form especially valuable on account of its being a late flowerer. A good deep coloured variety is coccinea, and the pretty little slender-habited tenuis is yet another well worthy of mention. One of the boldest growing of all is Alporti, with deep purple blossoms. This kind is the latest of all to bloom, and forms a good companion to Searlei. The double blossoms of flore-plena are not so showy as some of the others at a little distance, but nearer they can be seen to be decidedly double. Varieties possessing peculiarities of foliage or habit rather than the flowers would include pygmæa, which forms a dense cushion-like mass of a very deep green colour. So widely does this differ from the ordinary kind, that it resembles a cushion of Moss rather than a form of Heather. In aurea the foliage is of a golden tint, but I have met with a couple of very distinct varieties under this name, one being a bright yellow, and the other much deeper in colour; in fact, a sort of bronzy orange. This is a dwarf kind, and if planted alternately with the deep green pygmæa forms a good edging to beds of the larger kinds. The variety variegata is readily distinguished by the normal foliage being interspersed with leaves almost, if not quite, white. Unless required in large quantities the propagation of most of these Heaths is a simple affair, for the plants can generally be divided without trouble, and where such is not the case, from their close proximity to the ground a branch or two can be readily layered. T.

Holly berries.—Like "G. S. S.," I have seen old Holly berries on the trees in July. I only, however, remember seeing them once, and that was three years ago on a specimen in the grounds here. This tree had nearly all the old berries on it and a crop of young ones at the same time—a circumstance, I believe, to be very unusual. Has anyone noticed that the trees which bear heavy crops of fruit for a few years either get much weakened or die outright? This is the case with trees on this place.—J. C. C.

The Bladder Senna (Colutea arborescens).—For hot and sandy soils I know no flowering shrub that will surpass this, as even during dry seasons it will flower throughout the entire summer. Though the individual blooms are not so showy as those of many other Pea-flowered shrubs, they are very welcome at the time they make their appearance, besides which the curious bladder-like pods add another feature to the plant. As seedlings are raised plentifully in this country, there is a good deal of variety to be found amongst them, some having green pods even when ripe, while the majority are of a reddish hue. There are several varieties to be found in different lists, but the most widely removed from C. arborescens is that known as cruenta, whose orange-red flowers are quite distinct from the yellow ones of arborescens. The pods of cruenta, too, are much deeper, being of a bright, sometimes cherry-red, tint, and are then most conspicuous during sunshine. The foliage of cruenta is somewhat smaller than that of arborescens, and of rather a glaucous hue. These kinds are quite sufficient for the planter, as representing the two extreme forms, for the different intermediate tints which may be picked out from a bed of seedlings give too much of a sameness. These Bladder Sennas are old inhabitants of gardens, C. arborescens having been mentioned by Parkinson, while C. cruenta was introduced during the early part of the last century.—H. P.

BIRCH AS A SCREEN TREE.

We get a very various collection of trees recommended for screen planting, but I do not see enough said about the Birch. There are plenty who go in for Evergreens and also for such free-growing trees as the Poplar. There are many qualifications possessed by the Birch which none of these have. In situations where screens or wind breaks are wanted, it is clear that a very important consideration is to have a tree which is not liable to be torn about by the winds. Another thing is to have one which by its habit will afford protection down to the ground level. The commonest classes of trees which grow on a single stem are deficient in this respect, as there are very few which are feathered to the ground. The Birch, springing up, as it does, more in bush form with several stems from a stool, will very soon fill up space admirably, as if planted in belts some three rows deep and arranged in a zig-zag manner, the openings between the stools in the front row will be filled by the base of the tree in the second. This, of course, would apply to a great extent to all trees which have a bushy habit, but especially so to the Birch. Perhaps the greatest recommendation of the Birch is the beauty of its stems after a few years' growth. When, as I have said, the trees are arranged in belts two or three deep, the effect of the silver bark, as the stems incline at all angles, and the ramification of the smaller branches is hardly to be equalled. This applies to the winter aspect, but it is increased tenfold by the foliage during the summer. Another point about the Birch is that it does not grow to a very great height, and the stems do not reach a very large size. In certain classes of screen-planting it may be quite in character to employ trees which grow to towering heights and large sizes, but this is only for comparatively distant effects. For planting in proximity to residences such trees would be highly objectionable, as the portion of the tree which should really form the screen is away up in the air where it is not wanted, and there is the very appreciable danger of the whole thing being blown across the house with the chance of destroying property and perhaps life. With a tree like the Birch neither of these disadvantages exist, as the windbreak is where it is wanted, *i.e.*, near the ground, and the sizes of the trees are so small relatively, that very little risk is incurred even if they are planted near enough to buildings to fall upon them if blown over. In fact, I look upon the Birch as a *multum in parvo* to planters who have limited spaces to deal with and soils very diverse. There is no doubt that the Birch, like the Alder, will grow faster and to a larger size upon moderately moist sites, but it does not refuse to make progress in places the very reverse. In these remarks the term screen has been principally adopted in the sense of windbreak, and the value of Birch in this respect considered, but what is true of this part of the subject is true of it as a screen to shut out blotches in the landscape or to render lawns or premises more private. It is, perhaps, already used more in this direction than in the other, but it is equally suitable for both. The circumstance of its being devoid of leaves during the winter is from any point of view of little importance, and from some points it is a factor in its favour. It cannot be denied that, however grateful the green may be in the dull months, there is a certain monotony in the constant presence of foliage, but in the case of the Birch there is, as the seasons roll on, a never-ceasing succession of effect. D.

Olearia Haasti.—This beautiful hardy shrub is now in great beauty in the gardens of Mr Buchan, Wilton House, Southampton. It is a close-growing compact bush with small glaucous grey leaves and pure white flowers, produced in profusion. It blooms when only a few inches high, lasts a long time in flower, and continues to increase in beauty with size and age. How is it that this plant is so seldom seen? The genus is allied to Eurybia, a native, I believe, of New Zealand.—W. H. G.

SURFACE-DRESSING RHODODENDRONS.

Our latest additions to our collection of Rhododendrons have been The Queen, James Mason, Helen Waterer, and a few others—all certainly improvements on older kinds. Previous to The Queen, Alarm and Minnie were our best Rhododendrons, both of which The Queen surpasses. This variety may not, perhaps, flower so freely as the older sorts, but the flowers have better substance, are better in form, and the truss is bold and massive. James Mason is a striking flower, on account of its having a light centre and a bright scarlet edging. The habit of the plant, too, is good, and the blossoms freely produced. Helen Waterer is a fascinating variety, the flowers of which have a white ground colour margined with bright crimson. In my opinion, this is one of the most striking of Rhododendrons; but for making bold masses, it is very doubtful if we shall get any better than the kinds which we already possess. In John Waterer we have a variety capable of producing the most glowing masses of crimson imaginable; in Joseph Whitworth we have a grand purple-shaded flower; and in conces-um roseum the most beautiful of rose colours. Brayanum and Blandyanum are two well-known crimsons that have held their own amongst many rivals. Maculatum purpureum is a light purple; Mrs. John Penn, salmon-pink; Mrs. Thomas Brassey, white, shaded purple; Baron Schröder, plum colour; Countess of Headfort, lilac; and Crown Prince, rose with a yellow blotch. Without asserting that the sorts just named are the very best, I can say with truth that they are a selection that will disappoint no one. We have a few plants of the oldest of the arboreum section, with which I have had to deal tenderly long ago. The soil (which was made for them) has been exhausted during the last twenty years; they have been surface-dressed twice, and now they require that help again. Such surface dressings give them a new lease of life for at least a few years; the improvement in their condition the first year is not much, but the second it is more marked, and in the third and fourth their vigour seems to be quite restored. Our natural staple for this class of plants is loam, in which they thrive wonderfully well. Our largest specimen requires four good cartloads of loam for one dressing. It is spread all over its roots, and the plant is worth such dressings, for it is more than 30 feet high, and has a proportionate spread of branches. It would have been dead before now had it not been attended to in this way, while it is as vigorous now as ever it has been.

My experience as regards surface dressing Rhododendrons would certainly lead me to adopt the same plan in other cases in which there is decline in the way of vigour. Where the specimens are large, a mere sprinkle either of peat or loam is comparatively useless. Sufficient thickness of new soil is wanted to afford room for the formation of a good quantity of new roots, and then the benefit will be lasting. It will be well to remember, too, that the roots in a suitable medium extend farther than the branches; therefore, in order to benefit the outermost fibres, the new soil must also extend beyond them. Plants growing in the natural soil of any place may not need to be surface-dressed in order to maintain vigour, as the roots will have room to extend in a suitable soil; but where the soil has been made for them, and become exhausted, top dressing, as a remedy, might be resorted to with advantage. Where peat has to be used for surface-dressing, I should advise that it be beaten up rather fine and laid on early in September, so that the autumn rains may settle it down, and enable the roots to lay hold of it quickly. If applied in spring or during the summer, birds would probably scratch much of it away from the roots; as a rule, whatever the material used may be, it should be laid on 3 inches thick. With regard to plants that are grafted or obtained by layers, I do not know if my experience is different from that of other people; but I certainly prefer layered plants to others, because they are longest lived. At all events we have los

more grafted plants than others. Why this should be I cannot tell, further than that I believe the top dies before the roots, which seems to show a want of reciprocity between the two. Perhaps some reader of THE GARDEN can throw some light on this matter. In other respects I like grafted plants as well as others. They will sometimes throw up suckers from the crown below the graft; but an experienced eye can soon detect them and cut them out. The plants should be gone over every year at blooming time for this purpose.

On the subject of pruning some misapprehension seems to exist in the mind of amateurs; they appear to think that hybrid Rhododendrons will submit to being pruned the same as a common Laurel, and to a certain extent this is true. If we prune back only the young wood, it will break freely into growth again; but it is impossible to prune Rhododendrons without sacrificing one or more season's crop of flowers. If young branches only are cut back, then only one season's flowers will be lost; but if old hard wood has to be dealt with, it will take two or three years before new growth produces any flowers. Where old plants have to be pruned, the best plan is to cut all the branches down to within 2 feet of the ground. This should be done at the end of February, and then they will have a long season before them in which to make new growth, and it will have time to get hardened before winter; but in a general way it is best not to prune them at all. If in any case the plants have outgrown their space, it will generally prove more satisfactory to root them out and plant young ones than retain them. It is useless to cut down some of the old branches and leave some, because those left will rob those cut back, and they will die. Therefore it must be all or none. Rhododendrons make good single specimens on grass when suitable varieties for such positions are selected. It is necessary to know something of their habit of growth, some being loose and straggling. Sorts with short-jointed growth and a compact habit are the most suitable for such situations. Brayanum (crimson), Duc de Brabant (salmon-tinted white), Everestianum (rosy lilac), Exquisite (white), Nero (purple), and Vandyke (bright red) are all good kinds for the purpose named. J. C. C.

GARDEN IN THE HOUSE.

WHITE-FLOWERED PLANTS.

I FEEL satisfied that if we were to go carefully through the list of hardy plants and shrubs that bear white flowers there would be found a greater number than many are aware of. Not many white flowers can be had during the first two months of the year. But if one makes a speciality of the Christmas Roses and plants them in a warm sheltered corner, and puts a few handlights over them, there will be no scarcity, except in very severe weather. Double and single Snowdrops should also be largely planted in warm borders. In February the common white Arabis commences to flower. In March and April the number will increase. Double white Daisies and Primroses, Forget me nots, and Hyacinths will be well in flower if proper provision has been made for them. The pretty double white Anemone flowers in April; anybody can grow it, as it is indifferent about soil, sun, or shade, and no flower, either exotic or hardy, is purer in colour. A wreath or cross made wholly of this, associated with its own leaves as greenery, cannot fail to give satisfaction. In May and June there will be quite a wealth of white hardy flowers. The common garden Pink will be the first, and then should follow the white variety of East Lothian Stock, which is pure in colour and compact in growth. Lily of the Valley should form a strong feature; there should be a bed of it on a sunny border, and another in the shade of a north wall, which will make a difference of three weeks in their coming into flower. The double white Rocket should find a home in every garden, as its flowers are very fragrant, and if the individual blossoms are mounted on wires they are well suited for wreath making. In July and August there should be no scarcity of flowers. Roses should be plentiful, especially of such varieties as Boule de Neige and Aimée Vibert, both of which may be grown in any form desired. The last-named is an excellent climber for a wall of moderate height; it also does well as a standard. The other may be grown as a dwarf plant or standard. There are several capital herbaceous plants which flower in these two months. The white Phlox is one of them, but the two best are Achillea Ptarmica fl.-pl. and Campanula persicifolia alba. The Achillea is a hardy plant, which will thrive in any kind of soil. Its blossoms are pure white, and last long when cut; the Campanula, too, is both hardy and beautiful. It produces a number of blossoms of the purest white at intervals on erect stems. Nor must we omit Carnations, amongst which there are several fine white varieties. Saxifraga granulata and Spiræa Aruncus are also desirable plants; a wreath or cross made wholly with Lilium candidum would be very attractive, and everybody can grow it, if they do not plant the bulbs more than 2 inches under the surface, and choose a sunny spot for it. There are several annuals, too, which may be had in flower during the summer, particularly Sweet Peas, Candytufts, and double white Chrysanthemums. In order to furnish white flowers during September, everyone should grow the beautiful Anemone Honorine Jobert. It is not only a handsome plant when grown in masses, but its flowers are useful in a cut state. There are also one or two French Chrysanthemum-flowered Asters, the flowers of which, being snowy white, are admirably adapted for wreaths and crosses. These are grown in quantities by those who require white flowers in autumn, as is also a white Pompon Dahlia named Lady Blanche, which produces large numbers of flowers on individual plants. So highly is this little Dahlia valued by some, that it is grown in large pots, to enable the plants to be taken under glass on the approach of frost in autumn. If stood in a light, airy house, their season of flowering is prolonged for three weeks or more, and the colour of the flowers is whiter than that of those grown in the open.

For the late autumn months we must depend chiefly on Chrysanthemums, and if anyone sets about it in the right way, they can have a constant supply of them from the 1st of September until the end of November. Madame Desgrange is the best variety to grow for early flowering. The colour of its flowers is not pure white when grown in the open, but it flowers so early and so freely, that it makes up in some measure for that defect. Most people, moreover, could manage to find a few spare lights under which to grow it. We have only to mark out the size of the lights on a piece of ground that is fairly rich, warm, and sheltered, and to put out the plants 2 feet apart early in spring, and allow them to grow on without stopping, as strong growth is desirable. They must be supplied with water when necessary, and they will want the support of some sticks and ties to keep them from being injured by wind; and this is all the trouble they will give during summer. As soon as the flowers begin to show colour, which is generally about the end of August, a temporary framework of wood should be placed round them, strong enough to support the lights, which should be only a few inches above the plants. This is the only protection they want. The space all round should be left open, so that air can circulate amongst them. La Vierge is a good white variety belonging to the early-flowering section, if more than one is wanted. In order to get white Chrysanthemums as late as it is possible to have them, a variety from the late-flowering section must be chosen, and the best for this purpose is Mrs. George Rundle, on account of the purity of the colour of the flowers, as well as for the freedom with which they are produced. The best way in which to grow it is to plant it against a warm wall or fence, and to keep the plants neatly tied up during the summer time. As soon as they come into flower, a few mats should be hung up in front of them, or a piece of canvas to protect them from frost. There is no need to cover them up unless there are signs of frost; during the day the covering should be removed. Amongst hardy shrubs I may mention the lovely white Magnolia conspicua, which flowers so freely when trained to a wall in any but a north aspect; this flowers in April. In May and June there are white Lilac and the Guelder Rose (Viburnum Opulus), also Hoteia japonica; then there is Spiræa Thunbergi, with its long arching branches clothed with flowers at every bud. Nor must the double-blossomed Cherry be forgotten; its flowers are so clear and so neatly formed, that they make up admirably into wreaths. The white Jasmine, although its flowers are small, is still a favourite with many. Deutzia gracilis and D. scabra are two well-known hardy shrubs suitable for our purpose, as are also several Spiræas, especially S. ariæfolia. J. C. C.

NOTES FROM SHIPLEY HALL.

THE BEECHES.—One of the leading features in the grounds attached to Shipley Hall is the Beeches, of which there are large numbers of unusually fine trees, which stand irregularly on the ridge whereon the house is built. The trees collectively have attained a large size; they differ in character from examples of this tree usually met with in parks and pleasure grounds, which generally are furnished with drooping branches that clothe the trunks down to their base, such as result from their having in the early stages of their growth stood sufficiently far apart to admit of full development in the lower limbs. The trees in question have evidently been planted thickly and afterwards allowed to stand for a lengthened period near enough together to prevent the formation of side branches of any consequence, and when they had attained an unusual height have been thinned, after which they have formed massive spreading heads, whilst the trunks, straight and free from the semblance of branches for some 30 feet, have thickened out in a way that seldom occurs. The tallest are about 120 feet high.

HOLLIES.—Hollies thrive wonderfully and attain an immense size. The large-leaved varieties, such as Hodginsi and Shepherdi, show their remarkable freedom of growth. Of these, as of most of the best kinds, there are quantities of grand specimens dispersed about the grounds. Golden Queen and other golden varieties along with the best of the silver-leaved sorts are represented by large numbers of the most perfect specimens, the lower branches stretching out on the turf in a way that only occurs where the land suits them, and they have plenty of room and nothing to interfere with their growth.

EVERGREEN SHRUBS AND TREES.—The Retinosporas (Japan Cypresses) are special favourites here. The collection contains all the varieties worth growing, and, what is more, the plants continue to thrive, maintaining the densely clothed condition for which they are so much admired in the early stages of their existence, but which in so many places they unfortunately lose as soon as they attain any considerable height. From the fact that these beautiful plants are only met with in their best form in places where the soil is naturally moist, or where means are provided for giving them the water they require, it is evident that they not only need more moisture than the generality of Evergreens, but that to maintain them in a condition worth looking at when planted in dry localities they must in dry seasons be supplied with water. At Shipley Hall, I understand they are watered freely in dry periods during the summer. This points to the necessity of confining the planting of the Retinosporas to places where the soil is of a damp peaty nature, or localities where the annual rainfall is exceptionally heavy. A tree, however beautiful it may be, that will not continue to thrive with the water that it gets from the clouds can scarcely be reckoned suitable for planting everywhere. Anyone who has moved Retinosporas that have attained considerable size will have noticed how the roots in place of extending freely in the way common to other trees, keep in a compact body within a very limited space, crowding the soil for a few feet round the tree with a thick mass of feeding fibres, which are thus wholly dependent on the moisture present within a small space, and in this way soon exhaust that which is within their reach, and then are in a semi-perishing condition, which accounts for the thin, half-denuded of foliage state the plants usually get into when they have attained any size. In addition to the varieties usually met with there is

here a beautiful golden form of R. pisifera, much the brightest in colour that I have seen. R. obtusa aurea nana is 10 feet high; other varieties are proportionate in size to this. Amongst other golden-leaved Evergreens are several distinct varieties of Yew that have been raised in the Handsworth Nurseries; they are brighter in colour than the ordinary forms, and have a better and more erect habit of growth than most Yews. The largest of these is 16 feet in height. Interspersed, as they are, at sufficient distances apart amongst green-leaved trees, they are very effective. Abies Alcoquiana, planted six years ago, when about 4½ feet high, has now reached 16 feet. This handsome Japanese species promises to become one of the best of all the Spruce Firs.

Lilies are largely grown, quantities being dispersed about the pleasure grounds, occupying prominent positions in the large clumps of Evergreens, which serve as a background for the Lilies when in flower. Several large beds in the garden are filled with them. Two long beds were planted with L. auratum, one in autumn and one later on in the winter; the bulbs have done much the best that were put in first, the growth being double the size of that of those planted later, and they have come up more regularly; amongst them are some of the beautiful L. auratum platyphyllum, and also another fine variety, L. auratum vittatum rubrum. L. pardalinum, often supposed to require being grown in peat, does here well in the ordinary soil, reaching a height of 6 feet and increasing freely. L. Parryi is doing very well, flowering and increasing freely. This handsome yellow Lily can scarcely fail to become a favourite when it is better known.

Herbaceous plants.—Of these there is a nice collection, consisting of many of the most popular kinds. Noticeable amongst them are Spanish Irises, of which large quantities are dispersed about the garden. The soil seems to suit them, as they not only thrive and bloom well, but increase freely. Hyacinthus candicans does well; some that were planted four years ago, and have not been disturbed since, are remarkably strong. Herbaceous Pæonies also are well represented.

Plant houses.—In a large lofty conservatory, situated near the walled garden, many of the occupants are planted out in a roomy bed, which occupies the centre of the house, where, as usual under such conditions, the plants attain a large size. So treated, Neottopteris Nidus has leaves 6 feet long; whilst the scandent stems of Asparagus plumosus have attained some 20 feet in length In a narrow border running along the back wall several varieties of Bamboo are planted, and these, left to grow much as they will, make an excellent covering for the wall; the kinds are B. Metake, B. arundinacea, B. japonica, B. violescens, and B. nigra.

Fern house.—There is a fernery of considerable height adjoining the conservatory, in which the plants are turned out, the walls being covered with medium and small-growing kinds, that collectively are in fine condition. A long glass-covered way connects the house with the fernery; a portion of this next the mansion is kept gay with flowering and fine-leaved plants. In the remaining portion the walls on both sides are carried up to the roof, and are clothed with Ferns; here, as in the fernery, the plants are in beautiful order, with an absence of any that fail to thrive such as invariably exist where care has been wanting in confining the kinds to such as do not naturally grow to a size that causes them to smother the weaker growers. In the planting of ferneries in recent times, it is often apparent that there has been such a disposition to favour large-growing species, that the smaller and more elegant kinds did not get a chance of succeeding.

A warm house is principally devoted to the growth of small and medium sized Palms and other fine-leaved plants for general decorative purposes.

In a lean-to house, which is used for flowering Carnations early in spring and other things of a like nature, the singular-looking Lophospermum atrosanguineum (syn., Rhodochiton volubile) is grown on the roof, producing quantities of its curious dark-red flowers. It is an evergreen climber from Mexico, of quick, but not too rampant, growth, and, though seldom met with, it is well deserving a place, especially where climbers of strong vigorous habit are unsuitable. The spring-flowering Carnation W. P. Milner, a white variety with well-shaped flowers, full enough, but not so full as to cause the pods to split, is grown in quantity. Sir Beauchamp Seymour, salmon-red flaked with crimson, also comes in early in spring with a little warmth. These are both fine kinds, that may be relied on by those who have these favourite flowers to provide.

Orchids.—Amongst Orchids there is a good stock of Lælia anceps, which includes the white variety, and also one of the darkest-coloured forms that have appeared. A plant of this, after blooming at the usual season, is now again coming into flower. The cool kinds are represented by Odontoglossums and others that thrive in a like temperature.

Vines.—Fruit is well managed, as is evidenced by the success which Mr. Elphinstone has attained at most of the leading exhibitions. In three of the houses which it was thought desirable to replant the Vines have been pushed on this season so as to get the fruit ripe in time to admit of new Vines being planted; this has been done, and they have every appearance of making satisfactory progress before the end of the summer. In two of these houses Black Hamburgh and Madresfield Court are the principal kinds. In a house of Muscats three years planted the Vines have done very well, and are now carrying a good crop, nearly ripe. The latest house contains a very good crop coming on, consisting of Gros Maroc, Gros Colmar, Golden Queen, and Gros Guillaume.

Peaches and Figs. Peaches occupy three or four houses, which are high enough to admit of the trees on the back walls not being interfered with by those grown on the front trellises. The trees are in good condition, and in the case of those where the fruit was not cleared were carrying heavy crops. In the earliest house the fruit was ripe in April. Figs have a house to themselves. The varieties grown are Brown Turkey and Negro Largo; the latter fruits as freely as the former, but to secure this the roots are regulated annually. The trees were bearing an unusually heavy crop. T. B.

School gardens.—Can any of your readers tell us of experiments made with gardens as attached to schools, and whether the same have been a success or a failure? The school garden might become a most useful aid to education, and ought, as myself and others believe, to be made a *sine quâ non* in all rural and agricultural districts. My old friend Quibbler says that it is in the towns more especially that school children require gardens, and perhaps in a sense he is right, but, anywhere and everywhere, a good garden attached to a school, in good hands, would prove to be an ever-open book of knowledge, yielding a harvest of food for thought as well as of pleasure to the eye. If children were taught the names of all the common garden and field flowers, and such simple operations as tilling the ground, seed-sowing, and transplanting, they would never forget it, I feel sure. Quibbler says, if I want a garden to every school, somebody else will want a kitchen added, to teach the children cookery, and a carpenter's shop for the boys, &c., *ad infinitum!* But I do not quite see the point of his argument here, for all the girls will not be cooks, nor all the boys carpenters; whereas every thrifty artisan or labourer indeed ought to have a garden. Gardening is, as I take it, without a doubt the most simple and natural kind of amusement with which a man may beguile his leisure, and whatever else he possesses in the world, after a good, sound and healthy house, ought to be a garden, either before or behind, but, if possible, the garden should form a sacred circle around the home.—F. W. B.

Garden Flora.

PLATE 558.

TALL GROWING WINDFLOWERS.

(WITH A COLOURED PLATE OF PINK AND WHITE JAPANESE VARIETIES.*)

Amongst hardy herbaceous plants few genera are more popular than the Windflowers, or Anemones, as they are botanically called. In point of size they vary from the little vernalis or palmata to the gigantic A. Fannini lately introduced from Natal, where it blossoms from September until December. Its flowers are white and fragrant, about 3 inches in diameter, and its leaves measure from 1 foot to 2 feet across. It is likely to prove a useful plant for cool conservatory decoration, *i.e.*, if planted out and room given for proper development. Anemones of the coronaria and fulgens groups belong to quite another class, and require different treatment. We shall therefore in the following account confine our remarks to the tall-growing species, which are of a permanent character and suitable for borders. They like deep rich soil, and it must be well drained, especially for kinds that need a little shade. These conditions being provided, the less they are disturbed the better will they be. Most of them are easily propagated by root division and seeds, which they generally ripen freely, and which will germinate if sown in the open ground as soon as gathered.

Anemone alpina.—This, although one of the commonest of South European plants, being found on almost every great mountain and forming one of the roots generally gathered by tourists, is not so often met with in gardens as it deserves to be, a circumstance probably accounted for by its slow growth and the dislike to which it has to being disturbed. It is very variable, and by some botanists split up into many species. In strong soils it is very liable to be abnormal in form, adding rather than detracting from its value, as the number of segments is often thereby increased from six to nine, or even a dozen. It grows from 1 foot to 2 feet in height, roots strongly, and should have a deep, well-drained soil in which to grow in a sunny part of the rockery or ordinary border. Its flowers, which are few in an umbel, are creamy white inside and pale purplish outside, from 2 inches to 3 inches in diameter, and set on finely cut Fern-like leaves at the base of the umbel; the lower leaves, which are large, are finely divided. A variety called sulphurea has pale lemon or sulphur-coloured flowers, and is also a good border plant. Both flower in April and May, and the type has been cultivated in the Oxford Botanic Garden since 1658.

A. japonica, two varieties of which are here figured, is undoubtedly the finest of the tall-growing Anemones. It is a native of damp woods on a mountain called Kifune, in the neighbourhood of Miaho, Japan, and was first introduced to this country by Fortune. We have not heard of any attempts having been made to naturalise it in our wild gardens, but, if started well and left undisturbed, we see no reason why it should not become as much at home as our own wood Anemone (A. nemorosa) and its varieties. If disturbed, this Anemone not unfrequently takes two and even three years to recover from the effects of the interference. Our plan, and one which we think a good one, is to plant the offsets in deep boxes in good rich soil, and when well established, plant out the whole without breaking up the soil. Even for greenhouse decoration this plant is not nearly

* Drawn in Dr. Lowe's garden, Woodcote, Wimbledon Park, September 12, 1885.

THE PINK AND WHITE JAPANESE ANEMONE JAPONICA

so often used as it ought to be; it flowers freely in pots when well attended to with liquid manure, and blooms earlier than in the open; by a little management, too, in keeping back a portion of the stock, a succession of plants in flower may be had for a considerable time. There can be no

Anemone japonica alba.

question about the value of this Anemone and its varieties as hardy decorative plants; large clumps of them are strikingly effective all through the autumn months. The white variety, Honorine Jobert, is particularly handsome and easily managed; the secret of success lies in having a good deep bed of rich soil, and afterwards leaving the plants alone. If they show signs of degeneration at any time, supply what is needful either in the shape of liquid manure or top-dressing. Another variety called rubra, much deeper in colour than that recognised as the type, and generally with

Anemone sylvestris.

twice the number of segments, is also a desirable subject. It is more compact in habit, and has smaller flowers than the true A. japonica.

A. NARCISSIFLORA.—The annexed cut shows th habit and general appearance of this plant, whic is one of the freest-flowering species in the grou to which it belongs, each stem carrying a large head of beautiful delicate white flowers set on an involucre and making quite a charming bouquet in itself. It does well in the ordinary border, and with a little attention in the way of grouping it properly, it makes a grand show in early summer. It is said to be connected with A. polyanthes by intermediate forms, none of which, however, we have seen in cultivation. It is dwarfer in growth than that kind, rarely attaining more than a foot in height; the leaves are palmately five-parted, and the divisions are deeply cut into narrow or linear lobes. It has a wide distribution, being found on the Alps of Central and South Europe, Western Asia, Siberia, North-west America, and also in Cashmere.

A. OBTUSILOBA.—This species, if in cultivation at all at the present time, is very rare, although common at one time in good collections. It is nearly allied to A. polyanthes, but in its present state not nearly so valuable a decorative plant. It appears, however, judging by descriptions, to be very variable in colour, and if taken well in hand something could no doubt be made of it. The flowers are white, purplish, or golden, the latter two colours being very desirable in a tall Windflower that succeeds the Globe-flowers and Crowfoots. It grows from 1 foot to 2 feet high, and bears a few three-flowered stems, making a good and desirable plant. The lower leaves are stalked, nearly round, and deeply cordate, and three-parted, the divisions variously cut and lobed. It is a native of the temperate and alpine Himalayas from Cashmere to Sikkim, and is found at 9000 feet to 15,000 feet elevation. We hope soon to see this plant introduced.

Anemone narcissiflora.

A. POLYANTHES.—So far as our knowledge of Himalayan Windflowers extends, we know of none more worthy of a place in the flower garden or rockery than this white starry form. It has a sufficiently high elevation from 10,000 feet to 12,000 feet to withstand all the vicissitudes of our climate, and as it does not seem to be at all particular as to position, it will, when better known, make a first-rate companion to the well-known Japanese plant. It generally begins to flower a month earlier than A. japonica, and continues in bloom until that species succeeds it. In a low, damp, and half-shady position it attains a greater height than in the open, ranging from 18 inches to 2½ feet, and bearing a profusion of flowers, if equalled, certainly not surpassed, in quantity by that of A. japonica. This species has been confounded with that bearing the name of A. obtusiloba, but it is a far better garden plant than obtusiloba: while the latter bears only from one to three flowers in a head, there are rarely less than a dozen on A. polyanthes; the latter has much compressed and generally winged achenes, while in the other they are rarely if ever compressed, and the achenes have no wings. The whole plant is densely silky; the leaves are from five to seven-lobed, about 4 inches in diameter, and have long petioles. The flowers are large, about 2 inches in diameter, white, many in an umbel, and very showy; the involucre leaves are variable and more or less divided. It is sometimes stated to be a form of A. narcissiflora, which also extends to the Himalayas, but it is distinct enough for all cultural purposes. It flowers in June and July, sometimes earlier, and may be increased by division of the roots in autumn. The most satisfactory plan, however, is to raise it from seeds, which it ripens in abundance, and these sown in the open when gathered give no more trouble until they are ready for pricking off or planting out. It is a native of the inner Himalayas from Cashmere to Sikkim.

A. RIVULARIS.—This is a well-known garden plant, and a good companion to A. polyanthes, vitifolia, and others belonging to the tall-growing section. It is perhaps one of the easiest of Anemones to grow. It makes an excellent border plant, and is not at all particular whether the position be shady or not. When fully exposed it is much sturdier than in shade, and if anything more floriferous. The roots do not run so much as in some of the others; therefore it is less troublesome to keep in its proper place. The whole plant is covered more or less with a silky pubescence. The root-stock is stout, the lower

leaves three-parted, and the segments lobed and evenly serrate. It grows from 1 foot to 3 feet in height, branched, and bearing flattish heads of many flowers, each from 1 inch to 2 inches in diameter. They are star-shaped, white and often bluish tinted inside; the involucre leaves are large, and, like the others, three-parted. A monstrous form, with the inflorescence or leafy umbel often 6 inches in diameter, is said to be common in the Western Himalayas, but we have never seen it in cultivation. It flowers in early summer, and is said to be one of the most common plants in the temperate regions of India and Ceylon.

A. sylvestris.—This Snowdrop Windflower is a charming free-growing species, and one that should be in every collection, however small. In small borders it is apt, however, to become troublesome. It should have plenty of room in which to run about, and is an excellent plant for filling up odd corners. A sunny spot in the wood or wild garden suits it admirably, and there it soon makes a large patch. It flowers early in May, and the blossoms are followed in June by a display of white woolly seeds, which hang loosely together for a considerable time. It grows a foot or rarely more in height, producing on each stem one—seldom two—large white flowers, which in the bud state resemble Snowdrops; hence the common name. The involucre leaves are generally more finely divided than those lower down. It is propagated by offsets from the root, which may be planted where desired as soon as taken off. The annexed cut shows its habit of growth. It is a native of Central Europe and Siberia.

A. virginiana.—This is an American species, robust and unruly in habit, and suitable only for the woodland garden, where it will be found able to take care of itself. It produces a succession of flowers during the whole of the summer. Its near ally, A. pennsylvanica, is also a useful plant for the purpose just indicated. Its flowers are large, pure white, and striking.

A. vitifolia.—This species is found plentifully in Nepaul, where it is said to be one of the most common of native flowers. Although a very desirable border plant, flowering a fortnight or more earlier than A. japonica, and as easy to cultivate, it seems to be getting rapidly out of cultivation. The plant found in gardens under this name is generally a form of A. japonica, which it somewhat resembles in habit, but is widely different both in flowers and leaves. It seems to thrive best in a half-shady moist situation, or where the soil is stiff it will do well in the open, but it requires slight protection in severe weather. It varies in height from 1 foot to 3 feet, and is much branched. The lower leaves, which are very handsome, are from 5 inches to 8 inches in diameter, and deeply five-lobed. They are smooth above and densely covered with a white tomentum beneath. The involucre leaves, like the radical ones, are set on longish stalks and Vine-shaped. The flowers are about 2 inches in diameter, white, and in decompound flattened panicles. It may be propagated by division in autumn, but it increases very slowly; the offsets should be pricked off into a rich bed until ready for planting out. It is a native of the temperate Himalayas in Sikkim, but only in the inner ranges, from 5000 feet to 10,000 feet elevation. D. K.

NOTES.

The garden in August.—Bright yellow Composite flowers are waving in the warm breeze, with butterflies and bees in plenty on the soft lilac flower-heads of the Eupatorium, a plant that should certainly find a place along with Sedum spectabile in every insect-lover's garden. The gold-rayed Lilies and the shining trumpets of the long-flowered Lily of Japan are still lovely, as also are the vivid scarlet flowers of Lilium chalcedonicum, while a few odd flowers of L. excelsum (testaceum) yet linger in the shade. The Carnations are lovely on the borders, so, too, the Delphiniums, and a mass of Silene Schafta is like a rosy satin cushion laid on the ground in the sun. The showers have freshened up all things, and after planting out seedlings and rooted things many and varied, the almost everlasting labour of propagation is again begun afresh. Slips of all good hardy Carnations and Pinks, of Pentstemons, Veronicas, and Antirrhinums are now being planted in sand under handlights, where they will root and remain all the winter if weakly, being planted out as soon as they become rooted if strong. Most brilliant now are the scarlet Gladioli, the earliest Tiger Iris, and the Gaillardias as seen in the sun. Mutisia decurrens has been very effective, being one of the most vivid of all orange-scarlet flowers of its kind known to me. The single Dahlias are getting towards their best, and the white Japan Anemone is as ever most lovely. The best yellow Daisy is Helianthus rigidus, and Pentstemons and Campanula pyramidalis are in full bloom. On warms nights the garden is delightful, filled as it is with the breath of Musk and Mignonette, Jasmine, Myrtle, and Bergamot, Roses, Lavender and Thyme.

A Crocus Book.—In the tragedy of "Œdipus at Colonus" of Sophocles, as recently translated by Professor Jebb, of Cambridge, there occurs the following passage: "Stranger, in this land of goodly steeds, thou hast come to earth's fairest home, even to our white Colonus; where the nightingale, a constant guest, trills her clear note in the covert of green glades, dwelling amid the wine-dark Ivy and the god's inviolate bowers, rich in berries and fruit, unvisited by sun, unvexed by wind of any storm; where the reveller Dionysius ever walks the ground, companion of the nymphs that nursed him. And, fed of heavenly dew, the Narcissus blooms morn by morn with fair clusters, crown of the great goddesses from of yore; and *the Crocus blooms with golden beam.*" Go back far into times past as one may, we ever find the happy marriage of flowers and sunshine, but it is also pleasant to know of the progress of our own day also, and so it is pleasant to read in another place that, "After over eight years' work, Mr. G. Maw, of Benthall, has passed through the press his "Monograph on the Genus Crocus." The book will be one of the most exhaustive of its kind. The author has not only supplied the text, but has also furnished the illustrations—altogether eighty-one quarto plates. Besides these there is an elaborate map, showing the separate range of every species of Crocus; also diagrams of latitude and longitude, done on quite a novel plan." In a word, this modern tribute of intelligent thought is a noble offering to that brightest of our flowers of autumn and of the days of spring.

Wild Heather.—There is a purple veil of Heather once again on the hills, and it is wreathed as subtly around them as are the mists of dawn. The moors are carpeted with ruby colouring, and the bees are happy, for their richest harvest is that they win from the Heath and Ling. What a world of delights and of regrets also this blossoming of the wild Heather brings! Delight in rich sunny autumn days with the corn and fruit everywhere ripening. Regret that the halcyon days of summer are no more. And yet to anyone who has experienced the luxuriant sameness of the Tropics these constant changes in our climate are most satisfying and enchanting, and a ramble over the blossoming Heather becomes a positive delight. I saw to-day a tuft of Ling (Calluna vulgaris) growing in an Orchid house, it having come in with the peat a year or two ago. Every year it has flowered in the hothouse just at the same time as it would have done outside on the bleak moorland whence it came. No focussing of heat and sunshine under a glass roof has altered its blossoming. Again this year it is in bloom at its usual season with steadfast constancy. What if the Daffodils and Anemones and Apple blossoms have vanished for a season, are there not Apples large and rosy-cheeked now on every bough? Have we not the great Japan Lilies distilling their rich odours in the garden, and with them a hundred Daisy flowers waving over the grave where Narcissus sleeps, in certain hope of a beautiful resurrection in the spring?

Musk.—In many gardens Musk is, if grown at all, limited in its area to a flower-pot in the greenhouse or on the window-sill. In mild localities, however, it is quite hardy; indeed, it must be a cruel combination of cold wet soils and a hard winter that will actually kill its rhizomes anywhere. A broad carpet of Musk is now and then a good feature in the garden, but as it is extremely difficult of thorough eradication, it is as well to select a position where it cannot harm more delicate habited plants. One thing you may rely on most implicitly, and that is, the common Musk is more than a match for our native weeds on any ordinarily rich warm soil. Planted out and staked with a few short Fir or Larch boughs, you may have a clump of Musk a yard high and as much through, and if in full sunshine on a moist bottom, it will be studded with flowers for six months of the year. The hybrid Musk (Harrison's) grows outside well as a summer bedding plant, but is not so tenacious of life as is the typical kind. If you wish to see it at its best, grow it in a basket hung up near the roof of a light and airy greenhouse or porch. As so grown, it is elegant in habit and most floriferous, and if you wish to intensify the colour of its flowers, fill the centre of the basket with a rooted cutting of a purple-leaved Coleus, or with two or three bits of Iresine Herbsti, which shine like stained glass as seen between the eye and the light.

The Japan Eulalias.—The Eulalias are tall-growing Grasses, as graceful as Bamboos, and easier to manage in almost all gardens. There are three forms, viz., the green-leaved type, a variety having its long and slender leaves striped like ribbon Grass, and a third which has yellowish zebra-like markings on its long green leaves. All are well worth culture, either as solitary clumps or masses on the lawn, or as pot plants in the conservatory. No matter how grown their habit is most graceful, and as yielding good foliage for Gladiolus or other cut flowers they deserve more notice than they have hitherto obtained. We find their growths cut rather long most graceful, effective, and durable for indoor uses. They require a good deep warm soil and plenty of moisture, and then form tufts 5 feet or 6 feet high in the open border every year. Even when killed to the ground, as they are now and then during extra hard winters, their dead stalks have a grace and effect peculiarly their own. They are not difficult to increase either from seeds sown during the spring months in heat or by division of the roots. The two variegated forms striata and zebrina are peculiarly elegant and delicate looking as grown in small pots in a warm house, where they group well along with Ferns, Asparagus, Aralias, or Dragon trees. All three varieties are now flowering freely with us in the open air at 6 feet in height.

Genus hybrids.—This is the title used by Sachs for plants presumably raised or originated by cross-fertilisation between two genera, but it is, to say the least, questionable if this union of distinct genera ever takes place. It is quite true that man, as a botanist, has in times past set up straw men under the name of genera; and it is

equally true that man, as a hybridist, has, in following Nature's own laws, succeeded in knocking these straw images down again. In a word, it seems doubtful as to the definitions that should be assigned to the boundary lines of a genus. My own view is that hybridism should decide the question one way or the other; that is to say, if seedlings can be raised by the cross-breeding of any two genera, I should take that as proof absolute that such genera had been formed with an insufficiency of knowledge, and that the parent species really belonged to one genus instead of two! Take Phaius and Calanthe as a case in point. The production of Phaius irroratus as a hybrid between these once-supposed genera proves, as I imagine, most conclusively that they are really of one genus. The mere fact of one being deciduous and the other evergreen proves nothing more than that they have for ages grown under different natural conditions—the Calanthe on rocks or trees in the sun, the Phaius under leafage in the shade; and this is further shown by some Calanthes being evergreen and almost bulbless, as is the so-called Phaius. I admit that my line of argument cuts both ways. For example, no one has crossed the Gooseberry with its co-species the Currant, nor even the Black Currant with the white or the red varieties; and if this is really impossible, we shall here have to form two or three genera of what are now merely supposed to be species. I am certainly convinced that hybridism is the best proof of the natural relationship among plants.

The Feather Flowers.—In North America the species of Liatris are sometimes known as Snake Roots or Feather Flowers, and there is a soft and feathery look about their flower-stems as well developed in deep rich soils. There are several kinds, but L. pycnostachya is, as I believe, one of the best for garden culture. L. spicata is also a showy kind, and, like the former species, is easily raised from seeds or increased by division of the roots or crowns in spring. To see these singular composite plants at their best one must either rear them from seeds or divide them early every spring. Like many other things, they deteriorate if left in the same spot too long, and this is one of the real difficulties in hardy flower culture. Many plants will exist for ten or twenty years in the same place if once planted, but it does not follow that they satisfy one as so grown. In a word, rotation of crops, or good cultivation is as necessary for hardy flowers as for culinary vegetables. A Lily is as fond of good, fresh, deeply dug earth as is a Cabbage, and a change of soil is as essential to good Roses or Narcissi as it is to Beetroot or Potatoes. No one who is afraid of digging up and replanting will ever give us many pictures in the garden. And yet the man who uses a spade well has as much or even more power over beautiful flowers than a painter has with his colours. Both must use them freely and boldly in the right way.

Scarlet Tropæolums.—In town gardens I rarely see anything in the gardens or windows so fresh and brilliant as are these Nasturtiums of various kinds. For window boxes they are, as I think, well-nigh unequalled, and all one has to do is to sow the seeds in fresh, rich earth, and water the plants when necessary. Another good way of growing these flowers is in a bed on the Grass, where their shoots can ramble out on the closely-shaven lawn. They are very beautiful from May to November, and for carpeting bulb beds, or for a half-shady place, these dwarf Nasturtiums are more satisfactory than Pelargoniums or other bedding plants. The above relates only to the modern forms of Tropæolum majus, but where it will thrive there is nothing in the genus can surpass the blood-flowered T. speciosum in lightness of growth and in floral grace. We have at last succeeded in flowering this erratic beauty by planting some of its thick white roots on a moist border with an eastern exposure, and which is sheltered by shrubs from the midday sun. Even if it never flowered it is worth growing for its fresh green Maiden-hair-like leaves. I once saw a man digging Potatoes in a roadside garden in Scotland. The hedge next the road was scarlet with flowers, and the thick white roots of this lovely Tropæolum came up along with the Potatoes. "What will you do with these roots?" I asked. "Thraw 'em away," was the laconic reply. I asked for some, which were willingly given—an armful almost. "Now," said the donor, "be ye careful whare ye pit it—its the warst weedie you can ever git into a garden." And so it seemed to be there, and is in other places northwards, but with some it is one of the most capricious and stubborn of plants.

Rootwork.—I do not mean rootwork as opposed to rockwork, but wish to allude to the silent labours of the roots of living plants. There is nothing more mysterious than the silent root power ever going on in even the smallest of gardens. There they are, as it were, "the power behind the throne" unseen, but ruling all things, useful or beautiful, above them. We have roots as anchors or grips; roots as collectors of nourishment from the earth and air, and roots as storehouses or savings banks, for the surplus material collected during growth and secured ready for the demands of the season of flowering and seeding. Take our biennial vegetables, Beet, Turnips, or Parsnips, for example. They spend one season in the collection and storage of material, which they utilise during the next by developing it into flower and seed-bearing stems. The forethought, so to speak, and thrifty behaviour of many plants are simply wonderful, but none the less wonderfully true. Some plants make sure of a constant supply of nutriment by storing it up in their bulbed or swollen stems. The plants seem to have gradually developed this power of securing constant supplies and of obviating waste in a way analogous to that which prompted the old musicians to add a bag to their wooden pipes, or a wind-box to the organ. Ever since the days of Linnæus we have been led to consider the flower as the main locality of botanical characters. Now we are going a little nearer to the root of the matter. If there is a power in plants analogous to the reasoning brain of man, there can be no doubt that roots possess that power quite as fully, or more so than do the blossoms. We have no natural type of self-abnegation more noble than that of the roots, which labour silently in the dark, while their offspring, the flowers, plant themselves in the sunshine and in the light of open day.

Useful plants.—Just at the present moment, although I remember the names of many botanical collectors and botanists who have made special studies of Orchids, Palms, Ferns, Aroids, and even the microscopic Cryptogams, yet I do not remember the name of a solitary individual who has made a life study of the plants which are known to be useful to man. Even if only partially true, this almost passes belief, but, as a fact, there is in the world a vast field of research, and especially amongst the unknown allies of plants now well known for their useful properties. We reap the harvest of the whole world in plants useful as in other ways, and yet we have never appointed a man to make a special study of the plants on which our lives, our health, our food, our clothing, and our beverages depend. We have accepted many useful plants on the traditions of the native people who have proved them. It was so with Tobacco, Cinchona, india-rubber, and gutta-percha, and with many other economic things, but the question is not have we Cinchona or india-rubber, useful as they are, but have we discovered the species or kinds which yield us these products of the best quality? The local herbal medicines of the world would form a noble study for a student anxious for a subject and a name, and I believe I am right in saying that we have no one reference book worthy of the name devoted to such an interesting and pleasant subject as the edible fruits of both hemispheres. Food, fibre, and medicine represent the very trinity of our lives, but who is the authority on food, on textiles, and on *materia medica*?

Veronica.

WORK DONE IN WEEK ENDING AUG. 17.

August 11 to 17.

Throughout the week the weather has been favourable to our garden operations, and by no means unfavourable in other respects, as there has been an occasional light shower with a fair amount of sunshine, so that growth and maturing of crops have experienced no check. Perhaps of all the branches, kitchen gardening has during the week required, and has had the most attention. Winter Spinach has been sown on ground that has just been cleared of Potatoes, a dressing of soot and forking over being the preparation needed. Sowed Cabbage on a warm border open to the south and west; our autumn plantings to stand the winter will be made from this sowing, the remainder of the plants being left to winter where sown; hence the necessity of selecting a favourable wintering position. The sorts we prefer are Sutton's All Heart and Ellam's Dwarf. We sowed the Red Dutch for pickling purposes at the same time. Sowings of White Lisbon and Giant Tripoli Onions have also been made on rich, firm ground, in drills 15 inches apart, and Cauliflowers have been sown on a border having an eastern aspect, which being cooler than the south or west the plants do not get crippled with insects till of sufficient strength to resist their attacks; it is from this sowing that our plants are obtained for wintering in handlights, and for planting under the shelter of walls for early spring cutting; a later sowing will be made a fortnight hence on a south border to winter where they are sown. Thinned out Lettuces and Endive, and pulled up seeding Lettuces and prepared same ground for another sowing. Rotation of crops is all very well, but where ground is limited and supplies required excessive, it is an impossibility to adhere to the plan, and we have long since given it up as hopeless, though of course we favour and practise the plan of never repeating the same crop twice in succession on the same ground when it can by any means be avoided. Well watered and earthed up the earliest Celery. It is less labour to let the plants complete their growth before earthing up at all, but as a supply is often needed before the crop from this mode of treatment is ready, we earth up part now, but the remainder is left till it has done growing, and by the time that it is needed it is just as well blanched as that which was done early and at various times. Hoeing and earthing up Broccoli completes for the week the work of this department. Though we have had more than a sufficiency of work to keep all our indoor hands on at express speed, the variety of work has not been great. Strawberry potting is at last completed, and all are conveniently arranged in respect of being near to the water tank, of which they require plentiful supplies, and at night are well syringed. Runners already appearing on those first potted are pinched off as soon as perceived, as also are weeds. Chrysanthemums take up more than our spare time in the way of watering, tying, disbudding, and "taking" the buds. The latter are now showing in quantity, and mildew has appeared on a few of the plants, and dustings of sulphur is our remedy, and an effectual one, too, only it needs to be repeated so long as the least trace of the fungus remains. Pinched,
